The ſpecies of *rubeola* enumerated by Mr. Tournefort are theſe. 1. The broad leaved *rubeola*. 2. The narrow leaved *rubeola*. 3. The procumbent *rubeola* with a very long ſpike. 4. The common ſmooth purple flowered ſmall *rubeola*, called by many *rubia ſquinanchica* and ſquinancy wort. 5. The white flowered ſmooth four leaved *rubeola* or ſquinancy wort. 6. The rough Portugal *rubeola* with purple flowers. 7. The ſea *rubeola*. *Tourn.* Inſt. p. 130.

Theſe plants are called by Mr. Tournefort *rubeola* as a diminutive of *rubia*, or madder; moſt other authors have called them *rubia ſpicata*, or ſpiked madder. They differ principally from the galliums in the funnel ſhape of the flower.

RUBETA, the *toad*, in zoology, a creature ſufficiently known. It is larger than the frog, its body is thick, its back broad, and its belly ſwelled, and looking as if inflated, whence it is too heavy and unweildy to hop about as the frog does; its ſkin is conſiderably thick, and full of tubercles, of a duſky and blackiſh colour on the back, and ſpotted on the belly; and is naturally a loathſome and diſagreeable object.

It feeds on the ſame things that the frog does, worms, ſnails, flies, and other inſects; it ſeems alſo, that they are able to live on much lighter food, ſince there have been many inſtances of toads being found in the ſolid bodies of trees in holes, juſt big enough for them to turn about in; and where there could be no nouriſhment conveyed to them, except what they found in the juices of the tree. There are not wanting alſo inſtances of their having been found in the ſame manner in blocks of ſolid ſtone, if we can credit the generality of authors. *Ray*'s Syn. Quad. p. 252.

RUBETRA, in zoology, a name by which Geſner and ſome others have called that ſpecies of the *œnanthe*, commonly known by the name of the *ſtone-chatter*, *ſtone-ſmick*, or *moor-titling*. *Geſner* de Avib. See the article STONE-CHATTER.

RUBIA (*Cycl.*)—RUBIA, *madder*, in the Linnæan ſyſtem of botany, a diſtinct genus of plants, the characters of which are, that the calyx is an extremely ſmall perianthium, ſituated on the germen, and divided by four notches at its extremity. The flower is compoſed of one ſingle petal which is flat, divided into four ſegments, hollow at the baſe, but forming no tube. The ſtamina are four pointed filaments ſhorter than the flower. The antheræ are ſimple. The germen of the piſtil is double, and ſituated below the receptacle. The ſtyle is ſlender, and bifid at top, the ſtig-

mata are headed. The fruit is compoſed of two round bodies, ſmooth, and firmly joined together. The ſeeds are ſingle, roundiſh, and umbilicated. *Linnæi* Gen. Plant. p. 24.

The characters of this genus, according to Mr. Tournefort, are theſe. The flower conſiſts of one leaf, ſhaped like a bell, and very open at the mouth, and divided into ſeveral ſegments, and uſually perforated. The cup changes into a fruit compoſed of two ſucculent berries, which contain uſually an umbilicated ſeed. The leaves are all ſet in rundles about the ſtalk, ſeveral being placed at a joint in form of a radiated ſtar.

The ſpecies of *rubia* enumerated by Mr. Tournefort are theſe. 1. The common cultivated *madder*. 2. The great wild *madder* of Montpelier; and 3. The exotic four leaved ſhining *madder*. The diſpoſition of the leaves, about the ſtalks of theſe plants, ſerve to diſtinguiſh them from other claſſes, when they are not in flower; and this genus is abundantly diſtinguiſhed from all the others which have their leaves diſpoſed in this manner, by its having a berry, or juicy fruit, inſtead of the dry fruits of the others. *Tourn.* Inſt. p. 15. See MADDER, *Cycl.* and *Suppl.*

The root of the common *madder* cultivated for the uſe of the dyers, is an excellent aperient and diuretic. It is preſcribed with great ſucceſs in obſtructions of the liver and ſpleen, in ſuppreſſions of the menſes and urine, and in dropſies, jaundices, and cachexies. It is alſo recommended as a vulnerary, and ſaid to be peculiarly excellent in the diſſolving coagulated blood. The dyers prepare a red colour with it, and uſe it alſo as a firſt tint for ſeveral others.

RUBIA *icterita*, a term uſed by Paracelſus and his followers for the eriſipelas.

RUBICAN, in the manege. A horſe is ſaid to be of a *rubican* colour, that is a bay, ſorrel, or black, with a light grey or white upon the flanks; but ſo that this grey or white is not predominant there.

RUBICILLA *americana*, in zoology, a name given by Mr. Ray to the *guiratirica*, a Braſilian bird, of the bull-finch kind, very beautifully variegated with red, black and grey. See the article GUIRATIRICA.

RUBICULUS, in ichthyology, a name given by Figulus and ſome others to that ſpecies of fiſh which we call the *roach*. It is of the cyprinus kind, and is diſtinguiſhed by Artedi under the name of the red-eyed cyprinus, with the tail and belly fins red. See the article CYPRINUS.

RUBIGO, (*Cycl.*) in huſbandry, is the name by which the antients expreſſed what we call the *blight* in corn, *&c.* they gave it this name from the reſemblance of the colour of the blighted ſtalks to ruſty iron.

They generally thought that it came from heaven, being ignorant of its true cauſe, which is want of nouriſhment in the earth. Virgil gives this up as an incurable diſtemper, and tells the farmer, that if his corn is blighted he muſt live upon acorns, not ſuppoſing that any remedy could be deviſed for ſuch a diſtemper.

Palladius gives many receipts to cure the *blight*, and other diſtemperatures of corn that come from above, as they imagined at that time. The chief efficacy of theſe ſeems to conſiſt in certain ſecret ſympathies and antipathies, to fright the clouds away with. The world will eaſily judge how likely ſuch means as theſe were to have ſucceſs.

The antient farmers generally uſed prayers, ſupplications, and ſacrifices to their gods on this occaſion; and if theſe did not ſucceed, they proceeded to blaſphemy and threatenings, and brandiſhed bloody axes againſt the ſky, as a token to their gods to deſiſt from plaguing them, or elſe to expect no quarter. They uſed to hang up in their fields and gardens, on theſe occaſions, pieces of red cloth, and the feathers and heart of an owl, as a way to fright the clouds from coming over thoſe places. Theſe people in general having no true knowledge of the theory of huſbandry, had recourſe to magic, and uſed what they thought ſpells and enchantments on all occaſions. Cato, Varro, and even Columella, are full of theſe ridiculous devices. A better knowledge in the real nature of huſbandry, has taught us to underſtand this matter in a very different manner, and to apply more efficacious remedies to it. *Tull*'s Horſehoing Huſbandry, p. 68. See BLIGHT.

RUBINUS, the *ruby*, in natural hiſtory. See RUBY.

RUBRICA, in natural hiſtory, a red earth uſed for marking, and in painting. There are two kinds of it, a harder and a ſofter.

The firſt, or harder kind, is but little in uſe, except among the turners in wood, as it does not mark ſo eaſily, requiring to be firſt wetted, and then preſſed hard upon the ſubſtance to be marked. This is dug in Lincolnſhire, Hampſhire, and Suſſex; and is a hard and dry earth, of a ſomewhat pale red, like the common pale red bricks, and is of a very regular and cloſe texture, and always compoſed of a number of thin lamina, lying cloſely and evenly on one another. It is of a rough uneven ſurface, adheres firmly to the tongue, is not eaſily broken between the fingers, and ſtains the hands a little; it is of a very aſtringent taſte, and melts pretty readily in the mouth. It is very readily diffuſible in water, mouldering to powder, ſoon after being thrown into it, and makes no efferveſcence with acids.

The ſecond or ſofter kind is very common, and put to a number of different uſes. It makes ſimply a very good pale red for the painters, and is very ſerviceable to them in their mixed colours. It is in conſtant uſe in many parts of the kingdom for the marking of ſheep; and when waſhed and ſeparated from its ſandy particles, is, by ſome of our modern druggiſts, ſold under the name of bole armenic.

It is found in many parts of the world; the beſt in England is that from ſeveral parts of Derbyſhire, from whence the colour-ſhops and druggiſts of London are ſupplied; many of the latter thinking this a ſhorter method than the common one of our bole armenic makers, of preparing it from a mixture of tobacco pipe clay, and the red ochre called Spaniſh brown. See BOLE and BOLUS.

This ſoft, or common *ruddle*, is a looſe ponderous earth, of a lax texture, and very friable; and of a pale, but tolerably bright red, of a ſomewhat ſmooth and gloſſy ſurface, ſoft to the touch, adhering firmly to the tongue, eaſily broken between the fingers, and ſtaining the hands. It is of a rough auſtere taſte, very readily breaks, and falls to powder in water, and makes no efferveſcence with aqua fortis. *Hill*'s Hiſt. of Foſſ. p. 48.

RUBUS, the *blackberry buſh*, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the roſaceous kind, being compoſed of ſeveral petals, arranged in a circular form on a cup, from the middle of which there ariſes a piſtil, ſurrounded with a great number of ſtamina; this finally becomes a fruit of a globular form; compoſed, as it were, of a number of ſmall berries full of juice; theſe are affixed to a placenta, and contain oblong ſeeds. See Tab. 1. of Botany, Claſs 21.

The ſpecies of *rubus* enumerated by Mr. Tournefort are theſe. 1. The common *blackberry buſh* with black fruit. 2. The French white flowered *blackberry buſh*. 3. The *rubus* with double white flowers. 4. The Poliſh *rubus* without prickles, and with a large black fruit. 5. The common *rubus* without prickles. 6. The prickly *rubus* with the leaves and flower both elegantly divided. 7. The prickly *raſpberry buſh*. 8. The ſmooth *raſpberry buſh*. 9. The ſweet ſcented *rubus*. 10. The white *raſpberry*. 11. The creeping *rubus* with bluiſh fruit. 12. The dwarf alpine *rubus*. 13. The dwarf marſh *rubus*. 14. The creeping trifoliate *rubus*, with ſoft hoary leaves and large blue fruit. 15. The ſmall, erect, hoary, white flowered alpine *rubus*. 16. The trifoliate dwarf upright elegant *rubus*, with prickles like the roſe-buſh, and a fruit of the colour and taſte of the ſtrawberry. *Tourn.* Inſt. p. 614.

RUBUS, in ichthyology, a name given by Joannes Cuba, Albertus, and ſome other writers, to the ſpecies of *ray*, uſually called the *ſkaite* or *flaire*. See RAJA.

RUBY, *rubinus*, (*Cycl.*) in natural hiſtory, a gem, the diſtinguiſhing character of which is, that it is of a red colour with an admixture of purple.

The *ruby*, in its moſt perfect ſtate, is a gem of very great beauty, and of equal value. It is often found perfectly pure, and free from all ſpots or blemiſhes; but it is much more frequently debaſed by them, and greatly brought down in its value, eſpecially in the larger ſpecimens. It is of very great hardneſs equal to that of the ſapphire, and ſecond only to the diamond. It is various in ſize, but is leſs ſubject to variations in its ſhape than moſt of the other gems. It is moſt frequently found very ſmall; its common ſize being that of the heads of the larger ſorts of pins; and when of this ſize it is very cheap; but it is alſo found of four, ſix, and ten carrats; and ſometimes, though but very rarely, up to twenty, thirty, or forty; nay, we have accounts of ſome of more than an hundred. It is never found of an angular or cryſtalliform ſhape, but always of a pebble like figure, often roundiſh, ſometimes oblong, and much larger at one end than the other, and in ſome ſort reſembling a pear, and is uſually more or leſs flatted on one ſide.

It is commonly ſo naturally bright and pure on the ſurface as to need no poliſhing; and is worn in rings, and in the crowns of princes, in its rough or native ſtate. Its colour is red in very different degrees, from the deepeſt garnet colour to that of the paleſt red diamond, but it ever has with the red more or leſs of a purpliſh tinge: this is very plainly diſtinguiſhed in the deeper coloured ſpecimens, but in the pale ones is gradually leſs and leſs to be diſtinguiſhed in proportion to their degree of colour. Theſe are the diſtinguiſhing characters of the *ruby*, and by theſe it is eaſily known from the garnet, carbuncle, and other red gems.

Our jewellers are very nice, though not perfectly determinate in their diſtinctions; knowing this gem, in its different degrees of colour, under three names; the firſt is ſimply the *ruby:* this is the name they give it in its moſt perfect and ſtrongeſt coloured ſtate.

The ſecond is the *ſpinal ruby*. Under this name they know thoſe *rubies*, which are of a ſomewhat leſs deep and greatly leſs vivid colour, than what they call the true *ruby*, or ſimply the *ruby*.

The third is the *balaſs ruby*, a name derived from Balakeia,

the name of a country where the paler *rubies* are principally found. Under this name they expreſs a pale, yet very bright *ruby*, with a ſmaller admixture of the purple tinge than in the deeper coloured one, and ſomething reſembling the colour of the damaſk roſe. This is of conſiderable value, but leſs than the deeper, or as they call it the true *ruby*.

Beſide theſe, they know alſo two other ſtones, under the general name *rubies*, calling them the *rock ruby* and the *rubacelle*. But theſe are not truly of the *ruby* kind; the firſt being a very beautiful ſpecies of garnet, and having a tinge of blue with its red; and the other a hyacinth, having a manifeſt caſt of yellow.

We have the true *rubies* only from the Eaſt Indies. In Europe there are not unfrequently found cryſtals tinged to the true colour of the *ruby*, but theſe ever want its luſtre and hardneſs. In the Eaſt Indies, the true *rubies* are often found almoſt colourleſs, and not unfrequently variegated with ſpots or ſtains of a pure blue, evidently the ſame with that of the ſapphire. Doubtleſs alſo the *ruby* is ſometimes found like the other gems, wholly deſtitute of colour; but in this caſe, as the hardneſs of the ſtone is the only thing that proves it to be of the gem claſs; both this, and all the other colourleſs ſpecimens of the gems, are confounded under the name of the colourleſs ſapphire; or, as our jewellers chuſe to ſpeak it, the white ſapphire. *Hill*'s Hiſt. of Foſſ. p. 590. ſeq.

Arſenical RUBY, *rubinus arſenicalis*, in chemiſtry, a name given to a ſublimation of a mixture of arſenic and common ſulphur. Theſe two bodies mixed together in different proportions afford very different appearances. If arſenic, mixed with one tenth part of its weight of ſulphur, be thrown into a crucible red hot upon the fire, and covered immediately with a tile, and finally poured out after two minutes fuſion, it becomes a ſolid brittle maſs of a very pale yellow. If arſenic be melted in the ſame manner, with a fifth part of ſulphur, the maſs when cold will be of a red colour: and finally, if arſenic and ſulphur be melted or ſublimed together, in equal quantities, the product is a beautiful red tranſparent maſs, called *rubinus arſenicalis*.

Counterfeit RUBY. The way to give the true fine red of the *ruby*, with a fair tranſparence, to glaſſes, is as follows. Calcine, in earthen veſſels, gold diſſolved in aqua regis till it become a red powder. The operation will require many days in a hot furnace; when the powder is of a proper colour, take it out; and when it is to be uſed, melt the fineſt cryſtal glaſs, and purify it by often caſting it into water; finally add, by ſmall quantities, enough of this red powder, to give it the true colour of a *ruby*, with an elegant and perfect tranſparence. *Neri*'s Art of Glaſs, p. 192.

RUDD, in ichthyology, a name given by the Engliſh to a fiſh of the cyprinus kind; it is called *orfus* and *rutilus latus*, or the *broad roach* by authors, and in ſome parts of England the *finſcale*. See ORFUS, RUTILUS and CYPRINUS.

RUDDER (*Cycl.*)—RUDDER-*irons*, in a ſhip, are the cheeks of that iron, whereof the pintle is part, which is faſtened and nailed down about the rake of the *rudder*.

RUDDER-*rope*, in a ſhip. See ROPE, *Cycl.*

RUDDLE, *rubrica*, in natural hiſtory. See RUBRICA.

RUDDOCK, in zoology, an Engliſh name for the *rubecula*, more commonly known by the name of the *red breaſt*, or *robin red breaſt*. *Ray*'s Ornitholog. p. 160. See the article RUBECULA.

RUDMAS *day*, in our old writers, the feaſt of the *holy croſs*. There are two of thoſe feaſts, one on the third of May, being the invention of the *croſs*; and the other the fourteenth of September, called *holy rood-day*, and is the exaltation of the croſs. *Blount*.

The word is compounded of the Saxon *rode*, i. e. *crux*, and *maſs-day*, i. e. feaſt-day.

RUE, *ruta*, in botany, &c. See the article RUTA.

We have ſeveral ſorts of *rue* in the gardens of the curious, but the common kind only is propagated for medicinal uſe. All the kinds may be propagated, either by cuttings in the manner of roſemary, or elſe by ſeeds. Theſe ſhould be ſown in the ſpring on a bed of light earth; and when the young plants come up, they ſhould be removed at about two inches high to the places where they are to remain. *Miller*'s Gardners Dict.

Goats RUE, in medicine. See GALEGA.

Wild RUE. See the article HARMALA.

RUELLIA, in botany, the name of a genus of plants, deſcribed by Linnæus, Plumier, and others, the characters of which are theſe. The cup is compoſed of one leaf, and is divided into five erect narrow ſegments. The flower conſiſts of one petal, the tube is of the length of the cup; the neck broad and inclined, and the verge divided into five open ſegments. Theſe are all obtuſe at the points, and the two upper ones are longer than the reſt, and are turned a little backwards. The ſtamina are four filaments placed in the wide part of the tube in pairs. The germen of the piſtil is roundiſh, the ſtyle is ſlender, and of the length of the ſtamina; and the ſtigma is bifid and acute, and the lower ſegment of it is rolled back. The fruit is a cylindric capſule rounded at each end; it is of the length of the cup, compoſed of two valves and ſemibilocular: this contains ſome roundiſh but compreſſed ſeeds. *Linnæi* Gen. Pl. p. 298. *Plumier* Gen. 2. *Dillen.* Hort. Elth. 248, 249.

RUFFE, in zoology, the Engliſh name of the *cernua* or ſmall gilded pearch, a fiſh common in our rivers, and much reſembling the pearch in figure. *Ray*'s Ichthyol. p. 334. See the article CERNUA.

The *ruffe* is called by the generality of authors *cernua fluviatilis*; and by ſome *chærus acerina* and *aſpredo*. It is called by Johnſon and Charleton alſo *ſcrollus*. Willughby, as well as theſe authors, has mentioned the *ſcrollus* as another ſpecies of fiſh; but it is proved, by obſervation, that they are evidently the ſame ſpecies. Artedi makes this fiſh a pearch, or *perca*; and accurately diſtinguiſhes it from the other fiſh of that genus by the name of the pearch, with only one fin on the back, and with a cavernous head. See the articles CERNUA and PERCA.

This fiſh may be preſerved alive in glaſs jars with freſh water, and be made very tame. It muſt be fed, for it cannot ſubſiſt on the animalcula of river water as ſmall dace can. See DACE and Phil. Tranſ. N° 478. p. 25.

No fiſh ſhews the circulation of the blood in a finer manner than *ruffs*, whoſe fins are exceeding tranſparent. Beſides, it is a creature vaſtly tenacious of life, and will live twenty or thirty minutes out of water, without receiving much damage. Phil. Tranſ. l. c. p. 26.

RUFFE, in ornithology, the name of a male ſpecies of bird, the female of which is called *reeve*, and the Latin name for which is *aves pugnax*, or the fighting bird.

It is about five ounces in weight; its head is of a greyiſh brown with blackiſh ſpots, its neck is grey, and its back and ſhoulders variegated with black, white, and brown. Its breaſt and belly are white, and its throat of a greyiſh white, and ſomething mottled. Its wings are black and white. The females are ſomewhat ſmaller than the males, and they ſeldom fight. The males have a very remarkable circle of long feathers, ſurrounding their necks in the form of a *ruff*, worn antiently by ladies, and from this the bird has its name; the feathers of this are ſometimes white, but more uſually black, yellow, grey, or of a very ſhining blackiſh blue; nor is the diverſity of colour peculiar to the feathers of the *ruff* alone; but the whole body of the bird is ſo variable, in this reſpect, that at ſome ſeaſons it is ſcarce poſſible to find any two of the males which are exactly of the ſame colour; but about Midſummer, when they have newly moulted, they are all of the ſame colours, and continue ſo till toward the ſucceeding ſpring. The beak is ridged and triangular, and is blackiſh, and the feet of a yellowiſh red. They come over to us in vaſt numbers in ſpring, and remain the ſummer, building in ſome parts of Lincolnſhire, particularly in the fenny country about Crowland. When they firſt come over there are many more males than females among them; but theſe are ſo continually fighting, that their number ſoon decreaſes below an equality. They are fed up after they are taken with bread and milk, and become very fat, and a very delicate bird; but they are obliged to be kept in the dark, for as ſoon as the leaſt light is admitted they begin to fight. They are uſually taken with nets, while vaſt numbers of them are fighting together. *Ray*'s Ornitholog. p. 224, 225.

RUFFE is alſo the name of a particular ſpecies of pigeon, called by Moore the *columba cucullata rudis*.

It is in ſhape very like that ſpecies of pigeon called the *jacobine*, but is larger, and has a longer beak. The iris of the eye is ſometimes red, ſometimes pearl coloured. The feathers of the hood and chain are much longer than the *jacobine*, though they do not come down ſo low to the ſhoulders of the wings, nor are they ſo compact and cloſe, but are apt to blow about with every little blaſt of wind, and fall more backward off the head, and lie in a rough confuſed manner.

It is a common thing to match the *jacobine* pigeon with this ſpecies, with intent to improve its chain by the length of the *ruff*'s feathers; but the event is, that the pigeon is always worſe inſtead of better, being longer beaked, and looſer in its head and chain without any real advantage. *Moore*'s Columb. p. 48.

RUGGIOLA, a ſort of Spaniſh ſlate, ſerving in many places in the room of tiles and bricks. It is a flaky ſtone, of the nature of ſome of our grey ſlates, and is cut out of a mountain near Cordova; a plate of this being well heated on both ſides, will retain its warmth for twenty-four hours.

The people of Cornwal and ſome parts of Yorkſhire uſe a ſtone, which is of a talcky nature, to warm themſelves when in bed, applying it at the feet of the bed. This they call the warming ſtone from its uſe, and it will retain a ſenſible heat ſix or eight hours, after once moderately warming. *Plot*'s Oxfordſhire, p. 258.

RUGOSE *leaf*, among botaniſts. See LEAF.

RUININE *oil*, a name given by ſome authors to the oil of the *palma chriſti*, which is very common in the Weſt-Indies, and is uſed by the common people in lamps. It is a delicate ſweet and tranſparent oil, and has no peculiar operation in phyſic. They often give it in glyſters from one ſpoonful to three at a time, and it has only the effect of common oil:

but

but the leaves of the plant are one of the grand medicines of the negroes, bruiſed and applied to the head; they are thought to be an almoſt infallible remedy for the head-ach, of whatever kind, or from whatever cauſe.

RUKKAIA, in zoology, a name given by ſome to a peculiar kind of ſquirrel, found in the iſland of Ceylon. See the article SCIURUS.

RUM (*Cycl.*)—*Rum* differs from what we ſimply call ſugar ſpirit, in that it contains more of the natural flavour or eſſential oil of the ſugar cane; a great deal of raw juice and parts of the cane itſelf being often fermented in the liquor, or ſolution of which the *rum* is prepared.

The unctuous or oily flavour of *rum* is often ſuppoſed to proceed from the large quantity of fat uſed in boiling the ſugar; which fat, indeed, if coarſe, will uſually give a ſtinking flavour to the ſpirit, in our diſtillations of the ſugar liquor, or waſh, from our refining ſugar houſes; but this is nothing of kin to the flavour of the *rum*, which is really the effect of the natural flavour of the cane. The method of making *rum* is this:

When a ſufficient ſtock of the materials is got together, they add water to them, and ferment them in the common method, though the fermentation is always carried on very ſlowly at firſt; becauſe, at the beginning of the ſeaſon for making *rum* in the iſlands, they want yeaſt, or ſome other ferment to make it work; but by degrees, after this, they procure a ſufficient quantity of the ferment, which riſes up as a head to the liquor in the operation, and thus they are able afterwards to ferment and make their *rum* with a great deal of expedition, and in large quantities.

When the waſh is fully fermented, or to a due degree of acidity, the diſtillation is carried on in the common way, and the ſpirit is made up proof: though ſometimes it is reduced to a much greater ſtrength, nearly approaching to that of alcohol or ſpirit of wine, and it is then called double diſtilled *rum*. It might be eaſy to rectify the ſpirit, and bring it to much greater purity than we uſually find it to be of; for it brings over in the diſtillation a very large quantity of the oil; and this is often ſo diſagreeable, that the *rum* muſt be ſuffered to lie by a long time to mellow before it can be uſed; whereas, if well rectified, it would grow mellow much ſooner, and would have a much leſs potent flavour.

The beſt ſtate to keep *rum* in both for exportation, and other uſes, is doubtleſs that of alcohol, or rectified ſpirit. In this manner it would be tranſported in one half the bulk it uſually is, and might be let down to the common proof ſtrength with water when neceſſary: for the common uſe of making punch, it would likewiſe ſerve much better in the ſtate of alcohol; as the taſte would be cleaner, and the ſtrength might always be regulated to a much greater exactneſs than in the ordinary way.

The only uſe to which it would not ſo well ſerve in this ſtate, would be the common practice of adulteration among our diſtillers; for when they want to mix a large portion of cheaper ſpirit with the *rum*, their buſineſs is to have it of the proof ſtrength, and as full of the flavouring oil as they can, that it may drown the flavour of the ſpirits they mix with it and extend its own. If the buſineſs of rectifying *rum* was more nicely managed, it ſeems a very practicable ſcheme to throw out ſo much of the oil, as to have it in the fine light ſtate of a clear ſpirit, but lightly impregnated with it; in this caſe it would very nearly reſemble arrac, as is proved by the mixing a very ſmall quantity of it with a taſteleſs ſpirit, in which caſe the whole bears a very near reſemblance to arrac in flavour.

Rum is uſually very much adulterated in England, ſome are ſo barefaced as to do it with malt ſpirit; but when it is done with molaſſes ſpirit, the taſtes of both are ſo nearly allied that it is not eaſily diſcovered. The beſt method of judging of it is, by ſetting fire to a little of it; and when it has burnt away all the inflammable part, examining the phlegm both by the taſte and ſmell. *Shaw*'s Eſſay on Diſtillery.

RUMI, in the materia medica, a name given by Aviſenna and Serapio to maſtic of the finer kind. They diſtinguiſhed this drug into two ſorts; the one called by this name *rumi*, which was white and pure; the other called *cupti*, which was foul and blackiſh; the former came from the iſland of Chios, the latter from ſome part of Ægypt.

RUMOUR, in law. Spreading falſe *rumours* is criminal and puniſhable at common law. 1 *Hawk.* P. C. 234.

RUMPHIA, in the Linnæan ſyſtem of botany, the name of a plant which makes a diſtinct genus. The characters of which are, that the cup is a one leaved perianthium, divided by three notches at the extremity, and is placed erect, and is plain. The flower is compoſed of three petals, which are all oblong, obtuſe, and equal in ſize. The ſtamina are three pointed filaments of the length of the flower. The antheræ are very ſmall. The piſtil has a roundiſh germen. The ſtyle is pointed, and of the ſame length with the ſtamina, and the ſtigma is three cornered. The fruit is a ſkinny drupe of a turbinated form, and furrowed in three places. The ſeed is a whole nut of an oval figure, containing three cells, the nuts in each of theſe are three cornered in ſhape. *Linnæi* Gen. Pl. p. 9.

RUN (*Cycl.*)—RUN, in the manege. To *run* a horſe is to put him to his utmoſt ſpeed. Some uſe the word *running* for any kind of gallop.

RUNCARIA, in our old writers, ſignifies land full of brambles and briars. 1 Inſt. 5. The word comes from the Latin *runca*, a weed. *Blount.*

RUNCATION, a term uſed in the antient huſbandry, to expreſs the clearing away the weeds from among the corn and other ſown plants.

They uſed when the corn or other plants were an inch or two high, to draw a ſort of rake or harrow over the ground indiſcriminately over the corn and weeds, and when this was done a perſon followed over all the field, and picked up all the weeds with the hand; the treading down the young corn, however, by this perſon's feet, and the injury done to it by the rake, were ſo great, that the crop always ſuffered greatly by it; and many of the Romans choſe to omit the uſe of the rake or harrow, as a thing that did as much injury to the corn as to the weeds, and contented themſelves with the ſending a perſon to pick up the weeds without it.

This was a ſort of firſt hint to the horſehoing huſbandry of the moderns, though ſo injudiciouſly managed, that it was of very little, if any, uſe in this its infancy. But had theſe farmers been inſtructed to ſow their corn in rows, and then to uſe the rake or harrow as we do the hoe, only between thoſe rows, they would then have had all the advantage of deſtroying weeds by it, and of ſtirring the earth, and no injury would be done to the crop. *Tull*'s Huſbandry. See the article HUSBANDRY.

RUNGS, in a ſhip, the ſame with the floor or ground timbers, being the timbers which conſtitute her floor, and are bolted to the keel, whoſe ends are *rung-heads*.

RUNG-*heads*, in a ſhip, are made a little bending to direct the ſwip or mold of the *futtocks* and naval timbers: for here the lines, which make the compaſs and bearing of a ſhip, do begin.

RUNIC (*Cycl.*)—In ſeveral parts of Sweden, ſtones may be met with which were formerly ſet up as obeliſks in memory of the dead; and theſe monuments are marked with the antient northern letters called *runor*, or the *runic* characters. In ſome places, the characters vary from the *runic*, particularly in free ſtones found in Helſignland, of which Mr. Celſius has given us a deſcription, with an explanation. See Phil. Tranſ. N° 445. Sect. 3.

From theſe Helſingland inſcriptions an alphabet of ſixteen letters may be derived, which is very ſingular. In other alphabets different ſounds are generally denoted by different figures; but here the ſame character, according to the diverſity of its place and altitude between two parallels, denotes different ſounds.

But theſe characters, however different they may appear at the firſt ſight from the *runic*, may eaſily be derived from them; or *vice verſa*, the *runic* may be derived from the *helſingic*, if theſe be ſuppoſed the moſt antient. The ſubtraction of a perpendicular line in the firſt caſe, or its addition in the latter, brings the two characters to a near reſemblance.

The inſcription, which Mr. Celſius conſiders, was publiſhed in Monſ. de la Motraye's travels, but erroneouſly. See Phil. Tranſ. loc. cit.

RUNNING, in antiquity, made one of the exerciſes performed in the pentathlon or quinquertium. See the article PENTATHLON, *Cycl.*

This exerciſe was in ſo great eſteem among the antient Greeks; that ſuch as prepared themſelves for it, thought it worth their while to burn, or parch their ſpleen, becauſe it was believed to be an hindrance to them.

Indeed, all thoſe exerciſes, that conduced to fit men for war, were more eſpecially valued; and that ſwiftneſs was eſteemed ſuch in an eminent degree, appears from Homer's giving his hero the epithet of ποδας ωκυς Αχιλλευς. *Pott.* Arch. Græc. l. 2. c. 21.

RUNNING *of the eyes*, in infants. See INFANT.

RUNNING-*fights*, at ſea. See FIGHTS.

RUNNING-*ropes*, in a ſhip, are thoſe which run on blocks and ſhivers.

RUNOR. See the article RUNIC.

RUNT, the name uſed with the diſtinction of places for ſeveral ſpecies of pigeons. Theſe are the Leghorn, the Spaniſh, and the Frieſland *runt*, &c. The *columba domeſtica Piſarum, Hiſpaniæ & Friſiæ* of Moore.

The Leghorn *runt* is a ſtately large pigeon, ſeven inches or better in the legs, cloſe feathered and faſt fleſhed, extremely broad breaſted, and very ſhort in the back. He carries his tail, when he walks, ſomewhat turned up like a duck's; his neck is longer than any other pigeons, and he carries it bending like a gooſe or ſwan. He is gooſe headed, and his eye lies hollow in his head, with a thin ſkin round it, like that of the Dutch tumbler. His beak is very ſhort for ſo large a bird, and has a ſmall wattle on it, and the upper chap falls a little over. It is a very valuable pigeon, but is tender, and requires care.

The

The Spaniſh *runt* is the longeſt bodied of all the pigeons; it is ſhort legged, and looſe feathered, and does not walk ſo upright as the Leghorn *runt*. Theſe are of a great variety of colours, but are apt to have accidents in ſitting, from their ſitting too heavy, and often breaking their eggs.

The Frieſland *runt* is a large pigeon, and has all its feathers reverted, or looking as if placed the wrong way.

The Roman *runt* is a pigeon of the ſame general make with the common kind, but ſo large and heavy that it can hardly fly.

The Smyrna *runt* is middle ſized, and is feather footed, and that to ſuch a degree ſometimes, as to look as if there were wings upon the feet; the feathers of theſe are ſometimes four or five inches long, and often pull the eggs and young out of the neſts. The common *runt* is the common blue pigeon kept for the table, and known to every body. *Moore*'s Columb. p. 42.

RUNT is alſo a name given to Canary birds when three years old. See CANARY and PASSERES *Canarienſes*.

RUPELLENSIS *ſal*, in chemiſtry, a name given to a peculiar kind of ſalt, invented by Mr. Seignette at Paris, and extolled as a very valuable medicine.

The preparation of it was kept a great ſecret, till diſcovered by ſome members of the Paris academy. It was found to be a ſpecies of *ſal polycreſtum*, and was properly a ſoluble tartar compoſed of cream of tartar, and the fixed ſalt of common pot-aſhes well depurated. This ſalt is of a very ſingular nature; for though it be a true alcaline ſalt, it yet is capable of cryſtalization, and it does not eaſily diſſolve in the open air as other fixed ſalts do; but, on the contrary, it calcines therein like vitriol and the Glauber's ſalts. Phil. Tranſ. N° 436.

Another peculiar property of it is, that if it be ſatiated with vitriolic acids, and the liquor be evaporated, there is obtained a ſalt which has the figure of Glauber's ſalt, and all the properties requiſite to make Mr. Seignette's ſalt. In order to which, take ſalt of kali or pot-aſhes of Alicant well purified one pound; diſſolve it in water, and add to it cream of tartar half a pound: this is about the quantity uſually neceſſary; but the true proportion, in this caſe, can no more be determined than in the making the common ſoluble tartar, otherwiſe than by trial every time; either from the ſalt of kali's having retained more or leſs humidity, or from the tartar's having more or leſs foulneſs. Boil the whole together in order to diſſolve the tartar; and if the quantity of tartar have been too great after the fermentation is over, filtre the liquor, and as it cools the ſuperfluous tartar will fall to the bottom: after the ſeparation of the tartar, evaporate the lixivium over a gentle fire to a proper ſtandard, and then ſet it in a cool place, and there will ſhoot fine cryſtals. If the liquor be a little too far evaporated, there will be no cryſtals formed, but the whole liquor will congeal into a hard ſubſtance tranſparent like ice; but upon diſſolving this in more water, it will ſhoot as fair as it would have done if properly evaporated at firſt.

The virtues of this ſalt conſiſt in its being an excellent purge, its doſe is from one to two ounces; and it is to be diſſolved in a large quantity of water.

RUPERT's drops, a ſort of glaſs drops with long and ſlender tails, which burſt to pieces, on the breaking off thoſe tails in any parts, ſaid to have been invented by Prince Rupert, and therefore called after his name.

This ſurpriſing phænomenon is ſuppoſed to ariſe from hence; that while the glaſs is in fuſion, or in a melted ſtate, the particles of it are in a ſtate of repulſion; but being dropped into cold water, it ſo condenſes the particles in the external parts of their ſuperficies, that they are thereby reduced within the power of each other's attraction, and by that means they form a ſort of hard caſe, which keeps confined the before-mentioned particles in their repulſive ſtate; but when this outer caſe is broke by the breaking off the tail of the drop, the ſaid confined particles have then liberty to exert their force, which they do by burſting the body of the drop, and reducing it to a very peculiar form of powder.

This theory ſeems to be corroborated by making the drops red hot, and letting them cool again by gentle degrees in the open air, for then there is no ſuch effect. Yet it muſt be allowed, that there is another experiment which ſeems to impugn this hypotheſis; and that is by grinding away any part of the drop upon a grindſtone, when the remaining part continues entire; though there appears no reaſon why it ſhould not break, and burſt into duſt, if the internal parts be the cauſe of it; ſince by this means they muſt needs be ſet at liberty, in the moſt ample manner poſſible, unleſs it be that in grinding, the vacuities between the internal particles are filled up with the matter worn off from the ſtone; and by this means fixing the parts of the glaſs next the ſtone, they deſtroy their repulſive force; conſtituting as it were another ſort of hard external caſe, which confines the internal particles no leſs than the other did.

The hiſtory of theſe drops is this; they were firſt brought into England by prince Rupert out of Germany, and ſhewn to king Charles II. who communicated them to the Royal Society at Greſham College; and a committe appointed on this occaſion by the Society, gave the following account of them. They muſt be made of green glaſs well refined, for till the metal, as the glaſs men call it, is perfectly refined they never ſucceed if made of it; but always crack and break ſoon after they are dropped into the water. The beſt way of making them is to take up ſome of the metal out of the pot upon the end of an iron rod, and immediately let it drop into cold water, and there lie till it is cold. If the metal be too hot when it is dropped into the water, the buſineſs does not ſucceed, but the drop froſts and cracks all over, and falls to pieces in the water, and every one that does not crack in the water, but lies in it whole till it is quite cool, is ſure to be good: there is great nicety in the hitting a due degree of heat in the metal, and the workmen who beſt know their buſineſs cannot promiſe beforehand which ſhall ſucceed, but often two fail for one that hits right. Some of them froſt over the ſurface without falling to pieces, and others break into pieces before the red heat is quite over, and that with a ſmall noiſe; others break ſoon after the red heat is over and make a great noiſe, and ſome neither break nor crack till they ſeem to be quite cold; and others hold together while they are in the water, but fly to pieces with a ſmart noiſe when they are taken out of it; ſome do this on the inſtant, others an hour or two after, and others will keep ſeveral days, nay weeks, and at laſt fall to pieces without being touched. *Neri*'s art of glaſs by Merrett. p. 356.

If one of them be taken out of the water while it is hot, the ſmall part of the neck and ſo much of the thread or ſtring it hangs by, as has been in the water, will upon breaking fall into ſmall parts, but not the body, though it have as large cavities in it, as thoſe which burſt in pieces.

If one of theſe drops be cooled in the open air hanging on a thread, or on the ground, it becomes like common glaſs in hardneſs, ſolidity, and all other its qualities, and has nothing of the nature of the drops cooled in water.

When a glaſs drop falls into the water, it makes a hiſſing noiſe, the body of it continues red a pretty while, and there proceed from it many eruptions like ſparkles that crack, and make it leap up and move, and ſeveral bubbles ariſe from it till it cools; but if the water be ten or twelve inches deep theſe bubbles diminiſh ſo in the aſcending, that they vaniſh before they attain the ſuperficies of the water, where nothing is to be obſerved but a little thin ſteam.

The outſide of the glaſs drop is cloſe and ſmooth like other glaſs, but within it is full of ſpungy cavities and blebs. The figure is a ſort of oval or pear like ſhape, ſuch as pearls are painted in, the bottom of which is rounded, and the top terminates in a long neck which is uſually variouſly bent and crooked. Almoſt all thoſe that are made in water have a little protuberance or knob, a little above the largeſt part of the body, and moſt commonly placed on the ſide toward which the neck ends, but ſometimes it is upon that ſide that lies uppermoſt in the veſſel where it is made.

If the water be hot into which the glaſs drop is thrown, it always cracks and breaks in the water, either before the red heat is over or very ſoon after. If dropped into oil they do not miſcarry ſo often as when dropped into water: they produce alſo a greater number of large bubbles, and continue longer bubbling than when dropped into water: thoſe made in oil have alſo fewer blebs, and ſmaller than thoſe which are made in water; and frequently they are ſmooth all over, not having thoſe knobs which the others have. Some part of the neck of theſe alſo, and part of the ſmall thread that is quenched in it, cooled, breaks like common glaſs; but if the neck be broken off near the body, and the body held all the while cloſe in ones hand, it will crack and break all over; but even then it flies not into ſo ſmall parts, nor with ſo ſmart a force and noiſe as thoſe do which are made in water, and the pieces will hold together till they are parted, and there then appear long ſtreaks or rays upon them, pointing toward the center of the body, and thwarting the little blebs in it.

If the drops are dropped into vinegar, they froſt and crack, ſo that they are ſure to fall to pieces before they are cold, and the noiſe of their falling in is more loud and hiſſing than in water, but the bubbles are not ſo remarkable.

In milk they make no noiſe nor any bubbles that can be perceived, and never miſs to froſt and crack all over, and fall to pieces before they are cold. In ſpirit of wine they bubble more than in any other of the liquors, and while they remain entire, they tumble to and fro, and are more agitated than in other liquors, and they never fail to crack and fall to pieces; and by that time five or ſix of them have been dropped into this ſpirit it will be ſet on a flame, but it receives no particular taſte from them.

In water wherein nitre or ſal armoniac have been diſſolved they ſucceed no better than in vinegar. In oil of turpentine, the firſt broke as in the ſpirit of wine, and the ſecond ſet it on fire, ſo that it could not be uſed again. In quickſilver, being forced to ſink by a ſtick, it grew flat and rough on the upperſide; but the experiment could not be perfected, becauſe it could not be kept under till it cooled. In an experiment made in a cylindric glaſs like a beaker, filled with cold

cold water, out of ſeven that were tried one only ſucceeded, the reſt all cracking and breaking to pieces; and it was obſerved, in this experiment, that at the firſt falling of the drop into the water, and for ſome time after, while the red heat laſted, red ſparks were ſhot forth from the drops into the water; and that at the inſtant of the eruption of thoſe particles, and of the bubbles which manifeſtly break out of it into the water, it not only cracks, and that ſometimes with a conſiderable noiſe, but the body moves and leaps about, and that as well in thoſe which ſucceed as thoſe that break in the water.

A blow with a ſmall hammer, or other hard body, will not break one of theſe glaſs drops if ſtruck upon the body; but if the tip only of the neck be broke off, it flies to ſmall particles, which eaſily crumble into duſt; and if it be broken, when the particles have liberty to diſperſe themſelves, they will fly every way in an orb, in the manner of a granado.

If they are ground down ever ſo low into the body with water and emery they do not fly; but rubbed on a dry tile, they uſually fly to pieces as ſoon as the bottom is a little flatted, though ſometimes they bear rubbing away deeper; and ſome, when rubbed half down, have been laid by without burſting, and have flown to pieces a little while after without being touched.

If one of them be broken in the hand under water, it ſtrikes it more ſmartly than if in the open air; and if it be broken near the ſurface of the water, the particles it flies into do not diſperſe themſelves into an orb as in the air, but all fall regularly and evenly to the bottom; and they burſt in the ſame manner in the exhauſted receiver of the air pump as in the open air. One of theſe drops being faſtened into a cement, all but a part of the neck, and then the tip of it broken off, it made a pretty ſmart noiſe, but not ſo great as if broken in the hand; and though, on examining, it appeared to be all ſhivered to pieces within, and its colour turned greyiſh; yet the outſide remained ſmooth, though cracked, and being taken in pieces, the parts of it roſe like thoſe of the flaky bodies, talc, or the like; the flakes were many of them conical in ſhape, and were alſo cracked, that they eaſily fell into duſt.

Another drop faſtened into a ball of cement of half an inch in thickneſs upon the breaking off the tip of it, burſt the ball in pieces like a granado. And when attempted to be bored by a lapidary as they bore pearls, they fly to pieces as ſoon as the tool enters them, in the ſame manner as they do when the tip is broken off.

Theſe were the ſeveral experiments tried on them by the gentlemen of the royal ſociety, and theſe all tend to prove the before-mentioned account of their burſting to be true; and indeed none more than the dry and wet grinding of them; the wet emery, in the latter caſe, making a coat in the place of that it wore away; and the dry powder of tile in the former, ſcarce anſwering the ſame purpoſe, and at beſt but very imperfectly, and preſerving the body together only for a ſmall time. *Neri*'s Art of Glaſs, p. 362.

RUPICAPRA, in natural hiſtory, the name of a creature of the goat kind, from whoſe ſkin the chamois leather is made, the creature itſelf being called alſo the *chamois* by the French, and by the Germans the *gemp*. See Tab. of Quadrupeds, N° 8.

It is very common in the mountains of Helvetia, and in many other places. In the figure of its body it ſeems to approach very much to the ſtag kind; its belly, forehead, inner part of its ears and throat are white; it has a yellow ſtreak on each ſide near the eyes, and the reſt of the body is perfectly black; its tail alſo is black, and that equally on all ſides, not white on that part next the body as is the caſe in the deer. *Ray*'s Syn. Quad. p. 78.

The male and female both have horns, which are a hand's breadth and an half long, rough toward the bottom, and ſomewhat knotty; a new knot growing every year; they are nearly ſtrait, but at the top bent into the ſhape of a hook, black, and not ſmooth, but longitudinally ſtriated with ſlender ſtreaks, and their inner cavity is filled up with a ſolid bone proceeding from the ſkull.

This creature has two remarkable holes always open behind its ears: theſe ſome have imagined ſerved for reſpiration; and Appian, who had the *poetica licentia* for whatever he choſe to ſay, ſeems to have led them into this; but there is no ſort of probability of truth in it, ſince the ſkull is ſeen immediately under theſe holes, and there is no perforation through it, nor any duct diſcoverable from them. The vulgar have alſo ſome remarkable opinions founded on the ſtructure of the horns of this creature; the one, that in depreſſing them to rub his back, he often gets them ſo far within the ſkin that he cannot get them out again; and the other, that he hangs by his horns to the rocks.

RUPITANI, a name given to the Donatiſts. See CAMPITÆ.

RUPPIA, in botany, the name given by Linnæus to a genus of plants, called by Micheli *bucca ferrea*. The characters are theſe. The cup is compoſed of a ſubulated ſpadix, ſtrait, and of a very ſimple ſtructure, which becomes a little bent when the fruit is ripe, and is doubly beſet with fructifications. There are no petals, nor any ſtamina, but a number of kidney ſhaped antheræ placed on each ſide. The piſtils are ſeveral ſlender capillary ſtyles, each bearing an

an oval germen with a ſimple ſtigma. The fruit is an oval, pointed, thin capſule or cortex placed on the ſtyle, which becomes elongated. There are as many of theſe as there were piſtils on the plant, and each contains one roundiſh ſeed. *Linnæi* Gen. Pl. 442. *Micheli* 35.

RUSCUS, in botany, the name of a genus of plants, called in Engliſh *butchers broom*. The characters of the genus are theſe. The flower conſiſts of only one leaf, and is of the globoſe campaniform kind or hollow, with the belly or body larger than the rim. This is incloſed in a cup, divided into many ſegments, and from the baſe of it riſes a piſtil, which ripens into roundiſh ſoft fruit, containing one or two ſeeds which are uſually very hard.

There are four ſpecies of this plant. 1. The common myrtle leaved kind. 2. The broad leaved one with the flowers and fruit growing to the leaves called the Alexandrian bay. 3. The narrow leaved one with the fruit growing to the leaves, called *hippogloſſum* by authors; and 4. The narrow leaved kind with the fruit growing on the tops of the branches.

Authors have not been accurate in referring the plants of this genus to their proper name *ruſcus*, but the three latter have been called by different writers *hippogloſſum*, *bonifacia*, *laurus alexandrina*, *chamædaphne*, *laurotaxa*, and *radix idæa*; and many of them have, in their deſcriptions, miſtaken the calyx of ſome ſpecies for the flower. *Tourn.* Inſt. p. 79.

The root of *butchers broom* is one of the five aperient ones, and is celebrated by authors as a very powerful attenuant and reſolvent. It is good in all chronic caſes, and is frequently preſcribed in diet drinks, intended to open obſtructions of the viſcera, or to promote urine.

RUSH, in botany. See the article JUNCUS.

Petrified RUSHES. What is uſually called by this name is a kind of foſſile coral. But we have in England alſo another not uncommon ſubſtance, frequently called by the ſame name; this is an incruſtation of ſparry matter, in form of a ſtony cruſt on the outſides of real *ruſhes*; though, in this caſe, it is no real petrifaction, but only a covering of this ſtone-like matter. Incruſtations and petrifactions are uſually confounded together, and the generality of people do not attend to the diſtinction, which is, that in a real petrifaction, the ſtony matter penetrates the very ſubſtance of the body, as is the caſe in the petrified wood of Ireland and other places; whereas in theſe incruſtations the ſubſtance itſelf remains unaltered within, and its outer part alone is covered with the ſtony ſubſtance: this is the caſe with what is called petrified moſs at Scarborough and in other parts of England, and this is the caſe in regard to what we call ſometimes petrified *ruſhes*. Theſe being water plants, and growing by the ſides of ſprings, loaded with ſpar, often fall in, and become covered over with it. We have near Kettering in Northamptonſhire a ſpring which does this very quickly: a gentleman who tried the experiment, by putting in ſome *ruſhes*, at about thirty yards from the ſource, found them in one day covered with a thin ſkin of ſpar; but after lying ſome months there, it formed itſelf into a cruſt of half an inch thick round them; and was ſo hard, that it would not break by being thrown violently on the ground; but all this while the *ruſhes* were not petrified, but only incruſted. *Woodw.* Cat. Foſſ. Vol. 2. p. 78.

RUSH *graſs*. See the article JUNCAGO.

RUSMA, in natural hiſtory, the name given by the eaſtern nations to the ſubſtance, called by the antient Greeks *ſory*. It is properly an ore of vitriol, and is uſed as a depilatory, being mixed with lime. *Hill*'s Hiſt. of Foſſ. p. 6. See the article SORY.

Mr. Boyle tells us, he made a fine powder of equal parts of *ruſma* and quick-lime, and letting them ſoak a little time in water they became a ſoft paſte, which he ſpread on the part he would free from hair; and after letting this paſte lie on about three minutes he wiped it off with a wet cloth, and found the hair taken away by the roots, without any inconvenience to the part. *Boyle*'s Works Abr. Vol. 1. p. 137.

Orpiment and quick-lime is uſed in Europe for a depilatory. See the article HAIR, *Cycl.*

RUSSGANGENUM, in natural hiſtory, a name given by the people of the Eaſt-Indies to a yellow and braſs like foſſile ſubſtance, found in many places there; it reſembles the marcaſites, only that on trial it is found to contain very little ſulphur: it is probably an ore of zink.

RUST *of corn*, or BLIGHT, in huſbandry, the name given by our farmers to a diſeaſe in corn and other vegetables, in which their ſtalks and leaves ſeem burnt up, and appear of a ſort of *ruſt* colour.

Wheat is blighted at two ſeaſons, firſt in the bloſſom, and then its generation is prevented, many of the huſks being empty in the ear, and the rudiments of the grains not impregnated: ſecondly, wheat is blighted when the grains are brought to maturity; and in this caſe they become light, and are of little value for making of bread, having ſcarce any flour in them.

The firſt of theſe cannot happen in England from froſts, becauſe our wheat is not in flower till the month of June;

but it is long and continual rains that chill the bloſſoms, and in this manner prevent their fertility: this, however, does not often happen to us; theſe rains are not common at this ſeaſon of the year; and if they were, this country lying much of it open, the winds diſlodge theſe drops of water from the ears, and prevent the miſchief they would do there.

Lammas wheat does not retain theſe drops ſo long as the bearded or cone wheat; and, in conſequence of this, in the terrible blight in England in the year 1725, the bearded wheat received infinitely greater miſchief than the lammas wheat.

The ſecond kind of *blight* from light ears, is, that which is more frequent, and more general with us; this brings the greateſt ſcarcity of wheat, and the cauſe of this is plainly want of nouriſhment of the grain, by whatever means that want is occaſioned. Several accidents kill the plants, or injure their health, and in that caſe the grains are not filled: lightning does great miſchief to the farmer in this kind, as is plain by the ſeveral black ſpots and patches in fields of corn, in years, when there has been more lightning than uſual. This is a diſaſter that muſt be quietly ſuffered, ſince it can be neither prevented nor remedied; but the other cauſes of *blights*, which are moſt general, and do the moſt damage, may be prevented in ſome meaſure at leaſt.

One great and common cauſe of the *blight* is, the lodging or falling of corn; in this caſe the ſtalks are broken near the ear, and the veſſels are hurt which ſhould carry up the nouriſhment to the ear. In this caſe, there can juſt juices enough paſs for the keeping the plant alive, and bringing it to its full height, but it is languid all the time, and the grains can never be filled with flour. The earlier in the ſeaſon this lodging of the ſtalks happens, the thinner and poorer the ears will be: hence it happens, that when dung and tillage have brought a wheat land into ſo good a ſtate, that in April and May it ſeems to promiſe the farmer five or ſix quarters of wheat, it ſhall be all deſtroyed by falling in June, and ſcarce yield him five buſhels, and this ſo thin and lank, that the expences of reaping and thraſhing are more than its value. The wind is generally accuſed of the throwing down theſe ſtalks, but this does not ſeem to be truly the caſe; the wind may preſs upon the plants; but the cauſe of their giving way to it is a weakneſs in their ſtalks, and this ſeems owing either to the want of nouriſhment, or the want of air, or of the ſun's rays, and perhaps to the want of all three together.

A rich acre will maintain a crop of five quarters ſtanding, while a poor acre will not be able to ſupport ſuch a crop, as would have yielded only about three quarters had it ſtood. This is a proof of want of due nouriſhment being one great cauſe of the falling. Air is neceſſary to the nouriſhment of all plants, wheat in particular requires a very free air. It ſucceeds beſt in open hilly places where the wind comes freely to it, and ſhakes off the drops of water from the leaves, as well as their own recrements; and it is plain, that a great quantity of the ſun's rays is neceſſary to keep wheat ſtrong; becauſe in the hotter countries it is not ſubject to fall as it is with us, and in other northern countries.

There is another cauſe of the *blight*, which is the wheat's coming too late into bloſſom. It ſhould bloſſom in the beginning of June, becauſe there is not otherwiſe time during the hot weather for it to paſs through the different ſtages to the perfection of the grain.

The cauſes of the *blight* being thus known, the cure or prevention may be attempted by the farmer, on much more rational grounds than it was among the antients. It is advantageous to haſten as much as poſſible the time of bloſſoming of the corn, and to protract as long as we can the ripening of the grain, that it may have ſufficient time to fill and ſwell. The earlieſt ſown wheat is generally obſerved to eſcape the *blight* beſt, and this is owing to its coming ſooneſt into bloſſom. The antients uſed to let their ſheep feed upon the corn while young in the blade, by way of preventing it from lodging or falling afterwards: ſome of our own farmers uſe this method alſo; and, it is true, that the corn is prevented from falling by this; but the remedy is as bad as the diſeaſe, for the ſtalks are not made very ſtrong by this practice, but the ears lighter. They therefore do not weigh down and lodge the ſtalks indeed, but they are in ſome ſort blighted by this means, and the diſeaſe is cauſed by the means uſed to prevent it. This feeding the wheat with ſheep retards the time of its bloſſoming, and the only advantage of early ſowing is thus taken away by it: what grows after the eating of the ſheep is a ſort of latter crop, and is always weaker and later than the firſt. The longer the corn remains on the ground the more nouriſhment it requires from it; and in this unnatural remaining on the land, there is no proper ſupply provided.

The general remedy for all the caſes of the *blight* is the modern method of horſehoing huſbandry. In this the hoe ſtirs up the ground as often as the farmer pleaſes, and every ſuch ſtirring gives new life and nouriſhment to the plant: this way a ſupply of food for the ear may be given, whenever it is neceſſary, and the wide intervals left for the hoe in the drilling the wheat; for this ſort of huſbandry gives a free paſſage for the ſun and air to all the plants.

The moſt general *blight* of all that happen in theſe cold countries is cauſed by inſects, which ſome think are brought in the air by an eaſt wind, accompanied by moiſture, a little before the grain is filling with that milky juice which hardens into flour. Theſe inſects depoſite their eggs within the outer ſkin or rind of the ſtalks; and when the young ones are hatched they feed on the parenchyma, and eat off many of the veſſels which ſhould convey this juice; then the ear is deprived of it, and muſt in conſequence be thin and poor, in proportion to the number of the veſſels eaten, and as the inſects happen to come earlier or later; for ſometimes they come ſo late, that the grains are ſufficiently filled with this milky juice before they have any power to hurt the veſſels.

In this caſe, though the ſtraw, when examined by the microſcope, appears to have its veſſels eaten and torn, and to be full of black ſpecks, which are cauſed by the ſame inſects, yet the grain is plump and full. This is one of the many caſes in which the early ſown wheat eſcapes the *blight*. It has been ſeen, that of the crop of wheat, in the ſame field, ſome of which has been ſown earlier and ſome later, though there has been no other difference in the whole, yet the early ſown wheat has been full eared, and the late ſown has been light eared; and both have had their ſtalks equally eaten and ſpotted by the inſects.

A proof that theſe miſchievous inſects are brought by the eaſt wind, is, that the corn on the eaſt ſide of hedges is often found *blighted*, and deſtroyed by them, while that on the weſt ſide of the ſame hedge is unhurt. Some ſuppoſe they are bred in the earth, and crawl up the ſtalks, becauſe ſome whole fields are ſubject to them, and others eſcape them wholly; but this is more probably owing to the difference of the ſituation of theſe fields, as they are more or leſs expoſed to the eaſt. Some wheat is more liable to be hurt by this inſect-*blight* than another, and the beſt remedy in this evil is to plant fields which are moſt expoſed to theſe *blights*, with ſuch wheat as is leaſt ſubject to be injured by them. The white cone, or bearded wheat, which has its ſtalk or ſtraw like a ruſh, not hollow, but full of pith, except near the lower part, where it is very thick and ſtrong, is very proper on this occaſion; it is probable, that this plant has ſap veſſels, that lie deeper, and ſo are not to be deſtroyed like thoſe of common wheat; the ſtalks of this are often found ſpotted with black, which ſhews that the inſects have been there, and yet the ears are found full, and the grains plump in them.

There is another kind of *blight*, called by the farmers *moor loor*, this is occaſioned by the earth's falling away from the roots of the wheat, and is cured by throwing up ſmall furrows againſt the rows in the drilling method. The horſehoing huſbandry is beſt of all others calculated to prevent *blights*, and to cure them when they happen; but as there are ſome years when all wheat is *blighted*, even at theſe times, the horſehoing huſbandry has an advantage; for when the ſtalks fall they never lie abſolutely on the ground in this caſe, but the air has room to play between them; but the common ſown wheat has not this advantage. The ears in the *blighted* wheat of the drilled kind are not ſo light nor poor as in others, but make the farmer ſome amends in the corn, though greatly leſs than in the common produce. *Tull*'s Horſehoing Huſbandry.

Corn is always more ſubject to *blights* after a wet ſummer than at any other ſeaſon; the reaſon ſeems, that the roots being continually drenched with water, the plant runs up to ſtalk, and has very little ear, and the corn in the ear is never large or full.

It is obſerved, that when the mildews riſe or *blights* fall, they generally infeſt only one kind of grain, ſometimes wheat, ſometimes oats, and ſometimes barley only; and the ſame ſort of obſervation holds good in regard to fruit, ſometimes only apples are *blighted*, ſometimes only pears, ſometimes cherries, and ſo on. *Mortimer*'s Huſbandry. T. 1. p. 305. See the article BLIGHT.

RUSTICULA, in zoology, a name by which Aldrovand and ſome other authors have called the *godwit*, more commonly known by the name *ægocephalus*. *Aldrovand.* de Avib. See the article ÆGOCEPHALUS.

RUSTICULA *braſilienſis*, in zoology, the name given by Mr. Ray, and ſome others, to the *guarauna*, a water bird of the Braſils, of the ſize of our ſnipe. See GUARAUNA.

RUT (*Cycl.*)—RUT *of the ſea*, is where it daſhes againſt any thing.

RUTA, *rue*, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the roſaceous kind, uſually conſiſting of four hollowed petals, diſpoſed in a circular form. From the cup of the flower there ariſes a piſtil, which afterwards becomes a roundiſh fruit, approaching to a ſquare form, and compoſed of four capſules affixed to an axis, and uſually containing angular or kidney ſhaped ſeeds.

The ſpecies of *rue* enumerated by Mr. Tournefort are theſe. 1. The common broad leaved garden *rue*. 2. The more ſhrubby broad leaved garden *rue*. 3. The narrower or ſmaller leaved garden *rue*. 4. The larger wild *rue*. 5. The

ſmaller wild *rue*. 6. The broad leaved *rue* with hairy flowers. 7. The narrower leaved *rue* with hairy flowers. 8. The white-flowered coriander-leaved prickly mountain *rue*. 9. The Spaniſh flax-leaved wild *rue*.

The *rues* would ſeem to belong properly to the plants, with cruciform not roſaceous flowers; but that the number of the petals in each flower is in the cruciform flowers, always determinately four; but in this genus, as in the other roſaceous ones, it is ſometimes four, ſometimes five. *Tourn.* Inſt. p. 257.

Rue has always been held in great eſteem as a cephalic and alexipharmic. It is good in all nervous diſeaſes, fevers, ſmall-pox, meaſles; and greatly ſo in hyſteric caſes. It is given by many to ſtrengthen the ſtomach, and to prevent the return of habitual colics. It has alſo been given in pleuriſies and peripneumonies, and againſt the bites of venomous animals. There uſed to be a conſerve and a ſimple water of *rue*, but both are now rejected.

RUTA *muraria*, *wall-rue*, in botany, the name of a genus of plants, the characters of which are theſe. The leaves are of a ſhape nearly reſembling thoſe of garden *rue*. The flower is not diſcovered, but the fruit are a number of roundiſh membranaceous capſules ſurrounded by an elaſtic ring, on the contraction of which they burſt and throw out a great number of minute ſeeds.

The ſpecies of *wall-rue* enumerated by Mr. Tournefort are theſe. 1. The common *wall-rue*. 2. The broad leaved alpine *wall-rue*. 3. The taller German *wall-rue*; and 4. The tall climbing *wall-rue* with various leaves. See Tab. 1. of Botany, Claſs 16. *Tourn.* Inſt. p. 541.

RUTICILLA, in zoology, the name of a ſmall bird, called by the Greeks *phœnicurus*, and in Engliſh the *red-ſtart*. Its breaſt and rump are of a reddiſh brown, the lower part of its belly is white; its head, neck and back of a gloſſy lead colour; the head is marked before with a very fine white ſpot, which is ſeparated from the eyes and beak by a black line. Its throat is black, with an admixture of grey at the tops of the feathers. Its long wing feathers are all brown; its tail is compoſed of twelve feathers, the five outer ones of each ſide red, the two middle ones blackiſh. Its legs and beak are black, and its mouth yellow within. It feeds on flies, beetles, ſpiders, *&c.* *Ray*'s Ornithol. p. 159.

RUTILUS, in zoology, a very well known river fiſh, called in Engliſh the *roach*, remarkable for its livelineſs and vivacity.

In ſome parts of the world this fiſh will only live in ſtanding waters; with us it equally thrives in ponds and rivers, and is remarkable for its numerous progeny; a pond being much ſooner ſtocked with this than with any other fiſh. *Ray*'s Ichthyog. p. 262.

RUTILUS *latior*, in zoology, a name given by many authors to the fiſh called in Engliſh *rudd* or *finſcale*, and more uſually in Latin *rubellio fluviatilis*. Id. Ibid. p. 252.

RUTTEE, a weight uſed in the Eaſt Indies, one hundred of which make eighty-eight caracts. See CARACT.

RUTULUS, in Roman antiquity, the barrier of the cavea, or place where the wild beaſts uſed in amphitheatrical ſports were ſhut up. It was made of iron bars, which turned upon hinges, and all at once flew open with great ſwiftneſs. See *Pitiſc.* Lex. Ant. in voc. *rutulus* and *cavea*.

RUTY-PUNDOC, in natural hiſtory, a name given by the people of the Eaſt Indies to a peculiar ſpecies of yellow orpiment, which they find on the tops of the mountains there; and after ſeveral calcinations give internally in coughs and colds. The antient Greeks uſed this orpiment in the ſame manner; we have of late run into an opinion of its being a fatal poiſon. But Dr. Boerhaave, in his chemiſtry, affirms, on his own trials, that it is innocent and harmleſs. Theſe people, who have not the uſe of chemiſtry, give us a hint of the virtues of great numbers of our own foſſils, which are common alſo to their country. The ſelenitæ, fibroſe talcs, ſpars, and many other foſſils, which we wholly neglect, are in common uſe with them, and great cures are often performed by them. *Woodw.* Cat. Foſſ. Vol. 2. p. 13.

RYE, *ſecale*, in botany. See the article SECALE.

This ſort of grain ſucceeds very well on any ſort of dry land, even on the moſt barren gravel or ſand. The farmers ſow it about the beginning of September, after a ſummer's fallow, in the drieſt time they can. Two buſhels of ſeed is the quantity generally allowed to an acre of land; but if it be ground newly broken up, or if it be ſubject to worms, they then allow a peck more to the acre. A little ſprinkling of dung, or mud, upon *rye* land, will greatly advance the crop, though it is laid but half the thickneſs that it is for other corn; its produce is commonly about twenty buſhels upon an acre.

The farmer knows it is ripe when the ſtraw is yellow, the ear bends, and the grain feels hard. It is not apt to ſhed the ſeeds; and therefore, if there are many weeds among the crop, it may be left lying upon the ground, or gravel, as they call it, eight or nine days after it is cut, before it is bound up, if the weeds are not dry ſooner: for otherwiſe, they will grow moiſt in the barn, and cauſe the whole to give, and not to thraſh well, and ſometimes they will make it muſty.

As it is a grain that will grow in the ear ſooner than any other if it be wet, care muſt be taken if rain falls after it is cut, to turn it as it lies on the ground every other day; and at the ſame time to keep the ears as far from the earth, and as much above the ſtubble as may be; this will prevent the miſchief. If it be pretty clear of weeds it may be houſed as ſoon as it is cut. If either this grain or wheat lodge upon the ground, it is beſt to cut them, even though they are not ripe; for the ſtalk being broken will yield no more nouriſhment to the ear.

There is another very eſſential uſe to the farmer made of *rye*. April is the ſeaſon of the year when food is of all others the ſcarceſt for cattle, eſpecially for ſheep and lambs: on this occaſion ſome ſplit the ridges of the wheat ſtubble and ſow them with *rye*; they harrow this in, allowing about a buſhel to an acre: they feed the ſheep with this in April, and in May they plow it up for fallow. *Mortimer*'s Huſbandry, p. 136.

In many parts of France there have been certain years, in which this grain, from no apparent cauſe, has proved noxious, and ſometimes even poiſonous. Mr. Perrault travelling through Sologne, was informed that the *rye* of that province was ſometimes ſo corrupted, that thoſe who eat of the bread that had much of the corrupted grain in it, were ſeized with gangrenes in different parts of the body, which was not preceded by any fever, inflammation, or any conſiderable pain; and that the gangrened parts uſually fell off after a time of themſelves, without the aſſiſtance of chirurgical inſtruments.

The grains of *rye* thus degenerated are black on the outſide, and tolerably white within; and when they are dry, they are harder and cloſer than the natural good grain: they have no ill taſte, but ſometimes they have a viſcous metallic like honey hanging to one end of them. They grow longer than the other grains in the ſame ear, and are found from one or two, to ſeven or eight in the ſame ear. Some have ſuppoſed that theſe were not the proper ſeeds of the plant, but ſome other extraneous bodies that got in among them; but it is evident, from a cloſe inſpection, that they are really the genuine ſeeds only altered by ſome accident; the coats, and the furrow, and even the germen for the young plant, being entirely the ſame as in the natural ſeeds.

The places where the *rye* is found to degenerate in this manner, are all a dry and ſandy ſoil. In theſe places there is ſcarce any ſoil in which more or leſs of theſe large ſeeds are not found among the others, but where there are but few of them the ill effects are not perceived. The ſeaſons when the degeneracy is greateſt, and the effects the worſt of all, is, when there have been exceſſive rains in the ſpring, and there come on exceſſive heats in the ſucceeding ſummer.

The bread which is made of the *rye* that holds ever ſo much of this bad corn, is not diſtinguiſhable from other *rye* bread by the taſte, and ſeldom produces its ill effect, till ſome conſiderable time after it is taken. Beſide the gangrenes already mentioned, it not unfrequently brings on other bad conſequences, ſuch as drying up the milk of women who give ſuck, and occaſioning ſometimes malignant fevers, accompanied with drowſineſs, ravings, and other dangerous ſymptoms. The part uſually ſeized by the gangrene is the legs, and this often in a very frightful manner. The arms are the part moſt ſubject next, but all the other parts of the body are ſubject to it.

The firſt ſymptom of this approaching gangrene is a ſtupefaction and deadneſs in the part; after this there comes on ſome pain, though not violent, and the ſkin becomes livid; ſometimes the ſkin ſhews no mark of it, but the pain and ſwelling increaſe; and it is neceſſary to make an inciſion into the fleſh to find the gangrened part. In the more deſperate caſes, the only remedy is the taking off the part; and if this is neglected, the fleſh is all waſted, and the ſkin becomes black, and clings round the bones, and the gangrene appears again in the ſhoulders.

The poorer people are only ſubject to this diſeaſe; and, as they principally eat the *rye* bread; and as thoſe years when there is moſt of this bad grain among the ears of *rye* produce moſt of theſe diſorders, it has been judged certain that the *rye* is the occaſion of it. It may deſerve enquiry, however, whether that grain may not be innocent of the miſchief, and its degeneracy and the diſtemperature attributed to it may not both be the effect of the ſame bad conſtitution of the air. If it proves, on enquiry, that only thoſe who eat of the *rye* are ſubject to the diſeaſe, it will ſeem a proof of its being really owing to it; and in this caſe the miſchief may be prevented by the ſifting the grain before it is ground, the degenerated grains being ſo long that they will all remain in the ſieve that lets the others through. The experiment has been made on the ſpot, by giving the flower of the corrupted grains alone to animals, and it is ſaid they have been killed by it. Phil. Tranſ. N° 130.

RYSAGON, in the materia medica, a name by which ſome authors have called the *caſſumunar root*.

S.

S, in the Italian muſic, ſtands for *ſolo*; it is uſed in pieces of muſic of ſeveral parts, to intimate, that in ſuch places a voice, or inſtrument, is to perform alone. See the article SOLO.

SABAZIA, Σαβαζια, among the Greeks, nocturnal myſteries in honour of Jupiter *Sabazius*, into which all that were initiated had a golden ſerpent put in at their breaſts, and taken out at the lower part of their garments, in memory of Jupiter's raviſhing Proſerpina in form of a ſerpent. *Potter*, Archæol. Græc. l. 2. c. 20. T. 1. p. 429.

SABINA, *ſavin*, in medicine. See SAVIN.

SABINITES *lapis*, in natural hiſtory, a name given to a ſtone in which are preſerved the leaves of the common ſavin. See the article *foſſile* PLANTS.

SABLE (*Cycl.*)—SABLE, in zoology, the name of the animal whoſe fur is ſo much valued, and ſold under the ſame name. It is a creature of the weaſel kind, and called by authors *muſtella zibellina*. See the article ZIBELLINA.

SABLE *mouſe*, in natural hiſtory, the name of an animal found in Lapland, and in other cold countries; many extraordinary things are related of the manner of living of theſe creatures.

They are of the bigneſs of a ſquirrel, and their ſkin is ſtreaked with brown and black; there are alſo ſome ſpots beſide the ſtreaks; the black is a very fine deep colour, the brown is pale; they have two very ſharp teeth above, and two below of the ſame kind; their feet are like a ſquirrel's, and they have no tail; they are uſually very fat and fleſhy, and are ſo quarrelſome and fierce an animal, that if a ſtick be held out to them they will bite at it, and will hold it ſo faſt, that they may be toſſed and ſwung about in the air by it without letting it go. In their march they uſually keep a direct line from north eaſt to ſouth weſt, and always travel in thouſands in the ſame troop. The whole number forms a ſquare body, and they march only from the time of the twilight to the morning, lying ſtill all the day.

They march in lines, which are ſome ells diſtant, but always exactly parallel to each other, ſo that the places they have gone over look like the furrows of a ploughed field. If they meet with any thing in their way that might deter another animal, it never ſtops them; but, though it be fire, a deep well, a pond, a torrent, or a bog, they without heſitation venture through, and by that many thouſands of them are deſtroyed, and are found dead in the morning, in the waters, or otherwiſe.

If they be met ſwimming over lakes, and attacked by men in boats with the oars, boat hooks, or other inſtruments; they neither retreat nor offer to run up the oars, but hold on their courſe; and if they be put out of it they preſently return into it again. When they are met in the woods or fields, they ſet themſelves up on their hinder feet, and make a ſort of ſqueaking noiſe, ſomewhat like the barking of a dog; they will leap up at a man, and riſe as high as his head, and in this manner they will defend their line a long time; but if they find themſelves overpowered, they will diſperſe and run into holes, or any other places of ſecrecy, making a noiſe, which ſounds ſomething like the word *biob*, *biob*.

They never come into a houſe, nor meddle with any thing that we eat; if they chance to come to a houſe in their way, there they ſtop till they die; but if they come to a ſtack of hay, or corn, they eat their way through.

When they march over a meadow they do it great damage, by eating the roots of the graſs; but if they encamp there, they wholly deſtroy the produce; the land looks like a place where there had been a fire, and the whole ſurface looks as if ſtrewed with aſhes.

They are ſaid to be very fruitful, bringing forth eight or nine at a time; but it is certain, at leaſt, that they bring forth more than one, for in their marches it is not unuſual to ſee a female with a young one in her mouth and another on her back. They ſeem no great delicacy to creatures of prey. If dogs or cats kill them they eat only the head, and when a bird of prey ſeizes them it only feeds on the entrails; it is ſaid only on the heart: the poor Laplanders, however, in want of other food eat the whole body, and ſay it is as well taſted as a ſquirrel. In the ſeverity of winter theſe creatures lie under the ſnow, and have their breathing holes as the hares, and other inhabitants of theſe places uſe to have. The Laplanders are always glad to ſee theſe creatures on their march, for it always foretels plenty of more valuable creatures among them: the ſame cold that ſends theſe out, ſending alſo a number of fowl, ſquirrels, foxes, and other animals the ſame way. Wormius has written a complete treatiſe on this animal, calling it *mus norwegius*, this is reprinted at large in his Muſeum. Phil. Tranſ. N° 251. p. 112.

SABURRÆ, in natural hiſtory, the name of a genus of foſſils found in form of powder, and uſually confounded among the ſands, and called by the ſame name. Theſe are not compoſed like the genuine ſands of pure natural concretions, but are irregular particles, ſeeming to have been the fragments of other large bodies. They are not to be diſſolved or diſunited by water, but retain their figure in it, and do not cohere by means of it into a maſs. They are often very opake, and in many of the ſpecies will ferment with acids, and are often fouled with heterogene particles, taking in the coarſer, ſtony, mineral, and metalline particles, and are according to their colour divided into ſeveral kinds.

White SABURRÆ. Of theſe conſiſting of pure ſpar we have three kinds. 1. A fine ſnow white one; and 2. A dull coarſe white one found in different places on Mendip Hills; and 3. A fine cream coloured one found only in the iſlands of the Archipelago. Of theſe containing heterogene particles we have nine ſpecies. 1. A bright coarſe white one compoſed of cryſtal and ſpar found in Leiceſterſhire. 2. A white coarſe one with micæ common in Wales. 3. A dull white fine one found in Northamptonſhire. 4. A dull greyiſh white coarſe one common in Yorkſhire. 5. A fine dull browniſh white one common in Leiceſterſhire. 6. A fine glittering greyiſh white one found in Yorkſhire. 7. A fine greeniſh white ſpangled one found in Dorſetſhire. 8. A dull coarſe greeniſh grey one common in Yorkſhire; and 9. The *pulvis puteolanus*, a fine dull looking grey one found in Italy. See PUTEOLANUS.

Red SABURRÆ. Of thoſe which are pure we have five ſpecies. 1. A fine pale red one found in Briſtol. 2. A coarſe ſhining pale red one found on the coaſt of Fife. 3. A coarſe ſhining greyiſh red one found on the ſhores of the iſland of Minorca. 4. A coarſe greeniſh red dull one found on the ſhores of ſome parts of the Mediterranean. 5. A fine ſhining ferrugineous one found about Liſbon. Of thoſe variegated with talcy ſpangles we have nine ſpecies. 1. A fine red one with micæ found about Minorca. 2. A coarſe red variegated one with micæ. 3. A large bright fleſh coloured one with micæ. 4. A fine browniſh red variegated one with micæ. 5. A fine fleſh coloured micaceous one, all from the coaſts of Scotland. 6. A fine whitiſh red one with micæ, and variegations, found on the ſhores of the northern iſlands. 7. A browniſh red coarſe one found on the ſhores of the Red Sea. 8. A large coarſe blackiſh red one found on the ſhores of Sicily; and 9. A coarſe ſhining greeniſh red one found on the ſhores of the Mediterranean.

Green SABURRÆ. Of theſe we have only two known ſpecies. 1. A coarſe beautifully green dull one, which was the chryſocolla of the antients, ſee CHRYSOCOLLA. And 2. A fine ſhining green one found on the ſhores of the Red Sea.

Yellow SABURRÆ. We yet know only one ſpecies of this kind, which is the ſhining gold coloured micaceous one, which has deceived the world very often into an opinion of its containing gold. It is very common in Virginia and elſewhere.

Black SABURRÆ. Of this we have one pure ſpecies, a fine black one variegated with white, common in France. Of thoſe containing talcy particles we have two known ſpecies. 1. A fine variegated black and white one, with micæ found on the ſhores of the Mediterranean; and 2. A coarſe variegated black and grey one, frequent on the ſhores of Wales; and beſides theſe there are three of this colour which are full of metalline particles. 1. A ferrugineous black glittering one found on the ſhores of Italy. This is the ſhining black ſand, as it is called, uſed to throw over writing. 2. A coarſe glittering browniſh black one, common on the ſhores of Wales, and uſed there on the ſame occaſion; and 3. A fine bluiſh black glittering one, common alſo on the ſhores of Wales. All theſe are principally made up of lead ore. *Hill's* Hiſt of Foſſ. p. 569.

SACABURGH, SACABERE, or SAKEBERE, in our old writers, one that is robbed, or by theft deprived, of his money or goods, and puts in ſurety to proſecute the thief with freſh ſuit; according to Selden, in his titles of honour, and Briton. c. 15 & 29. with whom agrees Bracton (lib. 3. tract. 2. c. 32. n. 2.) *Furtum vero manifeſtum eſt, ubi latro deprehenſus ſit ſeiſitus de aliquo latrocinio*, ſcil. Honhabend

& Backberond & *insecutus fuerit per aliquem cujus res illa fuerit, qui dicitur* sacaburh, &c.

The word may come from the Saxon *sac* or *saca*, i. e. *lis, causa, prosecutio*, and *burh, pignus, hoc est furti symbolum. Spelm.* Gloss. in voc.

But Sir Edward Coke says, *sacabere*, or *sakebere*, is derived from *sac* and *bere*, that is, he that did bear the bag. 8 Inst. fol. 69. *Blount.* Law Dict. in voc.

SACCARII, among the Romans, were a company or fraternity of porters, who had the sole privilege to carry all goods from the harbour to the warehouses, none being allowed to employ their own slaves, and much less those of others, for that purpose. *Pitisc.* in voc.

SACCER. See the article SAKER, *Cycl.*

SACCHARUM (*Cycl.*)—SACCHARUM, in the Linnæan system of botany, is the name of the plant which produces sugar, and which makes a distinct genus by itself. The characters of this are, that there is no calyx or flower cup, but a downy substance longer than the flower, and including only one single flower, which is composed of two oblong and pointed valves, both equal in size, placed erect, hollowed and naked, or not bearded. The stamina are three capillary filaments of the length of the flower; the antheræ are somewhat oblong, the germen of the pistil is pointed. The styles are two and are hairy, the stigmata are simple. The flower encloses the seed which is single, oblong, narrow, and pointed. *Linnæi* Gen. Pl. p. 18.

SACCHARUM *saturni*, in medicine, is recommended by some internally for dysenteries, and hæmorrhages of all kinds; but the generality of the world condemn it, as containing all the poisonous qualities of the metal it is made from in their highest degree.

Externally it has been long famous for its virtues in the erysipelas, in inflammations of all kinds, and in embrocations. It is used also in small quantities in collyriums for the eyes; it deterges, dries, and cicatrises ulcers; and in gonorrhœas is mixed in injections with great success.

It is well known that this salt made with the common vegetable or mineral acids, when distilled, will not give back the acid again, but only yields a water without any sharp taste and an inflammable oil; but if it be made into the animal acid of pismires, whether procured by distilling those insects fresh, or by throwing large quantities of them into water till it is sufficiently impregnated, it will on distillation yield back the same proportion of acid of the same strength. Phil. Trans. N° 68. See TINCTURA *antiphthysica.*

SACCHARUM *lactis.* See the article MILK.

SACCINI, in our old writers, Monks so called, because they wore a garment of goat's hair next to their skins. *Saccus* is applied to coarse cloth made of such hair. *Blount.*

SACCO *beneditto.* See the article SANBENITO, *Cycl.*

SACCUS *cum brochia*, in our old writers, a service or tenure of finding a *jack* and a *broach* to the king, for the use of his army. Bract. lib. 2. c. 16. *Blount, Cowel.*

SACCUS *lacteus*, a name given by some anatomists to the *receptaculum chyli.*

SACER (*Cycl.*)—SACER, in ichthyology, a name given by Gaza and some others to that species of the *labrus*, distinguished by Artedi by the name of the red forked tailed *labrus*, and called by the generality of other authors the *anthias piscis.* See the article ANTHIAS.

SACHETTUS, in zoology, the name of a sea fish, much resembling the common river pearch in shape and colour, and having the same black obliquely transverse lines on its sides, and seeming the same with the *channadella* of Bellonius, Rondeletius, and other authors. It has only one long back fin, the foremost rays of which are prickly, the others smooth behind these prickly rays; it has a large black spot, which alone distinguishes this from all the other fish of its kind. Its mouth is large, and its lower jaw something longer than its upper. The belly fins are black, and the tail is forked; the scales are large; and as in the other fish of this kind, cover not only the body but the gills, and part of the head of the fish. It is common in the Mediterranean, and is brought to market at Rome, Venice, and elsewhere, and accounted a very delicate and well tasted fish. *Ray*'s Ichthyolog. p. 326.

SACRA (*Cycl.*)—SACRA *fistula*, a name given by some to the cavity, in which the spinal marrow is lodged, and by others to the spinal marrow itself.

SACRA *gentilitia*, among the Romans. Beside the public festivals observed by the whole Roman people, and beside the holy-days kept on birth-days, marriages, or any other personal account, there were likewise family feasts celebrated annually by the descendants only of particular families.

They thought themselves obliged to keep these with the utmost exactness and regularity, on pain of divine vengeance. Livy tells us that a young man of the Fabian family, when the capitol was besieged by the Gauls, made his way through the enemy's army, in order to celebrate the yearly festival of his family, to the no small astonishment both of the besiegers and besieged. Mem. Acad. Inscript. Vol. 8. p. 310.

SACRANUS *color*, a name given by some authors to purple, or very deep red.

SACRARIUM, among the Romans, a chapel in a private family. It differed from *lararium*, as being dedicated to some particular deity, and the *lararium* to the household gods in general. *Pitisc.* in voc.

SACRE, in zoology, the name of a species of falcon, called by authors *falco sacer*, and differently described by different authors, but by all agreed to be an extremely bold and active bird. The description Mr. Ray has selected of it is this. It is a larger bird than the common falcon. Its head is flat and of a greyish colour; its eyes large, and its beak bluish. Its back and wings are brown; its breast white, and variegated with brown spots. Its thighs are white within, and its tail is variegated with spots of the shape of a kidney. Its wings are very long, and its legs and feet of a bluish colour. The yearling birds of this species are called *sori*, and differ considerably in their plumage from those of a more advanced age, having their legs paler, and their breasts less spotted. It will seize upon the largest birds, and on young goats, &c. for food. *Ray*'s Ornithol. p. 43.

SACRIFICE (*Cycl.*)—SACRIFICES, among the Greeks, were of four kinds, *viz.* 1. Free-will offerings, or such as were paid in consequence of a vow, χαριστηια and Ευκλαια, for a victory obtained, the first fruits offered by husbandmen for a plentiful harvest, and the like. 2. Propitiatory offerings, ιλαστικα, to avert the anger of some offended deity, and such were all *sacrifices* used in expiation. 3. Petitionary sacrifices, Αιτητικα, for success in any enterprize. 4. *Sacrifices* expressly commanded by some oracle or prophet, τα απο μαντειας.

For the materials and rites of *sacrifices* see *Potter*, Archæol. Græc. T. 1. p. 209. seqq. and SACRIFICE, *Cycl.*

SACRIMA, among the Romans, the new wine which was offered to Bacchus as an acknowledgment of his protecting and preserving every thing that belonged to wine. *Pitisc.*

SACRO-COCCYGÆUS, in anatomy, a name given by Winslow to a muscle now generally called simply the *coccygæus*, he calls it also *coccygæus posterior.*

SACRO-LUMBARIS, a long complex muscle, narrow and thin at the upper part, and broad and thick at the lower, representing a kind of flat pyramid. It lies between the spine and posterior part of all the ribs, and along the back part of the regio lumbaris, all the way to the os sacrum. Through all this space it is closely accompanied by the longissimus dorsi, which lies between it and the spinal apophyses of the vertebræ, a narrow fatty or cellular line running between them; it is fixed below by a broad thin tendinous aponeurosis to the os sacrum, and part of the crista of the os ilium. From thence it runs upward, and a little laterally over all the regio lumbaris; afterwards it runs up obliquely over all the ribs, sometimes as high as the two or three lowest vertebræ of the neck. The side next the longissimus dorsi is all this way very even; but that next the ribs is divided into several digitations, resembling the branch of a palm tree. These are fixed in the transverse apophyses of the neck, in the tuberosity of the first rib, in the lower part of the angular impressions, in the following ribs, and near the extremity of the last. *Winslow*'s Anatomy, p. 245.

SACRO-LUMBARIS *pars superior*, in anatomy, a name given by Cowper and some others, to a muscle, called by Winslow *transversalis collateralis colli*, and by Albinus the *cervicalis descendens.* See the article TRANSVERSALIS.

SACRO-SCIATIC *ligaments.* These are two in number, the one broad and external, the other small, narrow, and internal. The broad, or external *sciatic* ligament, is slightly fastened to the inside of the tuberosity of the crista of the os ilium. It covers exteriorly the two posterior spines of that bone, and continues to be inserted along the anterior and exterior edges of the false transverse apophyses of the sacrum. From thence this ligament diminishing in breadth, descends obliquely toward the tuberosity of the os ischium, and is inserted immediately below the sinus, which lies between that tuberosity and the *sciatic* spine. This insertion is afterwards continued over the whole internal labium of the inferior portion of the os ischium, and of the ramus of that bone, and the inferior portion of the ramus of the neighbouring os pubis. Through all this latter course of its insertion, that is after its arrival at the tuberosity of the ischium, it produces a kind of ligamentary falx, one edge of which is fixed to the bones, the other lies loose; and by this situation of the falx, it seems, together with the bones, a kind of deep channel or groove. The small *sacro-sciatic*, or internal *sciatic* ligament, adheres closely to the inside of the posterior portion of the former. It is fixed interiorly also to the edge of the inferior part of the fourth false transverse apophysis of the os sacrum, and from thence all the way to the upper part of the os coccygis. From this insertion it runs up a little obliquely to the spine of the ischium, in the sharp point and upper part of which it is fixed. During this course it crosses the broad ligament, being closely united to the inside thereof, and loses but very little of its breadth. By these two ligaments two distinct openings are formed; a large one which is the superior *sciatic* sinus, and a small one with the inferior *sciatic* notch. *Winslow*'s Anatomy, p. 123.

SACRUM *os.* See the article Os *sacrum.*

SACTIM, a word uſed by ſome of the chemical writers to expreſs vitriol.

SADAF, in the materia medica, a name given by the Arabian writers, ſometimes to the purpura or purple fiſh, and ſometimes to the purple fucus, with which the antient Greek women uſed to ſtain their cheeks. This was the original of all painting, and the plant was the common purple ſea wracks. After this every thing was called fucus that was uſed by the women to paint their faces; and they had a fucus metallica made of white lead or ceruſs, and the purple root of alcanet, *&c.* were called fuci.

SADAR, or ALSADOR, the Arabian name of the medicinal *lotos*, deſcribed by Dioſcorides, and many others of the antients. This ſhrub was called by ſome of the antients *acanthus*, from its being full of thorns, and hence many have confounded it with the common *acanthus*, or *bear's breech*, and many with the *acanthus* of Theophraſtus, which is the acacia or gum arabic tree. The fruit of this tree, called by Virgil the berries of the *acanthus*, is the *nabac* of the Arabian writers, though ſome would have it to be a kind of fig. Serapion evidently declares the *ſadar* and *acanthus* of Virgil, that is the *lotus cyreniaca* of Herodotus, and the *lotus* of Dioſcorides to be one and the ſame plant. Bellonius has alſo deſcribed it under the name of *napeca*, a name probably derived from *nabac*, the appellation uſually given its fruit: he ſays it is an ever-green ſhrub, and was called by ſome of the Greek writers *œnoplia*. Proſper Alpinus, in his account of the Ægyptian plants, alſo deſcribes the *nabeca* as a thorny ſhrub; though authors have obſerved that there are two ſpecies of it, the one thorny and the other not. Leo Africanus, in his third book, mentions alſo the ſame tree; but he miſtakes the name, writing it *rabech* inſtead of *nabech*; he ſays it is a prickly tree, producing a fruit reſembling a cherry, but ſmaller, and of the taſte of the zizyphus. Theſe are the berries of the *acanthus* mentioned by Virgil. *Proſper Alpin.* de Plant. Ægypt.

SADDLE (*Cycl.*)—A hunting *ſaddle* is compoſed of two bows, two bands, fore-bolſters, pannels, and *ſaddle*-ſtraps: and the great *ſaddle* has beſide theſe parts, corks, hind-bolſters, and a trouſſequin. The pommel is common to both. See BOW, BAND, BOLSTER, *&c.*

A horſeman that would ſit a horſe well, ought always to ſit on his twiſt, and never on his buttocks, which ought never to touch the *ſaddle*; and whatever diſorder the horſe commits, he ought never to move above the *ſaddle*. *Guill.* Gent. Dict. P. 1. in voc.

SADDLE-*backed*, among horſemen, a name given to a horſe, that is hard to fit with a *ſaddle*, his reins being low, and his head and neck raiſed, ſo as to require a *ſaddle* to be made on purpoſe for him. *Guill.* loc. cit.

SADDLE *caſe*. See the article HOUSING, *Cycl.*

SADDLE *roll*. See the article TROUSSEQUIN, *Cycl.*

Cart-SADDLE. See the article CART.

SADDLE *ſtraps*, are ſmall leathern ſtraps, nailed to the bows of the *ſaddle*, which are uſed to hold the girths faſt to the *ſaddle*. See the article BOWS.

SADIR, a word uſed by ſome chemiſts to expreſs the ſcoria of any metal in fuſion.

SADRE, a title given by the Perſians to the chief of the Mahometan religion. See the article CALIPH.

SÆPÆ, a name given by ſome medical writers to ſharp corroding puſtules.

SAFFRON, *crocus*, (*Cycl.*) in botany. See CROCUS.

There is no accident attending the culture of this valuable and uſeful plant, which the farmers ſo much dread, as what they call the *rot* with us, and in French *la mort*. This is more common in the *ſaffron* fields of the Gatinois than in ours. Mr. du Hamel, who undertook to give the Paris academy ſome account of this malady of the plant, obſerves, that no author has given any account of it; and that the people employed in the culture of the *ſaffron*, know the terrible effects of it, without at all gueſſing at what may be its cauſe. It ſeems a ſort of contagion among the plants, ſpreading far and wide, and extending from one root as from a center all over a whole field, if not ſtopped; the ſeaſon of its moſt fatal ſpreading is the ſpring, and the miſchief is found to be ſtopped from farther progreſs, by digging deep trenches at that time of the year between the ſound and the tainted parts of the field.

Mr. du Hamel, in enquiring into the ſtate of the roots or bulbs of the *ſaffron* in many fields where this diſorder reigned, found that the roots in the center where the diſtemperature moſt raged, and thoſe at a middle diſtance from this part and the border of the field, and thoſe at the border, were all in three different ſtates, according to the degree of ſpreading of the infection. Thoſe in the middle where the infection began, were utterly deſtroyed, their ſeveral coats all ſhrivelled up and withered, their inner part reſembling only a dirty and rotten earth, and their ſuperficies being covered with ſeveral browniſh red glandulous bodies of the bigneſs of beans. Thoſe of the middle diſtance were found in a condition nearly allied to theſe; their integuments were flaccid, but not wholly withered; and there were ſome remains of the fleſhy bulb within; but this matter was a ſort of pulp, looking as if it had been boiled. It was eaſy to ſee from this, that theſe roots were ſpeedily approaching to the perfect ſtate of decay of the others; they were covered in the ſame manner on their outſides with glandulous ſubſtances, like thoſe of the middle roots, only that they ſeemed on theſe more plump, and well fed. At ſome diſtance from theſe he alſo obſerved a number of violet coloured threads, forming a ſort of network in the ground.

The roots at the edges of the field were found in a yet much ſounder ſtate than any of the others; their bulbs ſeemed unhurt, and the membranes ſound and freſh, but they were in many places covered with reticular violet coloured filaments, and from ſome parts of theſe there iſſued ſmall glandules, which ſeemed ready to grow into the ſame ſhape and ſize with thoſe on the decayed roots; though they, at this time, appeared only as ſo many purple ſpots lodged on the ſurface of the root or between its membranes. The earth all about theſe roots was alſo found to be full of theſe reticular violet coloured threads.

Theſe violet threads and their glandules being always found in the places where the rot was among the *ſaffron* roots, and never in any other place, it became very natural to ſuppoſe they had ſome conſiderable ſhare in the contagion; to examine, therefore, what they truly were, Mr. du Hamel picked ſeveral of them out of the earth, and having waſhed them clean, he found that they were very like the truffle in appearance; and in all their qualities they were ſeldom larger than a hazel nut, and were covered with a ſort of ſoft down or velvety coat, and they had a muſhroom like taſte, but with an earthy flavour. There were found ſome of them adhering to the bulbs of the *ſaffron*, and others two or three inches diſtant from them; the violet threads are of the thickneſs of a coarſe thread, and are covered with a velvety coat, in the ſame manner with the glandulous bodies; ſome of theſe extend themſelves from one to another between theſe glandules, while others ſpread themſelves over the ſurface of the bulb of the *ſaffron*, and pierced it in many directions quite to the center: they make numerous anaſtomoſes and inoſculations in the body of the root, and have faſtened to them in ſeveral places little knots or ganglions, which ſeem only ſmall tufts of the cottony or velvety matter which covers them.

From the whole it ſeems very clear, that this is a paraſitical plant, which grows very quick in its glandules; and by means of theſe threads, or filaments, ſucks its nutritious juices from the roots of the *ſaffron*, which it by that means deſtroys. It ſeems to grow in the ſame manner with the truffle, that is, it never appears above the ſurface of the earth, but is produced under ground, and there grows and propagates its ſpecies. It ſpreads very faſt, and ſoon occupies a large compaſs of ground, continually furniſhing new glandules at the end of the filamentous roots, in the manner of the potatoe and ſome other roots. Thus the diſeaſe of the *ſaffron*, wherever it begins, ſpreads itſelf every way in a circular direction; and there is nothing to be ſeen on the ſurface of the earth, which can give any opportunity of gueſſing at its cauſe.

It remained now to enquire whether this plant was peculiar to fields of *ſaffron*; and whether it was brought thither with the *ſaffron*, or was there before: and another material queſtion was, whether it could draw its nouriſhment from any other plants, or muſt have it from *ſaffron* only. To try this, Mr. du Hamel put ſome of the bulbs of the new plant into a pot of freſh earth, where he alſo planted ſome roots of *ſaffron*, of narciſſus, and of the common lilly. Six months afterwards, examining the whole, he found the glandules had greatly increaſed in number, and had fed upon the lilly roots as well as on the *ſaffron*; hence it appeared, that this was a real plant capable of increaſing itſelf, and not deſtined ſingly to that food; after this digging up the earth in ſeveral places where *ſaffron* had never been planted, he found in ſome places the ſame paraſitical plant, faſtening itſelf to the roots of the anonis, and ſome other plants, and letting alone ſeveral others, ſuch as the ſenecio, *&c.* The roots of muſcari were alſo ſometimes found affected by it; and a certain diſtemperature, which the floriſts complain of in their tulip roots, ſeems to be owing to the ſame cauſe.

This miſchievous plant, however fatal it prove to the *ſaffron* fields; may, on the contrary, prove a real benefit in corn fields, by deſtroying many of the pernicious herbs which hurt the corn, as it preys only on thoſe which ſend their roots deep into the earth, never hurting thoſe which are ſuperficially fixed, as corn, and the like are. The floriſt, however, is probably often as much injured by it, as the *ſaffron* cultivator; and doubtleſs, whole beds of plants are often deſtroyed without the proprietor's knowing what to attribute the miſchief to. One misfortune attending this deſtroying plant, is, that the common culture of land which deſtroys other weeds, ſerves rather to promote its increaſe, ſince it delights in light dry earth, not in wet, or undug lands: it is poſſible, however, to ſtop its progreſs, by digging pretty deep between the ſound and the infected roots; of the laſt, thoſe which are eaten to the heart can never recover again, but of thoſe which are only wounded ſuperficially there is ſome hope; ſince it is common for them to be

be cured by taking them up, peeling off their outer huſks, and drying them in the ſun. This ſeparates the worſt part of the deſtructive plant, and the reſt becomes ſoon dried and withered, and incapable of farther vegetation, while the root itſelf is uninjured, and when put into the ground will ſhoot again. Mem. Acad. Par. 1728.

The yellow tinge, which this medicine is able to give to the fluids, is carried ſo far, that no juice eſcapes it. Amatus Luſitanus gives an account of a fœtus in a mother's womb, tinged yellow, by her taking very frequently medicines with *ſaffron* in them. This had been diſputed and diſbelieved by many. But an experiment made at Leipſick on a bitch big with puppies, reſtored the credit of Amatus. For on giving this creature *ſaffron* frequently among her food, the puppies had their fleſh and the whites of their eyes, when opened, dyed yellow with it; though the chyle, in the lacteals, was not yellow but whitiſh. However, it does not ſeem improper to verify the experiment farther.

Tree SAFFRON, in natural hiſtory, the name of an Eaſt-Indian ſhrub, which grows to about two feet high, having ſquare branches, which are beſet with leaves in pairs. The pedicles of the flowers come from the alæ of the leaves, and are branched, each pedicle ſupporting about five flowers; theſe are of the ſhape of the jaſmine flowers, and are white above, and of the fine reddiſh yellow colour of *ſaffron* below. The flowers never open but in the night, and then do not perfectly expand themſelves, but all the petals remain in ſuch a poſition, that they can cloſe inſtantaneouſly on occaſion of the leaſt heat; they are placed each in a green cup, to which they are ſo ſlightly faſtened, that the leaſt motion makes them fall. They ſeldom ſtand more than four days, often not ſo long; the flowers have no ſmell, but are of a cordial virtue, approaching to that of *ſaffron*. Mem. Acad. Paris, 1699.

Meadow SAFFRON, *colchicum*, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the liliaceous kind, but conſiſts only of one leaf which ariſes immediately from the root, in form of a fine ſlender tube, and by degrees expands and enlarges, and becomes divided into ſix ſegments. The piſtil ariſes from the bottom of the flower, and terminates in ſeveral very ſlender filaments; this finally becomes a fruit of an oblong trigonal form, which is divided into three cells, and contains roundiſh ſeeds. To this it is to be added, that the root is doubly tuberoſe, one part being fleſhy, and the other tuberoſe, and both are covered with a common membrane.

The ſpecies of *colchicum* enumerated by Mr. Tournefort are theſe. 1. The common *colchicum*. 2. The white *colchicum* with purple lines. 3. The common *colchicum* with a leaf veined with white. 4. The common *colchicum* with a leaf painted with yellow. 5. The common French *colchicum* with ſingle blackiſh purple flowers. 6. The *colchicum* which flowers both in ſpring and autumn. 7. The Engliſh narrow leaved white flowered *colchicum*. 8. The *colchicum* with flowers mottled with white and red. 9. The many flowering *colchicum*. 10. The white *colchicum* with red ſtreaks. 11. The many flowered variegated *colchicum*. 12. The broad leaved variegated *colchicum*. 13. The *colchicum* variegated with a deep purple and ſnow white. 14. The *colchicum* variegated with a paler purple and a greyiſh white. 15. The *colchicum* with flowers, teſſelated like the fritillaries. 16. The Coan purple *colchicum*, with large, broad, and curled deep green leaves. 17. The double Portugal *colchicum* with fleſh coloured and purple flowers. 18. The *colchicum* with narrow variegated ſegments of the flower. 19. The double flowered variegated *colchicum*. 20. The many flowered, broad leaved, variegated *colchicum*. 21. The white many flowered *colchicum*. 22. The broad leaved many flowered *colchicum* with white hellebore leaves. 23. The double autumnal many flowered *colchicum*. 24. The vernal many flowered *colchicum* with broad convoluted leaves. 25. The double flowered common *colchicum*. 26. The many flowered double white *colchicum*. 27. The double many flowered *colchicum* with teſſelated flowers. 28. The vernal Spaniſh *colchicum*; and 29. The narrow leaved mountain *colchicum*. *Tourn.* Inſt. p. 349.

Syrup of SAFFRON. This medicine is thus made: take fine *ſaffron* an ounce, cut it ſmall, and put it to infuſe in a pint of mountain wine; let it ſtand three days without heat, then ſtrain off the wine; to which, after filtration, add twenty-five ounces of double refined ſugar: melt the ſugar over a gentle heat, and then ſet it by for uſe.

Tincture of SAFFRON, a preparation made as follows: take *ſaffron* an ounce, cut it ſmall, and pour on it in a matraſs a pint of proof ſpirit; let them ſtand together three days without heat, often ſhaking the veſſel, then filter off the tincture for uſe. Its doſe is from thirty drops to a drachm or more. It is good in all caſes where the *ſaffron* in ſubſtance is.

If the ſame quantity of wine be uſed inſtead of ſpirit, it is called *vinum crocatum*, *ſaffron* wine.

SAGADENON, a name given by the antients to what they ſay was the very fineſt kind of opobalſamum, produced in Paleſtine and the country thereabout.

SAGDA, or PSAGDA, in natural hiſtory, the name of a ſtone deſcribed by Aldrovand, which he ſays is of a green colour, and has the property of attracting wood.

Pliny and the antients give this name to a gem of a greeniſh colour, very much eſteemed at that time; and about the origin of which the antients had many fabulous reports. Solinus tells us, that it is produced at the bottom of the ſea, and thence riſes up of itſelf as ſhips paſs over the place where it is, and fixes itſelf to their bottoms, and that it cannot be got off again without cutting away a part of the wood. This author has generally taken his accounts of things from Pliny; though he has been at the pains to diſguiſe them, in ſuch a manner, that they are often unintelligible. All that Pliny ſays on this occaſion, is, that the *ſagda* was of a green colour, and was found by the Chaldæans at the bottoms of their ſhips; even this, however, is not very intelligible, unleſs they meant that the ſhips which traded to the Red Sea, and lay long in the harbours, and were ſometimes aground, picked up at their bottoms the ſtones which make up the ſhores, and ſome of theſe are of the jaſper kind, and uſually green; at this rate it could not be a ſtone of any great value, nor do we indeed find any where that it was, except in Solinus.

It is to be obſerved, that the antients called a certain ointment by the name *ſagda* as well as this ſtone; this ointment was green, and probably the ſtone had its name from the reſembling it in colour. This was a cuſtom common among the writers of early times; and they have the names of *libanotis*, *myrrhites*, *ſtactachates*, and *aromatites*, from the reſemblance which certain agates and jaſpers had to the drugs, *&c.* in common uſe among them.

SAGE, *ſalvia*, in botany. See SALVIA.

The ſeveral ſorts of *ſage* propagated either for the kitchen, or for medicine in our gardens, are to be produced by cuttings planted in any of the ſummer months, watering and ſhading them till they have taken root, and after that they ſhould be removed to a dry ſoil, where they may have the benefit of the ſun. *Miller's* Gardners Dict.

Sage has always been eſteemed a cephalic and ſudorific. An infuſion of it made in the manner of tea, has been long famous as the common drink of people in fevers. It is attenuant and diuretic, promotes the menſes, and is good in vertigoes, tremors, palſies, and catarrhs. There uſed to be a ſyrup, conſerve, and ſimple water of *ſage* kept in the ſhops; which are all diſuſed, and the dried herb only retained.

SAGE *apples*, a name given by naturaliſts to a ſort of ſoft gall, or protuberance, found frequently on the leaves and ſtalks of *ſage* in the eaſtern parts of the world, and much reſembling the ſoft gall of the oak leaf, called the *oak apple*.

Theſe are both owing to the ſame cauſe, the puncture of an inſect of the fly kind, which depoſits its eggs in the wound, and the worms or maggots hatched from thoſe eggs feed on the inſide of the gall, and occaſion a preternatural derivation of juices to the part, whence it ſwells and aſſumes this form. The leaves of many other plants are alſo liable to the ſame accident, particularly thoſe of ground-ivy, on which there grow eatable galls of this kind. The *ſage apples* are ſo frequent in the eaſt, that they are brought to market at Conſtantinople, and eaten as delicacies. See GALLS.

SAGENE, a Ruſſian meaſure equivalent to ſeven Engliſh feet. Five hundred *ſagenes* make a werſt. Phil. Tranſ. N° 445. Sect. 7. See WERST.

SAGIMEN *vitri*, a name given by ſome of the chemiſts to any alkaline ſalt.

SAGINA, in the Linnæan ſyſtem of botany, the name of a genus of plants, the characters of which are theſe. The cup is a four leaved perianthium remaining after the flower is fallen; the leaves being of an oval figure, hollow, and ſpread very open. The flower is compoſed of four oval obtuſe petals, ſhorter than the leaves of the cup, and ſpread wide open. The ſtamina are four capillary filaments, the antheræ are roundiſh. The germen of the piſtil is of a globoſe figure; the ſtyles are four in number, tapering in ſhape, and bent back; theſe are downy, and the ſtigmata are ſimple. The fruit is a capſule, of an oval figure, containing four cells, with four valves. The ſeeds are numerous and very ſmall, and are fixed to the receptacle. *Linnæi* Gen. Pl. p. 55.

SAGITTARIUM *alexipharmacum*, in the materia medica, the name of a root cultivated with great care in Jamaica, and ſuppoſed a remedy for the wounds of poiſonous arrows. The plant of which it is the root is the *canna indica radice alba*. *Sloan's* Hiſt. 1. p. 253. but its virtues have not yet brought it into uſe on this ſide the water. *Dale*, Pharm. p. 250.

SAGITTATED *leaf*, among botaniſts. See LEAF.

SAGOCHLAMYS, among the Romans, a ſort of garment that partly reſembled the *ſagum* and partly the *chlamys*. See SAGUM and CHLAMYS, *Cyc. Pitiſc.* in voc.

SAGOUIN, in zoology, the name of a very beautiful ſmall ſpecies of monkey, deſcribed by Cluſius, and ſeeming the ſame with *cogui minor* of Marggrave. See COGUI.

Cluſius ſays it is of the ſize of a ſquirrel, and has the look

of a lion about the head, and that it is a very tender and delicate little animal, and impatient of the ſlighteſt injury. *Ray*'s Syn. Quad. p. 154.

SAGULUM, among the Romans, a little, or ſhort *ſagum*. See the article SAGUM, *Cycl.*

SAHIRA, in the materia medica, a name given by Aviſenna to the *miſy* of Dioſcorides and the Greeks. Aviſenna has placed it among the zagi or atramenta, but deſcribes it in the very phraſe of Dioſcorides, ſaying that it is of a gold yellow colour, hard and ſparkling when broken. The Greek chemical writers call this *chalcanthum chloron*, or yellowiſh vitriol. There ſeems, however, ſome reaſon to ſuſpect that Aviſenna has, in this place, confounded two ſubſtances, and given to the melanteria the name of *ſchira*, and the deſcription of miſy; for the miſy has nothing in it to entitle it to the name of atramentum or ink; but the melanteria of the Greeks very well deſerves that name, as it immediately turns black on being wetted, though it be in itſelf naturally of a yellow colour reſembling ſulphur. The properties of theſe two ſubſtances are ſtrangely confounded by Aviſenna; his interpreters are generally cenſured, as being faulty; but the blame, in reality, lies upon the author himſelf, who did not clearly underſtand the things he was to deſcribe to others. See the articles MELANTERIA and MISY.

SAIC, one of the many names given by the antients to quickſilver. See MERCURY, *Cycl.* and *Suppl.*

SAIL (*Cycl.*)—*After*-SAILS, in a ſhip, are thoſe that belong to the main maſt and miſſen. They keep the ſhip to windward. On which account ſhips ſailing on a quarter wind require a *head-ſail* and an *after-ſail*; one to countermand the other.

Netting-SAIL, in a ſhip, is only a *ſail* laid over the *Nettings*.

SAINT CUTHBERT's BEADS, an Engliſh name for the *trochitæ* and *entrochi*, found in great abundance in the clay of Yorkſhire and ſome other counties with us. They are truly the remains of parts of the arms of the *ſtella arboreſcens*, or branching *ſtar-fiſh*; but have been ſo far miſtaken, by authors, as to be ſuppoſed a ſort of rock plants, or the parts of ſome unknown vegetable petrified.

Agricola judged very well of the nature of the matter they conſiſt of, ſaying they were of the ſame ſubſtance with the *lapis judaicus*, which is a ſpar, as they are, but theſe are uſually of a duſkier colour, ſometimes bluiſh, ſometimes whitiſh or reddiſh, though theſe latter colours are more rare. The ſame author obſerves alſo, that they make an effervescence with vinegar, and ſome of them move out of their places with it, becoming a ſort of creeping ſtones. This is no great mark of diſtinction, however, for all ſpars, or all foſſils, which vinegar will corode, will be acted upon, in the ſame manner by it, provided that they are broke into ſmall pieces, and that the bottom of the veſſel in which the vinegar is put, be not too rough or too ſlanting to a point. The ſingle joints are uſually thin, and regularly round; they have always a hole through the middle; though it is ſometimes filled up with earthy or ſtony matter; this has given them the name of *beads*, as by means of this they may be eaſily ſtrung together. The hole is uſually ſmall, and ſometimes oval, though commonly round.

The outermoſt round or circle is generally ſmooth, but the flat ſides are all thick drawn with rays or lines from the circumference to the central hole. Aldrovandus from theſe ſtriæ reſembling antimony, and the whole maſs in the compound pieces, or *entrochi*, reſembling the trunks of ſmall trees, with the hollow for the pith, and the ſeeming rudiments of branches growing from them, calls them *ſtelechitæ ſtibii facie*. Though in other parts of his book he diſcourſes of them after Geſner and Agricola, under the names of *trochitæ* and *entrochi*. In the compoſition of the compound ſtones or *entrochi*, the ſingle joints are applied cloſely to one another ſide by ſide, and they are fitted ſo nicely together by the rays of one meeting the cavities between the rays of another, that the whole maſs, when ſtruck violently, will not ſeparate into them, but breaks tranſverſely in an oblique direction, as all the other ſpars do; particularly the *lapides judaici* or ſpines of *echini* petrified. Phil. Tranſ. N° 100.

SAINT FOIN, *ſanum*, or *ſanctum fœnum*, the name given by the French, and continued by us to a ſpecies of plant, frequently uſed for the food of cattle, either freſh or dried; it is called *holy hay* or *wholeſome hay*, from its excellent nutritive quality. The ſtalks of the plant are commonly about two feet long, but they grow ſometimes to five or ſix feet, and it has tufts of red flowers of three, four, or five inches in length.

This plant will make a forty times greater increaſe in poor ground than the common turf; and this is owing to its having a long perpendicular root, of that kind, called tap roots, which ſinks to a great depth to attract its nouriſhment. The length of this root is ſcarce to be credited by any but thoſe who have ſeen it; it is frequently drawn out of the ground to the length of twelve or fourteen feet, but it is ſaid to be often thirty feet or more in length.

The farmers have a general opinion, that this plant never ſucceeds well in any land, where there is not an under ſtratum of ſtone, chalk, or ſome other hard matter, to ſtop its running; but that otherwiſe it ſpends itſelf in root, and comes to nothing above ground. This is an error too groſs to need much refutation. It is certain, that the roots being to plants, what the ſtomach and guts are to animals, the more and larger roots any plant has, the more nouriſhment it receives, and the better it thrives.

Saint foin always ſucceeds where its roots run deep, and the beſt crops of all are produced upon lands where there is no hard under ſoil to obſtruct their paſſage. An under ſoil of clay may kill the plants, by retaining the water, and chilling and rotting their roots.

The long root of *ſaint foin* has, near the ſurface, many horizontal roots iſſuing from it, which extend themſelves every way; there are of the ſame kind all the way down, as the roots go, but they grow ſhorter and ſhorter all the way. Any dry land may be made to produce this valuable and uſeful plant, though it be ever ſo poor; but the richeſt and beſt land will produce the fineſt crops of it. The beſt way of ſowing it is by drilling, but the earth muſt be very well prepared, and the ſeed well ordered, or elſe very little of it will grow. The heads of theſe ſeeds are ſo large, and their necks ſo weak, that if they be much more than half an inch deep, they are not able to riſe through the incumbent mould; and if they are not covered they will be malted, as the farmers expreſs it; that is, it will ſend out its root while it lies above ground, and be killed by the air; and whether the farmer plants bad ſeed that will not grow, or good ſeed that is buried or malted, the event will be the ſame. The ground will be underſtocked with plants. A buſhel of ſeed to an acre of land is full twenty ſeeds to each ſquare foot of land; but as there is ſome difference in the largeneſs of the ſeeds, there is no abſolute certainty as to this calculation. The worſt ſeaſons for planting it are the beginning of winter, and the drought of ſummer; the beſt is the beginning of the ſpring; and it is always ſtrongeſt when planted alone, and is not ſown together with corn, as is the practice of ſome farmers. If barley, oats, or any other corn, ſown with the *ſaint foin*, happen to be lodged afterwards, it kills the young *ſaint foin*. If it be planted with any other corn, it is beſt done by drilling in the horſehoing way; in this caſe it is not much liable to be killed by the lodging of the corn, as the drilled corn ſeldom falls at all, and when it does, never falls ſo low as the ſown corn.

The quantity of ſeed to be drilled upon an acre of land will depend wholly upon the goodneſs of it; for there is ſome ſeed of which not one in ten will ſtrike, whereas in good ſeed not one in twenty will fail. The method of knowing the goodneſs, is, by ſowing a certain number of the ſeeds, and ſeeing how many plants are produced by them. The external ſigns of the ſeed being good, are, that the huſk is of a bright colour, and the kernel plump, of a light grey or blue colour, and ſometimes of a ſhining black. The ſeed may be good though the huſk be black, as that is ſometimes owing to the letting it receive the wet in the field, not to its being half rotted in the heap.

If the kernel be cut acroſs, and appear greeniſh and freſh, it is a certain ſign that it is good. If it be of a yellowiſh colour, and friable, and look thin and pitted, they are bad ſigns.

The quantity of ſeeds allowed to the acre in the drill way, is much leſs than that by ſowing, and is to be computed according to the number of plants that are to be allowed in that ſpace, allowing for the common caſualties. It is not neceſſary to be exact in this calculation, or to ſay whether two, three, or four hundred plants are to be allowed to a ſquare perch; neither is it poſſible to know before-hand the preciſe number of plants that may live out of thoſe that come up; for ſometimes the grub takes them when they have only the two firſt leaves, and the crop is greatly diminiſhed by this means. Four gallons of good ſeed to an acre of land will cover the land with plants when judiciouſly managed.

Single plants of *ſaint foin* make the greateſt crops; but the farmers, in general, plant them ſo cloſe, that they ſtarve one another. The ſingle plants always run the deepeſt, and thoſe which do ſo will always draw moſt nouriſhment. The plants which ſtand crowded ſtarve one another, and often die after a few years; but the ſingle ones grow to a vaſt bigneſs, and are every year better and better.

The beſt way to calculate how many plants are to be allowed to a perch, is to compute how much hay each ſingle large plant will produce; for if kept ſingle, and well cultivated, they will all be large ones. Without culture theſe plants never arrive at a fourth part of the ſize that they do with it. The hay of a large ſingle cultivated plant will weigh more than half a pound, and a hundred and twelve plants upon a ſquare perch, weighing but a quarter of a pound a piece, one with another, amount to two tun to an acre. If *ſaint foin* be planted on ſome ſorts of land early in the ſpring and hoed, it will ſometimes produce a crop the following ſummer; in a garden the ſeeds ſown in February will yield plants of two feet high that will flower in the

month

month of June following; and though March be frosty the young plants seldom suffer by it. This shews, that this plant is naturally a quick grower; but the farmers usually plant it on poor or cold land, and give it too little culture, which makes it backward, and slow of growth with them. The poor land usually allotted to this plant also makes it generally yield but one crop a year, but on a rich land it will yield two very good crops annually, with a moderate share of culture and management.

The farmer who expects to make a profit of this plant must not expect a good crop the first year. Nothing is so injurious to *saint foin* as its standing too thick; if it be sown so thick as to cover the ground the first summer, the plants will starve one another for ever after; but if the owner will be content to place them so thinly as to have but a small crop the first year, they will increase prodigiously, and every succeeding crop will be better and better. When *saint foin* is well hoed, it will grow as much in a fortnight as it would otherwise do in six weeks; and this quick growing is of advantage to it every way, not only making the plants larger, but of better nourishment to the cattle, whether they are eaten green or made into hay.

The proper distance to drill this plant for the horsehoing husbandry is at double rows, with eight inch partitions between them, and thirty inch intervals between every two and two. These intervals need only be hoed alternately, leaving every other interval for making the hay on. This method of hoing is of vast advantage, and poor land by means of it will always produce two crops in a year. The land is always to be perfectly cleared of grass before the sowing the *saint foin*, and the lumps of earth carefully broken. But no harrowing is to be allowed after it is drilled, for that would bury it; and it is not proper to roll it at all, unless for the sake of barley, when they are sown together; and when that is done, it should be with a light roller and in dry weather. This should be done lengthwise of the rows, and as soon as it is drilled; if it be not done at this time, it is best to stay three weeks before it is done, that the necks of the young *saint foin* may not be broken.

No cattle are to be suffered to come in the first winter upon the *saint foin*, after the corn is cut, among which it was sown. Their feet would injure it by treading the ground hard, as much as their mouths, by cropping it, and it would never come to good. Sheep should not be suffered to come at it even the following summer and winter. One acre of drilled *saint foin*, considering the difference of the quantity and goodness of the crop, is worth two acres of sown *saint foin* on the same land, though the expence of drilling be twenty times less than that of sowing. The first winter is the time to lay on manure after the corn is reaped off. Pot-ashes, or the like, are very proper, and a small quantity of them will do, as there are at this time no other plants to partake of the benefit, but the young crop has it all; and the young plants being thus made strong at first, will continue so, and be long the better for it.

It is observed, however, that in the drilling and horsehoing way there is no necessity for any manure at all. Some farmers sow eight or ten bushels of the seed of *saint foin* to an acre along with their corn, with intent that it should kill all the other weeds; but the consequence is, that the plants stand close, and starve one another, and are no bigger than where the plant grows wild on the hills in Calabria, where it is so small and seemingly despicable a plant, that it seems a wonder that any body could be tempted to think of cultivating it: yet, when rightly managed, it seems capable of being as useful a plant as any in the world. Where these plants stand so thick they draw out all the nourishment from the ground, in a few first years, and soon die, though manured ever so carefully. Six or seven years seems their greatest duration; whereas, when the seed is drilled in, and the plants are horsehoed, they will be as strong and vigorous as ever, at thirty years standing.

Some people who have turned their thoughts to husbandry, have been of opinion, that the cytisus would succeed better with us than the *saint foin*; it is probable enough that it would grow well; but the labour of sheering it, would with us, where the pay of servants is so dear, run away with the greatest part of the profits of the crop.

Lucerne is another thing which many have thought of introducing among us in the place of *saint foin*, but it requires so much care to suit it with a proper soil, that whatever are the profits of it, it never can be so general as *saint foin*. *Tull*'s Horsehoing Husbandry, p. 76. seq.

Saint foin succeeds best also in high grounds, which is a great advantage in the article of making it into hay, as it has greatly more advantage of the sun, and less to fear of mischief from wet than grass which grows in low grounds. On the high grounds the wind will dry more in an hour than it will in meadows that lie low in a whole day; and often the crops of *saint foin* make very good hay in the same seasons in which all the grass hay is utterly spoiled. The sun, on the high grounds, has also a more benign influence, and sends off the dew there two hours earlier in the morning, and holds it up as much longer in the evening; by these advantages the *saint foin* has more time to dry, and is made with half the expence of common hay.

All kinds of hay differ greatly in their goodness, according to the manner in which they are made, but the hay of *saint foin* differs more than all.

There are properly four kinds of the *saint foin* hay, differing according to the times of cutting them. These are first, the virgin hay; secondly, the blossomed hay; thirdly, the full grown hay; and fourthly, the thrashed hay. The first of these, or virgin hay of *saint foin*, is the best of all, and excepting lucerne has not its equal in the world. The *saint foin* for this hay must be cut before it begins to blossom; for when it stands till full blown, the most volatile spirituous and nutritive parts of its juices are spent on the generation; and this being done at once, the sap is greatly depauperated, and the plant can never afterwards recover the strength, vigour, and nutritive qualities it had at that time. The exact time of cutting this is, when a few of the blossoms, which are forwarder than the rest, are beginning to look red. *Saint foin* cut in this state, even though the weather prove bad, may be made up in small ricks, and a chaff basket drawn in the middle of each; this easy care will prevent it from firing; and though the colour be a little altered, it will be as good and nourishing, as if made at the most favourable season. Working stone-horses have been kept fat the whole winter on this hay alone without corn, and they are so fond of it that they will refuse beans and oats mixed with chaff in the common way for it.

Sheep will also be fatted in pens in winter with only this hay and water better than with pease, oats, and the like; and if the hay be weighed to them, and the whole expence and profit computed, the clear profit will be found to amount to four pounds a tun. These creatures make no waste in this way of feeding, but eat up every morsel of the stalks, though ever so thick, for they are always brittle, and are as well tasted as the rest.

The blossom hay is very beautiful to the eye, and of a very sweet smell, but it does not fatten the sheep as the virgin hay does, nor can working horses be kept fat upon this without an admixture of some corn.

The land ought to be well tilled for the virgin hay; for if it stand on a poor land, without much culture, it will not be above four or five inches long before it flowers, and will therefore yield but a poor quantity, and will spring up again, but very slowly, for another crop; but when on good land and well tilled, it will yield at this time two or three tun to an acre, and will spring up immediately very strong for a second crop.

This virgin hay is seldom sold, it being worth a much greater price than the common, and being usually kept by the farmer for his own use. Id. Ibid.

Beside the advantage the farmer makes of this plant, as well for hay as for the feeding his cattle, there is a considerable profit to be made by selling the seed of it when properly managed.

The owner of a land of *saint foin* has three chances for the making his hay; since this may be done either when it is in the leaf, or in the bloom, or when full grown. If the weather should prove unfavourable all this time, he may still reserve the crop for seed, and for thrashed hay, to his no small advantage. The ordinary crop of seed from one acre is sufficient to plant a hundred acres in the way of horsehoing husbandry; but as this is not yet universally practised, there is a sufficient demand for what seed a few who practise it can spare.

But beside the use of *saint foin* seed in sowing for new crops, it is also an excellent provender for horses; and those, in general, who have tried it, affirm, that one bushel of it will go as far as a bushel and a quarter of oats. When this seed is well cured, it is extremely sweet, and all sorts of cattle are fond of it: hogs will eat it and be fattened very well by it. But the goodness of the seed, and of the remaining hay, from out of which it is thrashed, depends very much upon the manner of the managing of them. When the thrashed hay has been kept dry, it is found to be better food for horses than common grass hay; and when cut small with an engine it is found as good as chaff for any cattle. It requires some skill to know the time at which the *saint foin* should be cut for seed. The seeds never ripen all at once. The flowers grow in spikes, and begin opening at the bottom, from thence gradually opening to the top. It is several days before the whole succession of flowers are blown, and the seed ripens in the same manner, so that the lower part of the ear has ripe seed many days before the top; and, in consequence, if the farmer stays till the top seeds are quite ripe, the lower ones will be all shed and lost.

The propereſt time to cut it is when the greatest part of the seed is ripe, the top part beginning to be full and the bottom full ripe. The kernel or seed is bluish, and the husk brownish when ripe. The seeds and husks are green for some time after the flowers are fallen, and it is better to cut the plant while it is thus, than to let it stand too long; for the

the ſeeds will ripen and become bluiſh after cutting, which will be much better than the letting them be loſt by waiting till they ripen upon the ſtalks in bad weather.

The *ſaint foin* for ſeed muſt never be cut in the heat of the day, for then it will dry too faſt as it falls, and much of the ſeed will be loſt. It is beſt for the mowers to begin at day-break, and to leave off as ſoon as the ſun has any power, going to work again in the cool of the evening. If the plant be dry at the time of cutting, it may be immediately made up into little cocks; but if not, it muſt be made hay of, only obſerving never to turn it while the ſun is hot upon it: unleſs there happen rain it is ſcarce neceſſary to turn the ſwarths at all; and when this is done, it muſt be done very carefully, that the ears be not ſhaken.

There are two ways of thraſhing this plant; the one on the field, the other in the barn. The firſt can only be done in very fine weather, and while the ſun ſhines warmly upon the field. The middle of the day is the only time for this, and the method is to ſpread a large ſheet, and peg it down at the corners, and in this thraſh the plants from the cocks by ſmall parcels at a time. The ſtraw is to be ſeparated from the ſeed, and made up into ricks; and this is good food for horſes and other cattle, and the ſeed, *&c.* is to be collected, and afterwards winnowed, to ſeparate the chaff.

If the ſeed have been wetted in the time of thraſhing or lying in the ear, it may be put up immediately; but if it have been thraſhed and winnowed dry, it will ferment and ſpoil if laid together too ſoon. The common way of managing it is by ſpreading it in a malt-houſe, or on a barn floor, but in ſpite of this it will often heat and ſpoil; the beſt way of all is to ſpread a layer of ſtraw, and on this ſprinkle a layer of the ſeeds, then cover theſe with another layer of ſtraw, and this with more ſeeds, and ſo on, till the heap is raiſed ſix or ſeven feet high. The ſeed will thus be kept cool, and in ſpring it may be eaſily ſeparated from the ſtraw, and will be as freſh as if juſt thraſhed; if this be ſown, not one ſeed in twenty will fail of coming up. When the weather is not fine enough to give opportunity to the thraſhing the *ſaint foin* in the field, it muſt be very carefully carried into the barn with ſheets at the bottom of the carts, otherwiſe a great quantity of the ſeed will be loſt in the way. *Tull*'s Huſbandry, p. 90.

SAKER, in the manege, the ſame with *dock*. See DOCK.

SAL, *ſalt* (*Cycl.*)—See the article SALT.

SAL, in the hiſtory of the gems, a term uſed by Pliny and the antients, to ſignify a defect or flaw, which took off very much from the value of the gem. Martial having occaſion to mention this ſort of blemiſh, in cryſtal, calls it *nitrum* inſtead of *ſal*. *Et turbata levi queſtus cryſtallina nitro.*

The critics have ſometimes changed this word *nitro*, to *vitro*, and others have made the confuſion yet greater, by ſuppoſing that the poet did not mean rock cryſtal but cryſtalline glaſs: but theſe are all errors. It is plain, by what Pliny and others have ſaid on the ſame ſubject, that the author means here the ſame that others do by the word *ſal*. This was a duſky and duſty foulneſs, ſeemingly compoſed of a quantity of ſaline particles, ſhooting into their forms within the body of the cryſtal. The gems in general were ſubject to this blemiſh; and we find, in particular, that the emerald was frequently debaſed by it.

It is found at this time, indeed, that cryſtal is much more ſubject to it than any of the gems; but, as the Romans called all the green cryſtals found in the copper mines of Cyprus by the name of emeralds, it is eaſy to conceive, that the emerald, as they underſtood the word, muſt be frequently ſubject to it. The poets uſing the word *nitrum* inſtead of *ſal* is not wonderful, for the Greeks called common ſalt *halonitrum*, ſo that the words ſeem almoſt ſynonymous.

SAL *Ægypti*, in natural hiſtory, a name given by Hippocrates, and many other of the old writers, to the *natrum* of the antients, called alſo *nitrum* by ſome, though very different from our nitre. It had the name *natrum* from *natrium*, or *nitrium*, the name of a city of Ægypt; and therefore this, as well as the name uſed by Hippocrates, ſtood for Egyptian ſalt.

SAL *ammoniac*, or *armoniac*. See ARMONIAC, *Cycl.*

The ſubſtance known by the antients, under this denomination, was very different from the *ſalt* we now call by this name. It was indeed no other than a particular appearance of the *muria*, or common alimentary *ſalt*, in a ſtriated form. We have common *ſalt* of this very form now in ſome parts of the world, but though with us it is ſcarce, with them it was very frequent, and was in common uſe, and eſteemed the very beſt kind of *ſalt* for the uſe of the table. Dioſcorides is extremely accurate and expreſs in his account of it, and when he has reckoned up the various properties and uſes of common *ſalt*, he deſcribes the ſeveral ſorts of it, and particularly this ſtriated one among them, which, he ſays, was the very beſt of all the kinds; yet it ſeems owing to the deſcription of this author, that the common errors about this *ſalt* have ariſen; for he ſays that it was foſſile, and compoſed of ſtrait regular fibres. And after writers finding no *ſalt* of the common alimentary kind, anſwering to theſe characters, and perceiving that the compound maſs, we call *ſal armoniac*, was of this ſtructure and appearance, made no heſitation to determine this to be the *ſalt* called *ſal ammoniacum* by the antients, not conſidering the incongruity of the characters of that *ſalt* to their accounts, or the impoſſibility of its ever being uſed at table as common *ſalt*. *Hill*'s Hiſt. of Foſſ. p. 384.

The *ſal ammoniac* of the moderns may be eaſily prepared in the following manner: take four ounces of common volatile *ſalt* of ox bone, ſaturate it with ſtrong ſpirit of ſea *ſalt*, and evaporate the ſuperfluous moiſture, upon which there will be found a cake of true *ſal armoniac* left behind.

This is an experiment which regards both philoſophical and technical chemiſtry, as it ſhews that odours may depend upon the mechanical ſtructure and texture of bodies; and leads to a cheap way of making *ſal armoniac* in other countries, as well as in the Levant. The volatile *ſalt* here employed has a very quick and pungent odour; ſo likewiſe, though in a leſs degree, has the ſpirit of *ſalt*; but theſe two, upon mixing, deſtroy each other's odour, ſo as to leave the cake of *ſal armoniac* ſcentleſs; but if a little of this *ſal armoniac* be rubbed in a mortar with ſalt of tartar, or any other fixed alkali, this lays hold of the acid of the ſea *ſalt*, and leaves the volatile ſalt to ſtrike the noſe as pungently as before. *Shaw*'s Lectures, p. 422.

Our own volcanos, or ſubterraneous fires, which we have in the coal countries, afford us *ſal ammoniac*. It is found ſticking to the ſides of the openings of theſe volcanos, in conſiderable thick cruſts, under other cruſts of ſublimed ſulphur. There is no foſſile *ſalt* in theſe places, nor any thing elſe, that can form *ſal armoniac* in the common way we ſuppoſe it to be found in; but it appears truly, that it proceeds only from the coal that feeds theſe fires. It is certain, that *ſal armoniac* is ſometimes found on brick kilns, where nothing but coals and common brick clay are burnt; and as no one would ſuſpect it of being contained in the brick clay, there is here only the coal to afford it. The common coal ſlate of thoſe counties alſo contains alum, ſulphur, and *ſal armoniac*; for alum may be drawn from it by the common operations; and when it is burnt, as it frequently is there for hardening the coal ways, both brimſtone and *ſal armoniac* are found in the heaps in ſeveral places.

The *ſal armoniac* found in the openings of the burning mountains, particularly mount Ætna, is evidently the ſame in all reſpects with ours; and even this alſo may, for ought we know, be formed of coals, of which the inacceſſible bowels of that mountain may contain great ſtores; though none have been found riſing near enough to the ſurface to be dug for uſe. Other bitumens alſo may poſſibly afford this *ſalt* on burning as well as coal, and it is not to be doubted but many ſuch are to be found in the earth thereabouts. The *ſalt* on the ſides of the mouths of mount Ætna is found in large and thick cakes, and in dry weather may be collected in vaſt quantities, and poſſibly a great part of what the Venetians ſell into other parts of Europe may be from theſe places. Either this *ſalt*, or that of our own volcanos, may be uſed in all the proceſſes of chemiſtry, with the ſame ſucceſs as other *ſal armoniac*. It is of itſelf grey and coarſe, but on mixing it with lime, and wetting them, a volatile ſpirit is raiſed; and on ſubliming a mixture of it with pot-aſh, a dry and white volatile *ſalt* is obtained. If ſome ſpirit of wine be added to the mixture of *ſal armoniac* and pot-aſh, more of the volatile *ſalt* will be produced than any other way. Phil. Tranſ. N° 130.

We are well aſſured that this *ſalt* is a concrete, the acid of which is that of ſea *ſalt*, and its alkali, a volatile urinous one; both of which are found in dung burnt and raiſed into ſoot.

If there is occaſion to ſeparate the acid of ſea *ſalt* from *ſal ammoniac*, there need only be uſed the common vitriolic acid, which being well known to be ſtronger than that of ſea *ſalt*, it diveſts that acid of its alkali by its ſuperior power, and it becomes the baſis of a new concrete *ſalt* with this acid, while the acid of ſea *ſalt* now freed and ſeparated may be drawn off pure by diſtillation.

If on the other hand it were required to draw from *ſal ammoniac* its volatile alkali, the ſubſtances to be employed to this purpoſe are ſuch alkalies as act upon the acid of the ſea *ſalt*, abſorbing and retaining it; the volatile alkali becomes freed, and riſes with a very ſmall heat. This alkali thus raiſed appears in two different forms, the one a liquid, which is called ſpirit of *ſal ammoniac*, the other a dry one, which is called the ſublimed *ſalt* of *ſal ammoniac*; and though theſe are ſometimes obtained ſeparate, yet in ſome operations they are in part of the one and in part of the other kind. This is well explained by Mr. du Hamel in his courſe of experiments on this ſubſtance. Mem. Acad. Scien. Par. 1735.

As the adding an alkali is the way to ſeparate this natural volatile alkali from *ſal ammoniac*, the more powerful that added alkali is, the better may it be expected to perform its effect. Chalk, lime, *ſalt* of tartar, and pot-aſhes, have all been in common uſe to this purpoſe, and all except the lime give the volatile alkali in a dry form, which is no wonder, ſince theſe are all naturally dry bodies before the operation; but there is one circumſtance in theſe operations very worthy regard,

regard, which is, that the mixtures ſometimes afford more volatile alkali than the weight of the whole quantity of *ſal ammoniac* from which this volatile alkali is drawn; beſide that, there muſt be ſuppoſed to remain all the acid matter at the bottom of the veſſel; but the whole account of this muſt be, that this volatile urinous *ſalt* is ſo extremely powerful, that it raiſes and carries up with it a part of its other matter.

It remains, however, yet to enquire why lime alone being joined with *ſal ammoniac* in diſtillation, yields this volatile alkali in a liquid form, or in the ſtate of ſpirit of *ſal ammoniac*. There ſeldom riſes any thing in a dry form in this proceſs; when there does it is but very little; and when there ariſes no liquid, as is ſometimes the caſe, there ariſes often nothing at all; whereas, with the other alkalies, there ariſes, as has been ſeen, more than the weight of the whole quantity of *ſal ammoniac*. We very well know that this liquid ſubſtance, which we call ſpirit, is no other than the ſame volatile *ſalt* diſſolved in water, or in ſome other humidity, furniſhed by the matter, added to the ſalt in the diſtillation, and that this *ſalt* in riſing has brought up its diſſolvent with it. The lime, though deprived in a great degree of its humidity, by the operation which made it lime, yet retains enough for the purpoſe of melting the *ſalt* into what we call this ſpirit; and when the operation with lime does not ſucceed it is owing to this, that the calcination of the lime has been ſo perfect, as to deprive it of all its humidity; and the truth of this is evident, ſince the adding a little water will always enſure the riſing of a ſufficient quantity of ſpirit, and that with leſs fire than it can be obtained with when no water is added. We are yet at a loſs, however, to account for lime's acting differently from all the other additions to this *ſalt*, and making nothing ariſe in a dry form.

Mr. du Hamel obſerves, that by its formation, lime is diveſted of all acids, and of all humidity; but that by means of its fatty particles, whether they are from ſhells embodied in the ſtones from which it was made, or from the natural bitumen of ſtones, it is always endeavouring to recover what it has been diveſted of by fire; that it abounds with a vaſt number of fiery particles; and that by means of theſe, it is enabled to act upon the urinous, and therefore fatty matter of the *ſal ammoniac*; whether it be, that it unites itſelf intimately with it, ſo as never to be ſeparated from it, or whether it decompounds, and as it were burns it. And what confirms this conjecture, is, that Mr. du Hamel having diſtilled four drachms of ſpirit of *ſal ammoniac* with one drachm of freſh lime, he obtained a ſmall quantity of volatile *ſalt* in a dry form; the lime in ſo ſmall a proportion not being able to prevent the *ſalt* from this ſpirit from appearing in a dry form. And it is eaſy to conclude hence, that a volatile *ſalt* might be obtained from *ſal ammoniac* with lime, in a dry form, provided that the *ſal ammoniac* be mixed in an over proportion up to a certain quantity. Mem. Acad. Scien. Par. 1735.

The ſpirit and *ſalt* of *ſal ammoniac* being the ſame matter in a dry and a liquid form; it is evident, that the liquid muſt of the two be moſt ſtriking to the noſe, becauſe the particles of the *ſalt* are more eaſily diſunited from this latter union: and the *ſalt*, in a dry form, is ſo very volatile, that it entirely evaporates when laid on a hot iron, however fixed the matter may have been, which it originally carried up with it. It appears very plain from this, that the union between this volatile body and the particles of more fixed ones, which it carries up with it in ſublimation, and which are proper to give it the form of a dry concrete, is ſo intimate, that it will bear very ſevere trials and remain unaltered, and indeed, that it is ſcarce poſſible at all to decompoſe it.

It is no indifferent matter what the additions are with which *ſal ammoniac* is diſtilled; they muſt, by no means, be either ſuch as contain a nitrous, or a vitriolic acid; the former of theſe meeting with the fatty and ſulphurous part of the *ſal ammoniac*, may cauſe a detonation and burſt the veſſels; and the other, which is yet much more dangerous, might diſengage a portion of the ſea *ſalt*, which would again mix with the volatile part with which it has now no buſineſs to be allied, and with the fatty matter it might form a very diſagreeably ſcented ſulphur. Bole contains a vitriolic acid, and is therefore to be rejected. Gypſum mixed with it gives a ſmoaking liquor, whoſe odour is inſupportable, and chalk and common pot-aſhes are the beſt of all additions.

The firſt who gave *ſal ammoniac* internally was Platerus; but its uſe in fevers was not then known; he only uſing it in aſthmas. In ſucceeding times it became known as a febrifuge. It is frequently uſed in this intention, in Germany and Holland, and with great ſucceſs. The common doſe to a grown perſon is one drachm. The largeſt doſe, in caſes of the moſt robuſt conſtitutions, is two drachms. A perſon of eleven or twelve years old may take two ſcruples, and an infant of a year old may take fourteen grains. Its chief virtue is in intermittent fevers, in which it may be thus given. Let the doſe of *ſal ammoniac*, proportioned to the age and ſtrength of the patient, be diſſolved in an ounce of common water, or of any diſtilled water; and let the patient take it half an hour before the time that the fit is to come on. This is to be repeated in the ſame manner, before every fit, till the diſtemper is removed.

Though the great uſe of this medicine be in intermitting fevers; it is not, however, adapted only to thoſe, but may be of uſe in fevers of other kinds. The ſame doſe may be taken every five or ſix hours, drinking a baſon of ſage tea after it. It very frequently ſucceeds ſo well, that one doſe of it carries off the diſeaſe, ſo that it never returns again; but if the firſt doſe does not ſucceed in this manner a few others will. Two, three, or four doſes almoſt always prove ſufficient. This medicine has no viſible effect upon the body, more than the ſudden removal of the ſickneſs; for it neither operates by vomit, nor by ſtool, nor by ſweat: its effect ſeems to be owing to the correcting and altering of the matter of the diſeaſe, not the evacuating it out of the body.

The bark is ſuperior to this *ſalt* in the cures of quartan agues, and indeed in other caſes it is more certain in the ſtopping a ſecond fit; but there is another advantage in this, which the bark greatly wants, this is the preventing relapſes. Theſe are very frequent after cures in the common way, but are ſcarce ever found to follow in caſes when this *ſalt* has been uſed.

Another advantage of this medicine is the ſmall quantity of the doſe, and the few doſes that are neceſſary to be taken for a cure; whereas every one knows how many large doſes of the bark are neceſſary, and that often at ſuch ſmall diſtances of time, in caſes, that it is often difficult to perſuade the patient to be cured at the expence of ſo nauſeous a load of medicines. Act. Erudit. 1717.

SAL *aquarum*, in natural hiſtory, a name given by many of the antient writers to the nitre of the antients or *natrum*.

They had this *ſalt* principally from Ægypt, and called it in their works the produce of the evaporated waters of the Nile; for this reaſon Hippocrates ſometimes calls it *ſal ægypti*, and ſometimes *ſal in aquis creſcens*, a *ſalt* growing in the waters.

SAL *circulatum*, in chemiſtry, a term uſed by Paracelſius for a preparation of ſea *ſalt*, of which he diſtinguiſhes two kinds, under the name of the *circulatum minus* and *circulatum majus*. Theſe ſeem to have a great affinity with the famous alkaheſt or univerſal ſolvent, ſo much talked of in the works of this author, and his ſucceſſor Van Helmont.

The *circulatum minus* was a liquor procured by a tedious proceſs from ſea *ſalt*; this *ſalt*, he ſays, is that body in which nature has placed the greateſt perfection; and from this he, by incredible induſtry, procured a liquor which he calls a perpetual oil, and to which he alſo gives the name of the ens primum of *ſalts*. He calls it the higheſt and moſt ſucceſsful of all *ſalts*, and declares that all poiſons are ſubdued by it; and that being brought to the utmoſt degree of purity and ſubtilty, it pervades all bodies, and readily diſſolves them, itſelf remaining unaltered in the action. Theſe are all properties expreſsly attributed by Helmont to the famous alkaheſt. See ALKAHEST.

The *circulatum majus*, however, we are told, by the ſame author, was much more powerful and much more difficult to be obtained than the former. This he calls the matter of mercurial *ſalt*, and the living fire: he acknowledges that the higheſt fire and celeſtial life lie hid in common mercury, and ſays the quinteſſence of mercury is celeſtial fire: by this and a great many other enigmatic expreſſions in this writer, there is room to believe, that the alkaheſt, deſcribed by Helmont, is a preparation of mercury and ſea *ſalts*. *Boerh.* Chem. p. 573.

SAL *diureticus*, a form of medicine, of the nature of the *terra foliata tartari*, introduced into practice by the late college diſpenſatory. The method of preparing it is this: take of any alkaline fixed *ſalt* a pound, boil it in four or five pints of diſtilled vinegar in a gentle heat. When the fermentation is over, pour on more diſtilled vinegar; and when the fermentation ariſing from this addition is over, pour on ſtill more, and proceed thus till the moiſture being nearly all evaporated, freſh vinegar being added will excite no more fermentation: this generally happens when about ten quarts have been uſed; then evaporate to a dryneſs; the *ſalt* will be impure, and muſt be melted for a ſmall time, with a gentle heat, afterwards diſſolved in water, and filtered; if the melting has been rightly performed, the ſtrained liquor will be pellucid as water; then evaporate this in a gentle heat to a dryneſs, and you will have a very white *ſalt*, ſoluble either in water or ſpirit of wine. *Pemberton*'s Lond. Diſp. p. 187.

Jamblici SAL. See the article JAMBLICI *ſal*.

SAL *lucidum*, in natural hiſtory, a name given by ſome to nitre. Others uſe the phraſe to expreſs the nitre of the antients, that is the natrum.

SAL *marinus*, in ichthyography, the name of a truttaceous fiſh of the umbla kind, and very much approaching to that ſpecies called the *reutele*. See REUTELE. And by ſome ſuſpected not to be eſſentially different from that ſpecies. It is a very ſcarce fiſh, and is extremely valued for the table, but is never caught in any plenty, never keeping in ſhoals as many other fiſhes, but living ſingly. It loves clear ſtony rivers of a ſharp current, and feeds on ſmall fiſh. Its moſt frequent ſize is of about a pound weight, and it very rarely

exceeds

exceeds twice that. Its tail and fins are very red; its ſides and belly reddiſh, and its back of a ſort of orange colour or reddiſh yellow, having ſome yellow ſpots. Its ſcales are moderately large, and do not eaſily fall off on rubbing.

The *ſal marinus* is diſtinguiſhed by Artedi by the name of the forked tailed ſalmon, with a yellowiſh back, and with yellow ſpots. See SALMO.

SAL *marinum regeneratum*, in chemiſtry, the name given to a ſea *ſalt*, produced by adding an alkali to its acid ſpirit of *ſalt* drawn by diſtillation. The proceſs is thus, dilute four ounces of oil of tartar, with three times its weight of fair water; put this mixture into a tall glaſs body, and heat it, and drop into it any of the kinds of ſpirit of ſea *ſalt*, whether Glauber's, or that prepared with bole; ſhake the veſſel now and then, and continue to drop in the acid till the alkaline liquor is ſated, and there riſes no more effervеſcence; filter the liquor, and evaporate to a pellicle, and ſet it by to cryſtallize, and there will be procured cryſtals of perfect ſea *ſalt*, in all things agreeing with common *ſalt*. *Boerh.* Chem. Part II. p. 253.

SAL *martis*, *ſalt of iron*, a chemical preparation, which is made as follows: mix together a quart of water and eight ounces of oil of vitriol; pour the oil of vitriol in by a little at a time; and having put this mixture into a glaſs veſſel, add to it filings of iron, four ounces. When the ebullition is over, evaporate the liquor to a pellicle, and ſet it to ſhoot; there will be found a green vitriol or *ſalt* in fair cryſtals, which dry for uſe.

This *ſalt* is one of the moſt powerful preparations of iron; it opens obſtructions of all kinds, and ſtrengthens the viſcera; it is an excellent medicine in cachexies, obſtructions of the ſpleen and liver, and in ſuppreſſions of the menſes; it is alſo found good againſt worms.

The beſt manner of giving it is in ſolution, half an ounce in a quart of water, four ounces of which is a doſe; and if drank in the manner of the natural chalybeate waters, it will be found to exceed moſt of them in its good effects.

SAL *mirabile*. *Glauber's ſalts*. Though this be a well known preparation, and the reſult of a mixture of a vitriolic acid with marine *ſalt*, and the world has ſuppoſed it could be no other way found than by ſuch an union made by art; yet Mr. Heliot has communicated to the academy of ſciences of Paris, an account of its being found in vitriol alone, without the addition of any foreign matter.

The common green vitriol or copperas is well known to be made in England, by an union of the ſulphureous acid of the common pyrites, and iron. Old iron is thrown into large quantities of a ſolution of the pyrites, that it may be diſſolved, and the union produces a concrete in the form of a regular *ſalt*. This *ſalt* we well know contains a ſulphureous matter; whether that be obtained from the pyrites, or from the iron that enters its compoſition; ſince, in the diſtillation of its oil, there ever eſcapes a very ſtrong and penetrating ſcent of ſulphur through the junctures of the veſſels.

There are alſo ſome vitriols, particularly the common Swediſh kind, which may very probably be aluminous; ſince the yellow ſhining gold like marcaſite from which it is made, yields in its native ſtate true ſulphur in diſtillation, and afterwards affords vitriol in the lixivium, after the remainder has been long expoſed to the air, and finally it yields alſo alum by the addition of urine and pot-aſhes, to what they call the mother water of vitriol.

Mr. Lemery has ſhewn, that after a moderate diſtillation of green vitriol, a *ſalt* of the nature of alum may be drawn by a lixivium from the colcothar; and beſide this, Mr. Heliot has found in that colcothar a vitrifiable earth, and a genuine *Glauber's ſalt*. Thoſe who are at all acquainted with chemiſtry, know that *Glauber's ſalt* is a concrete compoſed of the vitriolic acid and ſea *ſalt*, and it is generally received as a certainty that any other acid joined to ſea *ſalt* cannot afford this concrete; therefore if *Glauber's ſalt* is to be produced from ſea ſalt alone, and yet is proved to be found in pure vitriol; it muſt follow, that pure vitriol does contain ſea ſalt, or at leaſt that ſubſtance which is the baſis of ſea ſalt: and this will prove a leſs ſingular obſervation, if it can be evinced, according to Becher, that all the known *ſalts* owe their origin to marine *ſalt*.

Mr. Lemery, in order to procure his aluminous *ſalt* from vitriol, does not puſh his diſtillation too far, that the acid may remain engaged and entangled in that earth, by the union with which it is to form this *ſalt*, which is afterwards to be ſeparated by lixiviation; but Mr. Heliot puſhes the diſtillation to the utmoſt degree with a violent fire of three or four days and nights, ſuch as Kunkel preſcribes, for the diveſting vitriol of all its acid, that the remainder in the retort may contain little or no *ſalt* at all. He took eighteen pounds of Engliſh vitriol, which he calcined to a redneſs, and by that means reduced it to ſix pounds. This quantity, though put in a covered earthen veſſel, acquired nine ounces in weight from the humidity of the air in two days; and in this ſtate it was put into a german retort, and urged to that degree by the violence of fire, for ſo long a continuance, that the remaining black maſs, though treated with all the care imaginable, and waſhed by repeated lixiviation, yielded only two ounces and a half of *ſalt*, and that of a very earthy kind. About nine ounces of phlegm had been ſeparated at the beginning of the diſtillation, but when the white vapours began to appear, the veſſels were all cloſed, and ſo kept to the end of the operation; the produce of which was an icy oil of vitriol, which was found in a black cryſtalline form.

The ſucceſs of the operation, as to the procuring this icy oil of vitriol, depends on the nice luting the junctures of the veſſels, ſo as to prevent all communication with the external air; for otherwiſe the vapours attract a moiſture from the air, which renders them fluid in the receiver. The receiver muſt alſo be placed at a conſiderable diſtance from the retort, that it may be cool enough to condenſe the vapours, and large enough to prevent their exploding, for want of room; for though the preceding calcination has carried off the more volatile parts, yet there remains matter enough for great exploſion, and for the formation of a ſubſtance not leſs inflammable, than crude ſulphur, were the acid in a leſs proportion.

The beſt method is to fit to the neck of the retort a receiver with two necks; the one of which receives that of the retort, and the other is received into a capacious ſingle receiver of the common kind.

The icy oil is not eaſily got out of the receiver, for it exhales ſo ſtrong a ſulphureous vapour, that if it be placed lower than the operator's head, it would ſuffocate him in a moment.

This icy oil is black, becauſe it carries over with it a quantity of that oily matter, which no vitriol is ever entirely free from, and which is always found in the mother water, as it is called, of vitriol, after the repeated cryſtalliſations of the *ſalt* from it; and it is well known, that any inflammable ſubſtance, in ever ſo ſmall a quantity, will turn the pureſt oil of vitriol black; nor is this all, for the acid ſpirits alſo, when urged by a violent fire, carry over with them iron, or at leaſt ſuch particles, as are capable of becoming iron. This is eaſily demonſtrated in either the common or the blackiſh cryſtals of the icy oil of vitriol; for if theſe be diſſolved in a large quantity of pure diſtilled water, and allowed to ſtand ſeven or eight days, there always precipitates to the bottom of the veſſel a ſediment, which, after it has been calcined, has many particles, which readily anſwer to the magnet.

Beſides this oily matter, and theſe particles of iron, the oil of vitriol carries with it alſo a white, heavy, and cryſtalline ſubſtance, of the nature of earth, which may be ſeparated, by means of ſpirit of wine, from oil of vitriol, ever ſo well rectified. The ſame ſort of earth is alſo found in the *ſalt*, which is extracted from the *caput mortuum*, left after the diſtillation of the icy oil. The lixivium made by this author from the remaining maſs, left after the diſtillation of the icy oil of vitriol, was expoſed to the air, in a glaſs cucurbit, for the ſpace of ſix months; and the ſaline liquor, concentrated by evaporation in a ſand-heat, became green, and would by no means cryſtallize. The firſt ſaline pellicles had a ſaline, but earthy taſte: theſe precipitated by degrees of themſelves, and were finally ſucceeded by others, which taſted acid, but not greatly ſo. This liquor being evaporated to a dryneſs, an ounce of the remainder was put into a retort, and four ounces of oil of vitriol was put on it, with one ounce of water, to forward the diſſolution; this was kept in digeſtion twenty days, at the end of which time the liquor acquired a green colour, which ſhewed that there were yet in the maſs metallic parts for it to diſſolve: this was finally diſtilled with a gentle heat, to ſeparate the phlegm, and afterwards the fire was encreaſed, to drive over the acid; the oil of vitriol came over as ſtrong, as it was when put on, but much more ſulphureous. The diſtilled oil being returned upon the *ſalt*, with the freſh addition of a ſmall quantity of water, became ſo hot, that the veſſel could not be held in the hand; which had not been the caſe in the firſt mixture, at leaſt not in any ſenſible degree. Several more cohobations made it yet more and more acid, and at length it became ſo cauſtic, as to leave an eſchar on being juſt touched upon the tongue.

The green colour, which the acid firſt received, became at length changed into a blue one, which gave ſuſpicion that there was copper, as well as iron in the vitriol. This might appear ſtrange, as it was Engliſh vitriol that was uſed; but Kunkel has proved by experiments, that there is ſome copper in all vitriol, even in the Engliſh; nay he advances, that in the vitriol of iron, made with oil of vitriol and filings of that metal, there may always be diſcovered ſome ſmall portion of copper; and, in fine, that there is no iron but contains ſome portion of copper, and no copper but contains ſome portion of iron.

After the ſixth cohobation of this blue liquor, there remained a granulated and filamentous ſaline ſediment, on the ſurface of which there was a ſmall quantity of a yellow ſublimation, reſembling flower of ſulphur; warm water being poured upon this matter, became of a greeniſh colour; and this being digeſted in a ſand-heat, became afterwards

reddiſh, and precipitated to the bottom a white and very heavy powder; which, on a ſeries of examinations, proved to be of the nature of that opake white ſtone, uſually found among the ores of metals, and called by the Germans *quartz*.

The ſaline liquor, from which this was ſeparated, became yet redder by long digeſtion, but when cold, it turned to a fine green.

This liquor being concentrated, by evaporation, to the quantity of two or three ounces, was put into a glaſs veſſel, with its pellicle, which ſoon precipitated itſelf to the bottom, in form of a thin cruſt, covering the ſurface of the glaſs in the manner of a wet paper. In five or ſix weeks time, there became formed in this veſſel, both at the bottom and ſides, a number of large cryſtals, of a beautiful green colour, and as the liquor dried away, theſe mouldered into a browniſh red powder.

In fine, there appeared, in the remainder of this liquor, another ſort of cryſtals; theſe were white and tranſparent, and were formed in ſquare columns, with their extremities cut in the manner of thoſe of the pyramids of the columns of *Glauber's ſalt*; they had alſo a bitter taſte, and left a remarkable ſenſe of coldneſs on the tongue. Theſe appeared indiſputably, by theſe and all other trials, to be true *Glauber's ſalt*. Mem. de l'Acad. Scien. Par. 1738.

Glauber's *ſal mirabile* was long thought to be the produce of art only; but of late years, a natural *ſalt*, perfectly ſimilar to Glauber's, has been found in many places. We have a full account, by Mr. Boulduc, of a ſubſtance of this kind, which had been found near Grenoble in Dauphine. The ſame gentleman alſo found a *ſal mirabile* in the waters of Paſſy. The true Epſom *ſalt*, deſcribed by Dr. Grew in 1696, is alſo either the ſame as Glauber's, or at leaſt Glauber's is the principal part of it. Stahl afterwards found a true *Glauber's ſalt* in the acidulæ, or ferrugineous waters, and did not ſcruple placing this among the natural mineral *ſalts*. Hoffman alſo found a ſpring of very bitter and purgative mineral water, a pound of which contained two drachms of this *ſalt*. The cathartic *ſalt*, found near Madrid, is alſo of the ſame nature. See Hiſt. de l'Acad. Par. 1727. p. 29, 30. and the Memoires of the ſame year, p. 375, ſeq. 4to.

It is to be obſerved, that though Glauber made his *ſalt* known about the middle of the preceding century, yet Kunckel, in his Laborat. Chymic. aſſures us, it was known in the electoral houſe of Saxony an hundred years before. However this be, we owe the knowledge of it to Glauber, who called it *admirable*; and it ſoon acquired, and has ever ſince maintained, the reputation of an excellent internal medicine in many caſes.

Glauber's ſalt may be obtained from borax, by mixing oil of vitriol with it. Mix four ounces of borax with one ounce and one drachm of oil of vitriol; upon ſublimation, this gives the *ſal ſedativum* of Homberg, and the reſiduum, expoſed to a ſtrong fire, affords *Glauber's ſalt*. This operation may be ſhortened very much, for inſtead of ſublimation, the *ſalt* may be obtained by cryſtallization, in light foliated laminæ. This *ſalt*, whether prepared by ſublimation, or by cryſtallization, has the property of diſſolving in ſpirit of wine; and if this ſpirit of wine be ſet on fire, the flame is green. Spirit of wine has no effect on borax, and the oil of vitriol digeſted with it, does not make its flame green. Therefore it is neceſſary, in order to give this greenneſs to the flame, that borax ſhould be united to an acid. Philoſ. Tranſ. N° 436. p. 39.

SAL *nitrium*. See NITRIUM *ſal*.

SAL *polychreſt of Seignette*, a ſoluble tartar made with *ſal kali*, inſtead of *ſalt* of tartar. Mr. Boulduc deſcribes this *ſalt* in the Mem. Acad. Scienc. 1731. See POLYCHREST, *Cycl.*

SAL *ſedativum of Homberg*, This uſed to be made by diſſolving borax in water, into which oil of vitriol was poured, and then diſtilling this mixture, quieting *ſalt* was obtained. Mr. Geoffroy has lately taught us an eaſier way of preparing it: he evaporates the liquor to the proper conſiſtence, and then allows it to cryſtallize. Mem. de l'Acad. Par. 1732. See SEDATIVUM *ſal*.

SALACSAE, in natural hiſtory, a name given by the inhabitants of the Philippine iſlands to a kind of bird, by whoſe flight they pretend to divine the event of things. All the account we have of the bird is, that it is of a ſmall ſize, and is variouſly coloured, and has a long and large beak.

SALAMANDRA, the *ſalamander*, in zoology, a name given by authors to ſeveral ſpecies of the lizard kind, but the principal are two, the *ſalamandra aquatica*, and *ſalamandra terreſtris*.

The *ſalamandra aquatica*, or water *ſalamander*, is our common water newt, or eft, which is very common in fiſh-ponds, and other ſtanding waters, and is diſtinguiſhed from the reſt by the flatneſs of its tail.

The manner of propagation in theſe animals is very ſingular, and ſerves to illuſtrate the analogy between animal and vegetable nature.

The *ſalamandra terreſtris*, or land *ſalamander*, is a ſpecies of lizard very like the green kind, except that its head, and its belly, are thicker. Its tail is ſhort, and its colour a fine black, marked with red ſpots, and of a bright, ſhining, and gloſſy appearance. It is very common in many mountainous places.

The difference between this and the water kind is not only in colour, but in the ſhape alſo of the tail; which in this is round, not flat as in that; yet there are ſome who affirm, there is no ſpecific difference between the two, but that the water kind, when it deſerts that element, and comes to live on ſhoar, alters in colour, and becomes round at the tail.

The opinion of this creature's being able to remain unhurt in the fire for a long ſpace of time, is wholly falſe and fabulous.

The *ſalamander* is evidently a viviparous animal, yet it is ſuppoſed that the young are hatched from perfect eggs, while in the body of the parent animal. *Ray*'s Synop. Quad. p. 274.

SALAMANDRINO, in ichthyology, a name given by the Italians to that ſpecies of ſalmon, which Salvian calls *ſalmarinus*. It is diſtinguiſhed from all the other ſpecies of this fiſh, by its having a yellowiſh back, with yellow ſpots, and a forked tail. The fleſh of this ſpecies is very delicate. It loves cold and clear rivers. *Willughby*'s Hiſt. Piſc. p. 199.

SALAMGA, in natural hiſtory, the name given by the people of the Philippine iſlands to a ſpecies of ſea ſwallow. This is the bird, whoſe neſts are ſo famous as an ingredient in ſoops.

SALANDRA. See the article CHELANDIUM.

SALANDRIA. See the article CHELANDIUM.

SALAR, in ichthyology, a name given by ſome authors to the trout. See TRUTTA.

Others apply the name to a young ſalmon while very ſmall. See SALMO.

SALAYASIR, in natural hiſtory, the name by which the people of the Philippine iſlands call that ſmall ſpecies of duck, which is ſo common thereabouts. This is an inhabitant of their lakes and marſhes, and is a perfect duck, and very beautifully coloured, but does not exceed the bigneſs of a man's fiſt.

SALEFUR, a name given by ſome of the chemiſts to garden ſaffron. See SAFFRON.

SALEP, in the materia medica, the root of a ſpecies of *orchis*. See the article ORCHIS.

Salep ſhould be choſen clean, firm, and hard; it is very little liable either to decay, or ſophiſtication.

The people of the Eaſt are extremely fond of *ſalep*; they look upon it as one of the greateſt reſtoratives, and provocatives to venery in the whole vegetable world.

That *ſalep* is the root of an *orchis*, no way differing from our common *orchis's* in virtue, but owing its appearance to the manner of preparing it, and conſequently, that *ſalep* may be prepared from the roots of *orchis* of our own growth, Mr. Geoffroy has proved in the following manner. He conſidered, that the method of curing one root in the eaſtern parts of the world was probably the ſame with that uſed in all; and obſerving that Kæmpfer had deſcribed the manner in which the Chineſe prepare their ginſeng, to make it pellucid, which was by firſt ſteeping, or macerating it in water, and afterwards carefully drying it; he determined to attempt the curing the roots of the common *orchis*, in a method not unlike that uſed to the ginſeng, in order to make *ſalep* of it. The *ſalep*, which we receive from Turkey, is a root of a white or reddiſh colour, according to its different age; and as we receive it, is always tranſparent. As to our own *orchis*, if we attempt to dry the roots in the common way, they never will appear at all like the *ſalep*, but will become ſhrivelled up and brown, and will always retain, or be ready to imbibe from a humid air, a great quantity of moiſture. To prepare theſe, in imitation of the *ſalep*, Mr. Geoffroy choſe the largeſt, plumpeſt, and faireſt roots he could find; theſe he nicely ſkinned, taking off the whole outer rind, then throwing them into cold water, he ſuffered them to macerate there ſome time; after this he lightly boiled them; and after this taking them out of the water, and draining them, he had them ſtrung upon threads, to be dried in a warm and dry air. When the roots were thoroughly dried, they were very tranſparent, and reſembled pieces of gum tragacanth, and continued dry and hard. The roots thus prepared, may be kept ever ſo long in a dry place, and will never attract humidity, or become mouldy and rotten; as they will always do in wet weather, if dried in the common way with their ſkins on.

The *orchis* roots thus prepared may be reduced to powder, this powder will diſſolve away in boiling water, and a ſcruple of it will make a baſon full of jelly, in the manner of the Turkiſh *ſalep*. This jelly is an admirable medicine in all the caſes, in which *ſalep* is preſcribed, and may be rendered agreeable by the addition of wine, ſugar, ſpice, &c. and the powder may be given with great ſucceſs in aſſes milk, for diſeaſes of the breaſt.

If the water, in which the roots have been boiled, be evaporated over a gentle fire in an earthen veſſel, there will remain an extract of a viſcous texture, and a very agreeable ſmell, reſembling that of a meadow of flowers when the wind blows over it. Mem. de l'Acad. Scienc. Par. 1740.

SALIÆ, in antiquity, Roman virgins, dreſſed after the manner of the ſalii, who aſſiſted the pontif in ſacrificing. *Pitiſc.* in voc. See the article SALII, *Cycl.*

SALIAN *dance*, in antiquity. See DANCE and SALII, *Cycl.*

SALICARIA, *willow herb*, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the roſaceous kind, conſiſting of ſeveral petals, diſpoſed in a circular form, and growing out of the ſegments of a tubular cup; from the bottom of this cup there ariſes alſo a petal, which finally becomes an oval bicapſular fruit, containing a number of ſmall ſeeds, affixed to a placenta, and uſually ſurrounded and covered by the cup.

The ſpecies of *ſalicaria*, enumerated by Mr. Tournefort, are theſe. 1. The common long leaved *ſalicaria* with purple flowers. 2. The trifoliate purple flowered *ſalicaria* with hexangular ſtalks. 3. The roundiſh leaved purple flowered *ſalicaria*. 4. The narrow leaved Portugal *ſalicaria*. 5. The broad hyſſop leaved *ſalicaria*. 6. The narrower hyſſop leaved *ſalicaria*. 7. The white flowered hyſſop leaved *ſalicaria*. 8. The Spaniſh hyſſop leaved *ſalicaria* with long deep blue flowers. 9. The ſmalleſt narrow leaved *ſalicaria*. 10. The ſmalleſt Portugal *ſalicaria* with leaves like moneywort. *Tourn.* Inſt. p. 253.

SALICARIA, in zoology, a name by which Geſner, and ſome others, have called a ſmall bird, very much reſembling the muſcicapa, or fly-catcher, if not the ſame ſpecies.

It lives among the willows in wet places, and feeds on ſpiders, flies, and other inſects. *Geſner.* de Avib. See the article MUSCICAPA.

SALICASTRUM, a name by which Pliny, and ſome other botanical authors, have called the *ſolanum lignoſum*, the woody nightſhade, or bitter ſweet. *Ger.* Emac. Ind. 2.

SALICHA, in the materia medica, a name given by ſome of the old writers to cinnamon. Aviſenna and Serapion uſe it for the bark we call *caſſia lignea*, and the Greeks *hylocaſia*, when ſtripped clean from the wood.

The antients had two ways of collecting the barks of trees and plants for medicinal uſes; the one was the ſtripping them from the branches of trees, as we do at this time; the other was the cutting off the branches, bark and all, and drying them together. The *ſalicha* ſignifies, however, the *caſſia*, or cinnamon, thus ſtripped from the wood, not cut with it. The word *ſelach*, in the Arabic, from which it is derived, ſignifying *exuviæ*, or the caſting off the outer part of any thing. The *ſelach alhaie* is the *exuviæ ſerpentis*, or caſt ſkin of a ſerpent, and ſo of the reſt. The determinate ſenſe of the word *ſalicha* is, therefore, the bark of *caſſia* ſtripped from its wood, and is what the antients called *caſſia fiſtula*, from its being rolled up in the form of a pipe. But we have perverted their meaning in this term, and applied it to the fruit of the pudding pipe tree, that being our *caſſia fiſtula*. Damocrates, in his iambics, and alſo in his antidote, mentions this bark under the name of *caſſia fiſtula*; and Scribonius Largus, among the reſt, expreſsly informs us, that it was the bark, not the fruit of a tree, that was at his time known by this name. Aviſenna, and the more correct writers, keep this word for the name of *caſſia*, never expreſſing cinnamon by it, though others do. They call cinnamon *darſini*.

SALICINEA, in the materia medica, a name uſed by Geſner, and ſome other authors, for the *nardus Celtica*, or Celtic ſpikenard. *Ger.* Emac. Ind. 2.

SALINE, a name given to a preparation of ſea *ſalt*, procured from the froth of the ſea, hardened by the ſun in hot countries. It is called by ſome authors *pilatro de Levante*, and is uſed in glaſs-making; and in the making the fine purple colour from cochineal, by boiling it in a ſmall quantity, with the bran and fœnugreek, of which the magiſtery is made for that purpoſe. *Neri*'s Art of Glaſs, p. 173.

SALINE is alſo the name given by authors to ſprings of *ſalt* water, called by us *ſalt wells*, *ſalt ſprings*, and *brine pits*. Moſt parts of the world are found to have theſe, but thoſe of Franché Compté, in France, ſeem to be the moſt remarkable. The ſprings are ſituated in deep caves, and theſe in the greater work are about four hundred feet in length, and fifty feet in breadth: into this work they deſcend by a ſtone ſtaircaſe of forty ſteps, and thence by a wooden one of twenty; at the bottom of theſe ſtairs is a cave with an arched roof. This firſt cave, or vault, is forty feet long, and thirty two feet and a half broad, and in it are ſix ſprings of *ſalt* water, and two ſprings of freſh water; all which iſſue out of the ſame rock, in the ſpace of fourteen feet in length. From this cave they go into others, which are ſupported in the middle, each by a row of thick pillars, from which are carried double rows of arches. They then paſs through two gates into a ſpacious vault, thirty five feet high, and ſupported, nigh the entrance, by four ſtrong pillars, placed in form of a ſquare. In the middle ſpace, between theſe pillars, is a baſon of a very conſiderable ſize, into which the *ſalt* water from ſeveral ſprings is collected: and in the ſame vault, beyond theſe pillars, are four others placed in a row, ſupporting different arches, of ſixty feet in length, and forty eight feet in breadth; beyond which there is an irregular ſpace, ſixty three feet long, in which are ſix or ſeven ſprings of *ſalt* water, and ten or twelve of freſh. The *ſalt* waters of theſe ſprings, and of the ſix ſprings before-mentioned, are kept ſeparate from the freſh water, and are all conveyed through gutters to the baſon before-mentioned. From this baſon, they are drawn out by a wheel and buckets into four large ſtone baſons or reſervoirs, one of which holds fifteen thouſand hogſheads, and the other three together twenty-five thouſand hogſheads. From theſe reſervoirs they are to be drawn off, as occaſion requires, into ſmall ciſterns placed near the boiling houſes; and the waters contained in the ſeveral baſons, as they are drawn from the ſprings, at different times, and are of different ſtrength, are mixed together before the boiling, in ſuch proportion, that each pound of the water yields about three ounces of *ſalt*.

The water of the freſh ſprings is alſo collected in the caves into a freſh water baſon prepared to receive it, and is raiſed by means of a crane to the level of a little brook, through which it runs away by a ſubterranean conduit. *Brownrig* of Salt, p. 94.

SALINE *principle*, a term uſed by the chemical writers, to expreſs a conſtituent part of ſeveral mixt bodies, on which their exiſtence in that form depends; and which, though always exiſtent in them, and always ſeparable by art, is yet not perceivable in many of them in the complex.

The *ſaline principle* of vitriol is of the number of thoſe made by ſome a neceſſary principle of the exiſtence of that body, and by others ſuppoſed not to exiſt at all, otherwiſe than in the general form of that compound *ſalt*. But the exiſtence of it, in a ſeparate ſtate, is proved by this experiment: take four or five gallons of the ſtrong vitriolate water at the water works, as it runs from the beds of pyrites to the great ciſtern; this is to be choſen, becauſe having yet undergone no operation but that of the air and water, it muſt needs be in the moſt ſimple and natural ſtate; diſtil from this about two thirds of the inſipid water, let the glaſſes cool, and the water will then let fall a vitriol of a lovely pale green colour, together with a large quantity of ochre or yellow earth. Evaporate away a third part of the remaining liquor, and more vitriol ſtill will be produced of a paler colour than the former, and ſome yellow earth will alſo be thrown down, though leſs in quantity than before; after this has been repeated five times, inſtead of vitriol, a yellow *ſalt* will be obtained; and after that, on more evaporations, a white *ſalt* will be every time obtained, which will be extremely different from vitriol both in colour and taſte, being fiery and pungent, and partaking ſcarce at all of that acrid and nauſeous aſtringent taſte, which is ſo peculiar to vitriol. It is unctuous like *ſalt* of tartar, and cleanſing like ſoap, rendering the hands waſhed with it ſoft and ſupple; whereas the common vitriol makes them very harſh and rough; finally, this laſt *ſalt* diſſolved in water appears fatty and mucilaginous.

From five pounds and a half of the laſt lixivium four pounds of this ſalt will be obtained, and half a pound of the liquamen will never congeal. It is remarkable, that this *ſaline* matter is the moſt ſoluble of all the ſorts, as the greateſt quantity of it may be kept fluid in the ſmalleſt quantity of water we know of in any experiment of this nature.

The liquamen remains thin, and is of an acrid and fiery taſte, ſcarce ſupportable on the tongue. See the article LIQUAMEN *pyriticum*.

The white ſalt, which is called the *ſaline principle* of vitriol, being put into a retort, and diſtilled in a ſand furnace; the far greater part of it comes over in form of a highly acid ſpirit, eſpecially that coming laſt in ſmall drops. This liquor being rectified in a tall glaſs body, a volatile ſulphureous liquor ariſes immediately on the application of the heat. The ſmell of this is ſo ſubtile, and penetrating, that it is almoſt inſupportable, and yet it is clear as water and inſipid to the taſte. This may be preſerved in its full perfection many years, only by keeping it cloſe ſtopped, not letting fall any ſediment. The remaining liquor is the common acid liquor of vitriol, and by diſtillation may be ſeparated into ſpirit of vitriol, and that heavy and corroſive liquor, commonly called oil of vitriol.

In alum, vitriol, and mineral ſulphur, the *ſaline principle*, which in each of them is by far the chief part, both in quantity and energy, has much the ſame nature and properties. In the laſt indeed it is clogged with ſulphur; for the true nature of common ſulphur is, that it is a vitriolic ſalt, the very ſame with that of common vitriol; and the ſulphureous parts, which give it that form and exiſtence which we expreſs by the word ſulphur, are leſs copious than could be imagined, compared with the *ſaline*, which are genuine vitriol, differing in nothing from the common vitriol, but that it contains a ſmaller admixture of terreſtrial and metalline parts. Phil. Tranſ. N° 103.

SALINE *earths*. The chemiſts under this, as a general head, reckon all thoſe *ſaline* and *earthy* ſubſtances, which are calcined or burnt in the fire; as all the kinds of lime, potaſhes, ſoot, and the like; theſe being ſo many mixtures of ſalt and *earth*; and all ſalts appearing to them, indeed, on a rigorous examination, to be only *earths* of different natures, which when reduced to a certain degree of ſubtility or fineneſs of parts, ſo as permanently to diſſolve in water, are then emphatically denominated ſalts. *Shaw*'s Lectures, p. 67.

SALIVAL (*Cycl.*)—SALIVAL *ducts*. Dr. Trew endeavours to ſhew, that the veſſels called *ſalival ducts*, by Coſchwitzius, are not truly *ſalival ducts*, but veins. Phil. Tranſ. N° 457. Sect. 7. p. 441.

SALIVARIS, in botany, a name given by ſome authors to the pellitory of Spain, or pyrethrum of the ſhops, from its quality of draining a large quantity of the ſaliva into the mouth by its great heat and acrimony. *Ger.* Emac. Ind. 2.

SALIX, the *willow*, in botany, the name of a genus of trees, the characters of which are theſe. The flower is of the amentaceous kind, being compoſed of a great number of ſtamina arranged in form of a ſpike. Theſe are the male flowers, and are barren; the embryo fruits appear on other trees of the ſame ſpecies, which produce no male flowers. Theſe are diſpoſed like the ſtamina into the form of a ſpike, and finally become conic capſules, which when ripe open into two parts, and diſcharge a ſeed winged with down.

The ſpecies of *willow* enumerated by Mr. Tournefort are theſe. 1. The common white tree *willow*. 2. The common black *willow* with leaves not ſerrated. 3. The common red *willow*. 4. The yellow *willow* with crenated leaves. 5. The almond *willow* with auriculated leaves, green on both ſides. 6. The *willow* with almond like leaves auriculated on each ſide, which caſts its bark. 7. The *willow* with long and very narrow leaves white on both ſides. 8. The long narrow leaved *willow*. 9. The long hoary and pointed leaved *willow*. 10. The brittle or crack *willow*. 11. The dwarf *willow* with ſcaly heads. 12. The great bay leaved mountain *willow*. 13. The round ſilvery leaved *willow*. 14. The dwarf broad leaved erect *willow*. 15. The broad leaved creeping *willow*. 16. The round leaved creeping dwarf alpine *willow* with leaves greyiſh underneath. 17. The round leaved dwarf *willow*. 18. The creeping round or alder leaved alpine *willow*. 19. The mountain creeping *willow* with leaves woolly on each ſide. 20. The dwarf *willow* with leaves ſmooth on both ſides. 21. The dwarf hoary flax leaved *willow*. 22. The dwarf *willow* with ſhort narrow and woolly leaves. 23. The Pyrenean mountain *willow*. 24. The ſmooth narrow leaved creeping *willow*. 25. The Alpine *willow* with ſhining leaves like ſerpyllum. 26. The ſallow or *willow* with broad roundiſh leaves. 27. The ſallow with pointed roundiſh leaves. 28. The broad leaved white *willow*. 29. The Portugal *willow* with auriculated ſage like leaves. *Tourn.* Inſt. p. 591. See Tab. 1. of Botany, Claſs 19.

SALIX *amerina*, in botany, is uſed for *agnus caſtus*. *Lemeri* Tr. des drog. p. 18. See AGNUS *caſtus*.

SALLIUS *lapis*, a name by which Ludovicus Dulcis, and ſome other writers of his time, have miſcalled the *lapis ſamius* of the antients. That author deſcribes it as being heavy, white, and brittle, and gives it the ſame virtues with the *lapis ſamius* of Pliny.

SALLY (*Cycl.*)—SALLY-*port*, in a fire ſhip, is a great opening in her ſide, made on purpoſe for the men to eſcape by, when they have grappled an enemy, and fired their train.

SALMO, the *ſalmon*, a well known fiſh. It is diſtinguiſhed from other fiſh of the truttaceous kind by theſe characters. It is of an oblong body covered with very ſmall ſcales, a ſmall head, a ſharp noſe, and a forked tail. Its back is bluiſh; the reſt of its body whitiſh, or reddiſh, and uſually ſpotted. Its under jaw is bent upwards, and that ſometimes ſo much as to make itſelf a ſinus in the upper, by conſtant motion, and ſometimes to perforate it. The *ſalmon* is firſt produced from its parent's ſpawn in freſh rivers, thence it goes into the ſea to acquire its growth and feed. And at the time of its full growth, and in the ſeaſon for ſpawning it removes into the freſh waters again.

The *ſalmon* in the different ſtages of its life and growth has different names. The Latins called it when young *ſalar*, when of a middle growth *ſario* or *fario*, and only when full grown *ſalmo*. In England the fiſhermen have names for it in every year of its growth. In the firſt it is called a *ſmelt*, in the ſecond a *ſprod*, in the third a *mort*, in the fourth a *fork-tail*, and in the fifth a *half fiſh*; finally, in the ſixth it is called a *ſalmon*. This is the common agreement of our fiſhermen, though there are ſome who ſay the *ſalmon* comes much ſooner to its full growth. *Willughby*'s Hiſt. Piſc. p. 139.

In the Artedian ſyſtem of ichthyology, the characters of this genus of fiſhes are theſe: the branchioſtege membrane on each ſide contains eleven, twelve, or nineteen bones. The body of the fiſh is generally variegated with ſpots. The back fins are placed nearer the head than thoſe of the belly, and the teeth are large, and are placed in the jaws, and palate, and on the tongue.

The ſpecies of this genus enumerated by Artedi are theſe. 1. The *ſalmon* with the ſnout often reaching beyond the lower jaw. This is the common *ſalmon*. The ſpots are black, and the back convex, the belly flat and plain. 2. The *ſalmon* with grey ſpots, and with the end of the tail equal. This is that ſort of *ſalmon* which we call the grey; its body is broader and thicker than the common *ſalmon* in proportion to its length. 3. The broad *ſalmon* with black and red ſpots, and with an even tail. This is the kind we call the *ſcurff*, or the *bull trout*. 4. The forked tailed *ſalmon* with only black ſpots, and with a longitudinal furrow on the belly. This is the *trutta lacuſtris* of authors. Its fleſh is red. Its weight about twenty pound, when full grown; it will ſometimes weigh much more. The upper jaw in the ſpawning time is crooked, the head and back are of a bluiſh green colour. 5. The *ſalmon* with the lower jaws ſomewhat longer than the upper, and with red ſpots. This is the common river trout. The tail of this fiſh is ſcarce at all divided; the pinna ani has ten rays; the ſpots below the lineæ laterales are red, thoſe on the head and back are blackiſh. 6. The oblong *ſalmon* with two rows of teeth in the palate, and with only black ſpots. This is that ſort of trout, called by the Germans *huch*; the ſides and the fins are red, and the body is ſlenderer than in the common river trout. There are ſome ſpots on the lower jaw, but none on any other part of the head. 7. The twelve inch *ſalmon* with five rows of teeth in the palate. This is the fiſh called by authors the *carpio lacus benaci*, and by us the *gilt charre*. The body is much broader than that of the common trout. The fleſh when boiled becomes red. It has eight ſpots on each ſide in the lower jaw, and black ſpots in the back. The ſides and belly are ſilver coloured, and the ſnout is bluiſh. 8. The twelve inch *ſalmon* with red belly fins, and the lower jaw ſomewhat the longer. This is the *ſalmo lapponicus* of Linnæus. The *torgoch* of the Welch, and probably the *red charre* of ſome parts of England. The body is more ſlender than that of the river trout. The belly is generally reddiſh. The fleſh of this ſpecies ſcarce becomes at all red in boiling; the ſpots are broad, but of a faint and obſcure colour. 9. The forked tail *ſalmon* with the lineæ laterales turning upwards, this is the umbla of authors; it has three or four foramina under the eyes, and has no middle line of teeth in the palate. The belly and the ſides below the lineæ laterales are yellow. The head is bluiſh, and there are ſome whitiſh ſpots above the lateral lines. 10. The twelve inch *ſalmon* with the upper jaw longer than the under. This is the fiſh called the *pavelin* by the Germans, and the *umbla altera* of authors: it has yellow ſpots on the ſides, and the belly and its fins are alſo yellowiſh. The lateral line is ſtrait. The middle row of teeth in the palate is ſcarce perceivable; but there is a double row of them in the upper jaw, with a ſkin reſembling a lip between them. The fleſh boils red. *Artedi*'s Gen. Piſc. p. 9.

The *ſalmon* is a very peculiar kind of fiſh. It is bred in rivers, but goes every year from thence into the ſea; and at a certain ſeaſon of the ſame year it always returns up into the freſh water again; and what is remarkable, is, that ſo far as obſervation has been able to trace them at any time, the ſame ſhoals of *ſalmon* always return into the ſame river out of which they ſwam, not into any other; ſo that the people who live on the *ſalmon* fiſhery are not afraid for their rivers being cleared, by all the fiſh in them going down into the ſea, for they know that they will all return up to them again at a proper time. When the *ſalmon* has once entered a freſh river, he always ſwims up againſt the ſtream, and often will go an hundred leagues up a river in the large and long rivers; and the people at this vaſt diſtance from the mouth have the pleaſure of taking a fiſh, that is properly in part of the ſea kind. It is alſo remarkable, that the rivers which moſt abound with *ſalmon* do not make the ſeas about their mouths any more abound with them than others, particularly the harbour of Breſt affords no *ſalmon*; though the river Chateaulin, which diſcharges itſelf into it, is the richeſt *ſalmon* river in France.

Another ſingularity, in regard to the *ſalmon*, is their ſwimming up the rivers together in ſuch vaſt numbers. It is to be allowed, indeed, that herrings, mackrel, and many other fiſh, do in the ſame manner appear on the coaſts at certain ſeaſons in prodigious numbers; but the reaſons for their coming together in theſe quantities, are much more eaſily explained than that of the *ſalmons* doing ſo. The herrings, when they come in ſuch prodigious ſhoals to the coaſts of Normandy, have been found to be allured thither in theſe numbers by a prodigious quantity of a particular ſort of ſea worms which are their favourite food, and which are found to cover the whole ſurface of the ſea at that time. Rondeletius has deſcribed theſe inſects under the names of ſea caterpillars; they always appear in the months of June, July, and Auguſt, which are the herring ſeaſons at that part of the world; and probably the ſame cauſe will be found to bring them to other places, if ſufficiently enquired into, as theſe and ſome other fiſh come to certain places in ſhoals to get food. The *ſalmons* do it in order to propagate their ſpecies. The ſpawn of the *ſalmon* is never depoſited but in rivers, and at the time that theſe fiſh are found up the rivers, it is only with this intent; the females go firſt, and the males follow as far as the others pleaſe to lead them, which is uſually to ſome convenient place in ſhallow water, where the ſpawn when depoſited is not buried under too great a quantity of water, but has the advantage of a continual warmth from the ſun's heat.

Salmon do not equally frequent all rivers, though they may ſeem to us equally proper for their reception. There are

two

two rivers which open themſelves into the harbour of Breſt very near one another; the one of theſe is famous for the quantity of *ſalmon* in it, and the great advantage of the fiſhery, the other never has any of theſe fiſh in it. It moſt probably is owing to their finding plenty of food, and proper places for the depoſiting their ſpawn in the one of theſe rivers, and not in the other, that makes this regular choice. *Des Landes* Trait. Phyſ.

SALMON *pipe*, in our old writers, an engine to catch *ſalmon*, or ſuch like fiſh. 25 H. 8. c. 7. *Blount*, *Cowel*.

SALMON *trout*, in zoology, the Engliſh name of the fiſh called *trutta lacuſtris*, by Geſner and other authors. It is caught in lakes, in mountainous countries, and grows to a very conſiderable ſize, ſometimes to thirty, forty, or fifty pounds weight. It reſembles the *trout* in figure, but its belly is very flat, and has, as it were, a long furrow or cavity running the length of the belly. Its back and head are of a very beautiful bluiſh green colour; and the whole fiſh, eſpecially its back and the upper parts of its ſides, are marked with numerous black ſpots. Its back fin is alſo ſpotted with black, and its ſcales are ſmall and ſilver coloured. *Geſner* de Piſc. p. 1210.

SALMULUS, in zoology, the name of a ſmall fiſh of the truttaceous kind, called in Engliſh a *ſamlet*.

It ſeldom grows to more than ſeven inches in length. It is very like the common trout, but differs in theſe particulars. 1. It is broader in proportion to its length. 2. It has fewer ſpots, and thoſe of a deader colour. 3. It is white in its general colour. 4. The tail is more forked. 5. The lines on the ſides are ſmaller and paler. 6. The ſides under the lines are yellowiſh; and 7thly, It has ſeveral bluiſh ſtreaks near the ſide lines. It is caught about Hereford, and in ſome other places. *Willughby*'s Hiſt. Piſc. p. 189.

SALPA, in zoology, the name of a fiſh caught in great plenty in the Mediterranean, and common in the markets of Italy and elſewhere. Its uſual ſize is about a foot in length, and it has a ſomewhat flatted, yet conſiderably thick body, and a ſtrait back. Its ſides are variegated with a number of fine gold coloured lines running longitudinally; the intermediate ſpaces between theſe toward the back are of a bluiſh green, toward the belly they are white; there are uſually eleven of theſe lines on each ſide. The mouth is extremely ſmall, and each jaw has only one row of teeth, which are thick and broad below, and terminate in a double point. It has only one back fin, the anterior rays of which are prickly, the hinder ones ſoft. It generally keeps about the ſhores, and ſwims in large ſhoals. Though it be a very beautiful fiſh it is no very delicate taſted one, nor much regarded, the poorer ſort of people uſually buying it up. *Rondelet* de Piſc. l. 5. c. 23. p. 154. *Aldrovand* de Piſc. l. 2. c. 21. See Tab. of Fiſhes, N° 55.

SALPUGA, in natural hiſtory, a name given by ſome of the Latin writers to the *ſolipuga*, a ſmall kind of ſpider, that buries itſelf in the ſands in hot countries, and bites men who come in its way in a very venomous manner. It is common in Africa, and in ſome parts of Europe; Sardinia in particular, according to Solinus, abounds with it. See the article SOLIPUGA.

SALSIRORA, in botany, a name uſed by ſome authors for the *ros ſolis*, or ſundew. *Ger.* Emac. Ind. 2.

SALT (*Cycl.*)—*Salts* are defined to be ſolid foſſile bodies, friable, pellucid, not inflammable, but fuſible by fire, and congealing again in the cold; ſoluble in water, ſo as to diſappear in it, naturally concreting into regularly figured cryſtals, and impreſſing a ſenſation of acrimony on the tongue.

Theſe are the characters and qualities common to all *ſalts*, and to no other bodies: and theſe they always manifeſt when pure and freed from heterogeneous ſubſtances; but in the ſtate in which they are naturally found in the earth, though they have that in their taſte alone which may ſufficiently diſtinguiſh them, yet they do not exhibit all their genuine characters: ſome of them being found ſolid and pure, either within the earth or on its ſurface, but commonly without their proper form; others embodied in earths and ſtones, as the particles of metals in their ores; and others in a fluid ſtate ſuſpended in waters.

Of the foſſils of this claſs, nature therefore affords us three diſtinct orders, and under thoſe they are diſtinguiſhable into five genera. The *ſalts* of the firſt order are thoſe found native and pure, either in the earth or without its ſurface, and exhibiting all other natural characters, though often without their proper form. Of the ſecond, are thoſe found not native, but in form of ores, never pure, but diſtinguiſhable by their taſte, and immerſed in and blended with the conſtituent matter of earths and ſtones in extremely ſmall particles. And of the third are thoſe naturally found ſuſpended in waters, and in a fluid form, but ready to aſſume their proper figures on the evaporation of a part of that water.

Of the firſt of theſe orders are the common *alimentary ſalt* or *muria*, and the *natrum* or *nitre* of the antients. Of the ſecond are *alum* and *nitrum*, and of the third are *borax*, and *halcryptium*, an alkaline *ſalt* hid in the chalybeate waters. *Hill*'s Hiſt. of Foſſ. p. 380. See the articles NATRUM, ALUM, NITRUM, BORAX, and HALCRYPTIUM.

The *muria* or *alimentary ſalt* is a body which appears to us under an almoſt infinite variety of forms, but is always immediately diſtinguiſhed by applying it to the tongue, and always aſſumes the ſame figures after a regular cryſtallization. Sea water, and that of *ſalt* ſprings, ſuſtain it in a liquid form; and beſide this ſtate, it is found in vaſt maſſes in the earth, either of a fine pellucid ſtructure, called *ſal gem*, or elſe variouſly debaſed and coloured, or in form of a ſtriated body, reſembling the fibrariæ, or fibroſe talcs, as they are called. This is the true *ſal ammoniac* of the antients. See SAL *ammoniac*. But in which ever of theſe forms this *ſalt* is found, it affords the ſame cryſtals on evaporation: theſe, according to the degree of heat uſed in the evaporation, are either pyramidal, cubic, or parallellopiped. All theſe *ſalts* are ſoluble in water, but they require different quantities of it to diſſolve them, and this makes one of their criterions. This *ſalt* requires three times and one ſeventh its own quantity of water, to make a perfect ſolution. The ſea water, in different parts of the world, is very differently ſated with it, ſome parts containing twice as much as others. *Hill*'s Hiſt. of Foſſ. p. 380.

Alimentary ſalt, according to the various ways of preparing it, may be diſtinguiſhed into ſeveral kinds. 1. *Bay ſalt*, prepared by evaporation by the heat of the ſun. 2. *Marine ſalt* boiled, which is extracted from ſea water by coction. 3. *Brine ſalt*, or fountain *ſalt*, prepared by boiling from natural brine, whether of ponds and fountains, or of lakes and rivers. 4. *White ſalt*, prepared from ſea water, or any other kind of *ſalt* water, firſt heightened into a ſtrong brine by the heat of the ſun, and operation of the air. 5. *White ſalt*, prepared from a ſtrong brine, or lixivium, drawn from earths, ſtones, or ſands, ſtrongly impregnated with common *ſalt*. 6. Refined *rock ſalt*, which is boiled from a ſolution of foſſile *ſalt* in *ſalt* water, or in freſh. And 7. *ſalt upon ſalt*, which is made from bay *ſalt* diſſolved in ſea water, or other water, and boiled to a white *ſalt*. *Brownrig*, on Salt, p. 50.

Bay SALT. This *ſalt* is of two kinds: the firſt drawn from ſea water, as is practiſed in France, Spain, and Portugal, and many other hot countries; the other from the water of *ſalt* ſprings, or lakes, as in the Cape Verd iſlands, in the iſland of Tortuga, Turks iſland, and many other parts of America.

The firſt kind is, in times of peace, imported into Great-Britain in very large quantities, and our colonies and fiſheries in America commonly ſupply themſelves with the latter.

There are ſeveral methods practiſed, in the different parts of the world, of making this uſeful *ſalt*; of which ſome are more ſimple and eaſy, others more complex. It is ſometimes prepared by a total exhalation of the water in which it was diſſolved; but the moſt ſimple and eaſy method of making it, is, when the water of ponds and lakes, impregnated with *ſalt*, is totally exhaled by the force of the ſun and air, and the *ſalt* is left concreted into a hard cruſt at the bottom of the lake. We have many inſtances of *ſalt* thus prepared, in the different parts of the world. In the Podolian deſerts, near the Boryſthenes, is a *ſalt* lake, whoſe water, by the heat of the ſun, is exhaled, and all its *ſalt* left in form of ice, in ſo hard cakes, that it is to be cut away in large pieces with tools; and in Ruſſia, on the borders of Crim Tartary, there are vaſt deſert plains, which in ſummer produce neither tree nor plant, but are covered with *ſalt*. In the Weſt-Indies we are told of a *ſalina* of this kind, called *garci mendoza*, forty leagues long, and ſixteen broad. And in the kingdom of Algiers there are many *ſalines*, which in winter are ſo many *ſalt* water lakes, and dry plains in ſummer, covered with a cruſt of *ſalt*, which is dug out, and ſold in very large quantities; and there are more of them in ſeveral parts of the world.

Large quantities of *ſalt* of this kind, however, are prepared by the art and labour of man. The Engliſh in the Cape Verd iſlands have long been uſed to prepare great quantities of it. The iſlands, which principally afford this *ſalt*, are chiefly Mayo, Bonaviſta, and Sall. The ſubjects of Great-Britain have long enjoyed a liberty of preparing *ſalt* in the two firſt of theſe, free of all taxes, except a late one impoſed on the captains for every aſs which they hire of the inhabitants, to carry the *ſalt* to their boats. *Brownrig* of Salt, p. 1 to 19.

The time of making this *ſalt* is in the dry ſeaſon, which in thoſe iſlands is uſually from November to July: thoſe ſhips, therefore, which are to load with *ſalt*, are to be there in the months of December or January. On the weſt ſide of Mayo, or May iſland, they find themſelves, as ſoon as on ſhoar, upon a bank of dry looſe ſand, fifty or ſixty yards broad; and when they have paſſed this, they enter upon the *ſalina*, or *ſalt* marſh. This is a plain of half a mile broad, and a mile long, the greater part of which is hollowed out into pits, which, at a proper ſeaſon of the year, are filled to the depth of eight inches with ſtrong brine, or pickle. See SALT-*marſh*, infra.

Some authors, who have given accounts of theſe works, ſay, that this brine is only ſea water, let in through holes in the bank at ſpring tides. But this is an error, the brine of theſe pits being much more ſtrongly impregnated with *ſalt*,

ſalt, than the ſea water, and being the real produce of *ſalt* ſprings, with which the whole iſland abounds at a certain depth. In moderate ſeaſons, the ſailors find theſe pits ready filled with brines, but in times of great drought, they are obliged to dig little wells to come at the water, and with this they fill the pits to the proper depth. The bottom of theſe pits is a kind of cloſe earth, which retains the water, and the ſailors, who firſt arrive at the place, clean out as many of theſe as they have occaſion for, and others, who follow them, do the like. After the pits are properly filled, the heat of the ſun exhales the water very freſh, and leaves all the *ſalt*, which forming itſelf into cryſtals, ſinks to the bottom from time to time. As this is done very quick in this ſeaſon, they twice a week draw out all the *ſalt* that is ready formed with rakes, and lay it in little heaps to drain; after this they add it to their general cargo in one large heap, where it ſoon dries entirely, and becomes fit to be put on board their ſhips.

If the weather be favourable, a large ſhip may be, in this manner, loaded with *ſalt* in a fortnight, and it is often done much ſooner, the ſailors finding the pits, at their arrival, ready filled with concreted *ſalt*.

Though a ſhip be thus very eaſily loaded with *ſalt* in good ſeaſons, yet bad weather, and delays upon the voyage, often are the occaſion of ſhips returning without their loading; for the wet deſtroys all the *ſalt* they had prepared, and the tornados toſs up the ſand, and mix it with the *ſalt*, and at the ſame time make it impoſſible to load it. This trade might therefore be carried on with much greater advantage, if there was a Britiſh factory eſtabliſhed at the place, whoſe buſineſs it ſhould be to make *ſalt* in the dry ſeaſon, and ſell it afterwards to the ſailors, and this might be done at a cheaper rate, than what the ſeamen can make it for, it uſually ſtanding them in about ſixpence a buſhel.

The *ſalt* is made at Bonaviſta in the ſame manner as in the iſland of May; but the brine is weaker, and the *ſalt* does not kern, as the ſailors call it; that is, it does not granulate, or cryſtallize, ſo ſoon as in the other place; but the ſhips are often forced to be contented with this, when either the iſle of May is too crouded, or when the rainy ſeaſon ſets in there, while they are at work; for though theſe iſlands are but eighteen leagues diſtant from one another, the rains are ſometimes ſeveral weeks later in one than in the other. The weather is not exceſſively hot in either of theſe iſlands, the ſailors finding it tempered continually by breezes from the ſea. *Brownrig* of Salt, p. 26.

The Britiſh colonies in America have alſo, for near a century paſt, been uſed to ſupply themſelves with *ſalt* of this kind from Tortuga, one of the Leeward iſlands, uninhabited, and ſituated near the coaſt of Caraccas, on the Spaniſh main, and the Turk's iſland, which lies not far from Hiſpaniola; and many veſſels, freighted from North-America to Barbadoes, and others of the Caribbee iſlands, were accuſtomed to go from thence to theſe *ſalt* iſlands, and carry back a loading of *ſalt*, for which they always found a market in Newfoundland, New-England, and other places in North-America. The Spaniards, who had been uſed to ſuffer this without moleſtation, at length ſeized ſuch ſhips as they found loaded with this *ſalt*, and the traders in this way were compelled to go in a ſort of fleet from Barbadoes, and the neighbouring places, and they kept together till out of danger. The method of making the *bay ſalt* in theſe places, is much the ſame with that already deſcribed; only in the American iſles they do not collect it out of ſmall pits, but out of large ponds and lakes; and the ſailors often find vaſt quantities of clean and good *ſalt* ready prepared, lying at the bottom of theſe lakes.

It has been reported, as a very extraordinary thing, that in theſe American iſlands the *ſalt* never kerns, or forms into grains, except during the hot ſeaſon of the year; but this is a ſtory much improved in the telling, and the whole truth ſeems to be this. During the conſtant rains, the ponds overflow, and great quantities of *ſalt* are waſhed away; and when theſe are over, the ponds and lakes remain full of a very weak brine, ſo that no *ſalt* can cryſtallize in them till moſt of the water is exhaled, and this does not happen, till toward the time of the rainy ſeaſon's ſetting in again; but as this ſeaſon begins only in ſhowers once in two or three days, and thoſe not great, the *ſalt* is eaſily prepared from the brine of the pits, which is then very rich, notwithſtanding this ſlight interruption. Theſe firſt ſhowers of the rainy ſeaſon are always a ſort of tornados, and waſh off a great quantity of *ſalt* from the ſurface of the earth into the ponds; and, in general, while they are ſo moderate, that there falls no more water in them, than is daily evaporated by the ſun, they are an advantage in keeping the ponds ſupplied, which otherwiſe, after the continuance of heat that has been at that time, would be dry, and in no condition for working.

Bay ſalts, prepared in France and other parts of Europe, are of the ſame kind, in the general meaning of the proceſſes, with thoſe of the African and American iſlands. As the *ſalt* is there prepared from the water of *ſalt* ſprings, it is in Europe made from ſea water. *Bay ſalt* is not extracted from ſea water, in the colder parts of Europe, as on the coaſts of Germany, Denmark, and Sweden, but in places ſituated in a more ſouthern climate, as on the coaſts of France, Spain, and Italy. Some marine *bay ſalt* has alſo, of late years, been made in England at Limington, and in ſome other parts of Hampſhire, and in the Iſle of Wight: but in theſe places it is only made in drier ſummers, and then rather by accident than deſign, it being collected from ponds, which were originally made for heightening of ſea water, or reducing it into a ſtrong brine by the heat of the ſun, in order to leſſen the expence of fuel, in boiling it into white *ſalts*. *Brownrig* of Salt, p. 35.

The ponds, in which this *ſalt* is made, nearly reſemble a rude kind of *ſalt* marſh, deſcribed by Agricola, in which the ſea water is received into a pool, and thence, by a trench, is conveyed into ſeveral pits dug in the earth; and when it has ſtood ſome time in theſe pits, it is ſuffered to run out into others, and ſo on, till the brine is ſtrong enough to cryſtallize.

This is the caſe in our Engliſh *ſalt* works; but the French marſhes, in which a vaſt quantity of *bay ſalt* is annually prepared, are made in a much more artful manner. A full account of which is given in the Philoſophical Tranſactions, N° 51. See SALT-*marſh*, infra.

When rainy weather happens, in the time that the French are making this *ſalt*, they keep it out of the pits as much as poſſible; but unleſs it rain much, the damage is not very great, the heat of the ſun ſufficiently exhaling it. If it rain very violently for a whole day, all the care in the world cannot ſo well keep it out, as to render it practicable to make *ſalt* for the three or four next days. But when it has rained ſucceſſively for five or ſix days, they are forced to empty all the water out of the beds, and take in freſh, before any *ſalt* can be made. This is an accident, however, that rarely happens to them. The hotteſt years always afford the moſt *ſalt*. In the very hot weather, there is *ſalt* made even in the night; and it is always obſerved, that there is more *ſalt* made in ſtormy weather than in calm. The weſt, and north-weſt winds, are always found to be moſt uſeful to the *ſalt* makers; and in good ſeaſons, the French *ſalt* workers draw out the *ſalt* from their pits every other day, and draw more than an hundred weight from every pit. This they do with inſtruments that will retain the *ſalt*, and are pierced full of ſmall holes, which let the water run off.

Thoſe pits which are made in a reddiſh earth, are always found to make the *ſalt* more grey; and thoſe in a bluiſh earth, more white; and it is always obſerved, that if more than the proper quantity of water be let in, the *ſalt* is the whiter, but there is the leſs of it in proportion. All the marſhes ſhould have a clayey viſcid earth, neither ſpungy nor ſandy. There is a great deal of caution to be uſed in drawing out the *ſalt*, that the earth, or other impurities of the pit, do not mix with it; for two workmen, who are differently ſkilled in their buſineſs, will procure from the ſame pit a very brown and foul, and a very clean and white *ſalt*; and they always ſeparate a pure and white *ſalt*, which riſes to the top of the water, before the other granulates, and falls to the bottom. This pure *ſalt* is not only of a better colour than the other, but is in ſmaller grains, and this is what the politer people uſe at their tables. Theſe marſhes are overflowed once a year, at the end of the ſeaſon, about a foot high, and this preſerves them from year to year. *Brownrig* of Salt, p. 44.

The French have ſo many works of this kind, that in favorable ſeaſons as much *bay ſalt* is made in a fortnight, as ſerves for the whole year, not only for the home conſumption, but for that of other nations, who purchaſe it of them, and who uſe much more of it than the French themſelves. But, on the contrary, when a rainy ſeaſon comes, there is often a ſcarcity for a whole year afterwards. It is wonderful, that though the method in which the French work has been long known among us, we have never attempted it ourſelves, either here, or in our American colonies, which would ſeem a very eaſy matter, the principal care being in the firſt erecting the works, or *ſalt* marſhes. See SALT *marſh*, infra.

The ſeveral kinds of *bay ſalt*, made in the different parts of the world, are found to differ greatly from one another in ſeveral particulars; as 1. in the ſize of the cryſtals, which is owing to the heat of the ſun, and the time it lies in the pits. The French cream of *ſalt*, and the blown *ſalt* of the iſle of May, are fine and ſmall grained. The Portugal *ſalt* is larger grained than that of France; and that of Tortuga is larger than either. 2. In purity. As all *bay ſalt* has ſome mud, ſlime, or the like, in the making, and ſome kinds are mixed with the bittern *ſalt*, or what is called Epſom *ſalt*, they are all more white while dry, and more pellucid when moiſt, and they differ in colour, according to the earth which makes the bottoms of the pits. Thus ſome of the French *bay ſalt* is grey, ſome reddiſh, and ſome white, according as a blue clay has lined the pits, or a red, or white one. 4. Some kinds of *bay ſalt* are more apt to contract a moiſture from the air than others: this is ſometimes owing

to the ſmallneſs of the grain, and ſometimes to a mixture of a calcarious, or alkaline *ſalt* with it. And 5. ſome kinds have an agreeable ſmell in large heaps; ſuch are the Portugal, and the Hampſhire *bay ſalts*; and this ſeems owing to the ſea water, they were made from, having a bituminous matter in it. 6. It differs greatly in taſte, according to the various foreign mixtures it contains; and it will often alter in taſte, and other qualities, by long keeping. Thus the *ſalt* of Peccais is ſo bitter, when new made, as not to be eatable, but after keeping a while, it becomes very pleaſant. This is owing to its containing at firſt a large portion of the bittern *ſalt*, or Epſom *ſalt*, which liquifies in keeping, and running off in form of a fluid, leaves the reſt of a good taſte. In general, *bay ſalt* is much fitter for uſe, after it has been kept ſome time in a dry place, than when it is firſt made.

From the accounts already given of the *bay ſalt* of other countries, and the manner of preparing it, it ſeems evident, that our being obliged to purchaſe it of other nations is the effect of our want of application to the making it ourſelves; ſince it is evident that it may be very well made, both in England, and in many of our American colonies. *Brownrig* of Salt, p. 202.

In England, a very advantageous ſort of works might be ſet on foot in the following manner. A number of *ſalt* pits ſhould be made in a row in the marſh, and their bottoms lined with plaiſter, or ſome ſtrong cement that will not eaſily break up; and by this caution, the *ſalt* may be drawn white and pure like the Portugal kind, not grey like the French. Over each pit covers ſhould be made of thin boards, or rather of canvas painted white, and ſtretched on frames of wood, and theſe ſhould be fixed to ſtrong poſts, erected on the north ſide of the pits, and contrived to be eaſily drawn back to them, in the manner of draw-bridges. Theſe covers, thus fixed, may be let down over the pits, in manner of a ſhed or penthouſe, in rainy weather, to keep the brine from being diluted with freſh water; and in dry weather they may be raiſed almoſt to a perpendicular, but inclining a little toward the ſouth, ſo as to form a wall with a ſouth aſpect; and thus they would ſerve for a double uſe, being a covering to the pits in rainy weather, and reflectors of the ſun's heat in fair. The reflexion of ſo large a body of the ſun's rays, in the courſe of a bright day, would greatly promote the evaporation of the brine; and the hinges, on which the reflectors turn, being placed at ten inches from the ground, when the reflectors ſtand upright, there will be a ſpace under them, through which the air will continually flow in a briſk current, and this will greatly promote the evaporation of the water.

The paſſages of communication between the pits muſt be narrow and winding, and muſt be wholly ſtopped up in wet weather, that no freſh water run into the brine. This channel ſhould be covered alſo with boards, and at the entrance of the pits there muſt not be a pond, as is the cuſtom in France, but only a narrow covered trench, running parallel with the ſide of the pits which is oppoſite to the reflectors; and the pond, which forms the entrance of the pits in the French *ſalt* marſhes, muſt in theſe be detached from them, and inſtead of it, there muſt be formed a fourth brine pond, communicating with the third by a long and narrow channel.

If theſe contrivances ſhould be reduced to practice in England, the *ſalt* will probably cryſtallize much faſter there than in the French marſhes, and the brine may be kept as deep, and even deeper than in the French pits; and a ſhower of rain will only retard the work for the ſmall time in which it is falling: whereas, in the French works, it throws them back three or four days, as no *ſalt* can be formed till all the water it brought be evaporated.

Four ciſterns may be dug adjoining to the brine pits, to admit the brine in the *ſalt* ponds, when the weather is very rainy; and as to the *ſalt* water in the reſervoir, if it ſhould be found neceſſary to preſerve it from rain in ciſterns, when ſo much rain falls, as to make it freſher than ſea water, it may be let out, and ſea water admitted in its place. And in order to promote the evaporation, and to make the *ſalt* water in the reſervoir fitter to ſupply the firſt brine pond with brine of a due ſtrength, it may be proper, by means of a ſmall fire engine, continually to force up the *ſalt* water in the reſervoir, as often as occaſion requires, and by means of a diverger, fitted to the engine, to make it deſcend again into the reſervoir like a ſhower of rain; by which means, the evaporation of the watery vapours will be greatly promoted, after much the ſame manner as is practiſed at ſeveral of the *ſalt* works in Germany, where the brine is very weak. *Brownrig* of Salt, p. 209.

Thus by augmenting the force of the ſun's heat, and of the air, by promoting the evaporation of the watery vapours, and preventing the brine from being diluted with rain, it is very probable that, during the ſummer ſeaſon, double the quantity of *ſalt* might be prepared at an Engliſh work with theſe contrivances, that is now uſually prepared at a French *ſalt* marſh of equal magnitude.

Beſide theſe methods of managing ſea water, it is certain that very large quantities of *bay ſalt* might be prepared in England with great eaſe, from the natural brine of *ſalt* ſprings, and from the common foſſile, or rock *ſalt* of Cheſhire, diſſolved in weak brine, or in ſea water. Upon the whole, *bay ſalt* might thus be made here at a moderate price, and in ſufficient quantities to ſupply both the nation itſelf, and all our colonies.

Brine SALT, a name given to that ſort of common *ſalt* which is not made from ſea water, but from the water of *ſalt* wells and ſprings. Great quantities of this *ſalt* are made in moſt of the inland countries, as in Germany, Switzerland, Hungary, and in ſome parts of France and England.

In Somerſetſhire, Cumberland, Weſtmoreland, Durham, and Yorkſhire, there are many *ſalt* ſprings, but they are either too weakly impregnated, or ſituated where fuel is ſcarce, and for thoſe, and other reaſons, are not worked; but in other parts of England there are many rich and valuable *ſalt* ſprings, which are worked to great advantage: of theſe ſome are ſituated in Staffordſhire, a great many in Lancaſhire, but the chief are thoſe at Droitwich in Worceſterſhire, and Nortwich in Cheſhire; about which laſt place there are many rich mines of foſſile *ſalt*, above and beneath the beds of which the *ſalt* ſprings are uſually found. At Nantwich, in the laſt county, there are alſo ſome *ſalt* wells, which have been of very long ſtanding, being ſuppoſed by many to have been worked in the time of the Romans. The *brine* of theſe ſprings is found to differ very greatly in its ſtrength and qualities; ſome yielding greatly more *ſalt* than others, and the *ſalt* extracted from ſome of them being found improper for many uſes, for which that of others ſerves very well.

The *brine* of Barton and Nortwich is almoſt fully ſaturated with *ſalt*, a pound of it yielding ſix ounces of *ſalt*; that of Droitwich, Upwich, and Middlewich, contains about one fourth *ſalt*; ſome of the ſprings at Nantwich yield a ſixth part *ſalt*, and thoſe of Weſton, in Staffordſhire, afford only one ninth part. In England, we ſeldom boil weaker brine than the laſt; but in Germany, and ſome other places, where *ſalt* is ſcarce, they work ſprings, whoſe water is not higher impregnated than the common ſea water, containing about $\frac{4}{3}\frac{1}{6}$ *ſalt*. *Brownrig* on Salt, p. 98.

Beſide common *ſalt*, the brine of moſt ſprings is impregnated with ſeveral other ingredients, the nature and properties of which ought to be known to every perſon who works the ſprings, in order to his managing his affairs with judgement. The brine of almoſt all *ſalt* wells has ſomewhat of a ſulphureous principle mixed in it, as may be obſerved from its fetid ſmell, but this ſoon goes off in the boiling. Dr. Liſter obſerves, that the brine of the pits at Droitwich ſtinks like rotten eggs, and will make any thing ſtink in twelve hours that is *ſalted* with it, whether it be fleſh of young, or of grown animals; and yet the *ſalt*, prepared from this brine, is accounted the beſt of any inland *ſalt* in England, and ſeems indeed as good as any in the world. Nay, this very brine, after it has been boiled a little and clarified, proves an excellent pickle for beef, or any other meat, and for other domeſtic uſes. Philoſ. Tranſ. Abr. Vol. 2. p. 362.

In the *ſalt* mines at Bevieux, in the Pais de Vaux, there are always found large veins of virgin ſulphur, and the people who dig in them are often killed with damps and exploſions. *Scheuchzer* of the Salt Works at Bevieux.

The brine of many of the Engliſh ſprings turns black as ink on being mixed with galls, and has in it a ferrugineous ochre, which ſubſides from it when it is expoſed to the air in an open veſſel, and falls to the bottom of the *ſalt* pan, as ſoon as the liquor begins to boil.

Brine of our *ſalt* ſprings has alſo uſually mixed with it a very large proportion of what is called *ſcratch*. This is a ſparry ſubſtance, analogous to that which forms the cruſts in our teakettles, and the incruſtations of moſs, &c. in our petrifying ſprings. The Droitwich brine is very free from this, but the other brines of England, as well as thoſe of Germany, and other places, all abound with it. At the bottom of ſome of our *ſalt* wells there is alſo found a black mud, which, when ſtirred up, blackens and infects the whole ſpring, like ink; and beſide theſe ingredients, the brine of moſt ſprings is impregnated with ſeveral other *ſalts*, as well as the marine one. In all the German *ſalt* ſprings the liquor leaves a bitter ponderous fluid, reſembling our bittern, produced in the working of ſea *ſalt*, but ſeeming to partake more of the muriatic, or calcarious *ſalt*, than the bitter purging one of ſea water, as may be concluded from the numerous experiments made on it by Hoffman. This is alſo obſerved by Leigh, in his Natural Hiſtory of Lancaſhire and Cheſhire, who obſerves, that beſide the marine *ſalt*, the waters of the *ſalt* wells in thoſe counties always contain a quantity of a calcarious nitre; and both the obſervations of Hoffman on the German brine pits, and the experiments made on the waters of ſeveral of our own ſprings, ſeem to confirm, that the waters of this kind in general contain among them other *ſalts*, or mineral alkalies. *Hoffman*, Obſ. Med. Chym. Lib. 2. Obſ. 18. *Leigh's* Nat. Hiſt. Lancaſhire, p. 44.

The antient methods of boiling brine into *ſalt*, in Cheſhire and Worceſterſhire, are accurately deſcribed in the tranſactions of the Royal Society; and the method, formerly uſed in Staffordſhire, is delivered in Dr. Plot's hiſtory of that county; but the method, now generally uſed in England, is this.

The brine being received from the well into a large ciſtern, is thence received, as occaſion requires, into the *ſalt* pan. Theſe pans are of the ſame form with thoſe uſed in the boiling of ſea *ſalt*, and uſually hold about eight hundred gallons: in ſome places theſe are made of iron, and in others of lead. When the brine is put into the pan, a little blood is mixed with it, in order to clarify it, and leaden pans are placed at the corners, to receive the ſcratch, or calcarious earth, that ſeparates from them in the boiling. An ounce of blood is ſufficient for eight hundred gallons of brine. As ſoon as it is boiled, it is carefully ſkimmed, and afterwards it is ſuffered to boil very briſkly for ſome time, till the *ſalt* is granulated; after this the ſcratch is ſeparated, and the fire ſlackened, till the whole *ſalt* is formed.

When they have ſeparated the ſcratch, and the *ſalt* is ready to cryſtallize, they put into the pan ſeveral ſorts of ſeaſonings, as they call them, ſuch as ale, butter, and the like, which they ſuppoſe correct the bad qualities of the brine, and make the *ſalt* of a ſmaller grain. After this they boil it very gently, and when as much *ſalt* is formed, as will fill two or three of their wicker baſkets, they rake it up to the ſides of the pan, and fill it into the baſkets, placing them over the leach trough, that the brine may drain into it from the *ſalt*. The *ſalt* taken out, they call a draught of *ſalt*, and the operation, a clearing of the pan. *Brownrig* of Salt, p. 104.

In this manner they draw the *ſalt*, and clear the pan five or ſix times during each proceſs, leaving at laſt only a few quarts of brine at the bottom of the pan. The baſkets, into which they put the *ſalt* out of the pan, are called alſo *barrows:* they uſually contain about a buſhel of *ſalt*, and are of a conic figure, open at the baſe. The whole proceſs of working a pan of brine uſually laſts about twenty four hours. After the *ſalt* has drained an hour or two in the baſkets, it is removed into the hot-houſe over the furnace, where it remains four or five hours to be thoroughly dried, and is then taken out of the baſkets, and laid up for ſale. In all the Engliſh *ſalt* works, the leach brine, which is what remains in the pan after the *ſalt* is cryſtallized, and what drains from the *ſalt* in the baſkets, is not thrown away, as it is in Germany, but is added to the pan next to be boiled. And beſide the *ſalt* made in this manner, they have, at moſt of the Engliſh *ſalt* works, a different kind, which they call *ſhivery ſalt*. See the article SHIVERY *ſalt*.

They have alſo another kind of *ſalt*, made up in form of ſugar loaves in ſmall wicker baſkets, which is thence called *loaf ſalt*, or *baſket ſalt*. This is the whiteſt, drieſt, and fineſt grained of any *ſalt*, and is therefore greatly eſteemed at table. In preparing this *ſalt* they uſe ſome reſin, and other additions, to break the grain, and render it very ſmall; others alſo, to this purpoſe, boil it the more briſkly, and ſtir it briſkly all the while. But in Cheſhire, where the beſt baſket *ſalt* is made, they uſe no particular proceſs about it, but only take the third draughts of every pan, which always are the pureſt *ſalt*; and they do not ſuffer theſe to lie ſo long in the pan, as when they make *ſalt* of a larger grain, but take it out before it can form large cryſtals: by this means they have it of a fine ſmall grain, and they then preſs it hard down into the wicker baſkets, and when dried in the ſtove, they let it remain in the baſkets for ſale. *Brownrig* of Salt, p. 107.

Not long ſince Mr. Lowndes publiſhed a method of greatly improving the Engliſh *brine ſalt*, ſo as to make it at leaſt equal to the French *bay ſalt*.

The method is this. Let a brine pan, containing about eight hundred gallons of liquor, be filled with brine to within an inch of the top; then make and light the fire, and when the brine is juſt lukewarm, put in either an ounce of blood from the butchers, or the whites of two eggs. Let the pan boil with all poſſible violence, and as the ſcum riſes take it off. When the freſh, or watery part is pretty well decreaſed, throw into the pan the third part of a pint of new ale, or the ſame quantity of the grounds of any malt liquor. When the brine begins to grain, add to it the quantity of a ſmall nut of freſh butter, and when the liquor has ſtood half an hour longer, draw out the *ſalt*. By this time the fire will be greatly abated, and ſo will the heat of the liquor; let no more fuel be thrown on the fire, but let the brine gently cool, till a perſon can juſt bear to put his hand into it; keep it in that degree of heat as nearly as poſſible, and when it has worked for ſome time, and is beginning to grain, throw in the quantity of a ſmall nutmeg of freſh butter, and about two minutes after that ſcatter throughout the pan, as equal as may be, an ounce and three quarters of common alum, pulveriſed very fine; then inſtantly, with the common iron ſcrape-pan, ſtir the brine very briſkly in every part of the pan for about a minute; then let the pan ſettle, and conſtantly feed the fire, ſo that the brine may never be quite ſcalding hot, yet always a great deal more than lukewarm; let the pan ſtand working thus for about three days and nights, and then draw it, or take out the *ſalt*. The brine remaining, will, by this time, be ſo cold, that it will not work at all, therefore freſh coals muſt be thrown upon the fire, and the brine muſt boil for about half an hour, but not near ſo violently as before the firſt drawing; then with the uſual inſtrument take out ſuch *ſalt* as is beginning to fall, and put it apart; then let the pan ſettle and cool. When the brine becomes no hotter than one can juſt put one's hand into it proceed as before, and let the quantity of alum not exceed an ounce and a quarter, and about eight and forty hours after draw the pan, and take out all the *ſalt*. *Lowndes*'s Brine Salt improved.

This is Mr. Lowndes's proceſs only; he afterwards directs cinders to be chiefly uſed in preparing the fires, the better to preſerve an equal heat, and by that means alſo he propoſes ſaving a conſiderable expence, aſſerting, that at preſent cinders are ſo little valued in Cheſhire, as to be thrown out into the highways. Mr. Lowndes adds, that in a pan of the ſize before-mentioned, there may be prepared, at each proceſs, ſixteen hundred pounds weight of *ſalt* from the beſt brine in Cheſhire, and one thouſand and ſixty-ſix pounds from the ordinary brine of that county. This, as the proceſs continues five days, is a little more than five buſhels and a half of *ſalt* a day, from the beſt brine, and a little more than four buſhels a day from the ordinary kind. *Brownrig* of Salt, p. 106.

Marine SALT, the name given by writers on this ſubject, expreſsly to that kind of common, or white *ſalt*, which is boiled from ſea water, without any previous preparation.

This *ſalt* is only made in countries where great quantity of fuel can be had at a very low price, or where the ſun has not force enough; and is therefore made in few counties of England, except on thoſe parts of the Britiſh coaſt which moſt abound in pit-coal. This has thence got the name of *Newcaſtle ſalt*, and is exported to Denmark and Norway, and ſome other countries, as well as ſent to London and other parts of England.

The moſt convenient works for the making this *ſalt* are conſtructed in the following manner. The ſaltern is erected at ſome convenient place near the ſhore; it is a long and low building, conſiſting of two parts, one called the fore-houſe, and the other the pan houſe or boiling-houſe. The fore-houſe ſerves to receive the fuel, and cover the workmen; and in the boiling houſe are placed the furnace, and the pan in which the *ſalt* is made. And in ſome places they have two pans, one at each end of the building, and the fuel and place for the workmen is in the middle. The furnace opens into the fore-houſe by two mouths, and from theſe is carried up a wall to prevent the aſhes from flying to the *ſalt* pans, and in this is a door of communication between the two houſes. The body of the furnace conſiſts of two chambers, divided from one another by a brickwork called the mid feather, which from a broad baſe terminates in a high edge nigh the top of the furnace, and by means of ſhort pillars of caſt iron fixed upon it, ſupports the *ſalt* pan. The pans are oblong and ſhallow, the common meaſure being fifteen feet in length, twelve feet in breadth, and ſixteen inches in depth; they are commonly made of plates of iron joined together with nails, and the joints filled with a ſtrong cement; and the bottom of the pan is prevented from bending down, or changing its figure, by hooks faſtened to ſtrong iron bars which are placed acroſs it.

Between the ſides of the pan and the walls of the boiling-houſe there runs a walk five or ſix feet broad, where the workmen ſtand to draw out the *ſalt*. The roofs are wood, and are faſtened with pegs of wood, nails mouldering away into ruſt in a few months.

Not far diſtant from the ſaltern on the ſea ſhore, between full ſea and low water mark, they make a little pond in the rocks, or with ſtones in the ſand; this they call a *lump*, and from this pond they lay a pipe; through which, when the ſea is in, the water runs into a well adjoining to the ſaltern, and by this well they pump it into troughs, by which it is conveyed into their ſhip or ciſtern, in which it is ſtored up till they have occaſion to uſe it.

The ciſtern is built cloſe to the ſaltern, and may be placed moſt conveniently between the boiling-houſes on the back-ſide of the fore-houſe. It is made either of wood, brick, or clay, and ſhould be covered with a ſhed, that the *ſalt* water in it may not be weakened by rains, and ſhould be placed ſo high that the water may conveniently run out of it into the pans. When the ſea water has ſtood in the ciſtern till the mud and ſand are ſettled from it, it is drawn off into the *ſalt* pan; and at the four corners of the *ſalt* pan, where it is ſupported by the brick work, and conſequently the flame does not touch its bottom, there are placed four ſmaller leaden pans and ſcratch pans, which for a *ſalt* pan of fifteen feet, are uſually about a foot and half long and a foot broad, and three inches deep. Theſe have a bow or circular handle of iron, by which they may be drawn out with a hook when the liquor in the pan is boiling.

The *ſalt* pan being filled with ſea water, a ſtrong fire of pit-

pit-coal is lighted in the furnace, and then, for a pan which contains about fourteen hundred gallons, the *ſalt* boiler takes the whites of three eggs, and incorporates them all with two or three gallons of ſea water, which he pours into the *ſalt* pan, while the water contained therein is only luke-warm, and mixes this with the reſt by ſtirring it about with a rake. In many places they uſe inſtead of eggs the blood of ſheep or oxen to clarify the ſea water; and in Scotland they do not give themſelves the trouble of clarifying it at all. As the water heats, there ariſes a black frothy ſcum upon it, which is to be taken off with wooden ſkimmers. After this the water appears perfectly clear, and by boiling it briſkly about four hours, a pan loaded in the common way, that is about fifteen inches deep, will begin to form cryſtals upon its ſurface. The pan is then filled up a ſecond time with freſh ſea water; and about the time when it is half filled, the ſcratch pans are taken out and emptied of a white powder, ſeeming a kind of calcarious earth, which ſeparates itſelf from the ſea water, during its boiling before the *ſalt* begins to ſhoot. When theſe have been emptied, they are again put into their places, where they are afterwards filled again. This powder being violently agitated by the boiling liquor, does not ſubſide till it comes to the corners of the pan where the motion of the maſs is ſmaller, and it there falls into theſe pans placed on purpoſe to receive it.

The ſecond filling of the pan is boiled down after clarifying in the ſame manner as the firſt, and ſo a third and a fourth; but in the evaporation of the fourth, when the cryſtals begin to form themſelves, they ſlacken the fire, and only keep the liquor ſimmering. In this heat they keep it all the while that the *ſalt* is granulating, which is nine or ten hours. The granules or cryſtals all fall to the bottom of the pan; and when the water is almoſt all evaporated, and the *ſalt* lies nearly dry at the bottom, they rake it all together into a long heap on one ſide of the pan, where it lies a while to drain from the brine, and then is put into barrows and carried to the ſtore-houſe, and delivered into the cuſtody of his majeſty's officers. In this manner the whole proceſs is uſually performed in twenty-four hours, the *ſalt* being commonly drawn out every morning. This is the method in moſt of our *ſalt* works, but in ſome they fill the pan ſeven times before they boil up the *ſalt*, and ſo take it out but once in two days, or five times in a fortnight. In the common way of four boilings, a pan of the uſual ſize, containing one thouſand three hundred gallons, they draw from fifteen to twenty buſhels of *ſalt* every day, each buſhel weighing fifty-ſix pounds.

When the *ſalt* is carried into the ſtore-houſe it is put into *drabs*, which are partitions, like ſtalls for horſes, lined at three ſides, and the bottom with boards, and having a ſliding board on the foreſide to draw up on occaſion. The bottoms are made ſhelving, being higheſt at the back, and gradually inclining forward; by this means the brine remaining among the *ſalt*, eaſily ſeparates and runs from it, and the *ſalt* in three or four days becomes ſufficiently dry; in ſome places they uſe cribs and barrows, which are long and conic wicker baſkets for this purpoſe, and in ſome places wooden troughs with holes in the bottom. The ſaline liquor which remains from the making of *ſalt* is what is called bittern. See the article BITTERN.

The ſides of the pans in which the *ſalt* is made, are ſoon cruſted over with the ſame ſort of matter formed into cakes or cruſts, that falls in powder into the ſcratch pans; this the workmen call ſtone ſcratch; they are obliged to cleanſe the pans of it once in a week or ten days, otherwiſe they will be burnt: in England they do this with iron picks, but at Hall in Saxony they have a much better method; for they then take out the pans, and turning them bottom upwards, burn ſtraw under them, by which means the matter of the cruſt looſens itſelf, and after this it falls off on being ſtruck with a mallet or hammer. *Brownrig* of Salt, p. 62.

In Lancaſhire, and ſome other parts of England, ſea *ſalt* is made in this manner: they pare off, in dry weather, in ſummer, the ſurface of the flats, which are covered at full ſea, and bare when the tide is out. When they have procured heaps of this they put it into troughs, and pour freſh water on it; this waſhes off the *ſalt* that hung about the ſand, and is received ſo impregnated into veſſels ſet underneath the troughs. So long as this liquor is ſtrong enough to bear an egg they put on more water; when an egg ſinks in it they throw the ſand out of the troughs, and put in freſh from the heaps. The water thus impregnated with *ſalt* they boil in leaden pans, and evaporate to a dryneſs, the *ſalt* remaining behind. *Ray*'s Engliſh word, p. 179.

Rock SALT, a name given by the common people of England to the foſſile *ſalt*, or *ſal* gem, found in ſeveral parts of the world.

It was in the year 1670 that we firſt diſcovered the mines of *rock ſalt* in Cheſhire, where it was accidentally found on the lands of Mr. Marbury, of Marbury, in that county, in boring for coal. It lay there thirty-three or thirty-four yards from the ſurface, and there iſſued from it a vigorous ſharp brine ſtronger than any of the Cheſhire *ſalt* ſprings before known afforded. Since that many other mines of it have been found in the ſame county, and a great many are now worked by a company of proprietors, and yield vaſt quantities of *ſalt*; but this is eſteemed unfit for domeſtic uſes in its natural ſtate, and for that reaſon the proprietors uſe the method practiſed in Poland, Hungary, and many other places on the coarſer *rock ſalt*, that is, the refining it, by diſſolving it in weak brine, and then boiling it into *ſalt* again; this is done with great quantities on the ſpot; and beſide this great quantities are carried in the rough ſtate to Liverpool, and there refined with the water of the river Merſey at full ſea, or elſe ſhipped at Liverpool, and thence tranſported to other parts of England and Ireland, where it is wrought into *ſalt* with ſea water.

The *rock ſalt* refined upon the ſpot is alſo exported to Ireland; and in times of war, to our American colonies, when they cannot have bay *ſalt*. The works where they refine the *rock ſalt* are called refineries, and the *rock ſalt* is broken ſmall and put into leaden ciſterns, where it is diſſolved cold in ſea water. When the ſolution has ſtood a day and night to ſettle, it is drawn off from the ſediment into the *ſalt* pan, and refined into *ſalt* in the ſame manner that common brine is boiled up. The ſame additions are uſed in the clarifying it, and the ſcratch or calcarious matter falling from it, forms a cruſt as in the other works. The brine left in the pans after the *ſalt* is taken out is not thrown away, but is added to the next quantity put into the pan, and ſo on to the end of the works. *Brownrig* on Salt, p. 139.

In Hungary, near the city of Eperes, they have a very remarkable mine of this *ſalt* which ſupplies the whole country thereabout. The mine is near two hundred fathoms deep, and in the greateſt part is ſunk through earth, not through rock. The veins of *ſalt* are ſo large, that there are many blocks of it weighing two thouſand pounds, ſome of ten or more. The *ſalt* is uſually hewn out into long ſquare pieces of about two feet, and is afterwards ground between two grindſtones, to reduce it to a powder fit for uſe. Though the mines of *ſalt* are uſually cold and damp, yet the *ſalt* itſelf being very ſolid, and in the rock or maſs, is ſeldom much affected by the dampneſs. The *ſalt* in many of the mines is not of a fine white, but ſuch as is of a duſky grey in the maſs, often becomes very white when powdered, and made fit for uſe.

Salt upon SALT, a name given to a kind of common *ſalt* prepared by the Dutch, of great uſe in preſerving herrings and other fiſh, and to which they principally owe their advantages in the herring trade. The Dutch prepare two kinds of refined *ſalt*, one of a ſmall grain, intended for the uſe of the table, and called butter *ſalt*. They export large quantities of this to the countries upon the Rhine, and into other parts of Germany. The other kind is a very ſtrong and pure *ſalt*, and is of the largeſt grain of any boiled *ſalt*, now made: this laſt they call the St. Ubes or Liſbon *ſalt*, from its reſemblance to the pure bay *ſalt* made in thoſe places.

The *ſalt*, which they refine, is altogether marine bay *ſalt*, and they chiefly have it from France and Spain; but they find, by experience, that any one kind of bay *ſalt* does not anſwer their purpoſes, ſo well as two or more kinds; they therefore frequently mix three parts of Cadiz *ſalt* with one part of that of Souſton, which is of great ſtrength, but very dirty, and of a green colour, and does not coſt above half the price of the Spaniſh *ſalt*; for diſſolving the bay *ſalt*, they uſe ſea water, which they bring in lighters to Dort and Rotterdam from below the Brill or Helvoet; out of theſe lighters it is craned into cellars, and is thus impregnated with bay *ſalt* to a certain degree of ſtrength, which they determine by hydrometers made for that purpoſe. After the heavy droſs of the *ſalt* is ſubſided to the bottom of the cellar, the clear brine is pumpted up into the *ſalt* pan through a mat, which retains the light ſcum, ſtraws, or other impurities, which floated on the ſurface of it. Theſe *ſalt* pans are of iron, of a round figure, and commonly forty feet in diameter, and eighteen inches deep. Theſe pans are placed over a hearth furnace, and the only fuel they uſe in the boiling the *ſalt* is dry turf. The fire is kept up ſo high, that the liquor boils briſkly all the time, and if any ſcum ariſes, they carefully take it off, but they uſe no clarifying mixtures. A little before the *ſalt* begins to granulate, they add to the pan a lump of butter, of the bigneſs of a walnut, and half a pint of ſour whey, which has ſtood at leaſt half a year. When theſe things are perfectly mixed in by a good ſtirring, they ſhut the doors and windows of the houſe, that no air can blow in cold, and the houſe is kept thus hot all the time that the *ſalt* is forming. This method is not new, or peculiar to the Dutch works, for Agricola deſcribes an apparatus of boards, to keep the cold air out of the *ſalt* pan all the time that the *ſalt* is forming; and the Germans uſe it in many places at this time.

It is out of this ſame brine, and by the ſame proceſs, that they make the table *ſalt* and the ſtrong *ſalt*; only toward the end of the proceſs they make this difference, if the pan is to be wrought into table *ſalt*, the brine is kept gently ſimmering during the whole operation, and all is finiſhed in twenty

twenty four hours; but if it be to be made into the ſtrong *ſalt*, they ſlacken the fire to ſuch a degree, that the operation takes up three days. In both caſes they let the *ſalt* remain in the pan till the whole is finiſhed; they then rake it out with wooden rakes, and after it has drained a while in wooden drabs, it is fit for uſe. The mother brine, of which there always remains a large quantity in the pan after the ſtrong *ſalt* is made, as alſo the drainings of the drabs where the *ſalt* is put, is reſerved to be boiled up into table *ſalt*; but the mother brine of the table *ſalt* becomes more ſharp and bitter after every proceſs, and is finally thrown away. *Brownrig* of Salt, p. 142.

Sea SALT. The common *ſea ſalt* is deſtructive to almoſt all plants, except thoſe which naturally grow in the ſea water, or on the ſhores. Mr. Tull has invented a method of determining how far the horizontal roots of plants run, by burying *ſalt* at a diſtance from them. See the article ROOT. It has been thought by ſome that this was an uncertain trial, becauſe, though the roots reaching the *ſalt* were deſtroyed by it, yet the plant would continue to be ſupplied by others, and would not periſh; but this is erroneous, for the roots of plants coming where *ſalt* is, are not killed by it, but they draw juices from the earth where it is buried, and carry it with thoſe juices to the plant, and by this means they fail not to kill it. One root, thus coming in the way of *ſalt*, is able to kill the whole plant, though it have ten thouſand roots, taking good nouriſhment from other places.

This is finally exemplified in the growing of mint in water. If a ſtrong and vigorous ſhoot of mint, growing in ſimple water, be placed near a glaſs of *ſalt* water, and one fibre of its roots be raiſed out of the glaſs in which it ſtands, and plunged into the *ſalt* water, the whole plant will be killed in a few days by this *ſalt*, taken in by this ſingle fibre, though all the reſt are taking in proper nouriſhment from the freſh water all the time. The ſame thing happens, if one of theſe roots be taken up and tied in a bag, containing a ſpoonful of dry *ſalt*; the *ſalt* will ſoon grow moiſt, and the plant will be killed. On taſting of the leaves of the plants thus killed, they are found to have imbibed a larger quantity of *ſalt* than could be conceived from ſuch a ſmall and ſingle root, the whole ſtalk, leaves, and every other part of the plant, taſting ſtrong of *ſea ſalt*. *Tull*'s Horſe-hoeing Huſbandry. See *Marine* SALT, ſupr.

Egra SALT. See the article EGRANUM *ſal*.

Eſſential SALTS. See *Salts of* PLANTS.

Fixt SALTS. Mr. Homberg has given, in the Memoirs of the Paris Academy, a very curious paper of the ſubject of volatilizing the *fixt ſalts* of plants. He obſerves, that the *fixt ſalt* of any plant is a *ſaline* matter, which has already loſt in the fire all, or the greater part at leaſt, of the volatile matter contained in the plant it is obtained from, as its phlegm, acid ſpirit, urinous ſpirit, its eſſential oil and urinous *ſalt*; and that its figure is in ſome degree that of a ſponge, the pores of which being always open, are ever ready to receive again ſuch ſorts of volatile ſubſtances, as the fire has before driven off from them; and that art may in ſuch a manner add theſe its deprived parts to it again, that the concrete ſhall loſe its fixity, and become volatile, as the whole was in a great meaſure before. The whole of this operation conſiſts in the adding to the lixivial *ſalt* one or more of thoſe volatile ſubſtances, the loſs of which gave it its preſent form. Theſe are to be introduced into the *ſalt* by repeated cohobations, which are to be continued till ſo much volatile matter is added to the fixt, that the whole becomes volatile together; the naturally volatile particles being mixed in ſuch proportion, as to be able to carry up the fixed in vapour with them. The ſeveral volatile ſubſtances of plants are of different kinds, and conſequently require different operations, to make them mix with the *ſalt*. Tartar may very well ſerve as a general inſtance in this caſe, and the manner of introducing into its *fixt ſalt* thoſe principles, of which the fire before diveſted it, and by this means rendring it volatile, may ſerve as a ſpecimen of the manner of doing it in all the reſt: but as *ſalt* of tartar, and all other fixt vegetable alkaline *ſalts*, however well purified, always contain a great deal of earth, the ſeveral volatiles employed act differently on this, according to their ſeveral natures; ſome carrying it all up in vapour, others carrying only a part of it, and leaving at the bottom of the veſſel more or leſs of an earthy matter, inſipid to the taſte, and wholly diveſted of its alkaline *ſalt*; every particle of which, even in this caſe, has been volatilized, and raiſed by the fire.

The alkaline *ſalt*, thus volatilized, appears alſo, according to the different ſubſtances employed, in very different forms; ſometimes in that of a *ſaline* liquor, ſometimes in an acid, and ſometimes in an urinous ſpirit: ſometimes alſo it becomes changed into a volatile *ſal ſalſus*, ſometimes into an acrid and fœtid *ſalt*, and finally, ſometimes into a volatile aromatic one. The firſt matter which fire drives out of tartar, or any other vegetable ſubſtance, is its phlegm: this being mere water, one would think at firſt ſhould be little able to change ſo fixed a ſubſtance as *ſalt* of tartar into a volatile one; but when we farther conſider the great power of water, when put in action by the fire, and that this agent is the cauſe of ſome of the greateſt changes that happen in animal and vegetable bodies, and perhaps of every thing of this kind that paſſes in our earth, we ſhall not wonder that it may be made, by the help of fire, one of the agents capable of raiſing, or volatilizing a part at leaſt of *ſalt* of tartar; but as phlegm is the leaſt active of all the principles which chemiſtry ſeparates from bodies, or at leaſt acts upon the others the moſt ſlowly, and with the leaſt violence, the method of volatilizing part of *ſalt* of tartar by means of this, muſt naturally be more tedious than by any of the other principles; yet it is to be done with time by this, as well as by the other.

The thing that put Mr. Homberg upon this courſe of experiments was, as he candidly acknowledges, an accident. He was diſpleaſed with the Venice ſoap, with which he ſhaved himſelf; and endeavouring to mend it, he cut it into thin ſlices, and after drying it three months in the ſhade, he powdered it in a mortar, and wetted it into a paſte again with oil of lavender and ſpirit of wine; and in continuing his trials to this purpoſe, he at length found part of the *ſalt* of the ſoap become volatile.

It is very well known that ſoap is made of the *ſalt* of kali, or pot aſhes and oil. On the event of this experiment, Mr. Homberg proceeded to judge, according to the known rules of chemiſtry, that oil, of which the volatile *ſalts* are generally ſuppoſed to borrow their volatility, being intimately mixed with the fixed alkaline *ſalts*, as here with that of the kali, might render them all volatile, as in this inſtance; for that in this ſtate they were no longer alkalis, their pores being now not open, but filled to the utmoſt with the particles of oil. All oils contain alſo an acid, and that acid being mixed with the alkali *ſalt*, the whole on this muſt ceaſe to be an alkali, and become a middle, or neutral *ſalt*, ſuch as common ſea *ſalt*; but then as the acid is not, in this caſe, joined to the alkali, but by the means of oil, and accompanied with oil, this new found neutral *ſalt* muſt neceſſarily be of an oily, or a ſulphureous nature.

In carrying on this idea, and trying by chemical experiments all the objects it offered, Mr. Homberg, in fine, found, that in order to volatilize the *fixt ſalts* of vegetables, it was neceſſary to begin, by converting them into ſoap; then to wait for the ſhooting of certain cryſtals, or bright points, which would appear upon the ſurface, and that theſe cryſtals were a neutral *ſalt*, volatilized of itſelf by the mere operation of nature: after this the matter is to be moiſtened with a new liquor, and then ſet upon the fire, and that thus there would be a new appearance of volatilized *fixed ſalt*; and the repeating this proceſs ſeveral times, affords always, at length, a very large proportion of the *fixed ſalt*, no longer ſuch, but truly volatilized. The choice of a proper liquor, for the wetting the matter, is a thing of no ſmall conſequence. Water is, of all others, the leaſt proper, and oil appears the moſt ſo; and of the different oils, thoſe drawn by diſtillation are much more effectual than the common expreſſed ones. The great reaſon of this is, that the liquor ought not only to be the moſt volatile that may be, but it muſt be alſo ſuch, as will moſt intimately unite with *ſalt*. Spirit of wine is very excellent for the purpoſe, but would be much more ſo, did it not want this laſt quality.

Mr. Homberg, by various trials, carried at length this attempt to ſo great a height, that he was able to volatilize nearly one half of *ſalt* of tartar, or of any other volatile *ſalt*. The new *ſalt* often appears in a dry form, the oil, which is employed in the making it, preſerving it from the effect of humid vapours, which would otherwiſe have reſolved it into a liquor. Mem. de l'Acad. Par. 1714.

Foſſile SALT. The iſland of Tſongming, in the Eaſt-Indies, affords the moſt remarkable kind of foſſile, or native dry *ſalt* in the world. The country is there, in general, very fruitful, but in certain parts of the iſland there are ſpots of ground, of ſeveral acres, which appear wholly barren, yielding not the leaſt appearance of any thing vegetable upon them.

Theſe ſpots of ground taſte very *ſalt*, and abound in *ſalt* in ſuch a manner, that they ſupply not only the whole iſland, but a great part of the neighbouring continent. When the people ſee the earth become dry, and covered with white ſpangles, which are pieces of *ſalt*, they dig it up about a foot deep, and carry it away to the work places, where they put it into large wooden veſſels of four or five inches deep, and many feet broad, ſet a little ſlanting. They pour water upon it in theſe. When it has ſtood a proper time they let it out, and add more, till all the *ſalt* is diſſolved; then they boil this water in the common way, and extract the *ſalt* from it. It is very remarkable, that the ſame pieces of land, which produce vegetables one year, will produce this *ſalt* another; and, on the contrary, the *ſalt* parts will ſome ſeaſons produce vegetables. The *ſalt* work there is a thing of great advantage to the inhabitants, and all the poor are, in the ſeaſon, employed in it; the men in collecting and wetting the earth, and the women in boiling up the water, which they attend as carefully as the men. Obſerv. ſur les Cout. de l'Aſie.

Glauber's SALT. See SAL *mirabile*, supr.

SALTS *of Count Lagarais*, a name by which the French and ſome other nations call a preparation of vegetable bodies, invented by the gentleman whoſe name it bears, but very improperly called by him a *ſalt*.

The hiſtory of theſe preparations is this: in the year 1731, the Count de Lagarais ſhewed the French king ſome powders, which he proved to be very uſeful in medicine, and which he called the *eſſential ſalts of certain plants*. The method of making theſe was long kept a ſecret, but at length the diſcoverer publiſhing it to the world, it appeared that they were made by means of water only, agitated in a violent and continued manner in a cloſe veſſel with an inſtrument reſembling a chocolate mill. Mr. Langelot had before attempted a reſolution of this kind of vegetable, and other ſubſtances, by means of water and motion, but his was done by grinding them with a very ſmall quantity of water at a time; whereas this of the Count's is by powdering the ingredients, mixing them with a large quantity of water, and breaking them to pieces by a continued motion of this ſort of mill made with four vanes, or flaps of thin wood, which was kept for ſix or eight hours in a continual motion by means of a larger wheel, ſuch as the lapidaries poliſh ſtones with.

There is no doubt but that the inſtrument, uſed by the Count, is of very great uſe, and that the reſult of the operation is a very valuable form of medicine; but it is not a *ſalt*, but an extremely fine extract, containing the gummy, reſinous, and *ſaline* parts of the body, and is a form capable of being reduced to powder, and eaſily adminiſtered, as it contains the virtues of the plant it is made from in an extremely ſmall compaſs, and is capable of ready ſolution in aqueous fluids. It is certainly a form of medicine worthy to be brought into practice, and muſt be a very proper way of adminiſtring the more bulky medicines to children, and perſons of tender conſtitutions.

To give a proper view of the nature of theſe preparations, and their difference from the extracts made in the common manner, it may be proper to enter, in ſome degree, into the manner of preparing the two forms. The common extracts of the ſhops are made either from the juices of ſucculent plants, as houſeleek, purſlain, or the like; or from a ſtrong decoction of the other drier plants in common water, which when ſeparated from the coarſer parts by ſubſidence, filtration, or the like means, are evaporated over a balneum mariæ to the conſiſtence of a thick honey.

There will, in proceſs of time, an eſſential *ſalt* ſeparate itſelf from theſe extracts, and many plants have, in the decoctions, a large quantity of a fine ſubſtance, which will never be made to paſs the filter: and the extracts, made by this means, contain the oil, the gummy and reſinous parts of the plants, and their eſſential *ſalts*, though this is but in a very inconſiderable quantity. Theſe are the common extracts of plants.

The method of making thoſe extracts, called *Count Lagarais's ſalts*, is this. They chooſe a glaſs veſſel, capable of holding ſix or ſeven pints, and having a wide mouth; into this they put an ounce of bark, ſena, guaiacum, or whatever other vegetable they are to make the extract of, firſt reduced to a coarſe powder. They pour on this two pints and an half of rain water, or diſtilled water, and then taking the veſſel to the place where the mill is fixed, they raiſe it ſo high, that the body of the mill is in the middle of the liquor; they then cover the top of the veſſel with a wet bladder, that the froth may not be thrown over, and then turning the large wheel, they make the mill move round very ſwiftly in the liquor for ſix or ſeven hours together; after this they let the liquor ſettle for an hour or two, till only the finer parts of the body remain ſuſpended in it, and then pour it off into a number of flat China, or ſtone ware diſhes, putting only a ſmall quantity into each diſh, and theſe they ſet in the ſun, or over a balneum mariæ prepared on purpoſe; for ſhould they attempt the evaporation in a ſand-heat, the ſmall quantity of extract in each diſh would be burned. When the whole is evaporated to a dryneſs, there remains on the whole inner ſurface of the diſhes a thin cruſt of an extract, which is to be ſeparated by ſcraping it off with a piece of ſtiff paper, and reſerved for uſe. This always breaks up in ſmall ſcales, which have a very ſhining ſurface on that part where they adhered to the diſhes, and it ſeems that this has given occaſion to ſome to believe, that they were particles of real *ſalt*.

There is no doubt, but this method of procuring a powerful extract might be of great uſe, in regard to all thoſe ſubſtances which water can have power to penetrate; but it is not eaſy to give credit to its being able to make the like valuable medicines from the metals, though that has been pretended. Gold and ſilver are pretended to be operated on in a powerful manner by it, but there ſeems a fallacy in this, ſince even iron itſelf, which is much more penetrable by water than thoſe metals, yields but little virtue to it, two ounces of the filings of this metal yielding, with the utmoſt care and accuracy, only about four grains of a white earthy matter, which is alſo much more likely to be a part of the water than of the metal.

The *ſalts of the metals*, as the Count called them, which were prepared by this means, were always ſuſpected to hold ſome *ſaline* quality, which they owed to the menſtruum, which, whatever was pretended, was not ſimple water, and a ſtrict examination of them always diſcovered a marine *ſalt* among them. It is true indeed, that according to Langelot's method of grinding, ſome leaves of gold were reduced, by the addition of a very ſmall quantity of water, into a liquor, from which, on diſtillation, a few red drops were ſeparated; but it is to be obſerved, that as Langelot's method is the grinding the ſubſtance with great vehemence, and for a long time, in an iron mortar, with a peſtil of the ſame metal, there is reaſon to ſuſpect, that what was found to come forth in red drops was a ſolution of iron, not of gold, as was pretended by thoſe who firſt prepared them. It is not to be doubted, but the method of evaporation of Count Lagarais's medicines is of great uſe, ſince no other can ſo well retain the finer parts of the medicines. Mr. Geoffroy tried it on roſes, violets, and ſome other flowers, and found great reaſon to wiſh that all the medicinal extracts could be prepared in the ſame manner; but the method is impracticable, when medicines are to be prepared for general uſe; for though the mills might be made to be moved in great numbers at once, by a current of water, and ſo this part of the work performed with tolerable eaſe, yet the evaporations, in ſuch quantities, could by no means be made in any tolerable room, or time, and they muſt be evaporated as ſoon as made, ſince they very quickly turn ſour, and loſe all their virtues. Mem. de l'Acad. Scienc. Par. 1739. See EXTRACT.

Lixivial SALTS. It may appear very natural, from conſidering the common method of making the *lixivial ſalts*, that they ſhould be all of them one and the ſame ſubſtance; and as the greater part of them agree perfectly, not only in taſte, ſmell, and colour, but even in their effects, in the niceſt chemical operations, in which it appears wholly the ſame thing, whether one or another of them be employed; many, even of the moſt celebrated chemiſts, have poſitively declared that they are all the ſame, and Kunkell has poſitively aſſerted this on many repeated experiments, allowing them no other difference, than that ſome contain more, ſome leſs earth; and this he affirms not to be owing to the different ſpecies of the plant, but from certain accidents in the burning.

This account, however ſpecious, is not true; for though there are many of the *lixivial ſalts* procured from different plants, which, on many trials, appear alike, yet there are ſome that greatly differ from the common kinds; as that of tamariſk, which wants the greateſt of all their characters, in that it is no alkali, but a true *ſal ſalſus*; and beſide this, there are probably many other as remarkable differences in others, which happen not yet to have been obſerved. Mr. Bourdelin, of the Paris Academy, having obſerved, that among the *lixivial ſalts* ſome were greatly more, ſome greatly leſs alkaline, and this laſt mentioned kind not at all, determined to ſearch minutely into their differences in this reſpect. In this attempt he tried the produce of a great number of different fruits and flowers of plants, many of which gave *lixivial ſalts*, conſiderably different from one another; but nothing more ſtrengthened his opinion of the eſſential differences of ſome of them, than the *ſalt* of guaiacum, which proved to be little more an alkali than the *ſalt* of tamariſk, and which he is of opinion may be prepared in ſuch a manner, as not to prove at all alkaline. Mem. de l'Acad. Par. 1728. See LIXIVIOUS, *Cycl.*

The opinion of the fixed *ſalts*, drawn by elixiviation from all plants, being the ſame, having greatly prevailed, Mr. Gmelin, of the Peterſburg Academy, went through a multitude of experiments with the *ſalts*, made carefully from a great number of different plants, on a number of different liquors; ſome mineral acids, others ſolutions and impregnations of different ſubſtances; and by theſe he found that they had very different qualities, beſide their differing greatly in the degree of their alkaline power, which had been looked upon as their eſſential character.

He obſerves, that theſe *ſalts* are not to be obtained pure by any means, except a violent and repeated calcination; and that this is not the method uſed with the ſeveral *ſalts* made for medicinal uſe, and conſequently that they are all impure. The additional matter, which makes theſe *ſalts* impure, is either an earthy, an oily, an acid, or a volatile alkaline ſubſtance, according as the plant, while recent, abounded with one or the other of thoſe principles, or as their mutual connexions with one another were more or leſs ſtrong in each. As therefore the ſeveral ſpecies of plants are well known to abound with different principles, it muſt neceſſarily follow that the *lixivial ſalts*, obtained from them in the common way, muſt differ in their nature and properties, as the acid abounds in one, the volatile alkali in another, and the earth or oil in a third.

This difference unqueſtionably owes its origin to the nature of

of the different plants; but beſides this it muſt be allowed, that there are ſeveral accidents by which the *ſalt* may alſo be rendered of a different nature, or at leaſt its natural diverſity from others may be encreaſed, and ſet in a ſtronger light. The different manner of burning the plant will occaſion a great change in the *ſalt* it yields; and two different *ſalts* will be obtained, if one half of the ſame quantity of aſhes be lixiviated with hot water, and the other half with cold. This has been fully proved by Stahl in his *Fundamenta Chemica*.

Theſe are only accidental differences in the ſame *ſalt*; what Mr. Gmelin takes upon him to prove by experiment, is, that there are more real differences between the *ſalts* of various plants, and thoſe wholly dependent on the nature of thoſe plants, than had been before ſuſpected.

That the *ſalts* of plants may be fairly compared together, it is neceſſary that they ſhould all be made in the ſame manner; the fire ſhould, in all the proceſſes, be raiſed to the ſame degree, and the time of the plants remaining in it ſhould be alſo aſcertained, and the lixivium from each be prepared in the ſame uniform manner: thus the volatile parts of one plant will be no farther evaporated than of another, and the lixivia will contain an equal ſhare of the principles of the ſeveral plants, proportioned to their ſeveral natures; for it is a certain fact, that if the lixivium of the ſame aſhes be made in part with hot water, and in part with cold, the *ſalt*, obtained from that made with the hot water, will contain more of the earthy and oily parts of the plant, than that made with the cold.

The method of making a fixt *lixivial ſalt* of a plant, ſo as to retain as much as may be of the virtues of the plant, is this. Let the plant continue on fire without breaking out into flame, and let the fire be continued till it fall into aſhes, but no longer, leſt ſome of the volatile parts be driven off, which might have been preſerved. Cold water, and not hot, ſhould be uſed to make the lixivium, that the *ſalt* may appear in its proper form; and as the water of wells, rivers, and other places, differ greatly from one another, the water uſed for this purpoſe ſhould be ſuch, as has been previouſly diſtilled two or three times over, and ſo rendered perfectly pure, and kept in glaſs veſſels, not in earthen, leaden, or wooden ones, leſt it contract ſome adventitious particles. Now if the lixiviums of plants, made with all theſe cautions, are found to differ from one another, there is no room to doubt, but that the *ſalts* of thoſe plants are really different one from another.

This evidently appeared from the labours of a Swediſh chemiſt, whoſe papers fell into Mr. Gmelin's hands, and who had with all this care and caution prepared the *ſalts* of a number of plants; a copious table of the different effects of which, in different mixtures, is added to Mr. Gmelin's account: but not only the *ſalts*, but the very aſhes of different plants, prepared in the ſame exact manner, are found to differ obviouſly to the ſenſes. The aſhes of mugwort, ſmall centaury, chervill, and dill, are of a browniſh grey; goats beard and lingwort afford white aſhes; thoſe of ſanicle are whitiſh; thoſe of Roman wormwood of a greeniſh grey; thoſe of rue, agrimony, and ſaxifrage, brown; thoſe of tanſy of a duſky green; thoſe of dodder of a fine green; eyebright, ſouthernwood, common wormwood, and ſcabious, afford them grey; ſcurvygraſs of a whitiſh grey; hyſſop, yarrow, and ſowbane, of a duſky grey; melilot and oak leaves, as alſo plantain, colts foot, pine tops, and fumitory, of a duſky brown; pennyroyal of a pale brown, with ſome ſpots of white; elder flowers, ſage, and mother of thyme, afford yellow aſhes; thoſe of ſtrawberry leaves are of a pale brimſtone colour; thoſe of catmint of a duſky red; of prunella brick coloured; of honeyſuckle blue; of ſern blackiſh; and thoſe of St. John's wort, feverfew, origanum, and pimpernel, are all of a deep black.

The quantity of aſhes, produced from an equal weight of different plants, is very different, ſome yielding a ſeventh part of their weight, others but a twelfth or thirteenth, and ſome particular plants much leſs than this; St. John's wort in particular yields but a twenty eighth part, and fern but a twenty fourth.

The lixiviums made from theſe different aſhes were ſome colourleſs from the beginning, others at firſt were bluiſh, greeniſh, or of other colours, but theſe tinges all went off after a few days, and the liquor became limpid.

The lixiviums of the ſeveral plants are very differently acrid to the taſte, though made exactly in the ſame manner and proportion, and thoſe of ſome plants are not acrid at all; that of ſtrawberry leaves has ſcarce any taſte; that of the barba capræ, inſtead of an acrid taſte, has a ſweet one; and the lixivium of mother of thyme has no taſte, by which it can be diſtinguiſhed from fair water: the lixiviums of pimpernel, dill, and ſtrawberry leaves, have a ſulphureous ſmell; thoſe of moſt other plants are wholly ſcentleſs. Act. Petropol. Vol. 4. p. 289.

SALTS *of metals*. See the article METAL.

SALT *of milk*. See MILK.

Mineral SALT. It has been for many ages a conſtant opinion among the chemiſts, that minerals contain no volatile *ſalt*. Mr. Homberg, however, found the means of preparing an acid mineral *ſalt*, in a dry form and volatile. This would diſſolve in ſpirit of wine, and that ſolution being thrown on marble, fermented, and diſſolved it in the manner of aqua fortis.

All the world knows that many mineral ſubſtances contain an acid, and that this is eaſily raiſed in diſtillation, and therefore is very volatile; but as this could never before be ſeparated, otherwiſe than in a liquid form, they eſteemed it ſomething of a peculiar nature, and called it an acid mineral ſpirit, baniſhing the word *ſalt* from its name. But Mr. Homberg found, that if the acid ſpirit of any mineral was ſo embarraſſed in the particles of ſome metal, as that it ceaſed to be fluid, that metal was always conſiderably increaſed in weight by it; and that if afterwards all the acid which had been added to it were again ſeparated from it, there would remain a volatile *ſalt* in a dry form, and that this *ſalt* if diſſolved in ſpirit of wine, or in common water, made an acid liquor, which would diſſolve all alkalies with an ebullition: from this, he ſays, it is plain, that the minerals have a volatile *ſalt*, as well as the animals or plants; which laſt were alſo long ſuppoſed to want it, and the volatile *ſalt* ſuppoſed peculiar to the animal kingdom: from this alſo it very plainly appears, that the acid ſpirits of minerals, as they are called, are in reality no other than theſe volatile *ſalts* diſſolved in their own phlegm.

The method of procuring this *ſalt* may be ſeen in the following inſtance. Take two ounces of fine ſilver, diſſolve it in five ounces of ſpirit of nitre; pour this ſolution, while hot, into a pint of river-water, in which there has been before diſſolved as much ſea *ſalt* as it can contain, the ſilver will precipitate itſelf in form of white ſcales. Waſh this precipitate till it is inſipid to the taſte, and then dry it; it will, when perfectly dried, weigh two ounces and an half.

After this calcine in an iron veſſel over a ſtrong fire two or three pounds of fine tin, in which there is no mixture of any other metal. Take of this calx of tin well dried an ounce and half, mix this carefully with the two ounces and half of the calx of ſilver, perfectly dry alſo: put the mixture into a matraſs, of which two thirds ſhall remain empty; expoſe this matraſs to the naked fire, with its neck turned downwards, there will run into the neck of the matraſs a black matter, which will immediately fix itſelf into a hard ſtone of a brown colour, this will weigh about an ounce and half; this ſtone is the calx of tin diſſolved by the acids, which remain in the calx of ſilver; and the caput mortuum, at the bottom of the matraſs, will be found to be the ſilver now diveſted of thoſe *ſalts*, which it had carried with it from its diſſolvent in the precipitation. This may be run into a maſs by the copel, and no part of it will be loſt.

Beat this brown ſtone to powder, let the powder be perfectly dry; then put it into a double veſſel, ſublime it according to art, and the reſult of the operation will be half an ounce of a volatile *ſalt*; this is to be rectified by re-ſubliming it two or three times over a very gentle fire, and it will then be a volatile and mineral *ſalt*, perfectly dry, of a fine white colour and tranſparent. The caput mortuum of this ſublimation is the calx of tin. Mem. Acad. Par. 1692.

SALT *of mineral waters*. See the article HALCRYPTIUM.

Pine SALT. See the article PINE.

SALTS *of plants*. See the article PLANT.

Sedative SALT, a name given by the modern chemiſts to a *ſalt*, of the virtues of which they boaſt much. Thoſe who firſt deſcribed it gave the proceſs for making it in a very enigmatical manner; and their ſucceſſors invented many different ways of preparing it. The truth is, that all mixtures of borax with the vitriolic acids furniſh us with a *ſedative ſalt*, as do alſo the mixtures of borax with ſpirit of nitre, or of ſea *ſalt*.

Becher firſt gave the enigmatic account of it, which Homberg traced to its origin, and found the way of making it with the vitriolic, as Lemery did with the other acids. This *ſalt* is formed by ſublimation, and is a congeries of ſaline flowers, not a little approaching to flowers of benjamin. Theſe flowers are ſo light and fine, that they ſwim upon water, and will not diſſolve in it unleſs it be made warm.

The *ſedative ſalt* is a perfect *ſal ſalſus*; it makes no alteration in the colour of the juice of violets, and has no ſenſible effect on the ſolution of corroſive ſublimate, or on a ſolution of mercury in ſpirit of nitre for a long time; but it finally precipitates a yellow powder from it as the borax does; there is this difference, however, between this precipitate, and that formed by crude borax, that the powder precipitated by the *ſedative ſalt*, does not as the other become white on waſhing with large quantities of water. Theſe experiments ſhew this *ſalt* to be wholly analogous to tartarum vitriolatum, or to the Glauber's *ſalts* in its effects.

When the compoſition of which this *ſalt* is to be made is placed on the fire, there ariſe different liquors before the *ſalt* appears; the firſt is a phlegm of a fattiſh complexion, and with the ſmell of ſoap; this is ſucceeded by a turbid white liquor, along with which there ariſe ſome of the firſt flowers.

ers. This makes a ſolution of mercury in ſpirit of nitre muddy after ſome time, and finally precipitates from it a ſmall quantity of a white powder. After this all the *ſalt* or flowers aſcend; theſe flowers, diſſolved in warm water, recryſtallize themſelves in it when cold, aſſuming the ſame form with that they had in the flowers, except that the combinations of particles are more denſe and heavy.

The uſual method of making this *ſalt* has been this. Take a glaſs retort, with a large neck, put into it four ounces of borax in fine powder, and pour on this half an ounce of common water to wet it into a ſort of ſoft paſte; then add to this an ounce and two drachms of concentrated oil of vitriol; place the retort in a reverberatory furnace, and give at firſt a ſmall fire, which raiſe by degrees till the retort is red hot: there will paſs over into the receiver about an ounce of aqueous matter; and after this the flowers, or *ſedative ſalt*, will riſe with a little more humidity; hence ſome part of the flowers will be diſſolved in the liquor, and run over into the recipient, but the greater quantity will remain in form of a dry ſublimation in the neck of the retort; they will finally ſtop up the whole orifice of the neck, and what ariſes after this uſually forms a circle of a ſort of gloſſy *ſalt*, about their baſes, out of which the flowers ſeem to ſhoot.

They are compoſed of multitudes of fine thin blades, or flakes, and are eaſily bruſhed out of the neck of the retort with a feather; the gloſſy circle at the bottom of them may be diſſolved in water, and recryſtallized, and by this means all the *ſalt* will be procured.

Mr. Geoffroy the younger has given, in the memoirs of the Paris academy in 1732, an account of a way of making this *ſalt* by ſolution and cryſtallization alone, without the trouble of diſtilling; he has alſo ſummed up the ſeveral other ways of making it with blue and white vitriol, but the method here mentioned is that by which the chemiſts now make it. Mem. Acad. Par. 1732.

Shivery SALT. See the article SHIVERY.

Vitreous SALT, in chemiſtry, a term uſed by ſome modern chemiſts for a kind of *ſalt*, which till of late has wanted a name, and which is found in and ſeparable from the fixed alkaline *ſalts* of vegetables.

It is bitter, hard, fixed, and not alkaline, and of a cryſtalline or gloſſy appearance.

The method preſcribed by Boerhaave for the procuring it with moſt eaſe, is this: put ſix pounds of the beſt pot-aſhes into a clean glaſs, add thereto twenty pints of cold rain water; ſtir them together with a ſtick, and ſuffer the whole to reſt. When the aſhes are thoroughly diſſolved, gently decant the clear lixivium; and there will be found at the bottom, mixed with the fæces, a number of ſmall greyiſh granules, of a bitter taſte, and of an almoſt glaſſy brittleneſs and hardneſs; theſe are the *ſalt* required, and contain no alkaline quality; but to obtain it in greater purity, diſſolve ſix pounds of pot-aſhes in fourteen times their weight of water; filter the lixivium while hot, and make it perfectly clear; then put it into a glaſs veſſel ready heated, and moiſtened, and ſuffer it to ſtand; a duſky cruſt will ſoon begin to ſhoot to the bottom and ſides of the glaſs, and will gradually become thicker and thicker; at length when no more appears to ſhoot, pour off the liquor, and there will remain behind a *ſalt* like the former, but purer, and in larger quantity: if the remaining lixivium be boiled a little, and ſet to cryſtallize again, it will afford a ſmall quantity more of this *ſalt*; but after this it will yield no more; whence there ſeems to be only a certain and determinate quantity of this *ſalt* contained in the alkali. If this *ſalt* be put into a veſſel of rain water and ſhook about, it does not diſſolve, only the alkali waſhes off, and the *ſalt* remains purer than before; after this it is to be gently dried and kept. *Boerh.* Chem. P. 2. p. 42.

It is well known among the chemiſts, that genuine fixed alkaline *ſalts* can hardly be cryſtallized; and though ſome have produced this *ſalt* as a cryſtallized alkali, the fallacy of the pretext is evident, ſince this appears on trial to be no alkali at all; and it remains not leſs difficult than before to cryſtallize pure alkali, though a *ſalt* different in its nature from it, may be cryſtallized in a certain quantity from among it.

This *vitreous ſalt* never runs ſpontaneouſly in the air, nor does it eaſily diſſolve in cold water; when boiled it requires a large proportion of water to diſſolve it, and as ſoon as cold it eaſily ſeparates itſelf from it again: it is laſtingly bitter to the taſte, and crackles very much when thrown into the fire: it is neither acid nor alkaline, nor approaches in its nature to any other *ſalt* hitherto known; but ſeems neareſt of all others to reſemble ſandiver. This may ſuggeſt a query, whether the fire in producing the fixed alkali, does not at the ſame time produce this *ſalt* from vegetables; and whether by combining the ſand and alkali together in glaſs-making, the fire does not again ſeparate and throw up this *ſalt* in ſandiver. Something of this kind ſeems to be the caſe, and a cloſe inquiry on theſe principles may ſhew us why tartar, in the ſtate of an alkali, does not afford this *ſalt*; for tartar proceeds from a ſubtile liquor, intimately fermented in all its parts. There yet remains the trying this *ſalt* on various bodies, by means of fire, to give a true knowledge of its nature, which is at preſent too little known. This is to be obſerved, however, that it differs ſo much from the alkali, in which it is contained, that the careful chemiſt, before he makes uſe of that alkali in any nice proceſs, or experiment, ought carefully to ſeparate this neutral *ſalt* from it. *Boerhaave's* Chem. P. 2. p. 100.

Fuſible SALT *of urine*. This *ſalt*, otherwiſe called by ſome *ſal microcoſmi*, and *native ſalt of urine*, is extracted from *urine* in a particular manner.

It is beſt prepared from putrified human *urine*; but it may be prepared from freſh. A quantity of the *urine* of ſound beer drinking men being putrified in a moderate heat, and then ſlowly boiled in glazed earthen veſſels to the conſiſtence of a ſyrup; if this liquor be placed in a cellar or cool place, in about four weeks time, or ſooner in winter, cryſtals of a peculiar figure will be formed. But theſe being impure, muſt again be diſſolved in a ſufficient quantity of water, and filtered as hot as poſſible through grey paper, and the ſolution again put in a cool place, where in a few days cryſtals will again be formed much cleaner than the former. Theſe being ſeparated from the liquor and dried, the operations of ſolution, filtration, and cryſtallization, muſt be reiterated twice or thrice, till the *ſalt* becomes perfectly white and without ſmell.

Mr. Marggraff ſays, that 100, or 120 meaſures of *urine* give about three or four ounces of this *ſalt*, which always cryſtallizes firſt, and is eaſily diſtinguiſhed from that which appears afterwards in cryſtals of a long and cubical form.

This *ſalt* is ammoniacal, but of a peculiar nature. It is a ſaline acid body. By diſtillation an urinous volatile ſpirit firſt riſes. The reſiduum may be reduced by a violent fire into a pellucid white tranſparent maſs like glaſs, of a very fixed nature, and from which neither acid nor any thing elſe can be ſeparated, without the addition of ſome other matter.

This vitreous ſubſtance may be entirely diſſolved in two or three parts of diſtilled water, and is thereby changed into a tranſparent liquor, ſomewhat thick, not unlike the concentrated oil of vitriol, and having the properties of all acids, ſuch as fermenting with volatile and fixed alcalies, forming neutral *ſalts* with them, precipitating bodies diſſolved in alcaline menſtruums, and diſſolving alcaline earths. It does not diſſolve gold nor ſilver; and copper, tin, and lead little; but iron very ſtrongly. It extracts a red colour from *cobaltum pro cæruleo*, in German, *blau farben-kobalde*, the mineral by which glaſs is tinged blue.

But this *ſalt*, in its dry ſtate attracts metals with much more vigour, and with them produces ſeveral remarkable and ſingular phænomena; for all which, as alſo for the relation their *ſalt* bears to acid, alcaline and neutral *ſalts*, we refer to the learned author, who has alſo examined its effects on ſeveral ſolutions of terreſtrial bodies. One moſt eminent property is, that mixed with the inflammable part of ſoot, and diſſolved in a cloſe veſſel, it produces a phoſphorus. An ounce of this *ſalt* of urine thus ſeparated from its urinous part, and exactly mixed with half an ounce of ſoot, affords in this way a drachm of the beſt phoſphorus. The reſiduum did not produce any when tried.

The learned author does not pretend to determine exactly the true origin of this *ſalt*, he thinks its acid may come into the human body from vegetable aliments. He has obſerved elſewhere that creſſes, muſtard, rocket, and even corn expoſed to a very violent fire, produce a phoſphorus. Hence he thinks this acid muſt be mixed with thoſe ſubſtances; and the like may happen in other vegetables. He thinks this conjecture ſtrengthened, becauſe urine in ſummer, when people eat moſt vegetables, always produces this *ſalt* in the greateſt quantity. *Marggraff*, in Mem. de l'Acad. de Berlin 1746. See alſo Miſcel. Berol. Tom. VII. p. 341.

Spirit of SALT. This menſtruum diſſolves iron into a yelloviſh green liquor, and copper into one of a very deep yellow colour: tin diſſolves in it with great violence and noiſe, and in great quantity; the ſolution becomes a thick but pellucid fluid: lead alſo diſſolves in it; but after this ſolution has ſtood for ſome time, there always ſubſides to the bottom a white powder. Silver, if it is perfectly pure, does not diſſolve in *ſpirit of ſalt*, but if it contain ever ſo little copper, as it is very ſeldom met with perfectly pure from that metal, its ſurface is then always corroded, and its colour ſullied. *Spirit of ſalt* diſſolves mercury into a limpid liquor; if diluted with water it does not diſſolve the regulus of antimony; and if this regulus is diſſolved by the moſt concentrated *ſpirit of ſalt*, if a little water be added, or it be only expoſed to a moiſt air, it is reduced to a fine powder. Zink diſſolves eaſily and perfectly in this menſtruum. *Cramer's* Art of Aſſaying, p. 38.

SALT-*marſh*, *ſalina*, a place where *ſalt* is made, of which there are many natural ones in the hotter countries, where the ſea exhaling the water of *ſalt* lakes, leaves the *ſalt* dry and ready for uſe at the bottom, without any art or labour of man to make it: thus in Muſcovy and ſome other places there are whole fields of *ſalt*. See *bay* SALT, ſupr.

The countries, however, where this is not naturally performed, may effect it by art, and make *ſalines* or *ſalt marſhes*, where they may uſe the ſun's heat to great advantage. This is annually done to great advantage in France, and there is no reaſon why we may not do the ſame, either at home or in our American colonies, though it has not yet been attempted.

In order to make a *ſaline* or *ſalt marſh*, a low plat of ground muſt be choſen, adjoining to the ſea, and diſtant from the mouths of large rivers, and this muſt be near ſome convenient harbour for veſſels. The ground muſt be free from freſh water ſprings, and out of the reach of land floods, and if poſſible ſhould have a clayey bottom; and finally, it muſt be well defended from the ſea, either by natural or artificial banks of earth of a proper ſtrength and thickneſs.

The ground thus choſen muſt be hollowed out to three ponds or receptacles. The firſt into which the ſea water is uſually admitted may be called the reſervoir. The ſecond receptacle, which is to be divided into three diſtinct ponds, communicating with each other by narrow paſſages, and containing brine of different degrees of ſtrength, may be called the brine ponds; and the third receptacle is to be furniſhed with an entrance, between which and the brine ponds there is to run a long narrow and winding channel; the reſt of it is to be divided into ſmall and ſhallow pits, containing a very ſtrongly ſaturated brine, which in them is to be converted into *ſalt*, and they may therefore very properly be called the *ſalt* pits.

The firſt receptacle or reſervoir muſt have a communication with the ſea by a ditch, defended on each ſide by walls of brick or ſtone, and made of ſuch a depth, that by it all the water of the reſervoir and other parts of the *ſalt marſhes* may be able to run out at low water, and by it alſo the ſea may be admitted into it at high tide. So that at neap tides the marſh may be filled with ſea water to the depth of ten inches in the reſervoir; and conſequently, at higher tides, to the depth of two feet, when there is occaſion to overflow the marſh, as is always to be done in the winter ſeaſon, when there is no *ſalt* to be made; for, by this means, the wood work is kept from decay, and the clay bottom from injuries by froſt. The ditch between the reſervoir and the ſea muſt have a flood-gate, by which the ſea water may be admitted, retained or let out as occaſion may require. *Brownrig* of Salts, p. 37. Phil. Tranſ. N° 51.

The ſeveral ponds or receptacles muſt not have all their bottoms upon the ſame level, but muſt be made of unequal depths, ſo that the firſt receptacle or reſervoir may be eight inches and a half deeper than the *ſalt* pits in the third receptacle. The three brine ponds alſo ſituated between the reſervoir and the *ſalt* pits muſt be of unequal depths. The next adjoining to the reſervoir muſt be the deepeſt, and that which is nigheſt the *ſalt* pits the ſhalloweſt, but all of them muſt be ſhallower than the reſervoir; and the three receptacles being thus conſtructed, the water ſtanding at the ſame height in them all, and forming with its ſurface one continued plain, will be ten inches deep in the reſervoir, when only an inch and half in the *ſalt* pits.

The length and breadth of the brine ponds and reſervoirs are to be at diſcretion; but it is beſt to err in making them too large, and in general they ought to be ſo large as to furniſh the *ſalt* pits with a conſtant ſupply of brine, fully ſaturated with *ſalt*; and, for this purpoſe, it is neceſſary to have them of different dimenſions, in different countries, according to the degree of heat.

The bottoms of the reſervoir and brine ponds are to be lined with any kind of lean and tough clay, or earth, that will hold water; and the French uſe a red, or blue clay, to be had in the neighbouring grounds. With them the blue always ſucceeds better than the red, which colours the *ſalt* much more; but in order to have a perfectly pure *ſalt* from this kind of manufacture, the bottom ſhould be lined with ſome clean cement, which will hold water perfectly, and will not be eaſily broken up. Id. Ibid.

The *ſaline* or marſh being thus conſtructed; the ſaltmen, at the proper ſeaſon of the year, open the flood-gate when the tide is out, and drain off all the ſtagnating water; when this is done, they repair the bottom of the marſh in ſeveral places, where it is found neceſſary, and cleanſe the ſeveral receptacles from mud and dirt: after this they admit the ſea water, at the next high tide, till it floats the whole marſh, and ſtands at about ten inches high in the reſervoir. In a day or two moſt of the water in the *ſalt* pits is exhaled, and what remains is a very ſtrong brine, they then let in more ſea water at the two or three following tides; and ſo take care to admit as much water freſh into the marſh as has been waſted in vapour by the heat, conſtantly raiſing it to the height of ten inches in the reſervoir, and conſequently to an inch and half in the *ſalt* pits; and when the weather is extremely hot, or there are ſharp drying winds, they fill them ſomething higher than this.

All the parts of the marſh are thus ſupplied with water out of the reſervoir, but the ſea water which is let into the reſervoir, is not confuſedly let into the other water or brine of the ponds and *ſalt* pits; for, as the ſeveral parts of the work communicate only by narrow channels: it is provided, that the *ſalt* water flowing out of the reſervoir never returns to it again, but gently flows along till it arrives at the ſecond brine pond, and from that to the third, being forced forward by the ſea water received from time to time into the reſervoir: during this flow courſe, the watery fluid alway flies off in great quantity by exhalations, and the brine is continually preparing for cryſtallization as it flows along gently, growing all the way ſtronger and ſtronger, as it approaches the *ſalt* pits; ſo that when it at length enters theſe pits, it is fully ſaturated with *ſalt*; and particular care is taken to guard the entrance of the *ſalt* pits by a long and narrow channel, by which means the ſtrong brine contained in theſe pits is prevented from returning back, and mixing with the weaker brine in the brine ponds; care is alſo taken, that the ſtrong brine in the *ſalt* pits is ſpread out very thin, and expoſed to the ſun and air with a large ſurface, by which means the water more quickly exhales from it, and the *ſalt* is left concreted into cryſtals. Theſe cryſtals, or *ſalt*, the workmen in France draw out every day, and diſpoſe them at length together in a pyramidal heap, which they cover over at the top with thatch or ſtraw, and ſo preſerve them from the injuries of weather. Thus at a ſmall expence and trouble a *ſalt* is prepared, which is found very fit for all domeſtic uſes; and France is furniſhed with a very profitable article for exportation into other countries. *Brownrig* of Salt, p. 43. See *Bay* SALT, ſupra.

SALT-*petre*. There are ſome lands in Jamaica and our other American plantations, which are ſaid to contain *ſalt-petre*; though there have been no works ſet up for the refining and preparing it. The earth containing it has been found to have very different effects on vegetables from thoſe of common earth.

The ſugar canes that grow on theſe ſpots ſhoot up much faſter, and grow larger than in other grounds; but they rot very ſoon if not ground, and they do not boil ſo well into ſugar as the others. Potatoes planted in theſe grounds are always found to be two months forwarder than others, but they muſt be uſed ſoon, otherwiſe they decay, the *ſalt-petre* eating away the ſkin, which is thinner on thoſe roots which grow in this ſort of ground than elſewhere; and the fleſhy part of this beginning to rot and moulder away. The tobacco planted, on the ſame grounds, is greatly altered in its nature alſo. It grows up very quickly, and becomes robuſt and ſtrong, but it will not be cured to ſo good a colour as that which grows on common earth, nor will it keep ſo well; many cargoes of this tobacco have wholly periſhed at ſea, by the leaves mouldering away to duſt. And it is reported, as a certainty, that this tobacco, when ſmoaked, flaſhes in the pipe with large flames. Phil. Tranſ. N° 33.

SALT *ſprings*. There is a copious *ſalt ſpring* in the neighbourhood of Durham, loſt to the country, by its riſing in the bed of the river Weare. It does not iſſue out of any one particular ſpot, but bubbles up from the mud and rocks for the ſpace of forty yards in length, and about ten yards in breadth. It is beſt examined in dry ſeaſons, in the middle of ſummer; for at this time the water of the river is all carried into another part of the channel, and this place left dry. The greateſt quantity at this time is found to iſſue out of a hard rock. It is as *ſalt* as any of the Cheſhire brines; and though but very ſmall in quantity, in proportion to the ſize of the river, yet it gives a manifeſt ſaltneſs to the water a hundred yards below. The brine has been collected in ſummer by ſome curious people, and evaporated, and is found to yield a very uſeful *ſalt*, not like that of the common inland *ſalt ſprings*, which is our white baſket *ſalt*, but rather like the bay *ſalt*, of a duſky colour, and not very pleaſant taſte, but as fit for all the uſes of life as any other *ſalt*. The water of this ſpring, as it runs among the ſtones in ſummer tinges them all of a reddiſh colour, which is a property not common to other brine. Phil. Tranſ. N° 163.

In Cheſhire, and many other counties, they make a great uſe of the water of theſe ſprings, as a manure for their lands. They let out the water of theſe ſprings for a certain time upon the lands, after there has been rain, and by this means the quantity of *ſalt* they contain is ſo blended with the rain water, that it is too weak to hurt the corn or graſs, and yet is ſtrong enough to kill worms, and other vermin.

The vegetables of all kinds are improved alſo by this, for there are no lands that fatten cattle ſooner, than the paſture grounds which are thus, at times, overflowed by the *ſalt* water.

We have inſtances of a like effect of ſea *ſalt* in ſmall quantity, and but occaſionally laid on, doing great good to paſture in thoſe high paſtures about Erith, which are only overflowed ſometimes in ſpring tides. Theſe fatten cattle of all kinds in a very ſurpriſing manner. It is a wonder that no body has yet attempted a regular manuring of land with *ſalt* upon this plan, for bay *ſalt* might be had at a very ſmall price in time of peace, and a buſhel or two allowed to an acre, would probably have all the advantages that theſe

overflowings of the high tides, and natural *ſalt* ſprings, are found to have. Some farmers have tried the ſcattering *ſalt* over their corn fields, as ſoon as ſown, in the quantity of two buſhels to an acre, and it is ſaid with good ſucceſs. *Mortimer*'s Huſbandry.

SALTS *microſcopically examined.* Mr. Lewenhoek has opened a very extenſive field for microſcopic obſervations, in the evaporation of certain fluids, in which *ſalts* of various plants, and other ſubſtances of a like kind, had been diſſolved.

The fixed *ſalts*, in general, are ſaid by chemiſts to admit of no cryſtallizations at all; but this curious obſerver found, that on being evaporated in ſmall quantities before the microſcope, they each would ſhoot into extremely minute, but regular cryſtals, and thoſe often of various forms in the ſame *ſalt*; but that theſe varieties were only of a certain number, and that no other *ſalt*, but that to which they belonged, had them all in the ſame regular manner.

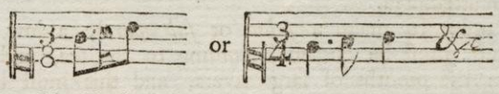
The ſophiſtications of *ſalts*, too common among our chemiſts, may be diſcovered by this means, and many other advantages may be obtained from it, as well as great amuſement, in the obſervation of the variety and beauty of the figures.

The moſt agreeable way of examining theſe *ſalts* is by the ſolar microſcope; but the moſt accurate, and fitteſt for making deductions from, is that by the common double microſcope. The way is to diſſolve a ſmall quantity of *ſalt*, of any kind, in water, and add to this about one fourth part of ſpirit of wine; this renders the whole a much leſs fit menſtruum for keeping the *ſalt* in ſolution, and conſequently it much more readily concretes from among it. A large drop of this liquor is to be laid on the ſurface of a thin and clear piece of glaſs, ſuch as may conveniently be laid upon the ſtand for receiving objects in this microſcope; then this glaſs is to be held till gently heated over a clear fire, and when it begins to evaporate, the glaſs is to be placed under the microſcope, and about a third magnifier uſed to examine it. The *ſalts* will ſoon be ſeen beginning to ſhoot, and will form themſelves under the eye into very beautiful figures; ſome reſembling branches of trees, others ruins and fortifications, and the like; but what are moſt to be depended upon, as eſſential to the *ſalt*, are certain little ſingle ſhoots, reſembling cryſtals; theſe are determinate in their figure, the others more vague and uncertain. Theſe will always be produced the ſame from the ſame *ſalt*, the others ſcarce twice from even the different drops of the ſame ſolution, alike in all reſpects. Philoſ. Tranſ. N° 172. p. 1075.

Carduus Benedictus affords three different kinds of *ſalts*, or cryſtals, ſingle and perfect in their kinds; the one is a thin ſquare, another an oblong, and thicker body, terminated by a point at each end, and reſembling in miniature the perfect double pointed ſhoots of rock cryſtal; and the third a quadrilateral pyramid, of the ſhape of the cryſtals of common *ſalt*. The oblong double pointed ſhoots are the moſt numerous in this *ſalt*, and ſeem to be the perfect figure of the genuine and purer *ſalt* of the plant. They are ſo numerous and minute, that Lewenhoek ſays he ſaw as many of them in the quantity of a ſingle grain of water, as the eye can count ſtars in a clear night.

Theſe, as alſo the cryſtals of many other *ſalts*, continue regular while the water is about them, but as that evaporates they join together, and become confuſed.

Wormwood affords a great variety of figures in its *ſalt*. When this begins to ſhoot by the evaporation of the water, there are diſcovered a number of very ſmall double pointed ſhoots, reſembling the ſhape of a weaver's ſhuttle; after theſe there are found ſome ſquare ones, then ſome which have ſix angles, yet are flat and thin; ſome others reſemble triangles with the corners cut off, and ſome are large and oblong; others large and ſquare, and bordered round with the reſemblance of the cut edges of a looking glaſs.



Blue vitriol, beſide its own rhomboidal cryſtals which ſhoot firſt, affords afterwards many oblong ones. The firſt rhomboidal ones have no ſenſible thickneſs, but they grow larger and thicker every inſtant, while the eye looks at them. They are pellucid and colourleſs at firſt, but afterwards they by degrees become blue, as they encreaſe in thickneſs.

Oil of tartar, made by diſſolving the *ſalt* into a liquor by the humidity of the air, firſt ſhoots into oblong and cylindric, but very thin bodies, reſembling ſmall cuttings of hairs; after theſe there appear certain flat bodies, having either two oblique ends, or one end ſtrait, and the other oblique.

Ruſſia pot-aſh firſt concretes into figures like a weaver's ſhuttle, but theſe ſoon after enlarge, and loſe their form: after this there appear hexangular figures with broad baſes, reſembling ſome of the native diamonds and cryſtals; among theſe there are others oblong and flat, but truncated at each end, and ſome roundiſh; others approaching to that figure, but with ſeveral angles, irregular both in number and ſize.

Camphor forms regular cryſtallizations, approaching to a rhomboidal figure, having ſix perfect ſides, though generally irregular in bigneſs, and their thickneſs is generally equal to their breadth. Among theſe are many irregular ones; ſome ſhaped like the flint of a gun, and ſome broad at the baſe, and running to a taper and fine point. Philoſ. Tranſact. N° 173. p. 1089. See Tab. of microſcopical Objects, Claſs 3.

SALTARELLA, or SALTARELLO, in the Italian muſic, is applied to triple time, the firſt note of which is pointed thus:

Airs in this kind of movement are ſaid to be in *ſaltarello*. Such are the Venetian forlanos, ſicilianas, ſome jigs and other gay dances.

SALTATIO *mimicorum*, in antiquity. See DANCE, *Cycl.*

SALTO, in the Italian muſic. See LEAP.

SALVIA, *ſage*, in the Linnæan ſyſtem of botany, makes a diſtinct genus of plants, comprehending the *horminum*, and *ſclarea* of Tournefort and other authors, as plants of the ſame characters, and properly of the ſame genus: the characters of which are, that the calyx is a one leaved perianthium hollow, ſtriated, larger and compreſſed above, with an erect bilabiated edge; the upper lip being divided into three ſegments, the lower into two. The flower is a ſingle petal in form of a tube, large, and compreſſed above, and labiated at the mouth; the upper lip is concave, compreſſed, bent, and rimmed round its edge; the lower is broad and trifid; the middle ſegment being large, roundiſh, and rimmed round the edge. The ſtamina are two filaments bifid from their middle; the two branches remote, and having an obtuſe ſinus, one branch being the longer, and hid under the upper lip of the flower, and on this the anthera is placed; the other is terminated by an obtuſe body, probably a nectarium. The piſtil has a quadrifid germen, a thread-like, and very long ſtyle, placed in the ſame direction with the ſtamina, and a bifid ſtigma. There is properly no fruit, the calyx or cup of the flower cloſing ſlightly, and containing in its bottom four roundiſh ſeeds. *Linnæi* Gen. Plant. p. 6. See Tab. 1. of Botany, Claſs 4.

The characters of this genus, according to Tournefort, are theſe. The flower conſiſts of one leaf, and is of the labiated kind; the upper lip is ſometimes only arched, ſometimes very much hooked, the lower is divided into three ſegments; the middle one being protuberant, not hollowed like a ſpoon, as in the claries. The piſtil ariſes from the cup, and is fixed in the manner of a nail into the hinder part of the flower, and is ſurrounded with four embryos, which afterwards become as many ſeeds of a roundiſh figure, which ripen in a tubular caſe, that was originally the cup of the flower. To theſe marks it may be added, that the ſtamina reſemble the os hyoides in animals. *Tourn.* Inſt. p. 180.

The ſpecies of *ſage* enumerated by Mr. Tournefort are theſe. 1. The greateſt yellow flowered mountain *ſage* with clary leaves. 2. The large broad leaved *ſage*. 3. The greater *ſage* with purple flower cups. 4. The greater *ſage* with changeable coloured leaves. 5. The great *ſage* with leaves variegated with green and yellow. 6. The three coloured ſilvery *ſage*. 7. The leſſer *ſage* with ſinuated leaves edged with yellow. 8. The roundiſh leaved *ſage*. 9. The broad leaved ſerrated *ſage*. 10. The wormwood *ſage*. 11. The berry-bearing *ſage*, or apple *ſage* of Candy. 12. The Candy *ſage* without apples. 13. The white flowered Candy *ſage* without apples. 14. The narrow leaved ſerrated *ſage*. 15. The leſſer auriculated, and not auriculated *ſage*. 16. The ſmall white flowered not auriculated *ſage*. 17. The leſſer *ſage* with variegated leaves. 18. The thin leaved Spaniſh *ſage*. 19. The lavender leaved Spaniſh *ſage*.

The common broad leaved *ſage*; or, as we uſually call it, from the colour of ſome of the leaves, red *ſage*, is a ſudorific and diuretic; it promotes the menſes, and is good in palſies, vertigoes, tremors and catarrhs; and mixed with honey, it is ſaid to be one of the beſt known cures for the aphthæ and eroſions of the mouths of children.

The ſmaller leaved *ſage* generally ſold among us under the name of *ſage* of virtue, has the ſame qualities in a greater degree.

SALUSANDRIA, in botany, a name given by ſome authors to the nigella, called in Engliſh *gith*, or fennel flower. *Ger.* Emac. Ind. 2.

SALUTATION, *ſalutatio*, among the Romans, was a daily homage paid by clients and inferiors to their ſuperiors.

Among the great the atrium was the place appointed for this purpoſe, but among people of middling condition the veſtibulum only. See the articles ATRIUM and VESTIBULUM.

This practice of *ſalutation* was not confined to the city, but took place in the army likewiſe, it being uſual for the private ſoldiers to go very early in the morning to *ſalute* their centurion, who at their head proceeded to *ſalute* the tribune, and then the tribune, with the reſt, went and *ſaluted* the imperator, or commander in chief.

The women too had their crowds of *ſaluters* attending them every morning. *Pitiſc.* in voc. *ſalutatio*.

The manner of receiving thoſe who came to pay their reſpects,

ſpects, was to receive thoſe of the better ſort with a kiſs, and the poorer ſort had a ſmall entertainment given them, and were even feaſted by ſuch as wanted to be thought more liberal than ordinary.

SALUTATORIUM, in nunneries, a place where the nuns receive the ſalutation of thoſe that come to ſee them. *Hofm.* Lex. univ. in voc.

Salutatorium is alſo uſed for the veſtry, or place where the biſhop was dreſſed, and received the ſalutation of viſitants before divine ſervice. Id. ibid.

SALUTIGERULI, among the Romans, were ſervants chiefly employed by the women in carrying ſalutations to one another. *Pitiſc.* in voc.

SAMALUM, in botany, a name by which Pliny and ſome other authors have called the *pulſatilla*, or paſque flower. *Ger.* Emac. Ind. 2.

SAMARRA, a garment worn by thoſe condemned by the Romiſh inquiſition to be burnt; ſuch are impenitents, and thoſe who confeſs themſelves guilty of hereſy, but repent, and renounce their errors before the execution.

It is a black kind of frock, made of ſackcloth, and painted with flames pointing downwards; ſometimes the unhappy ſufferer's picture is drawn to the life on it, and ſometimes devils are painted on it dragging, as it were, the perſon along with them to hell. It is otherwiſe called *ſambenito*, and *ſamaretta*. *Hofm.* Lex. univ. in voc.

SAMBAK, or ZAMBAK, in botany, a name uſed by ſome authors for the jaſmine, or common white jeſſamy. *Chabræus*, p. 112.

SAMBENITO, a kind of frock worn by thoſe who are condemned by the Romiſh inquiſition to be burnt. See the article SAMARRA.

SAMBUCA, among the antients, a triangular muſical inſtrument. *Pitiſc.* in voc.

SAMBUCUS, the *elder*, in botany, the name of a genus of trees, the characters of which are theſe. The flower conſiſts only of one leaf, and is of the rotated kind, and divided into many ſegments at the edges. The middle of the flower is perforated by the pointal of the cup, in the manner of a nail, and the cup finally becomes a berry, containing ſeveral oblong ſeeds.

The ſpecies of *elder*, enumerated by Mr. Tournefort, are theſe, 1. The common *elder* with black berries. 2. The common *elder* with white berries. 3. The racemoſe mountain *elder* with red berries. 4. The jagged leaved *elder*. 5. The dwarf *elder*, called *ebulus*, or danewort. 6. The dwarf ſhrubby *elder* with beautifully variegated leaves. 7. The jagged leaved *ebulus*, or danewort. *Tourn.* Inſt. p. 606.

SAMEL-*bricks*. See the article BRICK.

SAMIA *terra*, in the materia medica, an earth of the marl kind, found in the iſland of Samos, and much uſed both in medicine and in the pottery of the antients.

It is of two kinds, a white dull looking one, called the *collyrium ſamium*, and a browniſh and glittering one, called the *aſter ſamius*. *Hill*'s Hiſt. of Foſſ. p. 38.

The *collyrium ſamium* is ſtill to be found in the place from whence they had it, and from whence it has its name; and is a very fine and pure earth, of a cloſe, equal, and regular texture, and yet remarkably light. It is of a fine bright white colour, and of a ſmooth, even, and gloſſy ſurface. It is ſoft to the touch, adheres firmly to the tongue, is eaſily broken between the fingers, and does not at all ſtain the hands, but drawn along a rough ſurface, leaves a fine clean white line. It melts ſlowly in the mouth, and does not ferment with acids. Theſe are the characters by which it is to be diſtinguiſhed from the white earths: to which may be added its manner of lying in the earth; which is not, as that of moſt of the other earths, in a continued ſtratum, or bed, but in the perpendicular fiſſures, and horizontal cavities in the ſtrata of ſtone, in the manner of the European earths, called the *medullæ ſaxorum*, but in ſubſtance very different from them all.

The antients prepared them by burning, waſhing, and then uſed them with ſucceſs internally in hæmorrhages, and fluxes of all kinds, and externally in inflammations. They alſo uſed them, probably, both mixed together, and blended with ſome other viſcous earth, or clay, for the fineſt of their earthen ware. *Hill*'s Hiſt. of Foſſ. p. 38.

The other kind of *Samian* earth, called *aſter ſamius*, is ſtill found in the place from whence they had it, and lies in the ſame manner in which they have deſcribed it, in an horizontal cavity between two rocks.

It is a looſe, lax, and crumbly earth, of a mixed colour, between a duſky white and a pale brown, and all over ſpangled with ſmall glittering particles. It is of a looſe and incoherent ſtructure, but uſually breaks away into flat pieces, and ſeems ſomewhat of an obſcurely laminated make. It is of a dry duſty ſurface, falls to pieces very readily between the fingers, and though it duſts the hands, does not at all ſtain them. It melts very readily in the mouth, and when thrown into water parts immediately, with a hiſſing noiſe, into a number of flaky pieces, and from thence moulders into a looſe powder. It makes no efferveſcence with acid menſtrua, and when its glittering particles are ſeparated, and ſtrictly examined, they are found to be ſo many thin flakes of that ſpecies of foſſils, called *ſelenites*.

This, as well as the other ſpecies, or *collyrium*, was prepared by calcination and waſhing, and uſed by the antient phyſicians internally in fluxes and hæmorrhages, and externally in inflammations. It was alſo one of the moſt valued earths in the Roman pottery. *Hill*'s Hiſt. of Foſſ. p. 39.

SAMIARII, among the Romans, were a kind of furbiſhers, who with Samian earth poliſhed the arms of the prætorian ſoldiers and emperor's life guards. *Pitiſc.* in voc.

SAMIR, a kind of worm, which, according to the fabulous ſtories of the Jews, was made uſe of by Moſes in fitting and poliſhing the precious ſtones in the ephod, and the two tables of the law. *Hofm.* Lex. univ. in voc.

SAMLET, an Engliſh name for a fiſh of the truttaceous kind, caught in Herefordſhire, and ſome other parts of England, and called by Willughby *ſalmulus*. *Willughby*'s Hiſt. Piſc. p. 193. See SALMULUS.

SAMOLUS, in botany, the name of a genus of plants, the characters of which are theſe. The flower conſiſts of one leaf, is rotated, aad divided into ſegments at the edge. The piſtil ariſes from the cup, and is fixed in the manner of a nail to the lower part of the flower, and finally joining with the cup, it forms a ſhell, or capſule, which opens at the ſummit, and contains a great number of ſmall ſeeds.

The ſingle ſpecies of *ſamolus*, according to Mr. Tournefort, is the *ſamolus valerandi*, called *anagallis aquatica rotundifolia*, or the round leaved water brook lime, by authors. *Tourn.* Inſt. p. 143.

SAMP, in our American colonies, a name given to a ſort of bread made of the maiz, or Indian corn.

They firſt water the corn for about half an hour, and then beat it in a mortar, or grind it in a hand mill; they then ſift out the flour, and winnow the huſks from it; they then mix this into a thin paſte with water, and bake it in flat loaves, which they call *ſamp* loaves, or *ſamp* bread.

Beſide this they have another diſh prepared of this corn, which they eſteem a great delicacy, and call by the name of *ſamp*, without the addition of loaf or bread. To make this, they only bruiſe or grind the corn to the ſize of rice, and then winnowing away the huſks, they boil it gently till it is thoroughly tender, and then add to it milk and butter, and ſugar: this is not only a very wholſome, but a very pleaſant diſh. It was the firſt diet of our planters when newly ſettled there, and is ſtill in uſe, as an innocent food in ſickneſs as well as health.

The Indians, who feed on this ſort of food, are found never to be ſubject to the ſtone, and to eſcape ſeveral other painful diſeaſes.

The Engliſh have found a way of making a very good ſort of beer of the grain of this Indian corn: they do this either by uſing the bread made of it, or elſe by malting it as we do our own corn. When they make the beer of the maiz bread, they break or cut it into lumps as big as a man's fiſt; they maſh theſe in the ſame manner that we do malt, and boil up the wort in the ſame manner, either with or without hops. Phil. Tranſ. N° 142.

SAMPHORÆ, among the antients, were horſes marked with the letter Σ on their legs. *Pitiſc.* in voc.

SAMPSUCHUS, a word generally uſed as a name of the common ſweet marjoram. This is as old a cuſtom as Dioſcorides; for that author expreſsly ſays, that the plant *ſampſuchus* was called *amaracus* by the Cyzenians, and ſome others whom he names, and ſeems to make them proper ſynonyms of the ſame plant; yet afterwards mentioning the oils, called *oleum ſampſuchinum* and *oleum amaracinum*, he declares them to be different medicines.

This might ſeem to imply a falſe text, either by the error of the tranſcribers or printers, in one of the places, but thoſe who are verſed in the writings of Dioſcorides, will not infer ſo much; for there are too many inſtances of this ſort of contradiction in his works. It appears, however, from the moſt antient writers of all, that the *amaracus* and *ſampſuchus* were originally the names of different plants.

Meleager in his poem, where he compares the ſeveral poets of his own and former times to the flowers of various garden plants, compares one to the *amaracus*, and another to the *ſampſuchus*. Galen and Paulus Ægineta alſo make them different plants, and allot different chapters to the treating of them. This would never have been the caſe, had the general opinion of the world at that time made them one plant; and the teſtimony of Dioſcorides, that they were ſo, will weigh very little with thoſe who know how often that author, though excellent in his way, is guilty of inaccuracies of this kind.

Diocles, in Athenæus, indeed mentions *amaracus*, which ſome call *ſampſuchus*: but even allowing that ſome people did call the *amaracus* by this name, it does not follow but that this might be improperly done, and that the *ſampſuchus* might ſtill be the name of a different plant.

SAMYDA, in botany, the name of a genus of plants firſt deſcribed by Plumier, and called by him *guldonia*; the characters are theſe. The cup is a very large one-leaved peri-

anthium

anthium, divided into five ſegments, which ſtand wide expanded, and remain when the flower is fallen, and are of an oval figure. The flower is of the ſhape of a truncated cone; it is of the length of the cup, and is dentated at the edge, and ſulcated. There are no ſtamina, but the apices ſtand each at the ſummit of one of the jags of the flower, and are of a roundiſh figure. The germen of the piſtil is of an oval figure; the ſtyle is of the length of the flower, and is of a pointed form; and the ſtigma is headed. The fruit is an oval berry with four deep furrows, divided into four cells, and containing a number of kidney-ſhaped ſeeds in an oval receptacle. Linnæus thinks this nearly related to the *melia*. *Plumier*, 24. *Linnæi* Gen. Plant. p. 520.

SANALIA, a name given by ſome authors to thoſe tumors, commonly called *meliceres*.

SANAMUNDA, in botany, a name uſed by ſome authors for the ſea heath ſpurge, or empetrum of the ſhops; a plant of the thymelæa kind.

In the materia medica, however, according to moſt catalogues, the *ſanamunda* is appropriated to be the name of the heath ſpurge, another plant of the thymelæa kind, different from the ſea ſort. *Park.* Theatr. p. 203. *Dale*'s Pharmac. p. 314.

SANATES, among the Romans, an appellation given to thoſe people in the neighbourhood of Rome, who having revolted, ſoon ſubmitted themſelves again; on which account they had equal privileges with the other citizens, there being a law in the twelve tables ordaining *ut idem juris* ſanatibus *quod foretibus ſit*. *Pitiſc.* in voc.

SANATODOS, in natural hiſtory, a name given by the people of Sicily to the ſpungy excreſcence found on the ſtalk of the dog roſe, and more uſually called the *bedeguar*.

This they greatly eſteem in all venomous bites, and uſe it in fine powder, both internally and externally, in many parts of that country. They uſe no other remedy for the bite of a viper: the wound is ſcarified, and ſome of the powder is ſprinkled on, and large doſes of it are alſo given internally in ſtrong wine.

In the bite of a mad dog they apply it to the wound, ſoftened into a ſort of pultice with oil, or with ſtrong wine; and they give it in repeated doſes internally in broths, and other weak fluids. They give it alſo in continual fevers, and in many other caſes, particularly in the colic. It is ſaid, that a ſingle doſe of a dram of it, in red wine, takes off all the pain of the colic in an hour.

There ſeems a very old opinion on the ſide of this medicine, in the cure of a bite from a mad dog; for Pliny tells us, that the root of the wild roſe, from the ſtalks of which this ſubſtance grows, was revealed in a dream for the curing this terrible diſeaſe. People, who have found out ſome one virtue in a plant, are generally ready to attribute a great many more to it; but though too much may be ſaid in praiſe of the virtues of this ſubſtance, by the people of that part of the world, it is well worth trying whether it does not contain ſome of them, as it is a thing very common among us, and eaſily had in any quantities. *Boccone*'s Muſeo de Piante.

SANCTORIAN *tables*, is uſed to ſignify ſuch regiſters as exhibit the quantities of perſpiration, its proportion to ſtool or urine, *&c.* We have ſuch tables from the obſervations of Dr. Lining at Charles-Town, South-Carolina. See Philoſ. Tranſ. N° 470, and 475.

SANCTUARIUM, in eccleſiaſtical writers, the ſame with *brandeum*. See BRANDEUM.

SANDS, *arenæ*, in natural hiſtory, a genus of foſſils, the characters of which are; that they are found in minute concretions forming together a kind of powder, the genuine particles of which are all of a tendency to one determinate ſhape, and appear regular, though more or leſs compleat concretions; not to be diſſolved or diſunited by water, or formed into a coherent maſs by means of it, but retaining their figure in it; tranſparent, vitrifiable by extreme heat, and not diſſoluble in, nor efferveſcing with acids. *Hill*'s Hiſt. of Foſſ. p. 544.

Theſe are ſubject to be variouſly blended and intermixed either with homogene, or heterogene particles, particularly with flakes of talc; and according to theſe, and their different colours, are to be ſubdivided into ſeveral kinds.

White SANDS. Of ſuch of theſe as are pure and free from heterogene particles, we have only ſix known ſpecies. 1. A fine ſhining kind, commonly uſed for ſtrewing over writing, and common in many parts of the kingdom. 2. A large ſhining white *ſand*, found in great plenty about Maidſtone, and ſent up to London for the making our common white flint glaſs. 3. A very fine white glittering *ſand*, found on the ſhores of ſome rivers in Italy, and uſed there for the fineſt glaſs. 4. A browniſh white fine, but dull looking *ſand*, very common in France, and uſed there in glaſs-making for the green glaſs; but though common enough with us alſo, is ſo much inferior to the other kinds we have, that it is never uſed or regarded. 5. A yellowiſh white fine dull *ſand*, common in the deſerts of Africa, and not leſs ſo in Italy, America, and England, but made no uſe of. And 6. a reddiſh white one, common in Suſſex, and in many other places.

Of the white *ſands*, mixed with *ſandy* particles of other colours, we have three ſpecies. 1. A large browniſh white ſhining *ſand*, found, ſo far as is yet known, only in one place, which is in the loam pits in Hedgerley near Windſor; and this is the very *ſand*, of which with clay that loam is compoſed, and to which probably it owes its value. 2. A large yellowiſh white ſhining *ſand*, which nearly reſembles the former kind, and which might be of uſe to make an artificial loam, in the place of the natural one beforementioned, as alſo in the glaſs trade: this is found about Deptford, Highgate, Hampſtead, *&c.* 3. A large coarſe variegated *ſand*, made up of white, black, reddiſh, and brown: this is very common in our gravel pits, and on the ſhores of the ſea and rivers.

Of the white *ſands*, containing heterogene particles, there are alſo three kinds. 1. A fine dull browniſh white *ſand*, with micæ, or ſmall ſpangles of talc: this is common near the ſurface in moſt parts of England. 2. A fine dull greeniſh white *ſand*, with micæ, common about Deptford, Woolwich, *&c.* And 3. a fine glittering greyiſh white *ſand*, with micæ, found in great plenty on the ſhores of the iſlands of Scilly.

Red, or *reddiſh* SANDS. Of thoſe which are pure there are five ſpecies. 1. A large ſhining red *ſand*, found on the ſhores of the iſland of Santorini. 2. A large ſhining fleſh coloured *ſand*, common about Naples. 3. A coarſe ſhining browniſh red *ſand*, common on the heaths of Suſſex. 4. A fine browniſh red ſhining *ſand*, found near the ſurface on Hampſtead heath. 5. A fine pale browniſh red ſhining *ſand*, frequent near the ſurface on the heaths of Suſſex. *Hill*'s Hiſt. of Foſſils.

Of the impure reddiſh *ſand* we know only one ſpecies, a pale red very fine one, with micæ: this is common in the deſerts of Arabia, and not in any other place, ſo far as is yet known.

Yellow SANDS. Theſe are a very numerous ſort. Of thoſe which are wholly pure we have thirteen known ſpecies. 1. A fine pale browniſh yellow one, common on Hampſtead heath. 2. A fine ſhining pale reddiſh yellow one, common about Highgate. 3. A very fine ſhining pale yellow one, common in the deſerts of Arabia, and alſo found with us in Kent and Suſſex. 4. A fine ſhining gold coloured *ſand*, common on Hampſtead heath. 5. A very coarſe ſhining pale yellow one, frequent every where to the north of London. 6. A coarſe dull whitiſh yellow one, common in Hyde-Park. 7. A large ſhining yellow one, found alſo in Hyde-Park. 8. A coarſe very bright yellow one, found in Northamptonſhire, and in ſome other counties. 9. A large dull yellow one, common on the ſhores of our rivers. 10. A fine dull deep yellow one, common in America, and in England. 11. A duſky yellow ſhining coarſe one, found on Hampſtead heath. 12. A coarſe ſhining browniſh yellow one, common among gravel about London.

Of thoſe mixt with arenaceous particles of other colours, we have ſix known ſpecies. 1. A fine greeniſh yellow pale and dull one, found on Hampſtead heath. 2. A fine greeniſh and reddiſh yellow pale dull one, found in Suſſex. 3. A coarſe blackiſh yellow ſhining one, common about Tyburn and elſewhere. 4. A fine blackiſh yellow ſhining one, common about London. 5. A large ſhining blackiſh and pale yellow one, found about Hampſtead. 6. A fine deep yellowiſh brown ſhining one, found in Glouceſterſhire, and ſome other counties.

Of the yellow *ſands* which contain heterogene particles, not arenaceous, we have nine ſpecies. 1. A browniſh yellow fine one, with micæ, found about Hampſtead. 2. A fine pale reddiſh yellow one, with ſmall ſpangles, common in America, and found with us in Suſſex and elſewhere. 3. A coarſe ſtraw coloured *ſand*, with micæ, found in Suſſex, and about London. 4. A coarſe ſulphur coloured *ſand*, with micæ. This is a more ſcarce ſpecies. 5. A large ſhining yellow *ſand*, with micæ, found on Hampſtead heath. 6. A fine dull deep yellow one, with micæ, common in moſt parts of the kingdom. 7. A large deep yellow *ſand*, with micæ, found in Northamptonſhire, and ſome other counties. 8. A coarſe ſaffron coloured *ſand*, with micæ, common in Germany, and found alſo in Suſſex. 9. A deep browniſh yellow fine *ſand*, with micæ, found about Highgate.

Brown SANDS. Of thoſe of this colour which are pure, we have only three known ſpecies. 1. A fine brown *ſand*, frequent about Woolwich. 2. A coarſe ſhining pale brown one, found on the ſhores of the Thames. And 3. a coarſe purpliſh brown ſhining one, common about Briſtol.

Of thoſe containing heterogene particles, we have only two ſpecies. 1. A dull brown coarſe *ſand*; this has among it ſome fragments of ſpar. It is found on the ſhores of rivers. 2. A coarſe ſhining pale brown one, common among gravel on the beds of rivers.

Black SANDS. Of theſe we have only two ſpecies. 1. A fine ſhining greyiſh black one, found in Italy, but not with us. 2. A fine ſhining reddiſh black one, which ſeems peculiar to America.

Green SANDS. Of theſe we yet know only one ſpecies, which is a coarſe variegated duſky green one, common in Virgi-

nia, but not known elſewhere. *Hill*'s Hiſt. of Foſſ. p. 568.

It is remarkable that *ſand*, though it appear a very hard, denſe, and indiſſoluble body, yet is contained inviſibly in the brine, or ſalt water of our ſalt ſprings; and even on the ſhooting of the ſalt, after evaporation, there ſtill remain the particles of it in the clear pellucid ſalt; and this, though wholly ſoluble in water, yet when a brine, made by ſuch a ſolution, is boiled, depoſits as much of the *ſand* as the common brine of the pits, or ſea water.

Dr. Plot, who was very curious to know the true hiſtory of this ſingular effect, procured experiments to be made in the following manner. Eight folds of fine Holland, and as many of much finer cambrick, were put together, and a quantity of the brine of the Staffordſhire ſalt pits being ſtrained through this, there was nothing ſeparated from it but a ſmall quantity of black duſt, which ſeemed to have fallen in by accident, and which was not at all like *ſand*; yet on evaporating this brine, it was found to contain no leſs than one fourth part as much *ſand* as ſalt. The quantity of brine yielding a buſhel of ſalt, yielding alſo a peck of *ſand*.

Some have ſuppoſed from theſe, and the like obſervations, that the *ſand* was generated during the time of the boiling of the liquor, but the more careful examiners think otherwiſe; it appearing to them, that the particles of this *ſand* may be ſeen in the brine, by the help of a microſcope, before the boiling, in form of rectangular oblong plates, ſome nearly ſquare; theſe were ſo ſmall, as readily to paſs the ſtrainer with the water; and appearing as numerous in it after, as before the ſtraining, ſhew that they are no more to be kept, but by ſuch means, than the ſalt.

The pores of the fineſt ſtrainers, examined by the microſcope, appear twenty times bigger than theſe plates, or particles of the *ſand*, and therefore it is not to be wondered at, that they let them through. There requires, therefore, no more to the formation of the *ſand*, than the coaleſcing of ſeveral of theſe particles into one larger granule, and ſo on; and this is very likely to be done by means of the evaporation of a part of the fluid which kept them ſeparate, and of the motion given to them in boiling, which naturally and neceſſarily brought them into the ſpheres of their own mutual attractions, at a time when their attraction with the fluid they ſwam in, was alſo much diminiſhed with its quantity. This attraction ſeems even evidently to increaſe between the particles, as the water becomes evaporated, and when finally the ſalt is drawn from it, and it is examined as it drops from the baſkets, in which the ſalt is put to drain; it is ſeen to contain more numerous particles of this ſandy matter than before; and theſe are found to coaleſce into yet larger concretions, by degrees, as the remainder of the fluid evaporates from them on the glaſs.

The particles of this ſtony matter, when once thus united, are no more to be ſeparated by water, nor is the matter any longer ſoluble in that fluid. The common ſpar found in form of ſtalactites and incruſtations on the roofs, walls, and floors of old caverns, ſhews that it was once diſſolved in water, and by that means brought to thoſe places, and made into thoſe forms; and it ſhould ſeem, that this *ſand*, as it is called, was only this ſort of ſpar, which is contained more or leſs in all water; and which, on the evaporating of that water and ſeparation of the ſalt, which might help in making the water a menſtruum proper for the retaining it, ſhoots out into its own natural concretions; for the figure of theſe thin plates is the true and natural thin parallellopiped or rhomboidal figure of the ſmaller concretions of that matter, and even of thoſe pieces into which it falls on breaking. Phil. Tranſ. N° 145.

Sand ſeems to have been the firſt ſubſtance added to proper ſalts for the making of glaſs. Joſephus, Tacitus, Strabo, Pliny, Agricola, *&c.* all mention this, and tell us of the ſtores, from which the *ſand* for this uſe was brought, being inexhauſtible.

Later ages have found that ſtones which have cryſtal for their baſis make a finer glaſs than *ſand*, of this kind are flints, *&c.* but theſe all are ſo expenſive in their preparation, that *ſand* is ſtill uſed in much greater abundance than any other ingredient. All the preparation it requires, is, that it be well waſhed before it is uſed; which much of what is uſed is found ready to their hands, being brought from the ſhores and beds of rivers.

Our glaſs-houſes, in London, uſe for their white glaſs the common white *ſand* uſed in writing, and have it from Maidſtone in Kent in vaſt quantities. For their green glaſs they uſe a common coarſe and greeniſh looking *ſand*, of which there are vaſt ſtrata at Woolwich. *Merret*'s Notes on Neri, p. 260.

Common *ſand* is a very good addition by way of manure to all ſorts of clay lands, it warms them, and makes them more open and looſe. The beſt *ſand* for the farmers uſe is that which is waſhed by rains from roads, or hills, or that which is taken from the beds of rivers; the common *ſand* that is dug in pits never anſwers nearly ſo well. *Sand* mixed with dung is much better than laid on alone: and a very fine manure is made by covering the bottom of ſheep folds with ſeveral loads of *ſand* every week, which are to be taken away, and laid on cold ſtiff lands, impregnated as they are with the dung and the urine of the ſheep.

Beſide clay land there is another ſort of ground very improveable by *ſand*; this is that ſort of black foggy land on which buſhes and ſedge grow naturally, and which they cut into turff, in ſome places. Six hundred load of *ſand* being laid upon an acre of this land, according to the Cheſhire meaſure, which is near double the ſtatute acre, meliorate it ſo much, that without plowing, it will yield good crops of oats or tares, though before it would have produced ſcarce any thing. If after this crop is taken off, the land be well dunged, and laid down for graſs, it will yield a large crop of ſweet hay.

Once ſanding this land will improve it for a vaſt number of years, and it will yield two crops of hay in the year, if there be weather to make it in. Some land in Cheſhire has been, by this means, rendered of twelve times its former value to the owner. The bogs of Ireland, when drained, have been rendered very fruitful land, by mixing *ſand* in this manner among the earth, of which they conſiſt. Add to this, that in all theſe boggy lands, the burning them, or firing their own turff upon them, is alſo a great advantage. The common peat, or turff aſhes, mixed with the *ſand* for theſe purpoſes, add greatly to its virtue.

Sea *ſand*, which is thrown up in creeks and other places, is by much the richeſt of all *ſand* for manuring the earth, partly its ſaltneſs, and partly the fat and unctuous filth that is mixed among it give it this great virtue. In the weſtern parts of England, that lie upon the ſea coaſts, they make very great advantages of it. The fragments of ſea ſhells alſo, which are always in great abundance in this *ſand*, add to its virtues; and it is always the more eſteemed by the farmers, the more of theſe fragments there are among it.

The ſea *ſand* uſed as manure in different parts of the kingdom is of three kinds: that about Plymouth, and on other of the ſouthern coaſts, is of a blue grey colour like aſhes, which is probably owing to the ſhells of muſcles, and other fiſh of that or the like colour, being broken and mixed among it in great quantity. Weſtward, near the land's end, the ſea *ſand* is very white, and about the iſles of Scilly it is very gliſtering, with ſmall particles of talc; on the coaſts of the north ſea the *ſand* is yellowiſh, brown, or reddiſh, and contains ſo great a quantity of fragments of cockle ſhells, that it ſeems to be chiefly compoſed of them. That ſea *ſand* is accounted beſt, which is of a reddiſh colour: the next in value to this is the bluiſh, and the white is the worſt of all.

Sea *ſand* is beſt when taken up from under the water, or from *ſand* banks, which are covered by every tide.

The ſmall grained *ſand* is moſt ſudden in its operation, and is therefore beſt for the tenant who is only to take three or four crops; but the coarſe or large grained *ſand* is much better for the landlord, as the good it does laſts many years.

Where the *ſand* is dredged out of the ſea, it is uſually twice as dear as where it is taken from the *ſand* banks.

When the land has been well manured with the large *ſand*, they take four crops of corn from it, and then lay it down for paſture for ſix or ſeven years before they plow it again. The graſs is ſo good, that they commonly mow it for hay the firſt year; it always abounds very much with the white flowered clover. If the graſs grows but ſhort, it is the farmer's intereſt to feed his cattle upon it, and it will turn to as good account this way, being very ſweet and rich, and making the cattle fat, and the cows yield a very large quantity of milk. *Mortimer*'s Huſbandry.

Indian SAND. The ſubſtance, commonly called *Indian ſand*, is famous for anſwering to the magnet. It is brought into ſeveral parts of Europe, and is ſaid to be gathered on the ſea ſhore in Perſia. After it is gathered, it is boiled in water to waſh away the ſea ſalt and other impurities it may contain. After this operation, it is dried and ſent abroad in form of a black powder, conſiſting of grains of different ſizes. Some of theſe grains are very rough in every part of their ſurface, and others have one ſide only rough, the others perfectly ſmooth and gloſſy. Their figure is very irregular, and reſembles that of the grains of common *ſand* only; the grains of this *Indian ſand* are uſually ſmaller than thoſe of our common *ſands*.

Theſe little lumps have neither taſte nor ſmell, and are ſo friable, that they are eaſily reduced to an impalpable powder by rubbing. Some of the particles are ſtrongly attracted by the loadſtone, and others are ſo inactive as to be ſcarce at all affected by it. Thoſe particles, which are of the deepeſt duſky black, are moſt of all affected by the loadſtone; thoſe which are not affected by it, ſeem rather of the colour of lead, of a bluiſh black and ſhining; theſe are in the greateſt quantity, and the others are ſelected from among theſe by the loadſtone. Phil. Tranſ. N° 432. p. 298.

Muſchenbroek conſidering that ſome of the particles of this *ſand* had ſo ſtrong a magnetic virtue, and others ſcarce any at all, was tempted to try whether it might not be poſſible to increaſe the like virtue in theſe laſt, and after ſome trials he found a way to ſucceed in this attempt; ſuſpecting, that there

there might be too great a quantity of ſulphur adhering to the *ſand*, to ſuffer it to be turned into any metalline regulus by a long continuance in an open fire; he mixed it with half its quantity of pot-aſh, and toaſted it in an open crucible about two hours: after this the ſalt being waſhed away with common water the *ſand* was found to be much blacker than before, and about one fourth of it was now endued with a very powerful magnetic force.

The ſalt has a great ſhare in making this *ſand* magnetic after burning; for a burning of it, without that admixture, is found to give it, indeed, ſome power of this kind, but it is very little.

There is another matter, however, which being mixed with this ſand, contributes yet greatly more to its virtue, this is black ſoap. This *ſand* being mixed with an equal quantity of black ſoap is to be put into a crucible, and placed in a gentle fire, where the ſoap will ſwell and bubble up; as ſoon as this is over, and the moiſture all evaporated, the fire is to be increaſed, and the matter kept red hot, about half an hour, or a little longer than that; then the crucible being taken out, and cooled, the remainder is to be waſhed, and this will be then a black powder; every grain of which is magnetical, and that very beautifully. If the operation be ever ſo many times repeated on the ſame *ſand*, the power remains the ſame in it, neither being increaſed nor leſſened by all the work.

A mixture of one third of this *ſand*, one third of black ſoap, and one third of ſalt of tartar, treated in the ſame manner as the former, ſeems to increaſe the virtue of magnetiſm yet farther in the *ſand*, than when treated with the ſoap alone; beef ſuet mixed with the *ſand* gives it much of the magnetic virtue, after melting and burning it away on the fire; and common pitch treated in the ſame manner with it, yet greatly increaſes it. If it be too long kept over the fire, with any of theſe mixtures, the virtue decreaſes, and if not long enough, it does not ariſe to its utmoſt height; ſo that experiments only can ſettle the true degree of heat, neceſſary to its greateſt perfection.

The greateſt power that can be given to this *ſand*, in this quality of magnetiſm, is, however, to be given in the following manner. Mix together equal parts of the *ſand*, and of roſin, pitch, frankincenſe, and rape oil, put this into a crucible, and lute it well in all parts, then place it for an hour in a reverberatory furnace: when this is cooled, there will be found black grains of the *ſand*, between black coals of the oily matter, which, when ſeparated, will leap up to the magnet, when held at ſome diſtance over them; and ſhew, in all reſpects, the ſtrongeſt magnetic virtue, that we know communicable to this ſubſtance.

It might appear, from this experiment, that the *ſand* grew more ſenſible of the magnet, as its particles more approached to the nature of ſteel; but on making the trial by calcining the *ſand* with the ingredients uſed to turn iron into ſteel, ſuch as chimney ſoot, ſea ſalt, powdered charcoal and aſhes, it acquired ſome magnetic virtue indeed, but not nearly ſo great as that given it by the laſt proceſs, or by the ſimply mixing it with bluiſh ſoap before the calcination.

After theſe experiments, the queſtion naturally occurs, of what can this *ſand* be. It has been ſuppoſed by ſome, to be the granulæ or fragments of load-ſtones, or the ſeparated particles, which when concreted into a maſs, afford the common magnet; but this can by no means be the caſe, ſince common load-ſtones loſe of their force, by being calcined with the very ingredients which render this magnetic; and indeed the phænomena it affords on experiments are ſo very ſingular, that it is not eaſy to determine any thing about it.

There are ſeveral parts of the world which afford this *ſand*, but with ſome difference in the figure of its grains, and their magnetic virtue. Beſide Perſia it is found on the ſhores of Virginia; another ſort of it is found about Italy, and very common at Leghorn; this is very magnetic. There are two ſorts of it found in the river Eber in Haſſia, of which one is like the Italian, but the other conſiſts of large grains, almoſt as big as hempſeed, but having very little virtue. A very ſtrong ſort is found in Dalmatia, near old Raguſa; and probably future enquiries will ſhew, that there are yet many more kinds of it differing in ſtrength and ſize. Phil. Tranſ. N° 432. p. 301.

SAND *bags*, in the military art, are bags of earth or *ſand*, containing about a cubical foot; they are uſed for raiſing parapets in haſte, or to repair what is beaten down.

They are alſo of uſe when the ground is rocky, and affords no earth to carry on their approaches, becauſe they can eaſily be brought from far off, and removed at will.

The ſmaller *ſand-bags* hold about half a cubical foot of earth, and ſerve to be placed upon the ſuperior talus of the parapet, to cover thoſe that are behind, who fire through the embraſſures, or intervals, which are left betwixt them.

SAND *flood*, a term uſed by the people of Suffolk, and ſome other parts of England, to expreſs a miſchief to which they are ſubject, by having their lands covered with vaſt quantities of *ſand*, rolling in upon them like a deluge of water.

Mr. Wright, a ſufferer by one of theſe deluges, gives a very good account of them in the Philoſophical Tranſactions. In the neighbourhood of the plains, ſubject to this miſchief, there are always hills which are made up of *ſand*, and only covered with a thin turf. The plains themſelves, which are inevitably ruined by the deluge of this dry ſort, are alſo ſandy; having only the ſame ſort of thin turf on them, though capable of producing very good crops, and ſtanding all common accidents.

Violent winds break through the turf that covers theſe hills, and then the *ſand* lying looſe and naked, is ſoon carried down upon the plains, where it covers and buries the graſs, and in a very little time eats through the light turf, and mixing itſelf with the *ſand* underneath, becomes one bed of this dry matter never to be covered with a turf again. A large body of *ſand* being thus got together, nothing ſtops its progreſs; but it at every ſtorm rolls over more and more ground, ſo that in a few years it extends itſelf a vaſt way; eſpecially where the ground, over which it paſſes, is of the ſame ſandy nature, and only covered with a thin turf.

In ſome parts of Suffolk the ground encourages this change ſo greatly, that a bed of *ſand* broke looſe from a neighbouring hill, and covering only a few acres, perhaps eight or ten, will, before it has travelled four miles forward, which it does in a ſmall courſe of years, deluge a thouſand acres. It travels down hill faſter than any way elſe, but will not be ſtopped by aſcent, but will move up the ſteepeſt hill, only that it requires more time. The making of fences, in the common way, to keep it out is vain. It runs through the hedges, and flies over the tops of the banks; and when it reaches a village, in its courſe, will bury the cottages, unleſs preſerved at more charge than they are worth. It will in a very little time beat up to the eaves of a houſe, of the low kind, that are uſually built in country villages, and has often weight enough to break down walls in its paſſage.

The beſt way of ſtopping its progreſs is by hedges of furze, planted one over another as they become levelled; theſe, if well kept up, will, by degrees, ſtop or divert the progreſs; and ſome who have tried this, with reſolution, after they have had the *ſand* raiſed twenty feet high, have found it ſtop its increaſe; and then having manured this adventitious ſoil with dung, found it as good ground as that which made the ſurface before.

About Thetford the villages were wholly deſtroyed by this about ninety years ago; and the branch of the river Ouſe, called then Thetford river, ſo blocked up by it, that very ſmall veſſels only could go up it, where very large ones uſed before. The river has been of great ſervice in ſtopping its progreſs into Norfolk, where otherwiſe its courſe would have carried it, and its vaſt ſpreading ſideways in proportion of its going forward, would have made it bury vaſt quantities of land in a very few years.

The moſt probable conjecture, as to the cauſe of this ſtrange ſort of deluge in theſe parts of England, is, that this portion of the county of Suffolk lies eaſt north eaſt of a part of the great level of the fens, and is by this expoſed to very impetuous winds, which acquire more than ordinary force, by their paſſing through ſo large a tract of country uninterrupted; the ſtorms ſeem to be one great cauſe of the miſchief, and the ſandy nature of the ſoil the other. There are old ſtories in the country, of ſuits at law commenced among the farmers, for grounds blown out of the owner's poſſeſſion; but the people who gain this ſort of wandering land are the greateſt ſufferers. A little *ſand* ſprinkled by the winds over a tract of land, where there is a bed of *ſand* under the turf, ſoon eats through that obſtacle; and what was at firſt only a thin coat of *ſand*, becomes then a deep plain of it, capable of being blown away to the depth of eight, ten, twenty, or more feet, and is carried over every thing in its progreſs before the winds, when once taken up by them. Phil. Tranſ. N° 37.

SAND-*gavel*, a payment due to the lord of the manor of Rodley, in the county of Glouceſter, for liberty granted to the tenant to dig *ſand*, for their common uſe. *Blount.*

SAND-*lands*, a term uſed by our farmers to expreſs ſuch grounds, as conſiſt wholly of a pure ſheer *ſand*.

This is of different colours, as white, blackiſh, reddiſh, or yellowiſh, and is very different in its nature, and in the ſize of its particles, ſome being harſher and ſome milder, and ſome very light, ſeeming only to be mere duſt. The grey, black, and aſh-coloured *ſand*-lands are the worſt of all, and generally are found on heaths and commons. Gravelly lands approach much to the nature of theſe, and thoſe which conſiſt of largeſt ſtones, and are mixed with the harſheſt *ſands*, are of all the moſt barren.

The propereſt plants for arable land, of this kind, are white oats, rye, black wheat, and turneps. The natural produce, in weeds, is quick graſs, ſorrel, broom, furze, fern, and heath.

The beſt manure for them is either marl, or ſuch clay as will break with the froſts. Cow dung is alſo a good manure for theſe lands, and many uſe with ſucceſs chalk, mud, and the half rotten ſtraw from dunghils.

When

When the farmer has a mind to raiſe corn on theſe lands, he muſt order them, as the clays; (ſee CLAY-*lands*) but where they are over-run with broom, furzes, and ſuch ſort of weeds, marl is to be laid on in great quantities. This is the practice in Staffordſhire, and by it they rid themſelves of theſe troubleſome weeds, and procure good crops of corn, though at ſome expence.

The firſt ſowing of this land is with black wheat, and for this they make three fallowings in winter, and ſtir them in the May following; at this time they ſow them, allowing one buſhel of ſeed to an acre, which generally yields them ſixty again. Then once plowing theſe lands, after this crop is off, they are fit to ſow rye on.

In Oxfordſhire they ſeldom give theſe lands more than two fallowings for wheat, except they are very much over-run with weeds; and they eſteem the white and lammas wheat the moſt agreeable for this ſort of land, and then after a fallow rathripe barley. They afterwards generally fallow them every other year, and reckon them unfit for beans and peas, though they ſometimes ſow them with winter vetches. If they ſow peas on them, they eſteem the rathripe kinds the beſt.

In Herefordſhire they are much ſubject to moſs growing upon their *ſandy lands*, and they make a great improvement by burning it on the ground, and mixing the aſhes with lime, which they then plow in.

They generally ſow them with rye after this manure, and that yields a very great increaſe upon them, and brings on a very good kind of graſs, if they are laid down after a crop or two. *Mortimer*'s Huſbandry, p. 70.

SANDAL-*bricks*. See the article BRICK.

SANDALIGERULI, among the antients, ſervants whoſe buſineſs it was to carry their maſter's or miſtreſs's *ſandals*. *Pitiſc.* in voc. See SANDAL, *Cycl.*

SANDAPELONES, among the Romans, a kind of porters who were employed in carrying the bier called *ſandapila*. *Pitiſc.* in voc. See SANDAPILA.

SANDAPILA, among the Romans, a ſort of bier uſed for carrying out the bodies of people of low circumſtances.

It was not a bed, but a kind of wooden cheſt, made of a few boards nailed together, and was uſually burnt along with the body. *Pitiſc.* in voc.

SANDARACH, (*Cycl.*) in the works of ſome of the antients, a name by which the yellow matter collected on the legs of bees is called; others of them called it *erithace* and ſome *ambroſia*.

We uſually eſteem this to be wax; but the experiments of Reaumur, and others, evidently prove, that it is not real wax; though it contains the matter of which wax is to be made: it is only the farina of flowers, collected into lumps, and probably ſerves the bees as food; and after it has afforded them nouriſhment, ſuffers ſome change in their bowels, by which it is converted into the ſubſtance we call wax. *Reaumur*'s Hiſt. Inſ. V. 10. p. 510. See PAIN *d'abeile*.

Gum SANDARACH is eſteemed good in diarrhœas and hæmorrhages, its doſe being from ten grains to half a drachm. It is alſo ſometimes preſcribed in gonorrhœas and the fluor albus. See SANDARUS, infra.

SANDARESUS, in natural hiſtory, a gem, the chief property of which, according to Pliny, is its being pellucid, and containing in its ſubſtance a kind of gold coloured globules; which are likewiſe tranſparent, when ſeen betwixt one and the fire. *Hofm.* Lex. univ. in voc.

SANDARUS, in the materia medica, the original name of the gum, which later ages have, by corruption of the name, called *ſandarax* or *ſandaracha*. The latter name is peculiarly improper, as it confounds this innocent gum with a poiſonous mineral of the arſenic or orpiment kind.

The Arabians are not eaſily to be underſtood in what they ſay of this gum. Some deſcribe it as a diſtinct gum from all others, and ſay that it reſembled amber in its colour and properties; this ſeems to expreſs properly what we at this time call *ſandaracha*, which has much of the appearance of yellow reſin, and therefore cannot be wholly unlike amber; but, as this gum was uſed in varniſh, and ſeveral other gums were alſo uſed for the ſame purpoſe, theſe writers, according to their uſual cuſtom of attributing the ſame name to different things, which had the ſame properties, have ſometimes called the *cancamum* by this name, and ſometimes amber. Gum lacca has often been called alſo by this name by theſe authors; and the context only can clear up what is meant, when either the word *ſandarus* or *cancamum*, or vernix is uſed.

SANDASTER, in natural hiſtory, a kind of gem mentioned by Pliny, with gold coloured globules in it that ſhone like ſtars, and were in number and diſpoſition not unlike the ſeven ſtars. *Hofm.* Lex. in voc.

SANDIVER (*Cycl.*)—It is reported, by many authors of great credit, that this ſalt, in its genuine form, and no way differing from ſuch as is ſeparated from glaſs, is thrown out in great abundance in the eruptions of the burning mountains, and lies about in lumps of a ſpungy texture and great ſize, or in ſmaller ſolid ones among the ſciarri and aſhes thrown out at thoſe times. The more firm and ſolid pieces are the moſt pure, and are generally of a fine white; the others not unfrequently are tinged bluiſh or yellow, and have ſometimes ſome of the melted matter of the ſciarri blended among the maſs, and filling up ſome of the cavities. In the catalogue of the ſpecimens of ſubſtances thrown out of Mount Ætna in one of its eruptions, and ſent as a preſent to the Royal Society, we find mention of ſeveral pieces of *ſandiver*, but without any particular deſcription. Phil. Tranſ. N° 53.

SANDYX (*Cycl.*)—Though the generality of authors have taken this to be only a name for the fine red colour, ſome have plainly uſed it for a bluiſh green.

Strabo tells us, that the colours uſed by painters, in his time, and called *armenium pictorium*, was of a bluiſh green colour, and that it was called *ſandycis metallum* by ſome. Thus the word *zarnich* was made to expreſs the ſame two things with the addition of the yellow orpiment; and Aviſenna deſcribes them all together, telling us, that *zarnich* is yellow, red, or green. The two firſt of theſe colours are natural to zarnich, as the name of orpiment; and there is, indeed, a greeniſh zarnich now alſo known in the world, but that was unknown in his times; and, we find, that he meant the *lapis armenus* by the *green zarnich*.

SANE *memory*, i. e. Perfect and ſound memory to do any lawful act.

SANGUINALIS *lapis*, in natural hiſtory, the name of a ſtone, deſcribed by Monardes, and other authors, and celebrated for its great virtues againſt hæmorrhages.

It is of the Jaſper kind, and is properly to be called an accidental heliotrope, being of a duſky green, ſpotted and veined with red; and differing in nothing from our common heliotropes, which are brought from the Eaſt-Indies, but in that it is leſs tranſparent and coarſer. See the article HELIOTROPE.

SANGUINARIA, *bloodwort*, a name given by many botanical authors to the *lapathum ſanguineum*, or bloody dock, from the red veins in its leaves; and by ſome to the *cornu cervinum*, or buckſhorn plantain, from its ſuppoſed virtues. *Ger.* Emac. Ind. 2.

SANGUINARIA, in botany, the name of a genus of plants, the characters of which are theſe. The ſpatha is compoſed of two leaves, and is oval and concave, and ſhorter than the flower. The flower conſiſts of eight oblong and obtuſe petals; they ſtand very wide expanded, and the inner ones are narrower than the outer. The ſtamina are numerous ſimple filaments, ſhorter than the flower. The antheræ are ſimple. The germen of the piſtil is oblong and compreſſed. There is no ſtyle. The ſtigma is thick furrowed, with ſtriæ all along, and equals the ſtamina in height. The fruit is an oblong capſule, compoſed of two valves, and containing many round ſeeds. *Linnæi* Gen. Plant. p. 227. *Dillen*, Hort. Eltham, p. 252.

SANGUINEA, a name given by ſome of the chemiſts to nitre. See NITRE.

SANGUINEOUS *fevers*, a term uſed by the medical writers to expreſs a kind of fever, in which there is always a plethora, or fullneſs of blood, which nature is attempting to leſſen by means of this accelerated motion of it, either by forming ſome hæmorrhage, or by throwing a part of it off in form of ſweat. It is very obvious to reaſon, therefore, that bleeding is the firſt thing neceſſary in theſe fevers. The continent fevers, ſuch as the ephemera and ſynocha, are of this kind. *Junker*'s Conſp. Med. p. 252.

SANGUINEROLA, in ichthyology, a name given by the Italians to the *phoxinus*, or minow. Artedi makes this a ſpecies of cyprinus.

It has the Italian name from the blood red colour which diſplays itſelf under its belly. *Willughby*, Hiſt. Piſc. p. 268. See PHOXINUS.

SANGUINUS, in botany, a name given by ſome of the antients to the birch tree, from the deep reddiſh black colour of its twigs. Pliny calls it *ſanguineus frutex*, and not underſtanding that it was the ſame with the birch, mentions the name of that tree immediately after it, as if different from it. The Italians ſtill call the birch *ſanguino*; and ſome authors, from the redneſs of the twigs of ſome ſpecies of the alaternus, have called that ſhrub the *ſanguinus albus*. Some have ſuppoſed that this name was uſed to expreſs the birch tree alſo, but erroneouſly; for though the bark of the body of that tree is ſometimes white, there was no reaſon for adding that epithet to the word *ſanguinus*, which not being uſed for any other tree, could need no diſtinction. The Romans, and many other nations, uſed this tree as we do, for the puniſhment of children's faults; and it is poſſible that the name *ſanguinus* might be given it on this occaſion. *Pliny*, lib. 16. cap. 36.

SANGUIPURGIUM, a name given by ſome authors to a ſlight ſpecies of fever which was judged ſalutary, and only ſerving to purge and cleanſe the blood.

SANGUIS *draconis herba*, in botany, a name by which ſome authors call the *lapathum ſanguineum*, or bloody dock. *J. Bauhin*, Vol. 2. p. 988.

SANGUISORBA, in the Linnæan ſyſtem of botany, the name

of a diſtinct genus of plants, the characters of which are theſe. The cup is a perianthium, compoſed of two very ſhort leaves, placed oppoſite one to another, and falling with the flower. The flower is a ſingle petal, divided into four oval obtuſely pointed ſegments, which cohere only at their lower extremities. The ſtamina are four filaments, broad in the upper part, and of the ſame length with the flower. The antheræ are ſmall and roundiſh. The germen of the piſtil is ſquare, and ſituated between the cup and the flower. The ſtyle is ſlender, and extremely ſhort; and the ſtigma obtuſe. The fruit is a capſule containing two cells, filled with very ſmall ſeeds. *Linnæi* Gen. Plant. p. 46.

SANGUISUGA, in zoology, a name by which ſome authors expreſs the *hirudo*, or leech. *Charlt.* Inſ. p. 62. See the article HIRUDO.

SANGUISUGUM, a name given by ſome barbarous authors to a diſorder of the heart, ſuppoſed to ariſe from its retaining an abundant quantity of blood.

SANICULA, *ſanicle*, in botany, the name of a genus of the umbelliferous plants, the characters of which are theſe. The flower is compoſed of ſeveral petals, which are diſpoſed in a circular form, and have their points bending inwards. Theſe ſtand upon a cup, which finally becomes a fruit compoſed of two echinated ſeeds, which are gibboſe on one ſide, and flat on the other. Many of the flowers of the plants of this genus are barren.

The ſpecies of *ſanicle*, enumerated by Mr. Tournefort, are theſe. 1. The common wood *ſanicle*; and 2. the Canada *ſanicle*, with very large and jagged leaves. *Tourn.* Inſt. p. 326.

The medical writers all agree in celebrating this plant, as one of the greateſt vulneraries we have of our own growth. They recommend it for the healing freſh wounds and eroſions; and many go ſo far, as to talk of fiſtulas having been cured, by injecting a decoction of it: but the modern practice of ſurgery has fallen upon very different methods of practice, in theſe caſes, from their predeceſſors, and in conſequence of that, the whole tribe of vulnerary herbs are diſregarded.

SANIDIUM, in natural hiſtory, the name of a genus of foſſils, of the claſs of the ſelenitæ, but neither of the rhomboidal nor columnar kinds, nor any other way diſtinguiſhable by its external figure, being made up of ſeveral plain flat plates.

The word is derived from the Greek, Σανιδιον, tabella, a flat thin plate or table, and expreſſes a body made up only of ſuch plates. And the ſelenitæ of this genus are of no determinate form, nor conſiſt of any regular number of planes or angles, but are merely flat, broad, and thin plates or tables, compoſed of other yet thinner plates, like the talcs, but diſtinguiſhed from thoſe bodies by this, that theſe plates are made up of arangements of ſlender fibres, diſpoſed obliquely, but in uninterrupted lines acroſs the body.

The ſelenitæ having been always eſteemed (when meant of this claſs of bodies, for ſome have applied the word to certain ſpars and other ſubſtances) regularly figured foſſils, this genus has been overlooked by authors, and the ſpecimens of it which occurred, looked on as bodies of a different claſs, as ſpars or talcs. Their not fermenting with acids, however, determines them not to be ſpars; and their obliquely ſtriated ſtructure, their want of elaſticity, and their readily calcining in the fire, diſtinguiſh them from the talcs, and ſhew them to be true and genuine ſelenitæ. *Hill*'s Hiſt. of Foſſ. p. 122.

Of this genus there are only two known ſpecies, the one colourleſs and pellucid, the other whitiſh and opake. The firſt is found pretty frequently about Oxford, as alſo in Northamptonſhire, Yorkſhire, and other counties; the other is very common in all parts of Germany, and is found alſo in Leiceſterſhire, and ſome other parts of England, but with us it is not common. *Hill*'s Hiſt. of Foſſ. p. 144, 145.

SANIS, Σανις, among the Greeks, a kind of puniſhment, inflicted by binding the malefactor faſt to a piece of wood. *Potter*, Archæol. Græc. Tom. I. p. 131.

SANKIRA, in botany, a name given by ſome authors to the plant, of which the China root, uſed in medicine, is the root. *Kæmp.* Amœn. Exot. p. 781.

SANS *pareille*, in conchyliology, the name of a peculiar ſpecies of buccinum, which has its mouth opening a contrary way to that of all other buccina. This is a ſingle ſpecies among the recent buccina, but we find more than one kind with this peculiarity among the foſſile ſhells, and that in great abundance in many places in England.

SANTALUM, (*Cycl.*) in botany, the name of a genus of plants, the characters of which are theſe. The perianthium is a narrow rim, ſtanding on the germen of the piſtil, and rightly indented into four ſegments. The flower is monopetalous, and of the campanulated kind; its edge is divided into five acute ſegments. The ſtamina are eight filaments; they ſtand on the upper part of the tube of the flower, and are alternately one ſhorter than another. The antheræ are ſimple. The germen of the piſtil is turbinated. The ſtyle is of the length of the ſtamina; and the ſtigma is ſimple. The fruit is a berry. *Linnæi* Gen. Pl. p. 164.

SANTEO, in botany, a name given by the people of Guinea to an herb, which they eſteem remarkably good in all diſeaſes of the eyes, the herb being boiled in water, and the eyes waſhed with it. The leaves of this grow in pairs, oppoſite one to another, and have no footſtalks. The joints, or ſettings on of the leaves, are blackiſh, and they are of the ſize and ſhape of thoſe of the laurel. Philoſoph. Tranſact. N° 202.

SANTOLINA, *female ſouthernwood*, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the floſculous kind, and is of a globoſe ſhape. The ſeveral ſmall floſcules, it is compoſed of, are divided each into ſeveral ſegments at the end, and are placed upon the embryos, with imbricated leaves between them, and the whole contained in a ſcaly cup of a ſemiorbicular figure. The embryos ripen into ſeeds, which have no down, and the flowers are larger than thoſe of the wormwood, or abrotanum.

The ſpecies of *ſantolina*, enumerated by Mr. Tournefort, are theſe. 1. The common *ſantolina* with cylindric vermiculated leaves. 2. The *ſantolina* with hairy woolly leaves, and with large flowers. 3. The *ſantolina* with heath, or ſavin-like leaves. 4. The cypreſs leaved *ſantolina*. 5. The creeping hoary *ſantolina*. 6. The *ſantolina* with leſs hoary leaves. 7. The *ſantolina* with duſky green leaves, and ſulphur coloured flowers. 8. The *ſantolina* with duſky green leaves, and gold yellow flowers. 9. The great roſemary leaved *ſantolina*. 10. The leſſer roſemary leaved *ſantolina*. 11. The corymbiferous African *ſantolina* with a large coronopus leaf. 12. The corymbiferous African *ſantolina* with a ſmaller coronopus leaf. 13. The Spaniſh camomile leaved *ſantolina*. And 14. the Cretic *ſantolina* with vermiculated leaves. *Tourn.* Inſt. p. 460.

Santolina has the ſame virtues aſcribed to it with the *male ſouthernwood*. See SOUTHERNWOOD.

It is alſo particularly recommended in uterine complaints. It is uſed to deſtroy worms; and the powder of the dried leaves, half a drachm for the doſe, and to be continued for a conſiderable time, is eſteemed good in the fluor albus; alſo in pleuriſies and peripneumonies.

SANTONICUM *ſemen*, in the materia medica. See the article CHOUAN.

SANTSI, in botany, a name given by the Chineſe to a plant, famous among them for its medicinal virtues.

It is deſcribed by the writers, who have been on the ſpot, in ſo remarkable a manner, that it cannot eaſily be miſtaken, provided their deſcriptions are juſt. They tell us that it grows wild on the mountains in ſome of the provinces of China, and that each root of it uſually ſends up eight ſtalks, the middle one greatly higher than the reſt.

They have no branches, and have each only three leaves at the top, and the middle ſtalk bears cluſters of flowers. The root they ſay is four inches thick, and puſhes out ſeveral ſide branches, of the thickneſs of a finger. The bark of theſe roots is rough and brown, and their internal part ſoft and yellow.

The ſmall roots only are uſed in medicine, the great ones being ſeldom found. The plant flowers in the month of July, and the ſpring ſeaſon is accounted the beſt for taking up the roots.

The way of multiplying the plant is to cut the great root into ſlices tranſverſely, and plant theſe an inch deep in a good ſoil; they will ſoon ſhoot up the natural number of branches, and in three years the plant will grow to its utmoſt perfection.

The great uſe of the plant is in hæmorrhages, in which caſe it is ſaid to be almoſt infallible. Obſerv. ſur les Cout. de l'Aſie.

SAP *Cycl.—Courſe of the* SAP, a term uſed by gardners and nurſery men to expreſs the current of the *ſap* in trees.

This has been generally ſuppoſed to run in an equable and even manner; but Mr. Fairchild has ſhewn, that it has an irregular, and even contrary motion to its firſt courſe.

This is a diſcovery of more real uſe in gardening, than might at firſt thought be imagined; ſince this accurate experimenter obſerves, that by means of it he could render barren trees fruitful, and decaying trees healthful, and render the ſyſtem of gardening much better in itſelf, and more uſeful to the public.

The laureola grafted on the mezereon, and the evergreen oak of Virginia upon the common Engliſh oak; both theſe hold their leaves all the winter, and are in good ſtate and flouriſhing, though grafted on trees which drop their leaves in winter. This plainly ſhews that the juices riſe upwards in winter, even in thoſe trees which drop their leaves, otherwiſe theſe grafted ever-greens muſt have ſtarved at that ſeaſon.

If all the variety of foreign oaks were to be grafted on the Engliſh oak, it would make the timber more firm and laſting than it is, when raiſed from foreign acorns; for as the crab ſtock makes the wood of the apple more firm and laſting, than that of the apple ſtock, and the peaches and almonds, budded on plums, are more laſting than thoſe on peach ſtalks: ſo, by the contrary rule, all firm timber, graft-

ed

ed on ſpungy ſtocks, would be made worſe than it would be on its own bottom; as if the Engliſh elm were grafted upon the Dutch elm, it would partake ſo much of the nature of the ſtock, as to be a ſpungy wood, and not fit for the uſes it is uſually put to.

In grafting the New-England cedar, or juniper, upon the Virginia cedar, this experimenter found that the branch which was grafted, being left ſeveral inches below the grafting, that part continued growing, as well as the upper part above the grafting. The viburnum was another ſubject of his experiments. On bending down the top of this tree, and burying its upper branches in the earth, theſe became roots, and the proper roots were by degrees removed out of the ground as theſe took place. All the roots became branches, and finally the tree became inverted, and grew as well as in its natural ſtate.

A pear tree being inarched upon two pear ſtocks, continued in a flouriſhing ſtate, even when the root was raiſed out of the ground, and it received no nouriſhment, but from the two inarched branches. This tree, after it had ſtood ſome years in this condition, puſhed out new ſuckers from the root; which proves, that the branches are as uſeful to ſupply the root with nouriſhment, as that is to ſupply the branches; and hence it is no wonder that ſo many trees miſcarry in planting, when there are no branches left on the head. Philoſ. Tranſ. N° 384. p. 127.

SAPA, among the Romans, new wine boiled to the third part of its firſt quantity. *Pitiſc.* in voc.

SAPINDUS, the *ſoapberry tree*, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the roſaceous kind, being compoſed of ſeveral petals, arranged in a circular form; theſe are uſually four in number, and the cup is alſo compoſed of four leaves. The piſtil ariſes from the cup, and finally becomes a round fruit, which encloſes a ſtone of the ſame ſhape, with a roundiſh kernel in it.

There is only one known ſpecies of this genus, which is the *ſoapberry tree* with leaves growing to an alated rib. *Tourn.* Inſt. p. 659.

The berries of this tree are uſed as ſoap; they are of the ſize of a muſket-bullet, and are uſed in waſhing without any admixture of ſalt or oil. They perform the office of ſoap very well, as to the cleanſing the linnen, but they rot it in time.

The negroes in general uſe them for their coarſe apparel, which bears them much better than the finer linnen worn by the Europeans. Philoſ. Tranſ. N° 96.

SAPINUS, in botany, a name given by ſome of the modern botanical writers to the fir tree. This does not ſeem, however, to have been the tree ſo called by the antients. Some of thoſe writers have plainly deſcribed the pine tree under this name, and Pliny makes it the denomination of the pitch tree, ſuch as was manured in his time.

Matthiolus contends that no peculiar tree was ever called by this name, but that what the antients meant by this word, was, that part of the fir, or any other tree of that kind, which was above the ground, and below the branches. This is uſually a ſmooth part of the tree, free from knots; and the other part, where the branches grow, was called *fruſterna*. Matthiolus grounds this on the authority of Pliny, but that author errs in this; for that part of the tree was not called *ſapinus*, but expreſſed by the adjective *ſappinea*.

This is abundantly proved by Vitruvius; and on comparing the text of theſe two authors, it appears that Pliny took from Vitruvius what he ſays on this ſubject, though he did this erroneouſly; for Vitruvius ſays, that this part of the fir was called *ſappinea*, becauſe very ſmooth, and free from knots, like the *ſappinus*, or pine.

Pliny, in another place, diſtinguiſhes between the *ſapinus* and *ſappinus*. The *ſappinus* he ſeems to make the ſame with the common pitch tree, and the *ſapinus* with the pine, or with ſome other tree of the coniferous kind: he places this great diſtinction between them, that the *ſappinus*, when cut down, would never grow up again, but that the *ſapinus* would.

Some of the old gloſſaries diſtinguiſh alſo between the *ſapinus* and *ſappinus* in this manner, the one being always tranſlated the pine, πίτυς; and the *ſappinus* the fir, πεύκη. The obſervation of Pliny, of the one of theſe trees growing again from the root when cut down, and the other not, is contrary, however, to the ſentiments of the reſt of the antients.

Theophraſtus ſays of both the pine and fir, that when once cut down they never ſhoot up again; and Herodotus mentions the ſame thing, as a ſingularity among trees.

The word *ſapinus* ſeems to be only a contraction of *ſapapinus*, a name given by the Latins to the domeſtic or cultivated pine, from the vaſt quantity of juice or ſap it contained. They had a way of expreſſing this juice by the word *ſapa*; and Theophraſtus has, for the ſame reaſon, called the domeſtic pine by the name *orrus*, ὄρρος, a word ſignifying juice or ſap. This was the pine tree which bore the pine nuts uſed in medicine and in foods; and Pliny, who calls it the *manured pitch tree*, plainly errs, becauſe that tree cannot bear eſculent nuts, or anſwer to the reſt of the deſcription.

SAPO *amygdalinus*, *almond ſoap*, a new form of medicine got much into uſe of late in nephritic caſes, and made to ſupply the place of the common hard *ſoap* for internal uſes, in a more determinate manner for the phyſician, and a more cleanly one for the patient.

It is thus made. Take any quantity of freſh oil of almonds, and thrice its quantity of *ſoap* lees; digeſt them together in ſuch a heat as will make them but juſt boil, within a few hours the oil and lees will be united, and the liquor will ſoon after become ropy, and ſomething tranſparent, and will cool into the conſiſtence of a jelly; then throw in ſea ſalt till the boiling liquor has loſt its ropineſs; continue the boiling till drops of the liquor being received upon a tile, the water is ſeen to ſeparate freely from the coagulated *ſoap*; then take away the fire, and the *ſoap* will riſe to the top of the water, and is to be taken off for uſe. *Pemberton's* College Diſpenſ. p. 184.

SAPONACEA *terra*, in natural hiſtory, a term uſed by ſome to expreſs a kind of native alkali *ſalt*, of the nature of the nitre, or natron of the antients, which is found on the ſurface of the earth, mixed with dirt, &c. in the neighbourhood of Smyrna, and thence called by ſome *Smyrna earth*.

It is found principally in two places near Duraclea, a large open village, about ſix leagues to the eaſtward of Smyrna; and in a very flat plain, about a league weſtward from the river Hermus. It is at firſt gathering, a fine whitiſh *ſalt*, which of itſelf boils up, as it were, out of the ground. It is always gathered before ſun-riſe, and only in mornings in which there falls no dew; ſo that a ſtock ſufficient for the whole year muſt be laid in during the ſummer months. It comes up in ſome places an inch or two above the ſurface of the ground, but when the ſun riſes upon it, it dries and falls down again. The earth producing it lies low in both places, and in winter is waſhy. It is thinly covered with graſs.

It may be ſuſpected, at firſt ſight, that the neighbouring ſea impregnates this earth about Hermus, but the ground which produces it, and lies about Duraclea, is ſo far from the ſea, that it overthrows this ſpeculation; though every morning in ſummer the earth be ſwept clean of this *ſalt*, the next morning always produces a new crop.

Dr. Smyth, who made experiments upon this *ſalt*, informs us, that three hundred drachms of it being put into a retort, and this ſet in a ſand-heat with a very ſtrong fire for twelve hours, yielded between five and ſix ounces of an inſipid phlegm, of no other ſmell but ſuch as, in all ſuch operations, ariſes from the fire. It appeared from this, that the matter contained no volatile *ſalt*. After this the quantity of two hundred drachms, calcined in a German crucible, were diſſolved in water. This compoſition of earth and water, boiled into a lixivium, made five hundred drachms, after it had boiled three hours, and the foul ſcum had been continually taken off during that time, and been filtrated; the cloſe liquor being then evaporated to a dryneſs, there remained a pure white fixed alkaline *ſalt*, of the nature of pot-aſh.

The people of the place make ſoap with this earth in the following manner. They mix three fourths of this earth with one fourth of lime, and then pour boiling water upon the mixture: they ſtir this with a ſtick, and there ariſes to the top a thick browniſh ſubſtance, which they ſcum off; they ſave this in veſſels by itſelf. They uſe both this and the clear liquor in making ſoap, but this is much ſtronger than the liquor. They put fifty kintals of oil into a large copper boiling veſſel, and kindling a large fire under it, they let the oil boil a little, and then throw in by little and little firſt the ſcum of the lye, and afterwards the liquor itſelf; though ſometimes they uſe only the one, or only the other. They continue adding more and more of theſe, till the oil acquires the conſiſtence of ſoap, which is often ſeveral days. The fire muſt be all this time kept up very ſtrong. The ſcum of the lye, and the ſtronger part of the lye itſelf, mix with the oil in the boiling, and the weaker part unmixing itſelf, ſinks to the bottom, and is let out by a cock prepared for that purpoſe. This is not thrown away, but is let run upon freſh lime and earth, to make a lye for future uſe; and when the ſoap is perfectly made, it is ladled out, and put upon a brick or lime floor to harden.

The common proportion in the making the ſoap is two loads of earth, of five kintals each, to fifty kintals of oil, and the produce is between ſeventy and eighty kintals of ſoap. The earth is bought at a dollar a load, and the ſoap at 6½ a kintal. There is employed annually, in making ſoap at Smyrna, at leaſt ten thouſand kintals of oil. The bringing the ſoap earth to Smyrna employs a thouſand camels, or fifteen hundred, for eight months of the year, the four ſummer months being too hot for camels to travel in. A common ſoap houſe produces, at a medium, a thouſand dollars a year clear profit. Philoſ. Tranſ. N° 220. p. 230.

SAPONARIA, in the materia medica, a name given at different times to ſeveral plants, which had in ſome ſort the properties of ſoap.

The *ſtruthium* of the Greek, and *herba lanaria* of the Romans, having ſomewhat of this property, and being uſed in the cleaning of wool, ſeveral authors have explained it by the word *ſaponaria*; but this is leaving us as much in the dark, as to the plant, as we were before, not at all aſcertaining which, if any of the plants at one time or other ſo called, was to be underſtood as being the ſame with the *ſtruthium*.

The Greeks have many times called hyſſop by the name *ſaponaria*; others have given the ſame name to the anagallis, or pimpernel; and others to ſeveral different plants, which they ſuppoſed to have the effects of ſoap, or of nitre, in cleanſing of things.

None of the plants, however, that we have under the name *ſaponaria*, will at all agree with the *ſtruthium*, or *herba lanaria*, which was a thiſtle; and the very Arabians ſeem not to have known it, but have erroneouſly ſuppoſed their candiſi to be it.

SAPONARIA *terra*, in mineralogy, a name given by ſome authors to the common fullers earth. *Dale*'s Pharm. p. 19. See FULLERS *earth*, *Cycl.* and *Suppl.*

SAPONARIA *terra alba*, in natural hiſtory, a name given by ſome authors to the common tobaccopipe clay.

They call the common fullers earth alſo *ſaponaria terra*, and diſtinguiſh it from this by the epithet *purpuraſcens*; though it has no ſuch colour as purple about it. *Kentman*'s Nomenclator, foſſ. p. 1. See the article CIMOLIA.

SAPONARIUM *lixivium*. See LIXIVIUM *ſaponarium*.

SAPONEA, a name given by authors to a pectoral medicine made of oil of ſweet almonds and ſugar, mixed with the diſtilled water of violets.

SAPOTA, in botany, the name by which Plumier calls a genus of plants, ſince deſcribed by Linnæus under the name of *achras*. See the article ACHRAS.

SAPPAN, in the materia medica, a name uſed by ſome authors for the wood of the *arbor Campechiana*, or logwood uſed in dying. *Breyn.* Prodr. Vol. 2. p. 37.

SAPPHIRE, (*Cycl.*) the name given by the moderns to a beautiful pellucid gem of a blue colour: this is however extremely different from the ſtone the antients knew under the name of the *ſapphire*; for that was no pellucid gem, but an opake ſtone of a very deep blue, veined with white, and ſpotted with ſmall gold coloured ſpangles, in form of ſtars, and was only a more beautiful kind of their *cyanus*, which was the ſtone we call *lapis lazuli*.

The deſcriptions of all the authors of antiquity of the ſtone they called the *ſapphire*, plainly evince this; and hence authors of a later date have too haſtily concluded, that our *ſapphire* was wholly unknown to them: but this ſeems a very improbable conjecture, and a ſtrict enquiry into their writings will ſhew that they have very well deſcribed our *ſapphire*, under the name of *the ſky blue beryl*, or *beryllus aëroides*; and as it had among them no peculiar generical name, it could not have been better named than thus; as the beryl is plainly that of all the gems to which the *ſapphire* moſt approaches, and its colour is in the fineſt ſpecimens a pure ſky blue.

It is in its moſt perfect ſtate a very elegant and valuable gem, and is ſecond only to the diamond in luſtre, hardneſs, and price. It is met with of various ſizes, but ſeldom ſo very ſmall as many of the other gems, and has been ſometimes found up to three quarters of an inch in diameter. Its more uſual ſtandard is between a ſeventh and a ſixth of an inch. It is various in figure, being ſometimes found in the pebble, and ſometimes in the cryſtal form. Its moſt uſual appearance is in ſmall irregularly rounded, or oblong flattiſh ſtones, covered with no cruſt, and looking of a bright blue, but without the luſtre and fine poliſh of the native ruby. It is ſometimes alſo found in beautiful hexangular cryſtals, terminated by hexangular pyramids of a fine blue throughout, and naturally of a high poliſh. Sometimes alſo theſe ſprigs are only coloured at their points, and ſometimes they are wholly colourleſs.

The proper and only colour of the gem is blue; in ſome ſpecimens this is a fine deep colour, like that of the cleareſt ſky; and in others it varies into paleneſs in ſhades of all degrees, between that and the pure brightneſs and water of cryſtal, without the leaſt tinge of colour, but with a ſuperior brightneſs, that eaſily diſtinguiſhes it at ſight from cryſtal, it more than any ſtone approaching to the nature of the diamond; and in ſome it has a duſky whiteneſs, like that of milk: this laſt colour might be ſuppoſed owing to a mixture of a fine white earthy matter, but that it has been found that different mixtures of pellucid liquors, ſolutions of copper, and of different ſalts, are capable of producing the ſame colour.

It ſeems very clear, from a multitude of experiments, that this gem, in its pureſt and fineſt ſtate, owes its beautiful blue to copper; and the ſame metal being found capable of giving this milky look with a caſt of blue, the general opinion of this laſt mentioned milky looking ſtone being a true *ſapphire*, ſeems perfectly right.

The pebble *ſapphires* are always finer than the cryſtalliform ones, and moſt of the fine colourleſs *ſapphires*, which our jewellers commonly, but very improperly, call white *ſapphires*, as they have not the leaſt tinge of whiteneſs in them, but are abſolutely colourleſs, as the pureſt waters are of the pebble, not of the ſprig kind.

The *ſapphire* is of very different degrees of hardneſs and brightneſs in different parts of the world, and conſequently of very different value.

The antients uſed to diſtinguiſh the *ſapphire*, as they did all the other precious ſtones, into the male and female kind, according to the deeper or paler colour; and our jewellers, according to their cuſtom of dividing the gems into ſeveral kinds, according to their different accidents of purity, beauty, &c. make four kinds of *ſapphire*.

1. The firſt is the fine blue oriental *ſapphire*. This is the name they give the *ſapphire* when in its greateſt degree of purity and perfection, as hard as the ruby, and of a fine ſky blue.

2. The white *ſapphire*. This is the name they give the *ſapphire* when wholly colourleſs, and reſembling the diamond; and that whether it have been naturally found ſo, or reduced to that ſtate by art: for as all *ſapphires* loſe their colour on being put into the fire, it is a common practice with ſome jewellers, when they have *ſapphires* of a bad colour, to diveſt them wholly of it by fire, and bring them to what they call white *ſapphires*; but this, as before obſerved, is a very improper name, as the gem in this ſtate has not the leaſt tinge of white, but is wholly colourleſs, and as there is another white *ſapphire*, which is truly ſo, and which they call the milk *ſapphire*.

3. The third kind of *ſapphire* is what they call the water *ſapphire*. This alſo is a very improper name, not at all expreſſing what they mean by it; for they call by this name all the ſoft pale blue *ſapphires* which are found in Europe.

4. The laſt is the milk *ſapphire*. This is the name they give the *ſapphire* when of a white milky caſt, with a faint tinge of blue.

The fineſt *ſapphires* in the world are thoſe brought from the kingdom of Pegu in the Eaſt-Indies, where ſome are found perfectly colourleſs as cryſtal, and others of all ſhades of blue, up to the violet colour, but never with the leaſt tinge of purple, or any other colour but true blue: theſe are all found in the pebble form. We have other very fine *ſapphires*, both of the pebble and cryſtalliform kind, from Biſnagar, Conanor, Calicut, and the iſland of Ceylon: theſe are of all the ſhades of colour, and in Ceylon there are ſometimes found a ſort of baſtard gems, part red and part blue, ſeeming of a mixt nature between the *ſapphire* and the ruby.

The occidental *ſapphires* are from Sileſia, Bohemia, and many other parts of Europe, and are often very beautiful ſtones; but are greatly inferior, both in luſtre and hardneſs, to the oriental. *Hill*'s Hiſt. of Foſſ. p. 594.

SAPPHIRE-*colour*. To give this elegant and beautiful blue to glaſs, the workers in the glaſs-houſes uſe the following method. Take an hundred weight of rochetta fritt, and add to it a pound of prepared zaffer, and to this one ounce of manganeſe; mix all well together, and put them into the furnace to melt and purify, and when it is become perfectly pure and fine, work it into veſſels, &c. This ſmall quantity of manganeſe, with the zaffer, gives a moſt beautiful violet blue. *Neri*'s Art of Glaſs, p. 93.

SAPPHIRE-*paſte*. The method of making the counterfeit *ſapphires* in paſte is this. Take of cryſtal prepared two ounces, minium, or common red lead, ſix ounces, zaffer prepared five grains, manganeſe prepared ſeven grains; mix all the powders perfectly together, and put them into a crucible, cover it with a ſtrong lute, and put the whole into a potter's kiln, to ſtand in the hotteſt place for twenty four hours; it will be of a moſt beautiful deep *ſapphire*-colour. Blue paſtes of two other degrees of blue are alſo made in the following manner. For a ſky blue take cryſtal prepared two ounces, red lead ſix ounces, prepared zaffer twenty one grains; mix all well together, and bake them as before. For a deep violet blue take cryſtal two ounces, red lead four ounces, and four grains of painters blue ſmalt; mix all, and bake together in the kiln.

Theſe both make good blues, but much inferior to the firſt proceſs. *Neri*'s Art of Glaſs, p. 132.

SAPPHIRINA *aqua*, the *blue eye water*, is thus made. Pour a pint of ſtrong and freſh lime water into a copper veſſel; add to it a drachm of crude ſal armoniac, and throw in ſome filings, or ſmall pieces of copper, it ſoon acquires a beautiful blue colour, and is not only uſed as an eye water, but alſo to deterge old ulcers; and ſometimes is mixed with other things in injections for gonorrhœas.

SAPPHIRO-RUBINUS, in natural hiſtory, a name given by ſome modern writers on gems to a ſtone, partly a ſapphire, and partly a ruby, or, more properly ſpeaking, a ſapphire tinged in ſome part with the ruby colour, while the reſt

remains

remains blue. The Indians call this *nilacundi*. *Boet.* de Boot. See NILACUNDI.

SARABARA, among the antients, a Mediſh or Babyloniſh garment, which reached only to the knees. *Pitiſc.* in voc.

SARACHINUS, in ichthyology, a name given by Charleton and others to the fiſh, called by the generality of authors the *thriſſa*, by us the *ſhad*, or mother of the herrings.

Authors have given names to the herring kinds, according to their different growth and ſize, and multiplied the ſpecies much beyond what they ought to be. Artedi obſerves that the *agonus* and *ſarachinus* are only herrings of different growth, and that the *alauſa minor* of authors is the ſame with the *agonus*. See the article CLUPEA.

SARACUS, in zoology, a name given by ſome authors to a ſpecies of ſea fiſh of the herring kind, more uſually called *agonus*, and by many ſuſpected to have no eſſential difference from the *alauſa* or ſhad, but to be the ſame fiſh in another ſtate. *Ray*'s Ichthogr. p. 226.

SARAX, in botany, a name given by ſome authors to the whole claſs of the ferns. *Ger.* Emac. Ind. 2.

SARCITES, the *fleſh ſtone*, a name given by ſome authors to the cornelian, from its being of the colour of fleſh; as it is very exactly in ſome pieces.

SARCITES, or SAURITES, is alſo a ſtone ſuppoſed to be found in the belly of a lizard; it ſeems to have been a ſpecies of pale cornelian. Pliny mentions it, but gives no deſcription of it.

SARCITES, the *fleſh ſtone*, in natural hiſtory, is alſo a name given by ſome authors to a ſpecies of ſtone, whoſe fibres were ſuppoſed to repreſent thoſe of beef. It was of a black colour and firm texture.

SARCLIN-*time*, is the time or ſeaſon when huſbandmen weed their corn.

SARCOCOLLA (*Cycl.*)—It has been the opinion of many writers of the middle ages, that this was the gum of the beach tree. That fruit tree being very common in moſt parts of the world, and nothing at all like the *ſarcocolla* being found to come from it, people have been led to wonder how this abſurd opinion firſt got footing in the world; but this is eaſily explained by tracing up the authors who ſet it on foot to their origin.

Dioſcorides is the great fountain, from whom all theſe little ſtreams of knowledge have been ſupplied; and this author treating of *ſarcocolla*, ſays, that it is the gum of a Perſian tree. The words *perſian tree* and *peach tree* are the ſame both in Greek and Latin; and hence, what he ſaid of a tree growing in Perſia, has been attributed to the peach tree; and this gum, ſo very different from the gum of that tree, has been ſuppoſed to flow from it.

But this is not the only confuſion made in regard to this word. The later Greeks have given the name *ſarcocolla* to a plant, in nothing reſembling the *ſarcocolla* tree. The old Greeks called both the gum and the tree, which produced it by the ſame name of *ſarcocolla*, as they did in regard to the ſtyrax and galbanum, and many other of the medicinal gums, and the trees and plants which produced them. But among the later Greek writers, the little plant *argemone*, an herb of the poppy kind, was called *ſarcocolla*. Apuleius tells us, in his account of this plant, that the Greeks of later Ages called it *arſella* and *ſarcocolla*; and Strabo confirms this, giving the ſame name to the ſame plant, only that he miſtakes the Latin name, and writes *agrimonia* for *argemone*.

Marcellus Empiricus has the ſame obſervation; he ſays, in expreſs words, the plants which the Greeks called *ſarcocolla*, the Latins call *argemone*; and Neophytus, who deſcribes the plant, and ſpeaks largely of its virtues in bruiſes, and the like, ſays, that ſome of the Greeks call it *argemone*, ſome *artemone*, and others *arſella* and *ſarcocolla*.

The near alliance of the ſounds *argemone* and *agrimonia* ſeems to have deceived this author, and ſome others, and they ſometimes give us the plant agrimony, ſometimes argemone, as the *ſarcocolla* of the Greeks: Neophytus is of this number, for he calls it *argemone altera*, as a plant very different from the common argemone, and his deſcription ſuits with the agrimony. *Apuleii* Herb. c. 31. *Strabo* Hortul.

SARCO-EPIPLOCELE, a term uſed by the old medical writers, to expreſs a compound rupture, conſiſting of a deſcent of the *epiploon* and a *ſarcocele*; or a rupture of the indurated *epiploon*, whether umbilical or ſcrotal.

SARCOMA (*Cycl.*)—The *ſarcoma narium*, by ſome called alſo *hyperſarcoma narium*, is the ſame with what is commonly called the *polypus narium*, a caruncle of various ſize and conſiſtence in the noſtril. Theſe caruncles are uſually ſoft, extenſive, and capable of elongation, but ſometimes they are hard and rigid. They are ſometimes pale, ſometimes red, and are generally ſmall in their beginnings, and advance but gradually; though ſome of them grow ſo faſt, as to hang down out of the noſe in three or four days time. They are uſually not attended with pain; but ſome of them are hard, livid, very painful, and have a tendency to become cancerous. Some are wholly concealed in the noſe, others hang down to the lips, and others, though contained in the noſe, yet diſtend it greatly. Some are of an even ſurface, and others like a cluſter, ſome deſcend backward through the apertures by which we draw breath through the noſe into the fauces; and grow ſo big there as to be viſible behind the uvula, and occaſion difficulty of ſpeaking and ſwallowing, and ſometimes almoſt ſtrangle the patient.

They have uſually but one root, though ſometimes ſeveral, and are uſually formed in and from the pituitary membrane, and the diſorder ſeems to be really no other than a morbid diſpoſition of the ſpungy production and glands of this membrane. The *ſarcoma* and *polypus*, though diſorders of the ſame kind, may however be properly enough made two ſpecies; the *polypus* being ſoft, and hanging by a ſlender root, like the ſtalk of a fig; and the *ſarcoma* of a more fleſhy conſiſtence, and adhering by a large, firm, and immoveable baſis.

Theſe diſorders come ſometimes from internal cauſes, ſometimes from external injuries, and too often prove cancerous, or are attended with a ſpina ventoſa, or caries of the bones of the noſe. They may be ſometimes removed by cauſtics, but the extirpating them with the knife is the ſhorteſt, ſafeſt, and moſt eligible method. *Heiſter*'s Surgery, p. 437.

SACROMA *of the eyes*, a fleſhy excreſcence or tubercle formed on the inner ſurface of the eye-lids. Theſe tubercles, in their beginnings, are uſually ſmall; but they, by degrees, advance often to a very conſiderable bulk. Some of theſe are of ſmooth ſurfaces, others rough and unequal, like a raſberry or mulberry.

They are always to be cured by extirpation, getting them out by a hook, a pair of plyers, or a needle and thread, and then cutting them out to the roots with ſciſſars; the wound ſhould be ſuffered to bleed a while, and afterwards waſhed with a collyrium made of aloes, tutty, and ſugar of lead mixed in roſe water, till it is perfectly healed. Some uſe the cauſtic to theſe tumors, but the ſciſſars are more ſafe and leſs painful. *Heiſter*'s Surgery, p. 374.

SARCOTHLASMA, a term uſed by the old phyſicians to expreſs a bruiſe on the fleſh.

SARCULATION, a term uſed in the antient huſbandry, to expreſs a ſort of hoing, which they uſed among their peaſe and beans, and ſometimes among their corn.

The *ſarculum* was a ſort of narrow and long hoe, with which they rooted up the weeds among plants growing irregularly. We have the ſame kind of inſtrument in uſe at this time in ſome places for hoing between the plants of flax; but one way of ſowing, in rows, at preſent, has prevented the neceſſity of having recourſe to ſo inconvenient and troubleſome an inſtrument in other caſes.

SARCULATURA, in our old writers, weeding of corn; whence *una ſarculatura* was the tenant's ſervice of one day's weeding for the lord.—*Tenet in bondagio & debet unam* ſarculaturam, *&c.* *Kenn.* Paroch. Antiq. p. 403.

SARDA, the *cornelian*, in natural hiſtory, the name of a genus of the ſemi-pellucid gems: the characters of which are, that they are ſemi-pellucid ſtones, compoſed of cryſtal with a ſmall admixture of earth, of a plain uniform ſtructure, not tubulated nor cruſtated, and uſually of one ſimple colour.

Of this genus there are three ſpecies. 1. The *red cornelian*, which is a very common ſtone among our jewellers, and is of all the degrees of red from a deep blood colour, to that of the water in which raw fleſh has been ſoaked; and this laſt, if any can be called ſo, is its proper colour. It is uſually found in a roundiſh, or pebble like form, and its moſt frequent ſize is between half an inch and two inches in diameter, and is found in the Eaſt and Weſt Indies, and in many parts of Europe: our jewellers value none but the oriental, but there are very fine ones found in Sileſia and Bohemia, and on the ſhores of the Rhine. The antients, according to the degree of colour, divided theſe ſtones into male and female, the deeper coloured ones being called the male; and our jewellers call one ſort of it the beryll: this is the male *cornelian* of the antients, and is an oriental ſtone of a clear deep red; they have had this from the Italian lapidaries, who call every ſtone which is ſofter than the gems, and of a good colour, and capable of a fine poliſh, beryll, with the addition of its proper name, calling this therefore the beryll *cornelian*; and the brown cryſtal, the beryll cryſtal; but our dealers reject the proper name of the ſtone, and keep only the word, ſignifying its excellence; and both the one and the other of theſe ſubſtances are by them called ſimply the beryll. *Hill*'s Hiſt. of Foſſ. p. 460.

The ſecond ſpecies is the *yellow cornelian*. This is a ſtone, in the opinion of many, of greater value than the former, when in its moſt pure and perfect ſtate. It is found ſometimes in broad flat pieces, but more uſually in the ſhape of our common pebbles, and is of all degrees of yellow from the deepeſt that can be imagined to that of a lemon peel. It is of a greater degree of tranſparence than the red, and in its moſt common ſtate appears, when cut, like a piece of fine yellow amber. We have it principally from the Eaſt Indies; there are ſome ſpecimens of it found in Germany, but they are neither very good nor very frequent, and in England we ſometimes meet with large maſſes of it, but they are never thoroughly coloured.

The third ſpecies is the *white cornelian*. This, though leſs

beau-

beautiful than either of the others, is however a very beautiful ſtone; it is often found in the rugged ſhape of our common flints, though not unfrequently flattiſh or roundiſh like the reſt. It is the largeſt of all the *cornelians*, being found from two to ſix inches, and often more in diameter, and is of a very beautiful colour, not a clear white, but with an admixture of blue, bringing it to a ſort of pearl colour, and is leſs tranſparent than either the yellow or the red kind. It is found in the Eaſt Indies and in many parts of Europe; France has afforded very fine pieces of it, and Germany produces it in great abundance; but the beſt next the Oriental is that of New Spain. Ibid. p. 461.

Mr. du Fay, of the academy of ſciences of Paris, accidentally hit upon a very fine way of turning any part of a red *cornelian* white, ſo as to form veins or clouds of that colour at pleaſure in it. He had obſerved, that there was a way of making figures in white upon garnets, which was done by engraving the intended figure in the ſtone, and then filling up the engraving with the common white enamel, which, when poliſhed down to the level of the ſtone, ſeemed to make one body with it, and the figure to be naturally formed in white in it. Deſirous of trying this experiment on the *cornelian*, he had one engraved, and filled up the lines with white enamel in powder, then putting it over the fire to melt the enamel, he drew it back ſeveral times, to ſee how the proceſs ſucceeded, and at length found that this ſtone would not bear the neceſſary degree of fire for the operation, but would itſelf be calcined and ſpoiled before the enamel would run: on this he ſhook out the powder, but was ſurprized to find the bottom of the engraving had all been tinged white by it, though it had not melted. To continue this trial, he laid ſome of the powder enamel on a *cornelian* that was not engraved, but only the powder was laid on in a certain figure. A ſmall degree of heat having been given to this under a muffle in a wind furnace, the parts of the ſtone which had been covered with the powder were found to be white, and the others as red as before the ſtone was put into the fire.

It appeared hence, that this coating over a part of the ſtone was ſufficient to give it a whiteneſs by the help of fire; but the curious author of this invention did not ſtop here, he ſoon found that the matter of the enamel was not neceſſary to this change, but that any other denſe ſubſtance would produce the ſame effect. The common Spaniſh white, and ſeveral other colours, were found to ſucceed very well; but the beſt of all other ſubſtances, he obſerves, is a colcothar of vitriol carefully prepared; the finer part of which being ſeparated by waſhing, and afterwards mixed up with gum water, may be uſed to draw traces ever ſo beautiful, and theſe will be all ſhewn in white upon the ſtone after it has paſſed the fire. The different parts of a figure thus delineated will be more or leſs white, as the coat of colour has been laid more or leſs thick upon the ſtone, ſo that there only requires a nice hand to draw figures ever ſo beautifully diverſified, with the ſhades of a thicker or a clearer white. The counterpart of this experiment gives alſo very beautiful figures, that is, the covering the whole ſurface of the ſtone with a coat of the colour, and then drawing the intended figure or lines cut through this coat; this being done, and the whole ſet by to dry, when it has afterwards been in the fire, all the ſurface will be found white, except where the lines were cut in, and theſe will all be beautifully red, the colour of the ſtone having ſuffered no hurt in them. Thus the figure will be expreſſed in red upon a white ground, and even the minuteſt traces drawn by the point of a fine needle will not be loſt. Mem. Acad. Par. 1732.

All *cornelians* are not equally proper for this purpoſe. Thoſe of a fine deep red, which are all of one ſimple colour, and are commonly called by our jewellers *cornelians* of the old rock, always ſucceed perfectly well, and their natural deep red ſhews the white with much beauty. The common pale *cornelians* always loſe a part of their own colour in the fire; and the *cornelians*, which have veins of different colours, or ſhades of colour, never ſucceed well, becauſe every different vein receives the tinge in a different manner. The meaner ſort of *cornelians* are ſubject alſo to crack and fly, with the degree of heat neceſſary to this operation; whereas the finer ſtones of the old rock always bear it without hurt.

It would ſeem a natural conſequence from theſe experiments, that the black agate, the coloured jaſpers, and many other of that ſort of ſtones might ſucceed as well in the delineating figures on them; but Mr. du Fay, after repeated experience, found that the *cornelian* alone would do.

SARDA, in zoology, a name by which ſome call the fiſh, more uſually known by the name of *pelamys* or *pelamys ſarda*; a fiſh reſembling a young tunny, but having larger and longer teeth and no ſcales. *Geſner* de Piſc. p. 1151. See the article PELAMYS.

SARDACHATES, in the natural hiſtory of the antients, the name of a ſpecies of agate, found frequently at this time on the ſhores of rivers in the Eaſt-Indies; and ſeeming to contain an admixture of the matter of the common red cornelian, is very excellently characterized by the name the antients gave it.

It is a very elegant and beautiful ſpecies, and is often found of a conſiderable ſize. It is of a pale whitiſh ground, and has no veins or other variegations, except a multitude of minute ſpots, of a pale red, and of the matter of the red cornelian; theſe are ſcattered very ſparingly in ſome parts of the maſs, but in others they are ſo cluſtered together, as to make ſmall clouds of an elegant red. It is very hard, and is capable of an elegant poliſh. Our lapidaries do not much eſteem it, but in ſome other places it is wrought into toys which are much eſteemed. *Hill*'s Hiſt. of Foſſ. p. 483.

SARDANUS, in zoology, the name of a fiſh of the harengiform kind, caught in the Mediterranean, and common in the markets of Rome and Venice. Its body is broader than that of the pilchard, and its back green; and the line which runs along the belly is much leſs rough than in that fiſh. It is indeed eaſy to diſtinguiſh it from the pilchard, but not ſo eaſy to ſhew in what it differs from the common herring more than in ſize. It ſeems very probable, that it is no diſtinct ſpecies of fiſh; but, that the herring, like the pilchard, is always ſmaller in the Mediterranean than in the Ocean. *Willughby*'s Hiſt. Piſc. p. 225.

SARDAR, in the Turkiſh military orders, the title of an officer choſen from among the caias of the Janizaries on ſome particular occaſion, ſuch as to head a detachment ſent to war, or on any other occaſion.

The word is of Perſian origin, and is derived from *ſar*, which in the language ſignifies a head or chief.

This officer is a colonel of a detached body; he is attended in his expedition by his deputy, and two ſecretaries, and his office expires at his return from the buſineſs he was diſpatched on. *Pocock*'s Ægypt. p. 169.

SARDELLA, in zoology, a name by which ſome have called the pilchard of the Mediterranean ſea, ſuppoſing it different in ſpecies from that of the ocean, but it ſeems in reality to be no other than the common pilchard, only not growing ſo large there as in the Ocean. *Willughby*'s Hiſt. Piſc. p. 224. See the article PILCHARDUS.

SARDINA, in zoology, a name by which many have diſtinguiſhed a fiſh of the harengiform kind, which is in reality, however, no other than a ſmall pilchard, the pilchard growing to a larger ſize in the Ocean than in the Mediterranean. *Willughby*'s Hiſt. Piſc. p. 224. See PILCHARDUS.

SARDOA, or SARDOUM, in botany, a name given by the antients to the water crowfoot, with jagged leaves, called alſo *apiaſtrum* and *ranunculus apii folio*, from its leaves reſembling in ſome degree thoſe of the ſmallage. This has been in all ages characterized as a poiſon; but Pliny has found means to confound this with baum, under the name of apiaſtrum, which he ſays is fed on by the bees in Italy, but is very well known to be a dangerous poiſon in Sardinia.

SARDONIA *herba*, in botany, a name given by many of the antients to the poiſonous water *ranunculus*, which others call *apiaſtrum*, from its having leaves ſomewhat reſembling ſmallage; and our modern botaniſts call it the *ranunculus paluſtris apii folio*, or water crowfoot with ſmallage leaves.

It had the name *ſardonia* from its growing very plentifully in Sardinia. The old Greeks have generally written the name of that iſland *Sardonia*, not Sardinia; and hence they have called the plant alſo by the ſame name.

It is branded by all authors, both antient and modern, with the name of a poiſon, and we ſee that even the cattle will not touch it, though a very ſucculent and well looking herb.

SARDONYX, (*Cycl.*) in natural hiſtory, the name of a genus of the ſemi-pellucid gems, which are conſiderably tranſparent, of the true onyx ſtructure, either zoned or tabulated, and are compoſed of the true matter of the onyx, variegated with zones of that of the red or yellow cornelian.

Of this genus there are four known ſpecies. 1. The thin zoned red *ſardonyx*, or whitiſh onyx, with thin, ſnow white, and red zones; this is one of the moſt beautiful of the ſemi-pellucid gems. The ground of this is a cryſtalline matter, ſomewhat whitiſh, otherwiſe very little differing from pure cryſtal, either in colour or tranſparence; and the zones are always extremely fine and ſlender, and laid with a beautiful regularity over one another; they are of the true matter of the cornelian, and ſome are of the plain red cornelian, others of the white, and others often of a pale fleſh colour, made by an admixture of the former two. It is only found in the Eaſt Indies, and is greatly valued among our lapidaries. *Hill*'s Hiſt. of Foſſ. p. 493.

The ſecond ſpecies is the broad veined red *ſardonyx*, or horny onyx, with red punctated zones. This is a beautiful ſtone, though greatly inferior to the former kind. Its ground is of a true horn colour, and much reſembles that of many of the agates of the Eaſt Indies, and its zones are of the true matter of the red cornelian, but they are broad and coarſe to the naked eye; and when viewed with a microſcope, or even only attentively examined by the naked eye againſt a good light, they are found to be each compoſed of a number of thin ones, ſeparated from each other by narrow zones of the common matter of the ſtone, and each compoſed of ſeveral cloſe arrangements of ſmall red ſpots. This is found in New Spain and in ſome parts of Europe, and is ſometimes wrought into ſnuff-boxes, counters for cards, or other toys; but is very little eſteemed.

The

The third ſpecies is the yellow leaved *ſardonyx*, which, as its veins are as truly of the matter of the yellow cornelian, as thoſe of the former ſpecies are of the red, is certainly entitled as much as they to the name of *ſardonyx*. This is a very beautiful ſtone, and was well known among the antients by the name of the *onyx in qua chryſolithi color*, or the chryſolite onyx. The chryſolite of the antients was the gem we now call the topaz, and the zones of this ſtone are truly of that colour, though of leſs tranſparence and brightneſs. It is found in pretty large maſſes, but always flat, and full of numerous cracks and flaws, ſo that few pieces of it can be obtained of any ſize. Its zones are ſo many flat and regular plates or tables, laid evenly on one another, but divided by other zones of the matter of the ſtone: this is of a clear and beautiful pale brown, and the zones being of an extremely bright yellow, the whole is very beautiful. It is found in many parts of the world, but is no where common, it being rare to meet with two ſpecimens of it together. Arabia, Armenia, Perſia, China, and New-Spain, have all been known, at times, to produce it. In Italy it is very much valued, but with us it is hardly known.

The fourth ſpecies is the orange coloured *ſardonyx*, or the bluiſh white onyx with orange coloured and whitiſh zones. This is a very ſingular ſpecies, and is not without its beauty, though greatly inferior to the former. Its ground, or baſis, is a bluiſh white, and its zones are made of the matter of the deeper yellow and the white cornelian laid alternately, and often intermixed with other zones, made of the common matter of the ſtone. It is found in Ægypt, Arabia, and the Eaſt-Indies, and not unfrequently in Germany, but the European is greatly inferior to the Oriental.

Theſe are all the genuine *ſardonyxes*; but the ſtone called *ſardonyx*, in Pliny's time, being properly a camæa, not a *ſardonyx*, is to be ſeen under that head. *Hill*'s Hiſt. of Foſſ. p. 497.

SARFAR, a name given by ſome of the chemiſts to iron.

SARGAZO, or SARGASO, in botany, a name for the plant commonly called *ſea lentils*; a ſmall ſea plant found among the rocks, and ſometimes at open ſea, and ſuppoſed to be a good diuretic. *Mont.* Exot. p. 7. *Piſo*, p. 18.

SARGO, the name uſed by Aguſtino Scilla, in his book of petrifactions, for the name of one of thoſe kinds of ſea fiſh, in the hinder part of whoſe jaws are found thoſe round *dentes molares*, or grinder teeth, which, when found in a petrified ſtate, are called *bufonitæ*, or toadſtones.

It is very certain, that by *ſargo* Scilla means no other fiſh than the *ſargus*; yet Mr. Willughby ſays that the *ſargus* has none of theſe round grinders, or *tubercula oſſea*, as he calls them, and makes this one of the characters by which the *ſargus* is to be diſtinguiſhed from the ſparus and ſcarus, and other fiſhes of that tribe.

It is probable that Scilla, who wrote more expreſsly on theſe ſubjects, diſſected his *ſargus* with too much accuracy, to be miſtaken in this material part of it; and it is poſſible that Mr. Willughby, though a very accurate writer, might overlook theſe teeth in the hinder part of the jaw of a fiſh which he was only deſcribing in the common way, and had no peculiar reaſon for examining in ſo nice a manner juſt in this part. Philoſ. Tranſ. N° 219. p. 195.

SARGUS, in zoology, the name of a fiſh well known, and much eſteemed among the antients, and not uncommon at this time in the markets of Rome, Venice, *&c.* being caught in the Mediterranean and Adriatic in conſiderable quantities. See Tab. of Fiſhes, N° 54.

It ſomething reſembles the ſparus in figure, but its noſe is longer and more pointed, and turns up a little, and its foreteeth are ſhaped like two human teeth, which ſtand in the ſame part of the mouth. It has no tubercles in the hinder part of the jaws, as the ſparus has; and its whole body is variegated with brown tranſverſe rings, reſembling the variegations of the perch, and has only one fin on the back, the anterior rays of which are prickly, the hinder ones not at all ſo. *Willughby*, Hiſt. Piſc. p. 309. *Geſner*, de Piſc. p. 993.

SARGUS, in zoology, is alſo the name of a river fiſh, called by others *gardon*, *ſardus*, and *cephalus*, and by many ſuppoſed to be no way eſſentially different from our common roach.

It is a river fiſh, very much reſembling the chub in its general figure, and the ſize of its ſcales, but it has a ſmaller head, and a ſomewhat broader body than that fiſh. Its back is bluiſh, its neck greeniſh, and its belly white. It has no teeth. Its eyes are yellow, and it is uſually leſs fat than the chub.

It is a very briſk and lively fiſh, and is a ſort of emblem of health among the French, and uſed proverbially as ſuch in the ſame manner as the roach among us. We ſay of a healthy man, he is as ſound as a roach, they, he is as ſound as a *gardon*. It is common in the rivers of France, Italy, and Germany, and is eſteemed but a moderately fine fiſh for the table. *Willughby*'s Hiſt. Piſc. p. 260.

SARIGOY, in zoology, a name by which ſome call the creature we know by the name of the *opoſſum*. See the article OPOSSUM.

SARIO, in zoology, a term uſed by ſome authors for the ſalmon when in the middle ſtage of its growth, when it is paſt its younger ſtate, in which it is called a *ſalar*, and is not yet arrived at what is properly called a *ſalmon*. *Willughby*'s Hiſt. Piſc. p. 189. See the article SALMO.

SARISSA, in antiquity, a very long ſpear uſed by the Macedonians. Ælian ſays, that by the antient uſage they ought to be ſixteen cubits in length; but that in fact they were but fourteen, two cubits being allowed for the handle, and the other twelve to cover their bodies. *Pitiſc.* in voc.

SARMATICA *lues*, a name given by ſome authors to the *plica polonica*.

SARMENIUS *lapis*, a name given by the writers of the middle ages to a ſtone ſaid to be uſed in the poliſhing of gold, and to have virtues in medicine alſo; ſuch as preventing abortion, and the like.

It ſeems to have been only a corrupt way of ſpelling *famius lapis*, a ſtone to which Pliny has attributed the ſame virtues.

SARMENTOUS *ſtalk*. See the article STALK.

SARONIA, Σαρωνια, among the Greeks, a feſtival kept in honour of Diana, ſurnamed *Saronia*, from Saro the third king of Træzene, by whom a temple was erected, and this feſtival inſtituted to her. *Potter*, Archæol. Græc. Tom. I. p. 439.

SAROS, Σαρος, in chronology, a period of 223 lunar months. *Suidas* in voc. Σαρος Mem. Acad. Inſcr. Tom. 8. p. 283.

The etymology of the word is ſaid to be Chaldean, ſignifying reſtitution, or return of eclipſes; that is, conjunctions of the ſun and moon in nearly the ſame place of the ecliptic.

The *ſaros* was a cycle like to that of *meto*. See the article METONIC, *Cycl.*

SAROSEL, in the glaſs trade, the name of the room into which the mouth of the Leer opens, and in which the glaſs veſſels are placed, when taken out of the Leer.

The men who attend to do this are called the *ſarole* men. *Neri*'s Art of Glaſs, p. 244.

SARPA, in zoology, the name by which the *ſalpa*, a very beautiful fiſh of the Mediterranean, is known in the Italian markets. *Geſner* de Piſc. p. 979. See SALPA.

SARPICULA, among the Romans, a term uſed by the old Roman writers to ſignify a pruning hook. *Pitiſc.* in voc.

SARPLAR *of wool*, a quantity of wool otherwiſe called a pocket, or half ſack; a ſack containing eighty tod, a tod two ſtone, and a ſtone fourteen pounds. See the article SACK, *Cycl.*

In Scotland it is termed *ſarpliath*, and contains eighty ſtone. Vid. Dict. Ruſt. in voc.

SARPOE, a name given to the fiſh called by authors *ſalpa*. See SALPA.

SARRACENA, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the roſaceous kind, and is compoſed of ſeveral leaves, arranged in a circular form, and placed on a one leaved cup, divided into many ſegments at the edges, or ſometimes of a number of diſtinct leaves; from the center of the cup there ariſes a piſtil, which carries on its top a ſort of membranaceous ſhield, which finally becomes a roundiſh fruit, uſually divided into five cells, and containing oblong ſeeds.

There is only one known ſpecies of *ſarracena*, which is the *ſarracena* with hollow and auriculated leaves, commonly called *the hollow leaved ſea lavender*, the *limonio congener* of Cluſius. *Tourn.* Inſt. p. 657.

SARRITION, *ſarritio*, in Roman authors, the term uſed to expreſs what we call hoeing in huſbandry, or ſomething analogous to it, that is a way of ſtirring up the earth about young plants, and deſtroying the weeds that would grow among them. When the plants had been ſome time come up, they ſtirred the land with wooden rakes or harrows, and then went over the fields, and pulled up the weeds by hand.

Columella ſays, that they ſowed the medica by ſcattering the ſeeds on the ſurface of the ground, and then raking them in with iron rakes, and that at different times. After this they went over the ground again with the ſame inſtruments, to root up the weeds which would have choaked the young plant. They both harrowed and hoed *raſtris* with rakes; ſo that their *occatio* and *ſarritio* were performed with much the ſame ſort of inſtrument, and differed only in the time or ſeaſon at which they were performed: the firſt was at ſeed time, to cover the grain and level the ground, and the other was to move the ground after the plants were up.

They uſed two kinds of *ſarrition*; the one was intended only to move the ground, the other was to cover up the young plants, that they might grow the more ſtrong and vigorouſly. The antients all ſowed their corn under furrow; that is, they firſt levelled the ground by harrowing, then ſcattered the ſeed upon it, and afterwards plowed it in. This method left the ground very uneven, and the corn came up moſtly in the loweſt places betwixt the furrows, which always lay higher. This we ſee is always the caſe at preſent, where the ſame method is followed; and the underſtanding this explains a paſſage in Virgil, which many have been perplexed about, *cum ſulcos æquant fata*, when the corn is as high as the furrows, which it is plain it could not

be in this method of husbandry, till it was of some growth. When they only hoed to stir the surface of the ground, or used what they called plain *sarrition*, they harrowed or hoed lengthways of the furrows, which being somewhat hardened, there could be little earth thrown down thence upon the corn.

The other kind of *sarrition* was performed by stirring the earth crosways of the furrows, by which a great deal of it must needs be thrown down among the young corn. The husbandmen of these times supposed, that the falling down of this earth upon the stalk, burying it to some depth, was the occasion of its growing strongly and vigorously: but though this could not be the case, it is certain that the corn did grow better for the operation, because the ground was thoroughly stirred by it, and had an advantage for the plants, like that obtained by the modern practice of horse-hoeing.

The antients in many other cases, as well as this, seem to have mistaken the intent and meaning of their general practices in husbandry. Columella says that beans, pease, and other the like herbs, should all be well hoed when they are about four fingers high, excepting only the lupine, but that hoeing was injurious to this plant, which having only one root, when that was cut the whole plant perished.

He adds, that hoeing was not necessary to this plant, because it was of itself so strong a grower, that it kills all weeds, starving them out by drawing all the nourishment to itself.

If the husbandmen of these times had sowed their lupines in rows, and harrowed only between those rows, they would have been in no danger of cutting the roots of the plant; and had they been better acquainted with hoeing, they would have known that the killing the weeds is the least part of the advantage arising from it, the principal being the opening and dividing the earth, and giving it a kind of new tillage.

The *sarrition* used by the antients scratched only so slight a part of the surface of the ground, that it is to be doubted whether it was of much advantage; and this was done so indistinctly among the corn and weeds, without favouring one any more than another, that it is a dispute whether the good it did, in facilitating the runcation, or hand-weeding afterwards, was greater than the damage it did by tearing the corn; so that many of the husbandmen of those times chose to omit it, and only to employ the hand-weeders: but with us hoeing, when carefully practised, is of infinite advantage, no way injurious to the corn, though wholly destructive of the weeds.

It is an error therefore in the translators of the antients, to render the word *sarritio* by *hoeing*, without giving any farther explication of it; for the antients truly hoed their vineyards in an exact sense of the word, but not their corn; neither did they plant their corn in rows, without which they could not give it their vineyard hoeing. This sarculation was used only among small quantities of sown corn, and is yet in use for flax; for the sarculum, which is a sort of very narrow hoe, is still used among the plants of flax growing irregularly, but this is too tedious and expensive ever to have place in whole fields of corn.

If the antients hoed their crops of corn standing irregularly, as sown at random, they must have made very mad work of it, since they were at no pains to sow in rows, and hoe between them with their bidens, which was an instrument with which they tilled many of their vineyards, and which entered the ground as deep as the plow, and was a much better instrument than the English hoe, which is very ill calculated for the office its principal business lies in, which is stirring the ground. *Tull*'s Horse-hoeing Husbandry.

SARTORIUS (*Cycl.*)—This is the longest muscle of the human body; it is flat, and about two fingers in breadth, situated obliquely along the inside of the thigh. It is fixed above by a very short tendon, in the lower part of the anterior superior spine of the os ilium, before the musculus fasciæ latæ. The beginning of its body lies in the notch, between the two anterior spines of that bone. From thence it runs down obliquely over the vastus internus, and other muscles that lie near it, all the way to the inside of the knee, where it terminates in a small tendon, which grows broader near its extremity, and is inserted obliquely, and a little transversely, in the forepart of the inside of the head of the tibia, near the spine or tuberosity of that bone, immediately above the insertion of the gracilis interior.

The fleshy body of this muscle is enclosed in a vagina made by the fascia lata; its fibres in general are longitudinal, and when its lower tendon turns obliquely over toward the head of the tibia, it seems to be braced down, and secured in its place by a tendinous frænum or vagina. *Winslow*'s Anatomy, p. 214.

SASSAFRAS (*Cycl.*) The culture of this tree is a hard task, it being a very difficult tree to keep long alive, though it will do very well for some time. It will not live in greenhouses, and hard winters kill it in the open air.

The best way to manage it is to remove it in April into a warm and well defended place, where it will be safe from the cold winds, and from too much open sun. It must not, however, be under the droppings of other trees. In winter some mulch must be laid on the ground round the stem, and in the summer season all the weeds must be cleared away about it.

It is brought from Virginia and Carolina, in both which places it is common.

Ximenes, an author of considerable credit in the world, has ventured to tell us, that the chips of the *sassafras* tree put into sea water will, in a few days, render it fresh and potable. He was probably imposed on by some person, in whom he placed too much confidence in this article, for experiments shew it to be false; ever so large a quantity of this wood, kept for ever so long a time in sea water, having no such effect. *Redi*'s Esperienze.

The oil of *sassafras* forms into chrystals like the oil of thyme, observed by Mr. Neuman, and which he supposed like to camphor. Philos. Trans. N° 389, 390, and 450. See CAMPHOR and OIL *of sassafras*.

SASSAROLLO, in zoology, the name of a peculiar species of pigeon, called by some *columba rupicola*, or the rock pigeon.

It is of the shape of the common pigeon, but smaller, and has red legs, and a grey variegated back. It seems the same with the *livia* of other authors. *Aldrovand* de Avib. See the article LIVIA.

SATISFACTION, in law, is used for the giving of recompence for an injury done; or the payment of money due on bond, judgment, *&c.* In which last it must be entered on record. 2 *Lill.* Abr. 495. Terms of Law.

SATURATION, in chemistry, is the impregnation of an acid with an alkali, or of an alkali with an acid, till either will receive no more, and the mixture becomes neutral.

SATUREIA, in botany, the name of a genus of plants, the characters of which are these. The flower consists of one leaf, and is of the labiated kind. It differs from thyme, in that the flowers grow scatteredly in the alæ of the leaves; from calamint, in that they do not stand on ramose pedicles; and from the thymbræ, in that they are not verticillate.

The only species, properly of this genus, is the common garden *savory*.

SATURN (*Cycl.*)—The ring of *saturn* sometimes disappears, concerning which we have a paper in the Philosophical Transactions, N° 471. sect. 9. by Mr. Heinsius of Petersburg.

This phænomenon is rare. It ought to happen every fifteen years; but from the situation of the earth, with respect to the sun and to *saturn*, it happens not above once in 30 or 45 years. See Philos. Trans. loc. cit.

SATURNIAN, *saturnius*, in antient poetry, a kind of iambic verse used in satirical writings: it consisted of six feet, and a syllable over, and thence called *trimeter hypercatalectus*. *Pitisc.* in voc. See IAMBIC, *Cycl.*

SATURNINE, (*Cycl.*)—SATURNINE *tincture*, *tinctura saturnina*. See the article TINCTURE.

SAUEL, in ichthyology, a name given by the Portuguese to a kind of fish, very frequent on the coasts of China, which by the natives is called *xiyu*. In the months of April and May vast numbers of them are taken in the river Kiang, near Nanking: during which time one of the most honourable of the emperor's eunuchs takes care to have several ships filled with these fish; which being put into the ships alive, are buried, as it were, in ice provided for that purpose, and in this manner preserved for the summer's provision of the emperor. The ships made use of to carry these fish to the emperor's court at Pekin, are of the neatest kind, and richly adorned; and all other vessels are obliged to make way for them. *Hofm.* Lex. univ. in voc.

SAVELIN, in zoology, the name of a truttaceous fish of the umbla, or umbra kind, caught in the Danube, and in some other large rivers. Its back is black; its sides spotted with yellow spots; and its belly and the belly fins are yellow. The scales are very small, and on the head there is a very remarkable series of spotted lines running into a singular figure, and surrounding the eyes, and running afterwards to the angle of the gills. The upper jaw is much longer than the lower. Its most frequent size is about a foot in length, but it sometimes comes up to six or eight pound weight. It is a very fine tasted fish. *Willughby*, Hist. Pisc. p. 195.

SAVIN, *sabina*, in medicine, is a famous hysteric and attenuant; it promotes the discharges by urine; but its great effect is the promoting the menses, which it will do more forcibly than safely, if not under very careful management.

It is kept in the shops as an ingredient in many compositions, but is very rarely used in extemporaneous prescription. *Savin* is a species of *juniper*. See the article JUNIPER.

SAVORY, in botany. See SATUREIA.

SAURITES, a stone mentioned by Pliny, and supposed by the antients to be found in the belly of a lizard. It seems to have been a kind of cornelian of a pale flesh colour.

SAURURUS, in botany, the name of a genus of plants, the characters of which are these. The perianthium is oblong, coloured,

coloured, and permanent; it is compoſed of one leaf, and ſtands ſideways on the amentum. There are no petals, but the cup being coloured, has been by ſome taken for a flower. The ſtamina are ſix long capillary filaments, three ſtanding on each ſide. The antheræ are oblong and erect. The germen of the piſtil is oval, and divided into three lobes. There is no ſtyle. The ſtigmata are three, and are obtuſe and permanent. The fruit is an oval berry, having only one cell, and containing only one oval ſeed. *Linnæi* Gen. Pl. p. 155.

SAURUS, in ichthyography, a name given by ſome authors to the *lacertus*, or longer gar fiſh, called *aguglia imperiale* by the Italians, and the *girrock* by the Engliſh fiſhermen. *Willughby*, Hiſt. Piſc. p. 232.

SAURUS, the *lizard fiſh*, is alſo a name given by Salvian, and ſome other writers, to a fiſh of the cuculus kind, reſembling the mackrel in figure and taſte, and more uſually called *trachurus*. *Salvian*, de Aquat. p. 15. See the article TRACHURUS.

SAUSTRA *beady*, in natural hiſtory, a name given by the people of the Eaſt-Indies to a kind of foſſil, to which they attribute great virtues in medicine.

Before it is given internally, it undergoes an hundred calcinations, and ſeveral preparations with the juices of herbs. When the operation is over, they ſay it will cure a thouſand diſeaſes. It has its name from thence, the word *ſauſtra* ſignifying with them a thouſand.

It is a talcy ſtone, and in its native ſtate is of a reddiſh colour. *Woodw.* Cat. Foſſ. Vol. 2.

SAUVAGEA, in botany, the name of a genus of plants, the characters of which are theſe. The perianthium is compoſed of five acute and lanceolated leaves, and remains after the flower is fallen. The flower conſiſts of five plane, erect, obtuſe, emarginated petals, which are longer than the leaves of the cup. The ſtamina are numerous capillary filaments, about half the length of the flower. The antheræ are ſimple. The germen of the piſtil is buried in the cup. The ſtyle is ſimple and ſhort. The ſtigmata are ſix; they are of an oblong figure, and of the length of the ſtyle. The fruit is a covered oval capſule, conſiſting of one cell. The ſpatha and capſule open horizontally along the middle. The ſeeds are ſmall and numerous. *Linnæi* Gen. Pl. p. 240.

SAW *fiſh*, in ichthyology, the Engliſh name for the fiſh called by authors the *priſtes*, and *ſerra piſcis*. It has theſe names from the form of its ſnout, which reſembles a large toothed *ſaw*.

According to the new ſyſtem of Artedi, this is a ſpecies of ſqualus, and is diſtinguiſhed from the other ſpecies of the ſame genus, by the name of the ſqualus with a long pointed and flatted ſnout, dentated on each ſide. See Tab. of Fiſhes, N° 5. and SERRA *piſcis* and SQUALUS.

SAWING *aſunder*, a puniſhment very common among the antient oriental nations. See *Pitiſc.* in voc. *ſerra*.

SAXIFRAGE, *ſaxifraga*, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the roſaceous kind, conſiſting of ſeveral petals diſpoſed in a circular form; from the cup of which there ariſes a two horned piſtil, which finally becomes, together with the cup, a roundiſh, but two horned bicapſular ſeed veſſel, which uſually contains a number of very ſmall ſeeds.

The ſpecies of *ſaxifrage*, enumerated by Mr. Tournefort, are theſe. 1. The common round leaved *ſaxifrage*. 2. The *ſaxifrage* with bulbs at the leaves. 3. The ſmall annual ſpring *ſaxifrage*, called rue-leaved whitlow graſs. 4. The moſſy *ſaxifrage* with trifid leaves. 5. The trifid leaved alpine *ſaxifrage* with pale yellow flowers. 6. The ſmall hairy trifid leaved alpine *ſaxifrage*. 7. The white flowered trifid leaved rock *ſaxifrage*. 8. The many flowered houſeleek leaved white *ſaxifrage*. 9. The Pyrenean houſeleek leaved *ſaxifrage* with crenated leaves. 10. The narrower houſeleek *ſaxifrage* with ſerrated leaves. 11. The *ſaxifrage* with rounded ſerrated leaves. 12. The alpine houſeleek *ſaxifrage* with rough leaves. 13. The purple flowered heath-like alpine *ſaxifrage*. 14. The blue flowered heath-like alpine *ſaxifrage*. 15. The long leaved pyramidal mountain *ſaxifrage*. 16. The ſmalleſt yellow flowered Pyrenean *ſaxifrage* with leaves like houſeleek, very cloſely put together. 17. The ſmalleſt white flowered Pyrenean *ſaxifrage* with leaves very cloſely ſet together. 18. The ſmalleſt alpine *ſaxifrage* with bluiſh green leaves bending downwards. 19. The yellow alpine houſeleek leaved *ſaxifrage*. 20. The broad leaved Pyrenean trifid *ſaxifrage*. 21. The broad leaved rigid *ſaxifrage* with trifid leaves. 22. The ſmalleſt trifid leaved Pyrenean *ſaxifrage* with pale yellow flowers. 23. The Pyrenean *ſaxifrage* with leaves partly whole, and partly trifid. And 24. the ſmalleſt yellow flowered moſs-like Pyrenean *ſaxifrage*. *Tourn.* Inſt. p. 252.

In the materia medica we have two very different plants deſcribed under the name of *ſaxifrage*; ſo that the writers on theſe ſubjects ſeem often ſtrangely to contradict one another in their deſcriptions, when they are really deſcribing two perfectly different plants.

The one is the *ſaxifraga antiquorum*. This is a low plant, ſomewhat reſembling thyme, and its ſeed is of an agreeable ſmell, and warm and acrid taſte. The other is the common white meadow *ſaxifrage*, a plant of ſix or eight inches high, with roundiſh leaves and large white flowers. The root of this ſpecies is granuloſe, or made up of a number of ſmall knobs, and theſe are in moſt places uſed in the ſhops under the name of *ſaxifrage* ſeeds.

The ſeeds of *ſaxifrage* were once in great eſteem, as a diuretic and remedy for the ſtone, but they have of late loſt their credit. It may be obſerved, however, that we are not proper judges of what might have been the virtues of an acrid ſeed, while we uſe in its ſtead an inſipid root. *Lemery*'s Hiſt. of Drugs.

Golden SAXIFRAGE. See CHRYSOPLENIUM.

Red SAXIFRAGE, *ſaxifraga rubra*, a name given by ſome botanic authors to the *filipendula* or dropwort. *Ger.* Emac. Ind. 2. See FILIPENDULA.

Yellow SAXIFRAGE, *ſaxifraga lutea*, a name given by Fuchſius, and ſome other authors, to the common melilot. *Ger.* Emac. Ind. 2.

SAYACU, in zoology, the name of a Braſilian bird, of the ſize of our chaffinch, and all over of a greyiſh green colour, and very beautifully bright and ſhining in the back and wings. Its beak is black, as are alſo its eyes. *Marggrave*'s Hiſt. of Braſil.

SAYAN, in natural hiſtory, a name given by ſome to a ſpecies of ſea ſwallow. The bird whoſe neſts are ſo famous an ingredient in ſoops.

SCAB—*Crown* SCAB, in the manege, is a mealy ſcurf upon the paſterns of a horſe, that make the hair briſtle and ſtare.

SCABBARD, in the manege, is the ſkin that ſerves for a ſheath or caſe to a horſe's yard.

SCABBED-*heels or fruſh*, in the manege, is an eating putrefaction upon a horſe's fruſh, which is very hard to cure, and has a noiſome ſmell.

SCABIES, the *itch* (*Cycl.*)—Medical writers diſtinguiſh this hateful diſeaſe into two kinds, the benign and the malign.

The benign *itch* beſide being divided into the dry and moiſt, is alſo diſtinguiſhed into the chronic, which remains on the patient for many years, and the periodic, which returns and diſappears at certain periods. It is alſo divided by others into the ſuperficial and profound, the firſt affecting only the ſkin, and ariſing uſually from contagion, the other lying deeper in the blood and humors.

The malignant *itch* is of many kinds, diſtinguiſhed by the epithets ſerine, ſcorbutic, venereal, and leprous. In theſe caſes the malignant *itch* is ſometimes called alſo the complicated *itch*, as it is complicated with other diſorders, and is attended with various ſymptoms, not properly belonging to it as the *itch*.

Signs of the itch. The moſt obvious and general ſigns of the *itch* are the eruption of pimples, or puſtules, over the whole ſurface of the body, excepting only the head; which contain, in the end, a ſanious and ulcerous matter. Theſe puſtules uſually appear firſt in the hands, and ſuch other parts as are moſt expoſed to the air, and from theſe they gradually ſpread themſelves all over the body; the body is more turgid in thoſe places where the puſtules are ſituated, than in a ſtate of health; and theſe puſtules are attended with a violent itching, eſpecially in the night. After a few days they either break of themſelves, or are opened by ſcratching, and then become ſo many little ulcers; theſe, however, uſually heal of themſelves in a very little time, and leave no ſcar behind them. This kind of benign *itch* occupies no part but the ſkin, and indeed the matter always lies between the cutis and cuticula, whence the cutis not being deeply corroded, the cuticle eaſily heals. *Junker*'s Conſp. Med. p. 448.

In the *benign moiſt itch*, the puſtules contain a large quantity of matter, and when broken diſcharge a large flow of it; there is alſo round the baſis of the puſtules of this kind an inflammatory red circle; and, in fine, the more plainly that appears, the greater is the ſuppuration. The ulcerations, in this kind, are deeper than in the dry, and the puſtules rather give a ſenſation of pain and burning heat than of itching.

In the *benign dry itch*, the puſtules are much ſmaller than in this caſe, and are full of a limpid water; and they ulcerate the ſkin more ſuperficially, and cauſe a violent itching, rather than any ſoreneſs or heat in the parts.

The *malignant itch*, when of the ſerine kind, called alſo by ſome the ſcorbutic *itch*, is dry and ſcaly, and frequently ſhews bloody ſpots under the larger ſcales. The ſkin round about theſe is tinged by the ſtagnating blood, ſometimes to a red, ſometimes to a livid, or bluiſh black colour. The itching from this kind is much more violent than from the benign, and on any ſudden change of the body, either to hotter, or colder, becomes almoſt intolerable. When the ſcabs and cuticle are ſcratched off, as is very frequently the caſe, the cutis underneath is ſeen red and bloody, but neither blood nor lymph are diſcharged from the ſcabs in ſome caſes, in others a yellowiſh ſerous liquor runs out, and almoſt immediately hardens into a ſcab or cruſt like that which was pulled off.

The venereal or pocky itch. This is uſually rather dry than moiſt, and does not ſpread itſelf ſo quickly as the other kinds. It ſometimes occupies the body in general, ſometimes only particular places, as the thighs, the ſcrotum, or the face.

At its firſt appearance there are uſually felt certain little tumors under the ſkin; and after this there appears a ſcab which remains on the part a conſiderable time, and will not eaſily be removed or torn off. The pain of this is ſharp and eroſive, eſpecially when it is exaſperated by ſcratching; and while this is fixed to ſome one part, there are pains felt deep within the fleſh in other places, which are moſt intolerable in the night; and in women the fluor albus, or whites, is uſually an attendant on it; and in men ſometimes a gonorrhœa, ſometimes bubos and other tumors; and in infants, who are thus affected, from the diſeaſes of their parents, there are frequent excoriations, and often criſtated and verrucoſe excreſcences of fleſh about the anus.

The leprous itch. In this the head is frequently affected, the pains are very violent, and the hair and ſkin very frequently fall off. There iſſues from the ſcabs white ſanious matter, and the whole texture of the ſkin is altered; the cuticle being beſet with ſmall ſcales, and feeling rough like the ſkin of an elephant, whence the diſeaſe has been called by ſome *elephantiaſis*.

In other reſpects, this complaint is attended with no ſenſation of pain, or uneaſineſs; but the face is inflated, the teeth become black, the breath becomes fœtid, and tumors of the bubo kind appear on ſeveral parts of the body, all which become finally malignant ulcers; and in the progreſs of the diſeaſe, large ſcabs, with portions of the ſkin, fall from different parts of the face.

Perſons ſubject to the itch. Theſe are principally men of a ſanguineous temperament of body and phlegmatic diſpoſition, who moſt eaſily fall into the moiſt *itch* of the ſimple benign kind, and are of all others moſt difficultly cured of it. Thoſe, on the other hand, who are moſt ſubject to the ſimple dry *itch* are men of a dry temperament and choleric habit. All perſons who eat coarſe foods, with much ſalt, and drink ſour or decayed liquors, eaſily fall into this kind; as alſo ſuch as live in a damp foggy air, and thoſe who are ſubject to obſtructions of the liver, and who have long been afflicted with quartans. Thoſe who have a ſuppreſſion or diminution of the uſual quantity of urine, and by that means have the ſalt ſeroſities of the blood not duly carried off, are alſo more ſubject than others; as alſo, from the ſame cauſe, are ſuch as have had old ulcers ſuddenly ſtopped, or iſſues dried up; people who have been uſed to cupping, at certain regular times, and afterwards neglect it; and finally, thoſe of an idle and ſedentary courſe of life. Ibid. p. 450.

Cauſes of it. The cauſes of the ſimple benign *itch* are a ſtaſis and corruption of the lymphatic humors, and this is often occaſioned by the humid temperament of the air, which in cold ſeaſons prevents the going off of thoſe humors by ſweat, which had been directed to the ſkin by nature for that purpoſe, hence they remain there and corrupt; and there are other things which more or leſs concur to cauſing it; theſe are a change of the food and drink continued for ſome time, and with this a plethoric habit of body. It is ſometimes the criſis of other diſeaſes, as of a quartan, *&c.* Theſe are the cauſes, and theſe the perſons ſubject to the *itch*, as a primary diſeaſe beginning with them; but its uſual method of propagating itſelf is by contagion; fifty people, at leaſt, having it by this means, for one, on whom it appears of itſelf. A free uſe of ſalted food greatly exaſperates the *itch* in all perſons, but this alone can have but little effect toward the original producing it. The malignant or complicated *itch* owes its origin to other cauſes. The ferine *itch* is always cauſed by the ſcurvy, and the venereal or pocky *itch* owes its origin to a corruption of the lymph in the venereal diſeaſe.

Prognoſtics in the itch. The ſimple benign *itch*, of the moiſt kind, is the mildeſt of all the kinds, and in general the moſt eaſily cured; but as it is more ſubject to ulcerations than the other kinds, this ſometimes makes the cure in bad habits of body more difficult. The dry *itch* is more troubleſome, and takes more time in the cure than the moiſt, and is more troubleſome to the patient; but in the moiſt ſanious and ſuppurating *itch*, when it is raſhly treated by mercurial and ſulphureous ointments, by quickſilver girdles, by aſtringents and refrigerants, and is driven in, which is a very common caſe, there always ariſe very unhappy ſymptoms, ſuch as anxieties of the præcordia, aſthmas, ſuffocative catarrhs, intermittent fevers, and ſometimes inflammatory acute ones, both which are of a different appearance from thoſe diſtempers in their uſual ſtate; not unfrequently alſo terrible chronic complaints are brought on by this, as cachexies, anaſarcas and œdemas. The *itch*, in general, when newly caught by infection, is always much more eaſily cured, than when it ariſes from a fault in the humors, and is conſequently much more deeply rooted: for the ſame reaſon, the chronic *itch* is of all others the moſt difficult to be cured; and where there concurs with it a defect or fault of ſome of the viſcera, as is too often the caſe, the cure is yet greatly the more difficult. The malignant *itch* is always much more deeply rooted in the patient, and of conſequence is much more difficult of cure than the ſimple; and in particular, the ferine or ſcorbutic *itch* is one of the moſt ſtubborn diſeaſes we know of. In this caſe the food, and other circumſtances, often make the cure much more difficult than it naturally would be: poor people are often infeſted with this; and their diet not being in their choice, are with difficulty cured of it. The venereal *itch*, though generally accounted the moſt terrible of all the kinds, is yet much more eaſily cured than the ſcorbutic, and ſometimes than the ſimple chronic kind, when treated in a proper manner. *Junker's* Conſp. Med. p. 452.

Method of cure. The corrupt ſtate of the humors is to be corrected according to the ſeveral kinds. In the benign *itch*, this is effected by alexipharmics and diuretics, ſuch are decoctions of the woods of guaiacum, ſaſſafras, and the like, with elecampane and pimpernel roots, and the common abſorbents fated with acids, as the crabs eyes, or oiſter ſhells, ſaturated with lemon juice, or the like; and the acrimony of the humors is greatly taken off by ſulphur and nitre given in powders, or by the ſimple balſam of ſulphur in oil of almonds. After this external applications compleat the cure; of this kind are the mercurial ointments, and thoſe which contain ſulphur. In the dry *itch* fomentations and baths do much more than ointments; of this kind are decoctions of the oxylapathum root, and a lixivium of quick-lime and ſulphur, or the general bathing in mineral ſprings.

In the malignant itch, the ferine or ſcorbutic is to be treated as the ſcurvy, to which it owes its origin. The antiſcorbutic juices ſhould be taken for ſome time, and the decoction of tobacco made very ſtrong, is a good external application; mercurial ointments have alſo their uſe here, and the violent heat of the eruptions may be mitigated by camphor, and by the frogs ſpawn plaiſter.

In the venereal itch, the method to be uſed for a cure is the ſame with that for the venereal diſeaſe in any other appearance, but in this there muſt be always kept up a gentle perſpiration: mercurial ointments have peculiarly a place here: and when the diſeaſe is ſo rooted as to give way to no other means, recourſe is to be had to a ſalivation; and finally, the cure is to be completed by evacuating the corrected humors by ſtool, in which caſe calomel is a very uſeful ingredient in purges, and the decoctions of the diaphoretic and diuretic vegetables are of great ſervice in compleating it, and preventing a return. Ibid. p. 454.

SCABIOSA, *ſcabious*, in the Linnæan ſyſtem of botany, a diſtinct genus of plants; the characters of which are, that there is both a common and a proper perianthium, of which the latter is alſo double. The common perianthium is expanded, and compoſed of many leaves, and containing many flowers; its leaves are inſerted in the receptacle, and ſurround it in various ſeries, the inner ones becoming gradually leſs than the outer. The proper perianthium is double, but both are fixed on the germen of the piſtil. The outer perianthium is ſhort, membranaceous, and folded, and remains after the flower is fallen; the inner is divided into five ſegments, which are narrow, and pointed; the flowers are monopetalous, they are placed erect, and the petal forms a tube, which is widened at the extremity, and ſlightly divided either into five, or four ſegments, the exterior of which are the larger. The ſtamina are four ſmall and weak filaments. The antheræ are oblong, and laid cloſely upon them. The germen of the piſtil is placed below the proper receptacle of the flower; and is incloſed, as in a caſe, in its proper vagina. The ſtyle is ſlender, and of the length of the flower. The ſtigma is obtuſe, and is obliquely rimmed round the edge. The ſeeds are ſingle to each flower, of an oval oblong figure, and crowned with their proper cups, and contained in the common receptacle, which is convex, and divided by the perianthia of the ſeveral flowers. See Tab. 1. of Botany, Claſs 12. and *Linnæi* Gen. Plant. p. 23.

The characters of this genus, according to Tournefort, are theſe. The flower is of the floſculous kind, and is compoſed of ſeveral unequal floſcules, contained in one general or common cup. Thoſe floſcules, which are placed in the middle of the flower, are divided at the ends into four or five ſegments, and thoſe which make the outer circle or rim of the flower are bilabiated. Each of theſe ſtands on the coronated top of an embryo, and each is contained in its proper and peculiar capſule, which afterwards becomes either a ſimple or a funnel faſhioned capſule, containing a coronated ſeed. *Tourn.* Inſt. p. 464.

The ſpecies of *ſcabious* enumerated by Mr. Tournefort are theſe. 1. The common hairy field *ſcabious*, or *ſcabious* of the ſhops. 2. The greater *ſcabious* with purpliſh blue flowers. 3. The broad leaved white ſhrubby *ſcabious*. 4. The broad leaved ſhrubby *ſcabious* with bluiſh flowers. 5. The tall annual *ſcabious* with leaves like agrimony. 6. The narrow leaved white flowered ſhrubby *ſcabious*. 7. The larger white flowered, narrow leaved ſhrubby *ſcabious*. 8. The yellow flowered *ſcabious* with multifid leaves. 9. The double headed white *ſcabious*. 10. The broad leaved white proliferous *ſcabious*. 11. The proliferous *ſcabious* with gingidium leaves. 12. The ſmall fine leaved poliferous *ſcabious*. 13. The Alpine *ſcabious* with great centaury leaves. 14. The ſmooth mountain *ſcabious* with leaves like the common *ſcabious*. 15. The red flowered mountain *ſcabious* broad not

jagged

jagged leaves. 16. The red flowered mountain *ſcabious* with broader and longer undivided leaves. 17. The *ſcabious* with the virga paſtoris, or ſmall dipſacus leaf. 18. The narrow leaved ſilvery *ſcabious*. 19. The long headed red flowered exotic *ſcabious*. 20. The long headed *ſcabious* with fleſh coloured flowers. 21. The long headed *ſcabious* with variegated flowers. 22. The long headed *ſcabious* with blackiſh flowers, with the ſmell of civet. 23. The proliferous Indian *ſcabious*. 24. The Portugal *ſcabious* reſembling the Indian. 25. The greater round headed *ſcabious*, called the leſſer *ſcabious*. 26. The leſſer round headed *ſcabious*. 27. The leſſer *ſcabious* with deeply divided leaves. 28. The little *ſcabious* with ſweet ſcented heads. 29. The great leaved Spaniſh ſtarry *ſcabious*. 30. The ſtarry *ſcabious* with great jagged leaves. 31. The leſſer or ſea ſtarry *ſcabious* with jagged leaves. 32. The ſmalleſt ſtarry *ſcabious*. 33. The ſtarry *ſcabious* with undivided leaves. 34. The annual proliferous ſtarry *ſcabious*. 35. The Sicilian *ſcabious* with heart-wort leaves. 36. The ſhrubby procumbent mountain *ſcabious*, with leaves like the young leaves of the achillea. 37. The Sicilian ſhrub *ſcabious* with laureola leaves hoary underneath. 38. The ſhrub *ſcabious* with ſtock July flower leaves. 39. The narrow leaved umbelliferous and proliferous *ſcabious*, with leaves cut into the middle rib. 40. The fleſh coloured flowered *ſcabious*, with leaves like the hairy jagged devil's bit. 41. The great tree *ſcabious* of Africa, with undivided, wrinkled, and crenated leaves. 42. The ſmall ſea *ſcabious*. 43. The cut leaved *ſcabious* with large flowers in membranaceous cups, and with woolly ſeeds. 44. The leaſt annual erect *ſcabious* with angular ſeeds. 45. The daiſy leaved annual *ſcabious*. 46. The greyiſh hoary Pyrenean *ſcabious* with large flowers. 47. The ſmooth graſſy leaved *ſcabious*. 48. The hairy creeping Alpine *ſcabious* with divided leaves. 49. The *ſcabious* with hairy undivided leaves, called the devil's bit. 50. The *ſcabious* with ſmooth undivided leaves and blue flowers. 51. The *ſcabious* with undivided leaves and white flowers. 52. The fleſh coloured flowered *ſcabious* with undivided leaves. 53. The *ſcabious* with whole leaves, proliferous heads, and blue flowers. 54. The *ſcabious* with leaves like fraxinella. *Tourn.* Inſt. p. 465.

The muſk *ſcabious* and other garden kinds are propagated by ſowing their ſeeds in May or the beginning of June, and the next year they will be very ſtrong, flowering from June to September, and producing ripe ſeeds, which they will not do if ſown early in the ſpring, and ſo made to flower the ſame year. The ſeeds are to be ſown on ſhady borders, and at Michaelmas the young plants are to be removed to the places where they are to remain. They are very hardy, and ſeldom periſh, till after they have ripened their ſeeds. *Miller*'s Gardner's Dict.

The common *ſcabious*, of our corn fields, is accounted a great alexipharmic and pectoral; it is made an ingredient in ptyſans, and infuſions given in coughs and all diſorders of the lungs, and is recommended greatly by authors in pleuriſies, quinzies, coughs, aſthmas, and conſumptions. Some even recommend it in malignant fevers, and even in the plague.

It is alſo uſed externally, either in a ſtrong decoction, or elſe boiled into an ointment with lard in the itch, and many other diſorders of the ſkin.

Scabious, though ſo much celebrated with us for its medicinal virtues, has been ſuppoſed by many to have been wholly unknown to the antient Greeks: others who could not give into the opinion of their not knowing ſo common a plant, have ſuppoſed the *ſtæbe* of Theophraſtus and Dioſcorides to be the plant we call *ſcabious*, but there is no more juſtneſs in this than in the former opinion.

The antient Greeks knew two very different plants by the name of *ſtæbe*, but neither of theſe at all anſwered to the characters or virtues of *ſcabious*; the one was a ſhrub, the other an aquatic plant with woolly leaves. The ſhrub called *ſtæbe* was the ſame with the *pheos* and *hippopheos*, a prickly ſhrub of a cubit in height, but very full of branches, which grew on the ſhores of the iſland of Crete, and other the like places; and the plant *ſtæbe* was a ſmall gnaphalium, or cudweed, growing in wet places, and uſed for the ſtuffing of beds, and the packing up of earthen ware, and other brittle things, to prevent their breaking. The other was uſed by the fullers about cloaths.

It is ſufficiently evident, from theſe accounts, that neither the one nor the other of theſe *ſtæbes* had any of the qualities of *ſcabious*; but though neither of theſe was *ſcabious*, yet it does not follow that *ſcabious* was unknown.

Dioſcorides and Theophraſtus have deſcribed a plant called *pſorice*, from its virtues in curing cutaneous eruptions; and this agrees, in all reſpects, in figure, as well as qualities with our *ſcabious*. The later Greek writers have called this *pſora*, and thus it ſtands in Aëtius, and many others.

In times long after theſe, however, the names were forgot, though the plant and its virtues remained well known; the modern Greeks willing to deſcribe ſo uſeful a plant, but ignorant of its name, in their own language, called it *ſcampiuſa*, a name formed out of the Latin word *ſcabioſa*, by the common change of *b* into *mp*, and *o* into *u*. This was long retained in uſe; and as it was common with the Greeks to leave out the initial letter, *ſ*, in many words, ſo they ſometimes wrote this *campiuſa*.

Fuchſius, who was very deſirous of underſtanding the writings of Myrepſus, confeſſes, that he knew not what to make of the words *ſcampiuſa* and *campiuſa*, which he ſo frequently met with in that author; but though he gives no deſcription of the plant, the virtues he attributes to it are thoſe of *ſcabious*; and the names are ſo eaſily diſcovered to be derived from the Latin *ſcabioſa*, that there is no room for doubt of its being the ſame plant.

SCABROUS *leaf*, among botaniſts. See LEAF.

SCABROUS *ſtalk*. See the article STALK.

SCAD, the Engliſh name of a fiſh of the cuculus kind, reſembling the mackrel in ſhape, called by writers the *trachurus*. *Willughby*'s Hiſt. Piſc. p. 290. See TRACHURUS.

SCÆNANTH, or SCHÆNANTH, in the materia medica, the dried ſtalk of a plant brought to us from Arabia.

This plant is called, by the generality of botaniſts, *juncus odoratus* and *aromaticus*; but Linnæus gives it the name of *iſchæmum*, under which head its botanical characters are deſcribed. See ISCHÆMUM.

The ſtalk is uſually eight or ten inches in length, ſometimes conſiderably more; it is ſmooth and gloſſy on the ſurface, and about the thickneſs of a wheat-ſtraw, but much more rigid and firm. It is round, jointed, and not ſolid, but has a cavity in it filled with a central pith like that of our common ruſhes. Its colour is yelloviſh at the baſe, or toward the root, but toward the top it is purpliſh or greeniſh; it is very light, yet conſiderably hard, and is of a fragrant or aromatic ſmell, in which we may diſcover ſomething of a mixed ſcent, between that of the roſe and penny-royal. Its taſte is acrid and bitteriſh, but not unpleaſant.

It ſhould be choſen freſh, ſound, and clean, not duſty or decayed, of a good ſmell and ſtrong acrid taſte. *Hill*, Hiſt. Mat Med. p. 413.

The word *ſchænanth* ſignifying the flower of the ruſh, might naturally lead us to ſuppoſe, that what we now receive under that name, is not the drug that was ſo called by the antient Greeks and Romans, and ſome have very vigorouſly ſupported this opinion. But on enquiry into the Grecian materia medica, we find that none of their *ſchænanth* had flowers on it any more than ours.

Among the moderns, Garcias tells us, that though he bought up vaſt quantities of this drug in the Indies to ſend into Portugal, he never ſaw ſo much as one flower upon any of it; and among the antients Galen makes the very ſame obſervation. He ſays he wonders how this drug obtained the name of *ſcænanth*, for that he never met with any one piece that had a flower upon it. The reaſon alledged for this is very frivolous and trifling; namely, that the camels of that part of the world where it grew, cropped off the tops, and with them the flowers; but among the vaſt quantities of this drug, at one time or other ſent, there would be found ſome that had eſcaped the mouths of theſe creatures, and have preſerved its fine flowers, had it any ſuch as are aſcribed to it; ſo that the opinion advanced, by ſome, of its having flowers like roſes, is wholly falſe and groundleſs.

Anthos was a word uſed by the Greeks, as its Engliſh flower is, to ſignify the moſt perfect, or beſt of any kind of thing. We call the fineſt ſpecies of any thing the flower of it, and thus they called the fineſt gold the anthos and anthimion of gold, in the ſame manner this ruſh was called *ſcænanth*, or the flower of ruſhes, not for its being full of flowers, but for being the moſt excellent and valuable of all kinds of ruſhes.

The very oldeſt among the Greek writers do not uſe the term *ſcænanth*, but they call this drug *juncus aromaticus*, or *juncus odoratus*, σχοινον ἀρωματικον, and σχοινον ἐυωδη. are the names it goes by. Hippocrates calls it by the latter of theſe names; and Meleager, though he mentions it as an herb to be put into the poets crowns, yet ſays nothing of any flowers it has, but recommends it for its fragrant ſmell.

The antients uſed the whole plant in medicine, ſtalk, leaves, and flowers; its virtue reſiding pretty equally in every part of it, as is manifeſt from every part's poſſeſſing the ſame ſmell and taſte, and having the ſame pungency in the mouth. They preſcribed it as a deobſtruent and promoter of the menſes, but at preſent it is never heard of in extemporaneous preſcription, only kept as an ingredient in ſome compoſitions. Id. ibid.

SCALARE, in natural hiſtory, a name given by Rumphius to a peculiar ſpecies of *turbo*, or *ſcrew ſhell*; the ſeveral wreaths of which having an opening between them form an open ſpiral. See TURBO.

SCALE, (*Cycl.*)—Many have been the diſputes among antient and modern muſicians, about the conſtitution of muſical *ſcales*. Some of the antients, with Euclid, will have it compoſed of tones major, and limma's; ſo that the ſeven intervals of an octave would be thus expreſſed, $\frac{9}{8}$, $\frac{256}{243}$, $\frac{9}{8}$, $\frac{9}{8}$, $\frac{256}{243}$, $\frac{9}{8}$, $\frac{9}{8}$. Some modern authors have from hence inferred the imperfection of the Greek muſic. They alledge, we here find the ditonus, or an interval equal to two tones major

major expreſſed by $\frac{81}{64}$, inſtead of the true third major expreſſed by $\frac{5}{4}$. As there can be no queſtion of the beauty and elegance of the latter, the former therefore muſt be out of tune by a whole comma, which is very ſhocking to the ear. In like manner, the trihemitone of the antients falls ſhort of the third minor by a comma; which is alſo the deficiency of their hemi-tone, or limma, from the true ſemi-tone major, ſo eſſential to good melody. All which errors would make their *ſcale* appear much out of tune to us. A late learned author [a] ſays he readily grants the objection, but adds, that ſuch a *ſcale* alſo appeared out of tune to the antients themſelves; ſince they expreſsly tell us, that the intervals leſs than the diateſſaron, or fourth, as alſo the intervals between the fifth and octave, were diſſonant, and diſagreeable to the ear. Their *ſcale* here mentioned, and called by ſome *ſcala maxima*, was not intended to form the voice to ſing accurately, but was deſigned to repreſent the ſyſtem of their *modes* and *tones*, and give the true fourths and fifths of every key a compoſer might chooſe. Now if inſtead of tones major and limmas we take the tones major and minor, with the ſemi-tone major, as the moderns contend we ſhould, we ſhall have a good *ſcale* indeed, but a *ſcale* adapted only to the concinnous conſtitution of one key; and whenever we proceed from that into another, we find ſome fourth or fifth erroneous by a comma. This the antients did not admit of. If to diminiſh ſuch errors, we introduce a temperature, we ſhall have nothing in tune but the octave: ſo that this *ſcale* of the antients was not deſtitute of reaſon, and no good argument againſt the accuracy of their practice can from thence be formed [b].—[[a] Dr. *Pepuſch*, ap. Philoſ. Tranſ. N° 48. p. 268. Ibid. p. 269.]

The names of the notes of the Greek *ſcale*, ſee under the head DIAGRAM.

Hour SCALE. See the article HOUR.

SCALES, in natural hiſtory. What the naturaliſts underſtand by *ſcales*, are certain flat and ſemipellucid bodies, common to the fiſh, the ſerpent, and the lizard kind; conſiſting of a ſubſtance ſomewhat analogous to that of the horns and hoofs of other animals, as is found by cutting and burning them, and by their ſmell.

The *ſcales* in fiſhes are of ſo many different kinds and ſhapes, that they afford, in many caſes, very good characters for the diſtinction of the ſpecies. The differences of theſe parts of fiſh ariſe from their number, ſituation, figure and proportion, and to ſome other qualities peculiar to a few of them. Their differences, in regard to number, are theſe. There are none on ſeveral kinds of fiſh, as on the petromyza, the dolphin, and the whales. Upon ſome other fiſhes they are but very few in number, as on the conger, the eel, the clariæ, *&c.* And they are on others found in vaſtly great numbers, and placed in cluſters one over another, as in the pearch, ſalmon, *&c.*

In regard to their ſituation they differ in theſe particulars. 1. On ſome fiſh they are placed extremely thick and cloſe upon one another. 2. In others they ſtand in imbricated rows. The eſoces give us an example of the firſt, and the cyprini, in general, of the ſecond kind. And 3. in ſome they are ſcattered, and at ſuch diſtances, that they do not touch one another; as in the congers, the eels, the clariæ, *&c.* Their differences in figure are not leſs evident than thoſe in poſition. 1. Some are roundiſh, as thoſe of the clupeæ and ſalmons. 2. Some are oval, or of an oblong round figure, as thoſe of the gadi. 3. In ſome fiſh they are ſtrait on one ſide, and rounded on the others, as in the pearch and mullet. The proper deſcription of theſe is, that they have a rectilinear baſe, and rounded ſides.

Their differences in proportion are theſe; they are either in regard to one another, or to the *ſcales* of other fiſhes, or according to our ſenſes, in regard to the ſize of the fiſh, either very large, great, ſmall, middling, or extremely minute. Theſe are words, which give a ſort of uſeful idea in the deſcription, though they are far from being determinate or regular in their ſignifications. As to the other peculiar qualities of the *ſcales* of fiſhes, they are in ſome ſoft and ſmooth, as in the ſalmon and cyprini; and in others hard and rough, and as it were a little prickly: of this ſort are the *ſcales* of the pearch, the capriſcus, and ſome of the pleuronecti. *Artedi*, Ichthyol.

Scales of fiſhes make a ſet of very curious objects for the microſcope; they are formed with a ſurpriſing beauty and regularity, and in the different kinds exhibit almoſt an endleſs variety in their figure and contexture. Some are longiſh, ſome round, ſome triangular, and ſome ſquare; and there are others of all the ſhapes that can well be imagined. Again, ſome are armed with ſharp prickles, as thoſe of the ſoal and pearch; others have ſmooth edges, as thoſe of the cod, tench, carp, *&c.* and there is a great variety even in the *ſcales* of the ſame fiſh; for the *ſcales* of the back, belly, ſides, and head, are all different in ſhape and arrangement: theſe bear a very great analogy to the feathers, as they are called, on the wings of butterflies.

Theſe *ſcales* are not ſuppoſed to be ſhed every year, nor during the whole life of the fiſh, but to have an annual addition of a new *ſcale* growing over, and extending every way beyond the edges of the former, in proportion to the fiſhes growth; ſomewhat in the manner as the wood of trees encreaſes annually, by the addition of a new circle next the bark. And as the age of a tree may be known by the number of ringlets its trunk is made up of, ſo in fiſhes, the number of plates compoſing their *ſcales* denote to us their age. It is alſo probable, that as there is a time of the year when trees ceaſe to grow, or have any farther addition to their bulk, the ſame thing happens to the *ſcales* of fiſhes; and that afterwards, at another time of the year, a new addition, encreaſe, or growth begins.

Mr. Lewenhoek took ſome *ſcales* from an extremely large carp, forty two inches and a half long, Rynland meaſure, which were as broad as a dollar; theſe he macerated in water, to make them cut the eaſier, and then cutting obliquely through one of them, beginning with the firſt formed, or very little ſhell in the center, he by his microſcope plainly diſtinguiſhed forty lamellæ, or *ſcales*, glewed as it were to one another; whence he concluded the fiſh to be forty years old.

It is generally imagined that an eel has no *ſcales*; but if the ſlime be wiped clean away, and the ſkin then examined by a microſcope, it is found covered with extremely ſmall *ſcales*, ranged in a very orderly and pretty manner; and probably very few fiſhes, except ſuch as have ſhells, are truly free from *ſcales*.

The way of preparing *ſcales* for the microſcope is to take them off carefully with a pair of nippers, waſh them very clean, and then place them between the leaves of a book to make them dry flat; and when thoroughly dry, they are to be put between two ſlips of talc. The ſnake, viper and eft afford alſo a very beautiful and very different ſeries of *ſcales* from thoſe of fiſhes. *Baker*'s Microſcop. p. 237. *Lewenhoek*'s Arc. Nat. Tom. 3. p. 214.

SCALENI, (*Cycl.*) compound muſcles irregularly triangular. The antients call them only two in number; afterwards they were divided into ſix, three lying on each ſide, but uſually there are only two on each ſide, one lying upon the other.

The firſt, or *ſcalenus primus*, is fixed to the upper parts of the outſide of the firſt rib by two portions, commonly called its anterior and poſterior branches; the anterior is fixed to the middle portion of the rib, about an inch from the cartilage; and the poſterior more backward in the firſt rib, an interſtice of about an inch being left between it and the other branch; and they are both, at their other extremities, inſerted in the tranſverſe apophyſes of the vertebræ of the neck.

The ſecond, or *ſcalenus ſecundus*, is fixed a little more backward in the external labium of the upper edge of the ſecond rib; ſometimes by two ſeparate portions; and ſometimes without any diviſion. The anterior portion is fixed immediately under the poſterior portion of the firſt *ſcalenus* by a ſhort flat tendon, and is afterwards fixed by inſertions, partly tendinous, and partly fleſhy, in the tranſverſe apophyſes of the four firſt vertebræ of the neck. The poſterior portion is fixed in the ſecond rib, more backward than the other, and from thence is divided into two portions, and runs up to the tranſverſe apophyſes of the vertebræ of the neck; where the firſt is inſerted in the three firſt vertebræ, the other only in the two firſt. The vertebral inſertions of both the *ſcaleni* vary, being ſometimes confounded with each other, and ſometimes with thoſe of the neighbouring muſcles. *Winſlow*'s Anatomy, p. 230.

SCALENUS *lateralis*, in anatomy, a name given by Albinus to a muſcle, called by Cowper and others *ſcalenus ſecundus*, and by Winſlow, and the French anatomiſts, *portion anterieur du ſeconde ſcalene*. Morgagni calls it *ſcaleni pars a coſta ſecunda enata*; and Fallopius deſcribes it under the name of *octavi thoracis muſculi pars quæ inſeritur in ſecundum.*

SCALENUS *medius*, in anatomy, a name given by Albinus to a muſcle called the ſecond *ſcalenus* by Douglaſs, and the third *ſcalenus* by Cowper. The French call it by the name given by Winſlow, *la portion ou branche poſterieure du premier ſcalene*; and Veſalius has deſcribed it under the name of *pars tertii et quarti dorſum moventium.*

SCALENUS *minimus*, in anatomy, a name given by Albinus to a very ſmall muſcle, which other writers on this ſubject have omitted to deſcribe, and which the author acknowledges to be ſometimes wanting.

It is very ſmall, and ariſes from the upper edge of the firſt rib, and has two caudæ; the one of which is inſerted into the lower part of the ſpine, and the other a little higher. It often wants one, and ſometimes the other, or latter of theſe two caudæ, and is of the ſame uſe with the other *ſcalenus*.

SCALENUS *poſticus*, in anatomy, a determinate name given by Albinus to one of the *ſcaleni*, too much confounded by other authors with the reſt of the muſcles of that name, as they are in general with one another.

This is the muſcle deſcribed by Fallopius under the name of the *nonus thoracis muſculus*, and by Morgagni under the name of the *ſcaleni pars a ſecunda coſta enata*. The French call

call it *la portion poſterieure du ſecond ſcalene*; a name given it by Winſlow.

SCALLION, or ESCALLION, a ſort of onion which never forms any bulb at the root, but is uſed green in ſpring, before the other ſorts ſown in July are large enough.

This is however very ſcarce in London, the gardiners uſually ſelling in its place the ſhoots of ſuch decayed common onions, as have ſprouted in the houſe. Theſe they plant in a bed early in the ſpring, and they ſoon grow large enough for uſe, when they pull them out; and taking off all the old outer coat of the roots, they lay them in bunches, and ſell them at market for *ſcallions*.

The true *ſcallion* is eaſily propagated by parting the roots in autumn, and planting them three or four together in a hole, at ſix inches diſtance. Theſe will grow in any ſoil or ſituation, and will multiply very quickly, and in a very great abundance; and their being hardy enough to endure the ſevereſt winter, and fit for uſe ſo early in ſpring, makes them worthy a place in all kitchin gardens. *Miller*'s Gardner's Dictionary.

SCALLOP. The anatomy of this fiſh lets us greatly into the knowledge of the ſtructure of the parts of other bivalve ſhell fiſh.

The *ſcallop* is compoſed of two ſhells, which, as in many others, are one concave, and the other plane or flat. The cardo, or hinge, is lightly bent from the concave ſhell, and thence carried over a part of the plane ſhell, and all the way between it is firmly connected to a cartilage. In the middle of the length of the cardo there is placed another ſhort, black, and very ſtrong cardo.

It is eaſy to ſee, from hence, to what is owing that remarkably ſtrong power, which this creature has of ſhutting and opening its ſhell; and it is very poſſible, that by means of ſo ſtrong an apparatus of tendons or ligaments as it has in this part, it may be able to move the plane ſhell in ſo ſwift and regular, as well as forcible and eaſy a manner, that it may uſe it in moving from place to place; and poſſibly it may make a ſort of wing of it, to beat againſt the water, as the pinion of a bird does againſt the air; and what the antients have ſo frequently ſaid of its moving about in a very ſwift manner, from place to place, may be true, though we have been wanting in later obſervations to ſee it.

When the two ſhells are opened, the following particulars offer themſelves to the view. Firſt, the mouth: this is covered with a ſort of membranous hood, as in the oiſter; it does not ſtand on the center of the head, but toward the right hand, and the covering is only an elongation of the branchiæ, or gills of the fiſh: theſe are of a membranous nature, and ſurround the whole body from the mouth to the anus, which ſtands toward the left hand from the mouth, where they are connected again.

That branchia of the exterior pair, to which the flat or plane ſhell adheres, is fixed in its center to an immenſely ſtrong muſcle, which grows from the ſhell, and is fixed into the body of the fiſh at right angles: this branchia is fixed to the upper limb of that muſcle, and the other branchia is, in like manner, connected to the lower limb of the ſame ſtrong muſcle. Theſe two exterior, or ſpurious branchiæ, from this muſcle to a conſiderable extent, are formed only of a thin and pellucid membrane, and being carried to the middle of the valves on each ſide, they are there fixed down in ſuch a manner, that they cannot be removed by any means, without injuring or deſtroying them.

The uſe of theſe is to defend the body of the animal from the injuries of the water, and other ſubſtances let in with it, on the opening of the ſhell. From the place of this adheſion there is propagated a ſtrong and thick muſcle, of a truly wonderful ſtructure; this is a ſort of limb, or verge to the animal. It is contracted inward when the animal is dead, but while it is alive it is expanded, at the creature's pleaſure, a great way out beyond the edges of the ſhell, and is jagged, and variegated with lines and ſtreaks, in an amazing and elegant manner.

The uſe of this part ſeems eaſily gueſſed, it being, when expanded out at the mouth of the ſhell, a ſort of net, for the catching whatever the creature chuſes to feed upon. It is, at the pleaſure of the animal, either laid flat on the ſurface of the mud or rock, or arched into a part of a circle: when in any of theſe poſitions, any thing comes in its way which is proper food for the creature, it immediately gathers up like a net round about it, and withdrawing itſelf into the ſhell, takes in the prey with it. In this caſe, the uſe of its being cut or fringed, is alſo plainly ſeen; for it can, by means of this ſtructure, let out the water taken in with the prey through the jags, and yet retain the prey itſelf. Philoſ. Tranſ. N° 229. p. 567.

The uſe of this admirable muſcle, is not only the ſerving as a net for the taking the food, and afterwards as a ſtrainer for the ſeparating the water from it, but its muſcular force is ſo great, that it alſo ſerves as a weapon of death to the little animal it has ſeized, by compreſſing it to pieces if neceſſary, at leaſt by ſqueezing it till no life remains. This is a very neceſſary article in the preying of an animal, which can neither follow or reſiſt an animal in motion; but this is not all. When the prey is brought into the ſhell, it might there remain, where firſt laid down, without being of any uſe to the *ſcallop*, who cannot turn about her mouth to come to it: in this caſe the ſame wonderful muſcle, by its undulatory motion, ſerves to convey the prey to a part of the ſhell nearer the mouth of the animal; and when there, taking it up between the jags of the fringe, it holds it to the opening of the mouth; in this laſt office ſerving in the place of a hand. Theſe are the many and neceſſary uſes of this part.

But to come to the branchiæ, or gills, properly ſo called. The true branchiæ are four in number; they are of a yellowiſh colour, and are fringed in a very elegant manner: theſe every way ſurround the great central muſcle, and ſerve as a covering to the uterus of the animal, or its ovary; certainly, however, to the parts of generation, by whatever name they may be called.

The lower part of the body of the *ſcallop* is yellow, and its upper part white, and near its mouth there is very plainly to be diſcovered a proceſs with a double aperture. It ſeems probable, from all obſervation, that the *ſcallop* is an hermaphrodite animal, and contains the parts of generation of both ſexes in each individual; and it appears that the female part of generation is, on occaſion, puſhed out from one of theſe apertures, and the penis, or male part, from the other.

The mouth of the *ſcallop* is furniſhed with reddiſh lips, reſembling the branchiæ, or gills, in their ſtructure, but very ſhort and ſmall; and near the hinge there are two large circular cavities, reſembling the eyes of the turbot. Near the head there is a large maſs of blackiſh matter toward the left hand, and under that, or rather behind it, is ſituated the creature's heart. The pericardium is pellucid, and is of ſo fine a ſtructure, that the heart is eaſily ſeen through it: it is of a reddiſh colour, and its aorta, or large artery, is divided into a great number of branches, which are ſent every way round to the gills.

It is ſome doubt, however, whether this their membrane, before deſcribed, ſerves alone in the capacity of a pericardium; or whether all this black matter, that lies about it in a ſort of rhombic form, does not alſo, in ſome degree, ſupply that office. The lower part of this gives place to the urinary bladder, and the ſtrait gut ariſes from the baſe of this black ſubſtance, and is thence carried ſtrait over the pericardium; whence it runs on to the branchiæ, and is at length affixed to the great central muſcle.

This central muſcle is of a rounded figure, very ſmooth, and white, and even in the greater part of its bulk, where it is connected to the ſhell; but on the left it is divided, and forms another white and lacerated muſcle, which runs along a part of the ſhell, and ſtrengthens the connection of the body of the fiſh with this part of the plane valve. Philoſ. Tranſ. N° 229. p. 569.

SCALMUS, among the Romans, a block or round piece of wood in a boat, to which the oars were tied with a thong of leather called *ſtrappus*. See the article STRAPPUS.

Scalmus was alſo uſed to denote the boat, a part being taken for the whole. *Pitiſc.* in voc.

SCALPRA *dentalia*, inſtruments uſed by the ſurgeons to take off thoſe black, livid, or yellow cruſts, which infeſt the teeth, and not only looſen and deſtroy them, but taint the breath.

According to the varieties of the occaſion, the ſurgeon has theſe inſtruments of various ſhapes and ſizes; ſome are pointed, and narrow at the end, others are broader pointed, and have edges, others are hooked, or falciform, but theſe are uſually, for convenience of carriage, all adapted to one handle.

The manner of uſing them is to begin near the gums, ſupporting the blade with the left hand, and ſcraping all along the tooth, till the cruſt is taken off, taking care not to wound the gums, or diſplace the teeth. *Heiſter*'s Surgery, p. 456.

SCAMMA, Σκαμμα; among the Greeks, the mark in leaping, or throwing quoits; ſo called, from its being made by digging up the earth. *Potter*, Tom. I. p. 442.

SCAMMATHA, in the Jewiſh cuſtoms, a kind of excommunication, and the moſt terrible of all in uſe among that people. See the article NIDDUI.

SCAMMONY (*Cycl.*)—SCAMMONIA *Monſpeliaca*, *Montpelier ſcammony*, a name given by ſome botanical writers to a ſpecies of periploca, diſtinguiſhed by Mr. Tournefort by the name of *periploca Monſpeliaca foliis rotundioribus*.

SCAMPIUSA, in botany, a name uſed by Myrepſus and others for a plant, which they greatly recommend in the itch, and other cutaneous diſorders.

Fuchſius confeſſes himſelf at a loſs to gueſs what plant was meant by this name; but a little knowledge of the cuſtoms of the later Greeks, in adopting the Roman names for things, would have explained this to him. We find, by familiar inſtances without number, that in the words they adopted from the Latin, they uſually changed the *o* into *u*, and the Roman *b* into *mp*. If we look upon the word *ſcampiuſa* in this light, ſuppoſe it formed from a Roman word,

word, as moſt of the names of plants at that time were, and change the *u* into an *o*, and the *mp* into *b*, we immediately bring back the word to *ſcabioſa*; a very well known Latin word, and the name of a plant poſſeſſed of the ſame virtues they have given to the *ſcampiuſa*.

They ſometimes alſo wrote this *campiuſa*, without the initial *ſ*; but this cannot appear wonderful, when we recollect that the *milax* was in the ſame manner *ſmilax*, and the *ſmaragdus* was written *maragdus*, even by the antient Greeks themſelves.

SCANDIACA, in botany, a name given by ſome authors to the white flowered *lamium*, called archangel by others. *C. Bauhin*, Pin. 155. See LAMIUM.

SCANDULÆ, in antient houſe building, ſhingles, or flat pieces of wood, uſed by the Romans inſtead of tiles to cover houſes. This, according to Cornelius Nepos, was the only covering uſed in Rome till the war with Pyrrhus, or 470th year of the city. *Pitiſc.* in voc.

SCANDULARII, among the Romans, mechanics who prepared the *ſcandulæ* uſed in covering houſes, who were exempted from all public ſervices. See SCANDULÆ.

SCANDYX, *venus comb*, in botany, the name of a genus of plants of the umbelliferous kind, the characters of which are theſe. The flower is of the roſaceous kind, conſiſting of ſeveral petals, which are arranged in a circular order on a cup, which afterwards becomes a fruit compoſed of two oblong bodies, reſembling needles, and containing the ſeeds.

The ſpecies of *ſcandyx*, enumerated by Mr. Tournefort, are theſe. 1. The common *ſcandyx* with roſtrated ſeeds. 2. The larger Cretic *ſcandyx*. And 3. the ſmaller Cretic *ſcandyx*. *Tourn.* Inſt. p. 326.

SCANELLO, in the Italian muſic, is uſed for the bridge in violins and other inſtruments. It is the ſame with *ponticello* and *magas*. See the articles BRIDGE and MAGAS.

SCANSOR, in ichthyology, a name given by Geſner to the fiſh called by the generality of writers *lupus piſcis*. See the article LUPUS.

SCANTON, a word uſed by ſome to expreſs the fetid ſmell of wine.

SCAPE *goat*, in the Jewiſh antiquities, the goat which was ſet at liberty on the day of ſolemn expiation. For the ceremonies on this occaſion, ſee Levit. xvi. 5, 6, &c.

Some ſay that a piece of ſcarlet cloth, in form of a tongue, was tied on the forehead of the *ſcape goat*. *Hofm.* Lex. univ. in voc. *Lingua*.

Many have been the diſputes among the interpreters, concerning the meaning of the word *ſcape goat*, or rather of *azazel*, for which *ſcape goat* is put in our verſion of the Bible.

Spencer is of opinion that *azazel* is a proper name, ſignifying the devil, or evil dæmon. See his reaſons in his Book de leg. Hebr. ritual. Diſſert. viii. Among other things he obſerves, that the antient Jews uſed to ſubſtitute the name *ſamaël* for *azazel*, and many of them have ventured to affirm, that at the feaſt of expiation they were obliged to offer a gift to *ſamaël* to obtain his favour. Thus alſo the *goat*, ſent into the wilderneſs to *azazel*, was underſtood to be a gift or oblation. Some Chriſtians have been of the ſame opinion. But Spencer thinks that the genuine reaſons of the ceremony were, 1. That the *goat* loaded with the ſins of the people, and ſent to *azazel*, might be a ſymbolical repreſentation of the miſerable condition of ſinners. 2. God ſent the *goat* thus loaded to the evil dæmons, to ſhew that they were impure, thereby to deter the people from any converſation or familiarity with them. 3. That the *goat* ſent to *azazel* ſufficiently expiating all evils, the Iſraëlites might the more willingly abſtain from the expiatory ſacrifices of the Gentiles.

SCAPHA, in anatomy, is uſed to expreſs the external circumference of the ear.

It is in ſurgery uſed to expreſs a bandage for the head. See the article BANDAGE.

SCAPHEPHORI, Σκαφηφόροι, among the Athenians, an appellation given to the ſtrangers reſiding among them, becauſe they were obliged, at the feſtival Panathenæ, to carry little ſhips, called *ſcaphæ*, σκαφαι, which were a ſign of their foreign extraction. *Potter*, Archæol. Græc. Tom. I. p. 56.

SCAPHIUM, among the Romans, a cup of an oblong form, ſomewhat reſembling that of a boat, whence alſo it had its name. *Pitiſc.* in voc.

Scaphium likewiſe ſignifies a kind of dial, which, beſide the hours, ſhewed alſo the ſolſtices and æquinoxes. *Pitiſc.* Lex. Antiq. in voc.

SCAPHOIDES *os*, *(Cycl.)* in anatomy, the firſt bone of the firſt row in the carpus. It has its name from the Greek σκαφη, a boat, is ſometimes called *os naviculare* in Latin for the ſame reaſon, as ſuppoſed to reſemble a little boat. It has a convex ſide next the radius, by which it is articulated with the baſis of that bone, and with a tubercle, which is one of the four eminences on the concave ſide of the carpus. Toward the thumb it has two half ſides, one large one for the os trapezium, and the other a ſmall one for the os trapezoides. It has likewiſe a hollow ſide for the os magnum, and a ſmall ſemilunar ſide for the os lunare. Its inner and outer ſurfaces are rough. *Winſlow*'s Anatomy, p. 83.

SCAPHOIDES *tarſi*. This bone, which is called alſo *naviculare*, from its reſemblance to a ſmall flat boat, lies before the aſtragalus. It has two cartilaginous ſides, an oval circumference, and a tuberoſity. Its thickneſs is inconſiderable, when compared with its other dimenſions, and it lies as it were on its ſide, before the aſtragalus. The concave ſide is poſterior, and is articulated with the anterior convex ſide of the aſtragalus. The anterior convex ſide is divided by two ſmall lines into three planes, for the articulation of the three oſſa cuneiformia. The circumference forms an oval, which contracts by ſmall degrees, and terminates in an obtuſe point: one ſide of this circumference is more convex and rough than the other, and the inequalities in it ſerve for the inſertion of ligaments. The points of the oval ends in a tuberoſity, marked with a muſcular impreſſion. In the natural ſituation of this bone, the moſt convex ſide is uppermoſt, the other loweſt, and the tuberoſity turned inward and downward. By this ſituation, and the difference of the ſides, it is eaſy to diſtinguiſh the os naviculare of the right foot from that of the left. The ſmaller, or inferior convexity of the circumference has, near the tuberoſity, a ſuperficial notch, and on the oppoſite ſide a ſmall cartilaginous ſurface, and a ſmall tubercle for its articulation with the os cuboides, &c. for the inſertion of ligaments. *Winſlow*'s Anatomy, p. 98.

SCAPULA *(Cycl.)*—This is a large bone, ſituated laterally at the upper and poſterior part of the thorax, from about the firſt rib down to the ſeventh. The neck of the *ſcapula* is the largeſt of its three angles, and ought more juſtly to be called a head with a very ſhort neck, and a ſuperficial, or glenoide cavity in the top of it, which is lined with a cartilage, and of an oval figure, but pointed at the upper part, and rounded at the lower; and is much deeper in the natural ſtate, than when viewed in the ſceleton. In the natural ſituation of the *ſcapula* this cavity is turned obliquely forward, and not directly outward. Between the edge of this cavity and the contracted part, which is the true neck, ſome inequalities are obſervable, which are the remains of the ſymphyſis of oſſification. Above and below the glenoide cavity are two ſmall rough marks, or impreſſions, the loweſt of which extends itſelf a little over the neighbouring coſta. Theſe may be termed the muſcular impreſſions of the neck of the *ſcapula*. In the neck, ſpine, baſis, inferior coſta, and coracoide proceſs of the *ſcapula*, there is a diploe; the reſt of the bone is tranſparent, thin, and almoſt without any middle cellular ſubſtance. The *ſcapula* is articulated with the clavicle by the acromion, and with the os humeri by the glenoide cavity: it is likewiſe joined to the trunk by a fleſhy ſymphyſis, or ſyſſarcoſis. It ſerves to facilitate the motions of the arm, to give inſertion to a great many muſcles, and as a ſhield to defend the back parts of the thorax. *Winſlow*'s Anatomy, p. 73.

Fracture of the SCAPULA. The *ſcapula* is uſually fractured either near its acromion, or head, where it joins the clavicle, or in ſome more diſtant part. If the fracture happens in the proceſs of the acromion, the reduction will be eaſily made, by lifting up the arm to relax the deltoide muſcle, and puſhing the arm evenly upwards, making the fractured parts meet together with the fingers: but notwithſtanding their reduction is ſo eaſy, they eaſily ſlip away again from any ſlight cauſe, and ſo are difficultly agglutinated. They are in particular very eaſily ſeparated by the weight and motion of the arm, and by the contraction of the deltoide muſcle; inſomuch that there is ſcarce ever an inſtance of a fractured acromion being ſo perfectly cured, as to admit afterwards of a free motion of the arm upwards: all means muſt, however, be uſed to endeavour to keep the replaced bones in their proper ſituation. A compreſs, wet with ſpirit of wine, is to be applied to the fracture, a ball is to be put under the arm-pit to ſupport it; the whole is to be bound up with the bandage commonly called *ſpica*, and the arm is to be ſuſpended in a ſaſh or ſling hung about the neck. But if the neck of the *ſcapula*, which lies under the acromion, or its acetabulum, ſhould be fractured, which is a caſe that indeed very ſeldom happens, and when it does is very difficult to diſcover, it is a hundred to one but from the vicinity of the articulation, the tendons, muſcles, ligaments, nerves, and large veins and arteries, there will follow a ſtiffneſs and loſs of motion in the joint; great inflammation is alſo to be expected, and abſceſſes with the worſt ſymptoms, and ſometimes death itſelf.

SCAPULAM *antrorſum agens*, in anatomy, a name given by Veſalius, and ſome of his followers, to the muſcle generally known under the name of the *ſerratus anticus*. He has alſo, in another part of his work, called it *primus ſcapulam moventium*. Riolanus has called it the *ſerratus minor*, and ſeveral other authors the *ſecundus ſcapulæ*. See the article SERRATUS.

SCAPULAM *attollens*, in anatomy, a name given by Spigelius to a muſcle, which he alſo calls *muſculus patientiæ*. It is the *levator ſcapulæ* of Albinus and Cowper.

SCAPULAM *moventium ſecundus*, in anatomy, the name given by Veſalius to a muſcle, called by Winſlow and ſome others the

the *trapezia*, and by Albinus the *cucullaris*. Cowper calls it the *trapezius*, or *cucullaris*. See TRAPEZIUS.

SCAPUS, among botaniſts, a peculiar kind of ſtalk, which ſupports the parts of fructification of a plant. It does not grow from any part of the main ſtalk, but riſes immediately from the root. See STALK.

SCAR *crow*, in zoology, the name of a bird of the *larus*, or ſea gull kind, called by authors *larus niger*, or the black gull, and by the Germans *brandvogel* and *meyvogel*. It is a very long winged bird, and is all over black, and of the ſize of the common blackbird. Its legs are ſhort and red. It is common about the ſea coaſts, and feeds on inſects. It is a well taſted bird. *Ray*'s Ornithol. p. 296.

SCARABÆUS, the *beetle*. This is an extremely numerous genus of inſects; and in order to have a diſtinct idea of the differences of the ſpecies, they are arranged by Liſter into a ſort of method. The firſt general diſtinction is into thoſe which live on land, and thoſe which live in the water; of each of which there is a very great number. Thoſe *beetles* which live on land have ſome of them antennæ laminated at the end, others have them ſharp pointed. The outer wings, or caſes of the wings, in ſome are perfect, in others they ſeem mutilated. Some have the antennæ inſerted into a ſort of promuſcis. Theſe were called by the antients *gurguliones*, and in ſome there is only one juncture in this, in the middle, in others ſeveral near the end. Some have a ſharp pointed inſtrument at their head; theſe are called *cimices*. See the article CIMEX.

Of the water *beetles* there are two principal kinds, one ſort living in ſalt water, the other in freſh.

Of thoſe *beetles*, the extremity of whoſe antennæ are formed like a comb, there are ten ſpecies mentioned by Mr. Ray. 1. The great reddiſh *beetle* with the tail bending downwards, known among us under the name of the *chaffer*. This is too well known to need a deſcription; it is common among trees and buſhes at the end of May, and ſeems particularly fond of the maple. 2. The greyiſh yellow woolly *beetle*. This ſeems nearly allied to the former ſpecies, but is but about half as big. Theſe are very common in the ſouthern parts of England in the month of June; they fly about elms in vaſt ſwarms; they are very rare in the northern counties. 3. The greeniſh black *beetle* with reddiſh brown caſes of the wings. This is of the ſize of a horſe bean, and is found among roſe trees in May. 4. The great purpliſh black *beetle* with ſerrated legs. This is one of our largeſt *beetles*, and is very common on heaths, and in other places, in the month of March; it flies about in the evening, and makes a great noiſe; it is uſually infeſted with a great number of yellow lice, and is thence called the *louſy beetle*. 5. The large black *beetle* with two yellow undulated faſciæ on the caſes of the wings. This is ſometimes found without the faſciæ; it ſometimes flies, but rarely. It is found about human dung, and probably feeds on it, for it has always a very ſtrong ſcent of it. 6. The green *beetle* with red caſes for the wings. This is about the ſize of a horſe bean, and is found in woods in the month of June. 7. The ſmall *beetle*, called the *lady bird*. 8. The *lady bird* with only two large black ſpots, one on each of the caſes of the wings. This is common among buſhes in the beginning of June. 9. The yellow *beetle* with black ſpots. This is much ſmaller than the lady bird; its colour is a pale yellow, or lemon colour, and it has four black ſpots, of an oblong ſquare figure, on the caſes of the wings. 10. The reddiſh *beetle* with two ſpots on the ſhoulders, and ſeven white marks on each of the caſes of the wings. This is about the ſize of the common lady bird, and is found in June near rivers, among the ruſhes, and in cyperus graſſes. *Ray*'s Hiſt. Inſect. p. 384.

Of thoſe *beetles* which have antennæ terminating in ſlender points, there are a great number of ſpecies, which may be ſubdivided into ſome other general claſſes: ſome of them have whole and perfect caſes to their wings, and have long horns; theſe are by ſome called *capricorn beetles*; of theſe there are ſeveral ſpecies. See the article CAPRICORN.

Some *beetles* are covered with a very hard cruſt, and have ſcarce any wings underneath it. Theſe are generally very ſlow creepers, and of theſe we have in England three ſpecies. 1. The ſhort purpliſh black *beetle* with gibbous ſhoulders. This ſeems to be the ſame with the *cat beetle*, or *ſcarabæus feliformis* of Mouffet, and others. This is not unfrequently found on heaths in March, and at that time is often found in coitu. The male is conſiderably ſmaller than the female. This creature feeds on the yellow gallium, and when fatigued will caſt out at its mouth a yellowiſh liquor, which is of a pungent taſte like pepper. 2. The ſlow ſtinking black *beetle*, called the *blatta fœtida* by Pliny and others. This is of a deep duſky black colour, not at all gloſſy or ſhining. This is common in cellars, and other damp places, in the month of April. 3. The great purpliſh *beetle* with a caſt of green. This is common in gardens, and in April is always infeſted with a great number of lice.

Some *beetles* which have wings very rarely uſe them, but run very ſwiftly along the ground; of theſe we have two ſpecies common among us. 1. The black *beetle* with ſulcated wings. This is a very common inſect, and is frequent in pathways in April. 2. The black *beetle* with ſtriated wings, and with yellow legs and horns. This alſo is common in pathways in ſummer.

All theſe *beetles* have the antennæ laminated at the ends. Of the other kind, which have them go off to a ſlender and taper point, there are alſo many kinds: of theſe ſome have only ſhort caſes for their wings, as if they had been cut off near the root. The general characters of this claſs of *beetles* are, that they have oblong and ſlender bodies, and have two appendages forming a kind of fork at the tail. Of this kind are the common earwig, or forficula, and the ſtaphylinus, which is a large and long black *beetle*, with a ſharp fork at its tail, and with a naked body. It is of a deep and duſky black, not at all gloſſy; it has very large yellow wings, folded under the ſmall thecæ on the back; it turns up its tail in a threatning poſture when attempted to be caught, and throws out a ſort of white bladders at it; it runs very nimbly, and is a very voracious creature, feeding on other *beetles*, or on any inſects it can catch.

Some *beetles* are all over ſoft, and have no membranaceous wings. The bodies of theſe *beetles* ſeem covered with a cruſtaceous ſubſtance, but it is ſoft, and yields to the preſſure of the finger like a bladder; theſe all eat herbaceous or vegetable food; we have two ſpecies of them. 1. The oil *beetle*, a bluiſh black ſhining *beetle*, called *proſcarabæus* by Mouffet. This is found in meadows in great abundance, and feeds on the leaves of ſome of the ſpecies of ranunculus. 2. The ſhort legged black ſmooth *beetle*. This has ſcarce any antennæ, and when tired, rolls itſelf up into a round ball. This is found in May feeding on the aperine, or common cleavers; but Liſter ſuſpects whether this be not a worm ſtate of ſome *beetle*, rather than a perfect *beetle*.

Some *beetles* have long heads, ſhaped like the trunks of other inſects, and in theſe the horns are lodged: theſe were called by the antients *gurgulïones*. *Ray*'s Hiſt. Inſect. p. 391. See the article GURGULIO.

Some *beetles* have a forceps at the head, indented on each ſide in the manner of a ſaw. Of this kind we have only one known ſpecies in England; this is the green *beetle* with ten white ſpots on the caſes of the wings. This is found in June in the northern parts of England. It is a very voracious animal, deſtroying great numbers of other inſects, particularly caterpillars.

Some *beetles* have a very remarkable property of leaping, and this of a very peculiar kind; for they do not leap, like other inſects, by means of their hinder legs, but by means of their breaſt. There are ſome general marks by which this genus of *beetles* may be diſtinguiſhed from others; theſe are, 1. they are always of an oblong and flatted figure. 2. Their head is always joined in a very nice manner to the ſhoulders. 3. Their legs are extremely ſhort and ſlender.

Of this kind of *beetles* we have in England only two known ſpecies. 1. The cheſnut coloured leaping *beetle*. This is found frequently in corn-fields, and elſewhere. 2. The greeniſh black *beetle* with horns pectinated on one ſide. This is a ſcarce ſpecies, but is found in dry places in March. *Ray*'s Hiſt. Inſect. p. 387.

SCARABÆUS, in ichthyology, a name given by Gaza to that ſpecies of *ſparus*, which is called by others the *cantharus*. It is diſtinguiſhed by Artedi, by the name of the ſilver eyed *ſparus* with yellow longitudinal and parallel lines on the ſides. See the article SPARUS.

SCARABÆUS *tardipes*, the *ſlow beetle*. We have a very ſingular account of the longevity of this animal, and that without food, given by Mr. Baker from his own obſervation. In the year 1737 he found ſeveral *beetles* of this kind plunging themſelves in the mud at the bottom of an old ciſtern; theſe were about an inch in length, and of a ruſty black colour, and had long jointed antennæ: they had no wings, but only a thick ſhell, covering the whole body, and divided along the middle with a fiſſure, reſembling the meeting of the two caſe wings in other *beetles*; the tail turned up a little, and the legs were long, but moved ſlowly. Mr. Baker chuſing one of the largeſt of theſe, threw it into a cup of ſpirit of wine, in a little time it appeared to be dead, and was ſhut up in a ſmall box, and laid by, but ſome months after it was found alive and well: it was then plunged again into ſpirits of wine, and left a much longer time; and after being taken out as dead, and put in the ſame box again for ſome time, when it was found again come to life. It had now twice eſcaped from being plunged in ſpirits, and lived three months ſhut up without any ſuſtenance. After this the *beetle* was kept a month or two without ſuſtenance under a glaſs, and at the end of this time again put into ſpirit of wine, and left there a whole night; after this, however, it again recovered, and ſeemed the next day as well as before. He lived, in the whole, two years and an half, without any viſible food or drink. Several things were at times offered him by way of food, as bread, fruits, &c. and water ſet in his way, but he never touched either. It ſeems very probable that this creature received a ſufficient nouriſhment from the particles floating in the air; and it is very poſſible that lizards, ſnakes, &c. when they live ſo long without any viſible food, are ſupplied in the ſame man-

manner, though at other times they are capable of digesting more solid matters; as doubtless was also the case with the *beetle*, when in its own natural state. This is an instance of a creature's subsisting without visible food, longer than we have any other account of any kind; but it is possible, that though the larger animals cannot long subsist without supplies of solid food, yet many insects may find nourishment enough for their tender bodies in the particles floating in the air, though we want observations for proof of it.

While kept under the glass it did not walk about much, but usually placed its nose close against one edge of it for the benefit of the air. It was of an agreeable aromatic smell, and when touched communicated its scent to the fingers, which did not go off in a long time. Its smell is stronger in winter than in summer. This creature not only bears the plunging in spirit of wine much longer than any other animal, but it bears the exhausted receiver of an air pump without any injury or uneasiness. It has been kept under it half an hour, and would walk about without any concern; only when the air was let in it appeared startled, and drew up its legs for about a minute.

We know that the Ægyptians had a very high veneration for the *beetle*; this appears not only by the account historians give of its being one of their deities, but by the many images of it we find among their antiquities. As these were a wise and learned people, we cannot suppose they would, without some reason, pay so much regard to so contemptible an animal as this appears to be; and it is very possible they might have discovered this property of its living in this manner without food, and thence esteem it a symbol of the deity. It is not known how long Mr. Baker's *beetle* would have lived in this manner with him, for it at length got away, while a careless servant took up the glass to wipe it. Philos. Trans. N° 457. p. 447.

SCARABÆUS *vorax*, the *cankerworm*. This last term is used in the translation of our Bibles to signify a very destructive insect, of the nature of the locust, and usually mentioned as its companion. The septuagint gives it the name Βρουχος, *bruchus*, a name signifying an animal which makes a great noise, as this insect does both in eating and in flying. We generally understand by this word a reptile, but it certainly means no other than that sort of *beetle*, which we call the *cockchaffer*, or *dor*; a flying insect, very remarkable for the humming noise it makes with its wings when in motion, and which, when it is found in swarms sitting upon the hedges, makes a continual noise in eating, like the sawing of wood. This creature deserves very well to be placed with the locust, as a destroyer of the fruits of the earth. Our own experience in Norfolk has given a very late proof of this; and the histories of Ireland shew that this creature has, in that kingdom, devoured every green leaf from the trees, for whole tracks of land at a time. That we have a wrong translation of the word *bruchus* in *cankerworm*, is evident even from the scriptures themselves; for the prophet Nathan expressly says that it is a fly, and has wings, which cannot agree with any thing of the nature of what we understand by the word worm, which always signifies with us a reptile, or a creeping animal. This prophet has indeed described them so well, that it is wonderful that so obvious a thing should not have been observed by the commentators. He says they spoil, and then flee away; they camp in the hedges in the day, and when the sun ariseth they flee away, and their place is not known where they are. That is, they then retire again to the hedges, and hide themselves among the trees, where they lie quiet and concealed till the sun sets again. It is plain, by comparing these words with the common animal here mentioned, that the *bruchus* of the Old Testament is the same with our *cockchaffer*, and that the prophet has given us the natural history of the animal he describes in this short account.

In another part of the Old Testament, the same word *bruchus* is translated *locust*, or *beetle*; and this explains the rationale of that odd clause in the Jewish law, where Moses tells the Israelites, these may ye eat of: every flying creeping thing that goeth upon all four, which have legs above their feet to leap withal upon the earth; even these of them ye may eat: the locust after his kind, and the bald locust after his kind, and the *beetle* after his kind, and the grashopper after his kind.

It has appeared very strange to many, that here among the pure and clean foods, the *beetle*, and such other dry and nasty reptiles, should be recommended as wholesome food for man; but there appears reason on the side of this when thoroughly considered. It is very evident that neither the Jews, nor any other people, would eat such insects as these, while any thing better was to be had; but as they lived in a country often visited by locusts and these *cockchaffers*, which might at some time eat up all the fruits of the earth, then in the want of these the prophet tells them they might eat up the devourers themselves, and yet be clean. So also it appears that we are to understand what we are told of St. John the Baptist, that he fed on locusts and wild honey; for it was in the desert that he eat these, where no other food was to be had.

The poor people of Ireland have taught us, that the prophet advised his people to a wholesome food in this text; for some years ago, when the county of Gallway, and other neighbouring parts, were so infested with this vermin, that the whole face of the country was destroyed by them, and the trees stripped of their leaves and fruits, as much as in the depth of winter; the poor people wanting other food, eat the vermin themselves that had done the mischief; and the *cockchaffers*, which are doubtless what is meant by Moses under the name of the *beetle*, as they are truly of the *beetle* kind, were found to be a very good and wholesome food.

It is very probable also that this kind of *beetle*, so famous for devouring the fruits of the earth, is that kind to which the Ægyptians paid divine honours, and for which they had such high veneration, that they frequently engraved its figure on their obelisks; though the antiquaries give a very different account of it, supposing that the beetle was held sacred by them, as being an hieroglyphical representation of the sun. This seems a very forced conjecture; whereas nothing can be supposed more natural, than that a nation, addicted to polytheism, as the Ægyptians were, and in a country frequently suffering great mischief and scarcity from swarms of devouring insects, should, from a strong sense and fear of evil to come, give sacred worship to the visible authors of their sufferings, in hopes to render them more propitious for the future. The same Ægyptians, we very well know, worshipped the other great destroyer of their country, the crocodile; and the Romans, a much more civilized people, built a temple to the disease which raged most among them, the fever.

The ignorant people among the Irish, when the vast swarms of these *beetles* first appeared among them, were of the same turn, and rather reverenced than destroyed them, saying that they were the ghosts of their dead friends killed at the battle of Agrhim, who were come in this form to pester and annoy their heretical enemies, the English protestants. They even thought that the English families suffered more by them than the Irish; but this was only because the grounds of the former were better improved, and the creatures found plenty of better food there. Philos. Transact. N° 234.

SCARBOROUGH *water*. The water of this medicinal spring has been the subject of great contests and disputes among the physical people; all allowing it considerable virtues, but some attributing them to one ingredient, others to another. Dr. Witty alledges that its material principles are alum, nitre, and vitriol of iron; but though this author declares, that these principles are all to be separated out of it, Dr. Tonstall, on the other hand, affirms that it has no vitriol of iron in it, but a stone powder and a clay, leaving sand at the bottom of the vessel; and therefore that it is apt to breed the stone, and is bad in the gout, jaundice, and all other diseases where indurations of the parts, or stony concretions in the body, are the cause; and this author seems to speak very experimentally, when he alledges that he never had any symptoms of the stone till he drank the *Scarborough water*, but acquired that disease during the course of it.

Alum stone dissolved in water is always found to yield a purple tincture with galls, and therefore the colouring an infusion of this or other vegetable substances by the *Scarborough water*, which is by all allowed to contain this stone, is no proof of any vitriol of iron being contained in it; other than such a small portion of it, as is always found in this alum stone. All waters, which have dissolved iron, will yield vitriol as a salt from that metal on evaporation. The cliffs about *Scarborough* yield abundance of salt in shoots and efflorescences, plainly owing to the *waters* of the spring; yet all these are nitro-aluminous, none of them at all vitriolic. If the *Scarborough water* is set by for some days, after it is taken fresh from the spring, it precipitates a sediment; which being examined, is found not to be of a ferruginous nature, but a mere glebe of alum.

Upon the whole, the virtues of alum and vitriol are so far different, that it must be easy to see which of the two salts the *water* partakes most of, by its virtues; but as to the stony matter, which the one of these disputants calls an insipid clay, and the other a sandy stone, it is no other than spar, which is contained in all water; and which has been in general so far from being accused of breeding the stone in the bladder, that the general consent of mankind has seemed to esteem it a cure for that disorder. The spar, in the form of the lapis judaicus and ostracites, and the very waters which are so impregnated with it, as to encrust every thing with it that is put into them, are given for the cure of this disease. Philos. Trans. N° 85.

SCARFED, in the sea carpenters language, is the same as pierced, or fastened or joined in: thus they say the stem of a ship is *scarfed* into her keel. They also imply by it, that the two pieces are shaped away slanting, so as to join with one another close and even; which they call *wood and wood*.

SCARIFICATION *of the eye*. See the article EYE.

SCARLATINA *febris*, the *ſcarlet fever*, in medicine, the name of an eruptive *fever* uſually attacking young perſons, and not attended with any great danger. When it is moderate in degree, it may be left to nature alone, and will go off very well without the aſſiſtance of medicines, only obſerving a good regimen; but if it be more violent, it is to be treated with more care: the patient is to be kept warm in bed, and to be made to drink large quantities of warm diluting liquors, acidulated either with lemon juice, or ſpirit of ſulphur or vitriol, and draughts of the attemperating and diluting medicines are to be given every four or ſix hours, and by the attemperating and gently diaphoretic powder; but during the courſe of the cure all hot things are to be carefully avoided, as well in food as medicine, for every thing of this kind renders the diſeaſe worſe, when treated in the proper manner. The *ſcarlet* ſpots, after a few days, dry off, and the ſkin ſcales away, and after this the patient uſually is ſoon well. At this time two or three doſes of ſome gentle purge are to be given; and if the weather be bad, the patient is to be confined to his chamber for ſome days afterward, that the tranſpiration may be free and uninterrupted; by this means, the worſt kinds of this *fever* go well off.

But when this caution is neglected, it is very common to find the patient fall into a ſwelling of the belly after about three weeks, and ſometimes into an anaſarca; ſometimes attended with a fever, ſometimes without one, and often with tumors of the glands, and many other dangerous diſorders. The urine, in theſe caſes, becomes brown and turbid, and many are loſt in this manner. But as this new diſeaſe, as it is uſually called, though it is in reality no other than another period of the *ſcarlet fever*, owes its whole origin to the morbific matter which cauſed the firſt appearance of that, being in part retained in the body, the beſt method of cure is by thoſe remedies which are able to carry thoſe humors out of the body. Gentle purges are to be given at ſhort intervals, and the way nature indicates is to be carefully followed, by giving diuretics in the intermediate days; for the brown turbid urine, voided naturally in this caſe, is an attempt of nature to carry off the matter that way. The beſt of all diuretics in this caſe is a tincture of ſalt of tartar and ſpiritus nitri dulcis mixed together, and taken twenty drops, or more, three times a day. In young ſubjects, who will not take purges in the common way, a glyſter made of an infuſion of ſena purges them very well, and anſwers the purpoſe.

The common hot ſudorifics are not to be given in theſe caſes, for ſweat is ſcarce to be obtained by any means in this diſeaſe; and great care is to be taken to keep the tumid parts from the cold air, otherwiſe the patient is often carried off at once by the chilling them. If there be a fever with this ſecond complaint, as is uſually the caſe, the attemperating medicines are to be given in an afternoon and evening, and draughts of gently diuretic liquors to be drank after them.

In this, and in all other eruptive *fevers*, any thing that cools the patient is of the utmoſt conſequence, and the bed is not to be new made, nor the ſhirt changed by any means, during the courſe of the diſtemper. Immoderate heat, on the other hand, is almoſt as bad, and the middle regimen is the only proper one to be obſerved. The patient lying quiet, and being kept in an equal and moderate heat, in all caſes of eruptive *fevers*, as well as in this, the patient may be allowed, in the beginning, to walk about in his chamber, taking great care to keep out the cold, and need not be confined to his bed, ſo long as his ſtrength will permit his keeping up. *Heiſter*'s Compend. Med. p. 83.

SCARUS, in zoology, the name of a ſea fiſh, of which there have been ſeveral remarkable things aſſerted by the antients, ſome with and ſome without any foundation; as that it ruminates, or chews the cud like our oxen, *&c.* This Ariſtotle, Pliny, Oppian, and others affirm, but none of them of their own perſonal knowledge; they ſeem to have had it by hearſay, or elſe as authors often do, to have taken it from one another; for the thing is not true in fact.

It has been ſaid alſo to be the only fiſh which feeds on herbs; and it is ſo far true that it does feed on them, and that few other fiſh, but not that no other feed in the ſame manner. It has been reported alſo that this is the only fiſh that ſleeps. Geſner would perſuade us, that not only this, but many other fiſh, alſo ſleep. But this does not ſeem to be the fact; for this race of animals have no eye-brows, nor any membrane to cloſe and cover their eyes with, as other creatures have, which nature has allotted ſleep to. *Ray*'s Ichthyogr. p. 304.

The later naturaliſts have deſcribed three ſpecies of this fiſh, Rondeletius two, the *ſcarus onias*, and *ſcarus varius*; and Bellonius one, which is different from both theſe, and ſeems to have been the very fiſh the antients knew by this name.

The *ſcarus onias* is a ſea fiſh, found among rocks and near the ſhores. Its ſcales are large and very thin, and its back of a blackiſh blue; its belly of a fine white, and is of an oblong and rounded ſhape; its teeth are broad, not pointed, and reſemble thoſe in the human jaws; its eyes alſo are large, and its head over the eyes of a fine ſtrong and clear blue.

The *ſcarus varius* is of the ſhape and figure of the former, but its eyes and its belly are of a purple colour; its tail is of a fine clear and ſtrong blue, and the reſt of its body is of a greeniſh or bluiſh black; its ſcales are ſpotted and ſpeckled with duſky dots; its mouth is moderately large, and its teeth broad in the upper jaw, and ſomewhat pointed in the under. From the head to the tail, all along the ridge of the back, there runs a row of ſhort ſpines, which are connected at their bottoms by a membrane; and in the middle of the belly there are ſeveral purple ſpots. It is a very beautiful fiſh. *Rondelet.* de Piſc. lib. 5. cap. 3.

The *ſcarus Bellonii*, which differs from both theſe, and ſeems to be the ſame fiſh which the antients called by this name, is of a mixed bluiſh and red colour; its ſcales are broad and thin, and it has two tranſverſe protuberances near the ſides of the tail. Its body is rounded, but not very long; its teeth are ſtrong and obtuſe, and well fitted for their office, which is the tearing off the tough ſea herbs from the rocks, and chewing them for food. Its mouth is but ſmall, and it has only one fin on the back, which is prickly. Its uſual ſize is about five or ſix inches in length. It is accounted a very delicate fiſh, but is inſipid unleſs eaten with the guts, and all that they contain. The liver and ſtomach of this fiſh, with its contents, are cooked up by the Greeks into a very delicate diſh; the epicures among them not regarding the reſt of the fiſh. *Bellonius*, de Piſc. p. 126.

SCARY, in huſbandry, a term uſed by the farmers for a barren land, which has a poor or thin ſward, or coat of graſs, upon it. *Plot*'s Oxford. p. 247.

SCATARELLO, in zoology, the name of a ſmall bird of the ficedula kind, of a greyiſh brown on the back, and a pale yellow on the breaſt and belly. Its legs are black. It ſeems nearly allied to the beccifago. *Aldrovandus*, de Avibus. See the article BECCIFAGO.

SCATCH-*mouth*, in the manege, a bit-mouth, differing from a canon-mouth in this, that the canon is round, whereas a *ſcatch* is more upon the oval. That part of the *ſcatch-mouth* that joins the bit-mouth to the branch, is likewiſe different; a canon being ſtayed upon the branch by a fonceau, and a *ſcatch* by a chaperon, which ſurrounds the banquet. The effect of the *ſcatch-mouth* is ſomewhat greater than that of the canon-mouth, and keeps the mouth more in ſubjection. Commonly ſnaffles are *ſcatch-mouths*.

SCATEA, a word uſed by Paracelſus for a ſomewhat hard fabulous concretion in the urine.

SCAULEZ, in ichthyography, the name of a fiſh common on the Mediterranean ſhores, and called by authors *hepſetus* and *anguella*. *Willughby*'s Hiſt. Piſc. p. 210. See the article HEPSETUS.

SCAZONE, in ichthyology, a name given by Salvian and others to the fiſh which we call the *pricked dog*, or *hound*, and the generality of authors the *galeus ſpinax*. It is a ſpecies of ſqualus, diſtinguiſhed by the roundneſs of the body, and the having no pinna ani. See the article SQUALUS.

SCELETON, in anatomy. See the article SKELETON, *Cycl.* and *Suppl.*

SCEMI, in botany, a name given by ſome authors to the *carob*, or ſweet pipe tree. See the articles SILIQUA and CAROB.

SCENE (*Cycl.*)—The original *ſcene* for acting of plays was as ſimple as the repreſentations themſelves; it conſiſted only of a plain plat of ground, proper for the occaſion, which was in ſome degree ſhaded by the neighbouring trees, whoſe branches were made to meet together, and their vacancies ſupplied with boards, ſticks, and the like, to compleat the ſhelter; and theſe were ſometimes covered with ſkins, ſometimes only with the branches of other trees newly cut down, and full of leaves.

It does not appear that the antient poets were at all acquainted with the modern way of changing the *ſcenes*, in reſpect of the different parts of the play, but all was performed in the ſame place.

The firſt things repreſented in theſe new theatres were what they called *mimi*. Theſe were a very coarſe ſort of poems, repreſenting, in obſcene and indecent language, the vices and indecent actions of the principal people of the time. Sophrones and Xenarchus ſeem to have been the firſt writers of this ſort of comedy, and they uſed ſometimes proſe, ſometimes verſe, in theſe compoſitions. After the licentious things, thus repreſented, had given great offence to the magiſtracy, the poets hands were tyed up from writing at all, and the actors in theſe *ſcenes* were forbid to ſpeak. Hence aroſe a new way of entertaining the ſpectators, which we ſtill continue, under the name *pantomime*, the ſame by which they expreſſed it. In this all was repreſented in dumb ſhew, and the geſtures and motions of the limbs were all they had to repreſent the actions of others by.

This ſort of public diverſion ſeems to have been in faſhion in the days of Ariſtotle, and to have been continued long afterwards. Salmaſius is of opinion that Pylades was the firſt who ſeparated the pantomime and dancing from the plays,

plays, where the actors ſpoke. But this ſeems an error in that great critic, for they ſeem, by what hiſtories we have left of them, to have been repreſented ſingly long before that time, Pylades living in the time of Auguſtus Cæſar.

Poetry and dancing were early ſuppoſed to have ſome relation to one another; the firſt was called a *ſpeaking dance*, and the latter a *dumb poem*; a name afterwards, and not till long afterwards, given to a picture. Thus they were introduced on the ſame *ſcenes*, as things naturally connected together.

SCENT. Some animal carcaſſes, buried with lime, though ten feet under ground, have been obſerved to give ſo ſtrong a *ſcent*, as to attract dogs to the place. See LIME.

SCENT *bags*, in natural hiſtory, a name given by Tyſon to thoſe peculiar pouches, or bags, which certain animals, as the civet cat and muſk animal, have for the receiving the matter of their perfume. Theſe *bags* are common to more animals than is generally ſuppoſed, and in all have much the ſame qualities, the matter they contain being in moſt of them fœtid, and diſagreeable, while contained in the *bag*, and only becoming ſweet and pleaſant when dried, or taken at leaſt from the animal, and ſmelt in ſmall quantities. The weaſel and polecat with us have *bags* of this kind, and the famous bag, or pouch of the opoſſum, is of the nature of theſe; though it ſerves alſo to the other great purpoſe of receiving and ſheltering the young in time of danger. It contains, like the reſt, a tough and viſcous matter, which ouzes out of the glands, and is of a very offenſive ſmell while the creature lives; but as ſoon as it is taken out and dried, the ſmell changes into a fine perfume. The gland of the aper moſchiferus, as Tyſon calls it, is of this kind, containing a glutinous humor of a very offenſive ſmell when freſh, but when dried, becoming ſweet and perfumed as muſk. Philoſ. Tranſact. N° 239. p. 125. See the article APER.

SCEPASTRA, the name of a kind of bandage for the head, deſcribed by Galen.

SCHADIDA *calli*, in botany, a name given by ſome authors to the plant which affords the euphorbium of the ſhops. *Herm.* Cat. p. 31.

SCHÆNANTH, *ſchænanthus*, in botany, the ſame with *iſchæmum*. See SCÆNANTH and ISCHÆMUM.

Schænanth was much praiſed by the antients as a deobſtruent, and promoter of the menſes; but at preſent it is only kept as an ingredient in ſome officinal compoſitions.

SCHÆNICLOS, in zoology, the name of a bird, which, by the deſcription of Bellonius, ſeems to be the ſame with that called by the French *alouëtte de mer*, the *ſea lark*, and by us the *ſtint*. *Aldrovand.* lib. 20. cap. 56.

SCHAFFILT, in zoology, the name of a very ſmall owl, not larger than a thruſh, called *noctua minor* by authors.

Its eyes are very bright, and of a yellow colour; its ears very large; its feet are feathered to the toes, and the ſoles of its feet are yellow. It is caught in the woods in Germany. *Ray*'s Ornitholog. p. 69.

SCHAKARILLA, or SCHACARILLA, in the materia medica, a name given by ſome authors to the medicinal bark called *cortex thuris*, and *cortex elutherii* by others. *Montani* Exot. p. 8.

SCHAPHAN, in Jewiſh antiquity, the name of an animal declared unclean by the law of Moſes [b]. Interpreters do not agree in their explanations of this word.—[b Levit. xi. 5.] See the article CHOEROGRILLUS.

SCHASIS, a word uſed by ſome of the writers in ſurgery to expreſs ſcarification.

SCHEAT, or, as it is ſometimes written, SCHEAD, or *ſheart*, a name given by many to the jentling, a fiſh of the chub kind, caught in the Danube, and moſt of the larger rivers of Germany, and called by Geſner and Aldrovand *capito cæruleus*. *Willughby*'s Hiſt. Piſc. p. 256. See JENTLING.

This is the *glanus* of Pliny, and the other old Roman authors, and is diſtinguiſhed by Artedi by the name of the *ſilurus* with four beards near the mouth. This is its character in which it differs from the *lake*, another fiſh of this kind; which, though a genuine ſpecies of *ſilurus*, has only one beard.

SCHELLENT, in zoology, the name of a ſpecies of duck, found about the ſea coaſts, of the ſize of the common duck, and differing from the *capo roſſo* in this, that it is twice as large, and the eyes have yellow iris's; though agreeing with it in the colour of the head, which is of a reddiſh brown. Its neck is grey, and its back is of a blackiſh grey; its throat, breaſt and belly white, but near the anus there is a tranſverſe brown line. The long feathers of the wings are black and white, and the tail of a blackiſh grey. *Aldrovand*, de Avib. p. 223.

SCHELLEY, in zoology, a name given in ſome counties of England to the fiſh known among authors by the name of *ferra*. *Willughby*'s Hiſt. Piſc. p. 184. See FERRA.

SCHEME, (*Cycl.*) *ſchema*, σχημα, in the antient muſic, is uſed for the varieties ariſing from the different poſitions of the tones and ſemitones in a conſonance.

SCHETES, was formerly a term for uſury; and the commons prayed that order might be taken againſt this horrible vice, practiſed by the clergy as well as the laity. Rot. Parl. 14 Rich. II. *Blount.*

SCHETIC *diſeaſes*, a term uſed by the old writers in medicine to expreſs ſuch diſeaſes as were not deeply rooted in the conſtitution, but might be eaſily removed.

SCHEUKZERIA, in botany, the name of a genus of plants, the characters of which are theſe. The perianthium is divided into ſix oblong, acute, reflex and expanded leaves, remaining with the fruit. There is no flower of petals. The ſtamina are ſix very ſhort and flaccid capillary filaments. The antheræ are erect and obtuſe, very long, and of a compreſſed figure. The germina of the piſtils are three in number; they are of the ſize of the cup, and of an oval compreſſed figure; though there be no ſtyle. The ſtigmata are oblong, and obtuſe on the upper part; they grow on the outſide to the germina. The fruit conſiſts of as many capſules as the piſtil had germina; they are of a roundiſh figure, inflated and compreſſed, and each compoſed of two valves. The ſeeds are ſingle and oblong.

The number of the germina and capſules vary, from three up to ſix; the three ſeem, however, the moſt natural ſtate of the flower, and are the moſt frequent. *Linnæi* Gen. Plant. p. 152.

SCHILUS, in ichthyology, a name given by many to the fiſh called by the generality of authors *lucioperca*, or the pike fiſh. See LUCIOPERCA.

Artedi refers it to the genus of the *perca*, or pearch, and diſtinguiſhes it from the common pearch, by calling it the pale ſpotted pearch with two large teeth on each ſide the mouth. See the article PERCA.

SCHINELÆON, a word uſed by the antients to expreſs an oil of maſtich, or oil in which maſtich was diſſolved.

SCHINUS, in botany, the name by which Linnæus calls the genus of plants, deſcribed by Tournefort and others under the name of *molle*. The characters are theſe: the cup is very ſmall, and is lightly indented in five places. The flower conſiſts of five expanded petals. The ſtamina are a conſiderable number of oblong ſlender filaments. The germen of the piſtil is roundiſh, and the fruit is a globoſe berry, containing a large ſeed of the ſame globoſe figure. This plant, in its external appearance, reſembles very much the *rhus* and the *lentiſk*, in the fructification, but when cloſely examined, is found to differ from both; from the former, in having more than five ſtamina, and from the latter, in the petals. *Linnæi* Gen. Pl. p. 515.

SCHIRROSIS, a name given to a diſorder of the eye, ariſing from the violence of a long continued inflammation, when the fleſh increaſes in bulk, and aſſumes a livid colour.

SCHISMA, in muſic. Some, as Graſſineau, make this interval equal to half a comma, and ſay that eighteen of them are required to make a compleat tone, reckoning nine commas to a tone. But all this is inaccurate. See the article INTERVAL.

It is alſo uſed by ſome for the difference between the tones major and minor [c], called by others a *comma*.—[c *Deſcartes*, Comp. Muſic.] See COMMA, *Cycl.* and *Suppl.*

SCHIT-ELU, in botany, a name given by ſome authors to the plant, which produces the ſeed called *ſeſamum* in the ſhops. Hort. Mal. Vol. 9. p. 105.

SCHLEMMEN, a term uſed by the ſmalt-makers to expreſs the ſubſtance of the ſmalt after fuſion, when it is ſeparated from the *eſchel*; that is, a ſort of grey aſhes which adhere to it, and is ready for powdering for uſe.

SCHNOT *fiſh*, a name by which ſome call the haſela or haſler, a freſh water fiſh, approaching to the mullet or chub kinds, and at ſome ſeaſons eſteemed a very delicate diſh. *Willughby*'s Hiſt. Piſc. p. 261. See the article HASELA.

SCHOENAS, among the antients, a land meaſure containing two paraſangs, or ſixty ſtadia, according to Herodote; which makes ſeven and an half of our miles. But Pliny computes it at five miles, or fifty ſtadia. *Pitiſc.* in voc. See PARASANG and STADIUM, *Cycl.*

SCHOLARES, an eccleſiaſtic order, inſtituted by Innocent the third in the council of Lateran. *Hofm.* Lex. univ. in voc.

SCHOOL, (*Cycl.*) or SCHOOLING, in the manege, is uſed to ſignify the leſſon and labour both of the horſe and horſeman.

A *ſchool pace* or *gate* denotes the ſame with *ecoute*. See the article ECOUTE.

SCHRAITSER, in zoology, the name of a fiſh very common in the Danube, and in many things reſembling our ruff, or ſmall gilded pearch.

Its common ſize is about three inches in length; its tail is forked, and its back fin is ſupported by thirty rays or nerves, eighteen of which are rigid and prickly, and thoſe which ſtand behind them ſoft and flexile. The upper jaw has a membrane ſomewhat like a lip, which hangs from it, and the coverings of the gills terminate in a ſpine or prickle. The membrane of the back fin is variegated with black ſpots, and its general colour is ſomewhat paler than that of the pearch. It is a very well taſted fiſh. *Ray*'s Ichthyography, p. 335.

SCHWALBEA, in botany, the name of a genus of plants, the characters of which are these. The perianthium consists of one leaf, and is of a very singular figure, being tubular, inflated, and striated on the surface, and terminated by an oblique mouth, lightly divided into four segments. The upper segment is smallest of all, the two side ones are longer, and the bottom one is longer and broader than these, and is emarginated. The flower consists of one leaf, and is of the labiated kind. The tube is of the length of the cup, and the limb erect. The upper lip is erect, hollow, and undivided; the lower lip is of the same size, but is divided into three obtuse and equal segments. The stamina are four capillary filaments, of the length of the flower, but two of them are a little shorter than the others. The antheræ are incumbent. The germen of the pistil is round. The style is of the length and figure of the stamina, and is placed in the same situation. The stigma is thick and crooked. The seed is single, roundish, and small. *Linnæi* Gen. Pl. p. 291. Flor. Virgin. p. 71.

SCIADEPHORI, Σκιαδηφοροι, among the Athenians, an appellation given to the stranger women residing in Athens, because they were obliged, at the festival Panathenæa, to carry umbrellas to defend the free women from the weather. *Potter*, Archæol. Græc. lib. 1. cap. 10. Tom. I. p. 56.

The word comes from Σκιαδειον, an umbrella, and φερω, I carry.

SCIÆNA, in the Linnæan system of zoology, the name of a distinct genus of fishes, the characters of which are; that the opercula of the gills are scaly, and the back fin is bifid. Of this genus are the *umbra*, &c. *Linnæi* Syst. Nat. p. 54. The characters of this genus, according to the Artedian system, are these. The whole head, and the coverings of the gills, are scaly, and one of the laminæ of these coverings is serrated at the edge. The body is compressed and broad; the back is acute; and the teeth are only in the jaws and fauces, the palate and tongue being bare. There is only one fin on the back, but it is bifid, being so deeply divided at the middle, that it seems to make two. The tail is not forked, but even at the end. The appendices of the pylorus are seven or eight in number.

There are only two known species of this genus. 1. The *sciæna* with the upper jaw longest, and the lower jaw bearded. This is the *sciæna* and *umbra* of authors, and is called by Bellonius *chromis*. 2. The *sciæna* variegated with black, and with very black belly fins. This is the *umbrino* of the Italians, and is the fish called *corvulus* and *coracinus* by many authors. The lines are of various lengths and breadths, and are laid obliquely on the sides. The mouth is large, and the eyes brown. *Artedi*, Gen. Pisc. p. 29. See UMBRA and CORACINUS.

The name *sciæna* is of Grecian origin, derived from the word Σκια, a shadow. The fish had this name from its being of a dusky or shadowy colour.

SCIAMACHIA, the fighting with a person's own shadow, a sort of exercise prescribed by the antient physicians, in which the motion of the arms, and other parts of the body, were of very great service in many chronic cases.

SCIAPODES, Σκιαποδες, a fabulous race of men, mentioned by Pliny, who had only one leg.

They were called *sciapodes* from σκια τω ποδος, because in summer they held up their leg, and sheltered themselves from the heat with the shadow of their foot. *Hofm.* Lex. in voc. See the article MONOCOLI.

SCIARRI, in natural history, the matter which runs down in burning torrents from the craters of Mount Ætna.

This matter, when cold and hard, is hewed and employed at Catania, and other places. It is chiefly used for the basements and coinage of buildings. It probably contains mineral and metallic particles, being a ponderous, hard, grey stone. Philos. Trans. N° 481. p. 327, 328. See the article STONE.

Some of the *sciarri* are coarse, and others fine and polished on the surface; some of them are black, others reddish, and others of the colour of iron; and many of them have coverings of pure sulphur over the whole surface, or a part of it. Some very fine and smooth ones, resembling iron, but very light, are found in, or near the mouths of the eruption, and some are very hard and heavy, and of a mixed nature, seeming to be the result of many sorts of minerals melted together. These latter, when the mountains have poured out streams of fire, always remain in the places, and are the substance that was on fire cooled again.

At the time of the most terrible eruptions of this kind, these heaps of *sciarri*, which sometimes appear to be solid rocks of metalline matter, are only a sort of covered arches, under which the melted matter yet continues liquid and running, and bursts out, at times, in the several parts of their sides or surfaces. The general appearance of a train of these *sciarri*, left after the eruption of such a rivulet of fire, is much like that of the Thames, or some other such large river, in the time of a severe frost, the rocks of *sciarri* rising above the general surface, like the clods of ice in that scene; the colour only differing, the great quantities of the *sciarri* in these places being of a deep bluish hue.

It is remarkable, that the substance of these *sciarri*, even while melted and running in streams down the hill, is so firm and solid, that no weight will sink into it, nor any instrument make its way through the surface, any more than a solid mass of cold metal. It has been supposed by some, that the flowing matter concreted into the common pumice stone, but that is a vulgar error, the pumice being a wholly different substance. Philos. Trans. N° 49.

SCIATHERICA, a name given to *dialing*. See DIAL and DIALING, *Cycl.*

SCIATHERICUM *telescopium*, a horizontal dial with a telescope, adapted for observing the true time, both by day and night, to regulate and adjust pendulum-clocks, watches, and other time-keepers. It is the invention of the ingenious Mr. Molyneux, who has published a book with this title, containing an accurate description of this instrument, its uses, and application.

SCIERIA, Σκιηρια, in antiquity, a festival in honour of Bacchus, kept in Arcadia.

It was so called, because that God's image was exposed ὑπο τῃ σκιαδι, *i. e.* under an umbrella. At this time the women were beaten with scourges, in the same manner with the Spartan boys at the altar of Diana orthia, which they underwent in obedience to a command of the Delphian oracle. *Potter*, Archæol. Græc. Tom. I. p. 430.

SCILLONEORTE, Σκιλλων Ἑορτη, in antiquity, the festival of sea onions. It was observed in Sicily. The chief part of it was a combat, wherein youths beat one another with sea onions. He that obtained the victory was rewarded, by the gymnasiarch, with a bull. *Potter*, Archæol. Græc. Tom. I. p. 431.

SCIMPODIUM, Σκιμποδιον, among the antients, a small couch or bed, on which one person only could rest at a time. It was on the *scimpodium* that the Romans used to lay themselves, when weary or indisposed.

The *scimpodium* was sometimes used instead of the *lectica*, to carry both men and women, not only through the city, but likewise in journeys into the country. *Pitisc.* in voc. See LECTICA.

SCINCUS, the *skink*, in zoology, the name of a species of lizard, called also by some the land crocodile, *crocodilus terrestris*, and well known in the druggists shops as an ingredient in several compositions.

It resembles the smaller sort of lizards, being usually about six inches long, and its usual thickness is that of a man's thumb. It is of a silvery greyish colour, scaly, and has a rounded tail; its head is of an oblong figure; its nose sharp; and its feet, as it were, alated, having five toes each, armed with very sharp claws. It is very common in Egypt and Arabia. *Worm.* Mus. p. 86.

The dried flesh of the *scincus* is greatly commended, as possessing all the virtues of that of vipers, but in a more exalted degree. It is said to do wonders as a restorative, and provocative to venery. For this last purpose the belly is preferred to any other part of it; but there appears no reason for this in the dried animal. The people of Egypt cut the flesh to pieces, and boil it down to a strong broth or jelly; in which form it may do some service, though it fails with us. The only use made of it at present in the shops, is as an ingredient in some of the old compositions.

SCINDALMOS, a word used by the antients to express a fissure of the cranium, or of any other part.

SCINTILLA *veneris*, a term used by Paracelsus to express a resolution of the limbs, or deprivation of motion from a venereal cause.

SCIOGRAPHY, the art of shadows, or dialing. Also in architecture, it is sometimes used to denote the draught of a building, cut in its length or breadth, to shew the inside of it; as also the thickness of the walls, vaults, floors, timber works, &c.

SCIOMANTIA, Σκιομαντειια, in antiquity, a kind of divination, by raising the dead, who were said to appear in airy forms like shades. *Potter*, Archæol. Græc. Tom. I. p. 350.

SCIOPODÆ, in history, the name given by Pliny, and other of the old writers, to a nation of people which they place in Æthiopia, on the burning sands; and who they say, when too hot, lie down upon their bellies, and shadow themselves from the sun by lifting up their feet, which are very large and broad, against it. These are some of the *gentes mirabilis figuræ* of Pliny, and are worthy to stand among the monocoli, and other such monsters.

SCIRA, Σκιρα, a festival among the Athenians, otherwise called *scirrophoria*. See the article SCIRROPHORIA.

SCIRONA, a word used by some of the antients to express the autumnal dews.

SCIRPUS, the *rush*, in the Linnæan system of botany, makes a distinct genus of plants, the characters of which are; that the cup is an imbricated spike, made up of oval and bent scales, parting the several flowers. The flowers have no petals. The stamina are three long filaments; and the antheræ are oblong. The germen of the pistil is extremely small. The style is long and thread like. The stigmata are three in number, and extremely slender. The seed is single, three cornered, pointed, and is covered with hairs,

which are ſhorter than the cup. *Linnæi* Gen. Plant. p. 12. See JUNCUS.

SCIRRHUS (*Cycl.*)—The ſeat of a *ſcirrhus* is very various and uncertain; for this diſorder is not confined to the internal parts alone, to wit, to the liver, ſpleen, lungs, meſentery, pancreas, and in females to the uterus; but it frequently happens alſo to the external parts, as to the lips, tongue, tonſils, fauces, palate, gums, neck, mammæ, axillæ, inguina, penis and teſticles, and that generally after inflammations of thoſe parts; though it ſometimes alſo appears without any inflammation, eſpecially in perſons of a heavy phlegmatic habit; ſometimes alſo it is occaſioned by an external injury, as a fall, a blow, &c.

As ſoon as the *ſcirrhus* is formed, the immediate conſequence is, that the indurated part becomes unfit to perform the functions allotted by nature to it, and the neighbouring parts ſuffer preſſure, and become impeded in the performance of their ſeveral functions. It is therefore no wonder that they are found ſubject, in theſe caſes, to inflammations, ulcerations, cancers, gangrenes, tabes, ſtiffneſs, immobility, and the like, according to the nature of the injured part.

The more inveterate a *ſcirrhus* is, the greater will be the difficulty in the cure. When this diſorder happens to young people, and ſuch as are of a good habit of body, it is much more ſafe and tractable, than when it happens to older infirm perſons. When there is any thing venereal in the caſe, the difficulty is yet the greater. The *ſcirrhus* is of the more or leſs conſequence, according to the nature of the part it is ſeated in; and internal ones are always more dangerous, for this reaſon, than the external.

While a *ſcirrhus* continues free from pain, there is little danger from it; but when it becomes painful or ulcerated, it generally threatens a cancer. The cure of theſe diſorders is always difficult and uncertain, but in young robuſt habits ſometimes the knife and corroſives will effect it.

When the *ſcirrhus* is of long ſtanding, and in old people, great care muſt be taken how it is meddled with, leſt, while under treatment, it ſhould become cancerous. On the other hand, when the *ſcirrhus* is but newly formed, and you have no ſigns of vehement pain or hardneſs, where the patient is otherwiſe of a good habit of body, external and internal remedies are to be employed at once, to endeavour to ſet the confined fluids at liberty. The internal remedies, found of moſt ſervice on theſe occaſions, are the decoctions of the woods, digeſtive tinctures, or mild mercurials, giving between whiles relaxing medicines, to reſolve the inſpiſſated humors.

In regard to the external remedies, plaſters made of the warm gums, as ammoniacum, galbanum, ſagapenum, and the reſt, either alone or mixed together, and aſſiſted ſometimes by the powder of bryony root, or of the birthwort, are uſed. Mercurials ſerve greatly to this purpoſe, and the following compoſition is alſo excellent as a plaſter on theſe occaſions. Take galbanum and opoponax of each an ounce, ammoniacum and bdellium of each two ounces, oil of olives two pounds, yellow wax half a pound, powder of long and round birthwort, lapis calaminaris, myrrh and frankincenſe, of each one ounce, Venice turpentine four ounces; melt them all into a plaſter.

Next to plaſters, cataplaſms are found highly ſerviceable in theſe caſes, one of the beſt of which is made in the following manner. Take white bryony root four ounces, round birthwort and angelica of each an ounce, leaves of ſavin, rue, ſcordium, wormwood and camomile flowers, of each one handful; melilot, elder, marſhmallows and centaury, of each half a handful; let theſe be boiled together in a ſufficient quantity of water to the proper conſiſtence for a cataplaſm, adding, toward the end of the boiling, three ounces of galbanum, diſſolved in the yolk of an egg, two ounces of linſeed meal, and as much as is neceſſary of linſeed oil.

It is to be applied warm, and often renewed; and a fomentation made from the ſame ingredients, boiled in vinegar, is often found alſo of great uſe.

Inſtead of theſe remedies ſome highly extol the uſe of acid vapours on this occaſion; ſometimes the ſteam of boiling vinegar is ordered to be received on the part, and that either of plain vinegar, or of ſuch as has been medicated by infuſions of rue, lavender flowers, or other ſuch ingredients, or of the Venice treacle. Some ſprinkle vinegars of theſe kinds over a hot ſtove, and receive the vapour through a funnel; others adviſe the burning of common brimſtone, and holding the part over the fume; and others are fond of fumigations of cinnabar. Great care muſt be taken in theſe caſes not to raiſe too large a fume, nor to keep the patient over it too long; and he muſt be adviſed not to admit it into his noſe or mouth, for all theſe ſteams are injurious to the lungs; and in the laſt caſe, the quantity of mercury raiſed in vapour from the cinnabar may often be enough to raiſe a ſalivation.

Mercurial medicines are alſo found to perform wonders in theſe caſes, either adminiſtered in the beginning, or after all other remedies have failed. Beſide giving mercurials internally, an excellent mercurial ointment may be made, by mixing quickſilver firſt with a ſmall quantity of Venice turpentine, and afterwards with a much larger of hog's lard, by rubbing them together in a glaſs or marble mortar. The *ſcirrhus* ſhould be anointed two or three times a day with this, covering it with a common mercurial plaſter; and to prevent this method from raiſing a ſalivation, ſome purging medicine, as the extract of rudius, or jalap, is to be given in ſmall doſes every fourth or fifth day.

But if all theſe methods prove unſucceſsful, and the *ſcirrhus* is free and moveable, and its ſituation threatens no danger from the neighbourhood of any conſiderable veſſels, and if the patient's ſtrength ſhall be judged ſufficient to undergo the operation, the aſſiſtance of the knife muſt be called in, and the *ſcirrhus* cut out, to prevent its growing cancerous. When the *ſcirrhus* is thus taken out, the wound is to be dreſſed and healed with the common vulnerary balſams: but when the *ſcirrhus* is fixed, knotty, uneven, and deeply rooted; where the patient is of a bad habit of body, is ſubject to form *ſcirrhuſes* from an hereditary taint, or has formed ſeveral already; and laſtly, where the ſituation of the diſorder is ſuch, that from the vicinity of conſiderable veins and arteries, there is danger of bringing on an hæmorrhage, which may prove fatal, then all attempts to cure, whether by the knife, by digeſtives, or by corroſive medicines, are to be neglected; for this kind of *ſcirrhus* is almoſt always attended with very violent pains, and all that can be done is to attempt to alleviate thoſe pains, and prevent a cancer. *Heiſter*'s Surgery, p. 221.

SCIRRHUS *hepatis*, in medicine, a diſeaſe conſiſting in an indurated tumor of the liver, occaſioned by a ſtagnation of the humors which grow thick there, from an exhalation of their more fluid and ſubtle parts.

This differs from the *infarctus hepatis*, not only in degree, but in its ſymptoms, for it almoſt always is attended with a hectic, or with œdemato-hydropic ſwellings. *Junker*'s Conſp. Med. p. 208.

Signs of it. Theſe are a tumor and hardneſs in the right hypochondrium, or region of the liver, always evident to the patient, and often ſenſibly perceived by any body elſe, on touching the part. To this are to be added dull tenſive pains, and a ſenſe of a weight hanging there, and uſually aſthmatic ſymptoms, and a dry cough. It becomes painful to lie on the left, or oppoſite ſide; and with theſe a hectic comes on, with a waſting of the upper parts, and a ſwelling of the inferior ones; firſt of the feet, but afterwards upwards to the belly, which finally become very obſtinate, and truly aſcitic. The urine in this caſe is ſmall in quantity, and of a deep orange colour, and thick conſiſtence. It has uſually a mucid ſediment, and ſometimes a thick one of a roſe colour.

Cauſes of it. Theſe are uſually either an omiſſion of artificial diſcharges of the blood, by habitual bleedings at ſpring and autumn, or a ſuppreſſion of the natural ones, by the menſes or hæmorrhoidal veſſels: an improper treatment of intermittent fevers with aſtringents, of quartans with large quantities of bark, and of acute fevers with too cooling a regimen, or a violent quantity of the volatile ſalts, or a condenſation of the humors in a ſimple infarction, by means of cold external applications. The ſtopping hæmorrhages, which nature had brought on for her relief in plethoras, have alſo been ſometimes known to occaſion a *ſcirrhus* of the liver; as have alſo external injuries by blows, falls, and the like.

Prognoſticks. A recent *ſcirrhus* of the liver admits of a cure, but this not without great difficulty, and in a more confirmed one there is very little hope. This tumor has a continual tendency to corruption, either by ſphacelation, or by an inflammatory ſuppuration; neither of which can happen ſucceſsfully, for the firſt muſt occaſion inſtantaneous death, and the latter exulceration, and a ſucceeding fatal hectic. A *ſcirrhus* of the liver often follows, and ſometimes precedes a jaundice of the moſt violent kind.

Method of treating it. The bowels are firſt to be cleanſed and relaxed by a clyſter, made of a decoction of mallows, camomile flowers, mullein, and fennel ſeed; after this, bleeding in the foot is to be ordered, and then the nitrous and other reſolvent medicines are to be given, ſuch as tartar of vitriol, and the like. After this medicated wines ſhould be drank as the common drink, prepared with bryony and arum roots, centaury, hyſſop, and maidenhair leaves, ſaſſafras, ſenna, black hellebore, and rhubarb; and externally, plaſters of the reſolvent and ſtrengthening kinds are to be applied. But after all directions for the treatment, it is to be acknowledged, that an obdurate and inveterate *ſcirrhus* admits of no remedy. *Junker*'s Conſp. Med. p. 210.

SCIRRONES, a name given to a ſort of ſmall lice breeding under the ſkin.

SCIRROPHORIA, Σκιῤῥοφορια, in antiquity, an anniverſary ſolemnity at Athens, upon the twelfth day of the month *ſcirrophorion*. For its origin and ceremonies ſee *Potter*, Archæol. Græc. lib. 2. cap. 20. Tom. I. p. 430.

SCIRROPHORION, Σκιῤῥοφοριων, in antient chronology, the twelfth and laſt month of the Athenian year. It contained

twenty nine days, and anſwered to the latter part of our May and beginning of June. See MONTH.

It had its name from the feaſt *ſcirrophoria*, kept in it.

SCISSIMA, in botany, a name given by ſome authors to the beech tree. *Ger.* Emac. Ind. 2.

SCISSORS. Mr. Monro has given us the figure and deſcription of a pair of *ſciſſors*, the blades of which are crooked on their flat ſides. Theſe *ſciſſors* are very uſeful for taking off excreſcences from hollow parts, or for cutting in curve lines, which the common *ſciſſors* cannot eaſily be applied to. Med. Eſſ. Edinb. Vol. 5. art. 41.

SCIURUS, the *ſquirrel*, in the Linnæan ſyſtem of zoology, makes a diſtinct genus of animals, the characters of which are; that the creatures have four toes on the fore feet, and five on the hinder, with palms made for climbing and leaping, and all have woolly tails. *Linnæi* Syſtem. Natur. p. 33.

We have five ſpecies of this little animal deſcribed to us. 1. The common Engliſh kind. 2. The great grey Virginian one. 3. The black backed kind of Ceylon. 4. The American flying *ſquirrel*. And 5. the Barbary kind.

The common Engliſh *ſquirrel* is well known, and is diſtinguiſhed from the others by its ſize and colour. It is ſomething larger than the weaſel, but ſhorter bodied; its back and ſides are reddiſh; its throat and belly white; and it generally carries its long hairy tail erect over its back, ſo that it ſerves it for a ſhade. It is common in our woods, and feeds on all ſorts of fruit, but principally on hazel nuts; which it gathers in the ſeaſon, and lays up for its winter ſtore. The ſame ſpecies of *ſquirrel* with ours is found in Poland and Ruſſia, grey or aſh coloured.

The ſecond, or great grey American *ſquirrel*, is very common in Virginia, and is of the ſize of a rabbet. It is of a dark iron grey, ſuch as ſome rabbets are of; its fore feet have only four toes, its hinder ones five.

The third, or black backed *ſquirrel*, is found in the iſland of Ceylon, and called by ſome *rukkaia*, from the noiſe it makes. The hair on its back is ſometimes grey.

The fourth, or flying *ſquirrel*, is a very ſmall kind; its back is of a duſky mouſe-coloured grey; its throat and belly white; its eyes ſmall, black, and prominent, reſembling thoſe of the mouſe kind; its tail is very long, and very broad and flat. It has a thin and lax ſkin on each ſide, which is fixed to the fore and hinder legs, and conſequently, on the extending its legs, this ſkin expands on each ſide like a ſort of ſail: this it always does in leaping, and is by that means carried a great way; and hence has ariſen the opinion of its flying. It is very common in New Spain, and is ſometimes met with in the colder American countries. It very much approaches to the mouſe kind in many particulars, receding from the nature of the *ſquirrel*. Its furr is ſhort like that of the rat or mouſe, not long like the other *ſquirrels*. It never erects its tail on its back, nor turns or twiſts it round, as the other *ſquirrels* do. It has a very beautiful black line on each ſide the face, near the eyes.

The fifth kind, or Barbary *ſquirrel*, is of a mixed colour, between black and reddiſh, and is very beautifully variegated all down the ſides with brown and white longitudinal ſtreaks, laid in a regular alternate order, and each reaching the whole length of the body. Theſe lines are, in ſome of theſe creatures, not brown and white, but black and white; and the tail, when in a ſtate of reſt, is ſeen elegantly ſtreaked with the ſame colours, but when the creature erects it, the hairs ſtanding all upright, the beauty of this variegation is hid. The belly of this creature is blue and white. It is ſmaller than our *ſquirrel*, and has ſhorter ears, which are roundiſh, and lie cloſe on the head. The whole head has much of the figure of a frog's, in all other reſpects it is perfectly like our *ſquirrel*. *Ray*'s Synop. Quad. p. 214.

SCLAREA, in botany, the name of a genus of plants, the characters of which are theſe. The flower conſiſts of one leaf, and is of the labiated kind; the upper lip is hooked like a reaper's ſickle, and the under one divided into three ſegments, the middle one being largeſt, and hollowed like a ſpoon. The piſtil ariſes from the cup, and is fixed in the manner of a nail to the hinder part of the flower. It is ſurrounded by four embryos, which ripen into as many ſeeds, and are contained in a ſort of tubular capſule, which was the cup of the flower.

The ſpecies of *ſclarea*, enumerated by Mr. Tournefort, are theſe. 1. The *ſclarea*, called *gallitrichum ſativum* and *orvala* by authors. 2. The woolly *ſclarea* with very large flowers, called *Æthiopis* by many authors. 3. The jagged leaved *ſclarea*, called the *Æthiopis* with divided leaves. 4. The large leaved glutinous Portugal *ſclarea*. 5. The aſphodel rooted *ſclarea*. 6. The Indian *ſclarea* with variegated flowers. 7. The glutinous Pyrenean *ſclarea* with ſinuated leaves. 8. The ſtinking hairy white flowered *ſclarea*. 9. The early African annual *ſclarea*. 10. The great annual Bœtic *ſclarea* with pale blue flowers. 11. The blue flowered meadow *ſclarea* with ſerrated leaves. 12. The white flowered meadow *ſclarea* with ſerrated leaves. 13. The bright red flowered meadow *ſclarea* with ſerrated leaves. 14. The greater *ſclarea* with deeply divided leaves. 15. The white flowered Syrian *ſclarea*. 16. The blue flowered Syrian *ſclarea*. 17. The great ſpotted ſage leaved *ſclarea*. 18. The ſmall ſmooth ſage leaved *ſclarea*. 19. The purple flowered ſage leaved *ſclarea*. 20. The *ſclarea* with triangular dentated leaves. 21. The triangular leaved woolly ſtalked *ſclarea*. 22. The blue flowered betony leaved *ſclarea*. 23. The African ſhrub *ſclarea* with leaves like the helianthemum. 24. The large flowered dwarf *ſclarea* with jagged leaves. And 25. the Syrian *ſclarea* with rugged dentated leaves. *Tourn.* Inſt. p. 179.

SCLERIA, a word uſed by medical writers to expreſs a hardneſs of the inner part of the eyelids.

SCNIPS, in natural hiſtory, a name given by authors to the ſmall ſpecies of gnat, always found about the oak tree feeding on the juices of its leaves, which it ſucks by means of its ſharp trunk.

It is ſuppoſed by ſome to be hatched of the ſmall oblong white worm, that inhabits the oak apples.

SCOBS, a word uſed by ſome authors to expreſs the raſpings of ivory, hartſhorn, or other hard ſubſtances. Some alſo have uſed it to expreſs the ſcoriæ of metals; and ſome as a name for the *cineres clavellati*, or pot-aſhes, uſed in ſoap and glaſs-making.

SCODEGHINO, a name given by chirurgical authors to a peculiar ſpecies of inciſion knife, deſcribed by Scultetus, and uſed by Rouſſet in performing the Cæſarean operation.

SCODINEMA, a word uſed by ſome medical writers to expreſs a heavineſs of the head.

SCOLECIA, in the materia medica of the antients, a name given to a kind of verdigreaſe.

Of this there were two ſpecies, the one found native in the earth, the other fictitious.

The latter kind was prepared by rubbing a quantity of vinegar in a braſs mortar, with a braſs peſtle, till it became thick and ropy; when it was in this condition, a ſmall quantity of alum and ſea ſalt, or nitre, were added to it, and it was ſet in the ſun in the heat of the dog days. It was to ſtand thus till it became ropy, thick, and of a green colour; and then being drawn out into long threads, and dried, it had the reſemblance of worms in ſhape, and thence had its name.

SCOLION, among the antients, a kind of Bacchanal ſong uſed at entertainments. See *Pitiſc.* in voc.

SCOLIOSIS, a word uſed by Hippocrates to expreſs a diſtortion of the ſpine ſideways.

SCOLIUM, in antiquity. See the article SCOLION.

SCOLOPAX, the *woodcock*, a very well known bird, diſtinguiſhed by its ſize, which is ſomewhat ſmaller than that of the partridge, and by its colour, which is on the back a variegation of black, grey, and a reddiſh brown; and on the belly a pale grey, variegated with tranſverſe ſtreaks of brown. Its beak is three fingers breadth long, and the upper chap a little longer than the under.

In the Linnæan ſyſtem of zoology, the *ſcolopax* is the general name of a large order of birds, the diſtinguiſhing character of which is, that they have a ſomewhat cylindric beak, which is rounded, and obtuſe at the point. *Linnæi* Syſtem. Natur. p. 47.

SCOLOPAX, in ichthyography, the name of a ſea fiſh called in Engliſh the *trumpet*, or *bellows fiſh*.

It is a very ſmall fiſh, caught very frequently in the Mediterranean, and common in the markets of Rome, Venice, and elſewhere. Its common length is about three inches; its body is flat, and of about one finger's breadth, and covered with rough and harſh ſcales. The ſnout is extremely long, and is hard, ſtrait, and made all of one bone, broad at the head, and narrow at the end, and opening there tranſverſely with a membrane affixed to the under jaw, and ſerving to open and ſhut it at pleaſure. The eyes are large, and their iris's of a pale red. It has a thin fin at each of the gills. The anterior part of the belly is formed into a ſharp edge, and has no fins, but two bony ſubſtances, ſeeming the rudiments of belly fins; and a little lower on the belly it has one, which is longer and notched. Behind the anus there is a long fin, reaching to the tail, and on the back there are two others very oddly placed; the hinder ſtands very near the tail, the other higher up; and this laſt is no other than one long and large bony ſpine of two inches long, and ſet in a joint, by which it is moveable at pleaſure. Before this there ſtands another very fine prickle, and behind it three others, which make the whole a ſort of fin. *Geſner*, de Piſc. p. 1008.

SCOLOPENDRA, in zoology, an inſect of a very ſlender and long body, very ſmooth, and of a yellowiſh or reddiſh colour, furniſhed with a vaſt number of legs, and having two long antennæ, and a bifid tail.

It is uſed by ſome as a depilatory, being boiled in wine. *Dale*'s Pharmacop. p. 355.

There is a ſpecies of this animal, which naturally ſhines in the dark in the manner of a glow-worm, but with a fainter and more general light. Every part of the body of this animal will emit ſparks, if preſſed in the dark. It is covered with a ſoft down, or ſhort and fine hair, much reſembling in texture

ture the downy matter which grows on the back of colts-foot leaves.

The two ſides of the animal are covered alſo with two other liſts or ſtripes; theſe go off from the main ſtripe at the top, and theſe are about a quarter of an inch broad; they are covered with a fine and ſoft hairyneſs, of more than a quarter of an inch long, of a fine changeable red and green colour, and of prodigious beauty and brightneſs. Among this long hair of the ſtripes on the ſides there are ſet a vaſt number of long and ſharp prickles; they are about the ſame length with the hair, but they are as ſtiff as a hog's briſtle, and are very ſharp at the points, and of a black colour; there are ſeveral hundreds of theſe on the two ſides.

The tail, or ſmaller end, terminates on the back in two ſcales, which are very bright and fine; under this is the anus, at which the creature voids its excrements. The larger end has no part of the common characters of a head, except the mouth; but as it has this, and ſtands oppoſite to the tail, it is properly enough called ſo in deſcription. It has no horns, no eyes, nor any other of the common organs of inſects heads.

The mouth is very wide, in proportion to the ſize of the creature, and is not placed at the extremity, but ſomewhat under the belly part; ſo that when the back of the creature is viewed, the mouth is not ſeen. The belly is ſmooth and flat, and is covered with a thin ſkin, much paler coloured than that of the back, and irregularly variegated with a number of brown ſpots, of different ſizes and ſhapes. Within an inch of the tail there are ſeen on this under part ſeveral marks, like thoſe of the annular diviſions of the bodies of inſects, but they do not ſhew themſelves on the back. The legs are placed in two rows, each of the whole length of the body of the fiſh; they begin from the angle of the mouth on each ſide, and are continued to the tip of the tail. Thoſe ſtanding near the mouth are longer than the others, which gradually decreaſe till they are very ſhort at the tail; the longeſt are about a quarter of an inch in length, and the ſhorteſt not a ſixth of that length.

The whole number of legs is ſeventy two, thirty ſix ſtanding on each ſide. From within the body, through the middle of each leg, there paſſes a cluſter of three or four prickles; theſe are larger or ſmaller, according to the ſize of the leg, and vary alſo in number, the longeſt legs having moſt of them; they give ſtrength and firmneſs to the legs, ſerving them in the place of bones, and iſſuing out beyond the end of the leg, in the way of claws; they ſerve the creature for the laying faſt hold of any thing it pleaſes. On each ſide of the upper, or back part of the fiſh, there are alſo placed a number of ſoft, flat, and ſmooth fins; theſe ſtand near the legs, and are placed face to face in ſuch a manner, that each foot has its correſponding fin. The fins are exactly of the ſame number with the legs, and, like them, are largeſt toward the head, and go off gradually tapering toward the tail.

Theſe ſerve the creature in the office of a fiſh, giving it power to ſwim in the water, as the others ſerve it as a reptile to crawl upon the ground at the bottom. The fins on each ſide are fringed with the ſame changeable coloured hair, that the ſtripes on the back are.

On opening the body there appears a muſcular organization, elegantly contrived for the working ſo great a number of legs and fins. This appears in form of one large and broad red muſcular congeries, and from this there are propagated on each ſide thirty ſix pair of rays, or oblong and ſlender muſcles, every pair ſerving for the motion of one leg and one fin. Theſe are very diſtinctly viſible, and repreſent the ſpine and ribs in ſome fiſh. And in this the wonderful care of nature is ſeen, in regard to this little animal, which, by means of theſe diſtinct muſcles, is able to move every ſingle leg or fin ſeparately, and conſequently can put as many, or as few as it pleaſes, in motion at a time. It is plain alſo, from the ſtructure of the body of this creature, that it can at pleaſure roll up its body into a round form, and in that caſe will appear as a globe covered with long and ſharp prickles: this is probably its practice, when in danger of being devoured, and may ſerve it on many occaſions. It has been thought by ſome, that Rondeletius means this creature by his *phyſalus*; but this does not appear to be the caſe on a careful examination. Philoſ. Tranſ. N° 225.

SCOLOPENDRA *marina*, a name given by Dr. Molyneux to a new ſpecies of ſea animal, of the centipede *ſcolopendra* kind. See Tab. of Microſcopical Objects, Claſs. 1.

This remarkable inſect, taken in the Iriſh ſeas, is evidently the ſame animal deſcribed by Oligerus Jacobæus, in the *Acta medica Haffnenſia*, under the name of *vermis aureus*, or *erucæ marinæ ſpecies rarior*. It was caſt on ſhore in Holland, at Katwik op Zee; and Aldrovand ſeems to have meant it alſo under the name of the broad bodied cheſnut coloured ſea *ſcolopendra* with numerous yellow feet. The figures and deſcriptions in both theſe places are however very imperfect, and the account given by Dr. Molyneux is the only one at all to be relied on, of this ſtrange animal. Philoſ. Tranſ. N° 224.

SCOLOPENDRA *ſcutata*, in natural hiſtory, the name of an animal of the inſect kind, found in the year 1736 by Klein in Pruſſia, and at the ſame time by Mr. Brown in ſome parts of Kent.

It was met with in Pruſſia in vaſt abundance, in the places where they take crayfiſh, and having not been met with there before, ſurpriſed the people employed in that fiſhery ſo much, that they brought home many of them. In Kent its appearance was attended with greater ſingularity, Mr. Brown found it in a pond on Bexby common, where the country people had obſerved vaſt numbers of them for five or ſix weeks before. This pond was quite dry on the 24th of June that year, but being filled by the thunder ſhower on the 25th of the ſame month, the pond was obſerved to ſwarm with them in two days, by a farmer watering his cows there; and what is very obſervable is, that there appears no channel into this pond, that could convey them from any other place.

The creature is about an inch and half in length, and ſomewhat leſs than an inch in breadth, and though ſo ſmall, yet bears a great reſemblance, in many of its parts, to the great Molucca crab, called by ſome the *buckler crab*. When the back is viewed, it is ſeen to be covered with a caſe or ſhield, ſo that it in ſome meaſure reſembles a tortoiſe, only it is remarkably gibbous, or prominent all along the middle of the back, and has a triangular opening in the ſhell near the tail. This covering is of the conſiſtence of the upper wings of the beetles, and the eyes are prominent, and placed beyond it. When the creature is turned upon its back, ſo that the belly comes in ſight, there are obſerved a vaſt number of legs, and every one of theſe is furniſhed with a ſort of bag at the end, which finally divides itſelf into ſeveral fingers or toes, and all theſe are compoſed of a number of articulations, in the manner of the antennæ of the common inſects. There iſſue from the tail two long and ſlender bodies, articulated in the ſame manner; theſe are about a third of an inch in length, and greatly reſembling the common antennæ. On the head alſo it has two ſhort horns, ſtanding in the common place of the antennæ. When the caſe or ſhell is taken off, the rings of the body are found to be about thirty in number. The legs are very extraordinary, they are forty two on each ſide; the twenty that ſtand next the head are nearly of the ſame ſize, but then they grow gradually ſmaller towards the tail. The feet conſiſt each of five membranaceous claws; theſe are flat, and have a ſtiff rib in the middle, and are beſet at the edges with hairs, in the manner of the legs of a crab. On the lower ſide of the leg hangs an oval bag; and beyond that grows a large thin membrane, which can be extended at the creature's pleaſure by means of a ſtrong rib, which runs all the way along its middle. This membrane, and alſo the whole foot, are convex toward the head, and concave on that ſide that ſtands toward the tail; the thigh, or firſt joint of the leg, is webbed on each ſide, and indeed the whole ſtructure of the legs ſeems calculated for ſwimming, rather than for walking. Philoſ. Tranſ. N° 447. p. 151.

SCOLOPENDRITES *lapis*, in natural hiſtory, a name given by ſome authors to a ſpecies of the *lapis ſyringoides*, or pipe ſtone, the tubules of which they ſuppoſed to reſemble the figure of the body of the *ſcolopendra*.

SCOLYMUS, in botany, the name of a genus of plants, the characters of which are theſe. The flower is compoſed of a number of ſemifloſcules, each placed on an embryo ſeed, and perforated in its bottom part by the capillament which runs out from the embryo. The ſemifloſcules are ſeparated each from the next by a little leaf, and are all contained in a ſquammoſe cup. The embryos afterward become ſeeds affixed to the thalamus of the flower, and adhering to thoſe little leaves which ſeparated the ſemi-floſcules. See Tab. 1. of Botany, Claſs 13.

The ſpecies of *ſcolymus*, enumerated by Mr. Tournefort, are theſe. 1. The *ſcolymus* with gold yellow flowers, called by authors the *yellow flowered thiſtle*, and the *yellow thorn*. 2. The annual yellow flowered *ſcolymus*. And 3. the tall African yellow flowered *ſcolymus*. *Tourn.* Inſt. p. 489.

It is not certain that any of the antients uſed the word *ſcolymus* as the name of the plant we call the artichoak. Theophraſtus, Dioſcorides, and indeed all the antients, have deſcribed this plant; but Theophraſtus ſays that only its roots were eatable, and Dioſcorides ſays ſo of its young ſhoots. It ſeems, therefore, that they meant our chardon by this name, the ſtalks of which our gardiners have a way of blanching for the table.

Theſe Greek writers had indeed another name for the artichoak, they called it *acanthe*. This cannot be doubted by any, who will obſerve their accounts of the *acanthe*, which tell us that it was of the thiſtle kind, but had a large and roundiſh head, compoſed of ſcaly leaves, in the manner of the cone of the fir or pine, (the pine apple as we vulgarly call it) and that in this head was contained its only eſculent part.

This name *acanthe* being very like the word *acanthus*, the name of the *branca urſina*, or bear's breech, there have been many errors in the editions of the antient Greeks,

by confounding the two words. *Dioſcorides*, lib. 18. *Theophraſtus*, p. 72. See ACANTHE.

SCOMBER, the *mackrel*, a well known ſea fiſh of the thynnus kind, and diſtinguiſhed from the other fiſh of that genus by its extremely ſmall and thin ſcales; by its bluiſh green colour on the back, variegated with undulated and crooked black lines; by the forkedneſs of its tail, and the very ſubſtance of the fin of it, being almoſt entirely wanting at the angle of it; and by the largeneſs of its eye, in compariſon of the *amia*, and other fiſh of this kind, which moſt reſemble it in other reſpects. *Willughby*'s Hiſt. Piſc. p. 181.

In the Linnæan ſyſtem of zoology, the *ſcomber* is a diſtinct genus of fiſhes, of the general order of the acanthopterygii. The characters of this are, that the membrane of the gills has ſeven bones, and that the tail has lateral eminences. Of this genus are the *ſcomber*, *thynnus*, *amia*, and *trachurus*. *Linnæi* Syſt. Nat. p. 54.

In the Artedian ſyſtem of ichthyology, the characters of this genus of fiſh are theſe: the branchioſtege membrane on each ſide contains ſeven ſlender bones, the upper one of which is nearly covered by the covering of the gills. The tail is very forked, ſo as to reſemble the form of a creſcent. There are one or more eminences on each ſide toward the tail. The fins are either only two on the back, or elſe, beſide theſe, there are ſeveral other ſmall and ſhort ones, running all the way to the tail, as well on the upper as the under part of the body. The appendices to the pylorus are very numerous.

The ſpecies of this genus are theſe. 1. The *ſcomber* with five pinnules at the end of the back, and a ſhort ſpine at the anus. This is the common *mackrel*. 2. The *ſcomber* with eight or nine pinnules at the end of the back, and a furrow at the belly fins. This is the *tunny* fiſh. 3. The *ſcomber* with prickly lateral lines, and thirty bones in the pinna ani. This is the fiſh we call the *horſe mackrel*, and in ſome places the *ſcad*. 4. The *ſcomber* with two back fins, and with the laſt ray of the ſecond very long. This is the *amia* of Salvian, and the *glaucus* of Aldrovand. It grows to three feet long. 4. The *ſcomber* with the ſecond ray of the ſecond back fin very high. This is the *glaucus primus* of Willughby and Rondeletius. *Artedi*, Gen. Piſc. p. 25. See the articles GLAUCUS, &c.

SCOPELISMUS, Σκοπελισμος, an audacious crime practiſed by ſome villains among the Arabians.

It conſiſted in placing a certain number of ſtones upon the farm or field of perſons theſe miſcreants had a pique at; which ſtones ſerved as a denunciation of utter deſtruction to thoſe, who for the future ſhould attempt to till the ground on which they were laid. And ſuch terror attended this malevolent and clandeſtine threatening, that none ever ventured to till ſuch fields. *Pitiſc.* in voc.

SCOPS, in zoology, the name of a bird of the horn owl kind.

It is the ſmalleſt of all the owl kind, being ſcarce ſo large as a pigeon, and is grey on the head, and of a whitiſh brown, variegated with ſtreaks and ſpots of brown in other places. Its beak is ſhort, black, and crooked, and it has two ſeries of feathers, like the reſt of the horn owls, reſembling horns, which ſtand over its ears. It is very common in Italy. *Aldrovand.* de Avib. lib. 8. cap. 4. *Ray*'s Ornithol. p. 65.

SCORAX, a word uſed by ſome authors to expreſs the gum of the olive tree.

SCORDIUM (*Cycl.*)—This plant is propagated in our gardens for medicinal uſe, by parting the roots, or planting ſlips or cuttings in March, in beds of moiſt earth, at four or five inches diſtance, in July they will be in flower, and fit to cut for uſe. But every other year the bed ſhould be renewed, and that always on a freſh ſpot of ground, for they do not ſucceed well on the ſame. *Miller*'s Gardner's Dictionary.

Scordium, or *water germander*, is eſteemed a great ſudorific and alexipharmic. It is preſcribed in malignant and peſtilential fevers, and even the plague itſelf. It is an attenuant and diſſolvent, and is uſed to deſtroy worms. Externally it cleanſes foul ulcers, and, applied by way of cataplaſm, mitigates pain. It is never uſed alone, but merely kept in the ſhops as an ingredient in the *confectio Fracaſtorii*, which, though it contains ſeveral medicines of more virtue, yet takes its name *diaſcordium* from it.

SCORIA, (*Cycl.*) in metallurgy, the recrements of metals in fuſion, or more determinately ſpeaking, the maſs, or part of the maſs of a melted metal, converted by the action of the fire into a body, which when cold is brittle, fixed, not diſſoluble in water, but melts again when expoſed to the fire, and is properly a kind of glaſs.

Some authors call by this name that ſaline maſs, which is produced by melting ores and metals together with ſaline, and reducing fluxes. But the word *ſcoria* is not properly to be underſtood of all this maſs, but only of the vitrified particles which are lodged between, and adhere to the ſmall maſſes of the ſalts, and which may be ſeparated from them by water. *Cramer*'s Art of Aſſaying, p. 185.

SCORIFICATION, in metallurgy, is the art of reducing a body either entirely, or in part, into *ſcoria*.

It is uſed by metallurgiſts, in order that any metal, impriſoned in a ſolid body, may, on account of its weight, deſcend and ſeparate itſelf therefrom, and finally if that be required, be itſelf either wholly or in part converted into *ſcoria*. All fixed bodies are ſubject to this alteration, not totally excepting even gold and ſilver. There are alſo, among the volatile bodies, ſome that may be fixed, and which aſſume the form of *ſcoræ*, by adding fixed bodies to them.

It is often proper to make this *ſcorification* in a veſſel that may abſorb the *ſcoriæ*, and retain only the metallic part of the maſs under trial. In this caſe the operation is called *coſſpelling*, and veſſels made of aſhes, called *teſts* and *coppels*, ſerve for this purpoſe. It is evident in theſe proceſſes, that a great attenuation of the *ſcoriæ* is neceſſary, that they may be able to paſs through the veſſel; nor is there any fitter body to promote this operation than lead, which, by its undergoing itſelf a like attenuation in the fire, diſpoſes other bodies to be reduced into a ſubtle *ſcoria* for the ſame attenuation.

SCORITH, a word uſed by the chemical writers to expreſs ſulphur.

SCORPÆNA, in the Artedian ſyſtem of ichthyology, the name of a genus of fiſhes, of the acanthopterygious kind, the characters of which are theſe. The branchioſtege membrane on each ſide contains ſeven bones. The head is large, and very prickly. There is only one back fin, and that is lower in the middle than elſewhere. The body grows ſmall toward the tail. The eyes are placed near one another, and are covered with the common ſkin. There are teeth in the jaws, palate, and fauces; and the appendices to the pylorus are eight or nine.

The ſpecies of this genus are theſe. 1. The *ſcorpæna* with pinnules at the eyes and noſtrils. This is the *ſcorpius minor*, or *ſcorpæna* of authors. 2. The red *ſcorpæna* with many cirri about the mouth. This is the *ſcorpius major* of authors, and is three or four times larger than the other. *Artedi*, Gen. Piſc. 33.

According to Mr. Willughby, the *ſcorpæna* is a fiſh of the anguilliform kind, called by the people of Cornwall *father laſher*.

It is of about ſix inches in length, and in ſhape much reſembles the freſh water bullhead. Its head, and the forepart of its body, are very large, the hinder part ſmaller, the belly is flat and broad, and the whole body is without ſcales. It has a rough line running along both ſides. It is variegated with black and yellowiſh marks, and the belly is white. The mouth is large, and is furniſhed with ſeveral rows of ſmall teeth. It has large fins at the gills, and two on its back, which are ſomewhat prickly, and one ſtrait one on the belly. It keeps about the ſhores, and feeds on ſhrimps and ſmall fiſh. It is common in the Dutch and Engliſh ſeas.

Scorpæna is alſo the name of a fiſh caught in many parts of the Mediterranean. It ſeldom grows to more than a pound weight. Its body is of a long, not flatted form, and is moderately thick. Its head is extremely large, and is armed with prickles, and it grows gradually leſs from thence to the tail. Its belly is not flat, but tumid, and its back riſes in the middle. It ſomething reſembles the river pearch in ſhape, and is of a yellowiſh colour, variegated with ſpots of brown. Its ſcales are ſmall and rigid. The coverings of the gills are armed with ſpines, and there are others about the eyes and about the mouth. The ſpace between the eyes is hollowed, and over each eye there is a ſort of ſmall fin. The eyes are large and prominent, and are placed near one another. Its mouth is extremely large, but its teeth ſmall. It has only one back fin, but that being very low in the middle, gives an appearance of two. The anterior ſpines of this are rigid and prickly, the hinder ones ſoft and flexile. The prickles about the head are accounted venomous, and the fiſhermen uſually cut them off as ſoon as the fiſh is caught. Its tail is not forked, but rounded at the end. The belly and bellyfins are reddiſh. *Geſner*, de Piſc. p. 1018. *Aldrovand.* de Piſc. lib. 2. cap. 24.

SCORPIACA, the name of an antidote recommended by Galen againſt the ſtinging of ſcorpions.

SCORPIO, the *ſcorpion*, in zoology. See SCORPION.

SCORPIO, in botany, a name by which ſome of the old authors have called the *geniſta ſpinoſa*, or common furze buſh. *Ger.* Emac. Ind. 2.

SCORPIOIDES, in zoology, the name of a fiſh of the gottorugine kind, but differing in colour, being of a faint green, variegated with black ſpots; and in either wanting the eyefins, or elſe having them extremely minute. *Rondelet.* de Piſc. See GOTTORUGINE.

SCORPIOIDES, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the papilionaceous kind; the piſtil ariſes from the cup, and finally becomes a jointed pod of an oddly convoluted ſhape, reſembling a ſnail or caterpillar, and uſually containing in each of its joints a ſingle oval ſeed. See Tab. 1. of Botany, Claſ. 10.

The ſpecies of *ſcorpioides*, enumerated by Mr. Tournefort, are theſe. 1. The *ſcorpioides* with beupleurum, or hare's ear leaves. 2. The beupleurum leaved *ſcorpioides* with rough, and more contorted horns. 3. The *ſcorpioides* with thick pods. 4. The *ſcorpioides* with beupleurum leaves, and with ſmooth pods. 5. The *ſcorpioides* with cochleated and ſtriated pods. *Tourn.* Inſt. p. 402.

SCORPION (*Cycl.*)—The opinions of authors are very different as to the ſting of this creature; ſome aſſerting that there is an opening in it, through which a poiſonous liquor is thrown into the wound made by it, as is the caſe in the tooth of the viper, &c. and others affirming that there is no ſuch opening.

Galen affirms that there is none, but moſt of the writers of the middle ages aſſert that there is. But the whole is ſet in the cleareſt light by Segnior Redi, who took the pains of examining microſcopically the ſtings of *ſcorpions* brought alive from Tunis, Egypt, and Italy. Theſe he nicely examined by the beſt glaſſes in the Muſæum of the Great Duke of Tuſcany, and could find no aperture: but not ſatisfied with this, he preſſed the ſtings, to try if he could make any liquor flow out of them; they were, however, ſo hard and horny, that ſqueezing could have no effect on them; and finally he cauſed a *ſcorpion* to ſtrike upon a plate of iron, but no liquid was found thereon; ſo that he began to conclude Galen's opinion right, when he accidentally diſcovered an exceedingly ſmall drop of white liquor upon the ſting, and this he afterwards found in all the trials he made with ſeveral *ſcorpions*. And Mr. Lewenhoek diſcovered an opening on each ſide of the ſting of this creature, for the emiſſion of the poiſon, which he ſuppoſes is not diſcharged, till the ſting is buried in the wound. *Baker*'s Microſcope, p. 213.

Mr. de Maupertuis, having cauſed *ſcorpions* to bite ſeveral animals, of which very few died, or ſuffered any more than the pain of the ſting, is of opinion, that oil of *ſcorpions* and other vulgar antidotes to the poiſon of theſe animals, have rather got their reputation from the innocence of the ſting of theſe creatures, than from any conſiderable virtue in the medicines. Mem. de l'Acad. Scienc. 1731.

Water SCORPION, *ſcorpio paluſtris*, a name given to a very remarkable ſpecies of water inſect. It is a very thin and light little creature, yet is but a very ſlow mover. Its head is very ſmall, and is hard to the touch, and of a paler brown than the reſt of the body; and this is terminated by a very fine and ſharp hollow proboſcis, of the ſame colour and texture. The eyes are ſmall, but prominent, and are very hard and black. The ſhoulders are broad and flat; they are of the ſame colour with the head, and are wrinkled on the ſurface. The triangular ſpot between the wings is black and ſhining, the body is of a bright red lead colour on the back, and of a faint duſky brown on the belly, and is compoſed of ſix joints, covered with a ſort of ſcales. The outer wings are very hard and firm, and lie very far over one another; they are opake, and of a dark muddy brown, without any variations: the inner wings are of a duſky white, veined with a red lead colour. The two fore legs are broader and thicker than the reſt, and end in ſhort blunt claws; theſe the creature never walks with, but always uſes them as arms: the hinder pair are the longeſt, and both they and the middle ones end in a ſharp claw; they are all of a pale brown, and ſomewhat tranſparent. The tail is long and ſtrait, it is compoſed of two ſlender briſtles, of a pale brown; the creature ſcarce ever ſeparates theſe. It lives among the weeds in clear ſtanding waters, and is continually watching for its prey. It feeds on other inſects, and is particularly fond of the *cicada aquatica*, or worm of the great libella. It ſeizes its prey with the fore legs, and holds it faſt in them while the proboſcis pierces into the body, and ſucks the juices. See Tab. of Inſects, N° 8.

SCORPION *fly*, in natural hiſtory, a name given by Mouffet and other writers to a kind of fly, remarkable for carrying the end of its tail turned up in form of the *ſcorpion*'s ſting.

There are two very beautiful ſpecies of theſe. The one has ſilvery wings, variegated with three tranſverſe ſtreaks of black toward the ends; the head is black, and the breaſt, ſhoulders and feet whitiſh; the reſt of the body is black. The tail, which repreſents a ſting, has five joints, three of which are red, and the others black; the end of the tail alſo is forked, and the forks black, and turned up like the ſting of a *ſcorpion*.

The other reſembles this in many reſpects, but the end of the tail is thicker, and the forks blunter; the head is duniſh, the mouth long, and each wing variegated with ſix black ſpots, of a large ſize.

SCORPIUS, in ichthyology, the name of a fiſh caught in the Mediterranean, of a long and rounded body, not flatted, and with a very large head, from whence it gradually grows ſmaller to the tail. See Tab. of Fiſhes, N° 61.

It grows to three or four pounds weight, and is of a reddiſh colour, variegated with brown and blackiſh ſpots. It has ſeveral ſhort filaments or beards about its mouth, and the coverings of the gills are armed with ſeveral prickles. Its head alſo has ſeveral prickles about it, and the wounds they make are ſaid to be very venomous. The fiſh is however eaten, and accounted very well taſted. *Geſner*, de Piſc. p. 1017.

SCORTIUM, among the Romans, a meaſure of capacity of a round form, which uſed always to be heaped. *Pitiſc.* Lex. Antiq. in voc.

SCORZONERA, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the ſemiflоſcular kind, being compoſed of a number of ſemiflоſcules ſtanding on the embryo ſeeds, and contained in one general oblong cup. The embryos uſually ripen into ſeeds, which are covered with a ſort of coat or huſk, and are winged with down.

The ſpecies of *ſcorzonera*, enumerated by Mr. Tournefort, are theſe. 1. The *ſcorzonera* with broad ſinuated leaves. 2. The *ſcorzonera* with broad ſinuated leaves, and bitter roots. 3. The double flowered *ſcorzonera* with broad ſinuated leaves. 4. The Dutch broad leaved *ſcorzonera*. 5. The *ſcorzonera* with nervous leaves. 6. The low *ſcorzonera* with broad nervous leaves. 7. The common narrow leaved *ſcorzonera*. 8. The lower narrow leaved *ſcorzonera*. 9. The narrow leaved *ſcornozera* with little roots. 10. The narrow leaved *ſcorzonera* with bluiſh flowers. 11. The thick leaved Montpelier *ſcorzonera*. 12. The duſty flowered marſh *ſcorzonera*. 13. The *ſcorzonera* with jagged leaves. 14. The *ſcorzonera* with capillaceous leaves. 15. The plantain leaved Portugal *ſcorzonera*. 16. The graſs leaved Portugal *ſcorzonera* with pale yellow flowers. *Tourn.* Inſt. p. 476.

The root of this plant is uſed in medicine, and is eſteemed an alexipharmic and ſudorific. It is given in malignant fevers, and is by ſome recommended in epilepſies, vertigoes, and diſorders of the womb; but it is not frequently preſcribed in the preſent practice.

SCOTAL, or SCOTALE, is uſed where any officer of a foreſt keeps an alehouſe within the foreſt, by colour of his office cauſing people to come to his houſe, and there ſpend their money, for fear of his diſpleaſure. We find it mentioned in the Charter of the Foreſt, cap. 8. *Nullus foreſtarius faciat* ſcotallas, *vel garbas colligat, vel aliquam collectam faciat*, &c. *Manwood*, 216.

The word is compounded of *ſcot* and *ale*, and by tranſpoſition of the words, is otherwiſe called *aleſhot*. Terms of Law. *Blount*, *Cowel*.

SCOTER, in zoology, the name of a ſpecies of duck, called alſo in ſome places the *black diver*.

It is nearly of the ſize of the common duck, but of a rounder body, and is all over of a deep ſhining and beautiful black; in ſome the ſhoulder feathers are of a yet deeper black than the reſt; and in others there is a ſlight admixture of greyiſhneſs in the middle of the breaſt. The wings are black, without any variegation, and the beak is black, but has a little yellowneſs near the noſtrils: the feet alſo are black. It is very common on the ſhores of Lancaſhire, and ſome other counties. It lives only about ſalt waters, and is a very great diver. *Ray*'s Ornitholog. p. 80.

SCOTINUS, in botany, the name of a ſhrub called by the Latins *cotinus*, and *cotinus coriaria*, to diſtinguiſh it from the *cotinus*, κότινος, of the Greeks, which was the *oleaſter*, or wild olive.

The Italians call the *cotinus coriaria* ſometimes *ſcotinus*, and ſometimes *ſcotanus*; the latter word ſeems an erroneous way of writing the former, which is only the Roman name of the ſame tree, with an *ſ* put before the firſt letter: and this is very common with the Italians, in their adopting Latin words; what the Romans called *phalangium*, they call *ſphalangio*; what they called *conchylium*, theſe call *ſcongiglio*; and ſo of a number of other words.

SCOTODINOS, a term uſed by medical writers to expreſs a vertigo, or dizzineſs of the head, attended with a dimneſs of ſight.

SCOTOMA, a word uſed by ſome in the ſame ſenſe as *ſcotodines*, to expreſs a vertigo with dimneſs of ſight.

SCOUP *duck*, in zoology, the name of a ſpecies of duck, ſomewhat ſmaller than the common duck, and of a ſtrange diverſity of colours, even in the different birds of the ſame ſpecies, inſomuch that it is not eaſy to find any two perfectly alike in a flock of forty or fifty. The beak is blue, and its moſt general colours are theſe: the head, and part of the neck, are of a greeniſh black; the lower part of the neck has ſome whiteneſs, and the breaſt is black; the belly is white, with an admixture of yellow in its lower part, and near the anus it becomes black; the upper part of the neck is of a ſooty black; the middle of the back is white, variegated with duſky browniſh lines, and the rump and tail are brown, as are alſo the wings, but theſe have ſome tranſverſe ſtreaks of white. The tail is not above two inches long; the legs are bluiſh. *Ray*'s Ornithology, p. 279.

SCRATCH, in the language of the ſalt-workers of our country, the name of a calcarious earthy or ſtony ſubſtance, which ſeparates from ſea water in boiling it for ſalt.

This forms a thick cruſt in a few days on the ſides and bottoms of the pans, which they are forced to be at the pains

of taking off once in a week or ten days, otherwiſe the pans burn away, and are deſtroyed. See SALT.

This is no other than the ſame ſubſtance which cruſts over the inſides of our tea-kettles, and is truly a ſpar, ſuſtained more or leſs in all water, and ſeparable from it by boiling. The ſhells of ſea fiſh have great affinity in their ſubſtance and nature with this, both being powerful alkalis, and both eaſily calcining into lime.

The *magneſia alba*, ſo celebrated in Germany for its mild purgative and alkaline virtues, ſeems very nearly allied to this earth; and it is probable, according to Hoffman, that the purging virtues of many ſprings are owing to the quantities they contain of this ſubſtance.

SCRATCH *pans*, in the Engliſh ſalt-works, a name given to certain leaden pans, which are uſually made about a foot and half long, a foot broad, and three inches deep, and have a bow, or circular handle of iron, by which they may be drawn out with a hook, when the liquor in the pan is boiling. See SALT.

The uſe of theſe *pans* is to receive a calcarious earth, of the nature of that which incruſts our tea-kettles, which ſeparates from the water in boiling; this ſubſtance they call *ſcratch*; and theſe *pans* being placed at the corners of the ſalt pan, where the heat is leaſt violent, catch it as it ſubſides there.

SCREW (*Cycl.*)—SCREW, in the manege. See SPLENT and THOROUGH-*ſplent*.

SCREW-*ſhell*, the Engliſh name of the *turbo*. See the article TURBO.

SCRIPTULUM, among the Romans, the twenty fourth part of an ounce, and equal to two *oboli*. See the article OBOLUS, *Cycl.*

SCRIPTULUS, a word uſed by ſome inſtead of *ſcrupulus*, a ſcruple, or weight of twenty grains.

SCROFANELLO, in zoology, a name by which ſome have called a ſmall fiſh of the Mediterranean, more uſually known by the name of the *ſcorpæna*. *Salvian*, de Aquat. p. 94. See SCORPÆNA.

SCROPHULARIA, *figwort*, in botany, the name of a genus of plants, the characters of which are theſe. The flower conſiſts of one leaf, and is of a ſort of globoſe form, open at the mouth, and divided as it were into two lips, the upper of which has two ſmall leaves under it. The piſtil ariſes from the cup, and is fixed in the manner of a nail to the hinder part of the flower, and afterwards becomes a fruit or capſule, of a roundiſh but pointed figure, divided by an intermediate ſeptum into two cells, and containing ſmall ſeeds affixed to a placenta.

The ſpecies of *figwort*, enumerated by Mr. Tournefort, are theſe. 1. The common, or knobby rooted *figwort*. 2. The great hairy *figwort*. 3. The great *figwort* with green ſtalks and leaves. 4. The great water-*figwort*, commonly called *water-betony*. 5. The leſſer water *figwort*. 6. The yellow flowered *figwort*. 7. The nettle-leaved *figwort*. 8. The baum-leaved *figwort*. 9. The betony-leaved *figwort*. 10. The ſhrubby *figwort* with thick leaves, like in ſhape to thoſe of teucrium. 11. The ſmooth elder-leaved Spaniſh *figwort*. 12. The great hairy elder-leaved Portugal *figwort*. 13. The roundiſh thick and black leaved *figwort* with pale yellow flowers, and very turgid ſeed veſſels. 14. The fern-leaved *ſcrophularia*, or broad leaved dog's rue. 15. The ſhining ſtone *figwort* with laſerwort leaves. 16. The narrow leaved *figwort*, commonly called *dog's rue*. 17. The leſſer dog's rue *figwort*. 18. The vervain-leaved ſhrubby Portugal *figwort*. *Tourn.* Inſt. p. 167.

The root of *ſcrophularia* is eſteemed externally as a remedy for the piles and the king's evil. It is generally made into an ointment for theſe purpoſes; but ſome give it alſo internally in diet drinks.

This root is of a very ſingular figure, by which it is eaſily diſtinguiſhed at ſight from all other medicinal roots. It is uſually of the thickneſs of a man's finger, or more, of an oblong figure, nearly as thick at the one end as the other, and full of protuberances on the ſurface, reſembling a kind of little kernels; and between there are a great many fibres, which ſtrike deep into the ground. The root itſelf has no great ſmell, but its taſte is ſomewhat acrid and diſagreeable.

SCROTUM (*Cycl.*)—Many authors have given accounts of the diſtemperatures of this part, of various kinds, impeding the intent of the propagation of the ſpecies, but one of the moſt remarkable of theſe, is the exceſſive growth of that part, as well in length as in breadth and thickneſs. Securgius, in his *Spermatologia*, gives an account of a perſon, whoſe *ſcrotum* grew to ſuch a ſize, that it reached down to his knees, and the penis was ſo wholly loſt in it, that the paſſage for the urine was ſcarce viſible, and ſeveral orifices were made by a ſharp humor ouzing out of it in different places. The perſon lived a long time with it in this condition, and uſed to ſupport it by a bandage worn acroſs the ſhoulders.

The author gives alſo an account of another *ſcrotum* of this kind, which being at length taken off, partly by a mortification, and partly by the operation of a ſurgeon, was replaced again by nature in the ſame unuſual ſize.

SCRUTATORES, among the Romans, certain officers, or ſervants, whoſe buſineſs it was to ſearch every body that came to ſalute the emperor, in order to diſcover if they had any kind of arms concealed about them. They were firſt inſtituted under the emperor Claudius. *Pitiſc.* in voc.

SCULION, in ichthyology, the name given by Ariſtotle, and many other of the antient writers, to the fiſh called by later authors *catulus*, and *catulus major*, and in England the *bounce*. It is a ſpecies of the ſqualus, called by Artedi the reddiſh variegated *ſqualus* with the pinna ani placed in the middle, between the anus and the fin of the tail. See the article SQUALUS.

SCULPONEÆ, among the Romans, a kind of ſhoes worn by ſlaves of both ſexes. Theſe ſhoes were only blocks of wood made hollow, like the French *ſabots*.

SCUMA, a word uſed by ſome of the chemiſts for *ſquamma*, the ſcales of any metal, and particularly applied to the flakes flying off from hot iron under the hammer.

SCURFF, in zoology, an Engliſh name for a ſpecies of ſalmon, called alſo in ſome places the *bull-trout*. It never grows to any great ſize, and differs plainly from the ſalmon of the common kind in this, that its tail is even, and not forked. Its head is ſhort and thick, and its fleſh is leſs red than that of moſt of the ſalmon kind. *Willughby*, Hiſt. Piſc. p. 193.

SCURRA, in zoology, a name by which the antients have called the *monedula*, or common jackdaw. *Ray's* Ornithol. p. 85.

SCURVOGEL, in zoology, the name of an American bird, called by ſome the *nhender-apoa*, and by the Braſilians *jabiru-guacu*.

It is of the crane kind, or nearly approaching to that genus. Its beak is large, ſeven or eight fingers breadth long, rounded, and ſomewhat bent upwards at the end. In the ſummit of the head he has a ſort of boney crown, of a mixed greyiſh and whitiſh colour. Its neck is conſiderably long, and both that and the head are deſtitute of feathers, and are only covered by a ſquammoſe naked ſkin. It is about the ſize of the ſtork, and has a ſhort black tail; all the reſt of the feathers are white, except that the long wing feathers are blackiſh, with ſomewhat of a purpliſh gloſs. When the ſkin is taken off, it is dreſſed ſeveral ways, and is a very delicately taſted bird. *Ray's* Ornitholog. p. 202.

SCURVY (*Cycl.*)—There are ſome who derive all diſeaſes from the *ſcurvy*, which indeed muſt be allowed to create, or mimic moſt other maladies. Boerhaave tells us it produces pleuretic, colic, nephritic, hepatic pains, various fevers, as hot, malignant, and intermitting, dyſenteries, faintings, anxieties, dropſies, conſumptions, convulſions, palſies, fluxes of blood; in a word, it may be ſaid to contain the ſeeds and origin of almoſt all diſtempers. A cachexy, or ill habit, is much of the ſame nature with the *ſcurvy*. It is ſuppoſed by phyſicians, that the immediate cauſe of the *ſcurvy* lies in the blood, the fibrous part of which is thick, and the ſerum too thin and ſharp; and that hence ariſes the great difficulty in the cure, becauſe in the correcting of one part, regard muſt be had to the other. It is well known how extremely difficult it is to cure an inveterate *ſcurvy*; how many *ſcorbutic* patients have grown worſe by an injudicious courſe of evacuations; how many are even rendered incurable by the treatment of inconſiderate phyſicians; and how difficult, tedious, and uncertain the cure is, in the hands even of the beſt, who are obliged to uſe ſuch variety and change of medicines, in the different ſtages of that malady; which nevertheleſs may be cured, ſays the Biſhop of Cloyne, by the ſole, regular, conſtant, copious uſe of tar-water. In the cure of the *ſcurvy*, the principal aim is to ſubdue the acrimony of the blood and juices; but as this acrimony proceeds from different cauſes, or even oppoſite, as acid and alkaline, what is good in one ſort of *ſcurvy* proves dangerous, or even mortal, in another. It is well known, that hot anti-ſcorbutics, where the juices of the body are alkaleſcent, increaſe the diſeaſe; and ſour fruits and vegetables produce the like effect in the *ſcurvy* cauſed by acid-acrimony. Hence fatal blunders are committed by unwary practitioners, who, not diſtinguiſhing the nature of the diſeaſe, do frequently aggravate, inſtead of curing it. The biſhop ſays, if he may truſt what trials he has been able to make, this water is good in the ſeveral kinds of *ſcurvy*, whether acid, alkaline, or muriatic; and he believes it the only medicine that cures them all, without doing hurt in any. In a high degree of *ſcurvy* a mercurial ſalivation is looked on by many as the only cure; which, by the vehement ſhock it gives the whole frame, and the ſenſible ſecretion it produces, may be thought to be more adequate to ſuch an effect: but the diſorder, occaſioned by that violent proceſs, it is to be feared, may never be got over. The immediate danger, the frequent bad effects, the extreme trouble, and nice care attending ſuch a courſe, do very deſervedly make people afraid of it. And though the ſenſible ſecretion therein be ſo great, yet in a longer tract of time the uſe of tar-water may produce as great a diſcharge of *ſcorbutic* ſalts by urine and perſpiration; the effect of which laſt, though

though not ſo ſenſible, may yet be greater than that of ſalivation; if it be true, that inſenſible perſpiration is conſiderably more than all the reſt of the ſenſible ſecretions together. See TAR-*water*.

For the cure of the *ſcurvy* ſome have propoſed, that the patient ſhould be put into a warm or hot bath, till a ſweat is moderately raiſed, and then immediately taken out and immerſed into cold water. *Morgan*, Mech. Pract. of Phyſ. p. 354. ap. Med. Eſſ. Edinb.

SCURVY-*graſs*, *cochlearia*, in medicine, is a powerful attenuant and reſolvent; and on that principle is an excellent medicine in all diſeaſes ariſing from a viſcid ſtate of the fluids, and particularly in the *ſcurvy*. The beſt way of taking it, is to eat the whole herb by way of ſallad.

The *ſcurvy*, however, is a diſeaſe ſo various, that the ſame medicine cannot be good for all the kinds. Accordingly *ſcurvy-graſs* proves hurtful, where the *ſcurvy* is attended with a redneſs in the face, palpitations of the heart, frequent feveriſh heats, head-achs, purgings, and the like; in all which, acrid medicines of any kind do harm. See the article COCHLEARIA.

SCUTARIUS, among the Romans, beſide its ordinary ſignification of a ſhield-maker, was uſed to denote one of the emperor's life-guards, becauſe their whole body was covered with armour. *Pitiſc.* in voc.

SCUTELLARIA, in botany, a name given to a ſpecies of *caſſida*. See CASSIDA.

SCUTHINON, in botany, a name given by the antient Greeks to a yellow wood, called alſo *thapſum*, *chryſoxylon*, and *ſcythicum lignum*. It was of a beautiful yellow colour, and was uſed in dying and in colouring the hair yellow, which was the favourite colour of that time.

The ſame authors have ſometimes alſo called it *cythinon*, or *cuthinon*: this is only the former word with the initial *ſ* taken away, as it was common with them to do in regard to many words; thus they called the ſmilax *milax*, the ſmaragdus *maragdus*, and ſo of many more.

SCUTTLE-*hatch*, in a ſhip, the little hatch that covers the *ſcuttle*. See HATCH.

SCUTUM, in natural hiſtory, the name of a genus of the *echini marini*, the characters of which are; that it is a ſhell of an irregular figure, which on the lower part repreſents, in ſome meaſure, a ſhield; on the ſuperficies it has the ſhape of a five-leaved flower; its mouth is in the middle of the baſe, and the aperture for the anus at the edge. See Tab. of Teſtaceous Animals, N° 6 and 7.

Of this genus of the eſchini there are two kinds, the angular and the oval. The angular kind has its circumference notched into corners; on its back it has the cinquefoil leaf with very turgid marks, the lines being all crenated alſo at the edges, ſo that it in ſome meaſure repreſents the flowers of the gourd kinds when open. The aperture of the anus is at the broader ſide of the circumference.

The oval kind is a ſhell of a tolerably regular oval figure, with the cinquefoil mark upon its back, made up of leaves like thoſe of the olive, but ſplit as it were at the extremities. The mouth in this ſpecies is in the middle, the anus in the edge, and the baſe is a little hollowed.

Of the firſt of theſe kinds, the angular *ſcuta*, there are only two known ſpecies: the firſt a lower flattiſh kind, and the ſecond a more elevated one.

Of the ſecond, or the oval *ſcuta*, there are three known ſpecies. 1. A kind made up of extremely ſmall granuloſe circles. 2. A hollow baſed one ſhielded like the tortoiſe, and with a pentagonal aperture for the mouth. And 3. an echinated one with a very high top, and a ſlight ſulcus, or furrow, on that part where the anus is. *Klein*'s Echnod. p. 28.

SCUTUM, in pharmacy, a name given to a ſolid ſtomachic topic, whether made in form of a bag, with medicinal ingredients ſowed in it, or of a plaiſter. It is always faſhioned into the ſhape of a ſhield. The plaiſters, for this purpoſe, were uſed to be made of the warm ſtomachic gums, and the bags were filled with the warm aromatic powders; and they were worn to warm and ſtrengthen the ſtomach, correct a cold intemperature, and promote digeſtions, and prevent vomiting. The patella, or knee pan, is alſo ſometimes called by anatomiſts *ſcutum*.

SCYBALA, a term uſed by the antient phyſicians to expreſs the excrements of the inteſtines, hardened into lumps while in the body.

SCYBELITES, a term uſed by the antients to expreſs a ſort of muſt, or juice of the grapes, which diſtilled from them ſpontaneouſly without preſſing.

SCYLACION, a word by which the antients expreſſed the fleſh of puppies, which they recommended as of great ſervice in many chronic caſes.

SCYLDWIT, in our old writers, a mulct or fine for any fault. Leg. Hen. I.

It comes from the Saxon *ſcilde*, i. e. *delictum*, and *wite*, i. e. *pœna*. *Blount*.

SCYMNUS, in ichthyology, a name uſed by Ælian, Appian, and many other of the old Greek writers, for the fiſh called *ſculion* by Ariſtotle. This is a ſpecies of the ſqualus, called by Artedi and others the *ſqualus* with the pinna ani placed in the midſt, between the anus and tail; the *catulus vulgaris*, and *catulus major* of authors. See the article SQUALUS.

SCYPHUS, among the Romans, a very large kind of drinking cup. The *ſcyphus* was called the cup of Hercules, as that of Bacchus, *liberi patris*, was named *cantharus*. *Pitiſc.* in voc. See the article CANTHARUS.

SCYRA, in our old writers, a fine impoſed upon ſuch as neglected to attend the *ſcyregemot* court, which all tenants were bound to do. *Blount*, *Cowel*.

SCYRIUM *marmor*, a name given by the antients ſometimes to a white, and ſometimes to a yellowiſh marble, both uſed in the public buildings of the Romans, but ſeldom in ſtatuary, not being capable of a high poliſh.

SCYTALE, in zoology, the name given by the antients to a ſpecies of ſerpent, which was very long and thin, and equally big all along the body, ſo that the tail was not eaſily diſtinguiſhed from the head.

SCYTHÆ, Σκυθαι, among the Athenians, a deſignation ſometimes given to the officers, more uſually called *lexiarchi*.

They had the name *ſcythæ*, becauſe they were often natives of Scythia who were choſen *lexiarchi*, as being brawny and ſturdy fellows. See LEXIARCHI.

SCYTHARION, in botany, a name given by the antient Greek writers to a tree, whoſe wood was of a fine yellow colour, and was uſed in thoſe early times to dye things yellow; it was called alſo *Scythicum lignum*, from its country, and *chryſoxylon*, or golden wood, from its fine yellow colour. It has been ſuppoſed that this was the ſame with the *cotinus coriaria* of the Romans; but this is an erroneous conjecture, ſince the wood of this tree dyed a yellow colour, and that a browniſh red, or a clear and pure red, according as the infuſion was made more or leſs ſtrong. This *ſcytharion*, therefore, could not be the ſame with the *cotinus*, but it certainly is the ſame with the *thapſum* of the Greeks. See CHRYSOXYLON.

SCYTHIAN, a word uſed very often in the old Greek writers on the materia medica, to diſtinguiſh the peculiar ſort of gum, or other drug, brought from that place. The *Scythian* and Indian drugs have been by many ſuppoſed different kinds of the ſame medicine; but this is an error, for it appears very obvious, on comparing the writings of Galen, Aëtius, Ægineta, and other of the later writers among the Greeks, with thoſe of Dioſcorides, Theophraſtus, and the other old ones, that the words *Scythian* and Indian mean the ſame thing, and that what the old writers have called Indian, theſe have called *Scythian*.

The meaning of this is, that thoſe things were called *Scythian*, which were brought from the country of Indoſcythia, or that part of *Scythia* which lay at the oſtia of the river Indus: but it is to be obſerved, that though the later Greek writers mean this by their term *Scythian*, yet the word is uſed in a very different ſenſe by the Arabians, Aviſenna, Serapio, and others; and that wherever they mention a drug under the name of *Scythian*, they mean that it comes from the northern parts of *Scythia*, on the confines of Europe. Theſe authors having underſtood of this *Scythia*, what the Greek writers have ſaid of the other, have made no ſmall errors in regard to the hiſtory of drugs, having given bdellium, and many other gums, the produce of only the *Scythia* of the Greek medical writers, to the frozen *Scythia* beforementioned.

SCYTHICUM *lignum*, in botany, a name given by the antients to a tree, called alſo *ſcytharium* by the later writers of the Greeks. This is by ſome ſuppoſed to be the ſame with the *cotinus* of the antients uſed in dying.

The Greeks called the *oleaſter*, *cotinus* indeed, but that is not meant as the ſhrub ſuppoſed to be the ſame with the *Scythicum lignum*, but the *cotinus Romanorum*, or, as thoſe people expreſſed it, *cotinus coriaria*.

This however ſeems to be an error; for the *cotinus coriaria* was uſed to dye yellow, whereas the *Scythicum lignum* was uſed for a fine pale yellow, or citron colour, and was thence called *chryſoxylon*, the golden wood, or wood dying a gold colour.

Pliny ſays that the *cotinus coriaria* dyed things to the colour of the fine conchs, that is, to a fine bright fleſh colour; and Anguillara tells us, that the *ſcotano* of the Italians, which is the ſame with the *cotinus coriaria* of the Romans, dyes woollen things to a very agreeable red colour. The words of Pliny are, that it dyes things *conchylii colore*. Theſe have been underſtood as expreſſing the colour of the purple fiſh, or murex, which is a kind of ſhell fiſh, and whoſe colour is a true purple; in this ſenſe the colour would not be the ſame with that yielded by the modern *ſcotano*: but this is not the ſenſe of Pliny, for he often mentions the *conchylius color* as a kind of red, and in many places carefully diſtinguiſhes it from the purple colour yielded by the murex; and it ſeems, according to him, to be the fine pale red, which we ſee ſo beautiful in the mouths of the great conchylia, which our collectors of ſhells call *conchs*. See the articles SCOTANO, and CONCHYLIUS.

SEA (*Cycl.*)—The *ſea* differs in ſaltneſs in different parts; it is, in general, obſerved, that in hotteſt climates the water is ſalteſt.

When

When ſalt water freezes, it hath been thought to let fall all its ſalt; the ice of *ſea* water, and the water melted from it, taſting freſh, and being good for boiling meat and peaſe in. Captain Middleton, being in Hudſon's ſtreights in July 1738, took ice from under the ſurface of the *ſea*, which he melted till he got forty quarts of water; theſe he evaporated to dryneſs, and out of that quantity had only ſix ounces of ſalt, or about $\frac{1}{113}$. Philoſ. Tranſ. N° 461. ſect. 13.

The aſcent of the *ſea* water, for the formation of ſprings by a ſubterranean circulation of its water to their ſources, has been a great objection with many againſt the ſyſtem of their being formed of the *ſea*; but Dr. Plot has obſerved, that there are many ways by which the water may aſcend above its own level. 1. By the means of ſubterranean heats. 2. By filtration. 3. By the unequal height of ſeveral *ſeas*. 4. By the diſtance of the center of magnitude from the center of gravity in the terraqueous globe. The ſuperficies of the Pacific *ſea* is ſaid to be farther from the center of gravity, than the top of the higheſt hill on the adverſe part of the globe. And 5. by the help of ſtorms.

The *ſea* water actually aſcends above its own level in coming into wells, whoſe bottoms lie higher than the ſurface of the ſea at highwater mark. *Plot*, de Origine Font.

General motion of the SEA. Mr. Daſſie of Paris, in a work publiſhed about ſixty years ago, has been at great pains to prove that the *ſea* has a general motion, independent of winds and tides, and of more conſequence in navigation than is uſually ſuppoſed. He affirms that this motion is from eaſt to weſt, inclining toward the north, when the ſun has paſſed the equinoctial northward, and that during the time the ſun is in the northern ſigns; but the contrary way, after the ſun has paſſed the ſaid equinoctial ſouthward; adding, that when this general motion is changed, the diurnal flux is changed alſo: whence it happens, that in ſeveral places the tides come in during one part of the year, and go out during the other; as on the coaſts of Norway, in the Indies, at Goa, Cochinchina, *&c.* where, while the ſun is in the ſummer ſigns, the *ſea* runs to the ſhore, when in the winter ſigns, from it. On the moſt ſouthern coaſts of Tonquin and China, for the ſix ſummer months, the diurnal courſe runs from the north with the ocean; but the ſun having repaſſed the line toward the ſouth, the courſe declines alſo ſouthward. Philoſ. Tranſ. N° 135.

Baſon of the SEA, *fundus maris*, a term uſed by geographers, and other writers, to expreſs the bottom of the *ſea* in general.

Our honourable Mr. Boyle is the firſt who has written any thing on this part of the globe, and he has given us a treatiſe expreſsly upon it; but this only gives an account of its irregularities, and unequal depths, and is founded on the obſervations communicated to him by mariners, and people of too little curioſity to be depended upon for great diſcoveries.

The ingenious Count Marſigli has, ſince his time, given us a much fuller account of this part of the globe, in a great part from his own experiments in many places, particularly along the coaſts of Provence and Languedoc.

The entire baſon of the *ſea* is of ſuch immenſe extent, and covered in many places with ſuch an unfathomable depth of water, that it is not to be expected that it can be traced in every part; but as the whole may be gueſſed at, from ſome part of it, and as its general figure is of no conſequence in a ſearch of this kind, the obſervations of this curious author are of great value, in forming a judgment of the whole. *Marſigli*, Hiſt. de la Mer. p. 4.

The materials, which compoſe the bottom of the *ſea*, may very rationally be ſuppoſed, in ſome degree, to influence the taſte of its waters; and Marſigli has made many experiments to prove, that foſſile coal, and other bituminous ſubſtances, which are found in plenty at the bottom of the *ſea*, may communicate in great part its bitterneſs to it.

We are not, however, to judge haſtily, that there are not ſo many beds of theſe at the bottom of the *ſea*, as would be neceſſary for ſuch a purpoſe, or to judge too haſtily againſt the exiſtence of any other ſubſtances there, becauſe we do not find proofs of them by the plummet, which in ſounding brings up other ſubſtances, and not theſe; for the true bottom of the *ſea* is very often covered and obſcured from us by another accidental bottom, formed of various ſubſtances mingled together, and often covering it to a conſiderable depth.

The entire gulf of Lyons, ſituated between Cape Quiez in Rouſillon, and Cape Croiſit in Provence, forms a bank above the ſurface of the water at the ſhore, of the exact and perfect figure of an arch; and within this there is formed another ſuch arch, making the bottom of the *ſea* in that place for a very great way from ſhore, which is of different depths in various places, but uſually between ſixty and ſeventy fathom. See SHORES.

It is a general rule among ſailors, and is found to hold true in a great many inſtances, that the more the ſhores of any place are ſteep and high, forming perpendicular cliffs, the more deep the *ſea* is below; and that on the contrary, level ſhores denote ſhallow *ſeas*. Thus the deepeſt part of the Mediterranean is generally allowed to be under the height of Malta. The obſervation of the ſtrata of earth, and other foſſils, on and near the ſhores, may ſerve to form a very good judgment, as to the materials which are found in its bottom. The veins of ſalt and of bitumen doubtleſs run on the ſame, and in the ſame order in which we ſee them at land; and the ſtrata of rocks, that ſerve to ſupport the earth of hills and elevated places on ſhore, ſerve alſo, in the ſame continued chain, to ſupport the immenſe quantity of water in the baſon of the *ſea*. It is probable alſo that the veins of metals, and of other mineral ſubſtances, which are found in the neighbouring earth, are in the ſame manner continued into the depths of the *ſea*. The particles of metals, in this caſe, are probably carried off into deep water, and ſunk among the ſofter matter of the bottom, but ſome of the lighter minerals ſeem to have given colour to thoſe beautiful cruſts, which are found upon many *ſea* plants, and which loſe their luſtre in the drying. The ſubterranean rivers, and currents of water, make great changes in what would be the natural ſurface of the bottom of the *ſea*, where they ariſe, each having a peculiar baſon of its own. We are informed by numerous inſtances of ſubterranean currents, and as we ſee them break out in rivers on the ſurface of the earth in ſome parts, ſo in others we may be well aſſured that they break up the bottom of the *ſea*, and empty their freſh waters into the ſalt maſs.

In this caſe, the ruſhing up continually of ſuch a body of water makes a roundiſh cavity, and its running ſome one way lengthens and carries on that cavity, till by degrees it is loſt, as the freſh water by degrees becomes blended with the ſalt. Thus every river, that ariſes in the bottom of the *ſea*, alters the form of its ſurface, and makes a baſon for itſelf, in which it runs a conſiderable way. Many *ſeas* near the ſhore, and when the water is tolerably clear, ſhew the traces of theſe currents to the naked eye from the ſurface, and the water taken up from them is found more or leſs freſh. *Marſigli*, Hiſt. de la Mer. p. 13.

The coral fiſheries have given us occaſion to obſerve, that there are many, and thoſe very large, caverns or hollows in the bottom of the *ſea*, eſpecially when it is rocky; and that the like caverns are ſometimes found in the perpendicular rocks, which form the ſteep ſides of thoſe fiſheries. Theſe caverns are often of great depths, as well as extent, and have ſometimes wide mouths, equal to their largeſt diameter in any part, but ſometimes they have only narrow entrances into large and ſpacious hollows. It is the common opinion of the people about the place, that theſe caverns are prepared by nature for the circulating of the *ſea* water; but that operation, however neceſſary, may be performed as well without, as with theſe caverns, and they ſeem in reality to be only accidental.

We daily meet with immenſe hollows and caverns, naturally made in rocky mountains; and as this part of the bottom of the *ſea* is almoſt all rock, and its ſides of the ſame nature, it is no wonder that the ſame accidents ſhould happen, and like hollows be found, though with no particular intent of providence in their uſe. Nay there is this farther reaſon to expect them in the rocks buried under the *ſea* than in thoſe in hills, that the latter are in a ſtate of reſt and quiet, whereas the former are in continual reach of water, which will inſinuate itſelf into every crack or crevice nature has left in them, and may be eaſily ſuppoſed to have burrowed its way in a ſmall hole made by nature, till it has formed of it a very large one.

It ſeems plain from the whole, that the baſon of the *ſea* was at the creation, or at its ſecond formation after the univerſal deluge, covered with, or compoſed of the ſame ſubſtances, as the ſurface of the reſt of the earth is, that is of rocks, clay and ſand, and other ſuch ſubſtances. The common obſervations of ſeamen ſeem indeed to make againſt this opinion, but they may be eaſily ſolved, ſo as not to overthrow it. The plummet which they let down in ſounding, uſually brings up with it a matter compoſed of mud, tartarous incruſtations, or of dead weeds and broken ſhells, or numbers of various bodies of this kind, cemented together into a firm maſs by ſome ſparry or tartarous matter, depoſited from among the water, and agglutinating them together: theſe form an artificial bottom, covering the natural one; but it is eaſy to ſee, that ſuch a cruſt or coat as this muſt needs have been formed over the true bottom, in places where numbers of animals and vegetables are produced, and decay again, and where the waters being at reſt have time to depoſit their ſtony matter, in the ſame manner as the waters of ſeveral of our petrifying, or rather incruſtating ſprings do. And that theſe decayed ſubſtances, and this ſtony matter, falling to the bottom together, and there lying undiſturbed, muſt neceſſarily have formed juſt ſuch a cruſt as is found; and the natural bottom of the *ſea*, whether of ſtone, of ſand, or of clay, muſt be covered by ſuch accidental concretions, and that probably to ſuch a depth, that it is not eaſy now to break through it.

There are places however where, by ſome accidents, this ſort of adventitious cruſt either has never been formed, or elſe has been removed. In theſe places we find the natural

tural bottom, as deſcribed, that is of the ſame nature with the ſtrata in the body of the earth. The ſimile the Count Marſigli has made, between the baſon of the *ſea* and a caſk of wine, is very expreſſive and juſt. When wine has been a long time kept in a caſk, the whole internal ſurface of that caſk is ſo covered and encruſtated over with tartar, that it ſeems within to be really compoſed of it; yet as we know that this caſk is of wood, we are very certain that the true inner ſurface of it is of the ſame texture and nature with the tree from which it was cut, though we cannot get off the accidental ſurface formed by the liquor kept in it, and wholly covering it.

We very frequently meet with fine and pure ſand at the bottom of the *ſea*, and in theſe places are apt to believe that we certainly have the true and original bottom, but this is rather to be looked on as a probability than a certainty; and where the ſand is more than ordinarily fine, there is always reaſon to ſuſpect that the courſe of ſome ſubterranean river has brought it there, by opening into the *ſea* in this part; and that this is one of thoſe particular baſons, which theſe rivers form to themſelves within the baſon of the *ſea*, and which continue only to a ſmall diſtance from their ſource. *Marſigli*, Hiſt. de la Mer. p. 15.

The bottom of the *ſea* is covered with a variety of matters, ſuch as could not be imagined by any but thoſe who have examined into it, eſpecially in deep water, where the ſurface only is diſturbed by tides and ſtorms, the lower part, and conſequently its bed at the bottom, remaining for ages perhaps undiſturbed. The ſoundings, when the plummet firſt touches ground on approaching the ſhores, gives ſome idea of this. The bottom of the plummet is hollowed, and in that hollow there is placed a lump of tallow; this being the bottom of the lead, is what firſt touches ground, and the ſoft nature of this fat receives into it ſome part of thoſe ſubſtances, which it meets with at the bottom: this matter, thus brought up, is ſometimes pure ſand, ſometimes a ſort of ſand made of the fragments of ſhells, beat to a ſort of powder, ſometimes it is made of a like powder of the ſeveral ſorts of corals, and ſometimes it is compoſed of fragments of rocks; but beſide theſe appearances, which are natural enough, and are what might very well be expected, it brings up ſubſtances which are of the moſt beautiful colours. Things of as fine a ſcarlet, vermillion, purple, *&c.* as the fineſt paint could make them, and as yellow as a ſolution of gamboge, are common; and ſometimes, though not ſo frequently, the matter brought up is blue, green, or of a pure ſnowy whiteneſs. Theſe coloured matters ſometimes ſeem to have made up the whole bottom or maſs of the ſurface, but more uſually they have been formed upon other things, as upon the mud, or upon larger pieces of ſhells, corals, and the like, in the manner of tartarous cruſts, and thoſe in ſome degree reſembling the cruſtaceous coats of ſome of the *ſea* plants. The colours of theſe ſubſtances are not merely ſuperficial and tranſient, but many of them are ſo real and permanent, that they may be received into white wax melted, and poured upon them, or kept in fuſion about them; and when thus examined, they ſeem as if a proper care might make them of great value, as paints of the finer kinds, where little is to be uſed.

The ſame coloured matters that thus coat the ſubſtances, found at the bottom of the *ſea* in theſe places, are alſo ſometimes found extended over the ſurface of *ſea* plants of the harder kind, which grow in deep water. They are always, in this caſe, in a ſort of liquid form, being lodged within, or embodied among a ſort of jelly or glue of a tranſparent ſubſtance, which in theſe caſes perfectly coats over the whole plant. In this ſtate it gives the naturaliſt, who is preſent at the fiſhing up his treaſures, a tranſient proſpect of a very elegant kind; but this vaniſhes while he admires it. A piece of coral, or other hard *ſea* plant, thus coated over, appears, as it riſes to the ſurface of the water, of a delicate green, blue, or purple, but when taken above water, it is found that this fine colour is only in the coat of glue or jelly which covers the plant: as ſoon as this is wiped off, the colour is carried away with it, and the coral ſhews its own native tinge; and it is to no purpoſe to attempt the preſerving it, by ſuffering this glue to dry upon the plant, for the colour flies away by degrees, as the moiſture evaporates, and the coral or plant, whatever it be, is only ſo much the leſs beautiful, than it naturally would have been, as it is covered with a dry yellowiſh dirty looking horny matter. Theſe are beauties in the ſubmarine plants, therefore, which can be only ſeen by thoſe who venture out, in order to take them up.

The ſmall quantities of theſe elegant colours, which we thus find ſpread over the ſurfaces of plants and other bodies, as we approach deep water, may give a rational idea of what we ſhould find, were we able to examine the bottoms of the *ſea* in its deep and unfathomable receſſes. It is eaſy to conceive, that in theſe places we ſhould find great quantities of the moſt beautiful ſubſtances. *Marſigli*, Hiſt. Phyſ. de la Mer.

Dead SEA. Dr. Perry made ſeveral experiments on the water of the *Dead ſea*, in order to find what particles it contained. Upon infuſing ſome ſcrapings of galls in it, it becomes of a bright purple colour, but that not till it has ſtood a conſiderable time. On adding oil of tartar *per deliquium* to it, it becomes turbid, and looks as if globules of fat were fluctuating in it; this unctuous matter, upon its long ſtanding in repoſe, comes together in form of a ſediment at the bottom. On pouring ſpirit of vitriol into it, it depoſits a milk-white greaſy ſediment, which, after ſtanding twelve hours, occupies about one fifth part of the liquor. On putting a ſmall quantity of ſaccharum ſaturni to it, it depoſits a ſmall quantity of a greyiſh powder. Being ſeverally and ſeparately mixed with a ſolution of ſublimate, with ſpirit of ſal armoniac, and with ſugar of violets, it neither ferments, nor depoſits any ſediment, nor changes colour, except with the ſugar of violets, with which it becomes green. It is highly ſaturated with ſalt, ſo that it is to common water in ſpecific gravity, as five to four; and it has ſo acrid and ſtyptic a taſte, that on being held in the mouth, it conſtringes it in the manner of alum.

From all theſe experiments it appears, that this water is impregnated with a ſort of an acrid and alkaline nature, and a matter partly of a ſulphureous, partly of a bituminous nature. Philoſ. Tranſ. N° 462. p. 50.

SEA *adder*, an Engliſh name for a ſea fiſh of the acus kind, called by Willughby the *acus lumbriciformis*.

It is a ſmall fiſh of a cylindric ſhape, without ſcales, and of a greeniſh brown colour, with ſome admixture of a reddiſh yellow. The ſnout is long and hollow, and the mouth opens upwards at its end. The eyes are ſmall, and their iris red. The gills are four on each ſide, but are covered by a membrane, and the whole body divided into rings like the common earth-worm. It is uſually about three or four inches long, and of the thickneſs of a gooſe quill. It has but one fin, which is ſituated on the back. The anus is much nearer the head than the tail; and under the ſnout there is always a fleſhy tubercle. The fiſh is common on the coaſt of Cornwall. *Willughby*, Hiſt. Piſc. p. 160.

SEA *breaches*, a term uſed by the farmers to expreſs the overflowing of their low lands near the *ſea* by the *ſea* water.

Sea ſalt, moderately uſed, is a great improvement to all lands, but too much of it kills all ſorts of vegetables, except ſuch as nature has intended to live among it. The *ſea* breaking in upon lands thus, injures them greatly. The owner is to ſtop the breach by which it entered with all poſſible diligence, and then trenches and drains muſt be cut through all parts of the land, to carry the ſalt water into ſome one low place, from which it may be emptied by means of an engine; or if it be ſmall in quantity, it may be laded out by hand over the bank; or if yet leſs, the ſun and winds may dry it away: but in either caſe, the place where it was ſuffered to reſt muſt be covered with a large quantity of freſh earth, to take off from the too great ſaltneſs of the other; and the whole land ſhould be plowed for three or four years, to let in the rains and air to freſhen it. *Mortimer*'s Huſbandry.

SEA *bream*, in ichthyology, the Engliſh name for the fiſh called by the generality of authors the *pagrus* and *phagrus*. According to the new ſyſtem of Artedi, it is a ſpecies of the *ſpari*, and is diſtinguiſhed by the name of the *red ſparus* with the ſkin carried into a ſinus at the roots of the back fins, and the pinna ani. See PAGRUS and SPARUS.

SEA *calf*, *vitulus marinus*, in zoology. See PHOCA.

SEA *cow*, the Engliſh name of the *manati*, a ſpecies of fiſh ſo different from all the other of the cetaceous tribe, to which it properly belongs, that Artedi, in his new ſyſtem of ichthyology, allots it a peculiar generical name, which is *thricechus*.

It is called by Herrera *taurus marinus*, or the *ſea bull*, and by others the *tachas* and *la donna*. The French call it *lamantin*, or *namantin*, and the Portugueſe *pezze mouller*.

It may ſeem ſtrange, that ſo ill ſhaped a creature as this ſhould have given riſe to the ſtories of the ſyrens and mermaids, the *ſea* men and *ſea* women, yet there is great reaſon to believe, that all the fabulous accounts of theſe monſters are owing to the ſeeing this animal raiſe its head and ſhoulders above the water. See SEA *man*.

SEA *crow*, in zoology, a name given by the common people of many counties of England to the *pewit*. See the article PEWIT.

SEA *devil*, in ichthyology, an Engliſh name for the *rana piſcatrix*, or *lophius*. See RANA *piſcatrix*.

SEA *fox*, an Engliſh name for a fiſh of the ſqualus kind, called alſo the *ſea ape*; both names being given on occaſion of the length of its tail in proportion to the body.

It is a very ſingular fiſh, and, according to the new Artedian ſyſtem, is a ſpecies of *ſqualus*, diſtinguiſhed by that author by the name of the *ſqualus cauda longiore quam ipſum corpus*.

The old Greek writers have called it *alopæcia*, and the later *vulpes marina*, and *ſimia marina*, whence the names *ſea fox*, and *ſea ape*. See the articles VULPES and SQUALUS.

SEA-*gate*, at ſea. When two ſhips are aboard one another, by means of a wave or billow, the ſeamen ſay they *lie aboard one another in a ſea-gate*.

SEA *green*. To make this colour in the glaſs trade, the fineſt cryſtalline glaſs only muſt be uſed, and no manganeſe muſt be added at firſt to the metal. The cryſtal fritt muſt be melted thus alone, and the ſalt, which ſwims like oil on its top, muſt be taken off with an iron ladle very carefully. Then to a pot of twenty pound of this metal, add ſix ounces of calcined braſs, and a fourth part of the quantity of powdered zaffer: this powder muſt be well mixed, and put into the glaſs at three times, it will make the metal ſwell at firſt, and all muſt be thoroughly mixed in the pot. After it has ſtood in fuſion three hours, take out a little for a proof; if it be too pale, add more of the powder. Twenty four hours after the mixing the powder the whole will be ready to work, but muſt be well ſtirred together from the bottom, leſt the colour ſhould be deepeſt there, and the metal at the top leſs coloured, or even quite colourleſs. Some uſe for this purpoſe half cryſtal fritt, and half rochetta fritt, but the colour is much the fineſt when all cryſtal fritt is uſed. *Neri*'s Art of Glaſs, p. 39.

SEA *gudgeon*, an Engliſh name given to the fiſh called by the generality of writers *gobius niger*, and the *gobius marinus*.

Artedi, who has made a genus of the *gobii*, excludes the common *gudgeon*, or *gobio fluviatilis*, from it, but he admits this fiſh as a genuine ſpecies of it.

Athenæus tells us of three kinds of *gudgeons*, the black, the yellow, and the white. This ſeems to have been very plainly the black *gudgeon* of that author. Salvian, in his figure of this fiſh, has given three fins on the back, but it really has only two.

SEA *hen*, in zoology, a name given by ſome to the *lomwia*, a webfooted bird, common on our coaſts, and called the *guillemot*, or *kiddow*. See LOMWIA.

SEA *horſe*, the Engliſh name of the *hippocampus*, a ſpecies of the *acus*, according to the older writers, and one of the *ſyngnathi* of Artedi. See theſe heads.

The many idle tales reported of this vaſt amphibious creature, ſuch as his method of bleeding himſelf when diſtempered, his vomiting fire when enraged, and the like, have made people, in almoſt all ages, deſirous of ſeeing the animal. The Romans were fond of exhibiting it in their ſhews of wild beaſts, and the deſcription Pliny gave of it from thence, was all the world knew of the creature for many ages. That author's account, however, of its feeding on graſs on the banks of the Nile, no way agrees with the teeth we find its mouth furniſhed with.

The ſceletons of theſe animals, as rare as they are with us at preſent in their recent ſtate, yet are found not unfrequently, in part at leaſt, buried under ground, and that at great depths. The bones of the head are different from thoſe of any other known animal, and when found in ſome parts of France, had always puzzled the wits of the naturaliſts there, who had in vain compared them with thoſe of oxen, horſes, *&c.* but at length one of the heads of theſe animals being ſent over to France, cleared up the whole difficulty. The two jaws of this weighed forty five pounds, and were two feet long, a foot deep, and a foot and half wide. It is eaſy to conceive from this, that the accounts we have of the ſize of the animal are not fabulous, theſe bones correſponding very well with them. Mem. Acad. Par. 1724.

SEA *louſe*, *pediculus marinus*, a name given to the Molucca crab. See SQUILLA.

SEA *man*. We have many accounts, even from authors of credit, of ſomething reſembling the human figure ſeen at *ſea*, and fancy has carried them to ſuch a height, that the truth of the deſcription is loſt in moſt of them.

The ſyrens, which we have accounts of even in Bartholin, and the *ſea man*, or *homo marinus*, as it was called, ſeen and deſcribed by Barchewitz, give the greateſt credit to the ſtory; but writers are ſo fond of telling marvellous things, that great allowances are to be made in the reading.

The general deſcription of the *ſea man* is, that from the navel downwards the whole is only a ſhapeleſs lump of fleſh, without any the leaſt mark, either of limbs, fins, or tail. On the breaſt there ſtand two pectoral fins, which are each compoſed of five bones or rays, reſembling the human hand, and connected together by a membrane like the toes of a duck, or ſome other water fowl's foot.

Theſe fins are what have the appearance of ſomething human, and when ſeen about the boſom of a white bellied fiſh, may be taken for hands with ſhort arms, and the reſemblance of a head is eaſily fancied. Theſe fins are not peculiar to any one kind of fiſh, but the manati, or *ſea* cow, the rana piſcatrix, or lophius, and many others have them. It is probable from moſt of the accounts we have, that the manati, or *ſea* cow, is the creature, which being ſeen raiſing its head above water at a diſtance, and extending theſe pectoral fins, which are what it ſwims with, has given riſe to the idea of the upper part of a human figure.

As to the deſcription of a ſhapeleſs lump of fleſh making up the lower part of the animal, it ſeems too contrary to the courſe of nature in all other *ſea* animals, to have any foundation in reality, and probably was only the invention of the deſcriber, to make out what he did not ſee above water.

It is true that Barchewitz takes great pains to prove that the *ſea man*, or *homo marinus*, he deſcribes, was a wholly different creature from the *ſea* cow; but his deſcription of it carries too little the air of any thing in nature, to meet with an eaſy credit.

It is wonderful, that ſo judicious a writer as Artedi ſhould give any faith to the exiſtence of ſo ſtrange a fiſh as this, but he mentions it with a great air of diſtruſt, and wiſhes a more perfect hiſtory of it, if it any where exiſts.

The public are often impoſed upon by cheats, who ſhew different things under the name of *ſea men*, mermaids, and ſyrens; but if we may judge of the generality of theſe creatures, thus ſhewn by the lateſt inſtance among us, they are very wretched counterfeits indeed. This creature was ſaid to be a young mermaid, taken on the Acapulca ſhore, and maintained its credit ſo well in London, as to afford the proprietor a comfortable ſubſiſtence for ten months among us, though no other than a human fœtus of about eight months, with a hydrocephalus head, and with the two legs growing together, and covered by one common membrane. The toes of this fœtus were beat out into a reſemblance of fins.

SEA *owl*, in ichthyology, a name given by many to that fiſh, which we more uſually call the *lump fiſh*, the *lumpus* of Willughby, *&c.* and the *cyclopterus* of Artedi, which ſee.

SEA *pheaſant*, in zoology, the name of a bird of the duck kind, but differing from all the other ſpecies in the ſhape of its tail; which has two long feathers, ſtanding out beyond the reſt, and terminating in a point. It is called more generally the *cracker*. See the article CRACKER.

SEA *plants*. Count Marſigli, who was at indefatigable pains to collect the various *ſea plants* of ſeveral places, divides all thoſe productions into three claſſes.

The firſt claſs contains the ſoft, or herbaceous ones; the ſecond the ligneous ones, or ſuch as are of a woody hardneſs; and the third, thoſe which are of the hardneſs of ſtone.

Of the firſt claſs are the algas, called *ſea wracks*, the fucuſes, or *ſea oaks*, the *ſea moſſes*, or confervas, and the different ſpecies of ſpunges.

Of the ſecond kind are thoſe called *lythophyta* by the antients, as if their hardneſs approached to that of ſtones. All theſe conſiſt of two ſubſtances, a cortical and an internal: the cortical part, while in the *ſea*, is ſoft, but in drying it becomes as hard as chalk, or thereabouts, eaſily crumbling to pieces between the fingers; this is what deceived the antients into an opinion of its being of a ſtony nature. The internal ſubſtance, properly ſpeaking, ſeems more the nature of horn than of wood: if it is burnt, it throws out a ſpume, or froth, like that which horns or feathers of animals yield in the fire, and their ſmell in burning is of the ſame kind. The branches of theſe *plants* are very pliable, bending in the manner of whalebone, and they give the ſame reſiſtance to a knife in the cutting.

The ſtony *plants*, which ſhould properly be called the *lythophyta*, but which never are called ſo, are the ſeveral ſpecies of coral, madrepora, and the like. The madrepora differs from the coral, in having its ſurface pierced with almoſt innumerable holes.

The algas are the only *ſea plants* which have any roots, properly ſo called; theſe therefore grow out of the ſoft bottom of the *ſea*, as other plants out of the earth, but all the other *ſea plants*, without exception, appear fixed upon hard and ſolid bodies, incapable of affording them any nouriſhment; ſuch as ſtones, ſhells, pieces of iron, of wood, *&c.* and ſometimes on other *plants*; and they are not faſtened to theſe ſubſtances by fibres paſſing into, or ſurrounding them, but merely by a foot or pediment, capable of only fixing them down, not of drawing nouriſhment from the ſubſtances, were there any there. From this obſervation the author concludes, that all the *plants* which have no roots may be properly ſaid to be all root, or to perform the office of roots in their whole ſubſtance, or that they take in nouriſhment in every part by certain pores, which in many are viſible, and cover the whole ſurface.

This manner of receiving nouriſhment, he alſo obſerves, very well ſuits their condition, ſince they are always ſurrounded, on all ſides, with that water by which they are to be nouriſhed; whereas the plants, which grow at land, have only a part of them buried in the earth, from whence they are to be ſupplied with the proper juices. The roots of land plants, therefore, have only the neceſſary organs for receiving ſupplies; whereas the *ſea plants* he finds to be all over covered with ſmall glandules, whoſe office it is to receive and to convey, into the internal parts of the *plant*, the proper juices for its nouriſhment, and theſe he obſerves are, in general, of a glutinous and milky nature. The great difference between the land and *ſea plants* is ſeen in this familiar inſtance; a land plant will remain freſh for a long time, in all its parts, on one end of the ſtalk only being plunged in water, but a *ſea plant*, if part of it be out of water and part in, will always be freſh and vigorous in that part which is under water, while the part that is dry will wither and decay. It is eaſy hence to ſee, that the ſeveral parts of the land plants have connections with, and dependances on one another; whereas, in the *ſea plant*, every part takes in its

own nouriſhment, and lives and flouriſhes wholly independent of the reſt.

After having gone through this general ſyſtem, the author deſcends to ſeveral remarkable particulars. He mentions an inſtance of a fucus, whoſe ſtalk, when in its growing ſtate, is a quarter of an inch in diameter, yet in drying ſhrinks up ſo much, as to be not thicker than a ſingle thread. Another ſpecies, called by the fiſhermen the *ſea orange*, from its reſemblance to an orange in ſhape, he obſerves is properly a fucus; it has neither ſtalk nor branches, but conſiſts wholly of this globular body; it is not a ſolid ſubſtance, but a membrane of about $\frac{1}{9}$ of an inch in thickneſs, regularly diſtended into this ſhape, by being filled with *ſea* water. All over the ſides of this cavity there are fixed ſlender filaments, which traverſe the whole, and probably receive nouriſhment from the water contained in the cavity, and diſtribute it to the ſeveral parts of the ſides where they are inſerted.

Another *ſea plant* this author mentions, only appears in the ſhape of a bark; it affixes itſelf to the branches of the lythophyta, when they have loſt their natural bark, and ſometimes, in the ſame manner, coats and cruſts over the ſurfaces of ſtones. When it is freſh, it is of a lively red, of the conſiſtence of a muſhroom, and about the thickneſs of the back of a common knife, and its external ſurface is full of ſmall prominences, which contain a glutinous juice; round about theſe alſo there ſtand ſeveral yellow tubercles, which, with the red of the ground of the *plant*, make upon the whole a very beautiful appearance. Its under ſurface is perfectly ſmooth and gloſſy. This ſeems a much more remarkable *plant*, as to the manner of its vegetation, than thoſe which grow on other plants at land.

The ſame author obſerves, that ſeveral of the ſpunges, when taken out of the *ſea*, have a motion of the nature of a ſyſtole and diaſtole, which laſts as long as there remains any of the *ſea* water in their cavities. Some of the *ſea plants*, which while growing are as ſoft as the fucuſes, yet when dried are as eaſily rubbed to powder between the fingers, as the bark of the lithophytons. There is one of the lithophytons, which carries ſo large a quantity of branches, that they make the reſemblance of leaves; but as theſe leaf-like branches are all truly of the ſame nature with the reſt of the *plant*, this is no exception to the general rule, that the lithophyta have no leaves. One of the ſpecies of lithophyton is naturally deſtitute of a bark, and is covered in the place of one with a glutinous ſubſtance, of the nature of varniſh; this is moſt abundant at the foot. The whole *plant* is full of prickles, and theſe appear the moſt plainly on the ſummits of the branches, where this glutinous varniſh is more thinly ſpread. On this part of the *plant*, alſo, there appear certain globules of a glutinous matter, when it is taken out of the water, which, when it is again plunged into it, ſpread themſelves over the whole ſurface of the branches.

The madreporæ grow in the ſame places with the coral; they often hang pendulous from the hollow rocks, and often grow erect on the flat ones. They uſually change colour when taken out of the water, and are of very different kinds and different degrees of hardneſs; many of them are as hard as common ſtones, and many others are ſo brittle, that it is ſcarce poſſible to touch them without breaking their branches.

The flowers of the thorny and naked lithophyton appear to be wholly like thoſe of coral, and like them they are not found to contain any ſolid ſeed. Mem. de l'Acad. Par. 1710.

The many uſes of the numerous *ſea plants* to the ſyſtem of the world are not yet ſufficiently known. Among others, Dr. Liſter has obſerved that they ſerve to render a great deal of the *ſea* water freſh, and give it in miſts to the clouds, whence it again falls on the earth. This is eaſily proved by experiment thus: if a quantity of *ſea* water be put into a long glaſs body, and into it there be put a large and vigorous *ſea plant*, ſuch as the common *ſea* wrack, and the head placed on the glaſs, and a receiver fitted for it without cutting the joints, there will daily diſtil into the receiver, without giving any fire below, a clear and ſweet water, freſh and potable, and without any diſagreeable or unwholeſome quality. The quantity is but ſmall that is obtained this way, but it is evident, that in the ſame manner a very immenſe quantity of the *ſea* water is every hour made freſh, and raiſed up into the air from the infinite number of *plants* that grow in it. Dr. Liſter even thinks that the tropic winds, which blow conſtantly one way, may be owing to this ſort of cauſe. Philoſ. Tranſ. N° 156. See the article TROPIC *winds*.

SEA *ſalt*. The chemiſts have, for many ages, been acquainted with many of the qualities, and much of the nature of this common ſubſtance, but not with the whole; they know what they can ſeparate from it, and what they can afterwards procure, by admixtures with the reſiduum of the diſtillation, which is its baſis; but they do not ſeem to have thought, of a long time, of enquiring into what that baſe was. They have always known how to ſeparate an acid liquor from this *ſalt*, called the ſpirit of it, by breaking its union with the baſis of the *ſalt*; and they know, that if a vitriolic acid be added to this baſis, it makes what is called *Glauber*'s *ſalt*, if a nitrous one, they procure what is called *quadrangular nitre*: but they never procured, and brought into view this baſis of *ſea ſalt* ſeparate and pure, exempted from its acid, and in a ſtate of being known as to what it is; they have found out that the baſis of alum is a white calcarious earth, that the baſis of green vitriol is iron, and that the baſis of blue vitriol is copper; but they have been unacquainted with the baſis of this moſt common of all *ſalts*. For want of this knowledge, no body has been able to recompoſe *ſea ſalt*, or regenerate it after it has been decompounded by fire; and the judicious chemiſt never thinks he is maſter of a ſubject, till he can both deſtroy, and at pleaſure reproduce it.

It has been generally agreed, that the baſis of this *ſalt* is either an earth or an alkali; and it might be very poſſible to reconcile theſe opinions, by ſuppoſing it an alkaline earth, as there are many ſuch, and ſo blending the two opinions in one. Mr. Du Hamel, however, has been at great pains on this ſubject, and has communicated to the Academy of Sciences, as the reſult of them, a very accurate and valuable account of this body.

A haſty obſerver may fancy to himſelf, that he has found out this baſis at a very eaſy rate, by obſerving, that on the diſſolving *ſea ſalt* in oil of tartar by deliquium, there precipitates to the bottom a white earth. This was the firſt ſubject of Mr. Du Hamel's enquiries, but he found this could not be the real baſis of the *ſalt*, nor indeed any thing eſſential to it, ſince it was in too ſmall quantity to have ſufficed for ſo great a purpoſe; and after the precipitation of it, there remained much fine and unaltered *ſalt*, on which the menſtruum did not operate; and on all the trials he could make, he found it impoſſible to reproduce *ſea ſalt* from the mixture of this earth with ſpirit of ſalt. It ſeems therefore moſt probable, that this earth was only accidentally mixed with the *ſalt*, at the time of its formation, but having no eſſential ſhare in its compoſition. When an inflammable ſubſtance is mixed with nitre, its acid diſſipates itſelf with a very little heat, and leaves its baſis naked to the eye. Inflammable ſubſtances, mixed with vitriols, alſo greatly diminiſh the force of the union of their acid to their baſe, and conſequently facilitate their ſeparation; and on this principle Mr. Du Hamel had hopes that powder of charcoal, or filings of iron, might prove happy mediums for the ſeparation of the acid of *ſea ſalt* from its baſis, but theſe had no effect. Chemiſts had obſerved that the *ſea ſalt*, which enters the ſtomachs of animals with their food, was decompoſed in their bodies; hence this gentleman tried animal and vegetable ſubſtances for this purpoſe, as alſo the inflammable minerals, but all theſe alſo without ſucceſs.

When theſe trials had all proved fruitleſs, there appeared no way left, but that of the mixture of the vitriolic and nitrous acids, and the producing the Glauber's ſalt, and quadrangular nitre, for the ſubjects of after experiment. Having carefully made ſome Glauber's ſalt, the buſineſs was to drive off the acid from that mixt by fire; but no ſort of diſtillation was found able to do this, as no fire is ſtrong enough to diſunite this acid from any mixture with an alkaline ſalt. It is well known, however, that the vitriolic acid eaſily unites itſelf to inflammable ſubſtances, and in that union conſtitutes common ſulphur. The mixture of powder of charcoal with this Glauber's ſalt, produced readily a ſulphur, but the acid, in running into this union, had carried the baſis of the *ſea ſalt* along with it, not left it behind as was expected; but the ſeparation was afterwards effected, by pouring vinegar upon this ſulphur; the conſequence of which was, that the baſis of the *ſea ſalt* then remained charged only with the vegetable acid of the vinegar, much weaker than the mineral acid of vitriol, and therefore forming a combination much more eaſily broken, and from which the acid was to be raiſed into vapour, without any great difficulty, as it contained a large portion of an oily matter with it. This having then been wrought over by diſtillation, and the reſiduum ſtrongly calcined, the baſis of the *ſea ſalt* was at length obtained pure.

A ſecond operation of the ſame gentleman in this reſearch, was the adding a nitrous acid to the reſiduum of the diſtillation of *ſea ſalt* inſtead of a vitriolic one, and obtaining by that means a quadrangular nitre, inſtead of a Glauber's ſalt; and diſſipating this ſpirit, by burning in a red hot crucible, with powder of charcoal, the baſis of the *ſalt* was alſo prepared pure; and both this, and that by the former trial, appeared wholly the ſame ſubſtance.

The baſis of *ſea ſalt*, when thus found, appeared not to be an earth, as had been by many ſuſpected, but a true ſalt itſelf, eaſily ſoluble in water, and proving itſelf to be an alkali by its effects with acids. It will not run into a liquor in the air, but moulders away into a fine powder, and is very cold upon the tongue, and has a bitteriſh taſte. This ſalt appears much like the natrum, or nitre of the antients, or our common ſalt of the kali. The firſt of theſe is a native ſalt, found in the eaſtern countries, and which always has with it a large quantity of marine ſalt; and it is no wonder, when we know this to be what might have made

the basis of *sea salt*, that there should be found some places in the world where this basis may have concreted of itself, without any of that acid being near, which would have made it common salt, and that it therefore remained in the state of the base alone, and constituted this natrum. The other is also accounted for on the same principles, it being the salt produced by burning from a common *sea* plant, which must have imbibed a vast quantity of *sea salt*, and which may have been decomposed in its vessels, and left us only the base without the acid; which base cannot therefore but appear on the burning the plant, and evaporating water which had been poured upon its ashes.

This accurate account of Mr. Du Hamel's gives us a very perfect idea of what was, however, no new discovery in him, since Stahl had before affirmed this alkali to be the basis of *sea salt*, though he had wrapt up his meaning in so much obscurity, that it would never perhaps have been perfectly understood, without Mr. Du Hamel's assistance. Mem. de l'Acad. Par. 1736. See SALT.

SEA *sand*. This is one of the best improvements for many sorts of land, and if rightly understood by our farmers, might be of almost universal use; most of our shores are covered with it, where it is unregarded, and there are few places where it might not be had by water carriage. This *sand* is not of the nature of the common sand found in our pits, nor indeed properly to be called by that name, though it will be best understood by it among the people whose use it is recommended to. It is the fragments of *sea* shells beat to pieces against the shore, and ground almost to powder by the waves continually washing upon it. It is sometimes composed of shelly matter alone; but sometimes it is made up partly of this, and partly of broken stones: in this last case it is called *shelfy sand*, and is not much esteemed. See SAND.

In Cornwall they use this with great advantage, and have it of three colours. About Plymouth it is grey, or bluish, like ashes, which is owing to its being in great part made up of muscle and oister shells. Westward, near the Land's End, it is white; and in Scilly glistering, from a mixture of some spangles of talc among it. This last kind is made of the powder of scallop shells, and of the mouldering of a sort of moor stone, or white granite, not so hard as the common kind, and containing, like it, a large quantity of talc. On the northern side the *sand* is rich, and of a browniſh or reddish colour, and is principally composed of the broken shells of cockles; and it owes that colour to the wash of the Severn, which falls foul and dirty with a yellowish mud into the Severn sea.

Beside these differences in the colour of the *sand*, there is also another difference, which is in the largeness or smallness of the grain. In many places the different parts of the same shore afford a larger and a smaller sort, and these are chosen according to the several occasions. The smallest sort gives its virtues out the soonest, but the large kind keeps the land in heart for the longest time together: the tenant therefore is always best pleased with the smaller, and the landlord with the larger. Philos. Trans. N° 113.

SEA *sickness* is said to be prevented by drinking *sea* water mixed with wine.

SEA *swallow*, the name of a bird of the *larus*, or gull kind, called by authors *sterna*, and common on our coasts. See the article STERNA.

SEA-*turtle-dove*, in zoology, the name by which we commonly call the little diver, called by Mr. Ray *columba Groenlandica*.

It very much resembles the coulterneb, or *anas arctica* of Clusius, only it is much smaller, and its legs are red, and it has no hinder toe. Its beak is long, not compressed, or flatted sideways, as in that bird, and a little crooked and sharp at the end. It has a large white spot on each side of the forepart of its head, and excepting that it is all over black. *Ray*'s Ornitholog. p. 245.

SEA *water*. See the article WATER.

SEAH, in Jewish antiquity, a measure of capacity containing six cabs. See CAB.

SEAMS (*Cycl.*)—SEAMS *of a ship*, are places where her planks meet and join together. There is also a kind of peculiar *seam* in the sowing of sails, which they call a *monk's seam*.

SEAMS *of a sail*, are of two sorts, *monk's seam*, and *round-seam*. See MONKS, *&c.*

Round SEAM, of a sail, is so called, because round like the common *seam*.

SEASIN, or SEASING, in a ship, the name of a rope by which the boat rides by the ship's side when in harbour, *&c.*

SEAT (*Cycl.*)—SEAT, in the manege, is the posture or situation of a horseman upon the saddle.

To *seat* a horse upon his haunches or hips, see the article PUT.

SEB, a word used by some chemists to express gold, and by others for alum.

SEBAR, or CEBAR, in the materia medica, a name by which the Arabians call the *lignum aloes*, or aloe wood, a perfumed aromatic drug.

SEBEL, an Arabian name for the disorder of the eye, usually called a *pannus*.

SEBESTENA, in botany, the name given by Dillenius to a genus of plants called *cordia* by Plumier, and under that name characterised by Linnæus. See CORDIA.

SECACUL, in the materia medica of the antients, a name given by Avisenna, Serapion, and others, to a root which was like ginger, and was brought from the East-Indies, and used as a provocative to venery.

The interpreters of their works have rendered this word *iringo*, and hence some have supposed that our eryngium, or eryngo, was the root meant by it; but this does not appear to be the case on a strict enquiry, and there is some reason to believe that the famous root, at this time called *ginseng*, was what they meant.

SECALE, *rye*, in the Linnæan system of botany, makes a distinct genus of plants, the characters of which are these. The cup is a case or cover, composed of two valves, and containing two flowers. The valves are strait, erect, and placed opposite to one another; and are sharp pointed, and smaller than the leaves of the flower. The flower is bivalve; the outer valve is rigid bellied, pointed, somewhat compressed with a rim upon its lower edge, and is terminated by a long awn or beard: the interior valve is flat, and pointed. The stamina are three capillary filaments, hanging out of the flower. The antheræ are oblong, and split at the ends. The germen of the pistil is of a turbinated form. The styles are two, reflex and hairy. The stigmata are single. The flower closely wraps up the seed, and when it is ripe opens, and lets it out. The seed is single, oblong, somewhat cylindric, naked, and pointed. *Linnæi* Gen. Plant. p. 17.

SECAMONE, in botany, a name by which the Ægyptians call a species of periploca common there, and distinguished by Mr. Tournefort by the name of *periploca foliis oblongis angustioribus*, the long narrow leaved periploca. See the article PERIPLOCA.

SECESPITA, among the Romans, a knife with a round ivory handle, adorned with gold and silver, which the flamins and priests used at sacrifices. *Pitisc.* in voc.

SECIUM, among the Romans, a term used to signify every thing the priests cut with the knife *secespita*, as the *libum*, *placenta*, &c. See LIBUM, *&c.*

SECLIA, a name by which some authors have called wormwood. See SANTONICUM *semen*.

SECTINEUS, a small, flat, and pretty long muscle, broad at the upper part, and narrow at the lower; situated obliquely between the os pubis, and the upper part of the os femoris.

It is commonly a single muscle, but is sometimes found double. It is fixed above by fleshy fibres to all the sharp ridge, or crista of the os pubis, and to a small part of the oblong notch, or depression on the foreside of the crista, in which the upper extremity of this muscle is lodged; from thence it runs down obliquely towards the little trochanter, under, and a little behind which, it is inserted obliquely by a flat tendon between the superior insertion of the vastus internus, and inferior insertion of the triceps secundus, with which it is united. *Winslow*'s Anatomy, p. 206.

SECOMIÆ, in natural history, the name of a genus of fossils, of the class of the *septariæ*, the characters of which are; that they are bodies of a dusky hue, divided by septa, or partitions of a sparry matter, into several more or less regular portions, of a moderately firm texture, not giving fire with steel, but fermenting with acid menstrua, and easily calcining.

The *septariæ* of this genus are, of all others, the most common, and are what have been known by the little expressive, or mistaken names of the *waxen vein*, or *ludus Helmontii*. The English name was acquired by the likeness of the body of the mass in some of the species, and of the septa in others, to yellow wax: and the Latin one was owing to this, that the famed Paracelsus, who had the cubic pyritæ in great esteem for dissolving the stone, called those bodies, from their resembling a die in shape, *ludus*; and Van Helmont afterwards mistaking the bodies of this genus for the *ludus* of Paracelsus, gave them in the same cases, and called them by the same name.

We have many species of these bodies common among us. Of the whitish or browniſh kinds we have thirteen; of the yellowish five; and of the ferrugineous ones four.

Of the white or browniſh kinds are, 1. A brown one, externally grey, with yellowish white septa. This is very common in Germany, and the chemists and apothecaries there, who use it as a remedy for the stone, always choose this species. We have it also common among us, and that in the neighbourhood of London; the clay-pits behind Gray's Inn Lane, and about Islington, affording it in great abundance. 2. A hard brown one with fewer septa, common in the same places with the former. 3. A hard blackish brown one with whitish partitions. This is a coarser, and much less beautiful kind than any of the former, and generally lies near the surface. It is common about Pancras, and in many other places. 4. A hard browniſh yellow one, with yellowish white

white ſepta. This alſo is common about London, and generally lies near the ſurface. 5. A hard greyiſh brown one with brown ſepta. This is a very firm and hard one, and is found in the clay pits about London, but generally lies deep. 6. A hard ferrugineous brown one with brown partitions. This is a particularly ſtrong and firm kind, and is leſs common than the preceding kinds. It is found however in Surry, and on the coaſts of Yorkſhire. 7. A ſoft whitiſh one with browniſh yellow ſepta. This is the moſt ſoft, lax, and crumbly, of all the bodies of this genus, and is leſs common than moſt of the kinds. It is found in Leiceſterſhire and Yorkſhire, and has been met with at Paddington. 8. An elegant cruſtated one with a bluiſh nucleus, and browniſh yellow cruſts. This is very rare, and has been found only about Loughborough, and once in the neighbourhood of Deptford. 9. A hard duſky brown one with very thick ſepta. This is common in the cliffs, and on the ſhores of Yorkſhire, and has been found alſo in the clay-pits about Richmond and Deptford. 10. A hard greyiſh brown one, divided into talc by thick whitiſh partitions. This is found in Leiceſterſhire, Yorſhire, and Norfolk. 11. A brown compreſſed kind with yellow ſepta. This is often found of three feet in diameter. It is common in the cliffs, and on the ſhores of Yorkſhire, Suſſex, and Kent. 12. A whitiſh grey very hard kind, looking like flint. This is a very ſingular ſpecies, and greatly ſuperior to all the reſt in the cloſeneſs of its texture. It is found near Peterborough in Northamptonſhire, and ſometimes in the neighbourhood of London. And 13. a bluiſh one, brown on the outſide, with white ſepta. This is a very ſingular, though not very beautiful ſpecies, and is very ſcarce. It is not known of any where, except at Loughborough in Leiceſterſhire, and in the great clay-pit at Richmond. Theſe are the *ſecomiæ* of theſe colours.

The yellow *ſecomiæ* are, 1. A hard pale yellow one with few and thin partitions. This is found about Highgate, and is common on the ſhores of Yorkſhire. 2. A ſoft duſky yellow one with very thick ſepta. This has but little beauty, but it is very frequent in our clay pits, thoſe about Deptford abounding with it. 3. A hard bright yellow one, with variegations of brown. This is a ſingular and very beautiful ſpecies, the brown variegations being ſometimes found in veins, ſometimes as a central nucleus. This is not known of any where, except on Mendip-hills. 4. A very hard browniſh yellow undulated one, with very few, and thoſe whitiſh partitions. This elegant ſpecies is found alſo only on Mendip-hills. And 5. a hard greyiſh yellow one, divided into talc by thin yellow partitions. This is a very beautiful maſs, and is frequently met with on the Yorkſhire ſhores; ſometimes alſo about Highgate.

The ferrugineous *ſecomiæ* are theſe, 1. A round yellowiſh ruſt coloured one, with thin ſtraw coloured partitions, found in Somerſetſhire, and about Iſlington. 2. A roundiſh ferrugineous red one with yellow ſepta, very common in Northamptonſhire and Yorkſhire, and ſometimes found in the clay-pits about Iſlington. 3. A ferrugineous brown one with whitiſh ſepta; a ſpecies of very little beauty, found on the ſhores of Yorkſhire. And 4. a hard blackiſh brown one, with a yellow cruſtated coat, found about Richmond, and in ſome other places. *Hill*'s Hiſt. of Foſſ. p. 510, ſeq.

SECOND (*Cycl.*)—SECOND, in muſic. What is ſaid in the Cyclopædia under this head wants correction; the truth is this. There are three kinds of *ſeconds* occurring in practice, the leſſer, the greater, and the ſuperfluous *ſecond*; to which, if the enharmonic genus were reſtored, we might add, the diminiſhed *ſecond*. The leſſer *ſecond* is the ſemi-tone major, and is nearly equal to $5\frac{1}{5}$ commas. The greater *ſecond* is the tone, which being either major or minor, there muſt alſo be two greater *ſeconds*; one nearly equal to $8\frac{1}{2}$ commas, and the other to $9\frac{1}{2}$ commas: but practitioners uſually confound theſe two. The ſuperfluous *ſecond* is a tone major, and ſemi-tone minor [a]; the other ſuperfluous *ſecond*, ariſing from the tone minor and ſemi-tone minor, is not in uſe. Laſtly, the diminiſhed *ſecond* is a ſemi-tone minor leſs than the leſſer *ſecond*; that is, equal to the dieſis enharmonica. Thus between E and F ^{b}, or between A and B $^{b\,b}$, would be a diminiſhed *ſecond*, as alſo between G ſharp and A ^{b}. This laſt has been practiſed by an eminent muſician of this age [b]. —[[a] See the Table, under INTERVAL. [b] Mr. Handel, in the Oratorio of Samſon, in the ſecond part of the ſong, *Return, return, O God of hoſts.*]

Some authors, as Ozanam [c], call the ſemi-tone minor by the name of *diminiſhed ſecond*; but this is contrary to the analogy in like caſes, where diminiſhed is uſually applied to intervals a ſemi-tone minor leſs than a true diatonic interval. Thus the diminiſhed ſeventh is a ſemi-tone minor leſs than the flat ſeventh, or ſeventh minor.—[[c] Dict. Mathemat. p. 653.] See the Table, under INTERVAL.

Diminiſhed SECOND, in muſic. See DIMINISHED *ſecond*.

SECOND *de l'oreille*, in anatomy, a name given by Vieuſſens and others to a muſcle of the ear, called by Cowper and others *ſtapidaceus*, and *ſtapedis muſculus*; and by Albinus *ſtapedium*. Winſlow calls it *le muſcle de l'etrier*. See EAR.

SECOND *deliverance*, *ſecunda deliberatione*, a judicial writ that lies after nonſuit of the plaintiff in replevin, and a returno habendo of the cattle replevied, adjudged to him that diſtrained them; commanding the ſheriff to replevy the ſame cattle again, upon ſecurity given by the plaintiff in the replevin for a redelivery of them, if the diſtreſs be juſtified. It is a *ſecond* writ of replevin, *&c.* F. N. B. 68. Terms of Law. *Blount*, *Cowel.*

SECRETARIUM, among the Romans, a recluſe room, where the judges conſidered the cauſes that had been litigated before them, and came to a reſolution what ſentence they were to pronounce from the tribunal. It was moſt uſually ſeparated from the tribunal by a veil. *Pitiſc.* in voc.

SECTA (*Cycl.*)—SECTA *ad curiam*, a writ which lieth againſt him who refuſeth to perform his ſuit to the county court, or court baron. F. N. B. 158. *Blount*, *Cowel.*

SECTA *curiæ*, in our old writers, ſuits and ſervice done by the tenants at the court of their lord. *Paroch.* Antiq. 320.

SECTA *facienda per illam quæ habet æniciam partem*, a writ to compel the heir that hath the elder's part among coheirs, to perform ſervice for all the coparceners. Reg. orig. 177. *Cowel.*

SECTA *faldæ*. See FALDEGE, *Cycl.* Not.

SECTA *molendini*, a writ lying where a man by uſage, time out of mind, *&c.* has ground his corn at the mill of a certain perſon, and afterwards goes to another mill with his corn, thereby withdrawing his ſuit to the former. And this writ lies eſpecially for the lord againſt his tenants, who hold of him to do ſuit at his mill. Reg. orig. 153. F. N. B. 122. *Blount*, *Cowel.*

SECTA *regalis*, a ſuit by which all perſons were bound twice in a year to attend the ſheriff's tourn, and was called *regalis*, becauſe the ſheriff's tourn was the king's leet; wherein the people were to be obliged by oath to bear true allegiance to the king, *&c.* *Blount.*

SECTA *unica tantum facienda pro pluribus hæreditatibus*, a writ that lies for an heir who is diſtrained by the lord to do more ſuits than one, in reſpect of the land of divers heirs deſcended to him. Reg. orig. *Blount*, *Cowel.*

SECTILIA, among the Romans, pavements laid with ſtones cut into various forms. Suetonius diſtinguiſhes them from thoſe that were teſſelated. *Pitiſc.* in voc.

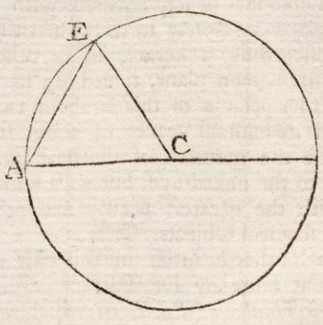
SECTION (*Cycl.*)—*Cæſarian* SECTION. Many have exclaimed againſt the cruelty of this operation, and certainly it is too terrible to be uſed on any, but the moſt emergent occaſions; but there ſeem three caſes in which it is juſtifiable, nay abſolutely neceſſary. The firſt is when the mother is dead, either in labour, or by ſome other accident, and the child is perceived to be alive. The ſecond is when the mother is living, and the fœtus dead, and incapable of being extracted by the common paſſages by any help of the midwife. And the laſt, when the mother and child are both living, and there is found an utter impoſſibility of delivery any other way. In all theſe caſes the Cæſarian practice is juſtifiable to ſave life, that muſt otherwiſe be inevitably loſt.

In the firſt caſe, the operation muſt be performed immediately after the death of the mother, otherwiſe it is to no purpoſe, for the child can live but a very little time afterwards in the body. The ſurgeon is, in this caſe, to make a crucial inciſion, as in the common diſſections; or a longitudinal one on one ſide, without regard to the courſe of the fibres or veſſels; and if the fœtus ſhould have fallen into the cavity of the abdomen, through a rupture of the uterus, it ſhould then be taken out; or if it be yet in the womb, or in the fallopian tube, theſe parts muſt be carefully opened, and the child being taken out, muſt have Hungary water, or the like, held at ſome ſmall diſtance from its noſe to revive it, and the navel ſtring be tied up as uſual. The fœtus is not always preſerved, or found alive after this operation; but as there is often a probability of it, it is certainly better to open an hundred dead women in vain, than to loſe the life of one infant.

In the ſecond caſe, when a dead fœtus is contained in the cavity of the abdomen, in the fallopian tube, or in a kind of hernia or ſacculus without the abdomen, of all which caſes there are inſtances recorded; or when from the particular ſtructure of the parts, as is ſometimes the caſe in crooked women, and others; and when, as in many inſtances, there is no poſſibility of the extraction of the infant, even by inciſion of it, there is no way but the opening the abdomen, and, if neceſſary, the uterus of the mother, and taking out the fœtus; and this is often the means of preſerving the mother, and when in parallel caſes the child is alſo alive, there have been not a few inſtances of both being preſerved. *Heiſter*'s Surgery, p. 29.

The Cæſarian *ſection* is recommended by ſeveral authors, and Mr. Helvetius communicated to the Academy of Sciences at Paris, a well atteſted hiſtory of a woman recovering after the operation had been performed upon her by a midwife. Vid. Hiſt. de l'Acad. des Scienc. 1731.

We have alſo an account of this operation ſucceſsfully performed by a midwife in Ireland. See Med. Eſſ. Edinb. Vol. 5. art. 37.



There

There is likewiſe an account of the Cæſarian operation ſucceſsfully performed by a butcher on a woman in Ireland. Vid. Phil. Tranſ. N° 461. ſect. 17.

Cyprianus, profeſſor at Franeker, gives an extraordinary caſe of the Cæſarian operation, whereby a fœtus, which had been dead twenty one months, was drawn out of the tuba uteri, yet the mother preſerved [d]. M. Jobert, phyſician at Chateau Thierri, relates the hiſtory of a woman in the neighbourhood of that place, who was twice delivered of children by the Cæſarian operation; the firſt time in 1682, the ſecond time eleven months after, and recovered from both [e]. —[[d] Act. Erud. Lipſ. An. 1711. p. 82, ſeq. [e] Jour. des Scav. Tom. 21. p. 374.]

SECTIS *non faciendis*, a writ brought by a woman, who for her dower, *&c.* ought not to perform ſuit of court. Reg. orig. 174. *Blount*, *Cowel.*

SECTOR (*Cycl.*)—SECTOR *of a ſphere*. The *ſector of a ſphere*, generated by the revolution of the *ſector* of a circle C A E about the radius A C, is equal to a cone, whoſe baſe is equal to the portion of the ſpherical ſurface generated by the arch A E, or to the circle deſcribed with the radius A E, and whoſe height is equal to C A, the radius of the ſphere. Arch. de Sphær. et Cyl. *Mac Laurin*'s Fluxions, Introd. p. 15.

SECULUM. See the article AGE.

SECUNDA (*Cycl.*)—SECUNDA *ſuper oneratione paſturæ*, a writ which lieth where admeaſurement of paſture hath been made; and he that firſt ſurcharged the common doth it a ſecond time, notwithſtanding the admeaſurement. Old Nat. Br. 73. *Blount*, *Cowel.*

SECUNDANS, in mathematics, an infinite ſeries of numbers, beginning from nothing, and proceeding as the ſquares of numbers in arithmetical progreſſion, as 0, 1, 4, 9, 16, 25, 36, 49, 64, *&c.*

SECUNDINES (*Cycl.*)—It very often happens that theſe are retained in the womb after childbirth, and great miſchiefs enſue from it. The aſſiſtance of a ſkilful hand is, in many caſes, neceſſary to the getting them out; and this is to be done with great care and ſpeed, before the uterus cloſes itſelf upon them, otherwiſe they occaſion terrible hæmorrhages, faintings, and often inflammatory and putrid fevers.

The patient herſelf may greatly promote the expulſion of theſe, by any forcible emotion of the body, as by a forced cough, or by ſneezing; the midwife at the ſame time is gently to pull them by the navel ſtring, but this muſt be done very cautiouſly, for fear of its breaking. If this fails, the cautious introducing the hand often ſets all right, or the uſe of gently pellent medicines may be called in; and to theſe may be added broths, with ſaffron in them, and by the uſe of common clyſters great good is often done: but, if after all this care, there yet remain ſome fragments of them behind, there uſually ariſes a fever within twelve hours; and in this caſe the utmoſt care muſt be taken to prevent putrefaction, and expel the remains of them. To theſe purpoſes medicines prepared with myrrh, amber, ſaffron, and the cortex eleutherii, are of the greateſt ſervice; and to theſe may be added occaſionally the colliquating and attemperating ſalts, ſuch as tartarum vitriolatum, and nitre. *Junker*'s Conſp. Med. p. 723.

Notwithſtanding the great danger that uſually attends the leaving any part of this behind, at the time of delivery, there are inſtances of ſome perſons lucky enough to eſcape; the ſubſtance left behind remaining uncorrupted, till the time of its being afterwards diſcharged.

Kerkring gives us an inſtance of this which fell under his own knowledge. A woman had a large portion of it left behind, where it remained four months, and at the end of that time was diſcharged uncorrupted, and without any hurt to the perſon. *Kerkring*'s Spicileg. Anat.

SECUNDUS (*Cycl.*)—SECUNDUS *mallei*, in anatomy, a name given by Duverney, and ſome others, to one of the muſcles of the ear. It is the *internus auris* of Cowper and others, and is moſt properly named by Albinus *tenſor tympani*.

SECUNDUS *oculum movens*, in anatomy, a name given by Veſalius to that muſcle of the eye, called by Riolanus and others *ſuperbus*, and *elevator oculi*, and by Albinus the *ſubductor*, one of his four muſculi recti of the eye.

SECURIDACA, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the papilionaceous kind, and its piſtil, which ariſes from the cup, finally becomes a ſtrait, flatted, annulated, and jointed pod, which contains in every joint one ſeed, of a rhomboidal form, and marginated on its inner ſide.

There is only one known ſpecies of this genus, which is the yellow *ſecuridaca*. *Tourn.* Inſt. p. 699.

SECURITATEM *inveniendi quod ſe non divercat ad partes exteras ſine licentia regis*, an antient writ lying for the king againſt any of his ſubjects, to ſtay them from going out of this kingdom into foreign parts; the ground whereof is, that every man is bound to ſerve and defend the commonwealth, as the king ſhall think fit. F. N. B. 85. *Blount*, *Cowel.*

SECUTOR, among the Romans, moſt commonly ſignified an attendant upon great men. *Pitiſc.* in voc.

Secutor, in a more limited ſenſe, denoted the gladiator who engaged with the *retiarius*. *Pitiſc.* Lex. Ant. in voc. See the article RETIARIUS.

SEDAB, in botany, a name given by the Arabian phyſicians to the wild, or mountain rue, a plant common in Syria, Greece, and other places. Aviſenna ſuppoſes the gum, which he calls *gentum*, or *jentum*, to be produced from this plant, but very erroneouſly, that gum being obtained from the roots of the thapſia, or deadly carrot.

SEDATIVUM *ſal*. This *ſalt* may be obtained by cryſtallization in the following manner. Take four ounces of borax, and one ounce one drachm of the moſt concentrated oil of vitriol; put the borax into a glaſs retort, pour on it half an ounce of common water after the oil of vitriol, and expoſe the mixture to a fire gradually encreaſed: after the phlegm has paſſed off, and even while it is paſſing, there ariſe flowers, or a volatile ſalt, in beautiful foliated laminæ, ſome of which always melt by the heat of the fire; after the operation is over, the fineſt of the flowers are to be carefully gathered: theſe are what ſtick to the neck of the retort. Thoſe that are grey, are to be thrown upon the remaining maſs; this maſs is to be diſſolved in water, filtrated, and evaporated gradually; ſometimes, even without evaporation, the ſhining talcous laminæ are to be ſeen in the liquor: after twenty four hours ſtanding the water is to be poured off from theſe laminæ, they are to be waſhed with freſh water, and then dried carefully in a warm place. If theſe cryſtals do not calcine in the place where they are put to dry, nor in the ſun's heat, it is a ſign there is nothing cryſtallized but the ſal neutrum; if they do calcine, it is a proof that there is ſome Glauber's ſalt formed of the borax and the vitriolic, and cryſtallized in the maſs. This method of procuring the *ſal ſedativum* by cryſtallization, was an invention of Mr. Geoffroy; every body had before thought it could only be obtained by ſublimation. Philoſ. Tranſ. N° 436. p. 40. See SAL.

SEDEM *attollens*, in anatomy, a name given by Veſalius and others to the muſcle, now more generally known by the name of *levator ani*.

SEDENTARIUM *os*, a name given by ſome anatomical writers to the protuberance of the os coxendicis, on which the whole weight of the body reſts in ſitting.

SEDINA, in the materia medica, a word uſed by ſome writers to expreſs dragon's blood.

SEDITION, among civilians, is uſed for an irregular commotion of the people, or an aſſembly of a number of citizens without lawful authority, tending to diſturb the peace and order of the ſociety.

This offence is of different kinds: ſome *ſeditions* more immediately threatening the ſupreme power, and the ſubverſion of the preſent conſtitution of the ſtate; others tending only towards the redreſs of private grievances. Among the Romans, therefore, it was variouſly puniſhed, according as its end and tendency threatened greater miſchief. See l. 1. cod. *de Seditioſis*, and Math. *de Crimin.* l. 2. n. 5. *de læſa majeſtate*. In the puniſhment, the authors and ringleaders were juſtly diſtinguiſhed from thoſe, who with leſs wicked intention joined, and made part of the multitude.

The ſame diſtinction holds in the law of England, and in that of Scotland. Some kinds of *ſedition* in England amount to high-treaſon, and come within the Stat. 25 Edw. III. as levying war againſt the king. And ſeveral *ſeditions* are mentioned in the Scotch Acts of Parliament as treaſonable. *Bayne*'s Crim. Law of Scotland, p. 33, 34.

The law of Scotland makes riotous and tumultuous aſſemblies a ſpecies of *ſedition*. But the law there, as well as in England, is now chiefly regulated by the Riot Act, made 1 Geo. I. only it is to be obſerved, that the proper officers in Scotland, to make the proclamation thereby enacted, are ſheriffs, ſtewards, and bailies of regalities, or their deputies; magiſtrates of royal burroughs, and all other inferior judges and magiſtrates; high and petty conſtables, or other officers of the peace in any county, ſtewartry, city or town. And in that part of the iſland, the puniſhment of the offence is death and confiſcation of moveables: in England it is felony. See RIOT, *Cycl.*

SEDMA, a word uſed by ſome as a name for the *lapis hæmatites*.

SEDUM, *houſeleek*, in botany, the name of a large genus of plants, the characters of which are theſe. The flower is of the roſaceous kind, conſiſting of ſeveral petals, arranged in a circular form. The piſtil, which ariſes from the cup, finally becomes a fruit, compoſed of ſeveral caſes or ſheaths, conſtipated together into a ſort of head, and containing a number of ſmall ſeeds.

The ſpecies of *houſeleek*, enumerated by Mr. Tournefort, are theſe. 1. The great tree *houſeleek*. 2. The common great *houſeleek*. 3. The narrower leaved great *houſeleek*. 4. The

largeſt

largeſt common *ſedum*. 5. The broad leaved *ſedum* with large white flowers. 6. The large mountain-*ſedum* with dentated leaves. 7. The large mountain-*ſedum* with whole leaves. 8. The woolly mountain-*houſeleek*. 9. The ſmaller woolly mountain-*ſedum*. 10. The large Alpine roſe-*ſedum* with ſharp pointed leaves. 11. The middle ſized Alpine roſe-*ſedum* with red prickles. 12. The greeniſh hairy Alpine roſe-*ſedum*. 13. The long leaved hairy Alpine *ſedum*. 14. The hairy Alpine *ſedum* with the diſk of the flower green, and the corona purple. 15. The ſmaller white flowered cylindric leaved *ſedum*. 16. The larger cylindric leaved white flowered *ſedum*. 17. The ſmall cylindric leaved *ſedum*, called the *leſſer houſeleek* of the ſhops. 18. The ſmaller cylindric leaved yellow flowered *ſedum*. 19. The ſmall round leaved *ſedum*. 20. The ſharp pointed leaved ſmall yellow *ſedum*. 21. The leſſer *ſedum* with broad and thick ſtalks. 22. The leſſer yellow *ſedum* with inflated ſtalks. 23. The deep yellow flowered long leaved *ſedum*. 24. The red flowered field-*ſedum*. 25. The little yellow flowered ſharp taſted *ſedum*. 26. The ſmalleſt yellow flowered *ſedum*, inſipid to the taſte. 27. The little inſipid white flowered *ſedum*. 28. The pale flowered Alpine *ſedum*. 29. The Alpine *ſedum* with large red flowers. 30. The hairy purple marſh-*ſedum*. 31. The white flowered echinated, or ſtellated *ſedum*. 32. The yellow flowered echinated *ſedum*. 33. The *ſedum*, commonly called *cepæa*. 34. The purple flowered *cepæa*. 35. The ſmalleſt mountain-*ſedum* with little purple flowers, and ſtellated ſeeds. 36. The coris-leaved Alpine *ſedum*. 37. The ſhrubby heath-like African *ſedum*. Theſe are the genuine ſpecies of *ſedum*; but beſide theſe, authors have called many other plants by this name, moſt of them properly of the ſaxifrage kind. *Tourn.* Inſt. p. 262.

The great *houſeleek* was called by many names among the Greeks, as *zoophthalmus*, and *buphthalmus*; the latter of theſe confound it with one of the corymbiferous plants, and it is not to be known which of two ſo different vegetables the authors mean, without examining the virtues they aſcribe to it.

There is however another name, by which it is called, which yet more perplexes the ſenſe; this is *ambroſia*, a word by which we expreſs the botrys, or oak of Jeruſalem, a ſmall garden plant, but by which they expreſſed the lilly, the *houſeleek*, and ſeveral other plants.

SEED (*Cycl.*)—The exterior form, and even the internal ſtructure, of the generality of vegetable *ſeeds*, have been ſuppoſed by ſome ſo much alike in the ſeveral kinds, and of ſo little curioſity and beauty in the whole, that they have been little regarded by the curious; but when nearly examined with the help of microſcopes, they are found to be worthy of a greater attention: thoſe which appear moſt like to one another, when viewed by the naked eye, often proving as different, when thus examined, in their ſeveral forms and characters, as the different genera of any other bodies of the creation. If their external forms carry all this variety and beauty about them, their internal ſtructure, when laid open by different ſections, appears yet more admirable.

The *ſeed* of the muſk ſcabious is amazing in its ſhape and ſtructure: it reſembles in figure an octagonal vaſe, with a ſcalloped brim; the whole is bell-faſhioned, having ribs or diviſions, which run down from the mouth of the vaſe, and thence becoming narrower, form the bottom. Between theſe ribs, down to the beginning of the narrow part, it is clear, though not wholly tranſparent, and from thence to the bottom the ribs are hairy. This vaſe contains a *ſeed*, which is like a peſtle ſtanding in a mortar. The peſtle ſtands looſe in an octagonal caſe, but the narrowneſs of the mouth of this vaſe hinders the peſtle's being drawn out, becauſe its extremity within is rounded, and thicker than any other part of it. From its upper end there ariſe five ſpiculated ariſtæ, or awns, whoſe little thorns are directed upwards, and are thereby prepared to cauſe the *ſeed* to recede from any thing that might injure it on being touched. The baſon, from which theſe ariſtæ riſe, is of a fine green colour, and they are of an elegant ſhining brown.

The *ſeed* of the angelica is one of the moſt fragrant in its ſmell in the world. When the outer huſk of this *ſeed* is pulled off, the nucleus appears of a browniſh colour, and of an elliptical ſhape. By the help of the microſcope we ſoon diſcover what it is that produces this charming ſmell; this is a fine amber coloured gum, which appears laid in ridges, diſpoſed alternately with others of a browniſh colour, longitudinally, all over the *ſeed*, and on the flat ſide there is a white part, which is a ſort of theca, which receives a very minute ſtylus from the pedicle that ſupports it.

The medicinal *ſeed*, commonly known in the ſhops under the name of *grain of paradiſe*, is one that promiſes very little from its external appearance, being only a brown *ſeed* of an irregular ſurface, with many flats and angles, and having an apex like the mouth of a purſe when drawn together with a ſtring; from this unpromiſing aſpect, however, there ariſes a very wonderful appearance on diſſection. In a longitudinal ſection we ſee firſt the edge of the brown cortex, next within that appears a black pitchy ſubſtance, and within that a very white matter, lodged in a radiated form: this reſembles a fine white ſalt, and is probably a mixture of a volatile ſalt, and a farinaceous matter. Its radiated diſpoſition, and extremely pungent taſte, favour alſo this opinion. But there is in this *ſeed* a yet far more curious particular than theſe; the center of every *ſeed* is occupied by a ſmall piece of perfect camphor: this is, in all reſpects, the ſame with the common camphor ſold in the ſhops, and is always of the figure of a vinegar cruet, having a round large bottom, and a long and narrow neck. This is invariably the appearance in every *ſeed*, and that not only in this, but in other *ſeeds* of the ſame kind.

The *ſeed* of the great maple, which we commonly, but improperly call the *ſycamore-tree*, conſiſts of a pod and its wing: two of theſe grow upon a pedicle with the pods together, which makes them reſemble the body of an inſect with its expanded wings. The wings are finely vaſculated, and the pods are winged with a fine white down, reſembling ſilk: this contains a round compact pellet, covered with a brown membrane, that ſticks very cloſely to it. When this is pulled off, inſtead of diſcerning a kernel, as in other *ſeeds*, there appears an entire green plant, folded up in a moſt ſurpriſing manner. The pedicle of this is about two eights of an inch long, and its ſeminal leaves of about ſix eighths each: between theſe the germina of the next pair of leaves are plainly viſible to the naked eye, but with a microſcope they are ſeen with the greateſt beauty and perfection. See Tab. of Microſcopical Objects, Claſs 2.

Theſe, and a number of ſuch other beauties in this part of the creation, are deſcribed at large by Dr. Parſons in his work, entitled *A Microſcopic Theatre of Seeds*, to which we refer for the reſt. Philoſ. Tranſ. N° 474. p. 187.

The increaſe of the *ſeeds* of plants is ſurpriſing. The upright mallow, for inſtance, has been computed to produce 200000 *ſeeds* from one. See Philoſ. Tranſ. N° 468. ſect. 4.

Moſt kinds of *ſeeds* ſhould be prepared for a microſcopical examination, by ſteeping them in warm water till their coats are ſeparated, and their ſeminal leaves may be opened without laceration. But *ſeeds*, while dry, and without any preparation, are of an almoſt infinite variety of ſhape, and afford a number of pleaſing objects for the microſcope.

The *ſeeds* of ſtrawberries riſe out of the pulp of the fruit, and appear themſelves like ſtrawberries. The *ſeeds* of the ſeveral ſorts of poppies reſemble kidneys in ſhape, but have a number of furrows and ridges on their ſurfaces, very curiouſly diſpoſed with regular ſides and angles. From theſe *ſeeds* there may alſo be commonly ſhaken a duſt, which looks very pretty before the microſcope, having nearly the ſame appearance with the ſurface of the *ſeeds*, but having the advantage of being tranſparent. This duſt is compoſed of the fine membranes which have lain between the *ſeeds*, and which by the preſſure of the *ſeeds* againſt them have received the very marks of every part of the *ſeeds*.

The *ſeeds* of the leſſer moonwort, of tobacco, chervil, lettuce, thyme, parſley, and a multitude of others, afford alſo a very pleaſing entertainment. The antients imagined, that the ferns and capillary plants produced no *ſeeds*, and their miſtake could never have been rectified by the naked eye; but the microſcope has diſcovered, that all the ſeveral ſorts of fern, harts-tongue, maiden-hair, and the like, are ſo far from being barren in this reſpect, that they are really amazingly fruitful. The *ſeed* veſſels of theſe plants are placed on the back part of their leaves, and the duſt which flies off from them in ſuch great quantities, when we handle them, is no other than their *ſeeds*. The *ſeed* veſſels appear to the naked eye like brown or black ſcurff, on the backſide of the leaf, but when viewed by the microſcope, they reſemble little circular tubes, divided into ſeveral cells, and containing a multitude of *ſeeds*. When the *ſeeds* are ripe, the veſſels fly open with a ſpring, and throw them out every way in form of duſt. *Baker*'s Microſcope, p. 250.

Mr. Lewenhoek obſerves, that the mealy ſubſtance in the *ſeeds* of beans, peaſe, wheat, barley, and other kinds of grain, and the generality of other large *ſeeds*, is always encloſed in certain ſmall membranes, repreſenting ſo many little bags or ſacks. On obſerving theſe membranes more nicely, they were found to be all full of ſmall holes, through which he could ſee the light, and which he judged to be no other than the remains of truncated veſſels, which had been torn off in ſeparating the part, and which ſerve to compoſe a great part of the membranes; and it is probable, that each minute particle of the farina of theſe *ſeeds* is nouriſhed by the veſſels, of which we, in this view, ſee the truncated ends. Theſe veſſels are more eaſily ſeen in beans and peaſe, than in the grains of wheat, &c. whoſe membranes are ſo extremely thin and brittle, that they are deſtroyed with the leaſt touch. In wheat, however, there is this ſingularity, that one globule of the farina being broken, is always ſeen to be compoſed of many more, or that many much ſmaller globules were contained in every one of theſe larger ones. The membranes in barley, in which the ſmall globules of farinaceous matter are contained, are much thicker and ſtronger than in wheat, but much leſs ſtrong than in the leguminous *ſeeds*. See Tab. of Microſcopical Objects, Claſs 2.

There is great reaſon to believe, that in all *ſeeds*, which contain a large quantity of farinaceous matter, the caſe is the ſame as in theſe, and that they all conſiſt internally of ſmall globules, collected into larger ones, and encloſed in membranes; which, on a ſtrict examination, appear to be little other than congeries of veſſels deſtined to ſend nouriſhment to the ſeveral incloſed globules.

The oil in almonds, and other ſuch *ſeeds*, is in the ſame manner contained in a ſort of ſmall veſſels, which are very numerous, and diſtinctly viſible. When a ſmall piece of the pulp is examined with a good microſcope, all theſe ſmall veſſels, and the membranes they make a part of, proceed from the ſkin or inner covering of the *ſeed*, in which they are found; and as the meally ſubſtance receives its encreaſe from the veſſels which are in the cells; and as the plant is formed between the cells, during the time that the *ſeed* lies in the earth; and as the little orifices in the ſkins of animals, and of fruits, are ſo formed, as to diſcharge the ſuperfluity of their moiſture, and are ſhut in ſuch a manner, that no moiſture from the common air can be received into them: ſo, on the contrary, the orifices of *ſeeds* are ſo formed, that they will admit moiſture to paſs inwards, and accordingly moiſture is driven into them as they lie in the earth. The *ſeed* upon this muſt neceſſarily ſwell, after this a fermentation ariſes, it requires then a greater ſpace, and according to the particular ſtate of the fibres, and the particles which lie in the cells, and which have derived their nouriſhment from the cells, the meally ſubſtance is by degrees driven out of them into the ſubſtance of the young plant; which by this means encreaſes ſo much in bulk, that the root is become able to furniſh it with nouriſhment from the earth. The office of the internal part of the *ſeed* is then over, and we ſee accordingly, that it is by that time almoſt wholly waſted. Phil. Tranſ. N° 368. p. 203. See Tab. of Microſcopical Objects, Claſs 2.

Many experiments have been made, in order to prove that the *ſeeds* of all plants derive their conſtituent matter from the woody central parts of the plant. Thus apple trees, when they grow hollow, will bear good fruit, but with empty and imperfect *ſeeds*. Barberry trees, when the roots are bored through, are ſaid to bear fruit abſolutely without *ſeeds*; and the gardiners ſay, that if the woody part of the roots of parſley be cut out, the plant will continue to thrive in all appearance, but that it will never afterwards produce *ſeeds* that will propagate the ſpecies. It is to be acknowledged that hollow oaks and elms produce *ſeed* that is as good as that growing on the ſoundeſt trees of the ſame ſpecies; but the elm is all timber to the bark, and an oak, when it is putrid to the heart, may ſtill have firm wood enough to convey a proper nouriſhment from the root to the acorn. The roots may be ſound, when the body of the tree is very much decayed by water let in at the top of the pollard tree, or at the loppings of the branches; and we ſee that beans, wheat, and other grain, grow well, if the eyes and parts next adjoining be whole, though the beans be full of great holes in other parts, or the main body of the wheat be cut off with ſciſſars.

The people who recommend boring of the barberry roots, to have fruit without ſtones, order therefore that the borings be very compleat in the roots for that purpoſe. It is obſerved, in countenance of this doctrine, that ſome trees are leſs fruitful, or even altogether barren, by the exceſſive growth and hardneſs of the timber, and theſe are cured by croſs hackings or cuts, done with ſharp inſtruments through the bark, and into the wood: they alſo do the like injuries to the roots on the ſame occaſion, and often ſplit them lengthwiſe, putting a ſtone into the ſlit, that they may not grow together again. When this remedy is applied both to the ſtem and roots, it ſeldom fails of ſucceſs, but when only to one, it ſometimes miſſes.

As the heart of the wood, or its more ſolid ſubſtance, are ſuppoſed thus to furniſh the matter of the *ſeeds*, the bark is ſuppoſed to furniſh the matter of the pulp of the fruit. The experiment has been made, by debaſing and vitiating its juice, and the fruits have accordingly been debaſed. Thus if reſts be made for water on the body of a Kentiſh codling tree, and water poured frequently into theſe cavities, ſo as always to keep up a ſupply for the bark, the apples will grow to an immoderate ſize, and be inſipid; part of their pulp will be ſo relaxed, as to look like the pulp of a lemon, and on hanging but a moderate time on the tree, they will be as rotten, as if laid on heaps when fully ripe. Philoſ. Tranſ. N° 46.

Change of SEED, a term uſed by the farmers to expreſs the common, and, as they ſuppoſe, neceſſary cuſtom, of changing among one another the *ſeed* of their lands, as wheat, and the like, it being a received opinion, that the *ſeed* produced on one land will grow better on another, than on that which produced it, though the ſame ſpecies of plant be ſown.

Seeds, in their natural climate, do not degenerate, unleſs culture has improved them; they then indeed are liable, upon omiſſion of that culture, to return to their natural ſtate again. Whatever benefit ariſes to the farmer from the changing the *ſeed* of the ſame ſpecies, is from cauſes which are themſelves the effects of different climates, ſuch as heat and moiſture, which may vary very much in the ſame neighbourhood. There is a mountain in the Mogul's country, which on the ſouth ſide produces Indian plants, and on the north ſide European ones, from different expoſures. Some land retaining water longer is colder, and ſome letting it paſs off quicker is warmer; as it may alſo be from the nature and figure of its parts, which retain more of the ſun's heat than others. Sandy and gravelly grounds are always warmer than others, if they have ſome hollow and ſpungy ſtratum underneath, that will let the water paſs off.

The benefit ariſing from the change of *ſeed* is owing to theſe changes, not to the change of food, and theſe cauſes ſhew their effects chiefly in the generation of the *ſeed*. Flax *ſeed*, brought from Holland, and ſown here, will produce as fine flax as it does there, but in the next generation it will degenerate, and become coarſer; by this means it will continue to degenerate every year, till after two or three years it is no better than our own *ſeed* produces, and yet the land ſhall be as good for this coarſe ſort, as when it produced the fine; ſo alſo it is, when the *ſeeds* of our own wheat are changed between farmer and farmer. And thus ſilk worms hatched and bred in France, of eggs brought from Italy, will make as fine ſilk as the Italian; but the eggs of thoſe laid in France, will produce worms that make no better ſilk than thoſe produced in France, though their food is all the while the ſame.

Common barley, once ſown in the burning ſands in Wiltſhire, will for many years after, if ſown on indifferent warm ground, be ripe ſooner than any other barley by two or three weeks; but if ſown on cold grounds farther north, it will be as late as any other barley, after two or three years. The weeds, which perplex the farmers in every field, grow as ſtrong and troubleſome one year as another, and that without any change of *ſeed* at all. Theſe ſeem therefore to have been the natural produce of our ſoil, and corn and other uſeful plants to have been brought from other places, and improved by culture; theſe will therefore no longer retain their perfection and value, than ſuch culture is continued to them.

Laurembergius has carried this notion of degeneracy and change from the ſoil, ſo far as to affirm that wheat will, in ſome places, degenerate into rye; and in other places, rye will be exalted into wheat by the ſoil: but thoſe who are acquainted with botany know, that a horſe might as ſoon be changed into a bull by feeding in an improper paſture, as one plant degenerate into another by fault of the ſoil. *Tull*'s Huſbandry, p. 116.

SEEDY, in the brandy trade, a term uſed by the dealers to expreſs a fault that is found in ſeveral parcels of French brandy, and which renders them unſaleable. The French ſuppoſe that theſe brandies obtain the flavour, which they expreſs by this name from the weeds which grew among the vines, from whence the wine, of which this brandy was made, was preſſed.

However it be, the thing is evident, and the taſte not of any one kind; but ſome pieces of brandy ſhall taſte ſtrongly of anniſeed, ſome of caraway ſeed, and ſome of other of the ſtrong flavoured ſeeds of plants, principally of the umbelliferous kind; ſo that it ſhall be rather taken for anniſeed, caraway, or ſome other water, than for brandy.

The proprietor of ſuch brandies is always at great trouble to get them off, and uſually is reduced to the neceſſity of mixing them in ſmall quantities with pieces of other brandies, ſo as to drown and conceal the taſte; and where he has not opportunities of doing this, is obliged to ſell them on very diſadvantageous terms.

The buſineſs of rectification of ſpirits is very little underſtood abroad, though very much practiſed with us; and a man in France or Holland, who could take off this taſte from theſe brandies, might get great advantages by it. There is no doubt but that the ſame means, which we uſe to rectify malt ſpirits, that is to clear it of its nauſeous and ſtinking oil, which always riſes with it in the firſt diſtillation, would alſo ſerve to purify theſe brandies, and by leaving theſe extraneous oils behind, render them as well taſted as any others; ſince there is no queſtion, but that the oil of malt, which is a principle of the ſame ingredient with the ſpirit, is more firmly united to it than theſe flavouring oils in the brandy, which are not the produce of the grape, but of ſome foreign matter only accidentally mixed with it. See the article RECTIFICATION.

It is a miſtake to imagine, that all the brandies made in France are ſo fine as thoſe which we meet with on the keys of London; on the contrary, there are many hundred pieces made every year, which are as badly flavoured as our coarſeſt malt ſpirit. But the caſe is this, they ſend the beſt brandies, and the beſt wines to England, where they can get the beſt prices for them. In Holland, on the contrary, the mart of goods of all ſorts, it is ſometimes difficult to pick one piece of good brandy out of fifty, the general run of them being either *ſeedy*, or muſty, oily, or otherwiſe infected with ſome unnatural and diſagreeable flavour; and

theſe are the ſorts which in France they deſpair of curing by re-diſtillation, or bringing to the ſtate of three fifths, or *trois cinques*, as they expreſs their ſtronger brandies. *Shaw*'s Eſſay on Diſtillery. See TROIS *cinques*.

SEELING (*Cycl.*)—SEELING, at ſea, is uſed in the ſame ſenſe nearly with heeling. When a ſhip lies down conſtantly, or ſteadily on one ſide, the ſeamen ſay ſhe *heels*; and they call it *ſeeling*, when ſhe tumbles on one ſide violently, and ſuddenly, by reaſon of the ſea forſaking her, as they call it; *i. e.* the waves leaving her for a time in a bowling ſea. When a ſhip thus tumbles to leeward, they call it *lee-ſeel*; and in this there is not much danger, even in a ſtorm, becauſe the ſea will preſently right her up again; but if ſhe rowls or *ſeels* to windward, there is fear of her coming over too ſhort or ſuddenly, and ſo by having the ſea break right into her, be either foundered, or elſe have ſome of her upper works carried away.

SEGITH, a word uſed by ſome of the chemical writers as a name for vitriol.

SEGMENTUM, among the Romans, an ornament of lace uſed by the women on their ſhoulders, which, according to ſome, reſembled our ſhoulder knots. *Pitiſc.* in voc.

Segmenta were likewiſe a kind of teſſelated, or Moſaic pavements, made up of pieces of various ſhapes and colours, but which had an uniform and regular arrangement. *Pitiſc.* Lex. Ant. in voc.

SEGUE, in the Italian muſic, is often found before *aria*, *alleluja*, *amen*, &c. to ſhew that thoſe portions or parts are to be ſung immediately after the laſt note of that part over which it is writ. But if theſe words, *ſe piace*, or *ad libitum*, are joined therewith, it ſignifies that theſe portions may be ſung, or not, at pleaſure.

SEGUENZA, in the Italian muſic, a kind of hymn ſung in the Roman church, generally in proſe. The *ſeguenze* are often ſung after the gradual, immediately before the goſpel, and ſometimes in the veſpers before the magnificat. They were formerly more uſed than at preſent.

The Romiſh church has retained three *ſeguenze*, called *le tre ſeguenze dell' anno*. They are *lauda Sion ſalvatorem*, &c. *victimæ paſchali laudes*, &c. *veni ſancte Spiritus*, &c. Theſe are ſung to muſic in many places. There is alſo one called *dies iræ*, *dies illa*, in the funeral ſervice, which is admirably well ſet, and on which Legrenzi, Lully, and others, have made excellent compoſitions. *Broſſard.*

SEIGNETTE's *ſalt*, a name given in France to a kind of ſal polycreſtus, famous a long time in that kingdom as a purge. It was otherwiſe called *ſal rupellenſis*, and was invented by Mr. Seignette. The Paris Academy took it into conſideration, and Mr. Geoffroy diſcovered that it was only a kind of ſoluble tartar, formed of cream of tartar and common pot-aſhes. See RUPELLENSIS *ſal.*

SEIGNIORY, *dominium*, in our law, is uſed for a manor or lordſhip. *Blount*, *Cowel.*

SEIM, in agriculture, a term uſed by the farmers of Cornwall to expreſs a certain determinate quantity of ſea ſand, which they uſe as manure to their lands.

They dredge this up on the ſea coaſts, and carry it as far toward the lands, where it is to be uſed, as they can by water. At the landing place the farmers bring a train of horſes to receive it, each horſe carrying a *ſeim*, that is a ſack of it, containing thirteen gallons. The land carriage of this ſand, in Cornwall alone, is ſuppoſed to coſt thirty two thouſand pounds annually; and yet the farmers find abundant encouragement to continue the uſe of it, it is ſo rich a manure. Philoſ. Tranſ. N° 103.

SEISACHTHEIA, Σεισαχθεια, in antiquity, a public ſacrifice at Athens, in memory of Solon's ordinance; whereby the debts of poor people were either entirely remitted, or at leaſt the intereſt due upon them leſſened, and the creditors hindered from ſeizing upon the perſons of their debtors, as had been cuſtomary before that time. *Potter*, Archæol. Græc. Tom. I. p. 430.

The word ſignifies the ſhaking off a burden.

SEISINA *habenda, quia rex habuit annum, diem et vaſtum*, in law, a writ that lies for delivery of *ſeiſin* to the lord of lands or tenements, after the king, in right of his prerogative, hath had the year, day, and waſte, on a felony committed. Reg. orig. 166. *Blount*, *Cowel.*

SEITAN, a name given by Aviſenna, and other of the Arabian writers, to a ſpecies of prickly tree, often recommended in their preſcriptions.

The word is ſometimes alſo written *ſeten*, *ſitan*, *ſetah*, or *ſetim.*

Pliny mentions this as a wood remarkably durable. He ſays it grew moſt plentifully in Egypt, and that it remained uncorrupted in waters. It is called by him, and others of the old Latin writers, *ſpina nigra*, the black thorn: and the durable nature of our common ſloe tree, or black thorn, growing in our hedges, has tempted ſome to believe it to be the ſame with the *ſetin*, or *ſpina nigra* of the antients; but this is overthrown by the common account of Pliny, and others, of ſhips being built of this wood, the ſmall ſize of our black thorn rendering it wholly impoſſible to put it to ſuch uſes.

Theodotion is to be underſtood of this wood, when he ſpeaks of the *ſetah*, or *acanthina.*

It is plain from Aviſenna, that this *ſetan*, or *ſeitan*, is no other than that ſpecies of *acacia*, which, from its producing our gum arabic, is called the gum arabic tree. Aviſenna calls the fruit of this *alcarad*, or *alcarath*; and in his account of it, he ſays that it is the fruit of a great thorny tree growing in Egypt, and in the region called Baſſera, and that the gum arabic exſudates from its trunk, and the acacia juice is prepared from its fruit alcarath. He adds, that the Ægyptians themſelves call it *ſitan*; and Proſper Alpinus tells us, that at this time they call it *ſant*. This word is eaſily derived from *ſitan*, and then the name is not a little inſtrumental to the proving what the tree was, as the *ſant* is evidently what Aviſenna ſays of the *ſitan*, the gum arabic tree.

We find the word *ſant* in ſome of the Arabians alſo, and they write it *ſatn*, whence the ſofter word *ſant* is as eaſily formed, as *botn*, the name of turpentine, is formed into *bont*, or, as ſome write it, *botin* or *botim*, and many other words in the materia medica of the antients, are ſpelt in the ſame manner. *Proſper Alpinus*, de Plant. Ægypt.

SEL, in the materia medica of the antients, a name given to the fruit of an Indian plant, reſembling the cucumber in its manner of growth, but bearing a fruit like a piſtachia nut.

There are three of theſe fruits mentioned by the Arabian writers, the *bel*, *fel*, and *ſel*. See BEL and FEL.

They tell us expreſsly that the *bel* and *fel*, as alſo the fruit *ſel*, were not the fruit of a tree, but of a plant, and that of the creeping kind. It is very probable, that the other *fel* of Aviſenna is the root of the *nymphæa indica*, which he mentions in the chapter of *nenuphar*, as poſſeſſing the ſame virtues which he attributes to this ſort of *fel*, that is the ſame with thoſe of mandrake.

SELAGINOIDES, in botany, the name of a genus of moſſes, the characters of which are theſe. The capſules are produced in the alæ of the leaves, in the manner of thoſe of the ſelago, but they are of a different form, being tricoccous, and ſometimes quadricoccous, and opening, when mature, into ſo many valves. See Tab. of Moſſes, N° 16.

Of this genus of moſs we have only one known ſpecies, which is the prickly *ſelaginoides*, commonly called *ſeeding mountain moſs*. This is found in the mountainous parts of Yorkſhire, and in Wales, and loves rocky and moiſt places. *Dillen.* Hiſt. Muſc. p. 461.

SELAGO, in the Linnæan ſyſtem of botany, the name of a genus of plants, the characters of which are theſe. The perianthium is ſmall, and remains after the flower is fallen. It is compoſed of one leaf, divided into four ſegments at the edge. The flower conſiſts of one petal, formed into a tube, which is very ſmall, and ſcarce ſenſibly perforated, and a limb or verge, which is expanded, and divided into five ſegments; the two upper of which are the ſmalleſt, and the under one the largeſt of all. The ſtamina are four capillary filaments, of the length of the flower, into which they are fixed at the baſe; the two upper ones of theſe are longer than the reſt, and their antheræ are ſimple. The germen of the piſtil is roundiſh. The ſtyle is ſlender, and of the length of the ſtamina. The ſtigma is ſimple and acute. The flower finally involves the ſeed, which is ſingle, and of a roundiſh figure. *Linnæi* Gen. Plant. p. 300.

The characters of this genus of moſſes, according to Dillenius, are theſe. The capſules are produced in the alæ of the leaves, and are either reniform, or globular, and have neither pedicle, operculum, nor calyptra, like the capſules of the other moſſes. They have only one cavity, and part into two valves when ripe. To this it may be added that the plants are all rigid and ſhrubby, and the ſtalks as well as roots are dichotomous. See Tab. of Moſſes, N° 13.

Of this genus of moſſes the following are all the known ſpecies. 1. The common upright fir moſs, or *ſelago*, reſembling the common ſpruce fir. This grows to four or five inches high, and is found in the crevices of ſtones, and in ſome places on the ground, in the mountainous parts of Yorkſhire and in Wales. There are three or four varieties of this moſs, found in different places, which might lead a new obſerver into the error of ſuppoſing them new ſpecies. 2. The American *ſelago* with notched and reflected leaves. This grows in Penſylvania, in wet clayey ſoils. 3. The camphorated leaved *ſelago*, called by ſome authors the *coris-leaved american moſs*. It is found in North America, and its branches are often a foot long, divided at different parts in a dichotomous manner; ſo that it ſpreads greatly, taking root all the way that it paſſes. It generally creeps upon the barks of trees. 4. The coris-leaved *ſelago*, called by Plumier the *great ſavin-leaved moſs*. This alſo grows in North America. 5. The toad-flax-leaved *ſelago*. This alſo is an American moſs, and grows on the trunks and branches of trees. *Dillen.* Hiſt. Muſc. p. 436.

SELANION, in botany, a name by which ſome authors have called the common *crocus vernus*, or the garden ſpring flower we call the *crocus*. *Ger.* Emac. Ind. 2.

SELATUS, one of the many names by which the chemical writers have called quickſilver.

SELENÆ,

SELENÆ, Σελῆναι, in antiquity, a kind of cakes uſed in ſacrifices, and ſo called from their being broad and horned, in imitation of the new moon. *Potter*, Tom. I. p. 214.

SELENDERS, in the manege, are chops or mangy ſores in the bending of a horſe's hough, as the malenders are in the knees. See MALENDERS.

SELENEUSIACA *terra*, *earth of Seleneuſia*, in the materia medica of the antients, a light fungous earth called by later naturaliſts *agaricus mineralis*, and when found in form of powder, or in a diſcontinuous ſtate, *lac lunæ*.

It is an earth common enough, wherever there are ſtone quarries, all over the world; but the fineſt ever met with, is that from Sicily, the place where the antient *Seleneuſia*, or *Selinus* ſtood, and from whence the antient phyſicians had it. Some of them have called it the *creta Seleneuſiaca*; but all their deſcriptions agree in proving it to be this very earth now found there. Dioſcorides and Galen mention its remarkable diffuſibility in water, and Pliny mentions its melting into a kind of juice, or ſmooth homogene ſubſtance with it; properties ſo very applicable to this earth, and ſo little ſo to any other, as to leave no doubt of their having been originally applied to the very ſame ſubſtance.

The antients gave it internally as an aſtringent; but its principal uſe was external, as a coſmetic among the ladies. And Dr. Plot recommends our lac lunæ, on perſonal experience, for the ſame purpoſes. *Hill*'s Hiſt. of Foſſils, p. 40. See the article AGARICUS *mineralis*.

SELENIACON, a name for a kind of amulet worn for the epilepſy.

SELENITES, (*Cycl.*) in natural hiſtory, the name of a large claſs of foſſils, the characters of which are theſe. They are bodies compoſed of ſlender, and ſcarce viſible filaments, arranged into fine, even, and thin flakes; and thoſe diſpoſed into regular figures, in the ſeveral different genera, approaching to a rhomboide, or hexangular column, or a rectangled parallellogram: fiſſile, like the talcs, but that not only in a horizontal, but alſo in a perpendicular direction: they are flexile in a ſmall degree, but not at all elaſtic: they do not ferment with acid menſtrua, but readily calcine in the fire. See Tab. of Foſſils, Claſs 2.

Of this claſs there are ſeven orders of bodies, and under thoſe ten genera. The *ſelenitæ* of the firſt order are thoſe compoſed of horizontal plates, and approaching to a rhomboidal form. Of the ſecond are thoſe compoſed of horizontal plates, arranged into a columnar and angular form. Of the third are thoſe whoſe filaments are ſcarce viſibly arranged into plates, but which, in the whole maſſes, appear rather of a ſtriated, than of a tabulated ſtructure. Of the fourth are thoſe which are flat, but of no determinately angular figure. Of the fifth are thoſe formed of plates, perpendicularly arranged. Of the ſixth are thoſe formed of congeries of plates, arranged into the figure of a ſtar. And of the ſeventh, are thoſe of a complex and indeterminate figure. *Hill*'s Hiſt. of Foſſ. p. 119, 120.

Of the firſt of theſe orders there are three genera. 1. The *leptodecarhombes*. Theſe are thin *ſelenitæ* of a rhomboidal figure. 2. The *pachodecarhombes*. Theſe are thicker *ſelenitæ* of a rhomboidal figure. The *ſelenitæ* of both theſe genera conſiſt of ten planes each. 3. The *tetradecarhombes*. Theſe are *ſelenitæ* of a rhomboidal figure, but conſiſting of fourteen inſtead of ten planes. See the articles LEPTODECARHOMBES, PACODECARHOMBES, and TETRADECARHOMBES.

Of the ſecond order there are alſo three genera. The firſt the *iſchnambluces*. Theſe are *ſelenitæ* of a flatted columnar octohaedral figure, conſiſting of ſix ſides, and two broken ends. 2. The *iſambluces*. Theſe are *ſelenitæ* of an octohaedral columnar form, but not flatted. 3. The *oxuciæ*. Theſe are *ſelenitæ* of a columnar form, but not truncated, or with broken ends, but tapering off at each end to a point. See the articles ISCHNAMBLUCIS, &c.

Of the third order there is only one known genus, the *inambluciæ*. Theſe are columnar *ſelenitæ* with abrupt ends, and of a fibroſe, not tabulated texture.

Of the fourth order there is alſo only one known genus, the *ſanidia*. Theſe are *ſelenitæ* of no determinate figure, but of a tabulated ſtructure, and reſembling the foliaceous tubes. See the articles INAMBLUCIA and SANIDIA.

Of the fifth order there is alſo only one known genus, the *cathetolipes*. Theſe are octohaedral *ſelenitæ* with perpendicular plates, and obtuſe angles. *Hill*'s Hiſt. of Foſſ. p. 121, 122, 123.

Of the ſixth order there are two genera. 1. The *lepaſtra*. Theſe are *ſelenitæ* compoſed of filaments, arranged into plates, and diſpoſed in form of a ſtar. 2. The *trichestra*. Theſe are *ſelenitæ* compoſed of filaments, ſcarce viſibly arranged into plates, but diſpoſed in threads into the form of a radiated ſtar, and appearing merely of a ſtriated texture. See the articles LEPASTRA and TRICHESTRA.

Of the ſeventh order there is only one genus, the *ſymplexia*. Theſe are *ſelenitæ* compoſed of various irregularly connected bodies, of the ſtructure and general figure of one or other of the former genera. See the article SYMPLEXIUM.

The ſtructure of the *ſelenitæ* of all the genera of the firſt order is exactly alike, they are all compoſod of a great number of broad flakes or plates, in a great meaſure externally reſembling the flakes of the foliaceous talcs. Theſe are of the length and breadth of the whole maſs. The top and bottom being each only one ſuch plate, and thoſe between them, in like manner, each compleat and ſingle, and the body may always be eaſily and evenly ſplit, according to the direction of theſe flakes. Theſe differ, however, extremely from the talcs; for they are each compoſed of a number of parallel threads, or filaments, which are uſually diſpoſed parallelly to the ſides of the body, though ſometimes parallelly to its ends. In many of the ſpecies they are alſo divided by parallel lines, placed at a conſiderable diſtance from each other, and the plates in ſplitting often break at theſe lines: add to this, that they are not elaſtic, and that they readily calcine. *Hill*'s Hiſt. of Foſſ. p. 120.

The ſtructure of thoſe of the ſecond order is the ſame with that of the firſt; but that in many of the ſpecimens of them, the filaments, of which the plates are compoſed, run in two directions, and meet in an obtuſe angle; and in the middle there is generally ſeen in this caſe a ſtrait line, running the whole length of the column, and ſmall parcels of clay inſinuating themſelves into this crack, repreſent in it the figure of an ear of graſs ſo naturally, as to have deceived many into a belief, that there was really an ear of graſs there. The other orders conſiſting only of ſingle genera, the ſtructure of each is explained under the generical name. *Hill*'s Hiſt. of Foſſ. p. 121. See the articles LEPTODECARHOMBIS, &c.

SELF (*Cycl.*)—SELF *opens*, a term uſed by the miners in the north of England to expreſs certain natural cavities, or chambers, which are frequently met with, ſome near the ſurface, ſome at very great depths, ſome ſmall, and others very large.

Theſe are of various figures, and often run into ſtrange ſinuſes. Dr. Liſter, in accounting for the origin of earthquakes, ſuppoſes the whole cruſt of the earth to be more or leſs hollowed in this manner; which he alſo argues for, from the ſtreams of waters which ariſe in large quantities from the ſides of mountains, and muſt have communication with theſe *ſelf opens* and ſupplies from them.

Theſe natural hollows the doctor thinks to be the means of continuing, and propagating earthquakes; the firſt cauſe of which he aſcribes to the breath of the pyrites, which he alſo ſays is the pyrites itſelf *tota ſubſtantia*. This he obſerves takes fire of itſelf, on being expoſed to the air in our ſight, and may do ſo, from various other cauſes, underground. The ſulphureous ſmell of the air and waters, before and after earthquakes, in the places where they happen, ſeems a proof that they owe their origin to ſome ſuch ſulphureous matter as this ſtone; and the rolling, and deſultory noiſe of an earthquake, ſeems alſo to ſhew that it is not expanded every way at once, but is propagated through a chain of theſe ſubterranean hollows.

It is not neceſſary that we ſhould ſuppoſe a continued chain of them, from the place where the earthquake begins to be felt, to the ſpot where it ends; but if there are many of them irregularly ſcattered about the earth, the force of the exploſion will be ſufficient to burſt through the ſolid parts between, and open a paſſage from one to the others, which may continue open no longer than the force continues, and after the ſhock is over cloſe together again, ſo as to leave no trace where it was.

Our miners not only find the natural caverns, but they alſo find them often full of what they call *fire damps*, which are inflammable vapours, of the very nature of thoſe which occaſion earthquakes, and when fired make the ſame exploſions, and cauſe the ſame effects in a certain degree. Theſe ſometimes require a candle, or other actual fire, to come in contact, in order to kindle them; but ſometimes they are found kindled of themſelves, and flaming on the ſurface of the waters, in the bottoms of the pits, or at the fiſſures of the coal. Philoſ. Tranſ. N° 157.

SELI, in botany, a word formed by an abbreviation of the word *ſeſeli*, and ſignifying the ſame plant. See the article SESELI.

SELICHA, a name given by the Arabians to a kind of cinnamon. See the article CINNAMUM.

SELIGONION, in botany, a name by which ſome authors have called piony. *Ger.* Emac. Ind. 2.

SELION *of land*, *ſelio terræ*, is derived from the French, *ſeillon*, which ſignifies a ridge of land, or ground ariſing between two furrows, and contains no certain quantity, but ſometimes more and ſometimes leſs. Therefore Crompton ſays, that a *ſelion of land* cannot be in demand, becauſe it is a thing uncertain. *Crompt.* Juriſ. 221. Terms of Law.

SELKIE, the name in Zetland for a ſeal. Many of theſe are found in that iſland. Philoſ. Tranſ. N° 473. ſect. 8.

SELL *bed*, in mining, a term uſed in ſome parts of England to expreſs ſome particularly rich parts of the vein of ore.

In Cornwall they ſometimes find the tin ore ſo pure, that it requires only bruiſing to dreſs it, without the waſhing and ſeparation by grates, launders, and the like means: they call theſe collections of ore the *ſell beds* of tin; and it is obſerved

ſerved that theſe never have any ſtrings iſſuing from them, as the other lands have. Philoſ. Tranſ. N° 69.

SELLA, among the Romans, a chair in which the old and infirm were carried by ſervants through the city, and in journeys. Sometimes the phyſicians preſcribed it as an exerciſe. *Pitiſc.* in voc.

SELLA *curulis*, among the Romans. See CURULE *chair*, *Cyc.*

SELLIGA, in the materia medica, a name by which ſome authors have called the *nardus Celtica*, or Celtic ſpikenard of the ſhops. *Ger.* Emac. Ind. 2.

SELLI, Σελλοι, in antiquity, an appellation given to thoſe who firſt delivered oracles. Theſe, according to Strabo and Euſtathius, were men, and the name *ſelli* is ſaid to come from *Sellæ*, a town in Epirus, or from the river called by Homer *Selleis*. *Potter*, Archæol. Græc. l. 2. c. 8. Tom. I. p. 267, ſeq.

SELTZER-*water*, the name of a mineral water of Germany, which ariſes near Neider Seltz, and is now uſed in England and many other countries.

We called it *Seltz*, or *Seltzer water*, and the phyſicians preſcribe it in many caſes, as ſcurveys, ſpaſmodic affections, and in conſumptions; in the laſt caſe, mixing it with aſſe's milk.

Hoffman, in his examination of the principles of this water, obſerves, 1. That on the mixing any acid with it, whether it be a weak or a ſtrong one, there is an immediate effervescence; and on the mixing it with Rheniſh wine and ſugar, there is a very remarkable emotion and noiſe, and the whole body of the liquor appears milky for ſome time. 2. If they are mixed in equal quantities with fine old Rheniſh wine alone, they become turbid, and acquire a brown colour, with a caſt of reddiſhneſs; like that produced by mixing oil of tartar, or the urinous ſpirit of ſal armoniac, with good wine. 3. The taſte of theſe waters is not of that penetrating, ſubacid kind, which moſt of the other mineral waters are of, but rather has a flavour like that of a diluted ſolution of a lixivial ſalt. 4. On putting powder of galls into them, they do not become purple, nor do they blacken the ſtools of thoſe who drink them. 5. On adding oil of tartar to them they become milky, but throw down no precipitate. 6. A quart of theſe waters gently evaporated, yields a drachm and twelve grains of a ſaline matter, and this diſſolved and filtrated, yields, on a ſecond evaporation, two ſcruples of a pure alkaline ſalt. This ſalt diſſolved in water, and added to a ſolution of corroſive ſublimate, precipitates a yellow powder, or turbith mineral; and mixed with an infuſion of rhubarb, gives it a reddiſh colour; mixed with ſal armoniac, it raiſes a pungent ſmell. 7. A quart of this water being ſaturated with ſpirit of vitriol, to the ceaſing of the ebullition on dropping it in, and afterwards gently evaporated, affords a drachm and a half of ſalt, no way diſtinguiſhable from tartarum vitriolatum. 8. No medicinal water is ſo ſubject to ſpoil and corrupt as this in the keeping; for which reaſon the jars muſt be well filled, and nicely ſecured with ſound corks, pitched over. 9. If a quantity of this water be ſet for a day or two in an open veſſel, it wholly loſes its natural flavour, and taſtes only as if oil of tartar had been mixed with common water: in this change it is obſervable alſo, that there is no earthy matter precipitated.

It appears from all theſe obſervations, that this water abounds with an alkaline ſalt in a much greater quantity, than any other of the known mineral waters; and it ſeems to contain no particle of the common ingredients of the other mineral waters, which are a ferrugineous earth, and a bitter purging ſalt, of the nature of Glauber's ſalt. Hence it does not purge by the belly, but generally goes off by urine. It is one of the mildeſt, and moſt innocent of all the mineral waters, and may be taken by perſons of the weakeſt conſtitution. *Hoffman*, Opera, Vol. 5. p. 144.

SEMAMPLEXICAULE *leaf*. See LEAF.

SEMBELLA, among the Romans, a ſmall ſilver coin, equal in value and weight to half the *libella*. *Pitiſc.* in voc. See the article LIBELLA.

SEMICIRCULARIS *palpebrarum muſculus*, in anatomy, a name given by Spigelius, and ſome others, to one of the muſcles of the face, called by Albinus and Winſlow the *muſculus orbicularis palpebrarum*. See MUSCULUS.

SEMI-CUBICAL *parabola*, a curve of the ſecond order, wherein the cubes of the ordinates are as the ſquares of the abſciſſes. Its equation is $axx = y^3$.

SEMI-DITONUS, in muſic, is uſed by ſome writers, as Salinas, for the third minor.

SEMIFLOSCULOUS, in botany, a term uſed to expreſs the flowers of a certain claſs of plants, of which the dandelion, hawkweed, and the like, are kinds.

This ſort of flower conſiſts of a number of *ſemifloſculi*, which are either diſpoſed into one or more circles, and all comprehended in the ſame cup, which often becomes inverted as the flower ripens. Theſe *ſemifloſcules* are petals, hollow in their lower part, but in their upper half are flat, and continued in the ſhape of a tongue. Theſe are often ſeparated from each other by intermediate leaves, and are placed upon the embryo fruit, from which there ſtands out a ſlender capillament, divided at the end into two parts; often carried beyond the vagina, ſupported by five props. The embryos are placed in the thalamus, or bottom of the cup, and finally become ſeeds, ſometimes winged with down, ſometimes naked, ſometimes coronated, and ſometimes foliated. See Tab. 1. of Botany, Claſs 1. *Tourn.* Inſt. p. 467.

SEMI-INTEROSSEUS *indicis*, a ſmall ſhort flat fleſhy muſcle, very like the antithenar, or internal *ſemi-interoſſeus* of the thumb. It is ſituated obliquely on one ſide of that of the thumb, between the firſt phalanx thereof, and the firſt metacarpal bone. It is fixed by one end to the outſide of the baſis of the firſt phalanx of the thumb, and a little to that bone of the carpus, by which this phalanx is ſupported; and by the other end it is fixed near the head of the firſt phalanx of the index, on that ſide next the thumb. It lies almoſt parallel to the antithenar, croſſing it a little; this muſcle lying on the convex ſide of the hand, and the antithenar on the concave. *Winſlow*'s Anatomy, p. 202.

SEMILUNARES *cochleæ*, in natural hiſtory, the name of a genus of ſea ſnails, ſo called, from their having ſemicircular mouths. See Tab. of Foſſils, Claſs 9. and Tab. of Shells, N° 6.

The characters of the genus are theſe. They are univalve ſhells of a compact body, with a flat ſemicircular, and often dentated mouth. Some of the ſpecies have exerted apices, and ſome depreſſed.

There are many diſtinctive and ſpecific characters in the ſeveral ſpecies of this genus, which arrange together conſiderable numbers of the ſpecies under each. Thus the *neritæ*, which are of this genus, are ſome of them umbilicated, and others have teeth, and a kind of gums. The *ſnail* kinds, diſtinctly ſo called, that fall under this genus, are very different from the *neritæ*, in that they have no teeth, no gums, and no palate. The term *ſemilunares cochleæ* was invented by Rumphius to expreſs their mouths, being of the ſhape of half of a circle.

Bonani is of opinion that the *neritæ* were ſo called, from their being born of the ſea, and called by a name expreſſive of that origin by way of eminence, as an honour to their watery parent. To make out the juſtice of this derivation, it was neceſſary to ſuppoſe the *nerita* more beautiful than other ſhells; and in order to give them a claim to this character, the author has introduced into the family of the *neritæ* the trumpet ſhells and porcellanes. Some authors have called them *natrices*, from their ſwimming, affirming that they ſwim in the manner of the nautilus, by ſetting their mouths before the wind. This is an opinion as old as Pliny, but it is as erroneous as many others of the opinions of that author. The *neritæ* generally inhabit caverns in the ſides of rocks, and uſually ſtick faſt to the ſtone. *Bonani*, Recreat. Ment. et Ocul. p. 56. *Aldrovand.* de Teſtac. l. 3. c. 80. *Plin.* l. 9. c. 33.

All the ſpecies of the *ſemilunar* ſhells have few convolutions, and have the extremity of the voluta ſmall, and uſually ſtanding a little out.

The ſpecies of the *ſemilunar cochleæ* are theſe, as arranged under the two general diviſions of dentated *neritæ*, and umbilicated *cochleæ*. 1. The dentated *nerita*, commonly called the *gum-ſhell*. 2. The bloody tooth-*nerita*. 3. The ox-palate-*nerita*. 4. The ſtriated and punctulated *nerita*. This ſpecies, when robbed of its outer coat, and poliſhed, aſſumes a very different appearance, and is ſeen in the cabinets of the curious, under the name of a faſciated *nerita* with black and yellow variegations. 5. The canaliculated *nerita*. 6. The furrowed *nerita*. 7. The thruſh-*nerita*. 8. The partridge-*nerita*.

Of the *neritæ* which have no teeth, the following are the known ſpecies. 1. The jaſper-*nerita* with a long beak. 2. The jaſper-*nerita* with an operculum. 3. The lemon-coloured pea-*nerita*. 4. The yellow pea-*nerita*. 5. The prickly *nerita*. 6. The reticulated *nerita*. 7. The *nerita* variegated with black ſpots. 8. The red and white faſciated *nerita*. 9. The lightly ſtriated green *nerita*. 10. The undulated *nerita*.

Of the umbilicated *ſnails*, we have the following ſpecies. 1. The long umbilicated *cochlea*. 2. The *cochlea* with an exerted apex. 3. The *cochlea* with a depreſſed apex. 4. The teſticulated *cochlea*. 5. The hermit *cochlea*. 6. The umbonated *cochlea*. 7. The ſmall nipple *cochlea*. 8. The heavy white *cochlea*. And 9. the orange-coloured *cochlea*. Hiſt. Naturel. Eclairc. Part 2. p. 256.

SEMIMEMBRANOSUS, in anatomy, a long thin muſcle, partly tendinous, and ſituated on the backſide of the thigh, a little toward the inſide.

It is fixed above by a ſtrong broad tendon, or long aponeuroſis, in the irregular obtuſe, prominent line, which goes from the acetabulum to the tuberoſity of the iſchium, a little above the inſertion of the ſeminervoſus, and between thoſe of the gemellus inferior, and quadratus; mixing ſome fibres with the triceps tertius. From thence it runs down fleſhy, in an oblique direction, behind the inner condyle of the os femoris; below which it terminates in a thick tendon, which is inſerted in the poſterior and interior ſide of the inner condyle of the tibia, by three ſhort branches; the firſt,

or uppermoſt of which, goes a little toward the inſide, the ſecond more backward, and the third lower down. Before it is inſerted, it ſends off ſometimes an aponeuroſis, like that of the biceps. *Winſlow*'s Anatomy, p. 216.

SEMINAL (*Cycl.*)—SEMINAL *leaves*, two ſoft, plain, and undivided leaves, that firſt ſhoot forth from the greateſt part of all ſown ſeeds, and are different from thoſe of the ſucceeding plant in figure, texture, and all other reſpects.

SEMINAL *root*, in natural hiſtory, a name given by Grew to that part of the ſeeds of plants, which may otherwiſe be called the inner body of the ſeed: this is diſtributed through the parenchyma of the ſeed, but is wholly different from it, and diſtinguiſhed by Dr. Grew from the radicle, which becomes the plant root in its future growth. The parenchyma of the ſeed is, in ſome degree, that to the *ſeminal root*, which the mould or earth is to the plant root, or radicle; and the *ſeminal root* is to the plant root, what the plant root is to the trunk. *Grew*'s Anat. of Plants.

SEMINALIS, in botany, a name by which ſome authors have called horſetail. *Ger.* Emac. Ind. 2.

SEMINARY, (*Cycl.*) in gardening, the term uſed for the ſeed plot, or place allotted for raiſing plants from ſeed, and keeping them till they are fit to be removed into the garden, or nurſery.

When the *ſeminary* is intended for trees, it muſt be large, and of a ſoil adapted to the generality of the trees intended to be raiſed in it: but that which is moſt in uſe, is for the ſupply of the flower-garden, and is the place where flowers are to be raiſed from their ſeeds, to procure varieties, or, as the floriſts expreſs it, new flowers; as alſo for the ſowing all the biennial plants, to ſucceed thoſe which decay in the flower garden.

The *ſeminary* ſhould always be ſituated at ſome diſtance from the houſe, and be walled or paled round, and kept under lock and key, to keep out dogs, *&c.* and to prevent a great deal of damage, that is frequently done by thoſe who are not acquainted with gardening, before they are aware of it. The ſeveral directions, for the management of the *ſeminary*, are to be ſeen under the names of the ſeveral plants intended to be raiſed in it. *Miller*'s Gard. Dict.

SEMINERVOSUS, in anatomy, a name given by Riolan, and ſome others, to a muſcle of the thigh, more generally known by the name of the *ſemitendinoſus*. The French in general, however, call it *le demi nerveux*. Cowper calls it *ſeminervoſus ſeu ſemitendinoſus*; and Albinus ſeems to claim the merit of aſcertaining its true name of *ſemitendinoſus*.

It is a long muſcle, half fleſhy and half tendinous, or like a nerve. It is ſituated a little obliquely on the poſterior and inner part of the thigh. It is fixed above to the poſterior part of the tuberoſity of the iſchium, immediately before, and a little more inward than the biceps. It is afterwards fixed by fleſhy fibres to the tendons of the biceps, for about the breadth of three fingers, much in the ſame manner as the coraco-brachialis is fixed to the biceps of the arm. From thence it runs down fleſhy toward the lower part of the inſide of the thigh, having a ſort of tendinous interſection in the inner part of its fleſhy portion. Having reached below the middle of the thigh, it terminates in a ſmall long round tendon, which runs down to the inſide of the knee, beſide that of the gracilis, where it expands in breadth. It is inſerted in the inſide of the upper part of the tibia, about two or three fingers breadth below the tuberoſity of the ſpine, immediately under the tendon of the gracilis internus, with which it communicates. It has the ſame oblique form with the gracilis and ſartorius, and ſends off a like kind of aponeuroſis. *Winſlow*'s Anatomy, p. 215.

SEMINIUM, a term uſed by the writers on foſſils to expreſs a ſort of firſt principle, from which the ſeveral figured ſtones, or, as they are more uſually called, the extraneous foſſils, are ſuppoſed to have their origin.

The generality of the learned world, at this time, ſuppoſe theſe to be the remains of real ſhells, *&c.* brought from the ſea to the places where they are now found, at the time of the univerſal deluge. See the article FIGURED *ſtones*.

But thoſe who diſſent from this ſyſtem pretend, that theſe foſſile bodies, though they exactly repreſent ſhells, *&c.* yet never were in the ſea at all, but that their minute firſt principles, or, to uſe their own term, their *ſeminia* have been carried from the ſea, through ſubterranean paſſages, to the places where we now find the compleat ſhells, *&c.* into which they have grown. Langius, who has written expreſsly on this ſubject, though he has candidly collected all that has been ſaid in favour of the diluvian ſyſtem, by the abettors of it, yet is not convinced by thoſe arguments, but rather inclines to the other ſide of the queſtion, or the riſe of ſuch foſſils from *ſeminia*.

The ſubſtance of this hypotheſis is as follows: that the ſenſible and perfectly formed ſeeds, or principles of growth of ſhell-fiſhes, and other ſea productions, which, yet extremely ſmall and light, is raiſed from among the fleſh of putrid, or at leaſt of dead ſea fiſh of theſe kinds; and thence, by its extreme lightneſs, is wafted up and down in the water, and after that is raiſed among the vapours iſſuing from that water; and being then received into the air, fluctuate about in that vehicle alſo, till it is received into the pores or inteſtines of the earth; and when there, is wafted about by the aſcent and motion of the vapours, and a number of other accidents, through the fiſſures of the ſeveral ſtrata, and even through the pores of ſtone; and that it thus wanders about, at the will of ſuch irregular agents, till in its courſe it chance to find ſome bed, or matrix, proper to its growth or expanſion, and when received into that it adheres firmly to it, and is no more the ſport of the paſſing exhalations, but remains there, till by the mediation of the ſubterranean heat its principles of growth are put in action, and its latent plaſtic power excited. Then they ſay, that by means of its ſeminal aura, and the lapidific, or petrifying nature of the place where it lies, all ſuch fluid matter, as is fitted to make a part of its ſubſtance, is collected to it, and is petrified, or hardened into ſtone, and conſequently that a ſtony body is thus found, of the ſame ſhape and figure in which a ſhelly one would have been formed in the ſea, where there would have been no petrifying principle to have made it aſſume the nature of a ſtone.

The arguments uſed, in ſupport of this hypotheſis, are theſe. That there are difficulties attending every ſyſtem, by which men have attempted to account for the finding of ſea ſhells at the tops of mountains; but that this ſyſtem is liable to leſs than the others, as it is much more eaſy to conceive how the *ſeminia*, or minute firſt principles of theſe things, ſhould be carried to ſuch diſtant and high places, than how the full grown bodies themſelves ſhould; and particularly, that it is very difficult to conceive how ſuch large and tender ſhells, as thoſe of the cornua ammonis, ſhould be carried unhurt to ſuch heights; though not very wonderful, that the *ſeminium* of ſuch a ſhell ſhould be carried thither, and there grow into the ſhape of its parent animal.

The congeries of extremely minute ſhells, that we find in ſome places immerſed in hard ſtones, are urged as another argument againſt the diluvian hypotheſis, as it is ſuppoſed that their tender ſtructure in that ſtate could never have ſupported the toſſing about in an ocean of waters; and Langius adds to theſe general arguments two others, from the cornua ammonis of the foſſile kingdom, which were in his own poſſeſſion; the one of which he ſays was truly in an embryo ſtate, and very incomplete, and the other had a vaſt number of ſmall ſhells of other kinds encloſed in it, which he ſuppoſes to have grown there. To this he adds the impoſſibility, as it appears, of certain conchitæ, which are compoſed of thin laminæ, bearing the daſhing of the waters, by which they muſt have been brought to the places where we find them, without being broken all to pieces, which yet are found whole and unhurt on mountains; and finally, that there occur in ſome ſtones the figures of ſhell-fiſh, of an uncommon, and even monſtrous kind, ſuch as it is ſuppoſed never exiſted in their mutilated or compleated figures in any living ſtate.

Theſe foſſile ſhells are uſually found throughout of one and the ſame ſubſtance, and that the moſt different imaginable from the ſubſtance of the living creatures which they repreſent; and often, though found in pairs, and perfectly cloſed on all ſides, yet when broken they are found full of the ſubſtance of the ſtone in which they lie, and the armature of ſeveral kinds of them, particularly of many of the cornua ammonis, is ſuppoſed to plead greatly in favour of this hypotheſis; as it is not of the nature of, or at all owing to the ſubſtance of the matrix, in which they lie, or of the matter of which they are formed, and is therefore to ariſe ſolely from the nature of the *ſeminium*, from which they are formed.

The immenſe number of the ſea ſhells, as they are called, thus found foſſile, is alſo thought to argue much on this ſide of the queſtion; as the favourers of this hypotheſis ſuppoſe that the ſea could not, at any one time, have given up ſuch numbers as the earth is ſtocked with, though there are no limits to the numbers ſuppoſed to be raiſed from *ſeminia*; and the immenſe columns of black marble, found in Ireland, and found of ſuch regular joints, are brought as a proof of the poſſibility of ſuch a formation of foſſils as this from *ſeminia*, which they ſuppoſe muſt have given origin to thoſe pillars.

The ſyſtem of the deluge, as delivered by Woodward, is the hardeſt thing for the abettors of this doctrine of the *ſeminia* to get over; but tho' they affirm that this author's account is contrary to reaſon, and to the ſcripture account of that fatal cataſtrophe, yet it is not eaſy to account for many things, in regard to foſſils, on any other foundation. They obſerve that as this deluge was univerſal, all places throughout the earth ought to have been furniſhed with foſſile ſhells by it; but that this is not the caſe, ſince many large tracts of land have none of them. It is uſually obſerved, that the deluge only could carry ſhells into the heart of mountains; but the aſſertors of this doctrine affirm, that this may be done according to their ſyſtem, ſince the *ſeminia* of foſſils may be as eaſily ſuſtained in the air, as thoſe of plants and animals, and that they may ſo be conveyed into the inmoſt receſſes of the earth through pores and cracks, not viſible to us: and they ſay, that when there they do not want a

proper nutritious matter, ſince the ſtony particles they find there are much of the nature of their natural ſhells in the ſea.

The growth of the foſſile ſhell from its *ſeminium* is ſuppoſed, by theſe writers, to be inſtantaneous, not progreſſive; and the reaſon they give for this is, that there is abundant matter for the formation of it in readineſs altogether. They advance, that it is not at all more difficult for nature to form a ſhell from ſuch a *ſeminium* in the earth than in the ſea, provided all the neceſſary requiſites are in readineſs, which they ſuppoſe, in this caſe, to be plainly the fact; and they diſallow the analogy between the formation of theſe bodies and cryſtals, becauſe they obſerve that theſe are formed from *ſeminia*, thoſe only from appoſition of particles. They alſo obſerve that theſe ſhells, as they are formed in the earth, can never have been inhabitants of the ſea in that form, becauſe they never have any thing truly of the nature of ſhelly matter about them. This is, however, abſolutely an error. The foſſile nautili have uſually a great deal of the true pearly matter of the ſhell about them, and all the arguments, given in favour of this ſtrange hypotheſis, ſeem as eaſily confuted. The reader has an opportunity, however, of examining this ſyſtem in its full force; and on comparing it with the diluvian ſyſtem, delivered under the article of FIGURED *ſtones*, will be able to judge whether the preſent age be in the right or not, in giving the preference to that ſyſtem. *Langii* Hiſt. Lap. Fig.

SEMIORBICULARIS *labiorum*, a name given by Winſlow, and others, to the muſcle called by Albinus *orbicularis oris*, and by others *conſtrictor*, and *ſphincter labiorum*.

SEMIREVERBERATORY *fire*, in chemiſtry, a term uſed to expreſs ſuch a reverberatory fire, in which the flame is only beaten back upon the bottom of the veſſel.

SEMIS, among the Romans, the half of the *as*. See the article As, *Cycl.*

SEMISICILICUS, a word uſed by ſome pharmaceutic writers to expreſs a drachm.

SEMISIDERATUS, a word uſed by ſome for a perſon ſtruck with a hemiplegia.

SEMI-SOSPIRO, in the Italian muſic, a little pauſe, of the eighth part of a bar in common time. See PAUSE, REST, CHARACTER, *Cycl.*

SEMI-SPINALIS, a muſcle, called alſo *tranſverſo-ſpinalis dorſi*. It is a fleſhy maſs, which, from all the ſpinal and tranſverſe apophyſes of the back and loins, is extended in diſtinct faſciculi over the vertebræ themſelves.

It is made up, like that of the neck, of ſeveral oblique converging muſcles, the uppermoſt of which is fixed below to the third tranſverſe apophyſis of the back, and above to the firſt ſpinal apophyſis. The loweſt is fixed below to the third tranſverſe apophyſis of the loins, and above the laſt ſpinal apophyſis of the back. They are divided by anatomiſts into the external, which are firſt diſcovered, and the internal, which lie immediately on the vertebræ. The external, from the firſt vertebra to the ſeventh incluſively, appear to be longer than the internal, which are covered by them. *Winſlow*'s Anatomy, p. 248.

SEMI-SPINALIS *colli*, a muſcle, called alſo *tranſverſo-ſpinalis colli*, and taking into its compoſition all that fleſhy maſs, which lies between the tranſverſe and ſpinal apophyſes, from the ſecond vertebra of the neck to the middle of the back, under the ſplenius and complexus major.

It is compoſed of ſeveral oblique converging muſcles, which may be divided into external and internal, of which the external are the longeſt. Theſe are fixed below to the tranſverſe apophyſes of the ſixth, ſeventh, eighth, or ninth vertebræ of the back, by tendinous extremities, which as they aſcend become fleſhy, and mix with each other. Their ſuperior inſertions in the neck are ſix in number, whereof the firſt, which is tendinous, is in the ſeventh ſpinal apophyſis, and the others, which are fleſhy, are in the five next ſpinal apophyſes. The internal are ſhorter, and more oblique than the external, and are partly covered by them. They are fixed, by their lower extremities, to the tranſverſe apophyſes of the three or four upper vertebræ of the back, and to the oblique apophyſes of the four or five lower vertebræ of the neck, and by their other extremities, they are inſerted in the ſix ſpinal apophyſes of the neck. Some of theſe internal muſcles are very ſhort, lying wholly between the ſpinal apophyſes, and the oblique or tranſverſe apophyſes next them. *Winſlow*'s Anatomy, p. 243.

SEMISPINATUS, (*Cycl.*) in anatomy, a name given by Riolanus, and ſome others, to the muſcle, more generally known by the name of *longiſſimus dorſi*.

SEMITALES, among the Romans, a name given to the Gods, who were the protectors of roads. See Hiſt. de l'Acad. des Inſcrip. Vol. 2. p. 22.

SEMI-TONE, (*Cycl.*) in muſic, is of two kinds, diſtinguiſhed by the addition of greater and leſs. The firſt is expreſſed by the ratio 16 to 15, or $\frac{16}{15}$; and the ſecond by 25 to 24, or $\frac{25}{24}$. Theſe two are ſo far from being nearly equal, as it is ſaid in the Cyclopædia, from Malcolm, that they differ by a whole enharmonic dieſis; which is an interval practicable by the voice [b], and was much in uſe among the antients, and not unknown even among the modern practitioners [c].—[[b] See DIESIS. [c] See Handel's Oratorio of Samſon, in the ſecond part of the ſong, *Return, return, O God of hoſts.*]

SEMI-TONE *major*.—The octave contains ten *ſemi-tones major*, and two dieſes, nearly; for the meaſure of the octave being expreſſed by the logarithm 1.000000, the *ſemi-tone major* will be meaſured by 0.093109. *Euler*, Tent. Nov. Theor. Muſ. p. 107. See INTERVAL.

SEMI-TONE *minor*.—The octave contains ſeventeen *ſemi-tones minor*, nearly. If the meaſure of the octave be the logarithm 1.000000, the meaſure of the *ſemi-tone minor* will be 0.058894. *Euler*, Tent. Nov. Theor. Muſ. p. 107. See the article INTERVAL.

SEMIVULPA, in zoology, a name by which Geſner, and ſome others, have called the *opoſſum*. See OPOSSUM.

SEMODIUS, among the Romans, a meaſure equal to half the modius, or the ſixth part of the amphora. See MODIUS and AMPHORA, *Cycl.*

SEMONES, among the antients, a claſs of Gods that were of a middle nature, between the celeſtial and terreſtrial Gods. Juſtin Martyr has miſtaken one of theſe for Simon Magus. Mem. de l'Acad. des Inſcrip. Vol. I. p. 270.

SEMYDA, in botany, the name of a tree, mentioned by Theophraſtus, and by ſome ſuppoſed to be the ſame with the *betula*, or birch tree, but very erroneouſly.

Gaza indeed has tranſlated the word by *betula*, and moſt of the later authors having conſulted only the Latin tranſlation, in their references to this author, have taken it upon credit that he meant the birch by this name.

Theophraſtus ſays that the *ſamyda*, or *ſemyda*, has a leaf like the walnut tree, only ſomething narrower; now that the *betula*, or birch tree, has no ſuch leaf, every one muſt know that ever ſaw it. He ſays alſo, that the bark of the *ſemyda* is variegated. This as little agrees with the *betula*, as the uſe he ſays was made of it. It was eſteemed the lighteſt of all woods, and therefore cut out into all things that required ſtrength without much weight. The uſe of the birch in rods for malefactors, is as old as any thing we know; and had it been the birch that the author was here deſcribing, he would not have omitted this uſe.

SENA, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the roſaceous kind, being uſually compoſed of five petals, diſpoſed in a circular form. The piſtil finally becomes a pod of a flatted ſhape, uſually ſomewhat crooked, and compoſed of two membranes, between which are lodged ſeeds, reſembling grape ſtones, and divided from one another by thin partitions. See Tab. 1. of Botany, Claſs 21.

The ſpecies of *ſena*, enumerated by Mr. Tournefort, are theſe. 1. The Alexandrian *ſena* with ſharp pointed leaves. 2. The Italian *ſena* with obtuſe leaves. And 3. the privet-leaved American *ſena*. *Tourn.* Inſt. p. 618.

The purgative virtue of this plant is found, though very different in degree, in infuſion, according to the manner in which that infuſion is made. In a cold infuſion it purges very gently, but this, according to the time it remains in the water, is different in degree; and in a warm infuſion it purges much more briſkly. It is eaſy to ſee from this, that its operation is very difficult to aſcertain, ſince the degree of heat, which it is not eaſy to reduce to any certainty, makes it ſtronger or weaker, though the quantity of the medicine be the ſame, and the variety of its effect depends on the manner in which it is penetrated by the water, which is to diſſolve its active principles.

It is obſerved that the follicles, or pods of *ſena*, operate more gently in infuſion, than the *ſena* itſelf: the reaſon of this is, that the texture of theſe pods is much more firm than that of the leaves, and therefore the water penetrates leſs into it, and extracts leſs of its active principles. It is certain that theſe pods are equally purgative with the leaves, nay every part of the plant is ſo; the very ſtalks, or pedicles of the leaves, having as much virtue as the reſt, but only requiring a longer time to boil, to communicate it to water, becauſe of their cloſer texture. See the article INFUSION.

The moſt certain way, therefore, of giving this medicine is in the form of Mr. Geoffroy's dry extract, which is made of a very ſtrong infuſion, evaporated to a dry and pulveriſable ſubſtance, eaſily taken, and of no ill taſte, and which operates in a very ſmall quantity, one third part containing the virtue of the whole, or nearly ſo; the niceſt calculations ſhewing, that twenty four grains of the extract, ſome part of which may be ſuppoſed to be earth, or other accidental or uſeleſs matter, poſſeſſes the virtues of a drachm in ſubſtance. Mem. de l'Acad. des Scienc. Par. 1738.

SENATE (*Cycl.*)—It has been a queſtion among the learned how ſenators were created, and how the vacancies of the *ſenate* in old Rome were ſupplied.

Dr. Middleton is of opinion, that the conſtant and regular ſupply of the *ſenate* was from the annual magiſtrates; who, by virtue of their ſeveral offices, acquired an immediate right to ſit and vote in that aſſembly. The uſual gradation of theſe offices was that of quæſtor, tribune of the people, ædile,

ædile, prætor, and conſul; which every candidate, in the ordinary forms of the conſtitution, was obliged to take in their order, with this exception only, that he might forego either the tribunate, or the ædileſhip, at his own choice, without a neceſſity of paſſing through them both. *Middleton's* Treat. of Rom. Senate, p. 6. See the articles QUÆSTOR, TRIBUNE, *&c.*

But though theſe offices gave both an immediate right, and actual entrance into the *ſenate*, yet the ſenatorian character was not eſteemed complete, till the new ſenators had been enrolled by the cenſors at the next luſtrum, or general review of all the orders of the city, which was generally held every five years. Yet this enrolment was but a matter of form, which could not be denied to any of them, except for ſome legal incapacity, or the notoriety of ſome crime, or infamy upon their characters; for which the ſame cenſors could expel, or deprive any other ſenator, of what rank or ſtanding ſoever. *Middleton* of Rom. Sen. p. 8. See the article CENSOR.

M. Vertot ſeems to perplex the queſtion; firſt, by conſidering the authority of the people, and that of the cenſors, as oppoſite and inconſiſtent with each other in the creation of ſenators, whereas they were both of them jointly neceſſary to make the act complete. Secondly, by aſſerting the cenſorian power to be the original and principal in that affair, whereas it was but ſecondary, or miniſterial to the ſovereign prerogative of the people. *Middleton* of Rom. Sen. p. 13.

It has been the opinion of ſome, that under the kings of Rome the choice and nomination of all the ſenators depended wholly on the will of the prince, without any right in the people, either direct or indirect; and the conſuls, who ſucceeded to the kingly power, enjoyed the ſame prerogative, till the creation of the cenſors, who ever after poſſeſſed the ſole and abſolute right of making and unmaking ſenators. But Dr. Middleton is of opinion, that the kings, the conſuls, and the cenſors, acted in this affair but miniſterially, and ſubordinately to the ſupreme will of the people, in whom the proper and abſolute power of creating ſenators always reſided. And the Doctor aſſures us, upon the ſtricteſt ſearch into the ſtate of the preſent queſtion, as it ſtood under the kingly government, he cannot but conclude, from the expreſs teſtimony of the beſt hiſtorians, the concurrence of ſimilar facts, and the probability of the thing itſelf, that the right of chuſing ſenators was originally and conſtitutionally veſted in the people. *Middleton* of Rom. Sen. p. 36.

The ſupreme power at home was in the collective body of the people, yet where haſte perhaps, or ſecrecy was required, and where the determinations of the *ſenate* were ſo juſt and equitable, that the conſent of the people might be preſumed, and taken for granted, the *ſenate* would naturally omit the trouble of calling them from their private affairs, to an unneceſſary attendance on the public; till by repeated omiſſions of this kind, begun at firſt in trivial matters, and proceeding inſenſibly to more ſerious, they acquired a ſpecial juriſdiction and cognizance in many points of great importance, to the excluſion even of the people; who yet, by the laws and conſtitution of the government, had the abſolute dominion over all. For example:

1. They aſſumed to themſelves the guardianſhip and ſuperintendence of the public religion; ſo that no new God could be introduced, nor altar erected, nor the Sibylline books conſulted, without their expreſs order. *Liv.* 9. 46. *Tertull.* Apol. 5. *Cic.* de Div. 54. ib. 1. 48.

2. They held it as their prerogative, to ſettle the number and condition of the foreign provinces, that were annually aſſigned to the magiſtrates, and to declare which of them ſhould be conſular, and which prætorian provinces. *Cic.* pro Dom. 9. Vid. in Vatin. 15.

3. They had the diſtribution of the public treaſure, and all the expences of the government; the appointment of ſtipends to their generals, with the number of their lieutenants and their troops, and the proviſions and cloathing of their armies. *Polyb.* l. 6. 461. *Cic.* pro Balb. 27.

4. They nominated all ambaſſadors ſent from Rome, out of their own body, and received and diſmiſſed all who came from foreign ſtates, with ſuch anſwers as they thought proper. *Cic.* in Vatin. Vid. *Polyb.* 461.

5. They had the right of decreeing all ſupplications, or public thankſgivings, for victories obtained, and of conferring the honour of an ovation, or triumph, with the title of emperor on their victorious generals. *Liv.* 5. 23. *Cic.* Phil. 14. 4, 5.

6. It was their province to inquire into public crimes or treaſons, either in Rome, or the other parts of Italy; and to hear and determine all diſputes among the allied and dependent cities. *Polyb.* 461. *Liv.* 30. 26. *Cic.* Off. 1. 10.

7. They exerciſed a power, not only of interpreting the laws, but of abſolving men from the obligation of them, and even of abrogating them. *Cic.* pro Dom. 27. pro Cornel. 1. pro Leg. Manil. 21. *Val. Maxim.* 8. 15. It. *Cic.* Phil. 5.

8. In the caſe of civil diſſenſions, or dangerous tumults within the city, they could arm the conſuls by a vote with abſolute power, to deſtroy and put to death, without the formality of a trial, all ſuch citizens as were concerned in exciting them. *Salluſt.* de Bell. Catilin. 29. *Cic.* in Cat. 1. 11.

9. They had a power to prorogue, or poſtpone the aſſemblies of the people, to decree the title of king to any prince whom they pleaſed; thanks and praiſe to thoſe who had deſerved them; pardon and reward to enemies, or the diſcoverers of any treaſon; to declare any one an enemy by a vote; and to preſcribe a general change of habit to the city, in caſes of any imminent danger or calamity. *Cic.* Epiſt. ad Att. 4. 16. pro Mur. 25. pro Deiat. 3. Vid. *Liv.* 30. 17. *Salluſt.* Bell. Cat. 30. *Cic.* in Catil. 4. 3. 3. 4. Phil. 11. 12. Ep. Fam. 12. 10. pro Sext. 12. *Middleton*, ibid. p. 118. ſeq.

The tribunes ſoon ſnatched from them that original right, which they had enjoyed from the very foundation of the city, of being the authors, or firſt movers of every thing, which was to be enacted by the people, and excluded them from any ſhare or influence in the aſſemblies of their tribes [d]: and though in the other aſſemblies of the curiæ and the centuries, they ſeemed to have reſerved to them their antient right, yet it was reduced to a mere form, without any real force; for inſtead of being what they had always been, the authors of each particular act, that was to be propoſed to the people's deliberation, they were obliged, by a ſpecial law, to authoriſe every aſſembly of the people, and whatever ſhould be determined in it, even before they had proceeded to any vote [e]. And C. Gracchus afterwards, in his famous tribunate, uſed to boaſt that he had demoliſhed the *ſenate* at once, by transferring to the equeſtrian order the right of judicature in all criminal cauſes, which the *ſenate* had poſſeſſed from the time of the kings [f].—[[d] Vid. *Dionyſ. Hal.* l. 41. 49. *Cic.* pro Planc. 3. [e] *Liv.* 8. 12. [f] *Appian.* de Bell. Civ. l. 1. *Middleton*, ibid. p. 125, ſeq.]

In the early ages of the republic, when the precincts of the city were ſmall, the ſenators were perſonally ſummoned by an apparitor [g]; and ſometimes by a public crier, when their affairs required immediate diſpatch [h]: but the uſual way of calling them, in later days, was by an edict, appointing the time and place, and publiſhed ſeveral days before, that the notice might be more public [i]. Theſe edicts were commonly underſtood to reach no farther than to thoſe who were reſident in Rome, or near it; yet when any extraordinary affair was in agitation, they ſeem to have been publiſhed alſo in the other cities of Italy [k]. If any ſenator refuſed, or neglected to obey this ſummons, the conſul could oblige him to give ſurety for the payment of a certain fine, if the reaſons of his abſence ſhould not be allowed [l]. But from ſixty years of age they were not liable to that penalty, nor obliged to any attendance, but what was voluntary [m].—[[g] *Cic.* de Sen. 16. [h] *Liv.* 3. 38. *App.* Bell. Civ. 1. [i] *Cic.* Phil. 3. 8. [k] *Cic.* de J. Cæſare ad Att. 9. 17. [l] *Liv.* 3. 38. *Cic.* Phil. 1. 5. [m] *Middleton* of Rom. Senate, p. 130, ſeq.]

The *ſenate* could not regularly be aſſembled in any private or profane place, but always in one ſet apart, and ſolemnly conſecrated to that uſe by the rites of augury. *A. Gell.* 14. 7. *Middleton*, ibid. p. 133.

The *ſenate* frequently met in certain curiæ. See CURIA. But their meetings were more commonly held in certain temples, dedicated to particular deities; as in that of Jupiter, Apollo, Mars, Vulcan, Caſtor, Bellona; of Concord, Faith, Virtue, the Earth, *&c.* *Middleton*, ibid. 134.

Theſe temples, on account of the uſe which the *ſenate* made of them, were called likewiſe *curiæ*; as well as the proper curiæ, or *ſenate* houſes, on account of their ſolemn dedication, are frequently called temples. *A. Gell.* 14. 7. *Cic.* pro Mil. 33. *Alex. Sev.* c. 6.

The *ſenate* uſed to meet on ſome occaſions in the open air, and eſpecially whenever a report was made to them in form, that an ox had ſpoken; which prodigy, as Pliny tells us, was common in the earlier ages. *Liv.* 26. 10. *Plin.* Hiſt. Nat. 8. 45. *Middleton*, ibid. p. 135, ſeq.

On two ſpecial occaſions the *ſenate* was always held without the gates of Rome, either in the temple of Bellona, or of Apollo. 1ſt. For the reception of foreign ambaſſadors; and eſpecially of thoſe who came from enemies, who were not permitted to enter the city. 2dly. To give audience, and tranſact buſineſs with their own generals, who were never allowed to come within the walls, as long as their commiſſion ſubſiſted, and they had the actual command of an army. *Liv.* 34. 43. Id. 42. 36. Id. 36. 39. *Senec.* de Benef. 5. 15. *Middleton*, ibid. p. 137, ſeq.

The *ſenate* met always of courſe on the firſt of January, for the inauguration of the new conſuls, who entered into their office on that day. *Middleton*, ibid. p. 140, ſeq.

The month of February, generally ſpeaking, was reſerved intire by old cuſtom to the *ſenate*, for the particular purpoſes of giving audience to foreign ambaſſadors. *Cic.* ad Frat. 2. 3. *Aſcon.* in Verr. 1. 35. Ep. ad Fra. 2. 12.

In all months, univerſally, there were three days, which ſeem to have been more eſpecially deſtined to the *ſenate*, the kalends, nones, and ides, from the frequent examples found in hiſtory, of its being convened on thoſe days. But Auguſtus

guſtus enacted afterwards, that the *ſenate* ſhould not meet regularly, or of courſe, except on two days only of each month, the kalends and ides. *Suet.* Aug. 35. *Middleton*, ibid. p. 142.

On their days of meeting, they could not enter upon any buſineſs before the ſun was riſen, nor finiſh any after it was ſet; every thing tranſacted by them, before or after that time, was null and void, and the author of it liable to cenſure [n]. Whence it became a ſtanding rule, that nothing new ſhould be moved after four o'clock in the afternoon [o]. —[n *A. Gell.* 14. 7. [o] *Middleton*, ibid. p. 143.]

The *ſenate*, as has been ſhewn above, was compoſed of all the principal magiſtrates of the city, and of all who had borne the ſame offices before them; and conſiſted therefore of ſeveral degrees and orders of men, who had each a different rank in it, according to the dignity of the character which he ſuſtained in the republic.

At the head of it ſat the two conſuls in chairs of ſtate [p]. Manutius thinks that the other magiſtrates ſat next to the conſular chair, each according to his rank; the prætors, cenſors, ædiles, tribunes, quæſtors [q]. But Dr. Middleton rather thinks that the conſular ſenators, who, in all ages of the republic, were the leaders and firſt ſpeakers in the *ſenate*, uſed to ſit next in order to the conſuls; and after them the prætors, and all who were of prætorian dignity, or had been prætors; then the ædiles, the tribunes, and the quæſtors, on diſtinct benches; and on the ſame bench with each, all who had borne the ſame offices: but the curule magiſtrates, as the prætors and ædiles, were perhaps diſtinguiſhed, at the head of their ſeveral benches, by ſeats ſomewhat raiſed, or ſeparated at leaſt from the reſt, in the form of our ſettees, or of that *longa cathedra*, which Juvenal [r] mentions, to denote the curule dignity.—[p *Cic.* in Cat. 4. 1. [q] Vid. *Paul Manut.* de Senatu Rom. cap. 9. [r] Sat. 9. 52. *Middleton*, ibid. p. 144, ſeq.]

All the private ſenators ſat on different benches, and in a different order of precedency, according to the dignity of the magiſtracies which they had ſeverally borne. Firſt the conſulars, then the prætorians, ædilitians, tribunitians, and quæſtorians; in which order, and by which titles, they are all enumerated by Cicero [s]. And as this was their order in ſitting, ſo it was the ſame alſo in delivering their opinions, when it came to their turn.—[s *Cic.* Phil. 13. 13, 14.]

The *ſenate* being aſſembled, the conſuls, or the magiſtrate, by whoſe authority they were ſummoned, having firſt taken the auſpices, and performed the uſual office of religion, by ſacrifice and prayer, uſed to open to them the reaſons of their being called together, and propoſe the ſubject of that day's deliberation; in which all things divine, or relating to the worſhip of the Gods, were diſpatched preferably to any other buſineſs [t]. When the conſul had moved any point, with intent to have it debated and carried into a decree, and had ſpoken upon it himſelf as long as he thought proper, he proceeded to aſk the opinions of the other ſenators, ſeverally by name, and in their proper order, beginning always with the conſulars, and going on to the prætorians, *&c.* It was the practice originally to aſk the prince of the *ſenate* the firſt; but that was ſoon laid aſide, and the compliment transferred to any other antient conſular, diſtinguiſhed by his integrity and ſuperior abilities; till in the later ages of the republic, it became an eſtabliſhed cuſtom to pay that reſpect to relations, or particular friends, or to thoſe who were likely to give an opinion the moſt favourable to their own views and ſentiments on the queſtion propoſed [u]. But whatever order the conſuls obſerved, in aſking opinions on the firſt of January, when they entered into their office, they generally purſued the ſame through the reſt of the year. Julius Cæſar indeed broke through this rule; for though he had aſked Craſſus the firſt, from the beginning of his conſulſhip, yet, upon the marriage of his daughter with Pompey, he gave that priority to his ſon-in-law, for which, however, he made an apology to the *ſenate* [w].—[t *A. Gell.* 14. 7. [u] Ibid. [w] *Suet.* Jul. Cæſar. 21. *A. Gell.* 4. 10.]

This honour of being aſked in an extraordinary manner, and preferably to all others of the ſame rank, though of ſuperior age or nobility, ſeems to have been ſeldom carried farther than to four or five diſtinguiſhed perſons of conſular dignity [x]; and the reſt were afterwards aſked according to their ſeniority. And this method, as has been ſaid, was obſerved generally throughout the year, till the election of the future conſuls, which was commonly held about the month of Auguſt; from which time, it was the conſtant cuſtom to aſk the opinions of the conſuls elect, preferably to all others, till they entered into their office, on the firſt day of January following [y].—[x *Cic.* ad Attic. 1. 13. *A. Gell.* 4. 10. [y] *Cic.* Epiſt. Fam. 8. 4. Vid. It. in Phil. 5. 13. *Middleton*, ibid. p. 149, ſeq.]

As the conſuls elect had this preference given in ſpeaking before all the conſulars, ſo the prætors, and tribunes elect, ſeem to have had the ſame, before the reſt of their particular orders. Vid. *Salluſt.* Bell. Cat. 51, 52. *Cic.* Ep. ad Att. l. 12. 21. It. *Pigh.* Annal.

None were allowed to ſpeak till it came to their turn, excepting the magiſtrates, who ſeem to have had a right of ſpeaking on all occaſions, whenever they thought fit; and for that reaſon, perhaps, were not particularly aſked, or called upon by the conſuls. *Middleton*, ibid. p. 153.

Several different motions might be made, and different queſtions be referred to the *ſenate* by different magiſtrates, in the ſame meeting [b]. And if any buſineſs of importance was expected or deſired, which the conſuls had omitted to propoſe, or were unwilling to bring into debate, it was uſual for the *ſenate*, by a ſort of general clamour, to call upon them to move it; and upon their refuſal, the other magiſtrates had a right to propound it, even againſt their will [c]. If any opinion, propoſed to them, was thought too general, and to include ſeveral diſtinct articles, ſome of which might be approved, and others rejected, it was uſual to require that it might be divided, and ſometimes by a general voice of the aſſembly calling out *divide*, *divide* [d].—[b *Cic.* Phil. 7. 1. [c] *Liv.* 30. 21. *Cic.* Ep. Fam. 10. 16. *Cic.* pro Leg. Man. 19. [d] *Senec.* Epiſt. 21. *Cic.* Ep. Fam. 1. 2. Vid. *Aſcon.* in Orat. pro Mil. 6.]

If in the debate ſeveral different opinions had been offered, and each ſupported by a number of ſenators, the conſul, in the cloſe of it, uſed to recite them all, that the *ſenate* might paſs a vote ſeparately upon each: but in this he gave what preference he thought fit to that opinion which he moſt favoured, and ſometimes even ſuppreſſed ſuch of them, as he wholly diſapproved. *Cæſ.* Comm. Bell. Civ. 429.

In caſes, however, where there appeared to be no difficulty or oppoſition, decrees were ſometimes made, without any opinion being aſked or delivered upon them. *Cic.* Phil. 1. 1.

When any queſtion was put to the vote, it was determined always by a diviſion, or ſeparation of the oppoſite parties, to different parts of the *ſenate* houſe; the conſul, or preſiding magiſtrate, having firſt given order for it in this form: *Let thoſe, who are of ſuch an opinion, paſs over to that ſide; thoſe, who think differently, to this. Feſt.* in voc. *Cic.* Ep. Fam. 1. 2.

What the majority of them approved was drawn up into a decree, which was generally conceived in words prepared and dictated by the firſt mover of the queſtion, or the principal ſpeaker in favour of it; who, after he had ſpoken what he thought ſufficient to recommend it to the *ſenate*, uſed to conclude his ſpeech, by ſumming up his opinion in the form of ſuch a decree as he deſired to obtain [e]. Which decree, when confirmed by the *ſenate*, was always ſigned and atteſted by a number of ſenators, who choſe to attend thro' the whole proceſs of it, for the ſake of adding their names to it, as a teſtimony of their particular approbation of the thing, as well as of reſpect to the perſon, by whoſe authority, or in whoſe favour it was drawn [f].—[e Vid. *Cic.* Philip. 3. 5. 89. x. 13. 14. [f] *Cic.* Ep. Fam. 15. 6. It. 8. 8. *Middleton*, ibid. 156, ſeq.]

When the *ſenate* appeared to be diſpoſed, and ready to paſs a decree, it was in the power of any one of the ten tribunes of the people to intercede, that is, to over-rule it. See the article INTERCESSION.

In all caſes, where the determinations of the *ſenate* were over-ruled by the negative of a tribune, of which there are numberleſs inſtances, if the *ſenate* was unanimous, or generally inclined to the decree ſo inhibited, they uſually paſſed a vote to the ſame purpoſe, and in the ſame words, which was called *an authority of the ſenate*, and was entered into their journals. *Cic.* Ep. Fam. 1. 2. *Liv.* 4. 57. Vid. *Dio.* 55. 550. See SENATUS *auctoritas.*

In order to deter any magiſtrate from acting factiouſly and arbitrarily, in affairs of importance, they often made it part of the decree, which they were going to enact, that if any one attempted to obſtruct it, he ſhould be deemed to act againſt the intereſt of the republic [g]. Yet this clauſe had ſeldom any effect on the hardy tribunes, who uſed to apply their negative in defiance of it as freely, as on any other more indifferent occaſion [h].—[g *Cic.* Ep. Fam. 88. ad Att. 4. 2. [h] *Middleton*, ibid. p. 160, ſeq.]

The factious, and leaders of parties, had ſeveral arts of obſtructing, or poſtponing a decree, by many pretexts and impediments which they could throw in its way. Sometimes they alledged ſcruples of religion, that the auſpices were not favourable, or not rightly taken; which, if confirmed by the augurs, put a ſtop to the buſineſs for that day [i]. At other times, they urged ſome pretended admonition from the Sibylline books, which were then to be conſulted and interpreted to a ſenſe, that ſerved their purpoſe [k]. But the moſt common method was to waſt the day, by ſpeaking for two or three hours ſucceſſively, ſo as to leave no time to finiſh the affair in that meeting: yet when ſome of the more turbulent magiſtrates were groſsly abuſing this right, againſt the general inclination of the aſſembly, the ſenators were ſometimes ſo impatient as to ſilence them, as it were, by force, and to diſturb them in ſuch a manner, by their clamour and hiſſing, as to oblige them to deſiſt [l].—[i *Cic.* Ep. Fam. 10. 12. [k] *Dio.* 39. p. 98. *Cic.* ad Fra. 2. 2. *Cic.* Ep. Fam. 1. 1. [l] *A. Gell.* 4. 10. *Cic.* ad Att. 4. 2. *Middleton*, ibid. 162, ſeq.]

It seems probable that a certain number of senators was required by law, as necessary to legitimate any act, and give force to a decree: yet there is no certain number specified by any of the old writers, except in one or two particular cases. *Middleton*, ibid. p. 164, seq.

The decrees of the *senate* were usually published, and openly read to the people soon after they were passed; and an authentic copy of them was always deposited in the public treasury of the city, or otherwise they were not considered as legal or valid. *Cic.* Phil. 5. 4. *Tacit.* Ann. 3. 51. *Middleton*, ibid. p. 166, seq.

As to the force of these decrees, it is difficult to define precisely what it was. It is certain that they were not considered as laws, but seem to have been designed originally as the ground-work, or preparatory step to a law, with a sort of provisional force, till a law of the same tenor should be enacted in form by the people; for in all ages of the republic, no law was ever made, but by the general suffrage of the people. *Middleton*, ibid. p. 167, seq.

Even under the kings, the collective body of the people was the real sovereign of Rome, and the dernier resort in all cases. But their power, though supreme and final, was yet qualified by this check, that they could not regularly enact any thing, which had not been previously considered and approved of by the *senate* [m]. This indeed continued to be the general way of proceeding in all quiet and regular times, from the beginning of the republic to the end of it: and the constant style of the old writers, in their accounts of the public transactions, is, that the *senate* voted or decreed, and the people commanded such and such an act [n].—[m *Dionys. Hal.* l. 7. 38. Edit. Oxon. *Middlet.* of Rom. Sen. p. 115. n *Liv.* 37. 35. *Middleton*, ibid. p. 117.]

SENATOR (*Cycl.*)—In antient Rome, the number of *senators* is commonly supposed to have been limited to three hundred, from the time of the kings to that of the Gracchi. But this must not be taken too strictly. The senate generally had that number, or thereabouts, and upon any remarkable deficiency, was filled up again to that complement by an extraordinary creation. But as the number of the public magistrates increased with the increase of their conquests and dominions, so the number of the senate, which was supplied of course by those magistrates, must be liable also to some variation. Sylla, when it was particularly exhausted, added three hundred to it at once from the equestrian order, which might probably raise the whole number to about five hundred; and in this state it seems to have continued, till the subversion of their liberty by Jul. Cæsar. For Cicero [o], in an account of a particular debate, in one of his letters to Atticus, mentions four hundred and fifteen to have been present at it, which he calls a full house [p].—[o Ad Attic. l. 1. 14. p *Middlet.* of Rom. Sen. p. 93, seq.]

In antient Rome, a certain age was required for a *senator*, as is often intimated by the old writers, though none of them have expressly signified what it was. The legal age for entring into the military service was settled, by Servius Tullius, at seventeen years [q]; and they were obliged, as Polybius [r] tells us, to serve ten years in the wars, before they could pretend to any civil magistracy. This fixes the proper age of suing for the quæstorship, or the first step of honour, to the twenty eighth year; and as this office gave an admission into the senate, so the generality of the learned seem to have given the same date to the *senatorian* age. Some writers indeed, on the authority of Dion Cassius, have imagined it to be twenty five years; not reflecting that Dion mentions it there as a regulation only, proposed to Augustus by his favourite, Mæcenas [s]. Dr. Middleton takes the quæstorian age, which was the same with the *senatorian*, to have been thirty years complete [t].—[q *A. Gell.* 10. 28. r *Polyb.* de Instit. rei milit. l. 6. p. 466. s Vid. *Dio.* l. 52. p. 477. *Lipsius* de Magistratib. Rom. t *Middleton* of Rom. Sen. p. 96.]

The laws concerning the age of magistrates were not very antient; and were made to check the forward ambition of the nobles, and to put all the citizens upon a level in the pursuit of honours [u]. And Livy [w] tells us, that L. Villius, a tribune of the people, was the first who introduced them, A. U. 573, and acquired by it the surname of Annalis [x].—[u *Cic.* Phil. 5. 17. w Lib. 40. 44. x *Middlet.* of Rom. Sen. p. 99.]

There was another qualification also required, as necessary to a *senator*, an estate proper to support his rank, the proportion of which was settled by the law. We may collect from Suetonius, that it was settled at eight hundred sestertia before the reign of Augustus [y], which are computed to amount to between six and seven thousand pounds of our money; and must not be taken, as it is by some, for an annual income, but the whole estate of a *senator*, real and personal, as estimated by the survey and valuation of the censors [z].—[y *Sueton.* in Aug. cap. 41. z *Middleton*, ibid. p. 100.]

This proportion of wealth may seem perhaps too low, and unequal to the high rank and dignity of a Roman *senator*, but it must be considered only as the lowest to which they could be reduced; for whenever they sunk below it, they forfeited their seats in the senate. *Middlet.* ibid. p. 101.

There was some law also subsisting from the earliest times, concerning the extraction and descent of *senators*, injoining that it should always be ingenuous; and as their morals were to be clear from all vice, so their birth likewise from any stain of base blood. In consequence of which, when Appius Claudius, in his censorship, attempted to introduce the grandsons of freed slaves into the senate, they were all immediately turned out again. *Middleton*, ibid. p. 104.

These are some of the laws by which the censors were obliged to act, in the enrollment of the new, or the omission of old *senators*: and when we read of any left out, without any intimation of their crime, it might probably be for the want of one or other of these legal, or customary qualifications. *Middleton*, ibid. p. 106.

It was from the *senatorian* order alone, that all ambassadors were chosen and sent to foreign states: and when they had occasion to travel abroad, even on their private affairs, they usually obtained from the senate the privilege of a free legation, as it was called; which gave them a right to be treated every where with the honours of an ambassador, and to be furnished on the road with a certain proportion of provisions and necessaries, for themselves and their attendants [b]: and as long as they resided in the Roman provinces, the governors used to assign them a number of lictors, or mace-bearers, to march before them in state, as before the magistrates in Rome [c]. And if they had any law-suit, or cause of property depending in those provinces, they seem to have had a right to require it to be remitted to Rome [d].—[b *Cic.* Epist. Fam. 11. 1. It. ad Att. 15. 11. *Cic.* Ep. Fam. 12. 21. *Suet.* in Tiber. 31. c *Cic.* Ep. Fam. 12. 21. d *Cic.* ibid. 13. 26. *Middleton*, ibid. p. 173, seq.]

At home, likewise, they were distinguished by peculiar honours and privileges; for at the public shews and plays they had particular seats apart, and appropriated to them, in the most commodious part of the theatre [e]: and on all solemn festivals, when sacrifices were offered to Jupiter by the magistrates, they had the sole right of feasting publickly in the capitol, in habits of ceremony, or such as were proper to the offices which they had borne in the city [f].—[e *Cic.* pro Clu. 47. Vid. It. *Plutarch.* in Flaminin. p. 380. A. f *Suet.* Aug. 35. *A. Gell.* 12. 8. *Dionys.* 55. 554. C. *Middlet.* ibid. 175, seq.]

The peculiar ornament of the *senatorian* tunic was the *latus clavus*, as it was called, being a broad strip of purple sewed upon the forepart of it, and running down the middle of the breast, which was the proper distinction between them and the knights, who wore a much narrower stripe of the same colour, and in the same manner [g]. The fashion also of their shoes was peculiar, and different from that of the rest of the city: this difference appeared in the colour, shape, and ornament of the shoes. The colour of them was black, while others wore them of any colour perhaps, agreeable to their several fancies; the form of them was somewhat like to a short boot, reaching up to the middle of the leg, as they are sometimes seen in antient statues and basreliefs; and the proper ornament of them was an half moon sewed, or fastened upon the forepart of them, near the ancle [h].—[g *Suet.* Jul. Cæs. 80. *Plin.* Hist. 33. 1. h *Juv.* 7. 192. *Hor.* sat. 1. 6. 28. *Middlet.* ibid.]

Consuls, prætors, ædiles, tribunes, *&c.* during the year of their magistracy, always wore the prætexta, or a gown bordered round with a stripe of purple [i]. In which habit also, as has been signified above, all the rest of the senate, who had already borne those offices, used to assist at the public festivals and solemnities [k].—[i *Cic.* post. red. in Sen. 5. k *Cic.* Phil. 2. 43. *Senec.* Controv. l. 1. 8. *Middleton*, ibid. p. 176, seq.]

As to other matters, relating to Roman *senators*, see SENATE, *supra*.

SENATUS *auctoritas*. In cases where the determinations of the senate were over-ruled by the negative of a tribune, if the senate was generally inclined to the decree so inhibited, they usually passed a vote to the same purpose, and in the same words, which, instead of a decree, was called *senatus auctoritas*, or the authority of the senate, and was entered into their journals; yet had no other force than to testify the judgment of the senate on that particular question, and to throw the odium of obstructing an useful act on the tribune who hindered it. Vid. *Cic.* Ep. Fam. l. 2. & 8. 8. ad Attic. 4. 2. *Liv.* 4. 57. *Dionys.* 55. 550. *Middlet.* of Rom. Senate, p. 161, 162. See SENATE.

SEND, is used by seamen, when a ship, either at an anchor or under sail, falls with her head, or stern, deep into the trough of the sea, *i. e.* into a hollow made between two waves, or billows. They say she *sends* much that way, whether it be a-head or a-stern.

SENDAL, in our old writers, a kind of thin fine silk, mentioned in the Stat. 2 Rich. II. cap. 1. *Blount.*

SENECIO, *groundsel*, in botany, the name of a genus of plants, the characters of which are these. The flower is of the flosculous kind, being composed of several small floscules, divided into many segments at the ends, and contained in a one-leaved cup; which is first of a cylindric shape, and afterwards of a conic, and is divided into many segments at

the end, which, as the ſeed comes to maturity, uſually turn downwards and backwards. The floſcules ſtand on embryos, which finally ripen into ſeeds, winged with down.

The ſpecies of *groundſel*, enumerated by Mr. Tournefort, are theſe. 1. The common ſmall *groundſel*. 2. The taller *groundſel* with ragwort leaves. 3. The tall, large-leaved American *groundſel*. And 4. the American *groundſel* with bluiſh purple flowers. *Tourn.* Inſt. p. 456.

The common *groundſel*, taken in a ſtrong infuſion, is an emetic. It is preſcribed in ſmaller doſes in dropſies, jaundices, and hæmorrhages. Externally it is uſed in ointments againſt cutaneous foulneſſes.

SENECTA *anguium*, the exuviæ, or ſloughs of ſerpents. The ſnakes caſt their whole ſkin, and with it were ſuppoſed to caſt off their age, and be born anew; whence the name of theſe caſt ſkins. A decoction, or infuſion of theſe, is recommended by medical writers againſt pains of the ears and eyes; and ſome ſuperſtitious people recommend it to women, to tye about their waſtes, to prevent miſcarriages, and about their thighs, in time of labour, to haſten delivery.

SENEKA, *rattleſnake-root*. This is a root lately brought into uſe among us, and which ſeems to deſerve very great regard. It is the root of a ſpecies of *polygala*, or milkwort, diſtinguiſhed by Gronovius, in his *Flora Virginica*, under the name of the erect *polygala* with a ſimple ſtalk, with oval leaves pointed at the end, and with an erect cluſter of flowers. We generally call it the *rattleſnake-root*, and the French, from the place whence it comes, *Seneka*. See POLYGALA.

The *root* is perennial, the thickneſs of it is generally about that of a man's little finger. It is four or five inches, or more, in length, and is variouſly contorted and twiſted, and divides into many branches, furniſhed with ſmall fibres, and with a membranaceous rim running all along it. It is yelloviſh on the outſide, and white within; very acrid, and ſomewhat bitter to the taſte, and has ſomewhat of an aromatic flavour. From this *root* ariſe numerous ſtalks, all ſimple, and without branches; ſome lie on the ground, others ſtand erect. Theſe are ten or twelve inches high, when full grown. The leaves ſtand alternately on the ſtalks, and the flowers are white, and perfectly like thoſe of our own kinds of polygala.

Dr. Tennent, who brought over a vaſt quantity of this *root* from America ſome years ago, and took great pains to introduce it into practice, praiſes it very largely as a diuretic, a diaphoretic, and an alexipharmic, and a very powerful attenuant and reſolvent. He ſays it will ſometimes vomit and purge.

The Indians firſt taught the uſe of it to the Europeans: they eſteem it a ſovereign remedy againſt the bite of the *rattleſnake*; and Dr. Tennent aſſures us that he ſaw two perſons, who had been bitten by this creature in the month of July, when its poiſon is moſt fatal, perfectly reſtored to health by it.

He afterwards gave it in pleuriſies and peripneumonies with great ſucceſs, and in all other caſes where the blood is inſpiſſated. If the firſt doſes of it provoke a vomiting, it is not at all the worſe, except in caſes in which the patient is very weak; and in ſuch this effect is eaſily prevented, by giving ſome of the teſtaceous powders with it.

In pleuriſies it is beſt to take away ten ounces of blood, before the entering on the uſe of the medicine; in other caſes no precaution is required, but it is to be given in powder, or tincture, in white wine, and the ordinary drink, during the uſe of it, ſhould be marſhmallow tea. *Gronov.* Flora Virgin. p. 80. *Geoffroy*, Mat. Med. Vol. 2. p. 140. *Tennent*'s Eſſay on the Pleuriſy.

This medicine may be given either in powder or decoction; but Dr. Tennent prefers the decoction, having obſerved it to give relief ſooner than the powder does. The doſe of the powder is thirty five grains, and he gives at once three ſpoonfuls of the decoction, prepared by boiling three ounces of the *root* bruiſed in a quart of water to near the half. The doſe is repeated every ſix hours. He is alſo fond of this *root* in the rheumatiſm, dropſy, and gout, in which laſt diſeaſe, he ſays, he has given it with ſucceſs. See his letter concerning the *Seneka*, or *rattleſnake-root*.

Meſſrs. Lemery, Du Hamel, and Juſſieu, vouch for the good effects of the *Seneka-root* in pleuriſies, and other inflammatory diſeaſes. Mem. de l'Acad. des Scienc. 1739.

SENEMBI, in zoology, the name of a ſpecies of Braſilian lizard, more commonly known by the name *iguana*. See IGUANA.

SENESCHALLO *et mareſhallo quod non teneant placita de libero tenemento*, a writ, directed to the ſteward and marſhal of England, inhibiting them to take cognizance of an action in their court that concerns freehold. Reg. Orig. 185, 191. *Blount*, *Cowel*.

SENORIÆ, in botany, a name by which ſome authors have called the bonana-tree, or *muſa fructu breviore*. Jonſ. Dendr. p. 143.

SENSITIVE (*Cycl.*)—SENSITIVE *fluid*. Some have imagined a *ſenſitive fluid* as the principle that preſerves animals from corruption, and to which we owe our ſenſation and motion. This animal fluid paſſes in the proper nervous tubes to the organs of motion, but is contained in the fibrous coats of the nerves to become an organ of ſenſation. This *ſenſitive fluid* is, according to Mr. Le Cat, capable of thinking, and is ſo modified by the ganglions, that what is lodged in each part, is capable of being impreſſed by the object proper to each organ. And from the doctrine concerning this animal fluid, he endeavours to account for moſt operations, which are generally ſaid to depend on the ſoul. Med. Eſſ. Edinb. Abrid. Vol. 2. p. 481.

But all theſe attempts to account for ſenſation and thought, from the properties of matter, ſeem to be very deſperate undertakings, not to ſay abſurd.

SENSITIVE *plant*. This is an herb ſufficiently known to the world for its remarkable property of receding from the touch, and giving ſigns, as it were, of animal life. Philoſophers in general have, however, contented themſelves with admiring the fact, without giving themſelves any trouble about the cauſe.

Mr. Hook indeed has made ſome conjectures about it; but the greateſt light, that has been given into the thing, is from the inquiries which Meſſrs. Du Fay and Du Hamel, gentlemen of the Academy of Sciences at Paris, concerted together, and afterwards made ſeparately on different ſhrubs, or at different times, that each might be able to correct the errors of the other.

The ſtructure of the *ſenſitive plant* is this. From the large ſtems, or main branches of the whole, there part off ſeveral other leſſer ones, and from theſe there go off others ſtill leſs, which by way of diſtinction may be called the ribs of the leaves, as they ſerve to ſupport a number of leaves arranged on each ſide, and ſtanding on ſhort pedicles in pairs, over againſt one another. Several other plants have theſe ſort of compound leaves, as the caſſia, colutea, and the like; and all theſe ſhut their leaves together at night, and open them again in the morning, in the ſame manner as the *ſenſitive plant* does. This periodical opening and ſhutting of the leaves is therefore common to many plants, not peculiar to the *ſenſitive plant*; but the marvel in this is, that beſide having this motion periodical and regular, it is to be brought on at other times, and by accidents, there requiring no more than the touching the *plant* to make it cloſe its leaves at any time of the day, which it ſoon afterwards naturally opens again. This is peculiar to this *plant*, and reſembles the action of an animal which had been injured or frighted. A cloſe obſervation alſo of the manner in which this is performed, will give many hints toward the finding its cauſe. It is a very difficult thing to touch the leaf of a vigorous *ſenſitive plant* ſo lightly, as not to make it cloſe. Its ſenſation is extremely delicate, and its large rib or nerve, which runs along its middle, is as it were a hinge, on which the two halves of the leaf move when they turn up on being touched, till they ſtand erect, and by that means meet one another. The ſlighteſt touch imaginable gives this motion to the ſide of the leaf which is touched, which is communicated immediately to the other ſide, or half, and they move together; and if the touch have been a very little rougher, the oppoſite leaf on the ſame rib receives the impreſſion, and cloſes up in the ſame manner with that which was actually touched.

Nor is this all; for when the two ſides of each of theſe leaves move upwards, the pedicle of each half moves upwards at the ſame time, and by this means they in ſome meaſure approach toward each other, and make the angles of their pedicles with the main rib, or ſtalk of the compoſit leaf, leſs than before; and the total motion of each leaf is compoſed of theſe two motions.

If the touch be ſtill rougher, the whole arrangement of leaves on the ſame rib feel its influence on each ſide, and all cloſe in the ſame manner with the ſingle pair in the precedent inſtance: and if the touch be yet ſtronger than this, the rib itſelf feels it, and attempts to cloſe in its way; moving itſelf upwards toward the branch from which it is produced, juſt as the ſingle pedicles of the leaves did toward it: and if the touch be yet more hard and rough, the very branches have the ſenſation propagated to them, and apply themſelves to the main ſtem, or trunk of the ſhrub, as the ſimple leaves did before to their rib, and that rib to the branch; ſo that the whole *plant* in this ſtate forms itſelf from a very complexly branched figure, into a ſort of ſtrait cylindric one. That motion which has, of all others, the greateſt effect upon this *plant*, is a ſhaking one.

Theſe three motions of the *plant* are performed by means of three diſtinct and ſenſible articulations; the firſt that of the ſingle leaf to its pedicle, the ſecond that of the pedicle to its branch, the third that of the branch to the trunk. The primary motion of all which, is the cloſing of the two halves of the leaf upon their rib, which ought alſo to be performed in a ſimilar manner, and by a ſimilar articulation. This, however, is much leſs viſible than the others.

Theſe motions are wholly independent on one another, as may be proved by experiment. It ſhould appear, that if the ſtalks are moved and collapſe toward the branches, or theſe toward the trunk, that the leaves, whoſe motion is uſually primary to theſe, ſhould be affected alſo; yet experiment

ment proves that it is poſſible to touch the branches in ſuch a manner, as to affect them only, and make them apply themſelves to the trunk, while the leaves feel nothing of the touch: but this cannot be, unleſs the branches are ſo diſpoſed, as that they can fall to the trunk without ſuffering their leaves to touch any other part of the *plant* in their paſſage; becauſe if they do, they immediately become affected. Winds and heavy rains cauſe the *ſenſitive plants* to ſhut up their leaves, while eaſy ſhowers do not at all affect them: it is plain hence, that the agitation of the *plant* by the wind, and the ſtrokes given by the large and haſty drops of rain, are what cauſe the contraction.

By whatever accident the *plant* has been made to cloſe its leaves, it always regularly opens them again afterwards. This however requires different times, according to ſeveral circumſtances, as the time of the day, the ſeaſon of the year, and the more leſs or vigorous and healthy ſtate of the *plant*: ſometimes this is done in ten minutes, ſometimes it requires half an hour. And the manner is not leſs different than the time; for ſometimes the leaves unfold themſelves firſt, and ſometimes the branches, whereas ſometimes all is done at once, and the whole *plant* ſeems in motion at a time.

In endeavouring to account for the motions of this *plant*, theſe gentlemen have conjectured that they are performed by means of a ſort of very nice and fine hinges, which communicate one with another by means of very minute and ſlender cords, which occaſion them to act as we ſee when the *plant* is ſufficiently diſturbed, and theſe cords ſhaken; and what gives a ſtrong probability to this conjecture is, that the decayed and dying leaves of the *plant* perform this motion as regularly and vigorouſly, as thoſe which are freſh and full of juice. It ſeems plain, that while the juices are evaporating, and the parenchymatous ſubſtance of the leaves drying up, theſe more ſolid parts, the lines and cordages, retain their figure; and conſequently, if it is by means of theſe that the motion is always performed, it will be as well performed in theſe as in the freſher leaves; which could not be the caſe, were it owing to the juices.

The natural opening and ſhutting of the leaves of this *plant* at night and morning, are not ſo fixed but that they are variable alſo, according to circumſtances of place, temperature, *&c.* In the month of Auguſt a *ſenſitive plant* was carried in a pot out of its uſual place into a dark cave, the motion that it received in the carriage ſhut up its leaves, and they did not open till twenty four hours afterwards. At this time they became moderately open, but were afterwards ſubject to no changes at night or morning, but remained three days and nights with their leaves in the ſame moderately open ſtate. At the end of this time they were brought out again into the air, and there recovered their natural periodical motions; ſhutting every night, and opening every morning, as naturally and as ſtrongly, as if it had not been in this forced ſtate; and while in the cave, it was obſerved to be very little leſs affected with the touch than when abroad in the open air.

Repeated experiments have proved, that it is not the light of the day that opens the leaves of this *plant*, nor the darkneſs of the night that cloſes them; neither is it the alternate warmth of the day, and cold of the night, that have this effect, ſince it ſhuts in nights which are much warmer than the days often are in which it opens; and the encreaſing the heat of the place in which it is kept, and marking the encreaſe or decreaſe on the thermometer, have been found to have not the leaſt effect, as to its ſooner or later opening or ſhutting its leaves.

The moſt probable conjecture ſeems, that it is not great heat, or great cold, ſuch as it can bear, that bring on this effect, but the ſudden change from one to the other; and this is confirmed by this experiment, that if one of theſe *plants* be raiſed under a glaſs bell, or caſe, and the bell or covering be taken off, it immediately cloſes, even though it be in the middle of the day; and this is alſo obſerved, that the more open or expoſed the *plant* ſtands, the more ſtrong and lively are its ſhutting and opening; and that they are moſt obſervable in ſummer, and much leſs ſo, when it is kept in a cloſe ſtove in winter.

The great heats of ſummer, when there is open ſunſhine at noon, affect the *plant* in ſome degree like cold, cauſing it to ſhut up its leaves a little, but never in any very great degree. The *plant*, however, is leaſt of all affected about nine o'clock in the morning, and that is conſequently the propereſt time to make experiments on it. A branch of the *ſenſitive plant* cut off, and laid by, retains yet its property of ſhutting up and opening in the morning for ſome days; and it holds it longer if kept with one end in water, than if left to dry more ſuddenly.

The leaves only of the *ſenſitive plant* ſhut up in the night, not the branches, and if it be touched at this time, the branches are affected in the ſame manner as in the day, ſhutting up, or approaching to the ſtalk or trunk, in the ſame manner, and often with more force. It is of no conſequence what the ſubſtance is with which the *plant* is touched, it anſwers alike to all; but there may be obſerved a little ſpot, diſtinguiſhable by its paler colour in the articulations of its leaves, where the greateſt and niceſt ſenſibility is evidently placed.

The *ſenſitive plant*, plunged into water, immediately cloſes its leaves, which is partly owing to the touch, partly to the coldneſs of the water; afterwards the leaves expand again, and if they are then touched, cloſe again as before, as if in the open air, only that they do it with leſs force.

If the end of one of the leaves be burned with the flame of a candle, or by a burning glaſs, or by touching it with hot iron, it cloſes up in a moment, and the oppoſite leaf does the ſame, and after that the whole ſeries of leaves on each ſide the rib, then the rib itſelf, then the branch, all do the ſame, if the burning has been in a ſufficient degree. This proves that there is a very nice communication between all the parts of the *plant*, by means of which the burning, which only is applied to the extremity of one leaf, diffuſes its influence through every part of the ſhrub.

If a drop of aquafortis be carefully laid upon a leaf of the *ſenſitive plant*, ſo as not to ſhake it in the leaſt, the leaf does not begin to move till the acrid liquor corrodes the ſubſtance of it; but at that time, not only that particular leaf, but all the leaves placed on the ſame rib, cloſe themſelves up. The vapour of burning ſulphur has alſo this effect on many leaves at once, according as they are more or leſs expoſed to it; but a bottle of very acrid and ſulphureous ſpirit of vitriol, placed under the branches unſtopped, produces no ſuch effect. The wetting the leaves with ſpirit of wine, has been obſerved alſo to have no effect, nor the rubbing oil of almonds over them; though this laſt application deſtroys many *plants*.

A branch of the *plant* was cut away longitudinally, till only a third part of the ſubſtance remained, yet it communicated the effects of the touch, in the ſame manner as before, to thoſe branches which aroſe lower on the ſhrub. The tranſpiration of the *plant* being retarded, is of no effect as to its periodical opening and cloſing; for one kept under a cloſe glaſs bell ſhuts and opens as regularly, night and morning, as when it ſtands in an open green-houſe. A branch of it put into the exhauſted receiver of an air-pump, is found to have its force of opening and cloſing up much impaired, but not wholly taken off. Mem. de l'Acad. des Scienc. Par. 1736.

SEPHIROS, a word uſed by Paracelſus, and his followers, to expreſs a ſort of dry and hard impoſtume, or kind of ſpurious ſcirrhus.

SEPHIROTH, a Hebrew word ſignifying brightneſſes; and the cabbaliſts give the name of *ſephiroth* to the moſt ſecret parts of their ſcience.

The knowledge of the *ſephiroth* is not acquired but with much ſtudy and labour, and is the higheſt ſtep of the contemplative theology. They reckon up ten *ſephiroths*, which are ſometimes repreſented by ten different circles, included in each other; and ſometimes by the figure of a tree, pretty much like what, in the ſchools, they call Porphyry's tree, to ſhew the different categories of ens or being. *Calm.* Dict. Bibl. in voc.

SE PIACE, in the Italian muſic, ſignifies that the part it is joined to may be repeated, or not, at pleaſure.

SEPS, in zoology, the name of a very peculiar animal of the lizard kind, but ſeeming as if of a middle nature between that genus and the ſnakes, and appearing rather a ſerpent with feet than a lizard. See Tab. of Quadrupeds and Serpents, N° 31.

It is a ſmall ſpecies; its body is rounded, and its back variegated with longitudinal lines of black. Its eyes are black; it has ears, and a ſmall and very ſlender tail. What appears moſt ſingular in it is, that it has four legs with feet, divided into toes; but theſe are wholly uſeleſs to the creature in its motions, and not at all aſſiſting it in walking. The firſt pair are placed very near the head, the other by the anus. The ſcales are laid in a reticulated manner; they are of an oblong figure, approaching to a rhomboides, and laid longitudinally. Its belly is white, with a ſlight caſt of blue, and it has noſtrils near the end of the ſnout. Columna took five living young ones out of the body of one of this ſpecies, ſome of which were included in membranes, and others looſe, as is the caſe in the fœtus found in the viper. *Ray*'s Syn. Quad. p. 272.

The bite of the *ſeps* is ſaid to occaſion an inſtant putrefaction of the fleſh of the whole body.

SEPTANA, a word uſed by the antient phyſicians for a ſeptenary fever, or one that performs its regular period in ſeven days.

SEPTARIÆ, in natural hiſtory, the name of a large claſs of foſſils, called by ſome *ludus Helmontii*, and by others the *waxen veins*. They are defined to be foſſile bodies not inflammable, nor ſoluble in water, naturally found in looſe detached maſſes of a moderately firm texture, and duſky hue, divided by ſeveral *ſepta*, or thin partitions, and compoſed of a ſparry matter greatly debaſed by earth, not giving fire with ſteel, fermenting with acids, and in great part diſſolved by them, and calcining in a moderate fire.

Of this claſs there are two diſtinct orders of bodies, and under thoſe ſix genera. The *ſeptariæ* of the firſt order are thoſe which are uſually found in large maſſes, of a ſimple uniform

uniform conſtruction, but divided by large *ſepta* either into larger and more irregular portions, or into ſmaller and more equal ones, called *talc*.

Thoſe of the ſecond order are ſuch as are uſually found in ſmaller maſſes of a cruſtated ſtructure, formed by various incruſtations round a central nucleus, and divided by very thin *ſepta*.

The genera of the firſt order are four. 1. Thoſe divided by *ſepta* of ſpar, called *ſecomiæ*. 2. Thoſe divided by *ſepta* of earthy matter, called *gaiophragmia*. 3. Thoſe divided by *ſepta* of the matter of the pyrites, called *pyritercia*. And 4. thoſe divided by *ſepta* of ſpar, with an admixture of cryſtal, called *diaugophragmia*. See all theſe under their ſeveral heads.

Of the ſecond order there are only two genera. 1. Thoſe with a ſhort roundiſh nucleus, encloſed within the body of the maſs. And 2. thoſe with a long nucleus, ſtanding out beyond the ends of the maſs. *Hill*'s Hiſtory of Foſſils, p. 500.

SEPTERION, Σεπτηριον, in antiquity, a Delphic feſtival, celebrated every ninth year, in memory of Apollo's victory over Python. The chief part of the ſolemnity was a repreſentation of Python purſued by Apollo. *Potter*, Archæol. Græc. Tom. I. p. 430.

SEPTIMONTIUM, among the Romans, a feſtival celebrated in December on all the ſeven hills of Rome; whence alſo it had this name, being otherwiſe called *agonalia*. See the article AGONALIA, *Cycl.*

SEQUATUR *ſub ſuo periculo*, a writ that lies when a *ſummons ad warrantizandum* is awarded, and the ſheriff returns that the party hath nothing whereby he may be ſummoned; then goes forth an *alias* and a *pluries*; and if he comes not in on the *pluries*, this writ ſhall iſſue. Old Nat. Br. 163. *Cowel.*

SEQUESTRATION (*Cycl.*)—SEQUESTRATION, *ſequeſtratio*, in chemiſtry, a term uſed by ſome writers to expreſs ſeparation.

SEQUESTRO *habendo*, a writ judicial for the diſcharging a *ſequeſtration* of the profits of a church benefice granted by the biſhop at the king's commandment, thereby to compel the parſon to appear at the ſuit of another. The parſon, upon his appearance, may have this writ for the releaſe of the *ſequeſtration*. Reg. Judic. 36. *Blount*, *Cowel.*

SERACH, in the Turkiſh military orders, an officer who holds the ſtirrup of the caia of the janizaries in charge, attends him when he goes out on horſe-back, and ſerves him as a meſſenger on all occaſions. After this office he has the title of *chous*; and after he has paſſed through this, he has the ſame office under the aga of the janizaries. *Pocock*'s Egypt, p. 168.

SERANGODES, a word uſed originally as an epithet for the pumice ſtone, and expreſſing cavernous, ſpungy, or full of holes. It has been hence uſed to ſinuous ulcers, and to all ſorts of things that are cavernous, or of a ſpungy texture.

SERAGE, in zoology, an Engliſh name for a bird of the larus, or gull kind, more uſually called the *ſea-ſwallow*, and by authors *ſtema*. See STEMA.

SERAPIAS, in the materia medica, the officinal name of the dried root, called *ſalep*. *Dale*'s Pharm. p. 254.

SERBAJEE, in the Eaſtern military orders, is a captain in the horſe in the ſervice of the grand ſeignior. *Pocock*'s Egypt, p. 166.

SERIANA, in botany, a name given by Plumier to a genus of plants, the ſame in its generical characters with his *cururu*; both which are compriſed by Linnæus under one genus, with the new name *paulinia*. *Plumier*, Gen. 35. See the article PAULINIA.

SERICH, the name of a ſeed uſed in the food of the Egyptian coptis. It is produced by an herb called *ſimſim*, and is pounded and put into oil. In this they dip their bread, which is always new, being baked as often as they eat in ſmall flat cakes. Theſe they eat dipped in this oil with raw onions, or elſe they break the cakes to pieces, and put them into a ſyrup of ſugar, made when the canes are green. *Pocock*'s Egypt, p. 183.

SERICUM, *ſilk*. See the article SILK.

SERICUM is alſo a name given by ſeveral chemical writers to the flowers of zink raiſed by ſublimation in an inclined open crucible. Theſe flowers are not reducible into zink again, and are of a fibroſe texture, and a beautiful bright white colour. This has made them be called alſo the *philoſophic cotton*, and others have named them the *aqua ſicca philoſophorum*. What has given the greateſt confuſion, however, in regard to them is, that ſome writers have choſen to call them talc, and a ſort of ſolution of them in vinegar, oil of talc. Others have reſtrained the word oil to a genuine oil, ſeparated from a ſolution of theſe flowers in vinegar; and have attributed to this oil the power of concentrating metals, and fixing ſilver, or reducing it to the ſolidity and weight of gold, and making it, like that metal, ſoluble only in aqua regia. Theſe, however, are mere chimeras, and this boaſted oil is, in reality, no other than the eſſential oil of the grape, and can have no ſuch properties.

SERINUS, in zoology, the name of a ſmall bird common in Germany and Italy, and called by the Auſtrians *haerngril*, or *hirngryl*. See Tab. of Birds, N° 37. Its back is of a reddiſh brown, and its head yellow; the colour being deeper in the male, and paler in the female. The rump is of a beautiful yellowiſh green, as is alſo the breaſt. The belly is white, and the ſides have ſome oblong blackiſh ſpots. The tail, and long feathers of the wings, are black, and a little greeniſh at their extremities. The beak is very thick, ſtrong, and ſhort, and is very ſharp at the point. It is kept in cages, and ſings very ſweetly. *Geſner*, de Avibus. *Aldrovand.* de Avib. lib. 18. cap. 20.

SERMOCINATION, *ſermocinatio*, in rhetoric, denotes diſcourſe in general, whether held by a perſon alone, or in company, and is the ſame with what is called *dialogiſm*. See the article DIALOGISM.

SERPEGER, in the manege, was uſed to denote the riding a horſe in a ſerpentine way, or in a tread with waved turnings, like the poſture of a ſerpent's body; but is now become obſolete.

SERPENT, (*Cycl.*) *ſerpens*, in zoology, the name of a genus of animals, which Mr. Ray defines to be creatures breathing by means of lungs, having only one ventricle in the heart, having no feet, and having a long body, covered with ſcales. To which he adds, that in cold ſeaſons they can bear hunger a long time. The greater part of the *ſerpent* claſs are poiſonous, and dangerous in their bite, leaving a miſchievous liquor in the wound made by their tooth, which mixing by this means immediately with the blood, is of fatal conſequence; though the whole creature may be eaten with ſafety, or even the poiſonous liquor, which does this miſchief in the wound, taſted without hurt.

Notwithſtanding that *ſerpents* reſpire by means of lungs, they do not take in and diſcharge their breath by ſuch ſhort intervals as other animals, but what they have once inſpired will ſerve them a long time; for as they are of a cold nature, and their naturally neceſſary vital warmth very ſmall, they do not require ſuch an eternally renewed ſupply of that pabulum of vital heat, as thoſe which have more of it; and as with us they lie half the year torpid, and half dead, their vital warmth at that time, like fire ſmothered under aſhes, barely exiſts, and needs perhaps no more air than what the creature took in at one inſpiration, before its laying itſelf down for the ſeaſon, which ſerves it till the life-renewing ſpring returns.

Serpents, according to Mr. Ray, may be divided into the poiſonous and the harmleſs; the firſt having long dentes exerti, with poiſonous liquors contained at their bottom, which on biting they diſcharge into the wound; the others wanting theſe teeth, and this poiſon.

They may alſo be divided, in regard to their generation, into the oviparous and viviparous; but this is a leſs firmly founded diſtinction than may be ſuppoſed, ſince all *ſerpents* are truly and properly produced of eggs; and the only difference is, that ſome depoſit their eggs in dung-hills, and the like places, to be hatched by accidental heat; while others retain thoſe eggs to be hatched in their own bodies, and ſo bring forth living young ones. Of the firſt kind is the common ſnake, of the latter the viper. *Ray*'s Syn. Quad. et Serp. p. 284. See Tab. of Quadrupeds and Serpents.

SERPENS *bubalinus*. Mr. Cleyer has given a very remarkable account, in the German Ephemerides, of the prodigious ſize, and voracious appetite of this *ſerpent*, and its manner of feeding.

This gentleman aſſures us that they grow to the length of twenty five feet, and are ſurpriſingly daring in attacking large creatures for prey. Their neck, he obſerves, is ſo ſmall, in proportion to the creatures they ſeize, that it is a wonder that they can ſwallow them whole, which yet experience ſhews they certainly do, having no power of tearing them to pieces. This gentleman ſaw a compleat ſtag taken out of the belly of one of theſe *ſnakes*, with all its limbs remaining on; and at another time a wild goat, which had been ſwallowed in the ſame manner; and from another a compleat porcupine, a very troubleſome morſel; and there was once an inſtance, in the Molucca iſlands, of a woman big with child being thus ſucked down whole by one of theſe creatures. *Ray*'s Syn. An. p. 333.

The method of their managing their prey is this. When thoroughly lank, lean, and hungry, the *ſnake* lies in wait for any thing it can ſeize; he darts out upon the prey, and ſeizing it with his mouth, winds his body round that of the creature; and this he is able to do with ſuch force, that he will often, in twiſting himſelf firmly round the creature, break the bones within its ſkin. This he continues, and at the ſame time is biting with his terrible mouth all the tender parts of the creature, till he has deſtroyed it; or if it be an animal too ſtrong to be killed by theſe ſimple folds, it will drag it to ſome neighbouring tree, and tying it faſt againſt that, draw its body ſo forcibly round it, as to cruſh all its bones to pieces by the help of that ſolid reſiſting body. The part it uſually ſeizes with its teeth, at the ſame time, is the creature's noſe, which he bites ſo forcibly, as not only to ſtop the breath, but to occaſion a diſcharge of blood, which helps to forward its deſtruction.

But the moſt ſingular attack, ever known to have been made by this creature, is that recorded by the ſame author,

of its ſeizing a buffalo; which it deſtroyed in the manner above deſcribed, though it was a long time about it, and was obliged to have recourſe to the method of tying it up to a tree, againſt which it broke its bones ſeverally, with a noiſe that was heard to a great diſtance. When the creature had thus deſtroyed its prey, it continued breaking of the bones, till there was not one left whole in the body, and the whole reſembled a ſhapeleſs maſs of matter.

The jaws and throat of this, and of the other *ſerpent* kind, though ſmall and narrow, are prodigiouſly extenſible, and made ſo by nature for the ſwallowing theſe morſels. The *ſnake*, when the prey lay in this ſtate before it, licked it all over, and covered it thick with its ſaliva, and that ſo regularly, that the whole carcaſe looked as if daubed over with glue. This done, it opened its jaws to a monſtrous extent, and ſucked in the head of the prey, and continuing inceſſantly ſucking, at length drew down the whole body.

This is a work of time, and very often two or three days are employed in it. And when the animal is thus got down, the *ſnake* is ſwelled and bloated up all over with it, and is no longer in a ſtate of offending, or even of defending itſelf, or ſo much as running away; and the people of the places where this ſpecies is common, well know this, and find it an eaſy thing to deſtroy them in this ſtate, and are very happy when they catch one, as their fleſh is a very delicate food. Ephem. Germ. Ann. 12. Obſ. 7.

SERPENS *marinus*, *ſea ſerpent*, the name of a fiſh of the eel kind, uſually of five or ſix feet in length, and a furrowed body, continuing all the way of the ſame thickneſs, till near the tail. See Tab. of Fiſhes, N° 12.

Its back is of a duſky yellow, and its belly a ſhining blue. Its ſnout is long, ſlender, and pointed, and the opening of its mouth extremely large. Near the end of the under jaw it has four or five large and ſharp teeth, which bend backwards, the reſt of the teeth are very ſmall, and ſtand cloſe together. At the very extremity of the upper jaw it has four very large teeth, and all the reſt are ſmall, and like thoſe in the under one; but the largeſt teeth of all are placed in a row, in the middle of the palate. It has only one pair of fins, which are placed near the gills. The openings of the gills are at a conſiderable diſtance from the head, and it is marked with dotted lines down its ſides. It is common in the Mediterranean, and its fleſh is very fine taſted, but full of ſmall bones. *Willughby*, Hiſt. Piſc. p. 108.

SERPENS *rubeſcens*, the *red ſerpent fiſh*, in ichthyography, the name of a fiſh, properly of the tænia kind.

It reſembles the common ſnake in figure, and is of a fine ſtrong red in colour, and marked with oblique lines all down the ſides, and long ones from the gills to the tail, one on each ſide. Its mouth is but ſmall, and its teeth ſharp and ſerrated; and it has all over its back a number of fine capillaments, ſet at diſtances from one another, even to the tail, and the ſame on the belly. Its tail ends in a ſingle fin. *Aldrovand.* de Piſc. lib. 3. cap. 28.

SERPENT-*ſtones*, a name given by ſome to the cornua ammonis, a beautiful foſſile ſhell, which reſembles a *ſerpent* coiled up.

Theſe are frequent in many parts of the world, beſide the plenty we have of them in England, and elſewhere. The accurate obſerver, Mr. Harenberg, found prodigious numbers of them on the banks, and among the ſand of a river in Germany. He traced this river through its ſeveral windings for many miles, and among a great variety of belemnitæ, cornua ammonis, and cochlitæ, of various kinds. He found alſo great quantities of wood, of recent petrifaction, carrying in it at that time the plain marks of the axe, by which it had been cut from the trees then growing on the ſhore. The water of this river he found, in a dry ſeaſon, and when the ſupplies of its natural ſprings were not diluted with rains, to be conſiderably heavier than common water; and many experiments ſhewed him that it contained ferrugineous, as well as ſtony particles, in great quantity, whence the petrifactions in it appeared the leſs wonderful, though many of them of recent date.

Of the cornua ammonis, or *ſerpent-ſtones*, he there obſerved more than thirty different ſpecies, and doubts not but there are many more yet unobſerved. They lie immerſed in a bluiſh foſſile ſtone, of a ſoft texture, and fatty appearance. They lie in this in prodigious numbers, and of a great variety of ſizes, from the larger known ſorts, down to ſuch as could not be ſeen without very accurate inſpection, or the aſſiſtance of a microſcope. Such as lie in the ſofteſt of theſe ſtones are ſoft, like their matrix, and eaſily crumble to pieces; others are harder. In a piece of this ſtone, of the bigneſs of a finger, it is common to find thirty, or more of theſe foſſils; and often they are ſeen only in form of white ſpecks, too minute to ſhew their figure, till examined by the microſcope. But what is moſt obſervable of the cornua ammonis of this place is, that they are often found growing not only to, but into one another, in ſuch a manner, that they cannot be ſuppoſed ever to have been inhabited by any living fiſh, eſpecially the ſpecimen which is pierced by the other. This author is of opinion that they grow, and are formed where they are; and attempts to prove it by affirming, that they have an actual increaſe in ſize there in a little time, and that not only if left in their beds, but if taken out, and put into a glaſs of the water. This is an opinion wholly different from the received one at preſent in the world, and perhaps will be found erroneous on farther trials. Act. Erudit. 1727. p. 140.

SERPENS *terrenus*, the *earth ſerpent*, a name given by ſome of the chemical writers to nitre. It was originally given to the nitre of the antients, a ſalt very different from that which we call nitre, but it has ſince been applied alſo to that ſalt.

SERPENTS *tongues*. The iſland of Malta abounds with *gloſſopetræ*, or the petrified teeth of ſharks, which, from their reſemblance to a tongue, are by the vulgar ſuppoſed to be the tongues of *ſerpents* turned into ſtone by ſome miracle of St. Paul, when he was there. This iſland abounds not only with theſe, but with bufonitæ, and vaſt numbers of other remains of ſea productions. Theſe things, notwithſtanding their perfect reſemblance of the ſame bodies now found recent in the mouths of living fiſhes, *&c.* are by ſome ſuppoſed never to have been real parts of fiſhes, but to have been formed where they now lie by ſome luſus of nature, or plaſtic ſeeds. This, however, is an idle and abſurd opinion; and Aguſtino Scilla, who has written at large on the foſſils of this iſland, gives a very rational account of their being the real remains of animals, which, according to his ſyſtem, it is no way wonderful to find there. The univerſal deluge has doubtleſs been of power to bring all the foſſils we find into the places where we now ſee them buried, even in the midſt of quarries of ſtone, in the middle of inland countries; but in regard to the iſland of Malta, which ſo abounds with them at this time, he ſuppoſes that long ſince the time of the creation, and even without the aſſiſtance of the general deluge, it may have been formed out of the ſea, and that it appears plainly to have been at firſt no other than a maſs of ſoft mud, with an immenſe number of ſea ſhells, teeth of fiſhes, and other remains of ſea animals, mingled among it; and that theſe ſubſiding as low as they could among that thickening matter, have made the iſland what we now find it, that is, a heap of earth with theſe things, in vaſt quantities, buried in it, and that at different depths, but principally not far from the ſurface. Philoſ. Tranſ. N° 219. p. 182.

That this collection of matter was occaſioned by a flood of ſome kind, is highly probable, but it is not neceſſary to have recourſe to Noah's flood for it, though that might as well cauſe it as any other; but it might alſo be formed by an irruption of the ocean into the Mediterranean, or by an inundation of the Tuſcan ſea driven by vehement winds, or any other means, that way: and when the origin of this iſland is thus allowed, it is not to be wondered at, that an immenſity of the refuſe parts of animals, inhabitants of thoſe waters, ſhould be left in the places where they had time to ſubſide. And though there are found among theſe teeth, *&c.* in the iſland of Malta, great quantities of ſhells, of ſuch ſpecies as are not natives of thoſe ſeas, this is no objection to the opinion; ſince it is well known that the winds when violent, as they probably were about the time of the formation of that iſland, will bring ſuch light bodies as ſhells a vaſt way in water.

It is a common obſervation, that the eaſt, and ſouth-eaſt winds, bring to the coaſt of Calabria great quantities of beautiful ſhells, none of which are found living in the ſeas thereabout. The *bufonitæ*, or toadſtones of Malta, are plainly the grinder teeth of the lupus and ſargus dentex, as alſo of the aurata, and ſeveral other fiſh, which have ſuch round teeth in the hinder part of their jaws. The ſhells found in this iſland, and other places, are ſo plainly thoſe of once living animals, that the remains of the body of the fiſh is plainly to be diſtinguiſhed in ſome of them; and in others the lamellæ are laid together, and coated over one another, in the very ſame manner as in the recent ſhell fiſh. Philoſ. Tranſ. N° 219. p. 186.

It is objected, that theſe ſhells are produced in the places where they lie, becauſe they are found in great cluſters together, all of the ſame kind; but this is no material objection, but is eaſily ſolved upon the common principles: for if we ſuppoſe a number of diſſimilar bodies, ſeveral of every kind, to be ſuſpended in the ſame quantity of water, and that water be put in motion, we ſhall ſee them all confuſedly blended together, while the motion is violent, but they will, as that becomes more calm, ſeparate themſelves, and thoſe of the ſame nature will, in a great meaſure, get together, and ſubſide in parcels ſeparately from the reſt. Thus if ſtraws, ſticks, egg-ſhells, pebbles, and common cockle-ſhells, were to be thus ſhook together, the conſequence would be, that in a large tub of water they would naturally each parcel ſubſide together in different parts of the bottom; and though in the neighbourhood of one another, yet the ſtraws would not be mixed with the pebbles, nor the egg-ſhells with the cockles, any more than it is really found, that the different ſpecies of ſhells are mingled in the earth.

It is to be added alſo, that theſe ſhells have ſubſided, not in water, but in a thicker fluid, compoſed of mud and water, and this has kept them more aſunder than common water alone would have done; and we ſhall find, on examining the bowels of the earth, that though the ſhells, in the ſame maſs of earth, or ſtone, are generally principally of one kind, yet they are neither always ſo, nor perfectly ſo, but that often they are confuſedly blended among other kinds, and more often have ſome few of other ſpecies blended among them; as a few cockle-ſhells might be among the pebbles, in the familiar inſtance mentioned above, and by ſome particular accidents, even in that caſe, the whole ſet of bodies, excepting the very lighteſt, might happen to be blended together.

The mountains of Sicily afford ſome few *gloſſopetræ*, or *ſnakes-tongues*, but they are few in number, and worſe prepared than thoſe of the iſland of Malta; which is probably owing to the high ground of thoſe mountains being leſs likely to receive the refuſe of the ſea, and its ſoil, which is ſandy, being leſs fitted to preſerve them when there, than the marl, of which the iſland of Malta conſiſts.

The *echini marini*, or ſea eggs, and their ſpecies, which are very frequent among the *ſerpents-tongues* of Malta, all lie upon the ſurface of the ground, or near it; whereas the *gloſſopetræ* lie deeper, though at no great depth. This is a plain effect of all theſe things having been really animal bodies, and having floated in the mud, of which that iſland was formed; for in this it could not be otherwiſe, but that the *gloſſopetræ*, or *ſerpents-tongues*, being heavy, would ſubſide in the water, while the light ſhells of theſe other animals would float on, or near the ſurface.

The opinion of theſe bodies growing from ſeminal principles, is alſo greatly weakened by the ſituation of them in the earth. If they grew from ſeeds, as plants, we ſhould doubtleſs ſee them, like plants, all bending one way, the points of all upwards, and their roots downward; but on the contrary, both in the iſland of Malta and elſewhere, theſe things are found in the moſt different directions imaginable; ſome with their bottoms upwards, ſome downwards, ſome horizontal, and others in all the intermediate angles. Some have ſuppoſed the *gloſſopetræ*, in particular, to grow from roots in the earth, becauſe they uſually have roots different from the other parts, and becauſe they ſtick very firmly in the earth at theſe roots, but are very eaſily looſened in any other part. It is certain indeed that theſe parts, at the bottom of the *gloſſopetræ*, are their roots, and that their ſpungy texture was intended for their taking in nouriſhment; but this was their uſe when in the head of the fiſh, not when in the earth; and the reaſon of their adhering more firmly to the earth in this, than in any other part, is only that they are more ſpungy and porous here, and that in other parts, where they are ſmooth and even, the earth can have no hold of them; but where they are thus rough, as they ſubſided with a moiſt earth like mud about them, they naturally become connected ſtrongly to it in drying, as part of it was received into their pores, and not broken from the reſt, till by forcing them out afterwards. Philoſ. Tranſ. N° 219. p. 189.

Some affirm that the *gloſſopetræ* are natural cryſtallizations of ſalt, and that to this their regular figure is owing; but it is to be anſwered, that their figure is not ſo regular as theſe objectors ſeem to ſuppoſe, but that there are as many different ſhapes of them as there are of teeth, in the different parts of the jaw of the ſame ſhark, or in the jaws of different ſpecies of ſharks now found living; and if they were cryſtallizations of ſalt, the whole cryſtallization would be of one and the ſame ſurface and texture; which is not the caſe, ſince the root, as before obſerved, is always very different from the body of the tooth, and the ſubſtance different in even the various parts of the body. Salts are ſalts throughout, and a ruby, a cryſtal, or a diamond, is the ſame in all its parts; but this is not the caſe in the *gloſſopetræ*, but they are compoſed of a cortical and a medullary part, like the teeth of living ſharks: and it is to be obſerved, that when any of theſe *gloſſopetræ* are found broken, as they frequently are, the fracture is found raw and unaltered, which ſhews that it has happened before they came to the place where they are now found, and that they have no growth or vegetation there, to heal or cover it; for if there were, it would be ſkinned over, as the wounds of plants and animals always are, when in a perfect ſtate and living.

Whenever the *gloſſopetræ* are taken carefully up out of the earth in Malta, the marl or earth, which ſerved for their bed, is found to contain all their minuteſt traces and lineaments, like wax from a ſeal. This is a proof that the marl was as ſoft as melted wax when they were put into it, and that they were of their full ſize and growth when placed there, not having grown, or had any encreaſe in that place.

The apophyſes, or proceſſes in the *gloſſopetræ*, are alſo a ſtrong proof of their being no other than real ſharks teeth, ſince they exactly anſwer to thoſe in the teeth of recent ſharks, by which every tooth is received or inſerted into its neighbour in the jaw. Nay, whereas ſharks teeth are mortiſed into one another in ſuch a manner, that a man may eaſily tell which belongs to each ſide, which lie near the throat, and which near the front of the mouth; and whereas in a ſhark's mouth, the teeth on the left ſide will not fit on the right, nor thoſe above ſerve below, but that on ſeeing a recent tooth, a perſon of judgment will be able to ſay what part of the mouth it belonged to; ſo in the foſſile ſhark's teeth, or *gloſſopetræ*, there is not any one which may not be referred to the particular part of the mouth of the living animal, and could have belonged to no other. *Aguſtino Scilla*, de Petrifac.

SERPENTINÆ, in natural hiſtory, a name given by later authors to the marbles which the antients called *ophitæ*, from their ſpots reſembling thoſe of ſerpents. See the article OPHITES.

SERPENTINE, (*Cycl.*) in the manege. A horſe is ſaid to have a *ſerpentine* tongue, if it is always friſking and moving, and ſometimes paſſing over the bit, inſtead of keeping in the void ſpace, called the liberty of the tongue.

SERPYLLUM, *mother of thyme*, in botany, the name of a genus of plants, the characters of which are theſe. The flowers and ſeeds are the ſame with thoſe of the common thyme, but the ſtalks are lower, leſs hard, and leſs woody. The ſpecies of *ſerpyllum*, enumerated by Mr. Tournefort, are theſe. 1. The broad-leaved hairy *ſerpyllum*. 2. The common large *ſerpyllum* with purple flowers. 3. The common large *ſerpyllum* with white flowers. 4. The common leſſer *ſerpyllum*. 5. The common leſſer *ſerpyllum* with white flowers. 6. The common ſmall *ſerpyllum* with flowers variegated with green and white. 7. The common ſmall *ſerpyllum* with woolly heads. 8. The citron-ſcented *ſerpyllum*. 9. The larger citron-ſcented *ſerpyllum*. 10. The narrow-leaved ſmooth *ſerpyllum*. 11. The narrow-leaved hairy *ſerpyllum*. 12. The loweſt thyme-leaved *ſerpyllum*. *Tourn.* Inſt. p. 197. For the medicinal virtues of *mother of thyme*, ſee the article THYMUS.

SERRA-*piſcis*, in zoology, a name given by many authors to the *piſtris*, or ſaw-fiſh. *Rondelet.* p. 114. See the article PISTRIS.

SERRA is alſo a name given by Pliny to a ſpecies of the baliſtes, called by the generality of writers *ſcolopax*. It is diſtinguiſhed by Artedi by the name of the *baliſtes* with two ſpines in the place of the belly fins, and one behind the anus.

SERRATA, a name given by ſome of the Roman authors to the plant which the Gauls, according to Pliny, had named *betonica*, and which the Greeks called *ceſtrum pſuchrotrophon*, and *priorites*. This was evidently the ſame plant with our *ſerratula*, or ſaw-wort. But beſide this there was another plant called by this name, and which, according to Pliny, was the *chamædrys* or *germander* of the Greeks. He ſays that the *chamædrys* of the Greeks was a plant called by the Latins *trixago*, and by ſome *chamedrope* and *teucrion*. He adds, that it had leaves like thoſe of mint in ſhape, but reſembling thoſe of the oak in their colour and diviſion, and that the flower was purple. He adds, that the leaves were ſo nicely ſerrated at the edge, that it was ſuppoſed men had taken the idea of a ſaw from them.

This author is not however to be abſolutely depended upon, and though he here expreſsly ſays that this *ſerrata* is the ſame with the *chamædrys* of the Greeks, yet he ſeems to run away from this aſſertion in his deſcription, and to make it the ſame with the other *ſerrata*. Dioſcorides ſays nothing of the *chamædrys*, but that its leaves were ſmall. And it is much more probable that the world ſhould take the idea of a ſaw from the leaves of the *ſerratula*, than from thoſe of this plant, they being much leſs nicely denticulated than thoſe. So that thoſe who have been influenced by Pliny, to ſuppoſe the *germander* and *ſerrata* of the antients to be the ſame plant, are in the wrong, though they have the countenance of this ſo generally reputed authentic author for it.

SERRATE *flies*, in natural hiſtory, a name given by authors to certain flies, diſtinguiſhed from all the other kinds by their having a weapon, reſembling a double ſaw, placed at the hinder part of the body: this ſerves ſeveral ſpecies of them to make holes in the branches of trees, in which they depoſit their eggs; but there are ſome of them which do not ſeem to make any uſe of this curious inſtrument, though they have it. See ROSE-*fly*.

The *fly* of this kind that lays its eggs on the gooſeberry buſh, depoſits them only on the ſurface of the middle rib of the leaf; and the oſier-fly, which is one of this genus, produced from a baſtard caterpillar of the oſier, lays its eggs on the intermediate ſurface of the leaves between the ribs. There appears to be no uſe made of this curious inſtrument in the depoſiting of theſe eggs, ſince they are only laid in rows upon the leaves, and fixed to them by means of a viſcous fluid which covers them. It is a very remarkable property in the eggs of this genus of *flies*, that they grow much larger after they are laid. This is obſervable in the eggs of the common roſe-fly, which are at firſt buried in the wood, and by their growth force out the ſurface into tumours of an oval figure: but in theſe of the oſier-fly it is moſt beautifully ſeen, and the whole growth of the fœtus in them is clearly ſeen, on examining them at different times

of their growth, which may be eaſily done without diſturbing them, as they lie naked on the ſurface of the leaf.

When firſt laid, theſe eggs are oblong, perfectly pellucid, and of a whitiſh colour; in a few days they are perceived to be much larger than at firſt, and a ſmall yellow ſpeck is ſeen in each of them: they after this continue to grow larger, till they are of twice the bigneſs that they were at firſt, and this yellow ſpot encreaſing, ſoon begins to put on the oblong form of the falſe caterpillar, which is to be hatched from it. After ſome days, there are evidently ſeen two black ſpots on one extremity of it, which are the eyes, and after this the growth of the included animal becomes ſo quick, that in a day or two after, if the egg be examined by holding it againſt a ſtrong light, the compleat animal may be ſeen in it, doubled in two in ſuch a manner, that its head and tail are brought to touch. Theſe eggs, when depoſited on the leaf, are fixed down to it by ſo ſtrongly viſcous a fluid, that they cannot be taken off without breaking; but there does not appear to have been any aperture made by the ſaw of the animal in the places where they are laid. It is poſſible that there might be a ſmall wound made in the leaf under each, which though not capable of receiving the egg, might however ſerve to pour forth a juice ſufficient to keep the egg moiſt; but theſe apertures muſt be very ſmall, if there are any ſuch, ſince the microſcope diſcovers no traces or remains of them. There ſeems a plain proof that the egg receives ſome ſort of benefit, and that a very eſſential one to its preſervation, from the juices of the plant on which it is depoſited, ſince if thoſe leaves be pulled off from the plant, and left to dry, the eggs always dry up with them, and periſh; whereas, if the ends of theſe leaves be put into water, and the leaf be by that means preſerved freſh and juicy, the creature hatches from it as well, as if it was left upon the tree. It ſhould ſeem from this that the eggs of theſe *flies*, when introduced into wounds in the branches of trees, become a ſort of grafts, and live on the juices of the plant, and that thoſe on the leaves have the ſame juices conveyed to them in ſome other manner. This is certain, that whereas the freſhneſs of the plant is abſolutely neceſſary to the hatching of theſe eggs, it is not at all ſo to the eggs of other inſects which lay upon them. The butterfly lays its eggs on ſome particular ſpecies of plant, according to its kind; but this is only that the caterpillar, when hatched from it, may have proper food; for if the leaf, on which theſe eggs are laid, be dried, the eggs nevertheleſs hatch at their proper period, and ſhew that the juices of the plant, or its continuing freſh, were of no neceſſity or uſe to them. The oſier-fly gives yet another difficulty, however, in regard to this ſyſtem, of the eggs of theſe *flies* receiving nouriſhment from the juices of the plant; for it frequently lays ſeveral rows of eggs on a leaf, and the eggs in ſome of theſe lie two deep: now the queſtion is, in what manner the juices of the plant, ſo neceſſary to theſe eggs, are carried to the upper row? unleſs we can ſolve this, by ſuppoſing that the eggs of the under row convey juices to the upper ones, by communications of veſſels, where they touch, the ſolution of this difficulty appears no eaſy taſk. *Reaumur*'s Hiſt. Inſ. Vol. 9. p. 164.

SERRATED *leaf*, in botany. See LEAF.

SERRATULA, *ſaw-wort*, in botany, a name given to ſeveral ſpecies of *jacea*. See JACCA.

It ſeems very expreſsly proved by Dioſcorides, Pliny, Antonius Muſa, and ſeveral other of the antients, that the *betonica*, or, as they ſometimes wrote it, *vettonica*, was our *ſerratula*. They mention its growing in woods, and having leaves deeply ſinuated, or cut in, and indented all about the edges, and ſay it grew in wet ſhady places. All this agrees very well with our cut-leaved *ſerratula*, and with the *betonica*, or *vettonica* of the antients. Apuleius confounds the *brittanica antiquorum* with the *betonica*, and ſays that it has large leaves like the dock.

Pliny and this author ſeem to have drawn their knowledge from the ſame ſource; and if Pliny, though he has not ſaid it, ſuppoſed, as this author does, that *betonica* and *brittanica* were the ſame, it is then no wonder that he ſays the *betonica* had leaves like a dock, for Dioſcorides himſelf ſays this of the *brittanica*.

SERRATUS (*Cycl.*)—SERRATUS *major*, in anatomy, a broad, fleſhy, and pretty thick muſcle, lying on the lateral part ofthe thorax, between the ribs and ſcapula, by which it is covered. Its figure is that of an irregular ſquare, its greateſt breadth being in the back part, where it terminates by digitations of unequal lengths in a radicated diſpoſition, their extremities deſcribing an arch or curve. From theſe digitations it is that it has its name.

It is inſerted backward in the internal labium of all the baſis of the ſcapula, from the ſuperior to the inferior angle; from thence running forward wholly fleſhy, it encreaſes gradually in breadth, and is inſerted in all the true ribs, and often in one or two of the falſe ones, by the ſame number of digitations. Though the digitations of this muſcle give it a radiated appearance from the ſcapula to the ribs, yet theſe radii do not all lie in that diſpoſition, which at firſt ſight one would be apt to imagine. The muſcle is made up of two planes, one great, the other ſmall: the ſmall plane looks like a diſtinct narrow muſcle, cloſely adhering to the ſuperior edge of the great plane. It is fixed by one extremity under the ſuperior angle of the ſcapula, and by the other to the firſt rib by a ſmall inſertion, and to the ſecond rib by a broad one. This plane is eaſily ſeen by turning the ſcapula forward, having firſt ſeparated the rhomboides; but when it is turned back, the pectoralis minor being firſt cut off, this plane does not appear, being covered and hid by the broad one. The broad plane may be divided into two portions, one ſuperior, the other inferior, adhering to each other at their edges.

The ſuperior portion is thin, and takes up about three quarters of the baſis of the ſcapula, reckoning from the ſuperior angle; from thence it contracts by ſmall degrees, and forms two digitations, very like thoſe of the ſmall plane, which they cover by their inſertions in the two firſt true ribs, or in the ſecond and third, and ſometimes in all the three. The inferior portion is fixed in the lower quarter of the baſis ſcapulæ, from whence it expands itſelf by ſix or ſeven very long fleſhy digitations, which decreaſe in breadth as they deſcend, and are inſerted in the manner beforementioned, in the ſix or ſeven ribs which follow the two firſt. *Winſlow*'s Anatomy, p. 176.

SERRATUS *minor*, in anatomy, a name given by Riolanus to the muſcle, more commonly known by the name of the *ſerratus anticus*. See SERRATUS, *Cycl.*

SERRATUS *poſticus ſuperior*, a flat thin muſcle, ſituated on the upper part of the back, fixed on one ſide by a broad aponeuroſis to the lower part of the poſterior cervical ligament, and to the ſpinal apophyſes of the two laſt vertebræ of the neck, and two firſt of the back; from thence it runs down a little obliquely forward, and is inſerted by broad fleſhy digitations in the poſterior part of the ſecond, third, fourth, and ſometimes of the fifth true ribs, near their angles; but ſometimes it has no inſertion in the ſecond rib. It is covered by the rhomboides, and cloſely united with it. *Winſlow*'s Anatomy, p. 231.

SERRATUS *poſticus inferior*, a flat thin muſcle, lying on the lower part of the back.

It is fixed in the laſt ſpinal apophyſis of the back, and in the three firſt of the loins by a broad aponeuroſis; from thence it runs up a little obliquely, and is fixed by fleſhy broad digitations in the laſt four falſe ribs. Its inſertions in the loweſt rib are near the cartilage, and in the other three near their angles. It is covered by the latiſſimus dorſi, to which it adheres very cloſely, and it covers the ſacro-lumbaris, and longiſſimus dorſi. *Winſlow*'s Anatomy, p. 231.

SERTA, *garlands*, among the antients. See the article GARLAND, *Cycl.*

SERTULA *campana*, in botany, a name given by ſome authors to melilot. *Ger.* Emac. Ind. 2.

SERTULARIA, in botany, the name of a genus of ſea plants, comprehending, according to Linnæus, the *corallines* and *acetabulums* of Tournefort, and the *opuntioides* of Boerhaave. The generical character of theſe plants is, that they are a kind of lithophyta, which are jointed and compoſed of ſeparate parts, faſtened to each other by the ends, in the manner of the gems of a bracelet, or beads of a lady's necklace.

SERVE, in the ſea language. To *ſerve* a rope, is to lay ſpun yarn, rope yarn, ſinnet, a piece of canvas, or the like, upon it, which is rolled faſt round about the rope, to keep it from fretting or galling in any place.

SERVITIIS *acquietandis*, a writ judicial that lies for a man diſtrained for ſervices to one, when he owes and performs them to another, for the acquittal of ſuch ſervices. Reg. Judic. 27. *Blount*, *Cowel.*

SERULA, in zoology, the name of a webfooted ſea-bird, a kind of mergus, very common about Venice, and called by Mr. Ray *mergus cirratus fuſcus*, the brown creſted diver, and ſuppoſed to be the *anas longiroſtra*, or long beaked duck of Geſner.

It is very nearly of the ſize of the duck; its head, and the upper part of its neck, are of a duſky yellow. The crown of the head is of a much duſkier and browner colour than the reſt, and has a creſt of feathers hanging down from it. Its back is of a browniſh hue, with a very faint admixture of grey. Its throat is of a pure white in its upper part, but lower down it is variegated with white, black, and a reddiſh brown. Its belly is all white. Its beak is ſlender, and rounded, and is three fingers breadth long. The upper chap is of a browniſh green, and the under one red. It terminates in a hooked point, and both chaps are all the way ſerrated, or notched like the teeth of a ſaw. The wings are very ſmall and ſhort. *Aldrovand.* Vol. 3. p. 281. *Ray*'s Ornitholog.

SERUM (*Cycl.*)—There have been inſtances, in which the blood has been found to contain with its coagulum a ſubſtance, very different from what we uſually underſtand by the word *ſerum*. Dr. Stuart has given an account of a man in an inflammatory fever, from whoſe arm eight ounces of blood was taken, which, when it had ſtood ſome time, afforded, inſtead of *ſerum*, half its quantity of a white liquor, like

like milk, ſwimming on the coagulum. This had no ſmell at firſt; but being kept for obſervation, after ſix days it contracted a ſmell like that of rotten eggs; and after ſtanding three weeks more, it neither altered its conſiſtence nor ſmell.

If this liquor was chyle, then is chyle a ſubſtance very different from milk, milk being apt to turn ſower, and become thick by keeping, and never contracting the ſmell of rotten eggs, as this liquor did. Whether it be not chyle turned putrid, and brought near to purulency by a long circulation in the blood veſſels, without being converted into blood, through ſome defect in the ſanguification, is a queſtion not eaſily decided. Five days after this being blooded again, the blood was found of the common kind, the *ſerum* being a thin pellucid water as uſual. Philoſoph. Tranſ. N° 442. p. 290.

SERUM *aluminoſum*, *alum-whey*, a form of medicine preſcribed in the late London Pharmacopœia, made of a pint of milk boiled to whey with a quarter of an ounce of alum. *Pemberton*'s Lond. Diſp. p. 255.

SERWOY, in natural hiſtory, a name given by Theodore de Bry, and others, to the animal called by us the *opoſſum*, and by the natives of Braſil the *carigueya*. Phil. Tranſ. N° 239. p. 107. See OPOSSUM.

SESAMION, a word uſed by the antients to expreſs a preparation of the *ſeſamum*, or oily grain. It was a cake made of ſeſamum, honey, and oil.

SESAMOIDE *bones* (*Cycl.*)—The *ſeſamoide bones* are very ſmall, and have their name from the ſeed of the *ſeſamum*, or oily grain, to which they are ſuppoſed to bear ſome reſemblance. There are ſeveral of them found, both in the joints of the toes and fingers. They are for the moſt part very ſmall, and affixed chiefly to ligaments, and only two of them are large enough to be commonly preſerved in ſceletons: theſe reſemble a large flat oval pearl, and are hollowed on one ſide.

They are of about the third of an inch in length, and are half as broad as long. They are connected very near each other, by a ſmall ſhort ligament, to the baſis of the firſt phalanx of the great toe, ſo as to ſlide on each ſide of the middle eminence of the double pulley, in the firſt metatarſal bone, like two ſmall patellæ. Though theſe are generally faſtened in ſceletons to the firſt bone of the metatarſus, they nevertheleſs belong only to the firſt phalanx of the great toe, as the patella belongs not to the os femoris, but to the tibia. *Winſlow*'s Anatomy, p. 104.

SESAMOIDES, in botany, the name of a genus of plants, the characters of which are theſe. The flower is wholly the ſame in ſhape with that of the reſeda, but the fruit is very different in the different ſpecies: in ſome it conſiſts of ſeveral horns or capſules, each containing one ſeed of a kidney-like ſhape; and in others it is multicapſular, or ſtellated.

The ſpecies of *ſeſamoides*, enumerated by Mr. Tournefort, are theſe. 1. The white-flowered *ſeſamoides* with hoary leaves. 2. The thick-leaved *ſeſamoides* with purpliſh green flowers. 3. The *ſeſamoides* with ſtellated fruit, called by many the *toad-flax-leaved reſeda*. *Tourn.* Inſt. p. 424.

SESAMUM, in botany, a name given by ſome authors to the *myagrum*, or gold of pleaſure. *Volk.* Flor. Norimb. 312.

SESELI, in botany, the name of a genus of plants, the characters of which, according to Linnæus, are theſe. The general umbel is uncertain in figure; the partial ones are very ſhort, multiple, and almoſt round. There is no general involucrum, and the partial ones are compoſed of ſeveral leaves, of the length of the umbellule, narrow, and pointed. The perianthium is ſcarce obſervable. The general corolla is nearly uniform; and the ſingle flowers are compoſed of five inflexo-cordated, and nearly equal petals. The ſtamina are five ſubulated filaments. The antheræ are ſimple. The germen of the piſtil ſtands under the receptacle. The ſtyles are two, and reflex. The ſtigmata are obtuſe. The fruit is ovated, ſmall, ſtriated, and ſeparable into two parts. The ſeeds are two in number, oval, convex on one ſide, and plane on the other.

Tournefort has referred the ſpecies of *ſeſeli* to the genus of fennel, *fœniculum*, from which, however, they greatly differ, in regard to their involucra. *Linnæi* Gen. Plant. p. 120. See FOENICULUM.

SESELI *ſeed*, in the materia medica, the name of the ſeed of a plant, called alſo by ſome *libanotis*, and growing three or four feet high, with leaves like fennel, but of a paler green. It is a native of warm climates. The *ſeed* ought to be choſen moderately large, of a longiſh ſhape, heavy, clean, and of a greeniſh colour, freſh, and of a grateful ſmell. It affords, by diſtillation, a very large quantity of an eſſential oil, and is hot and dry. It incides, opens, and diſcuſſes, and is cephalic, neurotic, pectoral, and nephritic. It is good againſt epilepſies, apoplexies, vertigos, and all diſorders of the head and nerves. *Lemery*'s Dict. of Drugs.

The ſeeds of the *ſeſeli creticum* are diuretic, uterine, and good in all diſorders of the breaſt and lungs. They are given in ſuppreſſions of urine, and of the menſes, and in all kinds of flatulencies; and are, among the German phyſicians, a common ingredient in medicines, intended to promote expectoration.

The ſeed of the french Hartwort, or *ſeſeli maſſilienſe*, is eſteemed of great virtue in diſeaſes of the head and nerves, in convulſions and epilepſies, and in weakneſſes of the ſight. It is alſo given in electuaries, intended againſt all diſorders of the breaſt and lungs, in coughs, catarrhs, and aſthmas, and in obſtructions of the liver. Some have recommended it ſingly, as a medicine of great efficacy againſt obſtructions of the menſes; and Schroder tells us, that it has the credit of being an antidote to the poiſon of hemlock.

The common hartwort is poſſeſſed of the ſame ſort of virtues with the other two, but its ſeed is more warm and acrid than that of either of them. It is eſteemed a very efficacious remedy in obſtructions of the menſes, and in all diſorders ariſing from indigeſtion, crudities, and flatulencies.

SESERINUS, in zoology, a name given by Rondeletius, and ſome other authors, to a broad and ſhort ſea fiſh, ſeeming the ſame with the *lampuga* of Italian fiſhermen; and deſcribed by authors in general, and by this very author in another place, under the name of *ſtromateus*. *Willughby*, Hiſt. Piſc. p. 137. See STROMATEUS.

SESQUITERTIONAL *proportion*. When any number or quantity contains another once and one third, they are *ſeſquitertional proportionals*.

SESSILE *roots*, among botaniſts, ſuch tuberous roots as adhere to the baſe of the ſtalk. See ROOT.

SESSILE *leaf*, among botaniſts. See LEAF.

SETS, a term uſed by the farmers to expreſs the young plants of the white thorn, and other ſhrubs, which they uſe to raiſe their quick, or quick-*ſet* hedges.

The white thorn is the beſt, of all trees, for this purpoſe, and under proper regulations, its *ſets* ſeldom fail of anſwering the farmers utmoſt expectations.

The firſt thing to be conſidered by the perſon, who is about to plant a quick-*ſet* hedge, is what nature the land is of where it is to ſtand, as whether it be clay, ſand, or gravel. It is always proper to take the *ſets* from a worſe land, than that they are to be planted on, otherwiſe they will never grow well. The *ſets* are about the thickneſs of a man's thumb, and cut within four or five inches of the ground. If the quick is intended only for a hedge, without a bank or ditch, let the *ſets* be planted almoſt perpendicular in two rows, at about twelve inches diſtance from each other; and if there is to be a ditch and a bank, that is to be firſt provided. The ground is to be marked out with a line, and a ditch dug three feet wide at the top, one foot wide at the bottom, and two feet deep. When the ditch is digging, on that ſide where the quick is to ſtand, let the turf be laid evenly on the ground, with the graſſy ſide downwards: upon this ſome fine mould is to be laid, to bed the quick-*ſets* in, and they are to be laid upon it with their ends enclining upwards, and at about twelve inches aſunder. They muſt be carefully gathered, and ſuch as are ſtrait, ſmooth, and well rooted, are only to be choſen. At every thirty feet there ſhould be planted with the *ſets* a young oak, aſh, or ſome other ſuch tree, to grow up along with the hedge. When a compleat row of the *ſets* is thus laid, cover them with a layer of fine mould, and lay over that another layer of the turf; add upon this a third layer of mould, ſo deep, that its ſurface may be a foot above the row of *ſets*: on this bed place another row of the like *ſets* at the ſame diſtances, but placed between the others; cover this as the other, and then make up the bank with the earth dug out of the bottom of the ditch, and on its top ſet the dry, or dead hedge: this will ſhade the under plantation, and will be a defence till the *ſets* are grown up into a live hedge. The ſtakes for the dead hedge are to be driven into the bank ſo low, as to reach the firm ground, and are to be placed at two feet and a half diſtance from one another. Oak ſtakes are the beſt for this purpoſe, and ſallow and black thorn are eſteemed next to theſe. The ſmall buſhes cut from them muſt be laid below, but not too thick, that they may ſhade the young plantation without ſmothering it, and defend its young ſhoots from the biting of cattle: the long buſhes are to be laid at top to bind in the ſtakes, by interweaving them. To add a farther ſtrength to the hedge it may be eddered, as the farmers call it: this is binding the tops of the ſtakes with ſome ſmall long poles, or ſticks, on each ſide. When this is all done, the ſtakes ſhould be new drove a little, becauſe the making the hedge, and the eddering it, are apt to looſen them a little.

The young plants muſt be conſtantly weeded, and great care muſt be taken to preſerve them from the bitings of cattle, eſpecially of ſheep. If they have been cropped, or are not found to grow well, it is a good cuſtom among the farmers to cut them down to the ground, or within an inch of it, for after this they uſually ſend out new roots, and ſhoot very vigorouſly. *Mortimer*'s Huſbandry.

SET-*bolts*, in a ſhip. See BOLTS.

SETACEUS *vermis*, in natural hiſtory, a name given by Dr. Liſter to that long and ſlender water worm, which ſo much reſembles a horſe-hair, that it has been ſuppoſed by the vulgar to be an animated hair of that creature.

Theſe

These creatures, ſuppoſed to be living hairs, are a peculiar ſort of inſects, which are bred and nouriſhed within the bodies of other inſects, as the worms of the ichneumon flies are in the bodies of the caterpillars.

Aldrovand deſcribes the creature, and tells us it was unknown to the antients, but called *ſeta aquatica*, and *vermis ſetarius* by the moderns; either from its figure reſembling that of a hair, or from the ſuppoſition of its having once been a hair of ſome animal. We generally ſuppoſe it, in the imaginary ſtate of the hair, to have belonged to a horſe, but the Germans ſay it was once the hair of a calf, and call it by a name ſignifying *vitulus aquaticus*, or the water-calf.

Albertus, an author much reverenced by the common people, has declared that this animal is generated of a hair; and adds, that any hair thrown into a ſtanding water will, in a very little time, obtain life and motion. Other authors have diſſented from this opinion, and ſuppoſed them generated of the fibrous roots of water plants, and others of the parts of graſshoppers fallen into the water. This laſt opinion is rejected by Aldrovand, as the moſt improbable of all, yet in reality it comes neareſt the truth of any of them. Standing and foul waters are moſt plentifully ſtored with them; but they are ſometimes found in the cleareſt and pureſt ſprings, and ſometimes out of the water, on the leaves of trees and plants, as on the fruit-trees in our gardens, and the elms in hedges. They are from three to five inches long, of the thickneſs of a large hair, and are brown upon the back, and white under the belly, and the tail is white on every part. *Aldrovand.* de Inſect. Phil. Tranſ. N° 83.

See the article AMPHISBÆNA *aquatica*.

SETAH, in botany, a name uſed by the oldeſt writers for the acacia. It is an orginal Hebrew word, and is explained by the lexicographers, by a thorn growing in the deſert. It is rendered by Theodotion *acantha*, one of the names of the acacia.

SETICAUDÆ, in natural hiſtory, a term uſed to expreſs ſuch flies as have one or more hairs growing out at their tails. There are many ſpecies of theſe, diſtinguiſhed by their having one, two, or three hairs.

SETINUM, in botany, a name given by ſome to the larch-tree, and by others to ſome other trees. The reaſon of giving it as the name of a tree is, that Dioſcorides mentions the agaric as growing on it, according to the accounts of ſome writers of his time. But it is an error in the copies of that author, that has given riſe to this imaginary name of a tree. The author ſays only, that it grew ſometimes on beams, and other timber, when expoſed to the weather. He has expreſſed beams by the word *ſtelechos*, and tranſcribers have made this *ſetinos*, or *ſetinum*.

This appears not only from ſome of the old manuſcript copies retaining the word properly written, but alſo by the accounts the Arabians give of this drug. Aviſenna and Serapion have both copied the words of this author, and they do not render the word in the original author, ſignifying the place of growth, or production of the agaric, by the name of any particular tree, but both ſay that it was formed of the putrefaction of trees and beams of timber, when they had been eaten by worms, or corrupted by wet; and they add from the ſame author, that the production of agaric ſeemed like that of the funguſes.

From this, and from Pliny's account, it appears that the female agaric of the antients was not a fungus, or any thing like our agaric; but by Dioſcorides's deſcription of its texture, and Pliny's account of its giving light like a fire in the night, it appears to have been only a peculiar kind of rotten wood, which they knew by that name. The other, or male agaric, was yet more unlike to ours, it being a root of ſome kind, and in ſhape reſembling the ſilphium.

SETSE, in botany, the name of a Chineſe tree, called alſo *chitſe*, and much eſteemed by the people of that country for its beauty, and for the goodneſs of its fruit. In the provinces of Cantong and Honan there are whole plains covered with theſe trees, many of which grow to the ſize of our wallnut-tree. The fruit ripens every where in the Eaſt, where the tree grows, but it is of a much more delicious flavour in ſome places than in others. The leaves are of the colour and ſhape of thoſe of the wallnut-tree, only that they are more round at the ends. The fruit is ſometimes round, ſometimes pointed at one end, ſometimes oval, ſometimes flat, and not unfrequently compoſed of two pieces, as it were, and reſembling two apples cut and joined together. The rind is always green, never changing yellow or red, and the fruit keeps its freſhneſs all the winter. They are about the ſize of the orange, and the ſkin is very tender and thin, and the fruit has a mixed taſte of the ſharp and the luſcious. It is very wholeſome and good. Obſerv. ſur les Coutumes de l'Aſie. p. 198.

SETTEE, a veſſel, very common in the Mediterranean, with one deck, and a very long and ſharp prow. They carry, ſome two maſts, ſome three, without top-maſts. Their yards and ſails are all like the miſen. The leaſt of them are of ſixty tons burthen. They ſerve to tranſport cannon, and proviſion for ſhips of war, and the like.

SETTING, (*Cycl.*) the term uſed by ſportſmen to expreſs a manner of attacking partridges, in order to the taking them, by means of a dog peculiarly trained to that purpoſe. The *ſetting*-dog generally uſed is a long land-ſpaniel, taught by nature to hunt partridges more than any other game, and in his untaught ſtate running over the fields, in ſearch of them, with an alacrity that is truly wonderful; yet by art this creature is brought under ſuch excellent command, that he will, in the midſt of his higheſt career, attend to the leaſt hem from his maſter, and ſtand ſtill to look in his face, and take his orders by the ſlighteſt ſignals; and when he is ſo near his game, that it is almoſt in his mouth, he will ſtand ſtock ſtill, or lie down on his belly, till his maſter arrive, and he receives his directions.

The *ſetting*-dog being taken to the haunt of the partridges, is to be caſt off, and ſent to range; but he muſt be made to keep near the ſportſman, and not to run wildly on, but to beat all the ground regularly. On being reproved for ranging too wildly and too far, he will keep cloſe the whole day, and at times look up in his maſter's face to know if he does right or wrong. If in the dog's ranging he ſtop of a ſudden, the ſportſman is to make up to him, and as there is certainly game before him, he muſt be ordered to advance; if he refuſe this, and look back and ſhake his tail, it is a ſignal that they are cloſe before him, and the ſportſman is then to take a circumference, and look with a careleſs eye before the dog's noſe to ſee where they are, and how they lie; then going up, and ſtaking down one end of the net, he is to command the dog to lie ſtill, and to draw the net gently over the birds, then making in with a noiſe, he is to ſpring them, and they will be entangled and taken as they riſe. It is a rule with fair ſportſmen, when they take a covey in this manner, always to let the cock and hen go.

SETTING *of bricks*. See the article BRICKS.

SETTLING *a deck*, at ſea, a term for taking a deck lower than it was at firſt.

SEVENTH (*Cycl.*)—SEVENTH, in muſic. In thorough baſſes the *ſeventh*, whether double, ſimple, major, or minor, is marked by a figure of 7; but if it be accidentally flat, or minor, thus, $^{\flat}7$, or $7^{\flat}$. If ſharp, or major, thus, $^{\sharp}7$, or $7^{\sharp}$. Again, if when it is naturally minor, it be marked with a flat, it muſt be diminiſhed.

Diminiſhed SEVENTH, in muſic. See the article DIMINISHED *ſeventh*.

SEVERAL (*Cycl.*)—SEVERAL *inheritance*, in law, an inheritance conveyed, ſo as to deſcend, or come to two perſons *ſeverally*, by moieties, or other parts.

SEVERAL *tenancy*, *tenura ſeparalis*, a plea, or exception taken to a writ that is laid againſt two perſons as joint tenants, who are *ſeveral*. Bro. 273. *Blount*, *Cowel*.

SEVERANCE (*Cycl.*)—SEVERANCE *of corn*. The cutting and carrying it from off the ground; and ſometimes the ſetting out the tithes from the reſt of the corn, is called *ſeverance*. 2 Cro. 325.

SEVIL, in the manege. The *ſevil* of the branches of a bridle is a nail turned round like a ring, with a large head, made faſt in the lower part of the branch, called *gargouille*. See the article BANQUET.

SEVIR, among the Romans, an officer who, according to Pitiſcus, commanded a whole wing of horſe; tho' others make him only the commander of a troop, *turmis*, a diviſion anſwering to our regiments.

SEVIRI, were alſo magiſtrates in the colonies, ſo called, from their being ſix in number. *Pitiſc.* in voc.

SEW, in the ſea language. When a ſhip at low water comes to lie on the ground, and to lie dry, they ſay ſhe is *ſewed*; and if ſhe be not quite left dry, they ſay ſhe *ſews* to ſuch a part.

SEWEL-*coronde*, a name given by the natives of Ceylon to a ſpecies of cinnamon, which, when chewed, is of a mucilaginous nature, like the caſſia: this dries well, and is very firm and hard, and has the appearance of a very fine cinnamon; but it has very little taſte, and a diſagreeable ſmell. The natives take advantage of the handſome appearance of this kind of cinnamon, and are very apt to mix it with the good kind, to the great detriment of the buyer. Philoſ. Tranſ. N° 409.

SEXANGLE, in geometry, a figure having ſix ſides, and conſequently ſix angles.

SEXTANS, (*Cycl.*) a word uſed by pharmaceutic writers for the ſixth part of a pound, that is, two ounces troy-weight, or ſixteen drachms. It is alſo uſed by ſome authors for a ſixth part of any other ſtanding weight, or meaſure.

SEXTERY *lands*, are lands given to a church, &c. for maintenance of the ſexton. *Blount*.

SEXTULA, a word uſed by ſome pharmaceutic writers to expreſs the ſixth part of an ounce, that is, four ſcruples, or one drachm and one ſcruple.

SEXTUS *oculi*, in anatomy, a name given by Fallopius to one of the muſcles of the eye, called by Albinus, and others, the *obliquus oculi inferior*, and by ſome the *obliquus oculi brevis*. See the articles OBLIQUUS *inferior*, and EYE.

SEXTUS *thoracis*, in anatomy, a name given by Fallopius, and others, to a muſcle, now generally known by the name of the *triangularis ſterni*.

SEXUALISTÆ, among botanical authors, thoſe who have eſtabliſhed the claſſes of plants upon the differences of the ſexes, and parts of fructification in plants, according to the modern method, as Linnæus, &c.

SEXUNX, in pharmacy, the weight of ſix ounces, or half a pound troy.

SEYGAR, in the materia medica, a name uſed by ſome authors for the nutmeg. *Ger.* Emac. Ind. 2.

SHACKLES, aboard a ſhip, are thoſe oblong iron rings, bigger at one end than at the other, with which the ports are ſhut faſt, by thruſting the wooden bar of the port through them. There are alſo a ſort of *ſhackles* to lift the hatches up with, of a like figure, but ſmaller. They are faſtened at the corners of the hatches.

SHAD, *alauſa*, in zoology, the name of a ſea-fiſh of the herring-kind, called alſo the *mother of herrings*, and by ſome authors *clupea* and *triſſa*, and by the antients *trichis*, or *trichias*. See Tab. of Fiſhes, N° 39.

It very much reſembles the herring in its general form, but it is flatter and broader, and grows to a cubit long, and four inches broad. It is of the colour of the pilchard, of a bluiſh black on the back, and a ſilvery white on the belly and ſides, and the coverings of the gills are ſometimes purpliſh, and ſometimes a little yellow. Near the gills it has alſo on each ſide a large black ſpot, and five or ſix others on each ſide, which are ſmaller, and placed behind them. Theſe are all moſt diſtinguiſhable when the fiſh is ſcaled. The ſcales are large, and eaſily fall off, and are dotted with ſmall black ſpots at their edges.

It is very common in many ſeas, and in ſome of our large rivers which lie near the ſea. They run up theſe in great numbers in the months of March and April, and are then very fat; in May they become lean, and then go down to the ſea again. They uſually ſwim in large ſhoals together. *Willughby*, Hiſt. Piſc. p. 227.

SHAFT (*Cycl.*)—SHAFT, in mining, is the ſame with a groove, or pit. *Shafts* are ſunk ſome ten, ſome twenty fathoms deep into the earth, more or leſs. *Houghton*'s Compl. Miner, in the Explan. of the Terms.

SHAGGE, in zoology, a name by which we commonly call a water fowl common on the northern coaſts, and called by Mr. Ray *corvus aquaticus minor*, or the leſſer cormorant, being properly a bird of the cormorant-kind.

It is ſomewhat larger than the common duck, and weighs about four pounds. Its beak is ſtrait and ſlender, and is not flatted, but roundiſh. It is four fingers breadth long, and is hooked at the end. Its mouth opens very wide, and its eyes are ſmall. Its head, neck, and back are of a fine ſhining black, with an admixture of a purpliſh, or greeniſh gloſs, ſhining like ſattin. Its breaſt is brown, and the middle of its belly greyiſh. Its tail is ſhort, and its wings, when folded, reach juſt to the end of it, and no farther. Its legs are covered with a cancellated ſkin, not a congeries of ſcales, and its toes are all connected by a membrane. It ſwims with its head erect, and moſt of its body under water, and is very ſhy, and with difficulty ſhot. It builds in trees as the common cormorant, and is evidently a ſpecies of that bird, though different in ſize, and in the colour of its belly. *Ray*'s Ornitholog. p. 219.

SHAKER *pigeon*, a kind of pigeons, of which there are two ſorts, the broad tailed, and the narrow tailed.

The firſt is the fineſt, and moſt valued. It has a beautiful long thin neck, which bends like the neck of a ſwan, leaning towards the back. It has a full breaſt, a very ſhort back, and a tail conſiſting of a great number of feathers, ſeldom leſs than four and twenty, which it ſpreads in an elegant manner, like the tail of a turkey-cock, and bends it up ſo, that it meets the head. It is commonly all white, but ſometimes is red, yellow, or blue-pied. The longer the neck of this bird is, the more it is valued.

The ſecond, or narrow-tailed *ſhaker*, has a ſhorter and thicker neck, and a longer back. It is eſteemed by many a different ſpecies, but ſeems only a mixed breed with ſome other pigeon. They are called *ſhakers*, from a tremulous motion which they have with their necks when courting. *Moore*'s Columbarium, p. 54.

SHAMBLE, in mining, a term uſed to expreſs a ſort of nich, or landing place, left at certain diſtances in the adits of mines. The method of digging the tin mines in Devonſhire, and ſome parts of Cornwall, is this; they ſink their way in ſuch a breadth, as is ſufficient for them to ſtand and work, and at every fathom they leave a ſquare place vacant, to which the ore is to be thrown up with ſhovels as it is dug. This they do from caſt to caſt; that is, as far as a man can conveniently throw up the ore with his ſhovel. Thus the ore, as it is dug by the beelmen, is thrown up by the ſhovellers, who follow them from *ſhamble* to *ſhamble*, till it comes to the top of the mine. This, however, is but an inconvenient way, and the uſe of theſe *ſhambles* is generally ſupplied by a winder at the opening of the mine, which manages two buckets, the one of which is ſent down empty, while the other is ſent up full; and one man employed below to load, and another above to empty. Phil. Tranſ. N° 69. See the article DIGGING.

SHAMBRIER, in the manege, is a long thong of leather, made faſt to the end of a cane, in order to animate a horſe, and puniſh him, if he refuſes to obey the rider.

SHANK *of an anchor*, on board a ſhip. See ANCHOR.

SHANK, in the manege, is that part of a horſe's fore leg, which lies between the knee and the fetlock, or paſtern-joint.

SHANK, or *Shank-painter*, in a ſhip, is a ſhort chain faſtened under the foremaſt-ſhrowds, by a bolt, to the ſhip's ſides, having at the other end a rope faſtened to it. On this *ſhank-painter* the whole weight of the aft part of the anchor reſts, when it lies by the ſhip's ſide. The rope, by which it is haled up, is made faſt about a timber-head.

SHARE, the name of that part of the plough which cuts the ground, and the wood to which it is fixed. The extremity of the iron forwards is called the point of the *ſhare*, and the end of the wood behind is called its tail.

The length of the whole *ſhare*, from point to tail, ſhould be three feet nine inches; at the top of the iron it has an upright piece, called the *fin*, and near the iron, at the other end, there is an oblong ſquared hollow, called the *ſocket*; the uſe of which is to receive the bottom of the ſheat. Near the tail there is a thin plate of iron, well rivetted to the wood; by means of this plate the tail of the *ſhare* is held firmly to the hinder ſheat of the plough by a ſmall iron pin, with a ſkrew at the end, and a nut ſkrewed on it, on the inner or right ſide of the ſheat.

The point of the *ſhare* is that part in which it does not run up into the fin: this point is generally made of three inches and a half in length, and ſhould be flat underneath, and round at the top, and the lower part of it muſt be of hard ſteel. The edge of the fin ſhould alſo be well ſteeled, and ſhould make an acute angle with the *ſhare*.

The ſocket is a ſort of mortiſe; it ſhould be a foot long, and about two inches deep: the fore end of it muſt not be perpendicular, but oblique, conformable to the end of the ſheat which enters into it. The upper edge of the fore part muſt be always made to bear againſt the ſheat; but if this end of the ſocket ſhould not be quite ſo oblique as the ſheat, it may be helped, by paring off a ſmall part of the wood at the point. *Tull*'s Huſbandry, p. 140. See the article PLOUGH.

SHARK. We know two different fiſh under the ſame name of *ſhark*, with the addition of their colour, blue and white. See Tab. of Fiſhes, N° 2, 3, 4.

The blue *ſhark* is that ſpecies of ſqualus called *glaucus*, and *galeus glaucus*, by authors, and diſtinguiſhed by Artedi by the name of the *ſqualus* with a triangular dent, or furrow, in the extremity of the back, and with no foramina about the eyes. See GALEUS.

The other is the *lamia*, or *canis carcharias* of authors, commonly called by us ſimply *the ſhark*. This is diſtinguiſhed by Artedi by the name of the *ſqualus* with a flat back, and with numerous teeth, ſerrated at the edges. See the article SQUALUS.

The white *ſhark*, or *lamia*, is a very dreadful and voracious fiſh, the largeſt of all the *ſharks*. They have been ſeen of four thouſand weight, with throats capable of ſwallowing a luſty man whole; nay, men have been found whole in them when opened. Some have, for this reaſon, imagined this, and not the whale, to have been the fiſh in whoſe belly the prophet Jonah lay. Its teeth are very ſharp and terrible; they are diſpoſed in ſix rows, and are all triangular, and notched like a ſaw on their edges. Theſe are, in the whole, a hundred and forty four in number, and are placed in various directions. Their number is not exactly determinate. Its back is ſhort and broad, in compariſon of the other fiſh of this kind, and its tail compoſed of two fins of a cubit in length each. Its ſkin is rough, and its eyes large and round. It is found both in the Ocean and Mediterranean, and is of all fiſh the moſt voracious of human fleſh.

It has its name from the Greek, λαίμος, a voracious feeder, or glutton. The foſſile bodies, called *gloſſopetræ*, or ſerpents tongues, and ſuppoſed to be real ſtones, are the teeth of this fiſh. *Willughby*, Hiſt. Piſc. p. 47.

Hammer-headed SHARK. See the article ZYGÆNA.

SHARP (*Cycl.*)—SHARP, in the ſea language, is to hale taut. Thus when they ſay, *ſharp the bow line*, it ſignifies to hale it taut.

SHARP *third*, in muſic, the third major. See the article INTERVAL.

SHARPLING, in ichthyology, the Engliſh name of the gaſterofteus. See GASTEROSTEUS.

SHASTRAM, the name of the bible of the Bramins. See the article BRAMINS.

SHAW, in our old writers, a grove of trees, or a wood. It is mentioned 1 Inſt. 4. *Blount.*

SHEAR *off*, in the ſea language, the ſame as to get away.

SHEARING (*Cycl.*)—The beſt time for *ſhearing* of ſheep is about the middle, or the latter end of June, becauſe it is good for them to ſweat in the wool before it is cut. They muſt be very well waſhed before the *ſhearing*, for this is a great addition to the price of the wool: after the waſhing, let them go three or four days in a clean dry ground. When they are cut, the ſhearer muſt be very careful not to wound their

their ſkins, becauſe this gives occaſion to the flies to teaze the poor creature in a terrible manner. Some *ſhear* their lambs, the firſt year eſpecially, behind; but before the doing of this they ought to be carefully tagged, as it is called, that is, their tails and thighs behind ſhould be well cleared of wool, that the dung may not hang there, which would elſe make them ſore, and ſubject them to the flies, which would blow them, and make them full of maggots.

In Glouceſterſhire they houſe their ſheep every night, and litter them with clean ſtraw. Their dung makes this a very good manure for the land, and the wool of the ſheep is rendered ſo much finer by it, that the farmers have a double advantage from the practice.

In Middleſex, and about London, they have Way-hill ſheep: theſe come from Hampſhire, Wiltſhire, *&c.* and lamb very early, before Chriſtmas. *Mortimer*'s Huſbandry.

SHEARING, in the ſea language. See CHEST-*rope*.

SHEAT *of a plough*, a word uſed by our farmers to expreſs a part of a plough, paſſing through the beam, and faſtened to the ſhare. The *ſheat*, or, as it is ſometimes called, the *fore-ſheat*, (there being another timber behind it, called the *hinder-ſheat*) ſhould be ſeven inches wide, and is faſtened to the beam by the retch, a piece of iron with two legs, and by a wedge driven with it, into the hole in the beam. The angle made by the *ſheat*, with the beam of the plow, ſhould be forty two, or forty three degrees. *Tull*'s Huſbandry. See the article PLOUGH.

SHEATS, in a ſhip, are ropes bent to the clews of the ſails, ſerving in the lower ſails to hale aft, or round-off the clew of the ſail; but in top-ſails they ſerve to hale home, as the word is, or to hale the clew of the ſail cloſe to the yard-arm.

If the main-ſail-*ſheats* are haled aft, it is in order to make a ſhip keep by a wind, but when the fore-*ſheats* are haled aft, it is that the ſhip may fall off from the wind; and if ſhe will not do it readily, they then hale the fore-ſail, by the *ſheat*, flat in, as near the ſhip's ſides as they can; and this they call *flatting in the fore-ſail*. When they ſay, *eaſe the ſheat*, they mean veer it, or let it go out gently; but when the word is, *let fly the ſheat*, they mean, let it go all at once, and run out as faſt as it can; and then the ſail will hang looſe, and hold no wind. In a very great gale, or guſt of wind, there is another rope bent to the clews of the main-ſail and fore-ſail, above the *ſheat*-block, to ſuccour and eaſe the *ſheat*, and this they call a *falſe ſheat*.

SHEATS, in a ſhip, alſo, are thoſe planks under water which come along her run, and are cloſed into the ſtern-poſt; ſo alſo that part within board, in the run of the ſhip, is called the *ſtern-ſheats*. The ſeamen ſay, when they would have the *ſheats* of the main or fore-ſail haled aft, *tally the ſheats*.

Falſe SHEAT, on board a ſhip, is a rope bent to the clews of the main-ſail and fore-ſail, above the *ſheat*-block, to ſuccour and eaſe the *ſheat* in a violent guſt of wind.

Overhale the SHEAT, in the ſea language, a word of command to hale upon the ſtanding part of the *ſheat*.

SHEAT *anchor*, in a ſhip. See ANCHOR.

SHEATHING (*Cycl.*)—SHEATHING *of a ſhip*, is caſing that part which is to be under water, with ſomething to keep the worms from eating into her planks. It is uſually done by laying tar and hair, mixed together, all over the old plank, and then nailing on thin new boards; but this hinders a ſhip's ſailing, and therefore of late ſome have been *ſheathed* with milled lead.

It is very well worth the trying what the new ſtone-pitch will do in this caſe; if it will defend from the worm, as perhaps it may, a ſhip might be paid with it cheaper than with the crown-pitch; and it will not crack nor ſcale off, as that will do, but keeps always ſoft and ſmooth. It has been found to continue on thirteen months, and to remain very black and ſoft all the time.

SHEDDING *of the hair*, in the manege. See CAST.

SHEEP, *ovis*, in zoology. See the article OVIS.

This is a kind of cattle that is kept at the leaſt expence of any to the farmer, and will thrive upon almoſt any ground, and for this reaſon many prefer them before the larger cattle.

The beſt ſort of *ſheep* for fine wool, are thoſe bred in Herefordſhire and Worceſterſhire, but they are ſmall, and black faced, and bear but a ſmall quantity.

Warwick, Leiceſterſhire, Buckingham, and Northamptonſhire, breed a large-boned *ſheep*, of the beſt ſhape, and deepeſt wool we have good. The marſhes of Lincolnſhire breed a very large kind of *ſheep*, but their wool is not good, unleſs the breed be mended by bringing in *ſheep* of other counties among them, which is a ſcheme of late very profitably followed there.

The northern counties in general breed *ſheep* with long, but hairy wool, and Wales bears a ſmall hardy kind of *ſheep*, which has the beſt taſted fleſh, but the worſt wool of all.

The farmer ſhould always buy his *ſheep* from a worſe land than his own, and they ſhould be big-boned, and have a long greaſy wool, curling cloſe and well. Theſe *ſheep* always breed the fineſt wool, and are alſo the moſt approved of by the butcher for ſale in the market.

For the choice of *ſheep* to breed, the ram muſt be young, and his ſkin of the ſame colour with his wool, for the lambs will be of the ſame colour with his ſkin. He ſhould have a large long body, a broad forehead, round, and well riſing, large eyes, and ſtrait and ſhort noſtrils. The polled *ſheep*, that is thoſe which have no horns, are found to be the beſt breeders. The ewe ſhould have a broad back, a large bending neck, ſmall, but ſhort, clean and nimble legs, and a thick deep wool covering her all over. To know whether they be ſound or not, the farmer ſhould examine the wool, that none of it be wanting, and ſee that the gums be red, the teeth white and even, and the briſket ſkin red, the wool firm, the breath ſweet, and the feet not hot. Two years old is the beſt time for beginning to breed, and their firſt lambs ſhould not be kept too long, to weaken them by ſuckling, but be ſold as ſoon as conveniently may be. They will breed advantageouſly, till they are ſeven years old.

The farmers have a method of knowing the age of a *ſheep*, as a horſe's is known by the mouth. When a *ſheep* is one ſhear, as they expreſs it, it has two broad teeth before; when it is two ſhear, it will have four; when three, ſix; and when four, eight: after this their mouths begin to break. The difference of land makes a very great difference in the *ſheep*. The fat paſtures breed ſtrait, tall *ſheep*, and the barren hills and downs breed ſquare ſhort ones; woods and mountains breed tall and ſlender *ſheep*, but the beſt of all are thoſe bred upon new-plowed land, and dry grounds. On the contrary, all wet and moiſt lands are bad for *ſheep*, eſpecially ſuch as are ſubject to be overflowed, and to have ſand and dirt left on them. The ſalt marſhes are, however, an exception to this general rule, for their ſaltneſs makes amends for their moiſture; any thing of ſalt, by reaſon of its drying quality, being of great advantage to *ſheep*.

As to the time of putting the rams to the ewes, the farmer muſt conſider at what time of the ſpring his graſs will be fit to maintain them and their lambs, and whether he has turneps to do it till the graſs comes; for very often both the ewes and lambs are deſtroyed by the want of food; or if this does not happen, if the lambs are only ſtunted in their growth by it, it is an accident that they never recover. The ewe goes twenty weeks with lamb, and according to this it is eaſy to calculate the proper time. The beſt time for them to yean is in April, unleſs the owner has very forward graſs, or turneps, or the *ſheep* are field-*ſheep*, where you have not encloſures to keep them in, then it may be proper they ſhould yean in January, that the lambs may be ſtrong by Mayday, and be able to follow the dam over the fallows, and water furrows; but then the lambs, that come ſo early, muſt have a great deal of care taken of them, and ſo indeed ſhould all other lambs at their firſt falling, elſe, while they are weak, the crows and magpies will peck their eyes out.

When *ſheep* are turned into fields of wheat or rye to feed, it muſt not be too rank firſt, for if it be, it generally throws them into ſcowerings. Ewes that are big ſhould be kept but bare, for it is very dangerous to them to be fat at the time of their bringing forth their young. They may be well fed indeed, like cows, a fortnight beforehand, to put them in heart. *Mortimer*'s Huſbandry, p. 243.

The feeding *ſheep* with turneps is one great advantage to the farmers, from the crops they raiſe of them: they ſoon fatten upon them, but there is ſome difficulty in getting them to feed on them; the old ones always refuſe them at firſt, and will ſometimes faſt three or four days, till almoſt famiſhed, but the young lambs fall to at once.

The common way, in ſome places, of turning a flock of *ſheep* at large into a field of turneps, is very diſadvantageous, for they will thus deſtroy as many in a fortnight as would have kept them a whole winter. There are three other ways of feeding them on this food, all of their ſeveral advantages.

The firſt way is to divide the land by hurdles, and allow the *ſheep* to come upon ſuch a portion only at a time, as they can eat in one day, and ſo advance the hurdles farther into the ground daily, till all be eaten. This is infinitely better than the former random method, but they never eat them clean even this way, but leave the bottoms and outſides ſcooped in the ground; the people pull up theſe indeed with iron crooks, and lay them before the *ſheep* again, but they are commonly ſo fouled with the creature's dung and urine, and with the dirt from their feet, that they do not care for them; they eat but little of them, and what they do, does not nouriſh them like the freſh roots.

The ſecond way is by encloſing the *ſheep* in hurdles, as in the former, but in this they pull up all the turneps they ſuppoſe the *ſheep* can eat in one day, and daily remove the hurdles over the ground, whence they have pulled up the turneps: by this means there is no waſte, and leſs expence, for a perſon may in two hours pull up all thoſe turneps; the remaining ſhells of which would have employed three or four labourers a day to get up with their crooks out of the ground, trodden hard by the feet of the *ſheep*; and the worſt is, that as in the method of pulling up firſt, the turneps are eat up clean; in this way, by the hook, they are waſted,

the *ſheep* do not eat any great part of them, and when the ground comes to be tilled afterwards for a crop of corn, the fragments of the turneps are ſeen in ſuch quantities on the ſurface, that half the crop at leaſt ſeems to have been waſted.

The third manner is to pull up the turneps, and remove them in a cart or waggon to ſome other place, ſpreading them on a freſh place every day; by this method the *ſheep* will eat them up clean, both root and leaves. The great advantage of this method, is, when there is a land not far off which wants dung more than that where the turneps grow, which perhaps is alſo too wet for the *ſheep* in winter, and then the turneps will, by the too great moiſture and dirt of the ſoil, ſometimes ſpoil the *ſheep*, and give them the rot. Yet ſuch ground will often bring forth more, and larger turneps than dry land, and when they are carried off, and eaten by the *ſheep* on plowed land in dry weather, and on green ſward in wet weather, the *ſheep* will ſucceed much the better; and the moiſt ſoil, where the turneps grow, not being trodden by the *ſheep*, will be much fitter for a crop of corn, than if they had been fed with the turneps on it. The expence of hurdles, and the trouble of moving them, is ſaved in this caſe, and this will counterbalance at leaſt the expence of pulling the turneps, and carrying them to the places where they are to be eaten. They muſt always be carried off for oxen. *Tull*'s Horſehoeing Huſbandry.

The uſe of ſalt preſerves *ſheep* from the rot. The animals muſt be made to take a ſmall handful of it two or three times in a few days, without permitting them to drink any thing for ſome hours afterward. *Boyle*'s Works abridged, Vol. 1. p. 109.

Folding of SHEEP. See the article FOLDING.

SHEEP*'s dung*. This is one of the beſt manures we know. It ſucceeds better upon cold clayey lands, than any other dung whatever; but as it is not ſo conveniently to be collected as the dung of larger animals, it is commonly conveyed to the land, it is intended for, by folding the *ſheep* upon it. The urine, as well as the dung, is thus given to the land, and is of very great advantage; but the farmer always ſhould plow in this ſort of manure as ſoon as he can, for the ſun ſoon robs it of a great part of its virtue.

In Northamptonſhire they begin to fold the *ſheep* upon the lands that they would dung by them, after the month of July, and the drier the lands are, the later they fold them. In Flanders they make many thouſand loads of manure annually from their *ſheep:* they cover the bottom of the folds conſiderably deep with ſome light and ſpungy earth, and when this has received the dung and urine of the animals for ſeven or eight days, they remove it, and lay freſh in its place: the earth thus impregnated, becomes an excellent improvement to land, and they raiſe large crops by means of it, in places where very little could be expected without it. In England we have a contrivance like this, which is the covering the bottoms of the folds deep with ſand, and changing it once in a week, or thereabouts: this is a kind of manure finely calculated for clayey lands, both the ſand, and this peculiar kind of dung, being appropriated things for it. *Mortimer*'s Huſbandry.

SHEEP*-noſe-worms*, in natural hiſtory, a ſpecies of fly-worm, found in the noſes of *ſheep*, goats, and ſtags, and produced there from the egg of a large two-winged fly.

The frontal ſinuſes above the noſe in *ſheep*, and other animals, are the places where theſe *worms* live, and attain their full growth. Theſe ſinuſes are always full of a ſoft white matter, which furniſhes theſe *worms* with a proper nouriſhment, and are ſufficiently large for their habitation; and when they have here acquired their deſtined growth, and come to the ſtate in which they are fit to undergo their changes for the fly-ſtate, they leave their old habitation, and falling to the earth, bury themſelves there; and when theſe are hatched into flies, the female, when ſhe has been impregnated by the male, knows that the noſe of a *ſheep*, or other animal, is the only place for her to depoſit her eggs, in order to their coming to good. *Reaumur*'s Hiſt. Inſ. Vol. 4. p. 552.

Mr. Valliſnieri, to whom the world owes ſo many diſcoveries in the inſect claſs, is the firſt who has given any true account of the origin of theſe *worms*. Though their true hiſtory had been, till that time, unknown, the creatures themſelves were very early diſcovered, and many ages ſince were eſteemed great medicines in epilepſies.

It is very common to find only one *worm* in the head of the creature that has them, often two are found, and ſometimes three, but very ſelom any more than that. *Reaumur*, ibid. p. 554.

Redi has given a very imperfect figure of this creature, nor is that of Mr. Valliſnieri much better. The *worm* is of the firſt claſs, and has two brown hooks at the anterior part of its head, placed parallel, or nearly parallel to one another. It is compoſed of eleven rings, which together form a conic figure, ſomething flatted, of which the head of the *worm* is the point. When the *worm* is young, it is very white, but has two brown ſpots placed over againſt each other, in the hinder part of its body, which are its two poſterior ſtigmata. Each of theſe ſpots is parted into two by a concentric circle, which is ſenſible, as it is whitiſh, the reſt of the ſpot being brown. It is plainly this very ſeparation which gives paſſage to the air. When the creature pleaſes it ſhews theſe, but it can alſo draw them into a ſort of purſe in its poſterior ring. The anus is juſt below, and is uſually hid by the folds of the ſkin. The hooks are brown and ſtrong; juſt above theſe are two little fleſhy horns, and between them is placed the mouth. *Reaumur*, ibid. p. 555.

This *worm*, when at its full growth, is conſiderably large, and becomes browniſh, or of a dirty white. Its belly, examined by the microſcope, is ſeen furniſhed with a number of fine ſhort prickles between the rings: the points of all theſe are turned backward, and one may even feel theſe prickles, in drawing the finger along the belly from the hinder part toward the head.

Theſe *worms* are capable of moving themſelves very ſwiftly; and it is doubtleſs owing to their motions in the head of the creature, and to the pain that the ſenſible membranes there muſt have from being wounded by the hooks and prickles of this creature, that *ſheep* are often ſeen to grow outragious, and ſtrike their heads againſt trees, and other hard bodies. Ibid. p. 556.

When theſe *worms* are taken out of the heads of *ſheep*, if they are put upon the earth, they immediately bury themſelves very deeply in it; and if not, yet at their full growth, or in a proper ſtate for their changes, they die there: but if it be near the time that they would naturally have quitted their antient habitation, which may be known by their being changed from their fine white to a browniſh colour, then they undergo all their proper changes under a ſhell, made by the hardening of their own ſkin. This ſhell is of the ſame ſhape with the animal itſelf, but is of a deep brown. Ibid. p. 557.

It takes ſome time for the creature to undergo its ſeveral changes, and that more or leſs, according to the ſeaſon. Mr. Valliſnieri had one produced in the perfect fly-ſtate, after forty days from the time of its firſt change. Mr. Reaumur found thoſe, which formed their ſhell on the twenty fourth of April, not to produce the fly before the twenty ſeventh of June. Ibid. p. 558.

The creature, when ready to appear in the fly-ſtate, has no great difficulty in the getting out of its caſe; the ſwelling and inflating its head, and throwing out its bladder, which is the practice of theſe creatures on this occaſion, eaſily detaches a piece of the ſhell, originally looſe, and gives the fly a ſufficient paſſage.

The fly, produced from this worm, has all the time of its life a very lazy diſpoſition, and does not like to make any uſe either of its legs or wings. Its head and corcelet togegether are about as long as its body, which is compoſed of five rings, ſtreaked on the back; a pale yellow and brown are there diſpoſed in irregular ſpots; the belly is of the ſame colours, but they are there more regularly diſpoſed, for the brown here makes three lines, one in the middle, and one on each ſide, and all the intermediate ſpaces are yellow. The wings are nearly of the ſame length with the body, and are a little inclined in their poſition, ſo as to lie upon the body; they do not, however, cover it, but a naked ſpace is left between them. The ailerons, or petty wings, which are found under each of the wings, are of a whitiſh colour, and perfectly cover the balancers, ſo that they are not to be ſeen without lifting up theſe. The upper part of the corcelet is full of ſmall black prominences, which, when examined by the microſcope, appear as ſo many corns of gunpowder. Its head is large, in proportion to the ſize of the body, and its reticular eyes are of a deep changeable green. Theſe eyes take up leſs ſpace in the head, than thoſe of moſt other flies; they leave a conſiderable ſpace between them, and in that are placed the three ſmaller, or gloſſy eyes, which are placed in form of a ſmall triangle, and ſtand ſo near, as to touch one another. The reſt of the upper part of the head is yellowiſh, and viewed by the microſcope, appears cavernous like a ſpunge, or morel, and in the bottom of each of theſe ſmall cavities is a little black prominence. There are two other hollows in the anterior part of the head, in which the antennæ are placed: theſe are of the battledoor form, but rather round than flat, and have each a large hair going from them. The under part of the head, which is rounder than the upper, is whitiſh, and very ſmooth; it has two ſorts of bands directed downward, which are the elongations of the rims of the arches where the antennæ are lodged. The ſmoothneſs of the underpart of the head makes one ſee very diſtinctly theſe three little tubercles; the upper one brown, the under ones of a pale deadiſh yellow. The mouth of the fly ſeems to be placed between theſe, immediately under the upper tubercle. Ibid. p. 559, 560.

The fly will live two months, after it is firſt produced from the ſhell, but will take no nouriſhment of any kind; and poſſibly it may be of the ſame nature with the butterflies, which never take any food during the whole time of their living in that ſtate. Ibid. p. 561.

SHEEP-*ſtealing*, is now made felony without benefit of clergy. See the article CATTLE.

The like penalty is enacted for killing *ſheep*, with an intent to ſteal the fat, or any part of the carcaſe, or for aſſiſting in any ſuch offence. Stat. 14 Geo. II. cap. 6. ſect. 1.

SHEERS, aboard a ſhip, a name the ſeamen give to two maſt's yards, or poles, ſet up and ſeized acroſs each other aloft, near the top. This pair of *ſheers*, as they call it, is placed below on the chain-wales of the ſhrouds, and laſhed faſt to the ſhip's ſide, to keep them ſteady aloft. Their uſe is to ſet in, or take out a maſt; for which end there is faſtened at the place where they croſs one another, a ſtrong double block with a ſtrap. They ſerve alſo to hoiſe in or out, of boats that have maſts, ſuch goods as are wanted to be taken in or out.

SHEER-*water*, in zoology, an Engliſh name for a bird common on our coaſts, and not known by any of the common authors, nor honoured with a Latin name. It is nearly of the ſize of a duck. Its head, which is large, neck and back, are of a browniſh black; its throat, breaſt and belly, white; its legs are red. Its three fore toes are connected by a membrane, but its hinder one is looſe. Its wings are very long, and when folded reach to the end of the tail. Its beak is ſtrong and ſharp, and is hooked at the end. It flies very ſwiftly along the ſurface of the water, whence it has its name. *Ray*'s Ornitholog. p. 252.

SHEET, in the manege. See CAPARASON, *Cycl.*

SHEIK, in the Oriental cuſtoms, the perſon who has the care of the moſques in Egypt; his duty is the ſame as that of the imams at Conſtantinople. There are more or fewer of theſe to every moſque, according to its ſize or revenues. One of theſe is head over the reſt, and anſwers to a pariſh prieſt with us, and has under him, in large moſques, the readers, and people who cry out to go to prayers; but in ſmall moſques the *ſheik* is obliged to do all this himſelf. In ſuch it is their buſineſs to open the moſque, to cry to prayers, and to begin their ſhort devotions at the head of the congregation, who ſtand rank and file in great order, and make all their motions together. Every Friday the *ſheik* makes an harangue to his congregation. *Pocock*'s Egypt. p. 171.

SHEIK-*bellet*, the name of an officer in the Oriental nations. In Egypt the *ſheik-bellet* is the head of a city, and is appointed by the paſha. The buſineſs of this officer is to take care that no innovations be made, which may be prejudicial to the port, and that they ſend no orders which may hurt the liberties of the people. But all his authority depends on his credit and intereſt, not his office: for the government of Egypt is of ſuch a kind, that often the people of the leaſt power by their poſts have the greateſt influence; and a caia of the janizaries, or Arabs, and ſometimes one of their meaneſt officers, an oda-baſha, finds means, by his parts and abilities, to govern all things. *Pocock*'s Egypt, p. 163.

SHELF, (*Cycl.*) a term uſed by the miners, in many parts of England, to expreſs a diſtinction of the inner ſtructure of the earth, ſo little known to philoſophers, that they have no word to expreſs it by. Theſe workmen ſometimes alſo expreſs it by the term *faſt ground*, or *faſt country*. What they mean by this, is, that part of the earth, which they find lying even, and in an orderly manner, and evidently having retained its primitive form and ſituation, unmoved by the waters of the general deluge, while the circumjacent, and upper ſtrata, have plainly been removed, and toſſed about.

It is evident to reaſon, that there muſt have been a very violent concuſſion of the ſuperficial part of the earth, in the time of its being covered by the waters of the deluge; and experience as much evinces this as reaſon. Before this concuſſion it appears probable, that the uppermoſt ſurface of mineral veins, or loads, did in moſt places lie even with the then ſurface of the earth. The remains of this ſurface, found at different depths in digging, the miners expreſs by the word *ſhelf*.

In this concuſſion of the waters covering the whole earth, its natural ſurface, together with the uppermoſt ſurface of thoſe mineral veins, were then in many places looſened, and torn off; and the earth, and with it the mineral nodules, called *ſhoad-ſtones*, were carried down with the deſcending waters from hills into the adjacent valleys, and ſometimes into the ſtreams of rivers, by which they were waſhed to yet greater diſtances from their original place. On this depends the method of training mines. Philoſoph. Tranſ. N° 69. See the article TRAINING.

SHELL (*Cycl.*)—SHELL-*fiſh*, *conchylia*. The world has for a long time wanted a regular method of claſſing of *ſhell-fiſh*, which a late author of the French nation has attempted, upon a new and very valuable plan. In this he throws aſide the vulgar diſtinction of *ſhells*, into the ſea, freſh water, and land kinds, and very judiciouſly arranges all under the ſame claſs, which have the ſame general characters.

The *ſhells* are all naturally to be arranged under three principal claſſes; theſe will contain all the ſpecies, and are afterwards to be divided into a number of families, or genera, and under theſe the ſeveral ſpecies regularly recounted; and at the end of each deſcription, the varieties may be added.

The firſt general claſs of *ſhells* contains thoſe which are found all of one piece, or have only one *ſhell*, not a pair. Theſe have been called by the Greeks *monothyræ*, and by the Latin authors *univalvia*, univalves.

The ſecond general claſs contains thoſe *ſhells* which are of two pieces, called *bivalves*, ſuch as oiſters, cockles, and the like. See Tab. of Shells, paſſim.

The third claſs contains thoſe which are compoſed of more than two pieces. Theſe are called *multivalves*; and of this kind are the pholas and balanus.

This method takes in the freſh-water-*ſhells*, as well as thoſe of the ſea; and as thoſe hitherto known are all of one or other of the firſt claſſes, their ſeveral ſpecies will be compriſed among, or after the ſea *ſhells* of each of thoſe claſſes.

The land-*ſhells* are of two kinds, the recent and the foſſile; the firſt kind, as far as hitherto known, are all univalves, and the latter are of all the three claſſes.

As each of theſe general claſſes contains a very great number of ſpecies, it may ſeem difficult to enter on this ſtudy, from the multiplicity of the bodies; but method renders all this eaſy, and it is no way difficult, in the following manner, to find of what claſs, what family, and what genus, any given *ſhell* is, from a bare inſpection.

The *ſhell* is firſt to be examined, to ſee whether it is compoſed of one, two, or more pieces. If it is found to conſiſt only of one piece, it is known thence to belong to the claſs of univalves; if of two, to the bivalves; and if of more, to the multivalves. When it is thus referred to its proper claſs, its family and genus will be found by farther examination of its general form, and the ſhape of its mouth, or aperture.

As ſoon as a given *ſhell* is found to be univalve, the five genera of that claſs are to be uſed in compariſon with it, in order to ſee to which of them it belongs. If it has no turn or twiſt, but forms one ſimple figure, approaching to a cone, and pointed at the top in the manner of the common limpet, or patella, it is known to be of the family of the *patellæ*; the character of which is to have only one valve, and that fixed in its natural ſtate to a ſtone, or other hard body, and of a flatted ſhape, though elevated into a ſort of point in the middle.

If the *ſhell* be not conic, but extremely flat, and ſomewhat of the ſhape of a man's ear, it is of the ſecond family of the *aures marinæ*, diſtinguiſhed by the epithet *planæ*, flat or plane. If it forms a tube or pipe, it is of the nature of the common *tubuli marini*, and is of that family. If, on the other hand, it reſemble a ſort of veſſel or boat, it is of the *nautilus* claſs, and belongs to the *naviculæ*.

Theſe are the diſtinctions, if it be plain, and without turnings; but if it have ſeveral twiſts, or wreaths, its aperture, commonly called the *mouth*, is to be examined, for this forms, in this caſe, the generical character. If the mouth be exactly round, the *ſhell* is of that family of the *cochleæ*, or ſnails, called by the antients *lunares*. If it be of a ſemicircular figure, it is of that family of ſnails called *ſemilunares*; under which family are compriſed the *neritæ*, as one genus.

If the *ſhell* approaches to a conic figure, and grows larger at the baſe, and has a flatted or oval mouth, it is of a ſeventh order of *cochleæ*, or ſnails diſtinguiſhed by the title *cochleæ ore depreſſo*.

If the *ſhell* have the exterior figure of a trumpet, and has a large tail, it belongs to the family of the *buccina*; of which, however, it is to be remarked, that there are ſome ſpecies which have not long tails: in this diſtinction we alſo have recourſe to the mouth, which is larger than that of the murex, leſs long, and its lower part is formed into a crooked beak. Theſe are the eſſential characters which diſtinguiſh this family of *ſhells*; a family, concerning which there is great confuſion among authors.

If the baſe of the *ſhell* be ſmall, and the whole diminiſh gradually in ſize from this to the end, which is pointed, then the *ſhell* is of the family of the *turbines*. If a *ſhell* form a cone, or cornet, there is no occaſion to look at the mouth, this figure alone determines it to be a *voluta*; and if one of its extremities is nearly as large as the other, it is then a rhombus. This genus of *ſhells* has been called *cylindri* by the Latins, and *rouleaux* by the French. When this rhombus, or cylinder, has a pointed baſe, frequently ornamented alſo with ſeveral ſmall eminences; and when its middle is large, and is in the ſame manner ſurrounded with tubercles, and its head is elongated by ſeveral turns, and its mouth of an oblong figure, and furniſhed with teeth; and when, as is often the caſe, there is an excreſcence of the plate that covers the mouth, called by authors an *ala*, or wing, this *ſhell* muſt be placed among the family of the *murex*, or, as the French call it, the *rocher*.

The *purpura* is diſtinctly not a ſynonymous term with the precedent, but expreſſes ſuch a *ſhell*, which, inſtead of being furniſhed with points, is cut and curled from top to bottom, in the manner of the leaves of our curled cabbages, or of the endive raiſed for ſallads. The body in this genus is alſo more compact, and more detached from the other parts,

parts, than in the other genera of this kind, and the mouth is uſually ſmall and round, and the tail long and crooked, furniſhed with long points, and hollowed within in form of a pipe.

If the *ſhell* is round, it belongs to that family of *ſhell-fiſh* called, from their figure, *globoſæ*, and in French *tonneaux*. It is to be obſerved, however, that all *ſhells*, which appear at firſt ſight of a rounded figure, are not to be placed at once in this family; for the helmet *ſhell*, for inſtance, which appears roundiſh, though ſomewhat triangular, is not to be ſuppoſed of this family, but is a murex. The ſummit of the head, and the little tuberoſities, on this occaſion, give the eſſential character, and point out its proper genus: for the *ſhells* of the globoſe kind are truly of a ſpherical figure; they are inflated in the middle, have no tubercles on the head, and have a large and hollowed mouth, but no teeth.

The laſt family of the univalves is the porcelain, or *concha veneris*, a genus ſo well known, that it needs no particular deſcription. Sometimes at the ſummit of this *ſhell* there is a ſmall ſpiral, and ſometimes its opening is not exactly in the middle. Some are light and thin, others very thick and hard: but theſe are only varieties of the ſame genus, the proper family of the *ſhell* being always thus determined by the mouth.

Bivalve SHELLS. The former are all the genera of the *ſhells* compoſed of one piece, and thence called *univalves:* and as any given *ſhell* may, by the characters given of each, be eaſily referred to that to which it belongs, ſo, in regard to the *bivalves*, the taſk is not more arduous, when entered on upon the ſame principles; and it is the eaſier in this reſpect, that the families of this claſs are much leſs numerous than thoſe of the other, theſe being only ſix. The firſt genus, or family of the *bivalves*, is that of the *oiſter*, *oſtreæ*. The variety in this one genus is almoſt infinite, and is extremely agreeable. Some are echinated ſo, as to repreſent the echini; others have excreſcences of parts in undulatory, or jagged forms, repreſenting the ears of animals, or the comb of a cock; and others form themſelves into very remarkable figures, by adhering and growing to trees, ſtones, corals, and other ſubſtances, either naturally growing in the ſea, or ſuch as have accidentally fallen into it. Sometimes alſo, the upper *ſhell* in an oiſter is ſmaller and flatter than the under one. Theſe, however, are all trifling varieties, and the *ſhells* are ſtill of the oiſter kind.

When the *bivalve ſhells*, under examination, differs from the oiſter kind, in being more elevated in the middle, and equally convex, or nearly ſo, in both *ſhells*, then it belongs to the family under the name of *chamæ*. Theſe differ alſo from oiſters, in that they are more ſmooth on the ſurface, and they often do not cloſe ſo evenly and regularly at the mouth, whence ſome have called them *conchylia ore patulo, et hianti*.

The third family is that of the *muſcles*. Theſe are all of the general ſhape of the common muſcle, and are thence eaſily known. It is to be obſerved, however, that ſome of them are equal at both ends; theſe are called *tellinæ:* and ſome others are extremely long at one end, and broad and ſhort at the other; theſe are called *pinnæ marinæ*.

The fourth genus, or family, is the cordiform kind, called in French *cœurs*. The eſſential character of this family is, that the *ſhells* are of a roundiſh elevated figure, and that they have no ears, as the pectens have, and they always repreſent the figure of a heart, in whatever view they are taken; tho' this is ſometimes of a triangular figure. Moſt of the ſpecies of this family, as well as of the following one of the pectens, are ſtriated.

The fifth family of the *bivalves*, is that of the *pectens*, or ſcallop-*ſhells*. Among theſe, ſome have two ears at the head of the *ſhell*; others have only one ear; and others have none at all. Some ſpecies are deeply furrowed, and others are full of ſmall protuberances. The general character of the pectens is to have the upper *ſhell* plain, and the under one ſomewhat hollow; and the ears are alſo a very obvious character in thoſe that have them.

The ſixth, and laſt family of the *bivalves*, is the *ſolen*, or razor-fiſh, called by the French *manche de couteau*. Theſe are very eaſily known by their figure, which reſembles that of a knife-haft, and therefore need no other mark of diſtinction.

Multivalve SHELLS. Theſe are not leſs eaſily diſtinguiſhed, than the other two general claſſes, into their ſeparate families. Of theſe alſo there are ſix families. The firſt is that of the *echini marini*, called in Engliſh *ſea-eggs*, and by the French *ourſins*, *boutons*, and *heriſſons de mer*. Theſe carry a very obvious diſtinction, in their being covered with ſpines, or prickles; and if we meet with them in a ſtate, when theſe are fallen off, they are ſtill eaſily known by the marks of their inſertion. This, and their general figure, which is alike in all, and in all unlike to all other ſpecies, is ſuch a diſtinction, as cannot ſuffer them to be miſtaken.

The ſecond family of theſe, is that of the *vermiculi marini*, particularly characterized in the ſpecies called the *ſea-organ*. Theſe are uſually of a beautiful red colour, and are of a very elegant ſtructure. They generally are found in very large cluſters, and are eaſily diſtinguiſhed from all other genera.

The third family of the *multivalves* conſiſts of the *balani marini*, called by the French *glands de mer*. Theſe are all ſo like one another, that they are eaſily known from all the other genera, by their all reſembling the common balanus, a *ſhell* too well known to need deſcription.

The fourth family is that of the *pollicipedes*, or, as the French call them, the *pouſſepieds*. Theſe are ſo eaſily known by their perfect reſemblance to one another, that there needs no other character than referring to their figure in the plate of *ſhells*.

The fifth family of the *multivalves* is that of the *conchæ anatiferæ*. Theſe were once ſuppoſed to produce a bird of the gooſe kind; and theſe are all ſo like to one another, that the referring to the figure of the common ſpecies, in the general plate, will ſhew the characters of all the ſpecies.

Finally, the ſixth genus of the *multivalves* is that of the *pholas*. Theſe *ſhells* are eaſily diſtinguiſhed by their figure, which is uſually oblong, and their colour, which is ſimply white in all the ſpecies. Theſe *ſhells* are often found encloſed in ſtone in the ſea, and ſome of them are compoſed of five valves.

By theſe characters it will be eaſy for an utter ſtranger to theſe ſtudies, to refer any *ſhell*, he occaſionally meets with, to its proper claſs and family. When this is done, it will be eaſy to obſerve the leſſer differences, which, though not ſufficient to conſtitute different families or genera, yet very well diſtinguiſh different ſpecies of the ſame genus, or family; and by comparing theſe with the names of the ſeveral ſpecies, to be found enumerated under the head treated of, in the name of that genus or family to which the *ſhell* is found to belong, it will be ſoon diſcerned whether, and which of theſe ſpecies it is of, or whether agreeing with none of thoſe names, it is a new ſpecies. In order to enquire into theſe ſpecific differences, it is neceſſary attentively to conſider the exterior parts of the *ſhell*, its figure, its mouth, its volutions, its alæ, and its ſmoothneſs or roughneſs, and its two extremities, the end of the clavicle, and the mouth. After the exterior parts have been thus examined, the interior ones muſt be taken into conſideration, as the length and hollow of the mouth, and whether it be furniſhed with teeth, or with ridges; and whether it have a chamber, or a tongue within.

In regard to *bivalves*, when the ſpecies are to be diſtinguiſhed, we muſt obſerve whether the two valves are equal, or unequal in ſhape and ſize; whether one is, or is not more elevated than the other; and whether theſe valves are ſmooth, or are covered with wrinkles and tuberoſities, or points; whether they have, or have not ears; and whether their ſtriæ are charged with points, or tubercles, or are plain and ſmooth on the ſurface; and finally, whether they are longitudinal, or tranſverſe, and whether the ends of the *ſhells* are even, or are terminated by a point, or beak.

The inſides are next to be obſerved, to find whether the *ſhells* naturally cloſe evenly and exactly, or whether they remain naturally open; and whether the fiſh is affixed to them by a ſingle ligament, as is the common caſe, or by ſix regular muſcles, as the ſea-muſcle does.

The mouth of a *ſhell* generally diſtinguiſhes it from others, but there are ſome ſpecies in which recourſe muſt be had to the other external parts of the *ſhell:* and we are not to be puzzled, on finding in the ſame family ſome ſmall differences in the figure of the mouth, as its being longer in one ſpecies, and wider in another; the one ſpecies having a tail, and the other not; the one having a ſummit elevated very high, the other flatted at the top; or, laſtly, the one being ſmooth, and the other covered with tubercles, do not prevent both from being of the ſame family, when the general characters are the ſame. Theſe then only diſtinguiſh the ſpecies and genera of the ſame family, which are to be placed one after another in the deſcriptions of it.

The ſpecies are diſtinguiſhed, when the generical characters being the ſame, one *ſhell* is umbilicated, another is not; one ſmooth, another rough, and ſo on. The varieties of the ſeveral *ſhells*, which are very numerous, and have by many been taken for real ſpecies, are diſtinguiſhed by leſs eſſential differences; ſuch as the ſize, the length, and the thickneſs of the *ſhell*, the difference of the colours, and the depth, or ſlightneſs of the furrows.

It may not be amiſs to explain all this in ſome one family of *ſhells*, in which there are many different genera, ſpecies, and varieties. When the buccinum, for example, has a long or a ſhort mouth; when its clavicle, or pyramid, is long, or is flatted; or when its beak is ſtrait, or crooked; theſe are the marks of genera, being very great and eſſential characters, and each of them belonging in common to a great number of *ſhells*, which are to be called ſpecies, and are to be diſtinguiſhed from one another only by ſome epithet, expreſſive of their ſlighter differences. Thus if the ſurface is ſmooth, it is called *buccinum læve*; if rough, *buccinum tuberoſum*; if it imitate a ſpindle, it is called *fuſus*; if it be of the figure of a tower, it is called *turris*; and if of a tiara, it is called *mitra papalis*. The varieties are after this diſtinguiſhed by their proper epithets; the white, red, or yellow, are ſo called, and the large and ſmall diſtinguiſhed by thoſe words

added

added to their name: and in this manner are all the claſſes to be ſubdivided.

In the examination of the freſh-water *ſhells*, the ſame method is to be obſerved, and the ſame characters enquired into; but theſe are a much leſs numerous ſeries of *ſhells*; we know of only ſeven families of the freſh water *univalves*, and there are only three families of *bivalves*, and not one of the *multivalve* claſs, ſo far as is yet known.

The land-*ſhells* are alſo to be diſtinguiſhed by the very ſame terms. The living land-*ſhells* conſtitute but a very few genera, and the foſſile ones being remains of marine bodies, are the ſame with the ſpecies found at ſea; only there are many ſpecies, and ſome whole genera of theſe, which we never find recent, or living at preſent: theſe are probably the inhabitants of the deep ſeas, and therefore never can come within our ſight at preſent. The univerſal deluge, which ſo overturned the whole face of the earth, might eaſily bring things from the deepeſt ſeas into our way, and bury them in the hearts of yet ſoft and unformed rocks, and leave them there as laſting memorials of that dreadful cataſtrophe. All theſe, however, are ſo nearly allied to the ſeveral genera of the ſame families found recent, that it is eaſy to reduce them to their proper places. Hiſt. Natur. Eclairc. Part 2. p. 126, ſeq.

There are alſo many kinds of *ſhelly* animals which live on land, not in the ſea-water, or in the freſh rivers or ponds. Of theſe we have ſeveral very elegant ſpecies.

It might be imagined that we had no land-*ſhells* of the limpet, or patella kind, but nature does afford ſuch. Fabius Columna gives the figure of a ſpecies of land-limpet, which he found living on the galls and protuberances of a myrtle in Italy. The *ſhell* of this ſpecies is of an aſh-colour, and is divided into ſeveral ſquares, in the manner of the tortoiſe-ſhell: they have in ſome places a purpliſh tinge, mixed with grey, and are no newly diſcovered animal, ſince Theophraſtus deſcribes them as being found on the protuberances of the fig tree.

Of the land-*ſnails* we have fifteen abſolutely diſtinct ſpecies. 1. The great round *ſnail*, called the *pomatia*. 2. The common great garden-*ſnail*. 3. The faſciated *ſnail*. 4. The common meadow-*ſnail*. 5. The yelloviſh *ſnail*. 6. The grey *ſnail*. 7. The marbled *ſnail*. 8. The land Saint Hubert's horn *ſnail*. 9. The umbilicated *ſnail*. 10. The *ſnail* with an elevated clavicle. 11. The land-*ſnail* with a dentated mouth. 12. The elegant land-*ſnail* of Jamaica. 13. The round mouthed land-*ſnail*. 14. The land-*ſnail* with a flatted mouth. 15. The land-*ſnail* with a twiſted clavicle.

Of the land-*buccina* we have the following ſpecies. 1. The yellow *buccinum* with ſix ſpires. 2. The *buccinum* with five ſpires. 3. The cheſnut-*buccinum* with ſix ſpires. 4. The *trochilus* with ſeven ſpires. 5. The *buccinum* with ten ſpires, and with the mouth turned the wrong way. And 6. the ſeven-ſpired *buccinum*, with its mouth turned the wrong way.

Of the *turbo*, or ſcrew *ſhell*, there is only one known ſpecies. Of the *dolia* we have, 1. the alated *dolium*. 2. The oblong *dolium*. Theſe are all the land *ſhell* animals found living at this time.

The common *ſnails* are never found crawling about, but in wet ſeaſons, or in the morning, while things are covered with dew. They hide themſelves in dry days, when the ſun is up, under the leaves of trees and plants, or in holes in the ground. In the winter they are never ſeen creeping about, but as that ſeaſon approaches, they hide themſelves in holes of walls, and in the cracks in the trunks of trees; and at this time their mouth is covered with a thin film.

The anus of the *ſnail* is an aperture in the neck, very little diſtant from the mouth, ſo that it takes in its nutriment, and voids its fæces very nearly in the ſame part. This is in general the caſe in the univalve *ſhell* animals; and in this they differ greatly from the bivalves, which have the anus in the oppoſite part of the body to that where the mouth is placed.

Every *ſnail* has four horns, two large, and two ſmall ones, and at the end of theſe ſtand ſmall black tubercles, which are the eyes. Hooke, in his Micrographia, ſays that they have nine teeth, and adds, that he had ſeen a common *ſnail* eat a leaf of a roſe-buſh.

The land-*buccina* have no operculum, but they cover themſelves, when withdrawn into the *ſhell*, with a ſort of ſlaver, which they void at the mouth. Theſe alſo have a long head, on which ſtand two pair of horns, a greater and a ſmaller pair, with eyes at the end of each. They are principally found on fruit. Their excrements are black, and are of a twiſted form. When the *ſhell* is broken, and taken off, they are found to conſiſt of a fleſhy body, formed of as many ſpires as the *ſhell* was formed of.

The land-*dolia* are very beautiful, their *ſhells* are ſo thin and tranſparent, that the body of the animal is ſeen through them. The mouth of this *ſhell* is very large, and when the creature moves, it thruſts out the whole body, ſo that the *ſhell* is empty, and it is then that its thinneſs and tranſparence are moſt viſible.

The number of land-*ſhells* is greatly encreaſed by ſome, who ſuppoſe ſeveral ſpecies of buccina, and other genera, to be land-*ſhells*, becauſe they are extremely thin and tender, and, as they ſuppoſe, wholly unfit for being in the ſea. But this is a groundleſs conjecture, and againſt all appearances. The reaſon drawn from the thinneſs of the *ſhell* is inſufficient; ſince we may recollect, that the *nautilus papyraceus*, and the *gondola-ſhell*, are both much thinner than any of theſe ſuppoſed land-*ſhells*, and yet theſe are both very well known to be ſea, and not land-*ſhells*.

Figures and colours of SHELLS. The variety in the figure, colours, and other characters of ſea-*ſhells*, is almoſt infinite. The number of diſtinct ſpecies we find in the cabinets of the curious is very great, and doubtleſs the deep bottoms of the ſea, and the yet unſearched ſhores, contain multitudes more, yet unknown to us. Even the ſame ſpecies differ in ſome degree in almoſt every individual, ſo that it is rare to find any two *ſhells* which are alike in all reſpects. *Bonan.* Recreat. Ment. et Ocul. p. 49.

This wonderful variety, however, is not all the produce of one ſea, or one country, the different parts of the world afford us their different beauties. Bonani obſerves, that the moſt beautiful *ſhells* we are acquainted with come from the Eaſt-Indies, and from the Red ſea. This is in ſome degree countenanced by what is found to this day; and from the general obſervations of the curious, it ſeems that the ſun, by the great heat that it gives to the countries near the line, exalts the colours of the *ſhells* produced there, and gives them a luſtre and brilliancy, that thoſe of colder climates always want: and it may be, that the waters of thoſe vaſt ſeas, which are not ſubject to be weakened by freſh rivers, give a nouriſhment to the fiſh, that may add to the brilliancy of their *ſhells*.

The ſhores of Aſia furniſh us with the pearl-oiſters and ſcallops in great perfection. About Amboina are found the moſt beautiful ſpecimens of the cabbage-*ſhell*, the arroſoir, the ducal mantle, and the coral-oiſters, or echinated oiſters. Here alſo are found a great variety of extremely beautiful muſcles, tellinæ, and volutæ; ſome fine buccinums, and the *ſhell* called the *Ethiopian crown*, in its greateſt perfection. The dolia, the murices, and the caſſandræ, are alſo found on theſe coaſts in great beauty. Many elegant ſnails and ſcrew-*ſhells* are alſo brought from thence; and finally the ſerapion and ſpider-*ſhells*. Hiſt. Nat. Eclairc. p. 168.

The Maldive, and Philippine iſlands, Bengal, and the coaſt of Malabar, abound with the moſt elegant of all the ſpecies of ſnails, and furniſh many other kinds of *ſhells* in great abundance and perfection. China abounds in the fineſt ſpecies of porcelain-*ſhells*, and has alſo a great variety of beautiful ſnails. Japan furniſhes us with all the thicker and larger bivalves; and the Iſle of Cyprus is famous, above all other parts of the world, for the beauty and variety of the patella, or limpet, found there.

America affords many very elegant *ſhells*, but neither in ſo great abundance nor beauty, as the ſhores of Aſia. Panama is famous for the cylinders, or rhombi; and we have beſide, from the ſame place, ſome good porcelains, and a very fine ſpecies of dolium, or *concha globoſa*, called, from this place, the *Panama-purple-ſhell*. One of the moſt beautiful of the cylinders is alſo known among our naturaliſts, under the name of the *Panama-ſhell*. About Braſil, and in the Gulf of Mexico, there are found murexes and dolia of extreme beauty; and alſo a great variety of porcelains, purpuræ, pectens, neritæ, bucardiæ, or heart-*ſhells*, and elegant limpets. The Iſle of Caienne affords one of the moſt beautiful of the buccinum-kind, and the Midas-ear is found principally about this place. Jamaica, and the Iſland of Barbadoes, have their ſhores covered with porcelains, chamæ, and buccina; and at St. Domingo there are found almoſt all the ſame ſpecies of *ſhells* that we have from the Eaſt-Indies, only they are leſs beautiful, and the colours more pale and dead. The pearl-oiſter is found alſo on this coaſt, but ſmaller than in the Perſian gulf. At Martinico there are found, in general, the ſame *ſhells* as at St. Domingo, but yet leſs beautiful. About Canada are found the violet chamæ, and the lakes of that country abound with muſcles of a very elegant pale blue, and pale red colours; ſome ſpecies of theſe are remarkably light and thin, others are very thick and heavy.

The Great Bank of Newfoundland is very barren in *ſhells*, the principal kind found there are muſcles of ſeveral ſpecies, ſome of which are of conſiderable beauty. About Carthagena there are many mother of pearl-*ſhells*, but they are not of ſo brilliant colours as thoſe of the Perſian gulf. The Iſland of Magellan, at the ſouthern point of America, furniſhes us with a very remarkable ſpecies of muſcle, called by its name; and ſeveral very elegant ſpecies of limpets are found there, particularly the pyramidal.

In Africa, on the coaſt of Guinea, there is a prodigious quantity of that ſmall ſpecies of porcelain, which is uſed there as money; and there is another ſpecies of porcelain on the ſame coaſt, which is all over white. The women make bracelets of theſe, and the people of the Levant adorn their hair with them.

The coaſt of Zanguebar is very rich in *ſhells*. We find there a vaſt variety of the large porcelains, many of them of great beauty; and the *nux maris*, or ſea-nut, is very fre-

quent there. Beſide theſe, and many other *ſhells*, there are found on this coaſt all the ſpecies of nautili, many of which are very beautiful.

The Canary iſles are found to abound with a vaſt variety of the murexes, and ſome other good ſhells; and we have, from Madeira great variety of the echini marini, or ſea-eggs, different from thoſe of the European ſeas. Several ſpecies of muſcles are alſo common there, and the auris marina is no where more abundant.

The Red Sea is beyond all other parts of the world abundant in *ſhells*, ſcarce any kind is wanting there; but what we principally have from thence are the purpuræ, porcelains, and echini marini.

The Mediterranean and northern Ocean contain a great variety of *ſhells*, and many of very remarkable elegance and beauty; they are upon the whole, however, greatly inferior to thoſe of the Eaſt-Indies. The Mediterranean abounds greatly more in *ſhells* than the Ocean. The gulf of Tarentum affords great variety of purpuræ, of porcelains, nautili, and elegant oiſters; the coaſts of Naples and Sardinia afford alſo the ſame, and with them a vaſt number of the ſolens of all the known ſpecies. The iſland of Sicily is famous for a very elegant kind of oiſter which is white all over; pinnæ marinæ and porcelains are alſo found in great plenty there with tellinæ and chamæ of many ſpecies, and a great variety of other beautiful *ſhells*. Corſica is famous, beyond all other places, for vaſt quantities of the pinnæ marinæ, and many other very beautiful *ſhells* are found there. *Liſter*, Hiſt. Conchyl.

About Syracuſe are found the gondola-*ſhell*, the alated murex, and a great variety of elegant ſnails, with ſome of the dolia and neritæ.

The Adriatic ſea or gulf of Venice is leſs furniſhed with *ſhells* than almoſt any of the ſeas thereabout. Muſcles and oiſters, of ſeveral ſpecies, are however found there, and ſome of the cordiformes or heart-*ſhells*; there are alſo ſome tellinæ. About Ancona there are found vaſt numbers of the pholades buried in ſtone, and the aures marinæ are particularly frequent about Puzzoli. *Bonani* Recreat. Ment. et Ocul.

The ports of Marſeilles, Toulon, and Antibes, are full of pinnæ marinæ, muſcles, tellinæ and chamæ. The coaſts of Bretagne afford great numbers of the conchæ anatiferæ and pouſſepieds, they are found on old rotten boards, on ſea-plants, and among cluſters of ſpunges. The other ports of France, as Rochelle, Dunkirk, Breſt, St. Malos, and others, furniſh oiſters, excellent for the table, but of the common kind, and of no beauty in their *ſhells*; great numbers of muſcles are alſo found there; and the common tellinæ, the onion-peel-oiſters, the ſolens and conchæ anatiferæ are alſo frequent there. At Granville, in Lower Normandy, there are found very beautiful pectens, and ſome of the cordiforms, or heart-*ſhells*. Our own Engliſh coaſts are not the leaſt fruitful in *ſhells*, though they do not produce ſuch elegantly painted ones as the Indies.

About Plymouth are found oiſters, muſcles, and ſolens in great abundance; and there, and on moſt of our other ſhores are numbers of the aures marinæ and dentalia, with pectens, which are very excellent food; and many elegant ſpecies of the chamæ and tellinæ are fiſhed up in the ſea, about Scarborough, and other places.

Ireland affords us great numbers of muſcles, and ſome very elegant ſcallop-*ſhells* in great abundance, and the pholades are frequent on moſt of our ſhores. We have alſo great variety of the buccina and cochleæ, ſome volutæ, and on the Guernſey coaſt a peculiarly beautiful ſnail, called thence the Guernſey-ſnail.

The coaſts of Spain and Portugal afford much the ſame ſpecies of *ſhells* with the Eaſt-Indies, but they are of much fainter colours, and greatly inferior in beauty. Hiſt. Nat. Eclairc. p. 172.

There are according to Tavernier and others ſome rivers in Bavaria, in which there are found pearls of a fine water. About Cadiz there are found very large pinnæ marinæ and ſome fine buccina. The iſles of Majorca and Minorca afford a great variety of extremely elegant *ſhells*. The pinnæ marinæ are alſo very numerous there, and their ſilk is wrought into gloves, ſtockings, and other things. The Baltic affords a great many beautiful ſpecies, but particularly an orange-coloured pecten, or ſcallop-*ſhell*, which is not found in any other part of the world.

The freſh-water-*ſhells* are found much more frequently, and in much greater plenty than the ſea-kinds. There is ſcarce a pond, a ditch, or a river of freſh water, in any part of the world, in which there are not found vaſt numbers of theſe *ſhells* with the fiſh living in them. All theſe *ſhells* are ſmall, and they are of very little beauty, being uſually of a plain greyiſh or browniſh colour. Our ditches afford us chamæ, buccina, neritæ, and ſome patellæ; but the Nile, and ſome other rivers, furniſhed the antients with a ſpecies of tellina, which was large and eatable, and ſo much ſuperior to the common ſea-tellina in flavour, that it is commonly known by the name of *tellina regia* the royal tellina. We have a ſmall ſpecies of buccinum common in our freſh waters, which is very elegant, and always has its operculum in the manner of the larger buccina; a ſmall kind of muſcle is alſo very common, which is ſo extremely thin and tender, that it can hardly be handled without breaking to pieces. The large freſh-water-muſcle, commonly called in England the *horſe-muſcle*, is too well known to need a deſcription, and the ſize of this, gives it a difference from all other freſh-water-*ſhells*.

Formation of SHELLS. The world, in general, has been much more inquiſitive, into the nature of the colours, and marks of the great variety of *ſhell*-fiſh, than what might appear much more worthy of enquiry, the manner of their production. It has been generally ſaid, that theſe *ſhells*, and thoſe of crabs and lobſters, which are of the cruſtaceous kind, were a ſort of bones, all of which in theſe creatures are placed by nature on the outſide of the body.

It has been ſuppoſed that both the *ſhell* and the body of the animal are produced from the ſame egg, and that the one developes and enlarges as the other does. But this, though a ſpecious reaſoning, does not ſeem to be the true ſtate of the caſe. On the contrary, it ſeems, as if the animal alone is produced from the egg, or contained in it, and that the production of the *ſhell* is a future piece of workmanſhip.

Mr. Reaumur is the firſt author who has publiſhed an account of the true production of *ſhells*, and has been at vaſt pains to make the neceſſary obſervations for this purpoſe. He obſerved, that the *ſhell* of the common garden-ſnail was plainly made of a viſcous matter, which tranſpired from the body of the creature in a liquid form, and hardened by degrees on contact with the air.

It is very well known that all animals continually perſpire, and are ſurrounded with a ſort of atmoſphere of their own, which is of the figure of their body; and all that is ſingular in the perſpiration of ſnails, is, that this atmoſphere of theirs hardens about them, till it forms a ſort of ſtony caſe, which being moulded upon their body muſt be of the ſame ſhape; while that of other animals, in general, diſſipates itſelf, and is loſt among the ambient air; and this difference plainly ariſes wholly from the nature of the matter perſpired, which in the ſnail is of a viſcous, and as it were a ſtony nature. It is evident, that this *ſhell* therefore is not at all of the nature of the bones of animals, being neither formed as they are, nor yet as any other parts of an animal body, but merely by an appoſition of particles: ſo that we have here an inſtance of a part of an animal body, which borrows its manner of formation from the ſtones, and other parts of the foſſile world. The head of the ſnail is always at the mouth or opening of the *ſhell*, and its tail at the other extremity, or as we uſually expreſs it, at the top of the *ſhell*; and the body of the ſnail from whatever cauſe, naturally turning itſelf into a ſpiral, gives origin to the volutæ of the *ſhell*.

When the ſnail is juſt hatched naked from the egg, and is in its utmoſt degree of ſmallneſs, it does not ceaſe to tranſpire, and immediately there is formed a *ſhell*, ſuited to its preſent ſmall ſtate, and exactly fitting every part of its body, which is yet too tender to twiſt itſelf into a ſpiral, ſo that this *ſhell* is only the center of that ſpiral, which is afterwards to be formed on that center, with a little part of the ſpiral proceeding from it. The animal after this grows, and if it now ceaſed to perſpire, it muſt be a neceſſary conſequence that the future part of the body muſt be naked. This, however, is not the caſe: it continues to perſpire, and every part of the body, as it is formed, becomes covered with the ſame ſhelly cruſt made by the hardning of that newly perſpired matter, as it comes in contact with the air. The body of the ſnail, in growing, turns itſelf round the firſt point, and afterwards round that again, ſo there is ſpiral upon ſpiral formed, and at the ſame time the *ſhell* is formed in the ſame ſhape to cover them. The other turns of the *ſhell* are afterwards formed juſt in the ſame manner, and theſe in the garden-ſnail ſometimes run as far as to the number four and an half.

It is a neceſſary conſequence of this manner of formation of theſe *ſhells*, that the firſt circles of a young ſnail, which has not yet above two of them, are of juſt the ſame ſize with the two firſt turns of a grown ſnail, which has four in the whole; for whatever part of the *ſhell* has been once formed, becomes ſubject to no increaſe in ſize afterwards in itſelf, but all the addition to it is made by the continual joining on of more new formed *ſhell* to its extreme edges. There is, however, an addition of matter to the inſides of theſe, to give them a greater ſtrength afterwards; for it may always be obſerved, that though theſe firſt turns, or ſpiral wreathes, in a young ſnail, are of the ſame ſize with thoſe in a more grown one, yet they are thicker afterwards by much than they are at firſt. The new grown part of the animal, which would otherwiſe have been naked, thus forms itſelf a covering by its perſpiration, to which the already covered part adds thickneſs and ſtrength.

In the common ſmaller and more beautiful garden-ſnails, the ground colour of the *ſhell* is uſually yellowiſh, whitiſh, or reddiſh, and is variegated with rays or lines of black, following

lowing the trace of the wreath. The neck of the growing ſnail is the part which principally forms the *ſhell*; this is always naked, and is always making itſelf a covering, which, while the neck grows beyond it, ſerves for the next part. Now if we ſuppoſe this neck to be yellow, with one black ſpot in a particular part; or rather, that it all over exſudates a yellow liquor, except in ſome one ſpot, where it exſudates a black one; then it neceſſarily follows, that as the growth of the animal is performed in a ſpiral line, and the *ſhell* made accordingly, while the yellow matter makes a wreath of yellow *ſhell* ſurrounding the former, the black part muſt alſo be drawn in the ſame ſpiral form, as we ſee a ſpiral line of that colour in the wreath. And accordingly, if there be more points than one of this kind, then there muſt be more rays or lines alſo in the *ſhell*; and if theſe points are of different colours, then the rays formed by them will be alſo of different colours; neither are theſe black points, or ſpots, to be treated as a mere conjecture; they in reality ever appear upon the animal; and if a growing ſnail be nicely inſpected, they are always found placed juſt even with the black lines, or rays, which are carrying round the *ſhell*.

The part of the body of the ſnail which immediately follows the neck, and fills up that part of the *ſhell* it has juſt formed, diſcharges neither a yellow nor a black liquor, but only a thin aqueous whitiſh humour; this condenſing on the inſide of the new formed *ſhell* coats it over, and forms its inner covering, which therefore is always whitiſh, and has no varieties of colour.

It will be very eaſy for every naturaliſt to extend what is here related of the common garden ſnail to all the other animals which are covered in the ſame manner with *ſhells*; and the differences of colour in the matter tranſpired through the neck of the growing animal, with the different number and diſpoſition of the variegating points or dots on it, may give ſufficient room to account for all the beautiful variety of colours, and all the variegations in the moſt elegant ſea-*ſhells*.

The other varieties of them may alſo be accounted for upon the ſame principle; thus, ſuppoſe the growing fiſh of one kind has a number of eminencies on its body, there cannot fail to be prominences of the ſame kind in the *ſhell* that is formed by the regular tranſpiration of its juices; and theſe will go on regularly, enlarging to the end of the *ſhell*, becauſe the prominences which form them will grow larger in the animal as it grows. If there be any certain ſeaſon of the year when the *ſhell* ceaſes to grow, that is when the animal ceaſes to enlarge its body, ſuppoſe this to be the ſummer or the winter, or whatever particular ſeaſon; in this caſe, the traces of the different times of the creature's beginning to grow again, will not fail to be marked upon the *ſhell*; and the age of the *ſhell* might, if theſe times were known, be perhaps, in many caſes, as well determined by theſe ſeveral junctions of new to the old matter, as trees are known by their annual concentric circles. Thus we ſee, that theſe tender animals are themſelves the architects of theſe their elegant habitations, which are ſo beautifully regular, merely becauſe they grow as it were with the body of that architect, whoſe different age and ſtate of life, if perfectly underſtood, they would be found elegantly to denote. Mem. Acad. Par. 1709.

The durable hardneſs and excellent poliſh of many of the *ſhells* of ſea-fiſhes, and that even in the thinneſt and tendereſt kinds, is a thing very amazing. In the ruins of the abbey of St. Edmundſbury, which is built of a kind of ſtone compoſed of grit or ſand, interſperſed with an infinite variety of very minute *ſhells*, principally of the ſmall ſmooth cockle-kind, Mr. Collinſon obſerved, that the ſtone having ſuffered greatly by the injuries of the air, the grit or ſand of which it was compoſed had diſunited and mouldered away, while the ſmalleſt of theſe *ſhells* ſtood the ſame injurious accidents unaltered, and were found ſtanding forth in the utmoſt perfection, and with all their beautiful natural poliſh; yet theſe are as thin and tender a *ſhell* as almoſt any of the ſame ſize that we know of.

It is poſſible, indeed, that theſe *ſhells* might have been altered in their nature, by the inſinuation of ſtony matter into their pores, as is a common caſe in *ſhells* lodged in ſtone; but thoſe, here mentioned, did not ſeem to have undergone any ſuch alteration; and it is very certain, that many of the like thin and tender *ſhells* are found preſerved through a long ſeries of ages, in places where they have been in the way of no ſuch alterations from the inſinuation of ſtony matter into their pores, and out of which they are taken fair and beautiful, and with all their natural poliſh, though not at all hardened in the time. Of this kind are the *ſhells* of the tender buccinums, and other thin kinds, found buried in earth, in the ſtrata of marl, clay, or loam, and even in chalk.

As hard as theſe *ſhells* naturally are, they do not, however, preſerve the fiſh, which inhabit them, from becoming the food of others, which ſeem to have no organs with which to break them. It is common to ſee the ſoal-fiſh with its belly prominent and hard, as if well filled with ſpawn, and yet when opened to find no ſpawn at all; but the prominence and hardneſs is occaſioned by the ſtomach and guts being filled with *ſhell*-fiſh, which the creature had ſwallowed whole, as food, without having any power of breaking or deſtroying them. A ſmall ſpecies of pectunculus, or cockle, is the fiſh that the ſoal uſually feeds upon; and when the guts are taken out of this fiſh, they often reſemble ſo many ſtrings of necklaces, from the continued ſeries of theſe *ſhells* which appear prominent in them. When theſe *ſhells* are taken out, many of them are uſually found in part diſſolved, and many entire and unaltered.

Shell-fiſh are well known to be the food of ſome other fiſhes of the larger kinds, particularly the ſea-porcupine, and a kind of the wray-fiſh, are known principally to feed upon them; but theſe fiſh are provided by nature, with a ſuitable apparatus fitted for the grinding, or reducing them into a ſtate more proper for digeſtion; their jaws being furniſhed with bony ſubſtances, extending to the palate and under part of the mouth, which are capable of reducing much ſtronger *ſhells* than theſe into an abſolute pulp. The ſoal-fiſh has no apparatus of this kind, and neither its jaws nor ſtomach are furniſhed with any thing capable of wearing them to pieces by attrition; but what appears to be the caſe, is, that nature has furniſhed this creature with a menſtruum in the body capable of digeſting them. Phil. Tranſ. N° 473. p. 39.

The crab, like the lobſter, *&c.* caſts its *ſhell* once every year. Againſt this extraordinary event, the creature always chooſes a cloſe and well ſecured retreat in the cavities of rocks, or under great ſtones; there they creep in, and wait till all the parts are by degrees diſengaged, which is effected by withdrawing their legs from their old *ſhells*, and leaving them and the upper part of their body *ſhell* behind. In this naked ſtate they make a very ſtrange appearance, being a mere ill-ſhapen lump of a fleſhy matter, covered with a ſort of jelly; this by degrees hardens into a *ſhell*, a degree larger than the old one caſt off. Phil. Tranſ. N° 478. Sect. 14.

Poliſhing of SHELLS. See the article POLISHING.

Foſſile SHELLS. The number and variety of ſea-*ſhells* which are found far from ſeas buried at great depths in the earth, and often immerſed in the hardeſt ſtones, is an object of great wonder.

Of theſe ſome are found remaining almoſt entirely in their native ſtate, but others are variouſly altered by being impregnated with particles of ſtone, and of other foſſiles; in the place of others there is found mere ſtone, or ſpar, or ſome other native mineral body, expreſſing all their lineaments in the greateſt nicety, as having been formed wholly from them, the *ſhell* having been firſt depoſited in ſome ſolid matrix, and thence diſſolved by very ſlow degrees, and this matter left in its place, on the cavities of ſtone and other ſolid ſubſtances, out of which *ſhells* had been diſſolved and waſhed away, being afterwards filled up leſs ſlowly with theſe different ſubſtances, whether ſpar or whatever elſe: theſe ſubſtances, ſo filling the cavities, can neceſſarily be of no other form than that of the *ſhell*, to the abſence of which the cavity was owing, though all the nicer lineaments may not be ſo exactly expreſſed. Beſide theſe, we have alſo in many places maſſes of ſtone formed within various *ſhells*; and theſe having been received into the cavities of the *ſhells* while they were perfectly fluid, and having therefore nicely filled all their cavities, muſt retain the perfect figures of the internal part of the *ſhell*, when the *ſhell* itſelf ſhould be worn away, or periſhed from their outſide. The various ſpecies we find of theſe are in many genera, as numerous as the known recent ones; and as we have in our own iſland not only the *ſhells* of our own ſhores, but thoſe of many other very diſtant ones, ſo we have alſo many ſpecies, and thoſe in great numbers, which are in their recent ſtate, the inhabitants of other yet unknown or unſearched ſeas and ſhores. The cockles, muſcles, oiſters, and the other common bivalves of our own ſeas are very abundant: but we have alſo an amazing number of the nautilus kind, particularly of the nautilus græcorum, which though a *ſhell* not found living in our own, or any neighbouring ſeas, yet is found buried in all our clay-pits about London and elſewhere; and the moſt frequent of all foſſile *ſhells*, in ſome of our counties, are the conchæ anomiæ, which yet we know not of in any part of the world in their recent ſtate. Of this ſort alſo are the cornua ammonis and the gryphitæ, with ſeveral of the echinitæ and others.

The exact ſimilitude of the known *ſhells* recent and foſſile in their ſeveral kinds, will by no means ſuffer us to believe, that theſe, though not yet known to us in their living ſtate, are as ſome have idly thought, a ſort of luſus naturæ. It is certain, that of the many known ſhores, very few, not even thoſe of our own iſland, have been yet carefully ſearched for the *ſhell*-fiſh that inhabit them; and as we ſee in the nautilus græcorum an inſtance of *ſhells* being brought from very diſtant parts of the world to be buried here, we cannot wonder that yet unknown ſhores, or the unknown bottoms of deep ſeas, ſhould have furniſhed us with many unknown *ſhell*-fiſh, which may have been brought with the reſt; whether that were at the time of the general deluge, or the effect of any other cataſtrophe of a like kind, or by whatever other means, to be left in the yet unhardened matter of our ſtony and clayey ſtrata. *Hill's* Hiſt. of Foſſ. p. 616.

The vaſt beds of foſſile *ſhells*, buried in many parts of the world, are not uſeleſs matter, but will ſerve to one of the greateſt purpoſes of huſbandry, the manuring of barren lands. The people of many parts of France, and in ſome places in our own country, dig up the maſſes of broken *ſhells*, connected into a ſort of ſtrata by marly, or other earths, for this purpoſe; and ſpreading them upon the lands as dung, they ſoon moulder away, and are found extremely beneficial to the earth.

Mr. Reaumur, deſirous of knowing in what manner theſe fragments of *ſhells* fertilized land, at firſt conjectured that they did the ſame as the various ſpecies of marls, diſſolving wholly away in time, and entering into, and fattening the earth; and carried it ſo far, as to believe that the common marls were a ſort of earth, which owed its origin merely to ſuch fragments of *ſhells* more perfectly diſſolved, and conſequently, that the rain and air, in ſome ſort, converted theſe *ſhells* into marl upon the earth. But he was ſoon convinced of the error of this opinion, by the experience of the peaſants, from whom he found that there was marl in the ſame pits whence they dug theſe *ſhells*, and that they uſed it alſo as manure, but to lands of a very different kind; thoſe which received benefit from the marl being always injured by the *ſhells*, and, on the contrary, thoſe which were meliorated by the *ſhells*, receiving no benefit from the marl. It might naturally enough be ſuppoſed that the ſalts, contained in theſe foſſile *ſhells*, helped to fertilize the earth, in the ſame manner with the ſalts of the common ſea-plants, which are uſed as manure in many places. It is not impoſſible, but that the ſalts may indeed have their uſe in the whole, but the great good theſe *ſhelly* fragments do to the lands they are uſed on, is to be explained in a much eaſier manner, when the nature of the lands, on which they are employed, is conſidered.

Theſe are uſually cold clayey lands, on which nothing can grow but heath, and a few uſeleſs weeds, the common plants not ſhooting in any ſtrength or perfection upon them; and they are always very wet upon the ſurface after any little rain, their texture being ſo cloſe and compact, that the water cannot penetrate into them, as it does into the ſpongy texture of the common fertile lands. This ſort of manure, which is very light, and is no other than a maſs of broken, and as it were half calcined *ſhells*, mixing with this earth, breaks its particles, and occaſions a multitude of voids and little cavities in it, which reduce it to ſomething like the common ſtate of other earth, and the rain penetrates it as it does other mould.

The effects of this ſort of manure are very laſting; a land well ſtrewn with theſe *ſhells* is manured for twenty years, and the rain no longer wets its ſurface only, but penetrates its ſubſtance, and moiſtens the roots of plants ſown in it. Theſe find alſo an eaſier paſſage, and penetrate to a proper depth; while the ploughman finds no leſs the benefit, his plough now eaſily turning up an earth, which before it was ſcarce able to cut. Some have imagined, indeed, that all theſe effects are owing to the ſalts in the *ſhells* operating in the manner of thoſe of dung, and by that means breaking the connections of the more minute molecules; but ocular examination will ſhew the *ſhells* to act, in this caſe, merely as particles of hard matter of that ſize and hardneſs, and to do no more than fragments of ſtone of the ſame ſize would do: and the peaſants are well acquainted with this, as they find it neceſſary to dung thoſe lands, which they have before manured with *ſhells*, in the ſame manner as they do any others.

There are in many foreign countries, as well as in our own, lands of ſuch a nature, that they never will become fertile, unleſs a large quantity of ſand is diſperſed over them. Theſe lands are all of the ſame nature with thoſe on which the farmers find their manure of *ſhells* to take effect. The ſand, and this manure of *ſhells*, evidently act upon the ſame principle, in meliorating land, which is only by dividing its parts when naturally too compact; but the *ſhells* are qualified to do it greatly the better of the two, becauſe they are in themſelves ſo conſiderably lighter. Somewhat analogous to this ſort of manure, is that of the throwing pebbles and rough fragments of ſtone on ſome earths, which are naturally tough and compact in a great degree. It is the general practice in huſbandry to take off all the ſtones, as far as it can be done, from the lands; but theſe ſoils are apt to crack, and burſt open in dry ſeaſons, and the more ſtones are mixed in them, the leſs they are obſerved to crack, and what cracks they have, are always the ſmaller and ſhorter. The earth is, by theſe ſtones, divided into ſo many ſeparate parcels, that no very large and continued cracks can be formed; and always is the more fruitful, the more ſtones it has upon it, provided that they be not too large.

The manure of *ſhells*, upon theſe lands, does not produce nearly ſo great an effect for the two firſt years, as it does in the ſucceeding ones; the reaſon of which is, that it is not then ſufficiently mixed, but in ſucceeding time it breaks itſelf into a number of very ſmall particles, and theſe all become intimately blended with the molecules of earth, and produce their effect more perfectly.

It is well known, that the *ſhells* of the common garden-ſnails always become calcined, as it were, in ſome degree, by lying in the earth; this becomes very friable, and may be mouldered to powder between the fingers: and the caſe is juſt the ſame in regard to theſe ſea-*ſhells*; they, by their long abode in the earth, are thus calcined, and happily for the farmer are reduced to a ſort of coarſe powder, the particles of which are juſt of ſuch a ſize, as may properly ſerve for the dividing and breaking the little clods of earth, and forming in the whole certain voids and ſpaces, juſt as large as they could be wiſhed, in order to give roots, and moiſture to ſwell them, an eaſy paſſage. And as theſe pieces of *ſhells* are not expected to act as bodies containing active principles, but merely as inert particles of matter, ſo long as they retain their form, that action will not be impeded; and notwithſtanding all the rude ſhocks they receive from the plough, and other inſtruments of huſbandry, they retain this their form without any great alteration for a long time, and therefore the operation of ſtrewing them on any piece of land, needs not to be repeated in twenty, or ſometimes in thirty years.

The manner in which the effects of this *ſhell*-manure wear off at length, will be eaſily ſeen, if parcels of earth, manured with it at different diſtances of time, be examined, by waſhing away the earth with water; the fragments of *ſhells*, left from the waſhing of earths of different years from the time of their being added to them, will be found growing ſmaller and ſmaller every year, till at length they make only a fine powder, mixing every way equally with the earth, and no longer opening its texture, or dividing its molecules, and it is then that theſe lands require a freſh quantity of it.

This breaking of the particles of the *ſhells* is not to be determined by any regular rule, as to time, but differs from a number of accidents; and accordingly the farmer cannot ſay when he ought to renew the work, till he finds that the fertility it occaſioned decreaſes. The ſize of the fragments in their original beds makes a great difference, the largeſt uſually, and as might naturally be ſuppoſed, laſting the longeſt; but beſide this, they are more or leſs calcined in the earth, and even according to the nature of that earth, upon which they are laid.

Mr. Reaumur concludes this uſeful account of theſe ſubſtances, by obſerving, that it is much more eaſy to account for the manner of their acting upon land, than for the manner of their coming where they are found. It has been the favourite ſyſtem of our Dr. Woodward, that all theſe *ſhells* were the remains of the univerſal deluge, which having overflowed the whole earth, might eaſily leave them in all places; but Mr. Reaumur has much more rationally accounted for their coming to thoſe parts of France, where they are found at this time in ſuch vaſt abundance, by carefully tracing the courſe of the beds of them ſo far as known there, and eaſily proving, that all that extent of country, under which they are found, may have been once overflowed by the ſea, without a deluge; it being the very track that a large body of waters, let in at one part of the kingdom, muſt have taken, in order to getting out at another. Mem. de l'Acad. Par. 1720.

Arabian-SHELL, a name given by ſome to a ſpecies of porcelain *ſhell*, not becauſe it is found on the coaſt of Arabia, but becauſe its lines and variegations are ſuppoſed to repreſent the figures of Arabic characters.

Aurora-SHELL, in natural hiſtory, a very remarkable ſpecies of *ſhell*-fiſh, found in cabinets of the curious. It is of the figure of a bird, having a head, wings, and tail, and is of a flame-colour. It owes much of its beauty, however, to art and accident. The *ſhell* is an oiſter of a peculiar variation of figure from the common one; the head of the bird is the cardo, or hinge; the wings are the body of the *ſhells*; and the tail is a peculiar proceſs, like that of the marteau, only ſingle. See MARTEAU.

It is naturally of a duſky brown on the outſide, and pearly within, but when its rough coat is taken off, it appears of this beautiful flame-colour.

Center-SHELL, in natural hiſtory, a name given to the balanus marinus, a kind of ſea-*ſhell*, of the multivalve kind with an open mouth, frequently found fixed to the bottoms of ſhips, and other things covered with ſea-water.

China-letter-SHELL, in natural hiſtory, a name given by many to that ſpecies of chama, uſually called by authors the *chama arabica*. It is of a pale browniſh ground, and is variegated with a great number of black lines, which are as ſlender as the ſtrokes of a pen, and are of ſuch odd figures, that they repreſent ſome of the Arabic, or, as others fancy, Chineſe characters. See the article CHAMA.

Ear-SHELL. See the article EAR.

Guinea-SHELL, the Engliſh name for a very beautiful variegated ſpecies of voluta, called by the French *la ſpeculation*. See VOLUTA.

Heart-SHELL. See the article HEART.

Helmet-SHELL, in natural hiſtory, the name of a kind of murex, of which there are ſeveral ſpecies. They all approach

ſome-

ſomewhat toward a triangular figure, and are free from any long ſpines. See MUREX.

Leopard-SHELL, in natural hiſtory, the Engliſh name of the pardus, a kind of voluta; ſo called, from its ſpots reſembling thoſe of a leopard. There are three kinds of this, one ſpotted with black, another with yellow, and another with red.

Leveret-SHELL, in natural hiſtory, a name given by many to a ſpecies of porcelain, reſembling a young hair in colour. See the article PORCELLANA.

Lightning-SHELL, in natural hiſtory, a name given by ſome authors to a ſpecies of murex with variegations on its body, reſembling the pictures we commonly ſee of flaſhes of lightning. See the article MUREX.

Map-SHELL, in natural hiſtory, the name given by ſome to a peculiar ſpecies of porcelain-*ſhell*, the figures on which repreſent the lines on a map. See PORCELLANA.

Noah's ark-SHELL. See the article NOAH.

Oiſter-SHELL. See the article OISTER.

Old wife-SHELL, the name given by ſome to that ſpecies of chama, which the French alſo have called *vielle ridée*. See the article VIELLE *ridée*.

Onion-SHELL. See the article OSTREA.

Pipe-SHELL, in the materia medica. See ENTALIUM.

Saddle-SHELL, in natural hiſtory, the name of a ſpecies of oiſter, which in ſome degree repreſents a ſaddle in its ſhape. See the article OSTREA.

St. James's SHELL, in natural hiſtory, a name given by writers on *ſhells* to a very beautiful ſpecies of variegated pecten. See the article PECTEN.

St. Michael's SHELL, in natural hiſtory, a name given by authors to a ſpecies of pecten, or ſcallop-*ſhell*. It is of a bright yellow colour. See PECTEN.

Scorpion-SHELL, in natural hiſtory, the name of a ſpecies of murex, very much approaching to the nature of the ſpider-*ſhell*. This is a common *ſhell* in cabinets. It is of a yellow colour, and very deeply ridged, and full of tubercles; there ariſe from the lip of the *ſhell* five large ſpines, or, as they are uſually called, fingers, and two others, which are very much bent, the one from the head, the other from the tail: theſe are very elegantly radiated with white and a fine violet colour on the lips. See the article MUREX.

Screw-SHELL. See the article TURBO.

Small-pox-SHELL, in natural hiſtory, a name given to a remarkable kind of concha venerea, or porcelain-*ſhell*, the protuberances on the ſurface of which are ſuppoſed to repreſent the puſtules of the ſmall-pox. There are two ſpecies of this *ſhell*, the one white with flattiſh protuberances, the other greeniſh with more elevated ones. See the article PORCELLANA.

Snake-SHELL, in natural hiſtory, the name given by many to that beautiful ſpecies of porcelain-*ſhell*, the ſpots of which repreſent thoſe of a ſnake's ſkin. See the article PORCELLANA.

Spider-SHELL, the name of a kind of murex. See the articles ARANCHA, CONCHA, and MUREX.

Strawberry-SHELL, in natural hiſtory, a name given by collectors of *ſhells* to a very beautiful ſpecies of cordiformis, ſpotted with ſmall round red ſpots.

Swallow-SHELL, in natural hiſtory, the name given by authors to a ſpecies of oiſter, which in ſome degree repreſents the figure of a ſmall bird flying. See OSTREA.

Swan-SHELL. See the article CIGNE.

Tiger-SHELL, in natural hiſtory, the name of a ſpecies of porcelain, or concha venerea, ſuppoſed to repreſent the ſpots on a tiger's ſkin. See PORCELLANA.

Trumpet-SHELL. See the article TRUMPET.

Turban-SHELL. See the article TURBAN.

Turnep-SHELL. This is a ſpecies of ſea-*ſhell*, by others called the *radiſh-ſhell*. It is exactly of the ſhape of a turnep, and is of the dolium, or concha globoſa kind. Thoſe who have called it the *radiſh-ſhell*, allude to the great black round-rooted radiſh, not to our common radiſh. See the article DOLIUM.

SHELL-*apple*, in zoology, an Engliſh name for the loxia, or croſsbill; given from his manner of ſplitting an apple, and feeding on the kernels, leaving the *ſhell* of the pulp untouched. *Ray's* Ornitholog. p. 181. See the article LOXIA.

SHELL-*drake*, in zoology, a common Engliſh name for the tadoma. See the article TADOMA.

SHELL-*fiſh*. Theſe animals are in general oviparous, very few inſtances having been found of ſuch as are viviparous. Among the oviparous kinds, anatomiſts have found that ſome ſpecies are of different ſexes in the different individuals of the ſame ſpecies, but others are hermaphrodites, every one being in itſelf both male and female: in both caſes their encreaſe is very numerous, and ſcarce inferior to that of plants, or of the moſt fruitful of the inſect claſs. The eggs are very ſmall, and are hung together in a ſort of cluſters by means of a glutinous humour, which is always placed about them, and is of the nature of the jelly of frogs ſpawn; by means of this they are not only kept together in the parcel, but the whole cluſter is faſtened to the rocks, *ſhells*, or other ſolid ſubſtances, and thus they are preſerved from being driven on ſhore by the waves, and left where they cannot ſucceed. *Langius*, Method. Teſtac.

SHELL-*gall-inſect*, an inſect of the gall-inſect claſs, ſomewhat reſembling thoſe which are called the boat-faſhioned ones, but differing in this, that as the two ends of that ſpecies are not very different in form, in this kind one of the ends is ſharp and pointed, in compariſon with the other. It has its name of *ſhell-inſect*, from the reſemblance it bears to a muſcle-*ſhell*; as it is, in its whole form, not unlike one of the two *ſhells*, in which the common ſea-muſcle is encloſed, but the pointed end of this *inſect* is much more extended in length, than the ſmaller end of this *ſhell*.

This ſpecies is extremely ſmall, and may be eaſily miſtaken for the minute caſe, out of which ſome ſmall inſect has eſcaped; or in another ſtate, for the neſt in which ſome ſmall inſect had depoſited its eggs: but if the aſſiſtance of the microſcope be called in, they will eaſily be diſcovered to be true gall-inſects, even as ſoon as they are hatched from the eggs. This ſpecies, at its full growth, is ſo ſmall, that it requires good eyes to diſcover it. It is brown, very ſmooth, and poliſhed on the ſurface, and much of the colour of the bark of ſome trees. It has uſually an edge of a cottony matter, viſible where its ſides touch the tree, and its eggs are always depoſited on a fine cottony bed. The young ones are white, flat, and have two ſmall horns, and ſix legs. In this ſtate they are known to be of the gall-inſect claſs; not by their likeneſs to their parent, but to the young gall-inſects of other ſpecies. They march about very briſkly for ſome time after they are hatched, and after that fix themſelves, and then begin to grow, and by degrees alter their form, till they at length are of the ſame ſhape with their parent. *Reaumur*, Hiſt. Inſ. Tom. 4. p. 69, 70.

SHELL-*ſand*, a name given by the farmers, in ſome parts of England, to the fragments of *ſhells* found on the ſea-ſhores, and ground to a ſort of powder, ſo that they reſemble ſand. There is alſo another kind uſed as this is, in ſome parts of Cornwall, and compoſed of fragments of a ſort of tender white coral. This is found principally about Falmouth, and is called by the ſame name of *ſhell-ſand*, though very improperly. All the kinds are of great uſe in agriculture, but they are differently eſteemed by the farmers, as they are more or leſs rich, which they know by their colours. The reddiſh kind is eſteemed moſt of all, next to this the blue is judged the beſt, and after this the white. Such as is dredged up from under the water, is always found better, than ſuch as is found dry on the ſhores; and ſuch as is entirely compoſed of *ſhells* is to be choſen, rather than ſuch as has fragments of ſtone among it, which is a very common caſe.

In Cornwall they uſe this as the general manure of their land; they carry it up in lighters as near the lands, where it is to be uſed, as they can, and thence it is ſometimes carried to the place, where it is to be uſed, by carts, and ſometimes by men with horſes, a horſe being able eaſily to carry thirteen gallons of it at a load. One man drives ſeven or eight of thoſe horſes in a train, and the farmers find it worth their while to carry it ten or twelve mile from the water ſide in this manner. At this diſtance it uſually coſts about eight pence the load, but where the lands lie near the water, the price is very inconſiderable. So much of this *ſand* is uſed in the county of Cornwall, that the land-carriage alone, at this eaſy rate, is found to amount to more than thirty thouſand pounds a year, and the advantages from it is very great; ſo that it is wonderful, that the practice is not extended all over the kingdom where the ſea-coaſts are near. Phil. Tranſ. N° 113.

SHELL-*toothed*, in the manege, an appellation given to a horſe that from five years old to old age naturally, and without any artifice, bears mark in all his fore teeth, and there ſtill keeps that hollow place with the black mark, which is called in French *germe de feve*, i. e. the eye of a bean; inſomuch, that at twelve or fifteen he appears with the mark of a horſe that is not yet ſix: for in the nippers of other horſes, the hollow place is filled, and the mark diſappears, towards the ſixth year, by reaſon of the wearing of the tooth. About the ſame age it is half worn out in the middling teeth, and towards the eighth year it diſappears in the corner teeth: but after a *ſhell-toothed* horſe has marked, he marks ſtill equally in the nippers, the middling, and the corner teeth; which proceeds from this, that having harder teeth than other horſes, his teeth do not wear, and ſo he does not loſe the black ſpot. Among the Poliſh, Hungarian, and Croatian horſes, we find a great many of them hollow-toothed; and generally the mares are more apt to be ſo than the horſes.

SHELTIE, the name of a ſmall, but ſtrong kind of horſe, found in the iſland of Zetland, commonly called *Shetland*. In the country, the price of one of theſe horſes is about a guinea. Phil. Tranſ. N° 473. ſect. 8.

SHERARDIA, in the Linnæan ſyſtem of botany, a diſtinct genus of plants, the characters of which are, that the cup is a ſmall perianthium, divided into four ſegments, ſituated on the germen, and remaining after the flower is fallen. The flower conſiſts of one petal, which is a long cylindric tube, divided into four ſegments at the end; the ſegments are pointed, and the flower placed flatwiſe. The ſtamina are four

four filaments, placed at the upper part of the tube. The antheræ are ſimple. The germen of the piſtil is double, oblong, and placed below the receptacle. The ſtyle is ſlender, and bifid at top; and the ſtigmata are headed. The fruit is an oblong body, ſeparable longitudinally into two ſeeds, which are long, convex on one ſide, and plane on the other, and marked with three points at their ſummit. *Linnæi* Gen. Plant. p. 25.

SHERARDIA is alſo a name given by Pontedera to the genus of plants, called by Linnæus *galenia*. *Ponteder*. Epiſt. 14. See the article GALENIA.

SHERIF, in the Egyptian orders, the relations of Mahomet, the ſame tribe of perſons called *emir* by the Turks.

The word is Perſian, and ſignifies great or noble; and theſe perſons have the privilege of being exempt from appearing before any judge but their own head: and if any of the military orders are obliged to puniſh them for any miſdemeanor, they firſt take off their green turban, in reſpect to their character; and the ſame is done, even when they are puniſhed by their own magiſtrate. *Pocock*'s Egypt, p. 171.

SHIELD (*Cycl.*)—The *ſhield* was that part of the antient armour, on which the perſons of diſtinction in the field of battle always had their arms painted; and moſt of the words, uſed at this time to expreſs the ſpace that holds the arms of families, are derived from the Latin name for a *ſhield*, *ſcutum*. The French *eſcu*, and *eſcuſſion*, and our Engliſh word, *eſcutcheon*, or, as we commonly ſpeak it, *ſcutcheon*, is evidently from this origin; and the Italian *ſcudo* ſignifies both the *ſhield* of arms, and that uſed in war.

The Latin name *clypeus*, for the ſame thing, ſeems alſo to be derived from the Greek word, γλυφειν, to engrave; and it had this name from the ſeveral figures engraved on it, as marks of diſtinction of the perſon who wore it. *Beckman*, Diſſ. 6. cap. 8.

The *ſhield* in war, among the Greeks and Romans, was not only uſeful in the defence of the body, but it was alſo a token, or badge of honour to the wearer, and he who returned from battle without it, was always treated with infamy afterwards.

People have at all times thought this honourable piece of the armour, the propereſt place to engrave, or figure on the ſigns of dignity of the poſſeſſor of it; and hence, when arms came to be painted for families in after-times, the heralds always choſe to repreſent them upon the figure of a *ſhield*, but with ſeveral exterior additions and ornaments, as the helmet, ſupporters, and the reſt. *Niſbet*'s Heraldry, p. 11.

The form of the *ſhield* has not only been found different in various nations, but even the people of the ſame nation, at different times, have varied its form extremely; and among ſeveral people there have been *ſhields* of ſeveral forms and ſizes in uſe, at the ſame period of time, and ſuited to different occaſions. *Baron*'s Heraldry.

The moſt antient and univerſal form of *ſhields*, in the earlier ages, ſeems to have been the triangular. This we ſee inſtances of in all the monuments and gems of antiquity: our own moſt early monuments ſhew it to have been the moſt antique ſhape alſo with us, and the heralds have found it the moſt convenient for their purpoſes, when they had any odd number of figures to repreſent; as if three, then two in the broad bottom part, and one in the narrow upper end, it held them very well; or if five, they ſtood as conveniently at three below, and two above. The other form of a *ſhield*, now univerſally uſed, is ſquare, rounded and pointed at the bottom: this is taken from the figure of the ſamnitic-*ſhield* uſed by the Romans, and ſince copied very generally by the Engliſh, French, and Germans. The Spaniards and Portugueſe have the like general form of *ſhields*, but they are round at the bottom without the point; and the Germans, beſide the ſamnite-*ſhield*, have two others pretty much in uſe: theſe are, 1. The bulging-*ſhield*, diſtinguiſhed by its ſwelling or bulging out at the flanks; and 2. the indented-*ſhield*, or *ſhield* chancrée, which has a number of notches and indentings all round its ſides. The uſe of the antient *ſhield* of this form was, that the notches ſerved to reſt the lance upon, that it might be firm while it gave the thruſt; but this form being leſs proper for the receiving armorial figures, the two former have been much more uſed in the heraldry of that nation.

Beſide this different form of the *ſhields* in heraldry, we find them alſo often diſtinguiſhed by their different poſitions, ſome of them ſtanding erect, and others ſlanting various ways, and in different degrees. This the heralds expreſs by the word *pendant*, hanging, they ſeeming to be hung up not by the center, but by the right or left corner. The French call theſe *ecu pendant*, and the common antique triangular ones *ecu ancien*. The Italians call this *ſcuto pendente*; and the reaſon given for exhibiting the *ſhield* in theſe figures in heraldry is, that in the antient tilts and tournaments, they who were to juſt at theſe military exerciſes, were obliged to hang up their *ſhields*, with their armories, or coats of arms on them, out at the windows and balconies of the houſes near the place; or upon trees, pavilions, or the barriers of the ground, if the exerciſe was to be performed in the field.

Thoſe who were to fight on foot, according to Columbier, had their *ſhields* hung up by the right corner, and thoſe who were to fight on horſeback, had theirs hung up by the left. This poſition of the *ſhields*, in heraldry, is called *couché* by ſome writers, though by the generality *pendant*.

It was very frequent, in all parts of Europe, in arms given between the eleventh and fourteenth centuries. But it is to be obſerved, that the hanging by the left corner, as it was the token of the owner's being to fight on horſeback, ſo it was eſteemed the moſt honourable and noble ſituation, and all the pendant *ſhields* of the ſons of the royal family of Scotland and England, and of our nobility at that time, are thus hanging from the left corner. The hanging from this corner, was a token of the owner's being of noble birth, and having fought in the tournaments before; but no ſovereign ever had a *ſhield* pendant any way, but always erect, as they never formally entered the liſts of the tournament.

The Italians generally have their *ſhields* of arms of an oval form: this ſeems to be done in imitation of thoſe of the popes, and other dignified clergy; but their herald, Petro Sancto, ſeems to regret the uſe of this figure of the *ſhield*, as an innovation brought in by the painters and engravers, as moſt convenient for holding the figures, but derogatory to the honour of the poſſeſſor, as not repreſenting either antiquity, or honours won in war, but rather the honours of ſome citizen, or perſon of learning. Some have carried it ſo far, as to ſay that thoſe, who either have no antient title to nobility, or have ſullied it by any unworthy action, cannot any longer wear their arms in *ſhields* properly figured, but were obliged to have them painted in an oval, or round *ſhield*. In Flanders, where this author lived, the round and oval *ſhields* are in the diſrepute he ſpeaks of; but in Italy, beſide the popes and dignified prelates, many of the firſt families of the laity have them. The ſecular princes, in many other countries, alſo retain this form of the *ſhield*, as the moſt antient, and truly expreſſive of the Roman clypeus. *Niſbet*'s Heraldry, p. 12. *Componille*, Herald.

SHIFTERS, on board a man of war, certain men who are employed by the cooks to ſhift or change the water, in which the fleſh or fiſh is put, and laid for ſome time, in order to fit it for the kettle.

SHILLING (*Cycl.*)—In the year 1560, there was a peculiar ſort of *ſhilling* ſtruck in Ireland, of the value of nine pence Engliſh, which paſſed in Ireland for twelve pence. The motto on the reverſe of theſe, is *poſui deum adjutorem meum*. Eighty two of theſe *ſhillings*, according to Malynes, went to the pound; they therefore weighed twenty grains one fourth each, which is ſomewhat heavier in proportion than the Engliſh *ſhilling* of that time, ſixty two whereof went to the pound, each weighing ninety two grains ſeven eighths; and the Iriſh *ſhilling* being valued at the Tower at nine pence Engliſh (that is one fourth part leſs than the Engliſh *ſhilling*) it ſhould therefore proportionably weigh one fourth part leſs, and its full weight be ſomewhat more than ſixty two grains, but ſome of them found at this time, though much worn, weighed ſixty nine grains. In the year 1598, five different pieces of money of this kind were ſtruck in England for the ſervice of the kingdom of Ireland.

Theſe were *ſhillings* to be current in Ireland as twelve pence each, half *ſhillings* to be current at ſix pence, and quarter *ſhillings* at three pence. Pennies and halfpennies were alſo ſtruck of the ſame kind, and ſent over for the payment of the army in Ireland. The money thus coined was of a very baſe mixture of copper and ſilver, and two years after there were more pieces of the ſame kinds ſtruck for the ſame ſervice, which were ſtill worſe; the former being three ounces of ſilver to nine ounces of copper, and theſe latter only two ounces eighteen pennyweights, to nine ounces two pennyweights of the alloy. *Simon*'s Iriſh Coins.

SHINGLING, in the iron-works, in many parts of England, is the operation of hammering the ſow, or caſt-iron, into blooms. The tongs, uſed for holding the iron in this operation, are called *ſhingling-tongs*, and the iron to be thus wrought is called a *loop*. *Ray*'s Engliſh Words, p. 128. See the articles LOOP and BLOOM.

SHIP (*Cycl.*)—It is highly neceſſary, to the health of ſeamen, that *ſhips* ſhould be cleared of foul air; for it has been found by frequent experience, that air ſhut up, and confined in a cloſe place, without a ſucceſſion and freſh ſupply of it, becomes unwholſome, and unfit for the uſe of life. This is more ſenſibly ſo, if any ſtagnating water be pent up with it. But it grows ſtill worſe, if ſuch an air as this is made uſe of in reſpiration; that is, becomes moiſter and hotter, by paſſing and repaſſing through the lungs. Theſe bad effects in different degrees, according to the different manner in which air is incloſed, are obſerved in many caſes; particularly in deep wells, and caverns of the earth; in priſons, or cloſe houſes, where people are ſhut up with heat and naſtineſs; but moſt of all in large *ſhips*, in which, with the ſtench of water in the hold, many men being crouded up in cloſe quarters, all the mentioned circumſtances concur in producing greater miſchiefs than would follow from any of them ſingle.

Mr. Sutton did therefore, a few years ago, propoſe, in order to clear the holds of *ſhips* of the bad air they contain, that the fire-place and aſh-place of the copper or boiler ſhould be both cloſed up with ſubſtantial and tight iron doors; and that a copper, or leaden-pipe, of ſufficient ſize, ſhould be laid from the hold into the aſh-place, for the draught of air to come in that way to feed the fire. And thus, from the natural elaſticity of the air, it ſeems plain, that there will be from the hold a conſtant diſcharge of the air therein contained; and conſequently, that the air ſo diſcharged muſt be as conſtantly ſupplied by freſh air below the hatches, or ſuch other communications as are open into the hold; whereby the ſame muſt be continually made freſh, and its air rendered more wholſome, and fit for reſpiration. And if into this principal pipe, ſo laid into the hold, other pipes are let in, communicating reſpectively either with the well, or lower decks, it muſt follow, that part of the air, conſumed in feeding the fire, muſt be reſpectively drawn out of all ſuch places, to which the communication ſhall be ſo made. Phil. Tranſ. N° 462. p. 42, 43.

To prevent *ſhips*, whoſe bottoms are worm-eaten, from leaking, this method has been propoſed [b]. Calk well the inſide planks, or lining; then fill the vacant ſpaces between the timbers, and the out and inſide planks with boiling pitch, or reſin, ſo high as the main-gun-deck. The pitch being put in very hot, will run into the ſmalleſt cranny, and make the *ſhip* as tight as a bottle. There will be no room left for vermin, as rats, *&c.* and the pitch will ſerve for other uſes when taken out; therefore the expence will be but ſmall.—[[b] Phil. Tranſ. N° 476. p. 372.]

SHIP *of pleaſure*, among the antients. See the article THALAMEGUS.

SHIP, in the ſalt-works, is a large ciſtern, out of which the ſalt-pans are ſupplied for boiling.

This ciſtern is built cloſe to the ſaltern, and is made either of wood, brick, or clay; and it ought always to be covered with a ſhed, that the ſea water, contained in it, may be kept clean from ſoot, and other impurities, and not mixed with freſh water in rains; and it muſt be always placed ſo high, that the water will eaſily run out of it into the pans, to ſupply them for boiling.

SHIRE (*Cycl.*)—SHIRE-*clerk*, he that keeps the county-court; and his office is ſo incident to that of the ſheriff, that the king cannot grant it away. 4 Rep. *Blount*, *Cowel*.

SHIRE-*man*, was antiently the judge of the *ſhire*, by whom trials for land, *&c.* were determined. Lamb. Peramb. 442. *Blount*.

SHIRE-*mote*, in our old writers, an aſſembly of the county or *ſhire* at the aſſizes, *&c.* *Blount*, *Cowel*. See the article SCYREGEMOT, *Cycl.*

SHIVERS, in a ſhip, the ſeamen's term for thoſe little round wheels, in which the rope of a pulley or block runs. They turn with the rope, and have pieces of braſs in their centers, (which they call the *cocks*) with holes in them, into which the pin of the block goes, and on which they turn.

Theſe *ſhivers* are uſually of wood; but ſome are of braſs, as thoſe in the heels of the top-maſts.

SHIVERY *ſalt*, a name given by the ſalt-workers to a ſort of ſalt, very little different from the common brine-ſalt.

It is prepared in the ſame manner, as that ſalt from the ſalt ſprings in Cheſhire, and other places, and is of a larger and firmer grain than that prepared in the common way, and is ſtronger, and therefore more fit for the preſerving meat. When they would make this *ſalt*, they fill the pans on Saturday night, and then, as they draw out no ſalt on Sundays, there is a very moderate fire kept up all that day, and on the Monday morning all the *ſalt* is taken out at one draught, having had time to form itſelf into larger cryſtals than ordinary, as it is eight and forty hours, inſtead of four and twenty in forming. *Brownrig* of Salt, p. 108. See the article SALT.

SHOAD, in mining, a term for a train of metalline ſtones mixed with earth, ſometimes lying near the ſurface, ſometimes at conſiderable depths; but always ſerving to the miners as a proof, that the load or vein of the metal is thereabout. The deeper the *ſhoad* lies, the nearer uſually the vein is. *Ray*'s Words, p. 120.

SHOAD-*ſtones*, a term uſed by the miners of Cornwall, and other parts of this kingdom, to expreſs ſuch looſe maſſes of ſtone, as are uſually found about the entrances into mines, ſometimes running in a ſtrait courſe, from the load or vein of ore, to the ſurface of the earth.

Theſe are ſtones of the common kinds, appearing to have been pieces broken from the ſtrata, or larger maſſes, but they uſually contain mundic, or marcaſetic matter, and more or leſs of the ore to be found in the mine. They appear to have been at ſome time rolled about in water, their corners being broken off, and their ſurface ſmoothed and rounded. The antimony mines in Cornwall are always eaſily diſcovered by the *ſhoad-ſtones*, theſe uſually lying up to the ſurface, or very nearly ſo; and the matter of the *ſtone* being a white ſpar, or debaſed cryſtal, in which the native colour of the ore, which is a ſhining bluiſh black, eaſily diſcovers itſelf in ſtreaks and threads.

Shoad-ſtones are of ſo many kinds, and of ſuch various appearances, that it is not eaſy to deſcribe, or know them; but the miners, to whom they are of greateſt uſe in the tracing, or ſearching after new mines, diſtinguiſh them from other ſtones by their weight: for if very ponderous, though they look ever ſo much like common ſtones, there is great reaſon to ſuſpect that they contain ſome metal. Another mark of them, is their being ſpungy and porous; this is a ſign of eſpecial uſe in the tin countries, for the tin *ſhoad-ſtones* are often ſo porous and ſpungy, that they reſemble large bones of animals thoroughly calcined. There are many other appearances of tin *ſhoads*, the very hardeſt and firmeſt *ſtones* often containing this metal.

When the miners, in tracing a *ſhoad* up a hill, meet with ſuch odd ſtones and earths, that they know not well what to make of them, they have recourſe to vanning, that is, they calcine and powder the ſtone, clay, or whatever elſe is ſuppoſed to contain the metal; and then waſhing it in an inſtrument, prepared for that purpoſe, and called a *vanning-ſhovel*, they find the earthy matter waſhed away; and of the remainder, the ſtoney, or gravelly matter lies behind, and the metalline matter at the point of the ſhovel. If the perſon, who performs this operation, has any judgment, he eaſily diſcovers not only what the metal is that is contained in the *ſhoad*, but alſo will make a very probable gueſs at what quantity the mine is likely to yield of it, in proportion to the ore. Phil. Tranſ. N° 69.

SHOE (*Cycl.*)—SHOE, in the manege. A horſe-*ſhoe* is a piece of flat iron, with two branches or wings, which being commonly forged according to the form of the hoof for which it is deſigned, is made round at the toe, and open at the heel.

A *ſhoe* for all feet, is one that is cut at the toe into two equal parts, which are joined by a riveted nail; upon which they are moveable in ſuch a manner, that the *ſhoe* is inlarged or contracted, leſs or more, at pleaſure, in order to make it fit all ſorts and ſizes of feet.

To *ſhoe* a horſe after the form of a lunette, a patin, *&c.* See LUNETTE, PATIN, *&c.*

SHOEING-*hammer*, in the manege, a hammer that the ſmith or farrier makes uſe of to adjuſt and fit the ſhoes upon the anvil, both hot and cold.

SHOOT, in the ſea language. They ſay the ballaſt *ſhoots*, when it runs over from one ſide to another.

SHOOTING (*Cycl.*)—SHOOTING *of ſalts*. It is to be obſerved, that the figures ariſing from the *ſhooting* of diſſolved ſalts are not conſtantly the ſame, but vary according to different circumſtances; ſuch as when they happen to *ſhoot* more or leſs haſtily, or in different proportions of liquor. *Boyle*'s Works Abridged, Vol. I. p. 241. See the article SALT.

SHORES (*Cycl.*)—The *ſhores* of the ſea are divided, by Count Marſigli, into three portions, according to which all his deſcriptions, in his accounts of the baſon of the ſea, are given.

The firſt part of the *ſhore*, is that tract of land to which the ſea juſt reaches in ſtorms and high tides, but which it never covers; the ſecond part of the *ſhore*, is that which is covered in high tides and ſtorms, but is dry at other times; and the third is the deſcent from this, which is always covered with water.

The firſt part is only a continuation of the continent, and ſuffers no alteration from the neighbourhood of the ſea, except that it is rendered fit for the growth of ſome plants, and wholly unfit for that of others, by the ſaline ſteams and impregnations; and it is ſcarce to be conceived by any, but thoſe who have obſerved it, how far in land the effects of the ſea reach, ſo as to make the earth proper for plants, which will not grow without this influence; there being ſeveral plants frequently found on high hills, and dry places, at three, four, and more miles from the ſea, which yet would not grow, unleſs in the neighbourhood of it, nor will ever be found elſewhere.

The ſecond part or portion of the *ſhores* is much more affected by the ſea than the former, being frequently waſhed and beaten by it. Its productions are rendered ſalt by the water, and it is covered with ſand, or with the fragments of ſhells in form of ſand, and in ſome places with a tartarous matter depoſited from the water, and the colour of this whole extent of ground is uſually duſky and dull, eſpecially where there are rocks and ſtones; and theſe are covered with a ſlimy matter.

The third part of the *ſhores* is more affected by the ſea than either of the others, and is covered with an uniform cruſt of the true nature of the bottom of the ſea, except that plants and animals have their reſidence in it, and the decayed parts of theſe alter it a little.

SHORLING *and morling*, in our old writers, words uſed to diſtinguiſh fells of ſheep; *ſhorling*, being the fells after the fleeces are ſhorn off the ſheeps back; and *morling*, the fells ſtead off after they die, or are killed: in ſome parts of England, they underſtand by a *ſhorling*, a ſheep whoſe fleece is ſhorn off; and by a *morling*, a ſheep that dies. Stat. 3 Ed. 4. c. 1. *Blount*. See MORLING.

SHORT (*Cycl.*)—SHORT-*jointed*, in the manege. A horſe is ſaid to be *ſhort-jointed*, that has a ſhort paſtern. When this joint, or the paſtern, is too ſhort, the horſe is ſubject to have his fore-legs, from the knee to the cronet, all in a ſtrait line. Commonly your *ſhort-jointed* horſes do not manege ſo well as the *long-jointed*; but out of the manege the *ſhort-jointed* are the beſt for travel or fatigue.

SHORT-*ſightedneſs*—A learned author thinks it probable, that out of ſo great a number of *ſhort-ſighted* perſons as are daily to be met with, few are born ſo. For it generally grows upon young people at the age of twenty or twenty-five, and therefore might poſſibly be prevented by uſing their eyes, while young, to all ſorts of conformations; that is, by often looking through glaſſes of all ſorts of figures, and by reading, writing, or working with ſpectacles, of ſeveral degrees of convexity. For whatever be the powers by which the eye conforms itſelf to diſtinct viſion, they may poſſibly grow weak, or loſe their extent one way or other, for want of variety of exerciſe. It ſeems an opinion, without foundation, to think that ſuch an exerciſe of the eyes can any wiſe injure them; provided, due care be taken to avoid looking at objects that are too bright. See Dr. Smith's Optics, Vol. 2. Rem. p. 10.

Short-ſightedneſs may come by accidents. Of this we have a remarkable inſtance, mentioned by Dr. Briggs in his Ophthalmographia, of a perſon, upwards of ſeventy years old, who had uſed ſpectacles for ten years, and yet by catching cold, he ſuddenly became ſo *ſhort-ſighted*, that he could not diſtinguiſh objects three feet off; and after the cold and defluxion were cured, he continued to read the ſmalleſt print without ſpectacles for many years. Dr. Smith mentions a young gentleman, who became *ſhort-ſighted* immediately after coming out of a cold bath, in which he did not totally immerſe himſelf, and has ever ſince uſed a concave glaſs for many years. Ibid.

It is commonly thought that *ſhort-ſightedneſs* wears off in old age, but the learned Doctor queſtions whether this be matter of fact, or hypotheſis only. Ibid.

It is remarkable, that *ſhort-ſighted* perſons commonly write a ſmall hand, and love a ſmall print, becauſe they can ſee more of it at a view. That it is cuſtomary with them not to look at the perſon they converſe with, becauſe they cannot well ſee the motion of his eyes and features, and are therefore attentive to his words only. That they ſee more diſtinctly, and ſomewhat farther off, by a ſtrong light, than by a weak one; becauſe a ſtrong light cauſes a contraction of the pupil, and conſequently of the pencils, both here, and at the return; which leſſens their mixture, and conſequently the apparent confuſion: and therefore to ſee more diſtinctly, they almoſt cloſe their eye-lids; for which reaſon they were antiently called *myopes*. Ibid. ſect. 62.

Dr. Jurin obſerves, that perſons who are much, and long accuſtomed to view objects at ſmall diſtances; as ſtudents in general, watchmakers, gravers, painters in miniature, *&c.* ſee better at ſmall diſtances, and not ſo well at great diſtances, as the reſt of mankind. The reaſon is, that in the eye, as well as in other parts, the muſcles, by conſtant exerciſe, are enabled to contract themſelves with more ſtrength, and by diſuſe are brought to leſs ſtrength. Hence, in the perſons beforementioned, the greater muſcular ring of the uvea contracts more eaſily and ſtrongly, and the cornea more readily obeys the contraction of the ring; whence they ſee better at ſmall diſtances. And the cornea, by being thus often and long bent into a greater convexity, does by degrees loſe ſomething of its elaſticity, ſo as not to return to its natural elaſticity, when the muſcular ring ceaſes to act upon it. This is one cauſe of their not ſeeing ſo well at great diſtances. Alſo the ligamentum ciliare, being ſeldom employed to leſſen the convexity of the capſula, does by degrees become leſs capable of performing that office: and the capſula being ſeldom drawn out, and put into tenſion, muſt loſe ſomething of its diſtenſile quality, ſo as leſs eaſily to comply with the action of the ligament. And this is another cauſe of their not ſeeing ſo well at great diſtances. *Jurin*, Eſſ. on diſt. and indiſt. Viſion.

SHORTFORD, an antient cuſtom in the city of Exeter, when the lord of the fee cannot be anſwered rent due to him out of his tenement, and no diſtreſs can be levied for the ſame. The lord is then to come to the tenement, and there take a ſtone, or ſome other dead thing off the tenement, and bring it before the mayor and bailiff, and thus he muſt do ſeven quarter-days ſucceſſively; and if on the ſeventh quarter-day, the lord is not ſatisfied his rent and arrears, then the tenement ſhall be adjudged to the lord to hold the ſame a year and a day; and forthwith proclamation is to be made in the court, that if any man claims any title to the ſaid tenement, he muſt appear within the year and day next following, and ſatisfy the lord of the ſaid rent and arrears. But if no appearance be made, and the rent not paid, the lord comes again to the court and prays that, according to the cuſtom, the ſaid tenement be adjudged to him in his demeſne as of fee, which is done accordingly; ſo as the lord hath from thenceforth the ſaid tenement, with the appurtenances, to him and his heirs.

SHOT (*Cycl.*)—SHOT *of a cable*, on ſhip-board, is the ſplicing of two cables together, that a ſhip may ride ſafe in deep waters and in great roads; for a ſhip will ride eaſier by one *ſhot of a cable*, than by three ſhort cables out a-head.

SHOVELER, in zoology, the name of a ſpecies of ſea-duck, remarkable for the breadth of its bill, and called by authors *anas latiroſtra*, the broad-beaked duck, and *taſchenmul*, and by ſome *anas clypeata*.

It is ſomething ſmaller than the common duck. The beak is remarkably broad, and grows broader and rounder toward the end, where it is hollowed like a ſhield. The iris of its eyes is very yellow, and the legs and feet red. The feet are ſmaller than in moſt other ducks. The head, and upper part of the neck, are of a very beautiful blue, ſometimes of a duſky green; the under part of the neck is white, the upper and the ſhoulders variegated with white and brown. The belly, and lower part of the breaſt, are red, but the feathers behind the anus, and immediately under the tail, are black. The back is brown, with a fine caſt of blue, purple and green. The tail is ſhort, and is variegated with black and white. *Ray*'s Ornithol. p. 280.

SHOULDER (*Cycl.*)—SHOULDER, in the manege, is the joint of a horſe's fore-quarters, that joins the end of the *ſhoulder*-blade with the extremity of the fore-thigh.

SHOULDER *of a branch*, is that part of it which begins at the lower part of the arch of the banquet, overagainſt the middle of the fonceau, or chaperon, and forms another arch under the banquet. The *ſhoulder of a branch* caſts a greater, or leſſer circumference, according as it is deſigned to fortify, or weaken the branch. See the articles BRIDLE, BANQUET, and BRANCH.

SHOULDER-*pegged horſes*, called in French *chevillées*, are ſuch as have their *ſhoulders* gourdy, ſtiff, and almoſt without motion. A horſe charged with *ſhoulders*, is one that has thick, fleſhy, and heavy *ſhoulders*.

Cartilages of the SHOULDER, in anatomy. The ſcapula in many ſubjects has a ſmall cartilaginous border along its whole baſis, which in children is remarkable enough, but in grown perſons it diſappears. The glenoide cavity of this bone is covered with a cartilage, which is thicker toward the circumference than in the middle, and a little raiſed above the edge of the bone. The ſmall cartilaginous ſurface of the acromion is thicker in freſh bones, than it appears in a dried ſceleton, and is a little convex. The ſmall triangular ſurface, at the extremity of the ſpine of the ſcapula, near the baſis, is covered with a very thin, ſmooth cartilaginous lamina; but this being tranſparent, does not appear very white. There are no other cartilages but theſe uſually found in the ſcapula in freſh ſubjects, notwithſtanding that in ſceletons of prepared bones, ſeveral places beſide ſeem to have been cartilaginous; theſe, however, are owing only to the dried remains of ligaments and tendons. *Winſlow*'s Anatomy, p. 137.

Ligaments of the SHOULDER. The articulation of the acromium with the extremity of the clavicle, is ſtrengthened all round by ſeveral ſmall, but ſtrong ligaments, which go directly from one bone to the other. Theſe ligaments lie very near one another, and withal are ſo tightly braced over the joint, as to hide it altogether: they appear indeed more like a cartilaginous covering, than a ligamentary texture; and the internal ſurface of theſe ligaments is lined with the capſula of the joint. When the ſmall inter-articular cartilage is found in this joint, its whole circumference is ever found connected to theſe ligaments. The articulation of the clavicle with the ſternum is ſuſtained by ſeveral ligaments, fixed by one end round the pectoral extremity of the clavicle, and inſerted at the other in the ſternum. There is alſo a long narrow ſtrong ligament, which goes from one clavicle to the other, behind the furca of the ſternum: this is fixed to the internal angle of the contiguous extremities of the bones, and may be properly called the *inter-clavicular ligament*. The neck of the ſcapula, at a ſmall diſtance from the glenoide cavity, gives inſertion to the capſular ligament, or mucilaginous bag, and to the articular ligaments of the joint of the ſcapula and os humeri. And beſide theſe articular ligaments of the ſcapula, there are three ligamentary cords fixed to the tuberoſity of the coracoide apophyſis; two of which, by their other extremities, are inſerted in the oblique eminence on the lower ſide of the humeral extremity of the clavicle, the third under the acromium. There is alſo a thin flat broad ligament, reaching between the criſta of the ſpine of the ſcapula, and the edge of the inferior coſta. *Winſlow*'s Anatomy, p. 138.

SHOULDER *of a baſtion*, in fortification, is where the face and the flank meet.

SHOUT, *clamor*, in antiquity, was frequently uſed both on eccleſiaſtical, civil and military occaſions, as a ſign of approbation, and ſometimes of indignation. Thus as Cicero, in an aſſembly of the people, was expoſing the arrogance of L. Antony, who had had the impudence to cauſe himſelf to be inſcribed the patron of the Romans, the people on hearing this raiſed a *ſhout*, to ſhew their indignation.

In the antient military diſcipline *ſhouts* were uſed, 1. upon occaſion of the general's making a ſpeech, or harangue to the army, from his tribunal. This they did in token of their approving

what

what had been propoſed. 2. Before an engagement, in order to encourage and ſpirit their own men, and fill the enemy with dread. This is a practice of great antiquity, beſides which it wants not the authority of reaſon to ſupport it; for as mankind are endowed with two ſenſes, hearing and ſeeing, by which fear is raiſed in the mind, it may be proper to make uſe of the ear, as well as the eye, for that purpoſe. *Shouts* were alſo raiſed in the antient theatre, when what was acted pleaſed the ſpectators. See ACCLAMATION.

It was uſual, for thoſe preſent at the burning the dead, to raiſe a great *ſhout*, and call the dead perſon by his name, before they ſet fire to the pile. See BURIAL.

SHREW, or SHREW-*mouſe*, in zoology, the common name of the creature called by authors *mus araneus*. See the article MUS *araneus*.

Hardy SHREW. See the article HARDY.

SHRIKE, in zoology, an Engliſh name for the lanius, or butcher-bird, a ſmall bird of the hawk-kind, a terrible deſtroyer of the little birds. *Ray*'s Ornithol. p. 52. See the article LANIUS.

SHRITE, in zoology, a name uſed by ſome for the larger thruſh, or *turdus viſcivorus major*, commonly known by the name of the *miſſel-bird*. It ſtays the whole year with us, and ſings very ſweetly. See MISSEL-*bird*.

SHRUB (*Cycl.*)—*Hardy* SHRUBS. See the article HARDY.

SI *action*, in law, the concluſion of a plea to the action, when the defendant demands judgment, if the plaintiff ought to have his action, *&c.*

SIAGONAGRA, a name given by ſome medical writers to the gout in the jaws.

SIALISMUS, a word uſed by the antients to expreſs a diſcharge of ſaliva, brought on by the holding hot things in the mouth; and by us for a ſalivation by mercury.

SIALOCHI, a term uſed by the antients to expreſs ſuch perſons as had a plentiful diſcharge of ſaliva, by whatever means. Hippocrates uſes it for a perſon in a quinſey, who diſcharges a very large quantity of ſaliva; others expreſs by it perſons, whoſe mouths naturally abound with a bitter ſaliva; and others ſuch perſons, as from having a very large tongue, ſpit into people's faces while talking with them.

SIALOGOGA, a term uſed by medical writers to expreſs ſuch medicines as promote a copious diſcharge of the ſaliva, ſuch as pellitory of Spain, and all the other hot and acrid vegetables; and mercury, the moſt powerful of all.

SIANKE, or SYNKE, in natural hiſtory, a name given by the people of ſome parts of the Eaſt-Indies to the caryophyllus, or clove-ſpice. The people of the Moluccas, according to Garcias, call it *chanque*, which is only a ſmall difference of pronunciation. The Turks and Perſians call the ſame ſpice *calafur*.

SICCHASIA, a word uſed by ſome writers to expreſs that uneaſineſs at the ſtomach, and loathing of food, which women are often afflicted with in their pregnancy.

SICCINNIS, in antiquity, a mixed kind of dance. See the article DANCE, *Cycl.*

SICERA, in the Jewiſh antiquities. The helleniſt Jews give this name to any inebriating liquor. St. Chryſoſtom, Theodoret, and Theophilus of Antioch, who were Syrians, and who therefore ought to know the ſignification and nature of *ſicera*, aſſure us, that it properly ſignifies palm-wine.

Pliny acknowledges, that the wine of the palm-tree was very well known through all the Eaſt, and that it was made by taking a buſhel of the dates of the palm-tree, and throwing them into three gallons of water; then ſqueezing out the juice, it would intoxicate like wine.

The wine of the palm-tree is white: when it is drank new, it has the taſte of the cocoa, and is ſweet as honey: when it is kept longer, it grows ſtrong, and intoxicates. After long keeping, it becomes vinegar. V. *Renaudot*'s Notes upon the Voyage to China, p. 12. *Calm.* Dict. Bibl.

SICILIANA, in botany, a name given by Dodonæus, and ſome other authors, to the great androſæmum, called *tutſan*, and *park-leaves*. *Ger.* Emac. Ind. 2.

SICILICUM, the name of a weight in uſe among the antients, which ſome ſay was equal to three drachms of our weight; others ſay only to two.

SICUB, or SICAP, in natural hiſtory, a name given by the inhabitants of the Philippine iſlands to a ſpecies of hawk, of the bigneſs of their common hawk, or banoy, which is ſomewhat larger than our ſparrow-hawk. This bird is very elegantly variegated all over its body with yellow, white, and black.

SICUS, in ichthyology, a name uſed by ſome authors to expreſs that ſpecies of coregonus, called by the generality of authors *albula nobilis*. See the articles COREGONUS and ALBULA.

SICYOIDES, in botany, the name of a genus of plants, the characters of which are theſe. The flower conſiſts of one leaf, and is ſhaped like a bell wide open at the mouth, and divided into ſeveral ſegments. Some of the flowers on this plant are ſteril, or male-flowers, having no embryo; others are fruitful, or female, having an embryo, which ripens into a fruit of the ſhape of an almond, fleſhy, prickly, uſually collected into a head, and containing only one ſeed under a thin ſkin.

The ſpecies of *ſicyoides*, enumerated by Mr. Tournefort, are theſe. 1. The American *ſicyoides* with angular leaves and echinated fruit, called by ſome authors *cucumis Canadenſis monoſpermos*, or the ſingle-ſeeded Canada cucumber. 2. The American *ſicyoides* with echinated fruit and deeply jagged leaves. *Tourn.* Inſt. p. 103.

SICYONE, a word uſed by Hippocrates to expreſs colocynth, and by others for a ſpecies of hard-ſhelled gourd, in the ſhape of a pear, and by ſome for a cupping-glaſs.

SICYONEUM *oleum*, a word uſed by the antients to expreſs a medicinal oil, of which there was among them three kinds in uſe. The firſt was called *ſicyonium ſimplex*. This was compoſed of two ounces of the root of the wild cucumber boiled ſeveral hours in a pint of oil. The ſecond ſort was called the *compound ſicyonium*, and was made of the root of the ſame plant, with many other ingredients. The third was another compound kind, made not with an infuſion of the root, but with the juice of the fruit of the wild cucumber.

SICYONII, among the Romans, were ſhoes of a more delicate form, and better ornamented than ordinary, and chiefly worn by the ladies and their gallants. *Pitiſc.* in voc.

SIDA, in botany, the name of a genus of plants, conſtituted by Linnæus, and comprehending the *malvinda* of Dillenius, and the *abutilon* of the ſame author and of Tournefort. The characters are theſe: the perianthium is compoſed of one leaf, of the figure of a cup, erect, and lightly divided into five ſegments, and does not fall with the flower. The flower conſiſts of five petals, which are broad at the top, and ſurrounded with a rim: they are much narrower at the bottom, and grow together there. The ſtamina are a great number of filaments, which at the bottom grow into a ſort of tube, and at the top are free. The antheræ are roundiſh. The germen of the piſtil is roundiſh. The ſtyle is ſhort, and is lightly divided into ſeveral ſegments. The ſtigmata are ſlender and obtuſe. The fruit is a roundiſh capſule, terminating in a point, and compoſed of ſeveral horns, which finally ſeparating, tear the complex veſſel to pieces. The ſeeds are roundiſh and pointed, the one ſide convex, and the other of an angular figure.

This genus is very nearly allied to the melochia, but differs in its numerous antheræ. The malvinda and abutilon agree in all the characters of this genus, but differ in this, that the firſt has always only five capſules which compoſe the general fruit, and the other has more. *Linnæi* Gen. Plant. p. 329. *Dillen.* Hort. Elth. p. 171. *Tournefort*, p. 25.

SIDA is alſo uſed by ſome authors for the *althæa*, or marſh-mallow. *Ger.* Emac. Ind. 2.

SIDE (*Cycl.*)—SIDES *of a ſhip*, are diſtinguiſhed into the *ſtarboard* and *larboard*; that is, into the right and left-hand-*ſide*, when ſtanding with the face towards the head of the veſſel. See the articles STARBOARD and LARBOARD.

Broad-SIDE, in the ſea language, is to fire all the guns on one *ſide* of the ſhip.

SIDE-*wind*, at ſea. See the article WIND.

SIDERIA, in natural hiſtory, the name of a genus of cryſtal. The word is derived from the Greek, σίδηρος, iron, and is uſed to expreſs cryſtals altered in their figure by particles of that metal. Theſe are of a rhomboidal form, compoſed only of ſix planes. Of this genus there are four known ſpecies: 1. a colourleſs, pellucid, and thin one, found in conſiderable quantities among the iron ores of the Foreſt of Dean in Glouceſterſhire, and in other the like places. 2. A dull, thick, and brown one, not uncommon in the ſame places with the former. And 3. a black and very gloſſy kind, a foſſil of very great beauty, found in the ſame place with the others, as alſo in Leiceſterſhire and Suſſex. See Tab. of Foſſils, Claſs 3. *Hill*'s Hiſt. of Foſſ. p. 197.

SIDERITIS, (*Cycl.*) *iron-wort*, in botany, the name of a genus of plants, the characters of which are theſe. The flower conſiſts of one leaf, and is of the labiated kind. The upper lip is erect, the lower divided into ſeveral ſegments. The piſtil ariſes from the cup, and is fixed in the manner of a nail into the hinder part of the flower, and ſurrounded by four embryos, which afterwards become ſo many ſeeds, ripening in an open capſule, which was the cup of the flower. To theſe marks it may be added, that in all the *ſideriteſ* the flowers grow in circles round the ſtalks, at the joinings of the leaves.

The ſpecies of *ſideritis*, enumerated by Mr. Tournefort, are theſe. 1. The hairy procumbent *ſideritis*, called *tetrahit* by many authors. 2. The hairy procumbent *ſideritis* with leaves very ſlightly crenated. 3. The hairy *ſideritis* with very deeply crenated leaves. 4. The hyſſop-leaved Alpine *ſideritis*. 5. The hyſſop-leaved Alpine *ſideritis* with leaves notched at the ends. 6. The narrower-leaved erect Spaniſh *ſideritis*. 7. The large procumbent Spaniſh *ſideritis* with crenated leaves, and white flowers. 8. The narrow-leaved crenated bituminoſe *ſideritis*. 9. The ſmooth ſtinking Spaniſh *ſideritis* with purple flowers, and hoary ſpikes. 10. The woody ſhrub Spaniſh *ſideritis*. 11. The ſmall procumbent

hyſſop-leaved Pyrenean *ſideritis*. 12. The mountain-*ſideritis* with trifid leaves. 13. The tall yellow-flowered Canada *ſideritis* with leaves like thoſe of figwort. 14. The purple-flowered tall figwort-leaved Canada *ſideritis*. There are ſome other plants, beſide theſe, called by authors *ſideritis*, but they are properly of the galeopſis, betony, or marrubiaſtrum-kind, which ſee. *Tourn.* Inſt. p. 191.

SIDEROMANTIA, Σιδηρομαντεια, in antiquity, a kind of divination performed with a red-hot iron, upon which they laid an odd number of ſtraws, and obſerved what figures, bendings, ſparklings, &c. they made in burning. *Potter*, Archæol. Græc. l. 2. c. 18. Tom. I. p. 353.

SIDEWAYS, in the manege. To ride a horſe *ſideways*, is to paſſage him, or make him go upon two treads, one of which is marked by his ſhoulders, and the other by his haunches.

SIGAH-*guſh*, in zoology, the name of a Perſian animal, of the lynx-kind, and no way differing from the lynx itſelf, but in that it has no ſpots. Its ears have the fine velvety black pencil of hairs at their top, which are the diſtinguiſhing character of the lynx; and theſe creatures differ ſo much in the variations and different diſpoſitions of their ſpots, that probably this is no other than an accidental variety of the ſame ſpecies. *Ray*'s Syn. Quad. p. 168.

SIGHT (*Cycl.*)—The Acta Leipſienſia give us an account of a man, who received a ſmart ſtroke on the pupil of one of his eyes from the end of a fiddle-ſtring, which broke while he was tuning the inſtrument, and chanced to fly that way. Some cooling things were applied to the eye, and a bandage uſed to ſhade it from the light; but at midnight the patient chancing to wake in the dark, found that he could ſee with that eye, though not with the other: this continued a long time, and on trial he found that he could read a ſmall print at midnight with this eye, but could ſcarce diſtinguiſh any thing with it in a bright and clear day.

We have, in the ſame collections, an account of a man, who, after the cure of a confirmed pox, ſaw every object double for a long time. Act. Leipſ. 1690.

It is a very common, and a very juſt obſervation, that children do not ſee any thing clearly when new-born, and if their eyes be then examined, they are found to want that brilliancy which they afterwards acquire; and finally, when any object is preſented to their view, they at firſt turn their eyes about in ſuch a manner, that it is evident they either do not ſee at all, or at beſt but very imperfectly and obſcurely.

This imperfection may either be owing to a fault in ſome one of the humours, or in their capſules, or, finally, in the retina, or complexly in them all together. It is impoſſible to diſcover whether there be any imperfection in the retina in this ſtate of life, that membrane being ever, in new-born infants, tender and ſoft like a jelly: if it be in any of the other parts that the imperfection lies, it muſt be either in their nature, or extent. Mr. Petit, of the Academy of Sciences at Paris, determined to enquire thoroughly into the cauſe of this, was at the pains of diſſecting the eyes of ſeveral infants which had died ſoon after their birth, and in three fourths of them he found the vitreous, the cryſtalline, and the capſule, all greatly deficient in their tranſparence. The uvea appeared alſo more opake than in adults, and the pupil over large; and that there was either none, or, at the utmoſt, very little of the aqueous humour: and in thoſe eyes, where the humours had not this opacity, they were all, as were alſo the membranes, of a reddiſh colour; and this was obſerved in fœtuſes of ſeven and nine months old.

The cornea in theſe eyes was alſo remarkably thick, which is, in general, found to be the caſe in the eyes of all fœtuſes. The thickneſs and opacity in theſe corneas gradually diminiſh in time, and that ſoon; ſo that the eyes of children appear much brighter at two or three months old, than when new-born. The aqueous humour ſeems alſo, in moſt fœtuſes, to be wholly wanting; and where it is found, is ever greatly in an under proportion to the other humours.

It therefore appears, that the dimneſs and imperfection of *ſight*, in new-born infants, is owing to the over-thickneſs of the cornea, and to the too ſmall portion of the aqueous or watery humour. It appears plainly alſo, from experience, that the eye is not able, in infants, to bear the light, till the pupil is greatly contracted; as is the caſe alſo, though in a leſs degree, in adults: and it is very probable, that the extreme ſoftneſs of the retina in this ſtate may make every ray of light affect it much more plainly, than when grown more firm.

Mr. Petit having continued his examinations of the eyes of infants, up to the age of five or ſix weeks, found in all his diſſections, that the cornea daily grew more and more convex and gloſſy; and this may be rationally concluded to be owing to the daily encreaſe of the aqueous humour, which muſt, by that accretion, throw it out into a greater convexity, and make it daily more and more thin and tranſparent. The uvea alſo acquires a greater extenſion, and its fibres become more moveable; whence the pupil acquires a power of enlarging or contracting itſelf, at the approach or abſence of light, with much more eaſe and readineſs than it could before. The humours thus all become capable of letting in a larger quantity of light; the retina is at the ſame time every day gaining a new firmneſs, and the pupil becomes capable of an eaſy dilatation, or reſtriction, for the letting in occaſionally a greater or leſs number of rays, and the refractions are perfected by the augmentation of the aqueous humour. It is plain, therefore, that the clearneſs of viſion muſt every day encreaſe. All this change comes on in infants only by time; and it may be judged of, as to its ſtate, by inſpection, by the brilliancy and convexity of the cornea, and by the manner of their turning their eyes toward objects ſet before them: and this time is not certain, or limited, but differs greatly in different children, ſome being able to ſee clearly at the end of a month, others not till after many months.

At the time that this gentleman was diſſecting the eyes of human fœtuſes and infants, he alſo curiouſly obſerved the eyes of young quadrupeds. The puppy, when newly brought forth, has always its eyes opake; the kitten, on the contrary, has them clear, and every way like thoſe of adults of the ſame ſpecies. In fœtuſes of other quadrupeds, the lamb has its cornea a little turbid and opake; the calf and the pig have them more or leſs opake, but the calf moſt ſo of all. Mem. de l'Acad. Par. 1727.

SIGIA, a name given by ſome authors to the liquid-ſtyrax.

SIGILLUM (*Cycl.*)—SIGILLUM *mariæ*, *lady*'s *ſeal*, in botany, a name by which ſome authors have called the *bryonia nigra*, or black bryony, a climbing plant, common in hedges. *Ger.* Emac. Ind. 2.

SIGMA, among the Romans, the ſame with the *ſtibadium*. See the article STIBADIUM.

SIGMOIDES, a word uſed by medical writers to expreſs any thing that is in the ſhape of the letter ſigma. The valves of the heart have this epithet applied to them; the coracoide proceſs of the ſcapula is alſo expreſſed by the ſame word; the ſemicircular cavity of the cubit, at the articulation of the fore-arm with the humerus, is ſometimes alſo called the *ſigmoidal-cavity*; and the cartilages of the *ſigmoide*-circles of the *aſpera arteria*, or wind-pipe, have their denomination from the ſame occaſions.

SIGNS, or SYMPTOMS, in medicine. See ASSIDENT.

Negative SIGN. See the article NEGATIVE *ſign*.

SIGNA, *ſtandards*, among the Romans, were of different ſorts; on ſome of them the image of the emperor was repreſented, and they that carried them were called *imaginiferi*; others had a hand ſtretched out, as a ſymbol of concord; and theſe enſign-bearers were called *ſigniferi*; ſome had a ſilver eagle, the bearers of which were called *aquiliferi*; others had a dragon with a ſilver head, and the reſt of his body of taffety, which was blown by the wind as if it had been a real dragon, and the bearers of this enſign were called *draconarii*; laſtly, the emperor's enſign was called *labarum*, and thoſe that carried it *labariferi*, which they carried out when he went in perſon to the field: it was of a purple colour, beſet with gold fringe, and adorned with precious ſtones.

All theſe enſigns were ſuſtained with a half-pike, ſharp at the end, that it might be the more eaſily fixed in the ground. *Danet.* in voc.

SIGNATORES, among the Romans, witneſſes who ſealed wills and marriage-contracts. *Pitiſc.* in voc.

SIGNIFER, among the Romans, an enſign-bearer, or the perſon who carried the ſtandard on which was repreſented a hand ſtretched out. See the article SIGNA.

SIGNINUM, among the Romans, a kind of pavement much eſteemed: it was made of poudered ſhells mixed with lime. *Pitiſc.* in voc.

SIGNUM *pugnæ*, the ſignal of battle, among the Romans, was a coat of arms, of a purple colour, ſet upon the general's pavilion. *Danet.* in voc.

SIGUETTE, in the manege, is a caveſſon of iron, with teeth or notches; that is, a ſemicircle of hollow and vaulted iron, with teeth like a ſaw, conſiſting of two or three pieces joined with hinges, and mounted with a head-ſtall and two ropes, as if they were the caveſſons that in former times were wont to be put upon the noſe of a fiery ſtiff-headed horſe, in order to keep him in ſubjection.

There is a ſort of *ſiguette*, that is a round iron all of one piece, ſewed under the noſe-band of the bridle, that it may not be in view. This *ſiguette* we employ with a martingale, when a horſe beats upon the hand.

SIL, in natural hiſtory, a name given by the antients to a red ochre, of which they had three diſtinct kinds, the *ſil ſyricum*, *ſil atticum*, and *ſil marmoroſum*; all of which are to be had at this time, and all very valuable paints.

SIL *ſyricum* is a ſubſtance well known among the painters of the preſent age, though not by name, being the red ochre, commonly uſed for a purple colour, in their coarſer works; though it is capable of yielding, by proper management, a colour fit for their fineſt. It is very heavy, and of a fine ſtrong red with ſome tendency to purple, of a looſe friable

texture, and very rough and dusty surface. It adheres firmly to the tongue, is somewhat soft to the touch, crumbles easily to pieces between the fingers, and stains the hands very much. It melts freely in the mouth, and has a strongly astringent taste. It burns to a much paler colour, and makes no effervescence with aqua fortis. These are the characters by which this is distinguished from all the other red earths. It is dug in many parts of England, and is sent to London in great quantities. *Hill*'s Hist. of Foss. p. 57.

SIL *atticum* is the purple ochre, called of later times *almagra*. See the articcle ALMAGRA.

SIL *marmorosum* is also a substance in some degree known in the world at this time. It sometimes falls into the hands of our painters who call it Indian stone red, but it has many other valuable qualities extremely worth enquiring into. It is the hardest and driest of all the ochres, and while in the stratum appears absolutely stony, forming thin, flat, regular strata, and is so hard that it is not to be dug without the pick-ax; it is also of an obscurely and irregular laminated structure, and naturally breaks into flat pieces. It is of a fine purplish red, and very heavy, and contains a multitude of fragments of a fine lead ore which are bright and bluish, and make a very pretty appearance, and beside these has always among it a small quantity of pure native cinnabar; both these substances are so nicely mixed with it, that it is scarce possible to break off a piece of an inch square from any part of the strata, that has not more or less of both in it. It is of a dusty surface, and rough to the touch, and adheres very firmly to the tongue, and stains the hands. It is of a very austere and astringent taste, and makes no effervescence with acids. There are considerable strata of it on the borders of China, and it is much used as a paint in the East-Indies. There is some of it at times brought over to us, but not enough to make it a regularly marketable commodity. Beside its use as a paint, it is worth enquiring into an account of the cinnabar it contains; three ounces of it having yielded, on trial, two drams and a scruple of pure quicksilver. *Hill*'s Hist. of Foss. p. 62.

SILACH, a word used by medical authors for a disorder of the eye-lid, consisting in a preternatural thickness of it, or a swelling without inflammation.

SILATUM, a word used by the antient Romans to express a morning's draught of wine. This was usually of a wine medicated with the plant sili, or seseli, and thence had its name. It has always been the custom to medicate the morning draughts of any strong liquor; we do it with wormwood, or the common bitter tincture, the Indians with ginger.

SILAUM, in botany, a name used by some authors for the *saxifraga pratensis*, or common meadow-saxifrage. *J. Bauhin.* Vol. 3. p. 170.

SILENE, in botany, the name of a genus of plants, the characters of which are these. The perianthium is oblong, smooth, and clavated, and consists of one leaf, divided into five segments at the edge. The flower consists of five petals: the ungues of these are as long as the tube of the cup, and their extremities form a limb, which lies flat and expanded: the apices of all the petals are obtuse and marginated. The nectarium is composed of certain denticuli, two of which are inserted near the base of every petal. The stamina are ten subulated filaments, inserted into the ungues of the flower. The antheræ are oblong. The germen of the pistil is cylindric. The styles are either three or five, and are of the length of the stamina, or somewhat more. The stigmata are always bent against the sun. The fruit is the germen enlarged, and divided into as many cells as there were styles: these contain numerous kidney-shaped seeds. Dillenius, in the Hortus Elthamensis, has described these plants under the name *viscago*. *Linnæi* Gen. Plant. p. 197. *Dillen.* Hort. Elth. p. 309.

SILER, in botany, a name given by the Latin writers of the later ages to the plant called by others *seseli*, an umbelliferous herb, growing in mountainous places.

The antient Roman authors, however, mean a very different thing by the word *siler*, a shrub growing in watery places, and having twigs very ductile and tough, and fit for basket-work, or any other use of that kind. The poets have often mentioned it, and always with the epithets of *molle* and *lentum*, soft and tough.

Nothing can be more obvious, than that the *siler* of the later authors is a plant wholly different from this; and it is very properly that some have denominated the umbelliferous plant *siler montanum*, to distinguish it from the shrub-*siler*, which only grows about waters.

Some of the old scholiasts and interpreters of the Roman authors have told us that the *siler*, mentioned by them, is the cyperus; but this must be a mistake. For though this plant grows in watery places, and has considerable tough stalks; yet it is not a shrub, but an herbaceous plant, and is remarkably harsh, and of all plants least deserves the epithet *molle*, which the antients bestowed on their *siler*.

Some have supposed it to be the willow; but this cannot be true: for the willow and *siler* are continually named together, by the same authors, as different plants. The willow, alder and *siler*, being the three shrubs generally mentioned together, as the shrubs that grow about the banks of rivers; the osier is a kind of willow, very frequent at the sides of rivers, and has all the qualities attributed to the *siler* by the antients. It has been supposed by some that this cannot be their *siler*, because as it is a kind of willow, they would have called it by the common name, *salix*; but our own example may plead against this, for we know it to be of the willow-kind, yet we call it by another name: osier is more different in sound from willow, than *siler* from salix, and probably both one and the other signify the same plant.

The error of confounding so different a plant as the *seseli* with this shrub, arises from the unhappy custom of abbreviation, so common among the old Greeks; instead of *seseli* they wrote the word sometimes only *seli*, and *sile*, thence it was easy for people, less acquainted with botanical distinctions, to add an *r* at the end, to reduce the word, which they did not know, to one that they did; and thus grew *siler* as a name for *seseli*. Hippocrates calls the seseli *sili*; and Pliny both *sili* and *seli*. See the article SILI.

SILESIACA-*terra*. See the article TERRA-*silesiaca*.

SILEX, *flint*, in natural history, the name of a genus of semipellucid stones, the matter of which is a crystal, debased by an admixture of a peculiar and appropriated earth, which is of a blackish grey; always free from veins, but, according to the different quantity and disposition of the earth in its composition, subject to clouds of a darker or paler colour, and naturally invested with a thin whitish crust.

Naturalists, in general, have accounted various species of *flint*, but erroneously; nature has established it into a genus of itself, and allowed no other species than one, which is ever composed of the same matter, and differs only in the proportions of its admixture. When crystalline matter is debased by earths of other colours, or clouded and veined, it ceases to be *flint*, and becomes the pebble, the agate, or the onyx; and the not attending to this distinction, has made many describe these variously-coloured bodies twice over: once under the name of *coloured flints*, and a second time under that of *English agates*, &c.

The characters of genuine *flint* are, that it is a stone of an extremely fine and even texture; of a very uncertain surface, sometimes rough, sometimes smooth; of a colour always, in some degree, between blackish and whitish, unless accidentally tinged, as all other fossils are subject to be; very readily giving fire with steel; not fermenting with acids. *Hill*'s Hist. of Fossils, p. 508. See the article FLINT.

SILI, in botany, a name given by the old Greeks to a plant called also *seseli*. Hippocrates always calls this *sili* and *sile*, and Pliny uses the same words as some of its names.

This however is not the only meaning of the word, for the epithet *cyprium* being added to it, it signified a very different plant, namely, the ricinus; and the letter *r* being added to the end, and the word written *siler*, it became the name of the osier, as well as of the seseli. This has occasioned great errors about the meaning of the antients, some misunderstanding them as speaking of the osier, when they are describing the virtues of the seseli.

SILICERNIUM, among the Romans, a funeral supper, which is otherwise called *exequium*. *Pitisc.* in voc. See the article EXEQUIUM.

SILILICON, in botany, a name given by some of the old Latin writers to the carob-tree, or *siliqua dulcis*. The Latins borrowed this name from the Greek *xyloglycon*, ξυλογλυκον, the sweet, or sweet-fruited tree. Isidore mispels the word *sililicon*, and making it only *silicon*, supposes it to be a barbarous way of spelling the word *siliqua*; but the evident derivation of the genuine word from the Greek shews his error, both as to the word itself, and the origin of it.

The Latins called this tree *siliqua*, because its fruit was in pods, and the Greeks *ceratium*, κεραΐιον, because its pods were bent so, as to resemble horns; but the names *xyloglycon*, and its derivative, *sililicon*, were wholly different from these.

The same Isidore observes, that the expressed juice of the fruit of this *silicon* is the drug called *acacia* in the shops; but in this he is guilty of a very great error, the fruit of the *silicon* being esculent, and the acacia a very powerful astringent.

What has led him into this error, has been an observation of the Glossaries on Avisenna, and the other Arabian physicians. These authors have called by the same name, *charub*, or *charnub*, both the carob, or *sililicon*, and the acacia, only distinguishing them by proper epithets. Isidore found in their Glossaries, that charnub was the *siliqua*, or carob-tree, and that the juice of the pods of charnub was acacia; he therefore not observing that there were two charnubs, gave to the latter the properties of the former, and so made the styptic and astringent drug the juice of an esculent plant.

SILICULA, in botany, a name given by some authors to fœnugreek. *Ger.* Emac. Ind. 2.

SILIQUA, (*Cycl.*) in botany, the name of a genus of trees, the characters of which are these. The flower is of the apetalous kind, being composed only of a number of stamina, which arise from the segments of the cup, the middle of which is occupied by a pistil, which finally becomes a

flatted pod of a fleſhy ſubſtance, and containing flat and roundiſh ſeeds.

The ſpecies of *ſiliqua*, enumerated by Mr. Tournefort, are theſe: 1. The common *ſiliqua*, called the *eatable ſiliqua*, or carouge. 2. The eſculent *ſiliqua* with ſhorter pods. 3. The eſculent *ſiliqua* with various pods. 4. The wild carouge, or not eſculent *ſiliqua*. *Tourn.* Inſt. p. 578.

SILIQUA, κεράτιον, among the antients, the third part of an obolus, or, what comes to the ſame, the ſixth part of a ſcruple. See the articles OBOLUS and SCRUPLE, *Cycl.*

SILIQUA *nabathæa*. See NABATHÆA *ſiliqua*.

SILIQUARIUS, among the Romans, an officer who exacted, or raiſed the toll *ſiliqua*. *Pitiſc.* in voc.

SILIQUASTRUM, *Judas-tree*, in botany, the name of a genus of trees, the characters of which are theſe. The flower is of the papilionaceous kind; the wings, however, ſtand over the vexillum, and the carina is compoſed of two leaves. The piſtil ariſes from the cup, and is ſurrounded by ſtamina; this finally becomes a flat membranaceous pod, filled with ſeeds of a kidney-like form. To this it is to be added, that the leaves ſtand alternately. See Tab. 1. of Botany, Claſs 22.

The ſpecies of *ſiliquaſtrum*, enumerated by Mr. Tournefort, are theſe: 1. The common *ſiliquaſtrum*, or *Judas-tree*. 2. The white-flowered *ſiliquaſtrum*. 3. The *ſiliquaſtrum* with large pods and pointed leaves. 4. The round-leaved Canada-*ſiliquaſtrum*. Tourn. Inſt. p. 646.

SILIQUASTRUM was uſed in the botanical writings of the antients for the name of a podded plant, growing wild in ſome places of Italy, and in others cultivated for domeſtic and medicinal uſes. Pliny, and many other of the antients, have mentioned this, but they have given ſuch imperfect accounts of it, that they have led their followers into many errors about it. At this diſtance of time, and with the few lights they have left us, it is not eaſy to ſay what this plant of the antients was; but it may be a means of leading the reader out of many errors, to ſay what it was not.

Many have ſuppoſed it to be the *zinziber caninum* of Aviſenna, and the *hydropiper* of Dioſcorides; but the name *ſiliquaſtrum* implying its having pods, is a ſufficient refutation of its being this plant, which is the common *perſicaria*, or biting arſmart.

Others have thought that the *ſiliquaſtrum* was the capſicum, or *Guinea-pepper*, as we call it; but however well this plant may agree with the name, as being podded, it can by no means be the plant, ſince Pliny deſcribes it as common in Italy, and growing wild, which it is very certain that this plant never did.

Many have ſuppoſed it to be the plant we call *piperitis*, or *dittander*; but though Pliny has called this plant *piperitis*, from its hot taſte of pepper, yet he plainly ſhews that it was not our *dittander*: for he afterwards deſcribes that as another ſort, ſaying, that there is another broad-leaved kind, which approached to the nature of iberis, but that the large leaves diſtinguiſhed it: this is plainly enough our *lepidium*, or *dittander*; and therefore the other *ſiliquaſtrum*, originally and properly ſo called, cannot be that plant. Julius Scaliger obſerves, that there is a ſhrub growing in Provence at this time, called *ſiliquaſtrum*; he ſuppoſes this to be the *ſiliquaſtrum* of Pliny: it has leaves reſembling thoſe of the olive, and ſhort crooked pods. But we do not find any thing either in Pliny, or any other of the antients, to countenance the opinion of the *ſiliquaſtrum* being a ſhrub.

SILIQUASTRUM, in natural hiſtory, the name given by Mr. Lhuyd, and others, to the bony palates of fiſhes, when found foſſile. See the article ICHTHYPERIA.

SILIQUATICUM, among the Romans, a cuſtom or toll paid for merchandiſe. This the Greeks called *ceratiſmus*. See the article CERATISMUS.

SILK (*Cycl.*)—Raw *ſilk*, which is a ſubſtance of no remarkable ſmell or taſte, yet contains a ſurpriſing quantity of a volatile ſalt. Fifteen ounces of raw *ſilk* cut ſmall, and put into a retort, when diſtilled with a gentle fire, will yield two ounces and two drachms of a dry volatile ſalt; whereas fifteen ounces of hartſhorn, a ſubſtance uſually ſuppoſed to contain more volatile ſalt than any other ſubſtance, except ſal armoniac, yields only half an ounce and half a drachm: from the ſame quantity of *ſilk* there may alſo be drawn three ounces and an half of volatile ſpirit; whereas, from the like quantity of hartſhorn, the quantity of ſpirit exceeds this, being four ounces and a half. But we are to conſider, that there requires but a ſmall proportion of volatile ſalt to be diſſolved in phlegm, to make it what they call a volatile ſpirit; and that upon the whole there is no doubt, but that the *ſilk* contains greatly the larger portion of ſalt. The caput mortuum, from this quantity of hartſhorn, weighed nine ounces and two drachms; whereas that from the *ſilk* was only five ounces and five drachms: whence it is plain, that the hartſhorn contains greatly more earth in the ſame quantity, and conſequently leſs active principles.

It has generally been agreed, that the ſpirit of hartſhorn is no other than a phlegm, impregnated with a volatile ſalt, and an extremely penetrating ſulphur: this is proved by the following experiment. If ſpirit of wine be poured upon ſpirit of ſal armoniac, or ſpirit of *ſilk*, there is immediately produced a large quantity of a ſaline concretion; and when the ſpirit of *ſilk* is uſed, this concretion is manifeſtly compoſed of conſiderably large and ſeparate granules of ſalt; whereas, in caſe the ſpirit of ſal armoniac has been uſed, the concretion is perfectly fine, and of an even texture, and it is not eaſy to ſay, at firſt ſight, whether it be ſaline, or ſulphureous: this is what has been called by authors *oſſa Helmontii*. It is proved, however, to be wholly ſaline, on the adding water to it, ſince that readily diſſolves it. The ſulphur, which is contained in theſe volatile ſpirits, manifeſts itſelf ſufficiently by its ſmell.

The ſpirit of raw *ſilk* rectified with ſome eſſential oil, is the medicine commonly known by the name of *guttæ Anglicanæ*, or Engliſh drops. Mem. de l'Acad. Par. 1700. See the article DROPS.

Silk being properly an animal fluid hardened by the air, is uſually much mended or depraved in its nature and qualities, according to the nouriſhment the worm receives from a good or bad leaf; a great deal, therefore, depends on the goodneſs or badneſs of the ſpring of the year, in the value of the *ſilk* produced. A warm ſpring is beſt, and it ſhould be moderately moiſt, not overmuch ſo, becauſe too great a fall of rain is always found to rot the leaves. Southerly winds alſo are to be feared, becauſe they burſt the worms; and northerly ones, when ſtrong, uſually ſpoil the leaves. All theſe being deſtructive, either of the animals themſelves, or of their food, very juſt preſages may be formed upon them of the produce of the enſuing year.

When theſe miſchiefs do not happen, but the ſpring is favourable, the people have little to do but to watch the feeding of the worms, and about Midſummer they are to begin to draw the *ſilk* from its cocoon, to ſee what it yields, and judge of its encreaſe or ſcarcity, and eſtimate its goodneſs and perfections; the principal of which are, that it proves clean, light, and ſtrong.

Great uſe may be made of theſe obſervations, provided the management be good. It requires great care to hatch the eggs, and when hatched, there muſt be a careful eye over the worms, even to the time of drawing off the *ſilk*. If the ſeaſon foretels a ſcarcity, the buſineſs of the prudent manager is to buy up all the old *ſilk* he can procure, and keep as much of the other as he can, to be employed in the beſt fabrics, that ſo they may not be obliged to hazard all the good at the price of the worſt: but when the ſeaſon proves favourable, they collect the new for the beſt fabrics, and compare it with the old, to ſee whether it be of a better quality, before they venture to determine their prices.

The goodneſs of *ſilk* is beſt diſtinguiſhed by its lightneſs, that being its moſt eſſential quality: this every one knows carries a very great profit with it, being bought by weight, and ſold by meaſure, at the firſt hand, after the collectors. The Organcine *ſilk* is the beſt of any made in the country of Piedmont, and two threads are equal in fineneſs, that is in ſmoothneſs, thickneſs, and length, for the thread of the firſt twiſt. For the ſecond, it matters not whether the ſingle thread be ſtrong before the two are joined, unleſs to ſee whether the firſt twiſt prove well. It is neceſſary that the *ſilk* be clean, and it is to be obſerved, that the ſtraw-coloured is generally the lighteſt, and the white the heavieſt of all. The ſkains ſhould be even, and all of an equality, which ſhews that they were wrought together; otherwiſe we may with juſtice ſuſpect that it is refuſe *ſilk*, and cannot be equally drawn out and ſpun, for one thread will be ſhorter than the other, which is labour and loſs.

It will alſo be requiſite to ſearch the bale more than once, and take from out of the parcels a ſkain to make an eſſay; for unleſs it be known by trial what one buys, there is the greateſt danger of being cheated in this commodity. To make an eſtimate, and know the lightneſs, fix the eſſay upon one eighth of a portée, or hand of *ſilk* of a hundred and ten aunes or ells of Lyons in length, and ſee what it makes of aunes by the eighth part. The ſkain, which is of eighty threads, muſt be multiplied by a hundred and ten aunes of Lyons, and from this number muſt be deducted one eighth; as for example, 110 by 80 makes 8800, the eighth part of which is 1100; and this is the eighth part of a portée, or hand of *ſilk*. Now to calculate what theſe 1100 aunes weigh, which is the eighth part of a portée, or of 110 aunes of Lyons, it will be proper to take a ſkain out of the parcels, which you take from out of the bale which you judge may contain, at leaſt, 1100 aunes, to make the one eighth part of a portée, which portée muſt be divided on two bobbings, half on each; then fix the two bobbings on the center, or beam, and from thence paſs it through the comb hurdiſſoir, *viz.* 550 from the two bobbings, will make 1100, which will be one eighth part of what you deſire to know. This done, you cut off your *ſilk*, and carry it to put on the hurdiſſoir; then weigh it, and multiply the weight by eight, it will weigh juſt as much as a portée of 110 aunes of Lyons, which is the general rule for calculating. When they draw the *ſilk* out by this means, one may learn to adjuſt the weight.

There are *ſilks* of Piedmont which are very light and clean, and are to be preferred before any on the ſale: the portée of *ſilk* of the lighteſt weighs near twenty four pennyweights, and

and from this it arises in gravity to twenty five, and twenty six pennyweights the portée, and sometimes to twenty seven and twenty eight; but even these weights may be dispensed with, provided that the other qualities be good, that is, that it be well wrought, even, and clean. When the *silk* is more than twenty eight pennyweights the portée, it must always be proportionably cheaper. Philos. Transact. N° 252. p. 186.

SILK-*worm*, *bombyx*. This insect consists of eleven rings, and each of these of a great number of other smaller ones, joined to each other; and the head, which terminates these rings, is furnished with two jaws, which work and cut the food, not by a perpendicular, but a lateral action. The humours, found in the body of this creature, all seem approaching to the nature of the *silk* which it spins, for on being rubbed in the hands, they leave a hard or solid crust behind them. Under the skin there is always found a mucous rosy-coloured membrane, enveloping the animal, and supposed to be the new skin in which it is to appear, on throwing off the old one. The heart of this creature reaches from the head to the tail, running the whole length of the body: it is indeed rather a series of many hearts connected together, than one. The motion of systole and diastole is very evident in this whole chain of hearts; and it is an elegant sight to observe the manner of the vital fluid's passing from one of them to the other. The stomach of this animal is as long as the heart, reaching, like it, from one end of the body to the other. This large receptacle for food, and the sudden passage of it through the animal, are very good reasons for its great voracity.

In the sides of the belly, all about the ventricle, there are deposited a vast number of vessels, which contain the *silky* juice; these run with various windings and meanders to the mouth, and are so disposed, that the creatures can discharge their contents at pleasure at the mouth; and according to the nature of the juices, that they are supplied with, furnish different sorts of *silk* from them, all the fluid contents of these vessels hardening in the air into that sort of thread, that we find the web, or balls of this creature consist of.

These creatures never are offended at any stench of whatever kind, but they always feel a southern wind, and an extremely hot air always makes them sick. *Malpighi* de Bombyce.

Chrysalis of the SILK-*worm*. See the article FEVE.

SILVER (*Cycl.*)—*Silver* works, as spurs, wrought hilts, *&c.* are boiled in salt, alum and argol, to give it a whiteness and clearness. *Boyle*'s Works Abr. Vol. I. p. 135.

Silver burnt on a glass-plate tinges it of a fine yellow or golden colour. *Boyle*'s Works, Vol. I. p. 147. See also p. 458. and Vol. II. p. 64.

Chemists have made frequent attempts to dissolve *silver* in vegetable acids, but with little success, according to Mr. Marggrave; who says, that he himself, at last, succeeded in the attempt.

The chief art required, is to find a proper precipitate of *silver*. Mr. Marggrave's is formed by precipitating a solution of *silver*, in the best spirit of nitre, with that salt of urine which he says is the basis of phosphorus. See SALT *fusible of urine*.

This precipitate reduced to a fine powder, and digested in a sand-heat with distilled vinegar, well concentrated by freezing, will in part be dissolved thereby.

But if this precipitation of the *silver* be made with salt of tartar, and then dried and pulverized, a considerable quantity of it may be dissolved in distilled vinegar, in juice of lemons, in Rhenish wine, and in other vegetable acids. The like may be done with mercury. Mem. de l'Acad. de Berlin, 1741. See MERCURY.

Purified SILVER. The most commodious and regular manner of purifying *silver* is this: put a large test, inclosed in an iron ring, into a furnace; when the test has been red-hot about half an hour, put into it the *silver* to be purified, wrapt up in pieces of cloth or paper, and divided into small portions; then fill the orifice of the furnace with burning coals, and blow with a pair of hand-bellows, till the *silver* is in fusion; then add, at several times, some lead, reduced to globules of a determined weight; continue adding lead, and keep the fire in such a degree, as is just sufficient to keep the metal in fusion, and continue thus, till the *silver* is rendered quite pure. This may be partly guessed, by the before made trial of its degree of impurity on the touch-stone, and by the quantity of lead, judged necessary for the operation, having been consumed; and farther known, by trial of it on a wire thrust into it while in fusion, and the examining what is found adhering to it when it is taken out. When the operation is finished, pour water in a small stream on the *silver* to make it grow solid, and taking it out of the test, clean it from all impurities that may adhere to its surface with a brush made of small brass wire. *Cramer*'s Art of Assaying, p. 204. 208.

The way of purifying *silver* by means of nitre is this: reduce the *silver* to grains, or small thin plates, put it into a crucible, and add one quarter part of nitre, well dried and powdered: put upon this crucible another of a smaller size, having a hole as big as a pea in its bottom; lute the joint of the two crucibles, and place them in a wind-furnace, put charcoal about them as high as the rim of the lower crucible, but no higher, then light the fire at top, and encrease it till the vessels are middlingly red-hot, then with a pair of tongs hold a burning coal directly over the hole in the upper crucible, but at the distance of one finger; if you see a sudden clear light produced near and about the coal, together with a crackling noise, this shews that the fire has the right degree of strength; but if this does not appear at all, or but very faintly, the fire must be encreased: but if, on the contrary, you hear a violent blast of air from the hole, and a loud crackling noise, without holding the coal over, the fire is then too fierce, and must be diminished, otherwise you will not only lose a large quantity of *silver*, but very often the vessels will burst.

When this is perfectly over, encrease the fire so far, as to be able to melt *silver* without any addition; then take out the vessels, and when they are cooled break the under one, and you will find the regulus of *silver* at the bottom, and an alkaline scoria, commonly green, at the top. If the *silver* is not yet thoroughly purified, put it into another crucible, and this open into a wind-furnace, throwing upon it a little nitre, and as soon as it melts, pour it into a mould for ingots; thus will it be purified from every thing but gold. *Cramer*'s Art of Assaying, p. 246.

When any quantity of this metal is contained in iron, it may, according to the rules of assaying, be precipitated from it by scarification, by the assistance either of strong acid menstrua, or of crude antimony; the latter method is the easier, and is performed thus: put one centner of the iron reduced to very fine filings, and two centners of crude antimony, into a small crucible, close it with a tile, and set it in a strong fire, that it may melt; when it has been in a perfect state of fusion for six or eight minutes, take it out, and let it cool, break the crucible, and you will find a mass, composed of scoria at top, and a regulus underneath; throw away the scoria, and powder the regulus, mix it with twelve centners of granulated lead, and scorify it in a continual, but not over-strong fire, till the lead is seen covered all over its surface with scoriæ, then take it out, and pour the mass into a mould: the regulus should now be tough, and of a light lead-colour, both within and without; if it be blackish and brittle, it must be returned into the test, and scorified again, and when brought to its proper state, and the antimony all consumed, let it be put into the coppel; and when the bead of *silver* is produced pure, subtract from its weight the before known quantity of the *silver* contained in the lead used in the process, and the rest is the weight of the silver obtained from the iron. *Cramer*'s Art of Assaying, p. 223.

SILVER, in medicine, is mightily cried up for its virtues by chemical writers; accordingly, they have endeavoured to introduce a train of lunar medicines, as they call them, such as *argentum potabile*, *diaphoreticum lunare*, *bezoardium lunare*, and fifty others, as pompous as insignificant.

The only preparations of *silver*, which keep up their credit in the shops, are the lunar crystals, and the lunar caustic, called *lapis infernalis*; both which are violent caustics, eating away the flesh, and even the bones, they are applied to. See CAUSTIC.

Inflammable SILVER, a chemical preparation of the lapis infernalis made by a small heat. The process is this: take an ignited piece of Dutch turf, after it ceases to smoak, place it with its upper flat surface parallel to the horizon, make a little cavity in the middle, and therein put a drachm of dry lapis infernalis; it will immediately melt and glow, and finally it will take flame, and hiss and shine like nitre: after the flame ceases, pure *silver* will be found in the hollow, as much in quantity as was used in the making so much lapis infernalis.

This curious experiment shews the physical manner in which acids do but superficially adhere to *silver*; and the manner wherein acids operate, when united to metals, while surrounding their metallic mass, they arm the ponderous principles thereof with spiculæ: it shews also the immutability of *silver* dissolved in an acid, and the various ways in which it may be concealed, yet still have its action: it also shews the difference of potable *silver*, while existing in a saline form, by means of an adhering acid, from that potable *silver* of the adepts, where the principles of *silver* are supposed converted into a fluid, that will mix with the juices of the body, and cannot be reduced to *silver* again; but the great thing to be here observed, is, that the acid spirit of nitre, adhering in a solid mass of *silver*, is in this state as inflammable, on coming in contact with an ignited combustible body, as crude nitre itself: this seems to happen with *silver* alone, which is unchangeable with spirit of nitre. Hence also we see one way, by which *silver* may be obtained pure from other adhering matters, by bare burning: the acid here acts neither upon the mercurial part of the *silver*, nor on its fixing sulphur. *Boerh.* Chem. Part 2. p. 297.

SILVER-*ores*. Some of the *ores* of *silver* are rendered very refractory in the working, by means of a mixture of unmetallic earths, from which no art can wash them clean. The

method to procure the *ſilver* from theſe by an aſſay is this: powder the *ore* very fine, and to a docimaſtical centner of it add an equal quantity of glaſs of lead, mix theſe thoroughly together; the glaſs of lead muſt, for this purpoſe, be reduced to as fine a powder as the *ore*; put this powder, when well mixed, into a teſt, with twelve centners of granulated lead, and put the teſt under a muffel in a furnace, make a ſtrong fire, till the lead boils well; when it is in this ſtate, diminiſh the fire a little, and keep it in this weaker ſtate for ſome time, then encreaſe it again to a great ſtrength, till the lead is reduced to ſcoriæ, and the *ſilver* is ſeen pure in the teſt; or elſe when the ſcorification is perfected, take out the matter together, and putting it into a coppel with more granulated lead, ſeparate the *ſilver* in a bead. Sometimes a refractory *ore* of this kind cannot be thus ſufficiently diſſolved, but a maſs, which has the clammyneſs of pitch, ſwims upon the ſurface of the regulus, and upon the ſcoriæ that are in part ſubdued: in this caſe, diminiſh the fire, and touch this clammy maſs with a ſmall cold iron hook, to which it will immediately ſtick; take it all carefully off, reduce it to fine powder, and mixing it with more glaſs of lead in powder, put it back into the teſt, then continue the ſcorification till it is perfected: but always obſerve that the ſcoriæ of theſe refractory *ores* muſt be examined, to ſee if ſome of the regulus does not remain among them, for ſometimes the ſcoriæ, by their clammyneſs, will retain part of the metal; if this appears to be the caſe, powder the ſcoriæ very fine, and the metal will be diſcovered and ſeparated, as it cannot be reduced to a fine powder. *Cramer*'s Art of Aſſaying, p. 218.

The method of precipitating *ſilver* out of an eaſily fuſible *ore* is this: pound the *ore* very fine in an iron mortar, and for an aſſay weigh one docimaſtical centner of it, and eight centners of granulated lead; pour into a new teſt about half the lead, ſtir it about with a finger, and ſpread it over the cavity of the teſt; put upon this lead the pounded *ore*, and then cover it with the remainder of the lead; put the teſt, thus loaded, under the muffle of an aſſay-furnace, and in the hinder part of it make the fire, and encreaſe it to a conſiderably high degree. The *ore* will ſoon be raiſed out of the melted lead, and ſwim upon it; a little after it will grow clammy, melt, and be thrown toward the border of the teſt; then the ſurface of the lead will appear clear in the middle of the teſt, and will ſmoak and boil; the fire muſt now be made a little leſs, till the boiling ceaſes, for a quarter of an hour, and then made violent again, and the ſurface of the lead will then diminiſh by degrees, and be covered with a maſs of ſcoriæ. At this time have at hand an iron hook ready heated, and with this ſtir all the matter from the ſides into the middle of the teſt; if the matter, adhering to the hook from the ſtirring, melts quickly again, and the extremity of the hook, when cold, is found covered with a ſhining cruſt, the ſcorification is perfected; but if the ſcoriæ feel clammy while ſtirred, and adhere in quantity to the hook, and are of a rough ſurface, the ſcorification is not perfect, but the matter adhering to the hook muſt be ſtruck off with a hammer, and beat to powder, and returned into the teſt, and the fire continued till the ſcorification is perfected; then take out the teſt, and pour the whole contents into a mould, heated and greaſed. This is the firſt proceſs, and this uſually takes up three quarters of an hour: the *ſilver* is now in form of a regulus, and muſt be ſeparated by the coppel in the uſual way. *Cramer*'s Art of Aſſaying, p. 205. See the article REGULUS.

Mundic is a very common thing in *ſilver-ores*, eſpecially in the leſs rich ones, and gives great trouble in working the metal. The method of ſeparating the *ſilver* from an *ore*, rendered refractory by this admixture, is thus: break the *ore* into a rough powder, and put a centner of it into a teſt for an aſſay; put upon this another teſt, by way of a cover, and put it under the muffle in a furnace; when the muffle is near red-hot, encreaſe the fire by degrees, there will be a crackling noiſe, which being ended, take away the upper teſt, for when the veſſels have been red-hot about a minute, the *ore* ceaſes to ſplit; leave the *ore* under the muffle, till the arſenic and ſulphur are in a great meaſure evaporated, which will be known by the ceſſation of the ſmoak from the *ore*, and of the ſmell of garlick, or the acid; then take out the teſt, and leave it in a place not too cold, that it may cool leiſurely of itſelf; take the roaſted *ore* clean out of the teſt, powder it very fine, and mix it with an equal quantity of glaſs of lead in fine powder; and finally, ſcorify the maſs in the ſame, or in a new teſt, if that was cracked, till the *ſilver* appear in form of a bright bead in the middle, after it has ſtood a minute or two; after this take it out of the fire, and when cold take out and weigh the pure *ſilver*. *Cramer*'s Art of Aſſaying, p. 221.

Alonſo Barba tells us, that the original method of extracting *ſilver* from the *ore*, in the mines of Potoſi, was only by quickſilver, but this was very difficult in many caſes. Thoſe *ores* which partake of copperas, which are very numerous there, will not bear quickſilver, but conſume and ſcatter it, breaking its particles, and rendering them unfit for the purpoſes they were intended for, of taking up the *ſilver* contained in the *ore*. Burning the *ore* was another method heretofore uſed with too little caution, and great loſſes were ſuſtained by it. The grinding the *ore* is always proper, and the finer it is ground, the better it will always ſucceed. Alonſo Barba alſo greatly recommends boiling the *ores*, in which the quickſilver is uſed, as of great advantage. The burning of *ores* is of no ſervice, but to render the ſtony matter more friable; but when there is marcaſite among the *ore*, this is never done without loſs, and that often very great. *Alonſo Barba* de Metall.

The largeſt piece of *ſilver-ore* we have account of any where, is at this time preſerved in the king of Denmark's Muſeum of Curioſities at Copenhagen; this was dug in the mines of Norway, and weighs five hundred and ſixty pounds. It is five feet ſix inches long, and meaſures four feet about: it is valued at five thouſand crowns. There is in the ſame place another alſo, which was dug in the ſame mine, valued at three thouſand two hundred and ſeventy crowns. Theſe are both ſo very rich, that they ſeem at leaſt three parts *ſilver*, and the metal appears in very elegant forms in them, and riſes up out of their ſurface in form of ſmall trees and buſhes. There are alſo ſeveral pieces of pure native, or virgin *ſilver* there, all of which repreſent trees or plants.

SILVER-*pill*, a chemical preparation of *ſilver*, formerly highly commended as a remedy for dropſies, and in many other diſeaſes.

The method of making it is this: diſſolve an ounce of pure nitre in diſtilled water, then diſſolve an ounce of cryſtals of *ſilver* made in the common way, with pure *ſilver* and aqua fortis, in three times the weight of water, ſo that the ſolution may be perfectly limpid; mix the two ſolutions together, they will become a clear homogene liquor, evaporate this to a pellicle, and cryſtals reſembling nitre will ſhoot; pour off the remaining nitre as before, and the remaining nitre will ſhoot with the *ſilver*, in form of cryſtals, again, upon a ſecond evaporation: let theſe cryſtals be dried upon a paper, and then placed in a glaſs veſſel in a very gentle heat, enough to make them ſmoak, but not run, ſtir it with a piece of glaſs all the time, and keep it over the fire, till no more fumes ariſe; thus the acid ſpirits will be driven off, and the *ſilver* remain of a very bitter taſte, and purging quality. It muſt be kept in a dry cloſe veſſel. This diſcovery has been made to ſerve to many other purpoſes, beſide its uſes in medicine, and has furniſhed the diſhoneſt pretenders to alchemy with one of their moſt cunning methods of deceit. They have been able, by this means, to conceal *ſilver* in nitre, and that in a very large proportion, as in one tenth part of the whole quantity; and this nitre being projected in an equal quantity on melted lead, gives an increaſe of one tenth part in *ſilver*, which remaining upon the teſt, will deceive the ignorant, as if a tenth part of the lead were converted into pure *ſilver*. People who are upon their guard may, however, diſcover the cheat, by diſſolving the pretended nitre in ten times its weight of water, and putting a poliſhed plate of copper into the ſolution; for every particle of the *ſilver* will then be precipitated out of the liquor upon the copper, and to the bottom of the veſſel. *Boerh.* Chem. Part 2. p. 296.

The medicinal uſe is this: the dried maſs, conſiſting of the ſalts of *ſilver* and nitre, is to be reduced to a fine powder; this powder applied to ulcers, acts in the manner of the lapis infernalis, or *ſilver*-cauſtic, only much milder: but for internal uſe, the quantity of two grains of it is to be ground to a fine powder, with ſix grains of loaf-ſugar, in a glaſs mortar, this is to be then mixed with ten grains of the crumb of bread, and formed into nine *pills*: theſe are to be taken by a grown perſon upon an empty ſtomach, drinking after them four or ſix ounces of hot water, ſweetened with honey. It purges gently, and brings away a liquid matter like water, often unperceived by the patient. It is ſaid to kill worms, and perform great things in many obſtinate ulcerous diſorders. It purges without griping, but it muſt not be uſed too freely, nor in too large a doſe, for it always proves weakening, and in ſome degree corroſive on the ſtomach; but this inconvenience is greatly alleviated by rob of juniper. *Boerh.* Chem. Part 2. p. 297.

SILVERING (*Cycl.*)—To *ſilver* braſs: fine *ſilver* is diſſolved in aqua fortis in a broad bottomed veſſel of glaſs, or glazed earth, and the aqua fortis being afterwards evaporated, water is poured upon the remaining calx. This water muſt alſo be evaporated, and the operation repeated as often as there is occaſion; the fire being increaſed towards the latter end, ſo as to leave a perfectly dry and white calx, which will be thus tolerably freed from the aqua fortis. Of this calx take one part, and an equal meaſure, not weight, of common ſalt, and of the cryſtals of tartar, and mix them together into a fine powder; then having firſt plunged the ſcowered braſs into fair water, rub ſome of the powder upon it with your wet fingers, till the cavities of its ſurface be ſufficiently filled therewith. Laſtly, waſh the metal well in water, and give it a gloſs by rubbing it hard with a dry cloth.

This

This washing, Mr. Boyle observes, is expeditious, cheap, requires no quicksilver, and may be made to last some years, and is easily renewable, when it begins to wear. See his Works Abr. Vol. I. p. 151.

SILVERING *of glasses*. An excellent method of turning spherical, and other glasses, into speculums by *silvering*, is this: take half an ounce of pure lead, and melt it into a mass with the same quantity of fine tin, then immediately add half an ounce of bismuth, and carefully skim off the dross; remove the ladle from the fire, and before the matter is cold, add to it five ounces of pure quicksilver, stir the whole together, and then put the fluid amalgam into a clean glass.

When this is to be used for foiling, or *silvering*, let it be strained through a linnen rag, and then gently pour some ounces of it into the glass intended to be foiled, by means of a paper funnel, reaching almost to the bottom, to prevent its flying up to the sides; then dexterously inclining the glass every way, endeavour thus to fasten the foil. When this is done, let the glass rest for some hours, then repeat the operation, till at length the whole fluid mass is evenly spread and fixed over the whole internal surface; then let the superfluous amalgam be poured out, and the outside of the glass polished. This is the method by which glass spheres are made to look as if full of quicksilver, and deserves to be tried on the common looking-glasses, as having many advantages over the usual way of *silvering* them. *Shaw*'s Lectures, p. 428.

SILURUS, in zoology, the name of a very large fish, commonly called in English the *sheat-fish*.

It is caught in the Vistula, and other large rivers, and grows to an immense size, some having been caught of more than an hundred weight, and of sixteen feet long, and sometimes considerably larger than that. It resembles the eel in colour, but the belly is variegated with black, white, and dusky spots. The body is without scales, and is covered with a mucous substance. The head is flat, short and broad, the opening of the mouth extremely large. The body down to the fundament is thick and cylindric, but the bottom of the belly is flat, and from the anus to the tail it is broader and flat. Its eyes are large, and have two antennæ, or slender excrescences before them; and four beards hang from the lower jaw. The gills are four on a side. It has only one small fin upon the back, and the tail is not forked. Its flesh is much esteemed for food, and is dressed for the table as the eel. It is a very voracious fish, and much dreaded whenever it comes among the smaller fry.

Gesner mentions two other species of it, one flatted toward the tail, and the other of a mixed green and yellow colour, and having two beards on the upper jaw, and three on the under: he only calls these *siluri secunda*, and *tertia species*. *Willughby*, Hist. Pisc. p. 128.

The name is of Grecian origin, and is derived from the words σεὶω, to move or shake, and οὐρὰ, a tail. It is given to this fish, from its remarkable quality of being almost continually moving its tail in the water.

SILURUS is also a name given by some authors to the sturgeon, called by others *accipenser*, but by the generality of writers *sturio*. *Salvian*, de Aquat. See the article STURIO.

SIMARONA, a name given by the Spaniards in America to a species of vanilla, called also *bastard-vanilla*. The pods of this kind are every way smaller than those of the true kind, and have very little liquor, or pulp in them when broken, and contain very few seeds. These are greatly inferior to the true kind, having scarce any smell. It is not yet certainly known, whether this species be the fruit of a different kind of vanilla-plant from the common, or whether it be the same fruit gathered at a different season, or from a plant growing in a different soil. See the article VANILLA.

SIMAROUBA. The bark of this plant is very successful in the cure of dysenteries, as Mr. Jussieu assures us from his experience. It is a thick yellow bark, of an astringent bitterish taste, and resembling, as it is said, the *macer* of the antients. It was first brought into Europe from America, in 1713; but of the tree, which produces it, we have no certain account.

This medicine is more successful in decoctions than in substance. The dose is about the third part of a quart of decoction, having two drachms of the bark in it. See Mem. de l'Acad. des Scienc. Anno 1729.

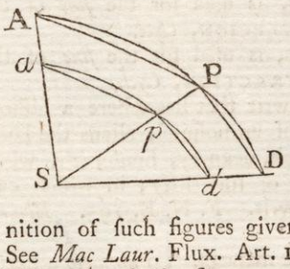
SIMARUM *musculus*, in anatomy, a name given by some of the old writers to a muscle, called by the moderns the *serratus magnus*. See SERRATUS.

SIMBALATH, in the materia medica, a name given by Avisenna and others to the spikenard, or *nardus Indica*.

The exact interpretation of the word is *spicigera*, and Avisenna, under this general name, distinguishes it into several kinds; the first he calls *alnardin*, or *nardin*. It has been supposed by some that he means the Indian *spikenard* by this word, but, on the contrary, it appears plainly that he means the Celtic *nard*; he calls it the *nardus Romani orbis*, and says that it is of European growth. After this he mentions the Asiatic *nards* of several kinds, which are only the Indian *spikenard*, growing in different places, and such as used to be brought thence in different degrees of perfection. See the article NARDUS.

SIMIA, the *ape* or *monkey*, is made by Linnæus a distinct genus of animals, the character of which is, that the creatures of this kind have teeth, have feet composed of five toes, and made for climbing, and have their paps on the breast. *Linnæi* System Nat. p. 34.

This genus comprehends the *monkey*, *ape*, and *baboon* classes, but more regularly, the word *simia* is the name of that kind only which has no tail, the tailed ones being, in distinction, called *cercopitheci*, or *tailed monkeys*.



The proper name of the *simia*, in English, is *ape*, and those which have tails, are distinguished by the name *monkey*. See CERCOPITHECUS.

There are many species of *apes*, and even many more than were supposed by authors; America affording us frequent instances of such as have not been described in any book. *Ray*'s Syn. Quad. p. 149.

SIMIA *marina*, the *sea-ape*, a name used by Bellonius, and some other authors, for the fish called *vulpes marina*, a kind of shark, remarkable for its long tail, from which probably it had both one and the other of these names. *Willughby*, Hist. Pisc. p. 54.

SIMICON, in antiquity, a musical instrument of the stringed-kind, with thirty five strings. Mem. de l'Acad. Inscript. Vol. 5. p. 168.

SIMILAR (*Cycl.*)—SIMILAR *curves*, in geometry. The *similarity* of curvilinear figures may be derived from that of rectilinear figures, that are always *similarly* described in them; or, we may comprehend all sorts of *similar* figures, planes, or solids, in this general definition: figures are *similar*, when they may be supposed to be placed in such a manner, that any right line being drawn from a determined point to the terms that bound them, the parts of the right line, intercepted betwixt that point and those terms, are always in one constant ratio to each other. Thus the figures ASD, *a*S*d*, are *similar*, when any line S P being drawn always from the same point S, meeting A D in P, and *a d* in *p*, the ratio of S P to *Sp* is invariable. It is manifest, that the rectilinear inscribed figures *a p d* S, A P D S, are *similar* in this case, according to the definition of such figures given in Euclid's Elements, Book 6. See *Mac Laur*. Flux. Art. 122.

When the *similar* figures are in the situation here described, they are also *similarly* situated, and all their homologous lines are either placed upon one another, or parallel.

SIMILAR *diameters* of two conic sections. When the diameters in two conic sections make the same angles with their ordinates, they are sometimes said to be *similar*.

SIMILAR *solids*, such as are contained under equal numbers of *similar* planes, alike situated.

SIMILAR *bodies*, in natural philosophy, such as have their particles of the same kind or nature one with another.

SIMILAR *animals*. We have a treatise by Dr. Martin, wherein he treats of the laws and proportions of the motions and forces of the solids and fluids of animals, of however different magnitudes, which are supposed of *similar* make and constitution. See Tractat. de Similibus animalibus.

SIMON, in zoology, a name by which some authors have called the dolphin. It is affirmed that this fish loves the name, and will come to a person who calls him by it; but this, though recorded by authors of credit, meets with no faith among the judicious readers. *Ray*'s Ichthyography, p. 31.

SIMPLE (*Cycl.*)—SIMPLE *leaf*, among botanists. See the article LEAF.

SIMPLE, or *single eccentricity*. See ECCENTRICITY, *Cycl.*

SIMPLE *problem*, in mathematics. See LINEAR *problem*, *Cycl.*

SIMPLE *roots*. See FIBROSE *roots*.

SIMPLE *waters*, in distillery. See WATERS.

SIMPULUM, among the Romans, a vessel with a long handle, and made like a cruet. It was used in sacrifices and libations, for taking a very little wine at a time. *Pitisc*. Lex. Antiq. in voc.

SIMULACRUM, among the Romans. See the articles IDOL and IDOLATRY, *Cycl.*

SIMUS, in zoology, the name used by some authors for the *nasus*, or *nase*, a fish common in the large rivers in Germany, and somewhat resembling our chub, and in some respects our common rudd. *Gesner*, de Pisc. p. 213. See the article NASUS.

SINAPI, *mustard*, in botany, the name of a genus of plants, the characters of which are these. The flower is composed of four leaves, and is of the cruciform-kind. The pistil arises from the cup, and finally becomes a long pod, divided by an intermediate membrane into two cells, and containing roundish seeds; the pod also usually terminates in a fungose horn, which has some seeds in it. To this it is to be added, that these plants have all a hot, acrid, and biting taste.

The ſpecies of *ſinapi*, enumerated by Mr. Tournefort, are theſe. 1. The turnep-leaved *muſtard*. 2. The white *muſtard* with hairy pods, and red and white ſeeds. 3. The early wild *muſtard* with black ſeeds, called by many *charlock*. 4. The early black-ſeeded field-*muſtard*, or charlock, with undivided leaves. 5. The rocket-leaved *muſtard*. 6. The Spaniſh *muſtard* with lobated leaves, and ſulphur-coloured flowers. 7. The creſs-leaved Spaniſh *muſtard*. 8. The ſmall radiſh-leaved Spaniſh *muſtard*. 9. The dwarf white Spaniſh *muſtard*. 10. The largeſt Indian lettuce-leaved *muſtard*. 11. The large Indian lettuce-leaved *muſtard* with narrower leaves. *Tourn.* Inſt. p. 227. See MUSTARD.

SINAPI *Perſicum*, *Perſian muſtard*, a name by which ſome botanical authors have called the *thlapſi*, or treacle-muſtard. *Ger.* Emac. Ind. 2.

SINAPISIS, a word uſed by ſome writers as a name for *Armenian bole*. *Caſt.* Lex. Med. in voc.

SINAPISTRUM, in botany, the name of a genus of plants, the characters of which are theſe. The flower conſiſts of four leaves, diſpoſed in the form of a croſs. The piſtil ariſes from the cup, and at length becomes a long cylindric bivalve pod, uſually containing roundiſh ſeeds.

The ſpecies of *ſinapiſtrum*, enumerated by Mr. Tournefort, are theſe. 1. The more prickly ſeven-leaved Egyptian *ſinapiſtrum* with fleſh-coloured flowers. 2. The leſſer, not thorny, five-leaved Indian *ſinapiſtrum* with fleſh-coloured flowers. 3. The trifoliate, not thorny, Indian *ſinapiſtrum* with fleſh-coloured flowers. 4. The ſhrubby trefoil American *ſinapiſtrum* with the taſte of creſſes. 5. The trifoliate red-flowered Portugal *ſinapiſtrum* with horned pods. *Tourn.* Inſt. p. 231.

SINASBARIUM, in botany, a name given by ſome authors to the *ſyſimbrium*, or water-mint, common in all our ditches and watery places. *Ger.* Emac. Ind. 2.

SINE (*Cycl.*)—SINE *of incidence*, in catoptrics and dioptrics, is uſed for the *ſine* of the angle of incidence. See the article INCIDENCE, *Cycl.*

SINE *of reflection*, in catoptrics, is uſed for the *ſine* of the angle of reflection. See REFLECION, *Cycl.*

SINE *of refraction*, in dioptrics, is uſed for the *ſine* of the angle of refraction. See REFRACTION, *Cycl.*

SINE *aſſenſu capituli*, in law, a writ that lies where a biſhop, dean, prebendary, or maſter of an hoſpital, aliens the lands holden in right of his biſhoprick, deanery, houſe, &c. without the aſſent of the chapter or fraternity; in which caſe his ſucceſſor ſhall have this writ. F. N. B. 195. *Blount*, *Cowel.*

SINEW (*Cycl.*)—SINEW, in the manege. To *unſinew* a horſe, called in French *enerver*, is to cut the two tendons on the ſide of the head, about five inches under the eyes; which two join in one at the tip, or end of the noſe, in order to perform its motion. This tendon, at the tip of the noſe, is likewiſe cut. We *unſinew*, in order to dry the head, and make it ſmaller.

SINEW-*ſhrunk*, is ſaid of a horſe that is over-rid, and ſo worn down with fatigue, that he becomes gaunt-bellied, through a ſtiffneſs and contraction of the two *ſinews* that are under his belly.

SINEW-*ſprung*, is a violent attaint, or over-reach, in which a horſe ſtrikes the toe of his hinder feet againſt the *ſinew* of the fore legs.

SINF, in the materia medica of the antients, a word uſed to expreſs the ſame as *agallochum*, or lignum aloes.

The Arabians formed an adjective of this word, and called the yellowiſh lignum aloes *ſinficum*, and the blackiſh *indicum*. Not that the ſinficum came from any other place, or that the Indicum was given as the name of the country, but that the colours only were expreſſed by theſe epithets; *indicum* being with the antients as a common word to expreſs black by. The only ſpecies of myrobalan they had of a black colour, was called the *Indian myrobalan*; not for its being peculiarly the produce of that country, but becauſe of its being of the colour they expreſſed by that word.

SINGERS, in the Jewiſh antiquities. See CHANTERS.

SINGLE (*Cycl.*)—SINGLE *caſt*, in huſbandry, a term uſed by the farmers for that ſort of ſowing, that diſperſes the neceſſary quantity of corn at one bout. *Plot*'s Oxfordſhire, p. 251.

SINGULATOR, among the Romans, a horſeman who rode with one horſe only. *Pitiſc.* in voc.

SINKING, or ABSORPTIONS *of the earth*. Kircher has written very largely on this ſubject, and antient and modern hiſtories agree in relating many ſuch facts. The *abſorptions* themſelves are indeed too common, and are the effects of earthquakes, ſubterranean fires, and many other accidents of the macrocoſm; but there are much fewer inſtances of the reſtoring the places thus *abſorbed*, and there are but few of thoſe inſtances, which are recorded of it, that deſerve credit, though ſome are unqueſtionable.

Pliny tells us, that in his own time the mountain Cymbotus, with the town of Eurites, which ſtood on its ſide, were wholly *abſorbed* into the earth, ſo that not the leaſt trace of either remained; and he records the like fate of the city Tantalis in Magneſia, and after it of the mountain Sypelus, both thus *abſorbed* by a violent opening of the earth. Galanis and Garnatus, towns once famous in Phœnicia, are recorded to have met the ſame fate; and the vaſt promontory, called Phlegium, in Æthiopia, after a violent earthquake in the night-time, was not to be ſeen in the morning, the whole having diſappeared, and the earth cloſed over it. Theſe and many other hiſtories, atteſted by the authors of greateſt credit among the antients, abundantly prove the fact in the earlier ages; and there have not been wanting too many inſtances of more modern date. *Kircher*'s Mund. Subter. p. 77. The mountain Picus, in one of the Molucca iſles, was ſo lofty, that it appeared at great diſtances as an immenſe column reared erect in the air, and ſerved as a land-mark to ſailors; an earthquake in this iſland deſtroyed it; at one inſtant the whole mountain was *abſorbed* into the bowels of the earth, and no mark of its place remained but a vaſt lake of water, exactly anſwering to the ſhape of the baſe of the mountain. A like accident, but of a more terrible kind, happened in China, in the year 1556, when a whole province of the mountainous parts of that kingdom was in one moment *abſorbed* into the earth, and all the towns buried, the whole number of the inhabitants *ſinking* with it, and an immenſe lake of water remaining in its place to this time. Of much later date is the deſtruction of a city in the confines of Swiſſerland; but this, though generally ſaid to have been ſwallowed up into the earth, was not properly an *abſorption*; for the whole city was buried by the fall of a mountain upon it.

The burning mountains, Veſuvius and Strongylus, both once very high, have in length of time loſt half their height, the upper part having been undermined by the burning, and having fallen into, and been *abſorbed* by the under part. And in the year 1646, during the terrible earthquake in the kingdom of Chili, ſeveral whole mountains of the Andes diſappeared, and were one after another wholly *abſorbed* in the earth.

Theſe, and a thouſand other accidents of a like kind, prove the truth of *abſorptions* in general; ſome of them leaving level ground in the place of the things *abſorbed*, ſome immenſe chaſms and cracks, and ſome lakes of freſh or ſalt water; and it may be, that many immenſe lakes were formed in ages, of which we have no hiſtories, by the like *abſorptions*.

Pliny gives many accounts of the reſtoring of places thus *abſorbed*, but later obſervations do not give an equal credit to theſe parts of his hiſtory. He tells us, that theſe reſtorations are made ſometimes in the ſame place, where the original mountain or iſland was *abſorbed*; ſometimes in others, as large ſpaces of ground ariſing out of the ſea in one place, which had been taken from the land in another; but theſe ſeem very vague relations. The iſlands of Rhodes and Delos, he ſays, are of this origin, as alſo that of Anephe beyond Melos, and Nea near Lemnos; that of Ajoue between Lebadus and Teus, and Hiera among the Cyclades; and finally, the iſland Thia, which he ſays appeared in his own time. A modern inſtance of this kind, is the ſudden production of the new iſland near Santorini; but this, and probably all the others alſo, was not the reſtoration of any thing before *abſorbed*, but the effect of a vulcano under water, which threw up a vaſt quantity of cinders and ſciarri, the whole iſland, as it is called, conſiſting of nothing elſe. In the ſame manner, in the year 1638, an iſland was raiſed near St. Michael's, in the Atlantic ocean, by ſubterranean fires, which threw up ſtones, and other ſubterranean productions, in ſuch quantities, that they formed an iſland of five miles in length. The mountain raiſed in one night, in the ſea near Puzzoli, is another inſtance of this ſudden production of theſe mountains: this appeared after one night's violent ſubterranean conflict, and ſtill keeps its place, and is known under the name of the *Mons Sanctus*. Not one of theſe, however, appeared in the place of any thing that was *abſorbed*; and there is more imagination, than judgment, in ſuppoſing them to have any connexion in the laws of nature with the *abſorptions* of other places, very diſtant, and at diſtant times. *Kircher*'s Mund. Subter. p. 79.

SINKOO, in the materia medica, a name given by ſome authors to the *lignum aloes*, or agallochum, uſed in medicine. *Dale*'s Pharm. p. 347.

SINNET, aboard a ſhip, is a line or ſtring made of rope-yarn, conſiſting generally of two, ſix, or nine ſtrings, which are divided into three parts, and are platted over one another, and then it is beaten ſmooth and flat with a wooden mallet. Its uſe is to ſerve the ropes, that is, to keep them from galling.

SINOPICA *terra*, in natural hiſtory, the name of a red earth of the ochre-kind, called alſo *rubrica Sinopica*, and by ſome authors *ſinopis*.

It is a very cloſe, compact, and weighty earth, of a fine glowing purple colour, but in ſome ſpecimens much deeper than in others, and in ſome degenerating into paleneſs; but even in its worſt condition, it is a very fine colour. It is of a pure texture, but not very hard, and of an even, but duſty ſurface. It adheres firmly to the tongue, is perfectly fine and ſmooth to the touch, does not crumble eaſily between the fingers, and ſtains the hands. It melts very ſlowly

in

in the mouth, and is perfectly pure and fine, and of a very auſtere aſtringent taſte, and ferments very violently with aqua fortis.

It was dug in Cappadocia, and carried for ſale to the city Sinope, whence it had its name. It is now found in plenty in the New Jerſeys in America, and is called by the people there *blood-ſtone*, from its ſtaining the hands to a blood colour, and may probably be had in many other places; and this deſerves thoroughly enquiring into, ſince there ſeems not one among the earths more worthy notice. Its fine texture and body, with its high florid colour, muſt make it very valuable to painters, and its powerful aſtringency equally ſo in medicine. The antients were well acquainted with it in fluxes and hæmorrhages, and experience ſhews it poſſeſſes the ſame virtues at this time. The deepeſt coloured is ever the moſt aſtringent. *Hill*'s Hiſt. of Foſſ. p. 60.

SINOPIS, in natural hiſtory, a name by which ſome authors have called the Sinopic ochre, commonly called *rubrica Sinopica*. *Hill*'s Hiſt. of Foſſils, p. 60. See the article SINOPICA *terra*, ſupra.

SINUATED *leaf*, in botany. See LEAF.

SINUS (*Cycl.*)—SINUS *of an artery*, is uſed by ſome for any part of an artery, where its ſides are ſtretched out beyond the ordinary proportional dimenſions elſewhere. Med. Eſſ. Edinb. Abridg. Vol. 2. p. 410.

Morgagni has obſerved four ſuch *ſinuſes* in the aorta; three of them anſwering to the ſemilunar valves, and the fourth is all that part of the aorta, between the former *ſinuſes* and the origin of the common trunk of the right ſubclavian and carotid arteries. He gives ſome reaſons to prove, that the nervus acceſſorius ariſes from the eighth pair, to be joined to the medulla ſpinalis. Med. Eſſ. ibid.

SINUS *of the womb*, is uſed for any cavity within its ſubſtance. Theſe *ſinuſes* are much of the ſame texture with the cells of the ſpleen, or rather of the corpora cavernoſa penis; being membranous cavities communicating with each other, and having numerous arteries ſpread on them, whoſe lateral branches open into the cells, from which veins go out to be joined to other veins, that return the blood from the other parts of the womb.

Theſe *ſinuſes* are diſtended with blood in the time of the menſes; and their orifices are then alſo enlarged.

During the time of pregnancy the *ſinuſes*, and their canals, that open into the womb, are gradually diſtended and enlarged; ſo that, at the end of nine months, the *ſinuſes* will contain the largeſt fingers, and the canals from them will receive the little finger. Vid. *Monro*, in Medic. Eſſ. Edinb. Vol. 2. Art. 9.

SIPHAC, a name uſed by ſome authors for the *peritonæum*.

SIPHILIS, a name uſed by ſome authors for the *lues venerea*, or French-pox.

SIPHITA, a word uſed by Paracelſus, and his followers, with the addition of *parva* and *magna*, for two diſorders. The *ſiphita parva* ſignifies the *chorea ſancti Viti*, or St. Vitus's dance; and the *ſiphita magna*, walking in time of ſleep.

SIPHNIUS *lapis*, in the natural hiſtory of the antients, a ſubſtance found in great plenty in the iſland Siphnus, in the Ægean ſea.

It was dug up in large maſſes in the neighbourhood of the ſea, and when freſh might be cut or worked by the turner into any ſorts of veſſels, by reaſon of its ſoftneſs; but when afterwards burnt and oiled over, it became black and ſolid, and was fit for any ſervice; and the veſſels made of it bore the fire very well, and as thoſe of earthen-ware with us, for the common offices of boiling, &c. In many parts of Europe they ſtill find the ſame ſubſtance, and call it *lapis lebetum*, uſing it in the ſame manner. It is no other than the *ſteatites*, or *ſoap-rock*, as it is called with us, common in Cornwall, though our people have not thought of putting it to that uſe. *Hill*'s Theophr. p. 106. See the article STEATITES.

SIPHONANTHEMUM, in botany, the name of a genus of plants eſtabliſhed by Dr. Amman. The name is derived from the Greek σιφων, a tube, and ανθεμον, a flower. The characters of the genus are theſe. The flower conſiſts of one petal, and is tubulated and divided into ſeveral ſegments at the edge. The piſtil ariſes from the cup, and finally becomes a fruit reſembling four berries, nicely joined together. It is divided into four cells, and contains a number of roundiſh ſeeds. The ſtalks of the plant are green and ſtriated. The leaves ſtand very cloſely together, and are placed in no order; they are very narrow, about three inches in length, and much reſemble thoſe of the willow; they ſtand on very ſhort pedicles, and are of a very deep green, both on the upper and under-ſide. From the alæ of the leaves, or a little above their inſertions toward the top of the ſtalks, there ariſe ſeveral pedicles, of about an inch in length, which divide into ſeveral others at their tops; uſually each part into three, but often into four or five: theſe are diſpoſed in the manner of the pedicles of the umbelliferous flowers, and each is terminated by a one-leaved cup, divided into five ſegments, from which ariſe flowers compoſed of a ſlender tube, two or three inches long, of a yellowiſh green, which at the end expands into four ſegments of a pale yellow: in the middle of theſe there ſtands a purple ſtyle, which is crooked, and is ſurrounded by four ſtamina of a purple colour, ſuſtaining each a triangular brown apex. In each of the four cells of the capſule there is contained one large greeniſh yellow ſeed. Act. Petrop. Vol. 8. p. 216.

SIPTACE, in natural hiſtory, the name given by the antients to a beautiful bird, of which they were very fond, and which was often kept in their houſes. Some have conjectured this to be the goldfinch, from the fine yellow they deſcribe about it; but Pliny plainly makes it the parrot: he tells us, among other things, that it imitated the human voice the beſt of all birds.

SIRA, a name by which ſome of the chemical writers have called orpiment.

SIRACAUSTUM, a name given by Meſue to a medicine he recommends in acute diſeaſes.

SIRÆUM, a word uſed by ſome to expreſs a ſweet decoction, whether given in that form, or firſt inſpiſſated into a ſort of rob by evaporation.

SIREN (*Cycl.*)—SIREN, in ichthyology, a name given by Artedi to the ſea-monſter often deſcribed by authors, but either not exiſting at all, or not ſo like man as their deſcriptions make it.

Artedi ſuppoſes it to conſtitute a peculiar genus of the plagiuri, or cetaceous fiſhes. The characters he gives of it are theſe: it has no pinnated tail; the head, neck, and breaſt, down to the navel, repreſent thoſe of the human ſpecies; there are only two fins on the whole body, and thoſe ſtand on the breaſt.

Bartholine, in his Hiſtory of Curioſities, deſcribes ſuch a fiſh as this, under the name of *ſyrene*, and Barchewitz under the name of *homo marinus*. This author ſays that he ſaw one at ſea, and that it is wholly different from the manati, and from all other fiſhes. The Philoſophical Tranſactions alſo contain an account of a ſea-man ſeen in the American ſeas, and ſeveral other writers of credit give countenance to the ſtory. Their deſcriptions tell us, that from the navel to the tail it is one ſhapeleſs maſs of fleſh, without any appearance of finny tail, or any other part of the ſtructure of a fiſh. The pectoral fins reſemble hands, and are compoſed of five bones, or fingers, joined by a membrane. With theſe it ſwims. It were much to be wiſhed, that ſome accurate ichthyologiſt might have an opportunity of ſeeing and examining this creature, if it really exiſts different from the other animals of the ſea. Artedi ſeems to doubt the truth of the accounts, but thinks it better not to judge of a thing not yet ſeen, than to pronounce any thing raſhly againſt the accounts of creditable authors. *Artedi*, Gener. Piſc. p. 52.

SIREN is alſo a name given by Mouffet, and other authors, to a ſpecies of bee; of which they diſtinguiſh two kinds, a larger and a ſmaller. Theſe differ greatly from the common bee, in that they live ſolitary, and never unite into ſwarms, or build neſts, or make combs.

SIRI, among the Romans, were ſubterranean caves, or vaults, in which wheat could be kept ſound and freſh for fifty years. *Pitiſc.* Lex. Ant. in voc.

SIRIASIS, a name given by medical writers to a diſeaſe to which children are ſubject; it conſiſts in an inflammation of the brain and its membranes, and is attended with a depreſſure of the fontanella, or hollowneſs of the eyes, a burning fever, a paleneſs and dryneſs of the whole body, and an utter loſs of appetite.

SIRICON *plumbi*, a name given by ſome chemical writers to calcined lead, or the grey powder made of lead by a ſlight calcination in an open fire.

SISARUM, *ſkirret*, in botany, the name of a genus of umbelliferous plants, the characters of which are theſe. The flower is of the roſaceous kind, being compoſed of ſeveral petals, arranged in a circular form. The cup becomes a fruit compoſed of two ſeeds, which are ſlender and gibboſe on one ſide, and flat on the other. To this it is to be added, that the roots are ſeveral large and long ones, hanging from the ſame head.

We know of no other ſpecies of this genus, but the common *ſiſarum*. *Tourn.* Inſt. p. 308. See SKIRRET.

The taſte of the *ſkirret*-root has ſomewhat of a bitterneſs and ſubaſtringency in it. It ſtrengthens the ſtomach, and is of good nouriſhment. It proves diuretic, and is by ſome pretended to be a remedy againſt the ill effects of mercury; but this is an idle opinion.

SISER, in botany, a name given to the ſkirret, otherwiſe called the white carrot, or yellow parſnep. See the article SISARUM.

SISKIN, in zoology, the common Engliſh name of a finging bird, kept in cages in ſome parts of England, where it is common, and called by authors *ſpinus* and *ligurinus*. *Ray*'s Ornithol. p. 192. See the article SPINUS.

SISON *ſyriacum*, in botany, a name given by ſome authors to the ammi, or biſhop's weed, a plant, whoſe ſeeds were once much in uſe in medicine. *Ger.* Emac. Ind. 2.

SISSITIEPTERIS, in botany, a name uſed by Pliny, and ſome others of the old authors, for the *pimpinella*, or burnet. *Ger.* Emac. Ind. 2.

SISTRUM, in antiquity, an inſtrument uſed for beating time in concerts. It was a plate of ſounding metal, of an oval form, the upper part of which was adorned with three figures; that of a cat with a human face in the middle, the head of Iſis on the right-ſide, and the head of Nephthys on the left. It was filled with wires of the ſame metal, which ſerved to beat againſt the plate when ſhaken. Mem. Acad. Inſcript. Vol. 7. p. 249, ſeq.

SISYMBRIUM, *ſpearmint*, in botany, the name of a genus of plants, the characters of which are theſe. The flower conſiſts of four leaves, and is of the cruciform kind. The piſtil ariſes from the cup, and is finally turned into a long pod, divided into two cells by an intermediate membrane, and furniſhed with roundiſh ſeeds. To theſe marks it may be added, that there is a peculiar general appearance of all theſe plants, which will eaſily diſtinguiſh them, at firſt ſight, from all the others of the ſame claſs.

The ſpecies of *ſiſymbrium*, enumerated by Mr. Tournefort, are theſe. 1. The water-*ſiſymbrium*, or common water-creſs. 2. The purple-flowered broad-leaved Pyrenean *ſiſymbrium*. 3. The ſmooth rocket-leaved *ſiſymbrium* with yellow flowers, commonly called *barbarea*, and *winter-creſſes*. 4. The ſmall early-flowering ſmooth rocket-leaved *ſiſymbrium*, or winter-creſs. 5. The double-flowered ſmooth rocket-leaved *ſiſymbrium*. 6. The rough rocket-leaved *ſiſymbrium* with yellow flowers. 7. The ſhort-podded radiſh-leaved water-*ſiſymbrium*. 8. The radiſh-leaved ſhort-podded water-*ſiſymbrium* with variegated leaves. 9. The ſhort-podded water-*ſiſymbrium* with more deeply divided leaves. The three laſt are uſually called by authors *water-radiſhes*. 10. The creeping water-*ſiſymbrium* with leaves like thoſe of the naſturtiums. This is called by ſome *water-rocket*. 11. The ſmall rough-podded marſh-*ſiſymbrium*, called by many *rough-podded muſtard*. 12. The ſmall ſmooth-podded marſh-*ſiſymbrium*. 13. The wormwood-leaved annual *ſiſymbrium*, called by many authors *ſophia chirurgorum*. *Tourn.* Inſt. p. 226.

Siſymbrium, among the Romans, was one of the ingredients, whereof the nuptial garlands were compoſed. See NUPTIAL and GARLAND.

SISYMBRIUM, in botany, is alſo a name uſed to expreſs the wild water-mint. *Dale*'s Pharm. p. 205. See the article MENTHA.

SISYRA, among the antients, a woolly ſkin uſed for a covering to beds. *Hofm.* Lex. Univ. in voc.

SISYRINCHIUM, in botany, the name of a genus of plants, the characters of which are theſe. The flower and fruit are the ſame with thoſe of the iris and xiphion, but the root is compoſed of two bulbs, the one lying upon the other, as in the gladiol and crocus.

The ſpecies of *ſiſyrinchium*, enumerated by Mr. Tournefort, are theſe. 1. The large *ſiſyrinchium* with the flower marked with a yellow ſpot. 2. The large *ſiſyrinchium* with the flower marked with a white ſpot. And 3. the leſſer *ſiſyrinchium*. *Tourn.* Inſt. p. 365.

SITHCUNDMAN, in our old writers, one whoſe province it was to lead the men of a town or pariſh. Leg. Inæ. c. 56. Dugdale ſays, that in Warwickſhire the hundreds were formerly called *ſitheſoca*, and that *ſitheſocundman* and *ſithcundman* was the chief officer within ſuch a diviſion, i. e. the high-conſtable of the hundred. *Dugd.* Antiq. Warwick. *Blount.* in voc.

SITHESOCA, in our old writers, is uſed to denote the diſtrict now called an *hundred*. The word is Saxon, ſignifying a franchiſe, or liberty. Rot. Parl. 16 Hen. II. *Blount.*

SITICINES, among the Romans, perſons who ſounded a kind of trumpet, having a very mournful tone, at the burying the dead. *Danet.* in voc. See the articles BURYING and BURIAL.

SITONÆ, Σιτῶναι, among the Athenians, officers appointed to lay in corn for the uſe of the city, for which purpoſe the ταμίας τῆς διοικήσεως, or the public treaſurer, was to furniſh them with as much money as they had occaſion for. *Potter*, Archæol. Græc. l. 1. c. 15. Tom. I. p. 83.

SITTA, in the Linnæan ſyſtem of zoology, the name of a diſtinct genus of birds, uſually confounded with the woodpecker-kind. The characters of this genus are, that the foot has three toes before, whereas the woodpecker has but two fore-toes on each foot; the bill is angular, and ends in the form of a wedge, and the tail is raiſed. The grey, or aſh-coloured picus is of this genus. *Linnæus*, Syſtem. Natur. p. 45.

The *picus cinereus*, or grey woodpecker, is called in Engliſh the *nut-hatch* or *nut-jobber*.

It is a ſmall bird, not quite ſo large as the chaffinch. Its head, neck and back are grey; its ſides under the wings are red, and its throat and breaſt of a pale yellow, with a mixture of a cheſnut brown. The lower part of its belly is covered with red feathers, with white tips or ends, and it has a long black ſtreak on each ſide, running from the angle of the beak to the neck. Its long wing-feathers are black, and its tail variegated with black and grey. Its legs are red, and its toes ſtand three before, and one behind; not as in the woodpecker, two each way. It builds in holes of trees, and when their entrance is too large, artfully ſtops them up with mud. It feeds on inſects and fruits. It hoards nuts for the winter, and breaks them by ſticking them in a cleft of a tree, and ſtriking them with its beak. *Ray*'s Ornitholog. p. 98.

SIUM, in botany, the name of a genus of umbelliferous plants, the characters of which are theſe. The flower is of the umbelliferous kind, being compoſed of ſeveral unequal leaves, arranged in a circular form. The cup finally becomes a roundiſh fruit, compoſed of two ſeeds, which are gibboſe and ſtriated on one ſide, and flat and plain on the other. To this it is to be added, that the leaves ſtand by pairs on the ribs, and have a ſingle one to terminate the ends.

The ſpecies of *ſium*, enumerated by Mr. Tournefort, are theſe. 1. The common, or long-leaved *ſium*, or water-parſnep. 2. The *ſium* with ſerrated leaves. 3. The great broad-leaved *ſium*. 4. The *ſium* with deeply jagged leaves. 5. The creeping umbelliferous *ſium*. 6. The *ſium* which has umbels at the joints of the ſtalks. 7. The field-*ſium*, called *honewort*, or *corn-parſley*, and by authors *ſelinum ſii foliis*. And 8. the aromatic *ſium*, or *ſiſon* of the ſhops, called by many *amomum*, and *Macedonian parſley*. *Tourn.* Inſt. p. 308.

SIXTH (*Cycl.*)—SIXTH, in muſic, is not properly an original concord, as is advanced in the Cyclopædia, ſince it ariſes from the ſubtraction of the third from the octave. There are properly but three original concords, the octave, fifth, and third major. Philoſ. Tranſ. N° 481. p. 267. See the article INTERVAL.

Diminiſhed SIXTH, in muſic. See DIMINISHED *ſixth*.

SIZE (*Cycl.*)—The ſhreds and parings of leather, parchment, or vellum, by being boiled in water, and ſtrained, make *ſize* [b]. This ſubſtance is uſeful in many trades. Mr. Boyle mentions, among other uſes, that fine red ſtands, and hanging ſhelves, are coloured with ground vermilion tempered with *ſize*, and when dry, are laid over with common varniſh [c].—[[b] See GLUE, *Cycl.* [c] *Boyle*'s Works Abridged, Vol. 1. p. 150.]

Gold SIZE. See GOLD *ſize*.

SIZEL, in coining, is uſed where pieces of money are cut out from the flat bars of ſilver, after having been drawn through a mill into the reſpective ſizes or dimenſions of the money to be made; the reſidue is called *ſizel*, and is melted down again. *Lownd*'s Eſſ. upon Coin, p. 96.

SIZING, in mineralogy, a term uſed by the Corniſh miners for a peculiar method of ſeparating the purer from the impurer parts of an ore by means of ſieves. When the ore has been powdered, they put it into a wire-ſieve with fine holes, and in this they ſift it till the fine part goes through: this is properly what is called *ſizing*. They ſend the larger, or coarſer part, to be powdered again, and putting the reſt into a ſieve with a cloſe bottom, they let in a ſtream of water from a cock, and by means of continued ſhaking it about, they cauſe the lighter and fouler parts to be waſhed over the rims of the ſieve, and the remaining powder is the black tin.

SKAITE, in ichthyology, the Engliſh name of a ſpecies of the ray-fiſh, called by the generality of authors *raia undulata*, and *raia lævis*, and by ſome *rubus*.

It is diſtinguiſhed by Artedi by the name of the variegated *ray-fiſh* with the middle of the back ſmooth, and with only one row of ſpines in the tail. See RAJA.

SKEGG, in a ſhip, that ſmall and ſlender part of the keel, which is cut ſlanting, and left a little without the ſtern-poſt. It is now much out of uſe.

SKELETON (*Cycl.*)—We have, in the Philoſophichal Tranſactions, an account of an human *ſkeleton*, all the bones of which were ſo united, as to make but one articulation from the back to the os ſacrum, and downwards a little way. On ſawing ſome of them, where they were unnaturally joined, they were found not to cohere throughout their whole ſubſtance, but only about a ſixth of an inch deep all round. The figure of the trunk was crooked, the ſpinæ making the convex, and the inſide of the vertebræ the concave part of the ſegment. The whole had been found in a charnel-houſe, and was of the ſize of a full grown perſon.

Vegetable SKELETON. The preparations of leaves, fruits, roots, *&c.* called *vegetable ſkeletons*, are made in this manner. Chuſe for this purpoſe the leaves of trees or plants, which are ſomewhat ſubſtantial and tough, and have woody fibres, ſuch as the leaves of orange, jaſmine, bay, laurel, cherry, apricot, peach, plum, apple, pear, poplar, oak, and the like; but avoid ſuch leaves as have none of the woody fibres, which are to be ſeparated and preſerved by this method; ſuch are the leaves of the vine, lime-tree, and the like. The leaves are to be gathered in the months of June or July, and ſuch to be choſen as are ſound and untouched by caterpillars, or other inſects. Theſe are to be put into an earthen or glaſs veſſel, and a large quantity of rain-water to be poured over them; and after this they are to be left to the open air, and to the heat of the ſun, without covering the veſſel; when the water evaporates, ſo as to leave the leaves dry, more muſt be added in its place: the

the leaves will by this means putrefy, but they require a different time for this, ſome will be finiſhed in a month, and others will require two months, or longer, according to the hardneſs of the parenchyma of them. When they have been in a ſtate of putrefaction ſome time, the two membranes will begin to ſeparate, and the green part of the leaf to become fluid; then the operation of clearing them is to be performed. The leaf is then to be put upon a flat white earthen-plate, and covered with clear water; and being gently ſqueezed with the finger, the membranes will begin to open, and the green ſubſtance will come out at the edges; the membranes muſt be carefully taken off with a finger, and great caution muſt be uſed in ſeparating them near the middle rib. When once there is an opening toward this ſeparation, the whole membrane always follows eaſily; when both membranes are taken off, the *ſkeleton* is finiſhed, and it is to be waſhed clean with water, and then preſerved between the leaves of a book.

The fruits are diveſted of their pulp, and made into *ſkeletons* in a different manner. Take, for inſtance, a fine large pear that is ſoft, and not ſtrong; let it be nicely pared without ſqueezing it, and without hurting either the crown or the ſtalk; then put it into a pot of rain-water, cover it, ſet it over the fire, and let it boil gently till it is perfectly ſoft, then take it out, and lay it in a diſh filled with cold water; then hold it by the ſtalk with one hand, and with the other hand rub off as much of the pulp as you can with the finger and thumb, beginning at the ſtalk, and rubbing it regularly towards the crown. The fibres are moſt tender toward the extremities, and are therefore to be treated with great care there. When the pulp is thus cleared pretty well off, the point of a fine penknife may be of uſe to pick away the pulp ſticking to the core. In order to ſee how the operation advances, the foul water muſt be thrown away from time to time, and clean poured on in its place. When the pulp is in this manner perfectly ſeparated, the clean *ſkeleton* is to be preſerved in ſpirit of wine.

Skeletons of roots which have woody fibres, ſuch as turneps, and the like, muſt be made by boiling the root without peeling it till it be ſoft, that the pulp may be ſqueezed away by the fingers, in the ſame manner, in a diſh of water. Many kinds of roots are thus made into elegant *ſkeletons*, and the ſame method ſucceeds with the barks of ſeveral kinds of trees; which when thus treated, afford extremely elegant views of their conſtituent fibres. Philoſ. Tranſ. N° 416.

SKEW, or SKILL *facets*, among jewellers. See FACETS.

SKIN (*Cycl.*)—The cuticle, or ſcarf-*ſkin* of the human body, is remarkable for its ſcales, and for its pores. Its ſcales are wholly a microſcopical diſcovery, for being ſo very minute, that two hundred of them may be covered with a grain of ſand, they never could have been diſcovered by the naked eye. Theſe are placed on our *ſkin* as on fiſhes, that is three deep, or each ſcale ſo far covered by two others, that only a third part of it appears; and theſe lying in this manner over one another, ſeem the reaſon of the *ſkin*'s appearing white; for about the mouth and lips, where they only juſt meet together, and do not fold over, the blood-veſſels are ſeen through, and the parts appear red. The perſpirable matter is ſuppoſed to iſſue from between theſe ſcales, which lie over the pores, or excretory veſſels, through which the watery and oily matters perſpire; and theſe may find vent in a hundred places round the edges of each ſcale: ſo that if a grain of ſand can cover two hundred of theſe ſcales, it may cover twenty thouſand places through which perſpiration may iſſue forth.

A piece of the *ſkin* taken from between the fingers, from the forehead, neck, arms, or any other ſoft part of the body, which is not hairy, ſerves to ſhew theſe ſcales; for where the ſkin is become hard and callous, they are faſtened confuſedly together. They are generally compoſed of five ſides, and may be ſeen very diſtinctly if ſcraped off with a penknife, and applied to the microſcope in a drop of water. *Baker*'s Microſcope, p. 169.

Every part of the *ſkin* of the human body is alſo full of excretory ducts, or pores, which continually emit the ſuperfluous humours from among the maſs of the circulating fluid. In order to view theſe pores, cut a ſlice of the upper *ſkin* with a ſharp razor, as thin as poſſible, then immediately cut alſo a ſecond ſlice from the ſame place, which apply to the microſcope; and in a piece of this, not larger than what a grain of ſand can cover, there may be diſcovered innumerable pores as plainly, as little holes pricked in paper by a fine needle may be perceived, when it is held up againſt the ſun. The ſcales of the upper *ſkin* prevent any diſtinct view of the pores, unleſs they are thus cut off firſt, or elſe ſcraped away with a penknife; but if a piece of the *ſkin* between the fingers, or in the palm of the hand, be ſo prepared, and then examined, the light will be ſeen very beautifully through its pores. *Lewenhoek*, Arcan. Nat. Tom. 3. p. 413.

Mr. Lewenhoek has attempted to give ſome ſlight notion of the number of the pores in the human body: he ſuppoſes that there are a hundred and twenty ſuch pores in a line one tenth of an inch long; however, to keep within compaſs, he reckons only a hundred; an inch in length will then contain a thouſand in a row, and a foot twelve thouſand. According to this computation, a foot ſquare muſt have in it a hundred and forty four millions; and ſuppoſing the ſuperficies of a moderate ſized man to be fourteen feet ſquare, there will be in his ſkin two thouſand and ſixteen millions of pores. Dr. Grew has obſerved that the pores, through which we perſpire, are more remarkably diſtinguiſhable in the hands and feet; for if the hands be well waſhed with ſoap, and examined with but an indifferent glaſs in the palm, or upon the ends and firſt joints of the thumb and finger, there will be found innumerable little ridges parallel to each other, and of equal bigneſs and diſtance; and upon theſe ridges the pores may be diſcovered by a very good eye, even without a glaſs, lying in rows, but viewed through a good glaſs, every pore ſeems like a little fountain, with the ſweat ſtanding therein as clear as rock water; and this, when wiped away, will be found to be immediately renewed again.

Probably fleas, gnats, and other inſects, which feed on our blood and humours, make no new holes, but prey upon us through theſe pores. Philoſ. Tranſ. N 159.

SKIN, in commerce. The Indians in Carolina and Virginia dreſs buck and doe-*ſkins* in this manner: the felt being taken off they ſtrain them with lines, or otherwiſe, much like the clothiers racks, in order only to dry them. When the hunting time is over the women dreſs the *ſkins*, by putting them in a pond, or hole of water, to ſoak them well; then with an old knife, fixed in a cleft ſtick, they force off the hair whilſt they remain wet. This done, they put them into a kettle, or earthen-pot, and a proportion of deers brains, dried and preſerved for this purpoſe, is put in along with them; this veſſel is ſet on the fire till they are more than blood-warm, which will make them lather and ſcour clean; after this, with ſmall ſticks, they wreſt and twiſt each *ſkin*, as long as they find any wet to drop from them, letting them remain ſo wreſted for ſome hours, and then they untwiſt and ſtretch each of them in a ſort of rack, ſo that every part is extended; and as the *ſkin* dries they take a dull hatchet, or ſome ſuch inſtrument, and rub them well over to force all the water and greaſe out of them, till they become perfectly dry, and then their work is done.

In this manner one woman (for the men never employ themſelves in this work) will dreſs eight or ten *ſkins* in a day, that is, begin and finiſh them. Phil. Tranſ. N° 194.

SKINK, *ſcincus*, in zoology, *&c.* See SCINCUS.

SKINUS, σκινὸς, a name given by the antient naturaliſts to the lentiſk-tree, and alſo to a peculiar ſpecies of the ſquill, or ſcilla, which was not nauſeous and emetic as the common ſquill, but eſculent and pleaſant to the taſte.

The generality of writers, even among the antients themſelves, have not obſerved the ſynonymous uſe of this word, and tranſcribing at random paſſages from one another, have confounded the names of the lentiſk-tree and of this eſculent ſquill, and related of the one what the original writer ſaid of the other. Hence many of the abſurdities which we find in the works of ſome, but which are by no means to be attributed to all of them.

Pericles was called, by way of deriſion among the comic writers of his time, *Skinocephalus*, this term expreſſing his having a head like the *ſkinos*, muſt be wholly unintelligible to thoſe, who ſuppoſed it meant as the name of the lentiſk-tree; but when it was underſtood to be meant of the ſquill, the ſatire was plain, as a large and miſhapen head, ſuch as that of Pericles was, could not eaſily be better likened to any thing, than to the irregular, large, and oblong bulbous root of this plant.

Epicharmus, in Athenæus, names the *ſkinos* as a kind of eatable ſquill; and Theophraſtus expreſsly ſays, that the roots of all ſquills were not eatable, but that they only eat thoſe of the *ſkinos*, or, as others called it, the *Epimenedian ſquill*, a ſort of that plant ſo called, after the name of one Epimenides, who firſt brought it into uſe. The after-writers run into great errors about this word, ſome of them tranſlating Theophraſtus's epithet into a ſubſtantive, and diſtinguiſhing the Epimenedium from the ſcilla. Pliny, in particular, is guilty of this error. This is the peculiar ſpecies of ſquill, which the Athenians afterwards diſtinguiſhed from the common kind, by the name *ſkinus*. Theopompus mentions the *ſkinus* as an eſculent kind of ſquill; and, in general, the word oftener occurs as the name of the ſquill, than as the name of the lentiſk-tree.

Theophraſtus mentions the inſerting an eſculent root on the *ſkinos*, or ſkilla, giving the choice of either of thoſe roots, and ſays that it will thrive much better on this, than in the earth alone; the tranſlators have rendered this the lentiſk: but where is the probability of this excellent botaniſt's adviſing the grafting an eſculent root upon a tree, or giving a tree, and a common bulbous plant, as indifferent to the choice which was to be uſed? *Pliny*, lib. 23. cap. 5. *Theophraſtus*, lib. 5. c. 7. See LENTISCUS.

SKIPPER, an Engliſh name for the common gar-fiſh. See ACUS.

SKIRRET, *ſiſarum*, in botany, *&c.* See SISARUM.

The *ſkirret*, though one of the moſt wholeſome and nouriſhing of all the eſculent roots, is very little cultivated with us.

It may be propagated either by ſowing the ſeeds, or by planting the ſlips and off-ſets, but the firſt is much the beſt method. It ſhould be ſowed on a moiſt rich ſoil, in the beginning of February; in April the young plants will come up, when they muſt be cleared of weeds, and houghed up to three inches aſunder; and about a month afterwards they muſt be thinned a ſecond time, leaving them only ſix inches diſtant. After this they muſt be carefully kept clear from weeds, and when their leaves are decayed, they ſhould be taken up for uſe; but this ſhould only be done as they are wanted, for they ſpoil with lying out of the ground. The leaves decay in October, and from that time till the middle of March the roots are in ſeaſon; after this the roots become good for little. *Miller*'s Gard. Dict.

SKITTISH, in the manege. A horſe is ſaid to be *ſkittiſh*, in French *ecouteux*, or *retenu*, that leaps inſtead of going forward; that does not ſet out, or part from the hand freely, nor employ himſelf as he ought to do.

SKOUT, in zoology, a name given by the people of Yorkſhire to the *lomwia*, called in many places the *kiddaw*, and in Scotland the *auk*, or razor-bill, another of the webfooted water-fowl. *Ray*'s Ornitholog. p. 244. See the articles ALKA and LOMWIA.

SKRABBA, in ichthyology, a name given by ſome to a fiſh called by Jonſton and Schoneveldt the *ſcorpius marinus*, but wholly different from the *ſcorpæna* of other authors.

It is a ſpecies of cottus, and is diſtinguiſhed by Artedi by the name of the *cottus* without ſcales, with ſeveral prickles upon its head, and with the upper jaw ſomewhat lower than the other. See the article COTTUS.

SKULL (*Cycl.*)—It is not uncommon to find in ſome human *ſkulls* a different ſtructure and conformation from that which nature has given to others, or to the generality of the ſpecies.

Frequently there are met with heads, the ſagittal ſuture of which is prolonged to the root of the noſe, and divides the coronal bone into two parts: and there have been anatomiſts, who have judged this ſort of conſtruction of the *ſkull* peculiar to one ſex, rather than common to both.

To find the true cauſe of this, we are to have recourſe to the ſtate of the *ſkull* in the infancy. This bone is, at that time, always found divided into two lateral portions; ſo the ſame ſeparation, which is found between the two ſides, is found alſo between the two pieces, which afterwards compoſe the coronal bone. The two pieces of this coronal bone unite one with another, by means of their indented edges, and theſe afterwards coaleſce ſo perfectly, that the ſuture is obliterated; and this coaleſcence, which thus in proper time takes place in the coronal bone, ſometimes extends itſelf, alſo, to almoſt all the other bones of the *ſkull*; but this only happens in old age. But if, on the contrary, the two pieces, of which the coronal bone is compoſed, acquire their full thickneſs and hardneſs, before this coaleſcence is brought about, the ſuture remains, and is not obliterated, except in extreme old age. This reflexion may be alſo carried much farther.

In the *ſkulls* of a great number of infants, the coronal and the two ſides ſo perfectly unite, as not to leave the leaſt trace of their original ſeparation. It ſeems as if the bones, having expanded and grown in theſe early ſtages too faſt for the brain, have been united to one another while yet ſoft and tender: but when the brain, on the other hand, grows too faſt for the bones of the *ſkull*, theſe bones, preſſed more from within outwards than any other way, have little diſpoſition to unite with one another; and thus acquiring their thickneſs and hardneſs before their coaleſcence, they become much leſs inclined to coaleſce than before.

From theſe conſiderations we may conclude, that in thoſe infants, in which the growth of the brain is ſlow, and that of the bones of the *ſkull* quick, the ſuture, which is between the two portions of the coronal bone, is very quickly obliterated; and, on the contrary, when the encreaſe of the brain is quick, and the growth of the bones is ſlow, the ſuture, which divides the coronal bone into two pieces, is found to a great age.

That which is the *ſkull* in the more advanced ſtate of the infant, is originally no other than a membrane, which is afterwards to oſſify: not unfrequently the oſſification is impeded, in different parts of this membrane; and in the *ſkulls* of young ſubjects it is common to ſee theſe diſtinct parts, which remain membranous while the reſt of the *ſkull* has acquired its proper bony hardneſs. If the cauſe, which impeded the progreſs of the oſſification, ſubſiſts ſo long, as till the other parts of the *ſkull* are hardened into bone, and have their full growth and hardneſs, then will that, which ſhould have been naturally only one bone, form two.

This is the origin of the ſingular and unnatural ſutures, found in ſome human *ſkulls*, and called by ſome *ſupernumerary ſutures*. Sometimes there are, from this cauſe, ſuch ſupernumerary ſutures in almoſt all the bones of the *ſkull*. The os planum frequently is found thus divided into two; and from the ſame principle in nature it is, that a ſmall ſuture is ſometimes found in the maxillary bone, below the orbit, along the canal, which forms the lower orbitary cavity: the place where this little ſuture is found has happened to remain a long time membranous, and the oſſification at laſt taking place on the two edges of the remaining membrane, there has been found a ſuture.

In other bones of the *ſkull* we alſo frequently meet with larger or ſmaller ſpaces, which have continued membranous; and there are inſtances, in which the oſſification may be plainly perceived juſt begun in the center of the membranous ſpots.

It might be ſuppoſed that the brain was little liable to an unnatural growth, or expanſion, when we conſider that the brain is no other than a vaſt aſſemblage of pipes, or tubes, of a moſt extreme fineneſs, and that the particles, which compoſe theſe tubes, have but a very weak band of union one with another. Indeed we know very well, that when an injection has penetrated to the cortical ſubſtance of the brain, if that ſubſtance be macerated a little in water, its parts detach themſelves from one another, the veſſels become wholly deſtroyed, and there remains nothing but a number of extremely fine filaments of the matter of the injection, which has found its way into theſe veſſels, and been formed into their ſhape by cooling in their cavities. As there are found, however, a great number of *ſkulls*, which have a ſingular and odd configuration, it cannot but be, that the brain muſt be expanded into the ſame form. We are informed, that the people of ſome nations preſs the forepart of the heads of their children, as ſoon as born, with conſiderable violence, and continue this, in order to reduce the forehead to a flatneſs; but theſe *ſkulls* are always found to get in length behind what they want before.

Sometimes there has been obſerved, in the *ſkulls* of perſons of an advanced age, in the middle of the ſagittal ſuture, a deep impreſſion, or ſinking in, which had remained there from infancy; but nature, in this caſe, ſupplies the cavity with two protuberances of bone from the ſides of the adjoining parts; and ſome *ſkulls* are found very narrow, and of a remarkable length, nature giving one way the room ſhe denied the other. Many other ſingular conſtructions of the *ſkull* have been obſerved by anatomiſts; and probably in the perſons, to whom they have belonged, the brain has been able to perform its functions but badly. Be that as it will, it is certain that the brain has expanded, and formed itſelf to the ſhape of the *ſkull* in all theſe its unnatural figures; and neceſſarily the parts, of which the brain in ſuch caſes is compoſed, have taken a very different figure and arrangement from what nature intended: and in this caſe it cannot be, but that ſome portions of the brain have extended themſelves farther than they naturally ſhould have done, and others much leſs than was allotted to them. Mem. Acad. Scienc. Par. 1740.

Bones of the SKULL. The eight principal bones of the *ſkull* are ordinarily divided into common and proper. By proper bones anatomiſts mean thoſe, which are wholly employed in forming the globe of the *ſkull*, and of theſe they reckon ſix; the os frontis, the two parietal bones, the occipital bone, and the oſſa temporum: the common bones are thoſe which contribute to form the face, as well as the *ſkull*, *viz.* the os ethmoides, and the os ſphenoides. But this diviſion is not juſt, for the os frontis, and oſſa temporum, deſerve as much to be called common, as the two that are uſually reckoned ſo; and thus, inſtead of ſix, there would be only three proper bones, the oſſa parietalia, and os occipitis; and inſtead of two, there would be five common ones, the os frontis, oſſa temporum, os ethmoides, and os ſphenoides. *Winſlow*'s Anatomy, p. 21.

The adheſion of the pericranium to the *ſkull*, has been thought a ſure ſign of the bones being entire, but this is a miſtake; and the ſeparation of the cranium from the *ſkull*, is as uncertain a ſign of the cranium's being broken. Mem. de l'Acad. de Chirurg. Tom. 1.

We have ſome very particular obſervations on the bones of the human *ſkull*, by Mr. Hunauld, in the Memoires de l'Acad. Royale des Sciences, An. 1730.

Concealed injuries of the SKULL. When a blunt inſtrument is the occaſion of an injury on the cranium, if the injured part does not ſufficiently appear of itſelf, great induſtry is to be uſed to diſcover it. Where the common integuments appear tumid and ſoft, they are in this caſe to be divided to the bone; but in making the inciſion, great care muſt be taken not to lay too much ſtreſs upon the knife, leſt ſplinters of the fractured cranium ſhould by that means be forced in upon the brain. The beſt way to make this inciſion is in form of the letter X, and about an inch and half in length; lifting up the ſkin at each angle, and leaving the bone bare. The blood that is ſpilt is to be taken up with a ſponge, and dry lint ſtuffed between the ſkin and the cranium; and having thus found out the injured part of the cranium, the trepan is to be applied, if it be found neceſſary. If ſplinters of the bone are now found, they muſt be removed either with the fingers or the forceps, or, when they hang to the pericranium, with ſciſſors; but when they adhere pretty firmly to the neighbouring parts of the cranium, it is more adviſeable to replace them, than to endeavour to remove them by violence. *Heiſter*'s Surgery, p. 85.

Fiſſures of the SKULL, cracks in the bone of the *ſkull*, made by falls, blows, or other injuries. When theſe are attended with no other bad ſymptoms but white, yellow, or brown ſpots upon the face of the bone, they may be remedied with boring ſeveral ſmall holes through the ſurface of the *ſkull*, down to the diploe, and dreſſing with balſamic medicines: but where violent ſymptoms come on, which demonſtrate an extravaſation of blood in the cavity of the cranium, the trepan is to be uſed without delay.

Depreſſions of the SKULL, a denting in of the bone of the *ſkull* by a blow, without any manifeſt fracture, or, at the utmoſt, with ſuch a fracture, that from its flexibility it does not ſtart out by means of it, but continues to adhere firmly to the neighbouring bones. The *ſkulls* of infants are frequently ſubject to this, but in adults this caſe cannot happen; for the bones in them are become ſo rigid, that it is impoſſible to beat in any part of the cranium, without beating the bone to pieces. Theſe injuries of the cranium are called by the ſurgeons *fractures*, and the brain is frequently injured by theſe accidents, and its actions diſturbed. The firſt thing to be done, to give relief in this diſorder, is to lift up any part of the bone that is depreſſed, or beaten in upon the brain, or to remove any other body by which it is compreſſed. Sometimes a ſplinter, which is quite ſeparated from the reſt of the bone, is driven into the cavity of the cranium, and lies conſtantly vellicating the brain and its membranes with its pointed parts; this is to be removed without delay.

When ſlight depreſſions are made in the *ſkulls* of infants, without bringing on any bad ſymptoms, the forcible methods of raiſing the depreſſed part are not to be uſed, but medicated bags, boiled in ſpirit of wine, warm fomentations, and ſuch remedies, are to be applied; and laſtly, a plaſter of melilot to cover all. Theſe ſlight applications frequently cure ſuch little depreſſions, and prevent the miſchievous conſequences which might be expected from them. When a very large depreſſion, however, happens to infants, the elevation, or reſtitution of the parts is to be performed in the following manner. After ſhaving the part, apply a plaſter made of gummy and very ſticking ingredients, and ſpread upon very ſtrong leather, with a cord faſtened to the middle of it: this plaſter is to be laid on pretty warm, and left in its ſituation till grown cold; the ſurgeon then taking hold of the cord, which is faſtened to it, is to pull it directly upwards, and with it the depreſſed part of the cranium will often riſe, and be reſtored to its place. When this method does not ſucceed at the firſt trial, it is to be repeated; and when this fails, the application of a cupping-glaſs to the depreſſed part will ſometimes ſucceed, eſpecially if you ſtop the patient's breath, both at the noſe and mouth, during the operation: but if neither the plaſter nor cupping prove ſucceſsful, it will be neceſſary to take in the aſſiſtance of an inſtrument.

But when the cranium is ſo depreſſed, whether in adults or infants, as to ſuffer a fracture or diviſion of its parts, it muſt inſtantly be relieved. Some praiſe very much the uſe of a ſternutatory powder on this occaſion, affirming, that the diſtention of the brain is ſo violent in the act of ſneezing, that it will reſtore the depreſſed parts of the bone to their former ſituation: but the ill conſequences, that may attend this practice, are ſo grievous, that it ought wholly to be rejected, and the trepan and elevatories always to be uſed. *Heiſter*'s Surgery, p. 87.

Wounds of the SKULL. In wounds of the cranium, or *ſkull*, the firſt buſineſs is to find whether they are terminated in the external parts of the cranium, or whether they penetrate into its cavity. This is to be known by the eye. 2. By the probe, which however muſt be uſed very gently here, for fear of bringing on farther miſchief. 3. By examining the inſtrument with which the blow was given, and conſidering the degree of force with which it was impelled. And laſtly, the preſence, or abſence of violent bad ſymptoms. A violent blow upon the head will always be attended with vomitings and vertigoes, and blood will be diſcharged by the noſe, ears, and mouth, and the wounded perſon will loſe alſo his ſpeech and ſenſes. Theſe diſorders will appear ſometimes ſooner, ſometimes later, but always are more violent than otherwiſe, when the wound is made by a fall, or by ſome blunt inſtrument; in which caſes the cranium is uſually much ſhattered. The blood which diſcharges itſelf by the wound, when that is made by a ſharp inſtrument, will inſinuate itſelf between the common integuments and the cranium: in the contuſions that are made with blunt inſtruments, ſometimes it will be concealed under the cranium, and by corrupting the periofteum and cranium, will bring on ulcers, and caries of the bone, and frequently occaſions fevers, convulſions, and death. *Heiſter*'s Surgery, p. 82.

SKY (*Cycl.*)—SKY-*colour*. To give this colour to glaſs, ſet in the furnace a pot of pure metal of fritt from rochetta, or barillia, but the rochetta fritt does beſt; as ſoon as the metal is well purified, take for a pot of twenty pound of metal ſix ounces of braſs calcined by itſelf, put it by degrees, at two or three times, into the metal, ſtirring and mixing it well every time, and diligently ſcumming the metal with a ladle: at the end of two hours the whole will be well mixed, and a proof may be taken; if the colour be found right, let the whole ſtand twenty four hours longer in the furnace, and it will then be fit to work, and will prove of a moſt beautiful *ſky-colour*. *Neri*'s Art of Glaſs, p. 40.

SLABBERING-*bit*, in the manege. See the article MASTIGADOUR.

SLABS *of tin*, the leſſer maſſes, which the workers at the tin-mines caſt the metal into: theſe are run into moulds made of ſtone. *Ray*'s Engliſh Words, p. 124.

SLACK *a leg*, in the manege, called in French *mollir la jambe*, is ſaid of a horſe when he trips or ſtumbles.

SLACK *the hand*, is to ſlack the bridle, or give a horſe head.

SLACKEN, in metallurgy, a term uſed by the miners to expreſs a ſpungy and ſemivitrified ſubſtance, which they uſe to mix with the ores of metals, to prevent their fuſion. It is the ſcoriæ or ſcum, ſeparated from the ſurface of the former fuſions of metals. To this they frequently add limeſtone, and ſometimes a kind of coarſe iron-ore, in the running of the poorer gold-ores.

SLATCH, at ſea. When a rope or cable hangs ſlack, the ſeamen call the middle part, which hangs down, *the ſlatch of the cable*, or rope: ſo alſo, after long foul weather, if there come a ſmall interval of fair, they ſay, *this is a ſlatch of fair weather*.

SLATE (*Cycl.*)—The ſtrata of this ſtone uſually lie very much inclining, and are of a conſiderable extent. At Mullinecke, in Wales, the *ſlate* lies thus, and reaches from near the ſurface to the level of the tide that flows up the river, in the cliffs of which it lies. It may go much deeper, for it has not been examined to the bottom there; but what is obſervable in this place, is, that there are evident flexures or bendings in ſeveral parts of the ſtrata, and theſe always run from the top downwards; in the other parts of the ſame ſtrata there are ſeveral perpendicular fiſſures or cracks, but they are ſmall like cracks, and always empty.

It appears from this, that at the time when the bed of *ſlate* cracked in ſome places, it was ſo tough, as to abide being bent in others, by which means theſe flexures were formed. Sometimes the beds of *ſlate* are cracked at the angles of theſe flexures, the intermediate maſs, though parted from the reſt, lying obliquely. It is obſerved thus cracked, alſo, in many parts of Yorkſhire. *Woodward*'s Cat. of Foſſils, Vol. 2. p. 5.

Iriſh SLATE. See TEGULA *Hybernica*.

SLAVE. For the cuſtom of marking, or ſtigmatizing ſlaves, ſee STIGMATIZING.

SLAUGHTER (*Cycl.*)—SLAUGHTER-*ſkins*, a term uſed by our curriers and leather-dreſſers for the ſkins of oxen, or other beaſts, when freſh, and covered with the hair: ſuch as they receive them from the *ſlaughter*-houſes where the butchers flea the carcaſe.

SLEDGE (*Cycl.*)—SLEDGE is a large ſmith's hammer, to be uſed with both hands: of this there are two ſorts, the *uphand-ſledge*, which is uſed by under workmen, when the work is not of the largeſt ſort; it is uſed with both the hands before, and they ſeldom raiſe it higher than their head. But the other, which is called the *about-ſledge*, and which is uſed for battering or drawing out the largeſt work, is held by the handle with both hands, and ſwung round over their heads, at their arm's end, to ſtrike as hard a blow as they can.

SLEDGE, among miners. See DIGGING.

SLEEPERS, in natural hiſtory, a name given to ſome animals which *ſleep* all the winter: ſuch are bears, marmotes, dormice, bats, hedge-hogs, ſwallows, *&c.* Theſe do not feed in winter, have no ſenſible evacuations, breath little, or not at all, and moſt of the viſcera ceaſe from their functions. Some of theſe creatures ſeem to be dead, and others to return to a ſtate like unto that of the fœtus before birth. In this condition they continue, till by length of time maturating the proceſs, or by new heat, the fluids are attenuated, the ſolids ſtimulated, and the functions begin where they left off. See Dr. Stevenſon in Med. Eſſ. Edinb. Vol. 5. Art. 77.

SLEEPERS, in the glaſs trade, are the large iron bars croſſing the ſmaller ones, and hindering the paſſage of the coals, but leaving room for the aſhes. *Neri*'s Art of Glaſs, Appendix.

SLEEPERS, in a ſhip, timbers lying before and aft in the bottom of a ſhip, as the rung-heads do: the lowermoſt of them is bolted to the rung-heads, and the uppermoſt to the futtocks, in order to ſtrengthen and faſten the futtocks and rungs.

SLICH, in metallurgy, the ore of any metal, particularly of gold, when it has been pounded, and prepared for farther working. The manner of preparing the *ſlich* at Chremnitz, in Hungary, is this: they lay a foundation of wood three yards deep, upon this they place the ore, and over this there are four and twenty beams, armed at their bottoms with iron; theſe, by a continual motion, beat and grind the ore, till they reduce it to powder: during all this operation, the ore is covered with water. There are four wheels uſed to move theſe beams, each wheel moving ſix; and the water, as it runs off, carrying ſome of the metalline particles with it, is received into ſeveral baſons, one placed behind another;

and

and finally, after having paſſed through them all, and depoſited ſome ſediments in each, it is let off into a very large pit, of almoſt half an acre of ground; in this it is ſuffered to ſtand ſo long, as to depoſit all its ſediment, of whatever kind, and after this it is let out. This work is carried on day and night, and the ore taken away, and replaced by more, as often as occaſion requires. That ore which lies next the beams, where it was pounded, is always the cleaneſt, or richeſt.

When the *ſlich* is waſhed as much as they can, an hundred weight of it uſually contains about an ounce, or perhaps but half an ounce of metal; which is not all gold neither, for there is always a mixture of gold and ſilver, but the gold is in the largeſt quantity, and uſually is two thirds of the mixture: they then put the *ſlich* into a furnace with ſome lime-ſtone, and ſlaken, or the ſcoriæ of former meltings, and run them together. The firſt melting produces a ſubſtance, called *lech*; this lech they burn with charcoal, to make it lighter, to open its body, and render it porous, after which it is called *roſt*; to this roſt they add ſand in ſuch quantity as they find neceſſary, and then melt it over again. They have at Chremnitz many other ways of reducing gold out of its ore, but particularly one, in which they employ no lead during the whole operation; whereas, in general, lead is always neceſſary, after the beforementioned proceſſes. See the article GOLD-*ore*.

SLING (*Cycl.*)—SLING, at ſea, a word uſed variouſly. There are *ſlings* to hoiſe up caſks, or any other heavy things; which are made of ropes ſpliced into themſelves at either end, with an eye big enough to hold the thing to be *ſlung*.

There are other *ſlings*, which are made longer, and with a ſmall eye at each end; one of which is put over the breech of a piece of ordnance, and the other eye comes over the end of an iron crow, which is put into the mouth of the piece, to weigh and hoiſe the gun as they pleaſe.

There are alſo *ſlings* for the yards; which is done by binding them faſt to the croſs-tree aloft, and to the head of the maſt, with a ſtrong rope or chain, that if the tie ſhould happen to break, or to be ſhot to pieces in fight, the yard, nevertheleſs, may not fall down upon the hatches.

SLINGING (*Cycl.*)—SLINGING *a man overboard*, in order to ſtop a leak in a ſhip, is done thus: the man is truſſed up about the middle in a piece of canvaſs, and a rope to keep him from ſinking, with his arms at liberty, a mallet in one hand, and a plug, wrapped in oakum and well tarred in a tarpawling clout, in the other, which he is to beat with all diſpatch into the hole, or leak.

SLOANEA, in botany, the name of a genus of plants, deſcribed by Linnæus and Plumier, the characters of which are theſe. The perianthium conſiſts of one leaf, divided into ſeven ſegments. There are no petals. The ſtamina are a great number of ſlender filaments, broader at the end than in any other part, and of the length of the cup. The antheræ grow to the ſides of theſe filaments. The germen of the piſtil ſtands in the bottom of the cup. The ſtyle is ſubulated, and longer than the ſtamina. The ſtigma is acute. The fruit is a large roundiſh echinated capſule, compoſed of four valves. The ſeeds are oval, obtuſe, and fleſhy, and have oblong nuclei. *Linnæi* Gen. Plant. p. 242. *Plumier*, p. 15.

SLOATH, in natural hiſtory, the name of an animal remarkable for its ſlow motion. This creature is ſo very tedious in all its motions, that it will be three or four days in climbing up, and coming down a tree, and does not go the length of fifty paces upon even ground in a day. The ſound of its voice ſeems only to expreſs the word *haii*, for which reaſon the Braſilians call him by that name; but he uſually repeats the ſound about ſix times together, deſcending, as if one ſhould ſing, *la*, *ſol*, *fa*, *mi*, *re*, *ut*. Whatever he takes hold of, he does it ſo ſtrongly, or rather ſo ſtiffly, that he will ſometimes ſleep ſecurely while he hangs at it. *Bartæus*, de Reb. Braſ. p. 222.

Cluſius, Margrave, Piſo, and others, have given deſcriptions of this animal, but they none of them mention the length of his fore feet; which, according to the animal preſerved in the Muſeum of the Royal Society of London, is double that of the hinder pair. *Grew*'s Muſ. p. 11.

From the ſhag of his body, the ſhape of his legs, and his having little or no tail, as alſo from the ſlowneſs of his gate, and his climbing up trees, as little bears uſe to do, he ſeems to come near the bear-kind; from which he differs chiefly, in having but three claws upon a foot. This creature breeds principally in Florida and Braſil. Id. ibid.

SLOATS *of a cart*, the underpieces which keep the bottom of the cart together. See CART.

SLOE, *prunus ſylveſtris*, the Engliſh name for the wild plum. See the article PRUNUS.

SLOE-*worm*, in natural hiſtory, the name of an inſect found on the leaves of *ſloe*, or black-thorn, and ſometimes on thoſe of the garden-plum.

This, and a like worm, found on the leaves of the oak, both remarkable for the hairs which cover them, each of which is forked or divided into two at the ends, are uſually eſteemed caterpillars, but they are in reality animals of a very different claſs; the caterpillar has, at the utmoſt, but ſixteen legs, theſe have each twenty two, and have all the other characters of that claſs of inſects, called by the French naturaliſts *fauſſes-chenilles*, or baſtard-caterpillars.

All the animals of that claſs are very remarkable for the different figure they make after the laſt change of their ſkins, but this is in none ſeen ſo obviouſly, as in theſe two ſpecies; that of the oak is of a greeniſh colour, and its hairs, which are ſo ſtiff that they almoſt deſerve the name of ſpines, are black: that of the *ſloe* is of a greyiſh hue, and its ſpines longer, and of a deep brown; every one of theſe is, toward the extremity, divided into two, in the manner of the tines of a fork. Theſe give the animal a very remarkable figure, and are caſt off with the ſeveral ſkins, while the new ſkins leave others in their place; but in the laſt change, before that into the nymph ſtate, the change made into the creature is ſuch, that it could never be ſuſpected to be the ſame animal by any one, who was not an eye-witneſs of the change.

The creature in this, throwing off its ſkin, becomes perfectly ſmooth, and of a dirty yellowiſh colour, with not the lighteſt variegation on it, nor the leaſt appearance even of the remains of the ſpines. In this ſtate it remains till it goes into the nymph ſtate, and from that, after about ſixteen days, it comes out in the ſhape of a four-winged-fly. The whole proceſs of the change is the ſame, in the two ſpecies of the oak and the *ſloe*, but the flies they produce are very different. *Reaumur*'s Hiſt. Inſ. Vol. 9. p. 119.

SLOT, (*Cycl.*) in the ſportſman's language, a term uſed to expreſs the mark of the foot of a ſtag, or other creature proper for the chaſe, in the clay or earth, by which they are able to gueſs how long the creature has been gone by, and which way he went. The *ſlot*, or treading of the ſtag, is very nicely ſtudied on this occaſion: if the *ſlot* be large, deep printed in the ground, and with an open cleft, and added to theſe marks, there is a large ſpace between mark and mark, it is certain that the ſtag is an old one. If there be obſerved the *ſlots*, or treadings of two, the one long, and the other round, and both of one ſize, the long *ſlot* is always that of the larger beaſt. There is alſo another way of knowing the old ones from the young ones by the treading; which is, that the hinder feet of the old ones never reach to their fore feet, whereas thoſe of the young ones do.

Old ſtags alſo are long jointed, and they never tread doubly, or falſely, as the young ones do, becauſe the tendons, that hold the joints of their feet, are ſtronger; but the feet of the young ones are ſometimes forced, for want of theſe ſtrong ſinews, to turn away double. It is to be obſerved alſo, that there is a great difference between the *ſlot* of a ſtag or hart, and that of a hind; for there is no hart of the ſecond head ſo young, but that he leaves a larger and wider *ſlot* than the hind, excepting when the hinds are big with young, for on that occaſion their claws will open as wide as thoſe of the hart.

Another method of knowing the age of a ſtag is by his fumets, though ſome general rules are to be known, before any thing can be judged from this article. Theſe are, that in April and May, they caſt their fumets, as it were, in cakes, and in June and July they caſt them in thin, long, and large crotels, and from thence to the end of Auguſt they hold the ſame form and ſize; but they are in this laſt month always hard and knotty. In all theſe caſes, the largeſt and longeſt fumets are eſteemed to be the marks of the largeſt and oldeſt ſtags. If they have been diſturbed, or if they have received any hurt, they uſually caſt them ſharp at one end, and dry. This alſo is conſtantly the caſe, when their new horns are juſt grown to their hardneſs, and they rub them againſt the trees to get off the cracked membranes, which were the velvetings in their firſt ſtate. There is always alſo a difference between the fumets of the morning and thoſe of the evening: thoſe made at night, when they go to relief, are better digeſted, and conſequently moiſter than thoſe made in the morning, becauſe having taken their reſt all day, there is a more perfect digeſtion made than can be in the night, as they are, during that time, ſeeking food.

There are alſo ſeveral other ways of judging of the growth and ſize of a ſtag, as by his carriage, or bearings, according to the huntſman's phraſe; that is, according to the breaking of the tender branches of trees which he makes with his horns in paſſing through. When the boughs are found bruiſed and broken very high, and to a good width, there is no doubt of his being an old one: but this judgment is not to be made in the months of March, April, May, and June, becauſe their horns are at that time either wholly wanting, or they are young and velvety. The heighth of the creature's entries into the woods is alſo another mark of his ſize, for the old ones are always proud and ſtately, and go in erect, but the young ones will creep.

The older the ſtag is the ſooner he goes to fray, and the larger are the trees he chooſes for this uſe; the young ones go later to it, and always chooſe the weaker and lower trees. Notwithſtanding that, after the ſixth year, the age is not certainly known by the horns, as there is, after this time,

time, no increaſe in the number of their branches, yet a probable gueſs may be made from their being all thicker and more robuſt, and the tops more open.

SLOUGH (*Cycl.*)—SLOUGH-*ſilver*, in our old writers, a rent paid in ſome places in lieu of certain days work in harveſt, heretofore reſerved to the lord from his tenants. *Blount.*

SLOW (*Cycl.*)—SLOW-*worm*, the Engliſh name of the *cæcilia*, called alſo the *blind-worm*, and by ſome the *deaf-adder*. See the article COECILIA.

SLUDS, a term uſed by the miners in Cornwall for half-roaſted ores. See the article ORE.

SMALL (*Cycl.*)—SMALL-*craft*, in the ſea language. See the article CRAFT.

SMALL-*pox*. See the article POX.

SMALL-*ſtones*, among jewellers, denote diamonds under the weight of a carrat. *Jeffreys* on Diamonds, p. 21.

SMALL-*work*, among jewellers, is uſed to denote the ſtar and ſhell-facets of diamonds. *Jeffreys* on Diamonds. See the article FACETS.

SMALLAGE, in botany, *&c.* See APIUM.

SMALT (*Cycl.*)—There is not a more precarious proceſs in all metallurgy, than the preparation of this fine blue glaſs from cobalt, nor any manufacture, in which ſo expert workmen are neceſſary. The carrying the heat to too great a degree, in the roaſting the cobalt, is a very miſchievous error, and the ſuffering as much of the arſenic, as may be, to remain in the earth, is greatly to the advantage of the *ſmalt*; and its colour may be greatly heightened, by adding common arſenic to it while it is in fuſion.

It is always neceſſary to make careful and repeated experiments on a new ore, or a kind of cobalt, which has not been worked before; by trying it with various degrees of heat in the roaſting, and with different proportions of the flints and pot-aſh in the fuſion. On comparing the ſeveral products of theſe experiments, it will eaſily be ſeen which yields the fineſt colour, and this muſt be always after followed in the great operations.

It is well known that the beautiful blue glaſs, called *ſmalt*, is prepared from the fixed earth of cobalt; but experiments have proved, that this earth alone will not acquire that fine colour. Dr. Link tried ſome of it, by keeping it eight hours in the moſt intenſe heat, yet on taking it out, it was only a grey glaſs, excepting that there were a few blue ſpecks in it near the edges of the crucible. Theſe ſpecks make no objection to this doctrine, when properly conſidered; for they were owing, doubtleſs, to the ſame ſubſtance which is found neceſſary to be uſed, in order to procure the blue colour.

Flints are the neceſſary addition to cobalt for the making the blue glaſs, or *ſmalt*, and the crucible being made of earth, might eaſily contain ſome particles of ſand. Every piece of ſand is a ſmall ſtone, of the nature of flint; that is, a piece of cryſtal debaſed by earth; and theſe ſmall flints mixing with the glaſs of the cobalt-earth, while in fuſion, rendered the ſmall ſpecks, where they were mixed, true *ſmalt*, while the reſt remained grey and unaltered.

This earth of cobalt evidently contains ſome portion of copper, though ſo ſmall in quantity, that it can never be diſcerned by the common ſigns, and ſo intimately blended with the earth, that it can never be procured ſeparate. The lightneſs of this earth alſo, in which the copper reſides after the ſublimation of the arſenic, is a proof that its quantity muſt be very ſmall; yet that it exiſts there, is evident from the colours it affords.

Copper is well known to yield a green colour with acids, and a fine blue with alkalies. Thus a ſolution of this earth in aqua fortis is of a deep green, and its glaſs, when mixed with the alkali of flints and of pot-aſh, is the fine deep blue *ſmalt:* nor is it wonderful, that the vitrified earth of cobalt will never become blue by calcination alone, ſince, if it owes this colour to copper, it cannot be ſuppoſed to ſhew itſelf till called forth by an alkali. Philoſ. Tranſ. N° 396. p. 201.

Some cobalt yields *ſmalt* before roaſting, even better than it would afterwards; this is a peculiar kind of cobalt, but is ſo like the reſt, that it cannot be diſtinguiſhed by the eye, but experiment alone ſhews this property in it. Though cobalt in general requires roaſting, in order to fit it for yielding the *ſmalt*, yet its different kinds require ſome more, and ſome leſs roaſting; and the degree can never be judged of by the inſpection of the mineral, but is only known by the experienced artiſt in the proceſs. Hence it is, that expert and intelligent perſons are neceſſary in the *ſmalt*-works more than in almoſt any other branch of this ſort of buſineſs.

The addition of a ſmall quantity of arſenic, or of the arſenical flowers, during the time that the *ſmalt* is in fuſion, adds greatly to the beauty of the colour: this is a practice kept ſecret by the workmen of ſome places; and by this means their *ſmalt* is always rendered better than that of their neighbours. It is eaſy to ſee from this, that the roaſting of the cobalt is the neceſſary beginning of the *ſmalt*-work, not the diveſting it of its arſenic, which only happens accidentally in that proceſs; and it would be much better if it did not happen, ſince we find the arſenic added afterwards exalts the colour. From hence it is evident, that thoſe cobalts which will make *ſmalt* without previous roaſting, muſt, as they are found to do, make the very fineſt *ſmalt*, becauſe their arſenic is yet left in them in great part: and from this alſo appears the neceſſity of having expert workmen for the *ſmalt*-making; ſince the knowing the degree of fire neceſſary to the ore is a moſt eſſential article, and after the roaſting has been carried to a ſufficient degree, every moment's heat diveſting it of more of its arſenic than was neceſſary, makes the colour of the *ſmalt* to be made afterwards ſo much the worſe. From this alſo appears the reaſon why the blue, made by precipitation from a ſolution of cobalt, is ſo much ſuperior to the common *ſmalt* made by fire; becauſe in this the arſenic is all preſerved, whereas, in the common way of preparing it by fire, it is driven off. Philoſ. Tranſ. N° 396.

SMARAGDUS, the *emerald*, (*Cycl.*) a very beautiful gem of a fine green colour.

The gem known by the antients under the name of the *ſmaragd*, or *emerald*, was the ſame with that we call at this time by the ſame name, which has not been the caſe in the hyacinth, ſapphire, and many others.

In the days of Pliny we find, however, that a great deal of error and confuſion had crept into the world in regard to this gem, that author giving a long liſt of the different kinds of *emeralds*, as he calls them; among which there are evidently jaſpers, coloured cryſtals, and ſpars, reckoned among the ſpecies of this gem.

Our jewellers know only what they call two ſpecies of the *emerald*, the Oriental and the Occidental, and ſuch there are without queſtion; that is, the *emeralds* of the Eaſt-Indies are, in their pureſt ſtate, much finer than thoſe of any other part of the world, as is the caſe in the other gems: but our jewellers ſeldom meeting with theſe fine ſtones, call the American *emeralds* Oriental, and uſually ſell cryſtal, accidentally tinged green, under the name of *Occidental emeralds*. Theſe laſt being alſo greatly more common than the others, there has grown an opinion among our lapidaries, that the *emerald* is no harder than cryſtal; and this has no other foundation, than their uſually meeting with cryſtal under the name of the *emerald*.

The genuine *emerald*, when in its moſt perfect ſtate, is perhaps the fineſt and moſt beautiful of all the gems. It is found of various ſizes, but uſually ſmall. Multitudes are met with of about the ſixteenth of an inch in diameter, and they are found from this up to the ſize of a wallnut. We have accounts of ſome of immenſe ſize among the antients; but they were evidently not *emeralds*, but jaſpers, or other green ſtones. The large ſpecimens at preſent are very ſcarce, and whether they are Oriental or Occidental, are of very great value. *Hill*'s Hiſt. of Foſſ. p. 596.

The *emerald* is naturally of different figures, like the diamond, and many of the other gems. It is ſometimes found in a roundiſh, or pebble-like form, but much more frequently in a columnar, or angular one, reſembling common cryſtal. The pebble *emeralds* are always the hardeſt and brighteſt, but are ſeldom found exceeding the ſize of a pea, very rarely coming up to that of a horſe-bean. The cryſtalliform uſually grow ſeveral together, and are often conſiderably large. The pebble *emeralds* are found looſe in the earth of mountains, and in the ſands of rivers; the columnar are uſually found adhering to, or bedded in a white opake cryſtalline matter, and ſometimes to the jaſper, or to the pruſius; which laſt has been therefore called by ſome the mother of the *emerald*.

The rough *emerald*, of whatever form, is uſually of a very bright, and naturally poliſhed ſurface, and is ever of a pure and beautiful green, without the leaſt admixture of any other colour. It is of all the various ſhades of green, from the deepeſt to the paleſt, and doubtleſs is ſometimes wholly colourleſs; but it is then eſteemed a ſapphire, all the harder gems, when colourleſs, being called by our jewellers *white ſapphires*.

The Oriental *emerald* is of the hardneſs of the ſapphire and ruby, and is ſecond only to the diamond in luſtre and brightneſs; the American is of the hardneſs of the garnet; and the European is ſtill ſofter than that, but conſiderably harder than cryſtal; yet the coloured cryſtals, uſually ſold under the name of *emeralds*, have very much debaſed the credit of this gem. It loſes its colour in the fire, and becomes undiſtinguiſhable from the white ſapphire.

The Oriental *emeralds* are very ſcarce, and are at preſent found only in the kingdom of Cambay: very few of them have of late been imported into Europe, inſomuch, that ſome have ſuppoſed that there were in nature no Oriental *emeralds*; but within theſe few years ſome have been brought from Cambay into Italy, which greatly exceed all the American ones in beauty, as well as hardneſs.

The American *emeralds*, which, as they are the fineſt that come to us, are called by our jewellers *Oriental*, are found principally about Peru, in the earth of ſome mountains. The European *emeralds* come principally from Sileſia, though there are of them in other places; and the coloured cryſtals,

which are what we uſually meet with under the name of *Occidental emeralds*, are from the mines of Germany.

The ſcarcity of *emeralds* from the Eaſt-Indies has ſo generally confirmed the opinion of there being none there, that the moſt ſkilful of our dealers in gems generally tell us, that there is no ſuch ſtone as an Oriental *emerald*, but that the fine ones are all from Peru; and Tavernier ſuppoſes that many *emeralds*, which, in the memory of the jewellers in his time, had certainly been brought from the Eaſt-Indies, were originally brought from Peru; and to ſupport this, he gives us an account of the Peruvians trading by the South-Sea to the Eaſt-Indies before the Europeans diſcovered America: but this is a far-fetched conjecture, as no footſtep of ſuch a trade ſubſiſts. The truth, in regard to the preſent ſcarcity of the Oriental *emeralds* with us, ſeems to be this; that though the people of the Eaſt-Indies were once in an humour to part with their *emeralds*, they have ſince choſe to keep them in their own hands; as it is well known to travellers, that the princes of the Eaſt are at leaſt as well acquainted with the value of gems as we, and are willing to purchaſe thoſe, which are not of the produce of their own country, at as great a price. *Hill's* Hiſt. of Foſſ. p. 597.

SMARIS, in zoology, the name of a ſmall fiſh caught in the Mediterranean, and common in the markets of Rome, Venice, and elſewhere, and ſold to the poorer ſort of people at a very ſmall price.

It is ſeldom of more than a finger's length, and of a round, not flatted body, of a duſky blackiſh green on the back and ſides, and not marked with any variegations, but having on each ſide, near the middle of the body, one large black ſpot. Its gill-fins and tail are of a faint red. The iris of the eyes is of a browniſh white, and the tail is forked. *Geſner*, de Piſc. p. 616.

SMATCH, in zoology, a name by which the common œnanthe is called in many parts of England. See the article OENANTHE.

SMECTIS, in natural hiſtory, a name uſed by ſeveral authors for the common fuller's earth, more commonly called *cimolia purpuraſcens*. *Hill's* Hiſt. of Foſſ. p. 49. See the article FULLER'*s earth*.

The *fuller's earth* of England is a much more valuable article of commerce, than many would believe. It has the property of imbibing oil or greaſe, or any other fat ſubſtance; and the great uſe that is made of it, is for the cleanſing of woollen-cloth. Every one knows, that tar is often employed in the external diſtemperatures of ſheep, as are alſo tallow, greaſe, and many other fatty and unctuous ſubſtances. The wool itſelf, after ſhearing, cannot be worked up without being firſt oiled, or greaſed. For theſe, and many other reaſons, all our woollen-cloth muſt neceſſarily be greaſed, but then all this greaſe muſt neceſſarily alſo be taken out of it again, before it can be ſold or worn, and nothing yet known ſerves to this purpoſe ſo well as this *earth*.

The *fuller's earth* is very plentiful in England, and as much excels that of all other nations in goodneſs, as in quantity and cheapneſs, and this is one great reaſon why we have the advantage of other nations in the woollen manufacture; to preſerve and ſecure this to us, the *fuller's earth* is forbid to be exported, under large penalties, by Act of Parliament. This *earth* is one great inſtance of the value of the Engliſh foſſils; and Dr. Woodward's love for his native country has carried him ſo far, as to make him affirm, from his own obſervation, that this iſland wants no foſſile ſubſtance known in the world, except diamonds, and ſome other gems, and quickſilver ores. *Woodward's* Cat. Foſſ. Vol. 1. p. 8.

SMEGMA, a kind of waſh in uſe among the antients. See the article DETERSORIUM.

SMELL, (*Cycl.*) is uſed as the name of a peculiar ſort of wine, of which there are two ſpecies; the one ſort is very fragrant, muſcatelline, and aromatic; this is called ſimply the *ſmell-wine*: but the other, which is very rank and offenſive to the noſe, is called by the Germans *ſmel-bruntzer*. Many have been the conjectures about the occaſion of the rank ſmell of this wine, it not being owing to the grape it is made from, thoſe of the ſame vineyard often affording the aromatic, and often the rank wine: ſome have imputed the ſtrange difference to the veſſel, others to the vine, and others to the earth it grows in; but the firſt of theſe is too trifling a cauſe for ſuch an effect, and the others are confuted by experience of the ſame vine, in the ſame place, yielding both. The opinion of Portzius, that the rankneſs of the *ſmell* of ſome of this wine is owing to ſome irregularities in the working; this is certain, that it never is perceived before the working. The *ſmell* is truly urinous, and is that of a volatile alkali; which not being embodied in, or ſubdued by the acid of the grape in this imperfect fermentation, ſhews itſelf in this rank manner. It is evident that the *ſmell* is of a volatile nature, for it is often loſt in the drawing the wine ſeveral times out of one veſſel into another, evaporating during the time of the drawing it out. *Portzius*, de Vin. Rhen.

SMELLING (*Cycl.*)—The ſenſe of *ſmelling* ſeems extremely fine in ſome inſects. It is reported of bees, that they will ſmell honey or wax above a mile; and on this quality, in that little creature, is founded a very profitable ſort of hunting in the woods in New-England, and ſome other places, for the honey which the wild bees collect. Theſe inſects are very numerous in the woods there, and have great ſtores of wax and honey; but it was always very difficult to find them, till this method was invented.

The hunter always chooſes for his purpoſe a fine, clear, and ſun-ſhiny day: he then goes out into the woods with a trencher in his hand, on which there is ſome honey; this he ſets down upon the ſtump of a tree. The bees ſoon find this out, and come to feed on it: as ſoon as three or four are come about it, he catches them ſeverally in little boxes, and after a few minutes he lets them out one by one, and obſerves their courſe. The creature always mounts to a little height in the air, and then goes directly forward in a ſtrait line to the tree in which the hive is. As the hunter cannot purſue this little creature in her flight through a thick wood, he always takes with him his pocket-compaſs, rule, and other inſtruments, with a ſheet of paper, and on this he ſets down the courſe; ſuppoſe it, for inſtance, to be weſt. By this he is certain, that the tree where the hive is muſt be ſomewhere in a line due weſt from the place where he is; but he wants to know the exact diſtance from his ſtation. In order to do that, he makes an off-ſet, either ſouth or north, ſuppoſe north, of an hundred perches, or rods; if it be more, it will be ſtill more exact, becauſe the angle will not be ſo acute. Then he goes to this ſecond ſtation, and lets out another bee, and obſerves its courſe alſo very carefully; for being loaded it will certainly, after mounting to a ſmall height in the air, fly directly to the hive as the former did. This ſecond courſe the hunter finds to be ſouth fifty four degrees weſt; then there remains nothing but to find out where the two courſes interſect, for in that place the tree, and the hive in it, certainly is.

The foundation of all this, is the ſtrait or direct motion of bees, which, when loaded with honey, always fly directly to their hive; and this is found to be an unalterable law of nature in theſe animals, ſo that the hunter is never diſappointed, when he takes his meaſures rightly, and vaſt quantities of honey are thus taken every year.

One very remarkable part of this hiſtory is, that though the bees are now ſo vaſtly plentiful in this part of the world, they are not natives there, and are only the produce of ſuch bees as were carried thither from England about an hundred and fifty years ago: for the firſt planters never ſaw a bee in the woods till long after the place was ſettled, and hives of bees, among other things, had been brought from us. What is a greater proof of this, is, that the natives of the place knew nothing of the bee till they ſaw ours; they have no word in their language to expreſs that creature, but commonly called it, for a long time, the *Engliſhman's fly*. Before this method of finding the hives was brought into practice, the planters uſed to watch the bees which they found in the woods by the eye, and after obſerving ſeveral, one after another, fly the ſame way, they would ſometimes hit upon the place; but it was with great uncertainty, as well as great difficulty. It is obſerved of the bees in that part of the world, that in ſwarming they never move northward, but always either due ſouth, or ſomething inclining that way. Philoſ. Tranſ. N° 367.

SMELT, *apua phalerica*, in ichthyology. See APUA.

Theſe fiſh will live almoſt any where, but they are very apt to degenerate. They are common in the rivers of New-England, and are as large as with us, often weighing two ounces and a half; but a pail-full of theſe being taken from one of their rivers, and put into an adjoining pond, they all degenerated in ſuch a manner, that they were afterwards found ſo ſmall, that the largeſt did not weigh more than five pennyweights. Though thus ſmall, however, they are much valued, and are better taſted than the others. They are very tranſparent, and of a beautiful ſhining pearl colour. Philoſ. Tranſ. N° 374. p. 232.

They are called *ſmelts*, becauſe they melt, as it were, or diſſolve between the fingers in handling them.

SMELT, among the fiſhermen in Yorkſhire, and ſome other parts of England, is alſo a name given to the ſalmon while in its firſt year. *Willughby's* Hiſt. Piſc. p. 189. See the article SALMON.

SMELTING (*Cycl.*)—SMELTING-*houſe*, a houſe where they run and melt the ore into lead; one of theſe will run a ton in ten or twelve hours; a fodder is their uſual day's work, that is, twenty two hundred and an half weight. *Houghton's* Compl. Min. in the Explan. of the Terms.

SMEW, in zoology, the Engliſh name of the common mergus, known among authors by the name *albellus*, and *mergus cirratus*. See MERGUS.

SMILAX, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the roſaceous kind, being compoſed of ſeveral petals arranged in a circular form. The piſtil finally becomes a ſoft roundiſh berry, containing a roundiſh or oval ſeed.

The ſpecies of *ſmilax*, enumerated by Mr. Tournefort, are theſe. 1. The rough *ſmilax* with red berries. 2. The rough *ſmilax* with fewer prickles, and with black fruit. 3. The

rough

rough *ſmilax* with broad and blunt-pointed leaves, and no notches or prickles at their edges. 4. The one-leaved dwarf *ſmilax*, called *one-leaf*, *unifolium*, and *little lilly of the valley*. 5. The rough racemoſe *ſmilax* with Solomon's ſeal leaves. 6. The ſpiked *ſmilax* with Solomon's ſeal leaves. *Tourn.* Inſt. p. 654.

SMILAX *aſpera*, is uſed for great ſcarlet oak, or ilex. *Tourn.* Inſt. p. 553.

SMILAX *lævis*, in botany, a name given by many authors to our common great white bind-weed. See the article CONVOLVULUS.

SMIRIS, in natural hiſtory. See EMERY.

SMITING-*line*, in a ſhip, is a ſmall rope faſtened to the miſſen-yard-arm, below at the deck, and is always furled up with the miſſen-ſail, even to the upper end of the yard, and from thence it comes down to the poop. Its uſe is to looſe the miſſen-ſail without ſtriking down the yard, which is eaſily done, becauſe the miſſen-ſail is furled up only with rope-yarns; and therefore when this rope is pulled hard, it breaks all the rope-yarns, and ſo the ſail falls down of itſelf. The word of art is, *ſmite the miſſen* (whence this rope takes its name) that is, hale by this rope that the ſail may fall down.

SMOKE *(Cycl.)*—SMOKE-*ſilver*, in our old writers. Lands were held in ſome places by the payment of the ſum of ſixpence yearly to the ſheriff, called *ſmoke-ſilver*. Pat. 4 Edw. 6. *Smoke-ſilver*, and *ſmoke-penny*, are to be paid to the miniſters of divers pariſhes as a modus, in lieu of tithe-wood; and in ſome manors, formerly belonging to religious houſes, there is ſtill paid, as appendant to the ſaid manors, the antient Peter-pence, by the name of *ſmoke-money*. *Blount.*

SMORZATO, in the Italian muſic, is uſed to ſignify that the bow, or fiddle-ſtick, ſhould be drawn to its full length, not with the ſame ſtrength of hand throughout, but bearing lighter and lighter on it by degrees, till at laſt ſcarce any ſound be heard. This term is not much uſed at preſent. *Broſſard.* Dict. Muſ.

SMUT *(Cycl.)*—SMUT, in huſbandry, a diſeaſe in corn, in which the grains, inſtead of being filled with flower, are full of a black ſtinking powder.

Many things have been ſuſpected as the cauſes of this diſtemperature in corn; but Mr. Tull ſeems convinced by experiment, that it is cauſed only by too much moiſture, the ſeveral plants of corn, which he had taken up by the roots and planted in troughs of very moiſt earth, all bringing forth *ſmutty* ears, while very few ſuch were found in the corn of the field from whence theſe plants were taken. It is obſervable, alſo, that thoſe ears, the grains of which are to be *ſmutty*, never ſend up any flowers at all.

The two things, recommended by writers of huſbandry as remedies, or preventions of this diſeaſe, are brining, and changing the ſeed. The firſt of theſe methods was accidentally diſcovered about a century ago: a ſhip load of wheat was, about autumn, ſunk near Briſtol, and afterwards was taken up at the ebbs at ſeveral times, after being thoroughly ſoaked in ſea-water. When the wheat was all taken up, it was found unfit to make bread of, but a farmer trying ſome of it for ſowing, found it anſwer very well, and himſelf, and the neighbouring farmers, bought it all up at a ſmall price; the country all about was ſown out of this cargo. It happened that *ſmuttyneſs* in the wheat-corn was a reigning diſtemper in all parts of the kingdom at that time, but it was remarkable, that all the fields ſown with this ſalt wheat were abſolutely free from the miſchief: this eaſily introduced the practice of ſoaking wheat, before ſowing, in a brine of ſalt and water, to prevent it in other places, and it has ſucceeded well. Mr. Tull gives an inſtance of the certainty of its effect, in the caſe of two farmers whom he perſonally knew, and whoſe farms lay intermixed: theſe men bought the ſame ſeed between them from a very good change of land, and parted every land between them in the field; the oldeſt farmer believed the brining to be a fancy, and ſowed his ſeed unbrined, the other brined all his ſeed, and the conſequence was, that the old farmer had a great deal of *ſmut* in his corn, while the other had not one *ſmutty* ear.

When wheat is intended for drilling, it muſt be ſoaked in no other brine than that of pure ſalt and water, for if there be any greaſe among it, it will never be dry enough for this manner of ſowing. If ſeed wheat be ſoaked in urine, it will not grow, and if it be only ſprinkled with it, it will moſt of it die, unleſs it be planted preſently. The moſt expeditious way of brining wheat for drilling, is to lay it in a heap, and waſh it with a ſtrong brine ſprinkled on it, ſtirring it up with a ſhovel, that it may be all equally brined, or wetted with it; after this ſift on ſome fine lime all over the ſurface, and ſtir it up, ſtill ſifting on more in the ſame manner till the whole is duſted with the lime, it will then be ſoon dry enough to be drilled without farther trouble. It muſt be quick lime, in its full ſtrength, that is uſed on this occaſion.

Bad years will cauſe *ſmut* in corn, and good years will prevent it: it is, however, obſervable, that the crops in which there is *ſmutty* corn will, if uſed for ſeed, be liable to produce *ſmutty* corn again, rather than other ſeed. The brining is a defence againſt bad years, and againſt the miſchiefs attending the ſowing corn among which there has been *ſmut*.

The other method of changing the ſeed is by many held effectual to prevent *ſmuttyneſs* in the crop; ſeveral, who have tried this with due care, have found perfect ſucceſs from it: and it is to be obſerved, as to the great ſucceſs of the drowned wheat at Briſtol, that it was a change of ſeed to the lands on which it was ſown, as well as a brined ſeed.

Seed-wheat ſhould be bought from the crop on a ſtrong clay-land, whatever kind of land it is to be ſowed upon. A white clay is a good change for a red clay, and a red clay for a white; but whatever the land be, from which the ſeed is taken, it may be infected, if that be not changed there the preceding year; and then there may be danger, though it be had from ever ſo proper a land. It is a rule among the farmers, never to buy ſeed-wheat from a ſandy ſoil; they expreſs their diſlike of this by the coarſe rhime; *ſand* is a change for no *land*.

A crop of wheat, very early planted, is not ſo apt to be *ſmutty*, as one planted leſs early; and the farmers have obſerved, that the largeſt and plumpeſt ground fat wheat is more liable to be *ſmutty* than the ſmall ground wheat. *Tull's* Horſehoeing Huſbandry.

The *ſmut* of corn uſually happens after rain, followed by a bright ſunſhine; and when the *ſmutted* ſtalks are examined, they are found to be ſpotted, and pricked as it were with ſmall burnt places. The cauſe of the malady, therefore, probably is, that thoſe ſmall drops of rain, which remain upon the ſtalks before they are dried up by the ſun, act as ſo many lenſes, or ſmall burning-glaſſes, and their focus being very near them, their effect falls upon the ſtalk which ſupports them; wherefore the ſun's rays, collected in this point, muſt burn, and this burning dries up the ſtalk, and prevents the ear from graining, or producing its proper ſeeds. See the article BLIGHT.

Smutty corn is of a very miſchievous nature to thoſe who eat it. Schober has publiſhed a diſſertation on a terrible epidemical malady that raged, in the year 1722, in many parts of Germany, and carried off a great many people of all ages and ſexes: this he attributes wholly to their eating flower and bread made of corn, among which a larger than ordinary quantity of this *ſmut* had been produced the year before, and ground down with it. From this it appears, that theſe black ears have a ſtupefactive and narcotic quality, depending on a peculiar ſulphur they are endowed with, and to this ſulphur it is owing, that they are ſo inflammable beyond other corn. This ſulphureous principle is very hurtful to the nerves, and never fails to cauſe diſorders of them, of various kinds, when taken in any quantity; contractions, and convulſions of the limbs, vertigos, ſleepineſs, and, in fine, light-headedneſs, were the ſymptoms of the diſeaſes brought on by the eating it on the occaſion abovementioned; and ſometimes true, and incurable epilepſies come on. Some were ſeized with fevers, and children in particular were found more ſubject to the ſmall-pox that year, than they had been obſerved to be, and they had commonly very bad kinds.

SMYRHIZA, in botany, a name uſed by Pliny, and ſome other of the old authors, for the common myrrhis, or chervil. *Ger.* Emac. Ind. 2.

SMYRNIUM, *Alexanders*, in botany, the name of a genus of the umbelliferous plants, the characters of which are theſe. The flower is of the roſaceous kind, conſiſting of ſeveral petals, arranged in a circular order on a cup, which afterwards becomes a fruit of a ſort of globular figure, compoſed of two thick and, in ſome degree, lunated ſeeds, being gibboſe and ſtriated on one ſide, and flat and ſmooth on the other. See Tab. 1. of Botany, Claſs 7.

The ſpecies of *ſmyrnium*, enumerated by Mr. Tournefort, are theſe. 1. The common great *ſmyrnium*, or herb *Alexanders*. 2. The round-leaved Candy *ſmyrnium*. 3. The leſſer parſley-leaved Portugal *ſmyrnium*. *Tourn.* Inſt. p. 31.

The antient Greeks have plainly deſcribed two different plants under this name; the one the common *Alexanders*, the other the *petroſelinum Cilicium*, or Cilician parſley. The former of theſe plants loves moiſt and rich ground, and the other grows no where but on rocky hills, and in the drieſt and moſt barren places. Pliny, not obſerving that the antient writers knew two plants under this name, accuſes them of an error, in ſaying that the *ſmyrnium* loved dry and barren places, whereas the Romans, who cultivated the *ſmyrnium* at that time, found it delighted only in rich moiſt ſoils; but the antients, whom he cenſures thus, had ſpoke what he records of the *petroſelinum*, not of the great water-*ſmyrnium*.

SMYRUS, in ichthyology, a name ſometimes given by Pliny to the fiſh called by authors *myrus*, and by Willughby the *ſea-ſerpent* with a compreſſed tail.

It is a ſpecies of the muræna, according to Artedi, and is diſtinguiſhed from all the others by that author, under the name of the *muræna* with a ſharp ſnout, variegated with white

white ſpots, and with the edge of the back fin black. See the article MURÆNA.

SMYTHAM, in mineralogy, lead-ore ſtamped and pounded down, like powder or ſand, to cleanſe the ſtones and earth from the ore. *Houghton*'s Compl. Miner in the Explan. of the Terms.

SNAFFLE, in the manege, a well known kind of bridle. The *ſnaffle*, after the Engliſh faſhion, is a very ſlender bit-mouth without any branches: they are much uſed in England inſtead of true bridles, which are only employed in the ſervice of war. The French call them *bridons*, by way of diſtinction from *brides*, i. e. bridles.

The *ſnaffle*, or ſmall watering-bit, is commonly a ſcatch-mouth, accoutred with two little very ſtraight branches, and a curb, and mounted with a head-ſtall and two long reins of Hungary leather.

SNAIL, in ichthyography. See LIPARIS *noſtras*.

Perrault doubts of *ſnails* having eyes, and Dr. Brown denies it; but according to Dr. Porterfield, a good microſcope ſhews them diſtinctly. Med. Eſſ. Edinb. Vol. 3. Art. 12.

The eyes of *ſnails* are lodged in their four horns, one at the end of each horn, which they can retract at pleaſure. Id. ibid.

The manner of examining theſe eyes is this: when the horns are out, cut off nimbly the extremity of one of them, and placing it before the microſcope, you may diſcover the black ſpot at the end to be really a ſemiglobular eye.

The diſſection of this animal is very curious; for by this means, the microſcope not only diſcovers the heart beating juſt againſt the round hole near the neck, which ſeems the place of reſpiration, but alſo the liver, ſpleen, ſtomach, and inteſtines, with the veins, arteries, mouth, and teeth, are plainly obſervable. The guts of this creature are green, from its eating of herbs, and are branched all over with fine capillary white veins. The mouth is like a hare's, or rabbet's, with four or ſix needle-teeth, reſembling thoſe of leeches, and of a ſubſtance like horn.

Snails are all hermaphrodites, having all each ſex united in the individual; they lay their eggs with great care in the earth, and the young ones are hatched with ſhells compleatly formed.

Cutting off a *ſnail*'s head, a little ſtone appears, which is ſuppoſed to be a great diuretic, and good in all nephritic diſorders. Immediately under this ſtone the heart is ſeen beating, and the auricles are evidently diſtinguiſhable, and are membranous, and of a white colour; as are alſo the veſſels which proceed from them.

Snails diſcharge their excrements at a hole in their neck; they alſo breathe by this hole, and their parts of generation are ſituated very near it. The penis is very long, and in ſhape reſembles that of a whale. *Baker*'s Microſcope, p. 217.

So ſmall an animal as the *ſnail* is not free from the plague of ſupporting other ſmaller animals on its body; and as in other animals we find theſe ſecondary ones either living only on their ſurface, as lice, &c. or only in the inteſtines, as worms, it is very remarkable that this creature infeſts the *ſnail* in both theſe manners, being found ſometimes on the ſurface of its body, and ſometimes within its inteſtines.

There is a part of the common garden-*ſnail*, and of other of the like kinds, commonly called the *collar*; this ſurrounds the neck of the *ſnail*, and is conſiderably thick, and is the only part that is viſible, when the animal is retired quietly into its ſhell. In this ſtate of the animal theſe inſects, which infeſt it, are uſually ſeen in conſiderable numbers marching about very nimbly on this part: this nimble motion is almoſt peculiar to them, moſt other creatures of this kind being very ſlow in their motions: they may be ſeen in many other circumſtances of the animal, but it is this in which they are moſt obvious to the naked eye. Though they are very ſmall, they cannot however make their way under the ſhell, to run over the reſt of the body of the *ſnail*, every part of it adheres too firmly to the ſhell to ſuffer that; but they have another very different way of enlarging their place of abode: the *ſnail*, every time it has occaſion to open its anus, gives them a place by which to enter into its inteſtines, and they often ſeize the opportunity. The anus of this creature is ſituated not within the ſhell, but in this collar, which ſurrounds the mouth of it; and the *ſnail* ſeldom moves, to go a little way out of its ſhell, without opening it, as it does alſo in many other circumſtances.

Theſe inſects always take advantage of the opening, and ſwiftly get in and run up into the inteſtines, inſomuch that their natural reſidence ſeems there, and that they never are upon the ſurface of the animal but by accident, and much againſt their will; they ſeem to be driven thither by this accident: the fæces of the *ſnail* fill up the whole width of the inteſtine, and when they are diſcharged, muſt neceſſarily carry out with them whatever is between them and the anus; now it may eaſily happen, that a number of theſe ſmall animals may be in that part of the inteſtine, which is between the anus and the fæces: all theſe muſt be diſcharged with them, and while they are walking about upon the neck of the animal, the aperture of the anus cloſes, and leaves them no power of entering back again, till another opportunity; and the frequency of this accident may eaſily drive out enough of theſe inſects, to keep always ſome upon the neck, though every one of them, while there, is ſeeking the firſt opportunity of getting into the inteſtines again.

Theſe inſects infeſt every kind of *ſnail*, though they are moſt frequent on the common large garden-kind; but there is a ſmall ſpecies of *ſnail*, remarkable for a ſort of cover, nearly as hard as the ſhell, with which the creature cloſes up its mouth upon occaſion: in this theſe creatures may be diſtinguiſhed, even within the inteſtines. The ſkin of this *ſnail* is very thin and tranſparent; and if the ſhell be broken off a little way, and the eye kept attentively on that part, theſe little inſects will be diſtinguiſhed through the ſkin running nimbly about in the inteſtines.

Though theſe inſects are found in all ſorts of *ſnails*, they are not to be ſeen at all times; rainy ſeaſons ſeem particularly diſadvantageous to them, and it is only in dry times that they are always to be found when looked for; whether it be that the rain deſtroys the animals, when already formed, or that they are in themſelves but ſhort-lived, and the rain prevents the hatching of the eggs for more. The inſects are content with the naked body of the *ſnail* alone as their habitation, they never get upon the ſhell, and if they are forced to it, they as ſoon as poſſible quit it again, and get to their old poſt. They appear of a whitiſh colour to the naked eye, ſome of a dirty greyiſh white, and ſome of a white with a mixture of reddiſhneſs; but a microſcope is neceſſary to give us a view of their different parts and ſtructure. They have a regular trunk, in the manner of many other inſects, which they occaſionally can bend downwards, and in a great meaſure hide from the ſight: this trunk, which ſerves them to ſuck in their nouriſhment from the body of the *ſnail*, is placed between two little horns, which are extremely moveable every way, and are capable of being extended in length, or ſhortened, in the manner of the horns of the *ſnail*, which is a circumſtance not obſervable in the horns, or antennæ of other inſects. The body is divided into ſix rings, beſide the anterior part, on which are placed the horns and the trunk. The creature has four legs on each ſide, two of which on each are articulated into the anterior part, which gives riſe to the horns and trunk, and the other two into the firſt ring of the body; ſo that they ſtand in pairs, the ſecond and third on each ſide being greatly more diſtant from one another than the firſt and ſecond, or the third and fourth: theſe legs are all furniſhed with very long hairs, and ſeem to terminate, each in two or three points, in the manner of the legs of many of the beetles. The back is elevated into a convex form, the ſides alſo are rounded, and each ornamented with three or four hairs; but there are none under the belly. Mem. Acad. Par. 1711.

Snails are great deſtroyers of fruit in our gardens, eſpecially to the bitter ſorts of wall-fruit. Lime and aſhes ſprinkled on the ground where they moſt reſort, will drive them away, and deſtroy the young brood of them. It is a common practice to pull off the fruit they have bitten, but this ſhould never be done, for they will eat no other till they have wholly eat up this, if it be left for them.

The Romans were fond of *ſnails*, and had them fed on purpoſe for their tables. Their taſte is not delicious, but rather diſagreeable; but this they diſguiſed by means of good ſauces, and had other reaſons for the receiving them into the liſt of foods. They uſed them as provocatives, or inciters to venery, and with this intent they eat only the necks, as the part in which the parts of generation of the creature were placed; and they had the greater opinion of the efficacy of theſe, as the parts of generation were double in each individual, that is, the male and female parts both ſituated in the neck of every *ſnail*.

Ariſtotle, and the old Greeks, had no idea of the generation of theſe inſects, in the manner of other animals, but ſuppoſed them produced ſpontaneouſly; but the Romans ſhew, by many paſſages in their writings, that they had got over this error, and even ſeem, by the preference they gave to the neck of this animal, in this intention to have underſtood the hermaphrodite ſtructure of this inſect, which much later ages have pretended to make a new diſcovery.

The Eaſtern nations at preſent run much into the opinions of the Romans of old, as to provocatives; they uſe, as the others did, every thing that ſerves to the purpoſes of generation in other animals, and every thing that has but the reſemblance of the external figure of the parts ſubſervient to it. The orchis roots, which reſemble the teſticles of animals in ſhape, and contain a white and ſlimy, or viſcous liquor, have introduced themſelves into uſe on this plan, and ſo of many other things. Phil. Tranſ. N° 50.

Oat-SNAIL, a name given by Dr. Liſter, in the Philoſophical Tranſactions, to a ſmall *ſnail*, which he obſerved under the looſe bark of old willows, elms, and others trees, and which is of a very ſingular ſtructure; the ſhell reſembling an oat-corn, whence the name, and its volutæ, or wreaths, running contrary to the direction of them in other *ſnails*, that

is eaſt and weſt, as the philoſophers expreſs it, referring it to the motion of the ſun; but theſe ſhells, to uſe that language, have the turns weſt and eaſt, or more plainly, they have the turns running from the right-hand to the left, not from the left to the right as other ſnails. Philoſ. Tranſ. N° 250.

SNAKE, *(Cycl.) anguis.* See the article ANGUIS.

The poiſonous qualities of ſome of the *ſerpent*-kind, have given the generality of the world a diſtaſte to all of them, but our common *ſnake* is a harmleſs and inoffenſive animal, and might even be kept tame in our houſes, where it would deſtroy vermin, and never be of any hurt to any thing. This animal may be ſuppoſed as far from tameneſs in its nature, as any that could be thought of, yet, in the Acta Leipſienſia, we have an account of ſeveral which were kept tame in a houſe, and taught ſo far, as to go regularly into their boxes every night. The perſon, who diverted himſelf with keeping theſe, had the entertainment of ſeeing them change their ſkins ſeveral times, and of obſerving their laying their eggs, of which they would depoſit twelve or thirteen in the ſpace of half an hour. Act. Leipſienſ. Anno 1670.

That *ſnakes* are viviparous, ſee Philoſ. Tranſact. N° 8. p. 138.

SNAKE *with two heads*, a kind of *ſnake* in Braſil, having a ſwelling at its tail, which at a diſtance has the appearance of a head.

The Portugueſe call it *ſnake* with two heads; their fear of this creature, for the bite of which they pretend there is no remedy, having prevented their examining into the truth. They alſo pretend that it is dangerous to meddle with theſe *ſnakes* after they are dead, and that barely touching them will give the itch. Mr. Couplet was, notwithſtanding, bold enough to flea ſeveral of them, but found himſelf, after having performed this operation on two or three, all covered with puſtules filled with a reddiſh water. Theſe remained on him a conſiderable time, and he was not quite well in three months.

The country of Braſil abounds with large *ſnakes*, the bite of which is venomous; but the natives and blacks make no ſcruple of eating them. Mem. de l'Acad. des Scienc. 1700. p. 228, 229.

Blood-SNAKE. See the article HÆMORRHOUS.

Rattle-SNAKE. See RATTLE-*ſnake*.

Sea-SNAKE. See the article SERPENS *marinus*.

Spectacle-SNAKE. See COBRAS *de capello*.

SNAKE-*ſtone*, *ammonitæ*, in natural hiſtory, the name of a large genus of foſſile ſhells, very few, if any, of which are yet known in their recent ſtate, or living either on our own, or any other ſhores, ſo that it ſeems wonderful whence ſo vaſt a number and variety of them ſhould be brought into our ſubterranean regions. They ſeem indeed diſperſed in great plenty throughout the world, but no where are found in greater numbers, beauty, and variety, than in our own iſland. See SERPENT-*ſtones*.

They are of very different ſizes, as well as ſpecies, ſome being found of the ſize of a ſixpence, or leſs than that, and others of more than two feet in diameter: they are all made up of ſeveral circles, like thoſe of a *ſnake* when rolled up, the tail lying in the center, and the larger end, where was the mouth of the fiſh, at the other. Some of them are rounded, others greatly compreſſed, or flatted, and they are at times found lodged in almoſt all the different ſtrata of earth or ſtone.

Some of them repreſent the nave of a cart-wheel, and of theſe ſome are plain, and others ſtudded; ſome alſo are ſmooth, or wholly free from ridges, and others have ridges more or leſs broad; and among theſe, the ridges in ſome only reach acroſs the ſides, without going to the back, and others paſs the back, and form continued lines, going quite round the ſeveral volutæ of the ſhell; and ſome are plain, others ſtudded at their ends; ſome ſpecies have ſimple, and others bifurcated ſtriæ, and ſome are ſtudded and umbilicated; ſome alſo, both of theſe and of the nautili, have a ſort of foliaceous work about their ſutures, which gives a great beauty to the whole. The back of theſe ſhells alſo greatly differs in the different kinds; many of them have a ridge running all the way along the back, which in ſome is plain, and in others is denticulated, or ſerrated; and of theſe ſome have a furrow on each ſide of the ridge, which others want, and ſome have elegant rows of ſtuds running on each ſide this furrow; and finally, ſome have only a ſingle furrow running all the way along their backs. They all conſiſt of ſeveral volutæ, which are different in number in the different ſpecies; and their ſtriæ are alſo extremely various, ſome very deep, and the ridges very high between them, others very ſlight, ſome ſtrait, others irregularly crooked, others undulated, and ſome terminating in dots, tubercles, or cavities, toward the back, and others having tubercles in two or three places.

They are all compoſed of a great number of chambers, or cells, in the manner of the *nautilus Græcorum*, each having a communication with the others, by means of a pipe or ſiphunculus. There is a ſmall white ſhell-fiſh of Barbadoes, which ſeems truly a recent animal of this genus; and in the Eaſt-Indies there is another alſo, ſmall and greyiſh; but the large, and beautifully marked ones, are found only foſſile. They are compoſed of various foſſile bodies, often of quarry-ſtone, ſometimes of the matter of the common pyrites, and of a great variety of other ſubſtances; and though they appear uſually mere ſtones, yet in ſome the pearly part of the original ſhell is preſerved in all its beauty. Sometimes alſo, while the outer ſubſtance is of the matter of the pyrites, or other coarſe ſtony, or mineral matter, the inner cavity is filled with a pure white ſpar of the common plated texture. This gives a great beauty to the ſpecimen. *Hill*'s Hiſt. of Foſſ. p. 649, 650.

The cornua ammonis, or *ſnake-ſtones*, are found in many parts of England, particularly in Yorkſhire, where it is very plentiful in the alum rocks of ſeveral ſizes. See Tab. of Foſſils, Claſs 9.

The people of the place have a tradition, that all the country hereabouts was very much annoyed with *ſnakes*, but that by the prayers of St. Hilda, who lived there, they were all ſent down into the earth, and there turned into ſtone. The common people of this part of the kingdom pay an unſhaken credit to this idle ſtory; but they ſhould conſider, that if a miracle at all, it muſt have been a much more extenſive one of their ſaint than they imagine, for theſe foſſils are found not only in Yorkſhire, but in almoſt every part of the known world. Phil. Tranſ. N° 142.

SNAKE-*weed*, in botany. See BISTORT.

SNAPDRAGON, *antirrhinum*, in botany, the name of a genus of plants, the characters of which are theſe. The flower conſiſts of one leaf of a tubular form, perſonated, and having two lips, the upper of which is bifid, and the lower trifid. The piſtil ariſes from the cup, and is fixed, in the manner of a nail, in the hinder part of the flower; and afterwards becomes a ſeed-veſſel, of the ſhape of the head of a hog, divided into two cells, and uſually filled with ſmall ſeeds fixed to a placenta. See Tab. 1. of Botany, Claſs 3.

The ſpecies of *ſnapdragon*, enumerated by Mr. Tournefort, are theſe. 1. The common *ſnapdragon*. 2. The larger long-leaved *ſnapdragon* with purpliſh white flowers. 3. The white-flowered *ſnapdragon* with reddiſh edges. 4. The white-flowered *ſnapdragon* with very red edges. 5. The white-flowered *ſnapdragon* with yellow edges. 6. The yellow-flowered *ſnapdragon*. 7. The broad-leaved *ſnapdragon* with large pale yellow flowers. 8. The great narrow-leaved *ſnapdragon* with bright red flowers. 9. The Portugal *ſnapdragon* with very large and beautiful red flowers. 10. The great long-leaved Italian *ſnapdragon* with large ſnow-white milky flowers. 11. The hairy origanum-leaved Spaniſh *ſnapdragon*. 12. The hairy Spaniſh *ſnapdragon* with red valerian leaves. 13. The talleſt Spaniſh *ſnapdragon* with very narrow leaves. 14. The middle-ſized *antirrhinum* with a large and wide-open white flower. 15. The greater field-*ſnapdragon* with red flowers. 16. The greater field-*ſnapdragon* with white flowers. 17. The great ſtone *ſnapdragon* with very narrow leaves, and a ſmall purple flower.

The plant called by Caſpar Bauhine, and ſome others, the *cut-leaved ſnapdragon*, is properly a ſpecies of *pedicularis*, and the leſſer field-*ſnapdragon*, and the ſtone mother-of-thyme-leaved *ſnapdragon*, are both ſpecies of toad-flax, or *linaria*. Tourn. Inſt. p. 168. See the articles PEDICULARIS and LINARIA.

Many of the ſpecies of this plant are very beautiful, and much eſteemed in gardens, and are all eaſily propagated from ſeeds, which muſt be ſown in a dry ſoil, not too rich, in April or May. In July the plants may be planted out into large borders, where they will flower the ſpring following, or they may be ſown early in ſpring, and they will then flower in the next autumn; but then they are not ſo likely to ſtand the winter, and if the autumn prove not kindly, they will hardly produce a perfect thin ſeed. They all grow very well on old walls, where they have happened to ſow themſelves. *Miller*'s Gard. Dict.

SNATCH-*block*, in a ſhip, is a great block with a ſhiver in it, having a notch cut through one of its cheeks, for the more ready receiving in of any rope; for by this notch, the middle part of a rope may be reeved into this *block*, without paſſing it in endways. This ready *block* is commonly faſtened with a ſtrap about the main-maſt, cloſe to the upper-deck, and is chiefly uſed for the fall of the winding-tackle, which is reeved into this *block*, and then brought to the capſtan.

SNIEGULKA, in natural hiſtory, a name given by the common people of Poland to a bird of paſſage, that only comes to them in the colder months.

The name ſignifies the ſnow-bird, and Rzaczinſki, in his Hiſtory of Poland, calls it *nivalis avis*. The people preſage, from its coming, the mildneſs or ſeverity of their winter.

SNIGGLING, a method of fiſhing for eels, chiefly uſed in the day-time, when they are found to abſcond themſelves near wears, mills, or flood-gates. It is performed thus: take a ſtrong line and hook, baited with a lob or garden-worm, and obſerving the holes where the eels lie hid, thruſt your bait into them by help of a ſtick, and if there be any, you

ſhall be ſure to have a bite; and may, if your tackling hold, get the largeſt of eels. Vid. *Cox*, Gentl. Recr. Part 4. p. 39.

SNIPE, in zoology. See the article GALLINAGO *minor*.

Theſe birds are eaſily taken, by means of lime-twigs, in this manner: take fifty or ſixty birchen-twigs, and lime them all very well together; take theſe out into places where there are *ſnipes*, and having found the places which they moſt frequent, which may be ſeen by their dung, ſet the twigs in theſe places, at about a yard diſtance one from another. Other places, are thoſe where the water lies open in hard froſty and ſnowy weather: in theſe places alſo, and where-ever they are ſuſpected to come to feed, let more lime-twigs be placed in the ſame manner. The twigs are not to be placed perpendicularly in the ground, but ſloping, ſome one way, ſome another; the ſportſman is then to retire to a diſtance, and watch the coming of the birds to theſe places. When they fly to them, they naturally take a ſweep round the earth, and by this means they will almoſt always be caught by one or other of the twigs. When a firſt *ſnipe* is taken, the ſportſman is not to run to take it up, for it will feed with the twig under its wings, and this will be a means of bringing down more of them to the place. When three or four are taken, they may be taken up, only leaving one faſt to entice others; and thus the ſport may be continued, as long as there are any birds of this kind about the place. It may be very proper, when the twigs are planted, to go about, and beat all the open and watery places near, that they may be raiſed from thence, and fly to thoſe places where the twigs are placed to receive them.

SNORT, in the manege, called in French *ebrouer*, denotes a certain ſound which a horſe of fire makes by breathing through his noſtrils; as if he had a mind to expel ſomething that was in his noſe, and hindered him to take breath.

This noiſe or ſound is performed by means of a cartilage within the noſtrils, called in French *ſouris*. Horſes of much mettle *ſnort*, when you offer to keep them in. See the article SOURIS.

SNOTTOLF, a name uſed by ſome authors for a ſpecies of the *orbis*, or globe-fiſh, called by Cluſius, and other authors, the *orbis ranæ ritu*, or frog-mouthed globe-fiſh.

It is uſually of about ſixteen inches in length. It is of a brown colour, variegated with white ſpots. Its head is very thick, and its mouth large and wide, and very much reſembling that of a frog. It has one irregular fin on the back, running nearly all the way to the tail, and two rows of tubercles on each ſide, one on the middle part of the body, the other nearer the belly. It is frequent in the German, and in many other ſeas. The name is Dutch. *Geſner*. p. 747. *Bartholin*. Cent. Obſ. 2. Hiſt. 1.

This fiſh is the *cyclopterus* of Artedi, and the *lumpus* of other authors. See the article LUMPUS.

SNOW (*Cycl.*)—*Snow* may be preſerved by ramming it down in a dry place underground, and covering it well with chaff. At Leghorn they uſe barley-chaff for this purpoſe. See Phil. Tranſ. N° 8. p. 140.

Snow and ice are alſo preſerved with ſtraw or reeds. Mr. Boyle has deſcribed the manner in his experimental hiſtory of cold.

It is uſual in hot countries to mix *ſnow* and ice with their wine. Hence Pliny [b] ſays, *Hi nives, illi glaciem potant, pœnaſque montium in voluptatem gulæ vertunt.*—[[b] Lib. 19. cap. 4. Martial has an epigram on this ſubject, Lib. 14. Epigr. 117.]

SNOW-*drop-tree*, a very beautiful American tree, which bears the cold of our climate in the open air; but it is very difficult to encreaſe, the layers being two years before they take root, nor will they ever take root at all, except the branches are very young, and are ſlit in the joint, as in the laying carnations. When thoroughly rooted, they may be tranſplanted into ſmall quarters of flowering-ſhrubs, where, among thoſe of a middling growth, they add much to the variety. *Miller*'s Gard. Dict.

SNOW-*ſtone*, in natural hiſtory, a name given by ſome to a very beautiful ſtone found in America; of which the Spaniards are very fond, making it into tables, and other ornaments in their houſes. Alonſo Barba, who had ſeen much of it, tells us, that it is found in the province of Atocama, and is uſually found in pieces of four feet long, and four or five inches broad; ſo that it is forced to be joined in the working. Its general thickneſs is about two inches. It has a great variety of colours, which form clouds and variegations of a very beautiful kind. The principal colours are red, yellow, green, black, and white. The white is generally formed into ſpots on the very blackeſt parts of the maſs, and is ſo beautifully diſpoſed, that it repreſents *ſnow* falling in all its whiteneſs upon a jetty ſurface. *Alonſo Barba* of Metals.

SNUFF (*Cycl.*)—The many miſchiefs attending an unnatural practice of taking this powder of tobacco at the noſtrils, have been deſcribed by the writers in general on theſe ſubjects, ſince this pernicious cuſtom has reigned in the world; but one of the moſt remarkable accidents, occaſioned by it, is related in the Acta Eruditorum.

The caſe is this. A fat perſon, greatly addicted to the taking Spaniſh *ſnuff*, after many years continued uſe of it, complained one day of a mighty uneaſineſs which it occaſioned in the middle of his œſophagus, and ſoon after this he began to find his ſwallowing difficult. He applied for relief to a phyſician, and naming nothing of the pain which had preceded this difficulty of ſwallowing, it was treated as a complaint ariſing from ſome glutinous humor in the œſophagus, it is no wonder that the medicines in this intention had no effect. The patient grew worſe, and tired of this doctor, applied to another, who ſuppoſing the complaint aroſe from ſome ſharp humor vellicating the parts, gave medicines in that intention, equally without ſucceſs. After this a common quack tried the moſt violent medicines on him, but without ſucceſs; and finally he applied to the uſe of the excutia ventriculi, an inſtrument made to be thruſt down the œſophagus into the ſtomach, but this he never could get down; and in the uſe of this inſtrument he firſt felt, that there was abſolutely a lump of fleſh, which ſtopped its paſſage farther than the place where the ſeat of his complaint was. The diſtemper after this encreaſed upon him, till he could only ſwallow liquids, and thoſe at laſt by no other means, but the ſucking them through a quill, by which means he could get down milk, water-gruel, and the like, by a little at a time. At length conſulting another phyſician, and telling him of the immoderate quantity of Spaniſh *ſnuff* he had been uſed to take, and that it often happened to him on taking the drieſt *ſnuff* of this kind; that it got into his œſophagus, and occaſioned violent pain, coughing, and ſpitting of blood, he ſoon concluded that a polypus had formed itſelf in the œſophagus, wounded by this ſharp powder, and that there was no relief, but that the death of the patient was quickly approaching. The man, from a very corpulent habit, was ſo extenuated, that he appeared a mere ſceleton; he died ſome little time after of abſolute hunger, the œſophagus being ſo entirely filled up by this unnatural ſwelling, that not the leaſt drop of a liquid could get down.

After death the œſophagus was opened, and a fleſhy excreſcence, or polypus, was diſcovered, of the bigneſs of the cavity of the part, and taking its origin about the middle, from the back part of the œſophagus, it reached down to the pylorus. This was of a whitiſh colour, and much reſembled a large worm, and its ſubſtance was fibrous, and very tender. Act. Erudit. Anno 1715. p. 457.

SNUFF, or *Snuffler*, in the manege. See the article SNORT.

SOAGGIO, the name of a fiſh common in the markets of Rome and Venice, and of the turbot-kind.

It is the *rhomboides* of Rondeletius, and the *rhombus non aculeatus ſquammoſus* of Willughby.

We have it alſo on our own ſhores, and the Corniſh people, who frequently catch it, call it the *lug-a-leaf*. It has no rough lines at the roots of its fins. Its eyes are large, and ſet at a conſiderable diſtance, and it is covered with extremely minute ſcales. It is extremely flat and thin, and of an aſh-colour.

It is a very ſingular ſpecies of fiſh, differing, in ſome particulars, from both thoſe genera to which it ſeems allied. It differs from the plaiſe-kind, in that it has the eyes, fins, *&c.* of the turbot, or rhombus; and from that fiſh, in that it is ſcaly, as the plaiſe, and the other fiſh of that genus. *Willughby*, Hiſt. Piſc. p. 95. *Rondel.* de Piſc. p. 358.

SOAL, in ichthyology, the Engliſh name of the fiſh, called by the generality of authors the *bugloſſus*, by ſome *ſolea*.

It is, according to the new ſyſtem of Artedi, a ſpecies of the pleuronectes, and is of that kind which have the eyes placed on the left ſide. Some authors call it the *linguacula*. See BUGLOSSUS and PLEURONECTES.

SOAP (*Cycl.*)—The making of *ſoap* depending only on the mixing the ſalt of pot-aſh with oil or fat, though this is at preſent procured by a tedious operation, and long boiling, it ſeems very practicable to ſhorten, and make the proceſs much eaſier, and leſs expenſive, by ſubſtituting motion in the place of fire. This motion might be eaſily given by an engine to any quantities of the ingredients at a time; and we find it practicable to make *ſoap* by this means, only by mixing in a large vial half a pint of *ſoap*-lees, and an ounce, or more, of oil-olive; for by ſhaking theſe together for a quarter of an hour, an abſolute *ſoap* is procured in a cake at the top of the liquor, which hardens on being expoſed to the air. *Shaw*'s Lectures, p. 160.

The uſe of *ſoap* has, of late, been much extolled in medicine; but then thoſe, who magnify it moſt, except againſt the uſe of it in ſuch caſes where obſtructions are attended with a putrefactive alkali, or where an inflammatory diſpoſition appears. It is acknowledged to be very dangerous in a pthiſis, fever, and ſome other caſes. The biſhop of Cloyne, in his Siris, ſeems to think tar-water an uſeful and ſafe ſubſtitute for it. See the article TAR-*water*.

SOAP-*rock*, or *Soap-earth*, in natural hiſtory. See the article STEATITES.

There is great reaſon to believe, that when we know the proper manner of working, this will, one way or other, make a great ingredient in our porcelain manufactures.

The

The Chineſe have of late diſcovered a ſort of earth, which they call *hoache*. They ſay that this is hard, ſmooth, and ſoft to the touch, like *ſoap*; theſe, and its other qualities, ſeem to prove it to be the ſame with our *ſoap-rock*, and this with them makes a ſort of porcelain, ſuperior to the common kind in beauty, and in the compactneſs of its texture, but it is more apt to crack. They uſe it ſeveral ways, ſometimes alone, ſometimes with the petunſe, which is a ſtone, and ſometimes they make a varniſh, by diſſolving this in water, with which they coat over the common China, covering it finally with the other varniſh. All theſe ways of uſing it produce very beautiful wares, and it will be extremely worth our while to try them all round, before we give up the uſe of ſo valuable a thing. Obſerv. ſur les Coutumes de l'Aſie. See the article HOACHE.

SOAR-*hawk*. See the article FALCON.

SOATTO, a Venetian name of a fiſh, common in the markets there, and of a middle nature between the plaiſe and turbot. *Willughby*, Hiſt. Piſc. p. 95. See the article SOAGGIO.

SOAVE, or SOAVEMENTE, in the Italian muſic, ſignifies to ſing or play in a ſweet and agreeable manner.

SOBRE *buena*, a name given by the Spaniards in America to a ſpecies of vanilla, which is greatly ſuperior to all the other kinds.

The pods of this are of the ſame ſhape with thoſe of the common vanilla, but are nearly twice as large. A bundle, of about fifty of theſe, uſually weighs five ounces, and ſuch a bundle of the *ſobre buena* kind often weighs eight. Theſe are full of a blackiſh balſamic liquor, in which are contained a number of ſmall ſeeds.

SOCAGERS, in our old writers, ſuch tenants as held by the tenure called *ſocage*. They were otherwiſe called *ſockmen*. See the article SOCKMEN.

SOCCELLI, among the Romans, were ſwaths or bands, which covered the leg down to the ſoccus. *Pitiſc.* in voc. See the article SOCCUS, *Cycl.*

SOCII, *allies*, among the Romans. See ALLIANCE, *Cycl.*

SOCK (*Cycl.*)—SOCK and ſythe-land. See the article HUSBAND-*land*.

SOCKET (*Cycl.*)—SOCKETS, in a ſhip, are the holes which the pintles of the murthering pieces go into.

SOCMEN, or SOKEMEN, *ſocmanni*, ſuch tenants as held their lands and tenements in *ſocage*; but the tenants in antient demeſne ſeem moſt properly to be called *ſocmans*. F. N. B. 14. Briton. c. 66. Terms of Law. *Blount*, *Cowel.*

SOCNA, in our old writers, a privilege, liberty, or franchiſe. *Blount*. The word is Saxon.

SOCO, in zoology, the name of a Braſilian bird of the heron-kind, but remarkable, beyond all the reſt of that genus, for the length of its neck. It is very common in the Braſils. It is ſmaller than the common heron; its beak is ſtrong, ſtrait, and ſharp; its tail ſhort; its head and neck brown, and variegated with black; and its body is of the ſame colours in different variegations, but its wings have a mixture of whiteneſs. *Marggrave*'s Hiſt. Braſil.

SODA, in medicine, the name of a diſtemper, conſiſting in an uneaſy and troubleſome ſenſation of heat about the orifice of the ſtomach, which ſometimes is owing to external, ſometimes to internal cauſes. It is to be obſerved, that what we underſtand by the word *ſoda* is to be diſtinguiſhed from the *ſoda* of the antients, for they expreſſed by this word a peculiarly ſharp and terrible pain in the head.

Signs of a SODA. The perſons afflicted with it complain of a diſagreeable ſenſation in the ſtomach, particularly about the œſophagus, which they do not well know whether to term cold or heat; but it ſeems rather ſuch a ſenſation of heat as is produced by the violent colds of winter, than any other, according to the old phraſe, that *frigus adurat*, cold burns. With this ſenſation there is always joined a tenſive and preſſing weight of the other parts of the ſtomach, and a light conſtriction running all the way up the œſophagus, from the ſtomach to the fauces, attended with a running up of water into the mouth, and a nauſea, and frequently a reaching to vomit. It is a diſtemper that moſtly affects perſons of plethoric habits, and ſuch as are ſubject to commotions of the blood.

The internal cauſes of this diſorder are congeſtions of blood about the ſtomach and inteſtines; a bilious foulneſs in the primæ viæ, and a tremulous motion of the fibres of the ſtomach. The external cauſes are the eating great quantities of fat things, and drinking immediately after them, and taking great quantities of the hot aromatics, which exagitate the blood, and bring on a continual irritation. A ſudden cooling of the ſtomach, while the body is very hot, will alſo occaſion this; and the taking of hot medicines, under a notion of ſtrengthening the ſtomach; and finally, the drinking of feculent liquors, and the eating ſower foods.

This is in itſelf a diſtemper of no great conſequence, but when it is ſuffered to grow upon the patient, and eſpecially when injudiciouſly treated, it often is attended with bad ſymptoms, and ſometimes brings on dangerous diſorders.

Method of cure. It is often a diſeaſe ſcarce worthy the conſideration of a phyſician, but when it is ſo, the fixed alkalis, combined with ſome volatile ſalt, ſeem the moſt proper remedies; ſuch are the tincture of ſalt of tartar, mixed with ſpirit of hartſhorn, or the alkalis alone, as ten or twenty drops of the oil of tartar: but in thoſe particular caſes, where it ariſes from great commotions of the blood, gentle acids are, on the contrary, the proper means of cure, or the compound powders of nitre and cinnabar. When a bilious foulneſs is in the cure, the nitrous medicines, with the teſtaceous abſorbents, as crabs eyes, oiſter-ſhells, and the like, are the proper remedies; and in all caſes, the frequently taking draughts of warm liquors, as of tea, and the like, is extremely proper: and people, who are very much troubled with returns of this complaint, and are of a plethoric habit, are to be adviſed to bleed and purge every ſpring and autumn.

The common opinion being, that this complaint is merely owing to an acid humor, has given riſe to the uſe of chalk in it as an univerſal remedy; and people, who are afflicted with it, uſually ſwallow chalk alone, and that in large quantities, for their cure. But this is by no means a ſafe, or adviſable method: for the chalk meeting with an acid, becomes a violent aſtringent on mixing with it, and powerfully contracts the tender fibrillæ of the ſtomach. Whence it often happens, that inſtead of a cure, the conſequences are more painful cardialgias, with obſtructions of the viſcera, anorexies, and often in women ſuppreſſions of the menſes. Some give the powder of bricks inſtead of chalk: but this is more dangerous than the chalk, as it is in itſelf more aſtringent. In people, who are afflicted with this complaint from eating fat things, a draught of brandy often proves an immediate cure. *Junker*'s Conſp. Med. p. 589.

SODA *ſubethica*, a term uſed to expreſs a heavy and dull pain in the head.

SODDING *of brick*. See the article BRICK.

SODE-*ſhoats*, in botany, a name given by ſome to the tree, whoſe inſpiſſated juice is the gum tachamahacca of the ſhops. Par. Bat. Prodr. p. 379.

SODOMY (*Cycl.*)—There is no Statute in Scotland againſt *ſodomy*; the libel of this crime is therefore founded on the divine law, and practice makes its puniſhment to be burning alive.

SOFFIETTA, the bellows-fiſh, a name by which ſome have called the ſcolopax, a ſmall ſea-fiſh, common in the markets of Rome and Venice. *Willughby*, Hiſt. Piſc. p. 161. See the article SCOLOPAX.

SOGETTO, *ſubject*, in the Italian muſic, is uſed for a ſong or melody, on which ſome counterpoint is to be made: this may be done variouſly; thus, 1. *contrapunto ſopra il ſogetto*, a counterpoint above the ſubject, is that of which the ſubject is the baſs. 2. *Contrapunto ſotto il ſogetto*, when the given ſubject is the higher part. If the ſubject, in either caſe, does not change its notes, it is called *ſogetto invariato*. But if the notes be changed, either in figure or poſition, it is called *ſogetto variato*. 3. *Sogetto* is alſo uſed for the words to which a ſong is to be made. 4. *Sogetto* is likewiſe applied to a ſeries of notes, from which a fugue is formed. See the article FUGUE.

SOIL (*Cycl.*)—The land of England, as conſidered by the farmer, is reduced into nine ſorts of *ſoils*; the ſandy, the gravelly, the chalky, the ſtony, the rocky, the hazely, the black earth, the marſh, and the clay land. Of this laſt kind there are four varieties, diſtinguiſhed by their colours; the black, the blue, the yellow, and the red.

In many places theſe *ſoils* are mixed and blended together, and where it is ſo, it is much better than where they are ſeparate or ſingle; eſpecially where the mixtures happen to be of a right kind, as thoſe of the hot and the dry *ſoils* blended with the cold and the moiſt. Nature does this often, and art may imitate it. All ſands are hot, and all clays are cold, and therefore the laying clay upon ſandy lands, or ſand upon clayey lands, is the beſt of all manure: this alters and changes for the better the very nature of the land itſelf, whereas dung only improves it for a time, and after that leaves it as bad as it was before. Mixt ſoils, that tend to the clayey-kind, are the beſt of all others for corn. It is not only the natural *ſoil* we are to conſider, but the depth of it, and what *ſoil* is underneath; for the richeſt *ſoil*, if it be only eight or ten inches deep, and lies upon a cold clay, or upon ſtone, will not be ſo fruitful to the farmer as the leaner *ſoils* that lie upon better under-ſtrata. Gravel or ſand are the beſt under-ſtrata, of all others, to make the land above prolific. *Mortimer*'s Huſbandry, p. 64.

Cold and wet clays are much more fruitful in the ſouthern parts of England, than in the north. The climates, therefore, are to be conſidered, and the quantities or proportions of the different kinds in the mixed ſoils. The natural produce of the land, as to weeds or graſs, is alſo to be greatly regarded by the perſon who intends to improve upon it. What is the effect of plowing is next to be enquired into, and experiment muſt ſhew what kind of corn agrees beſt with it.

All land that moulders into duſt with froſt, with all ſorts of warm lands, black mould, yellow clays, if not too ſpewy when wet, and all that turn black after rain, are in general good lands for corn. Land that produces large trees, as alſo ſuch as produces black thorn, weeds, thiſtles, rank graſs, and the like, and that lies in bottoms open to the eaſt or ſouth, being well ſheltered from other winds, may be always eſteemed to bid fair for good land. Thyme, ſtrawberries, betony, and wild ſage, direct to the places where woods will thrive beſt; and camomile is always an indication of a land being diſpoſed to bear corn in large crops.

All land that binds after froſt and rain, all that turns white, and is full of worms, or is very moiſt and cold, or that is too hot and dry, and that lies open to the north on the ſides of hills, expoſed to cold winds and froſts in winter, and to the ſun's ſcorching heat in ſummer; and all that bears naturally holly, box, ivy, juniper, fern or brakes, furzes, broom, and heath; and lands that bear moſſes, ruſhes, yarrow, and wild tanzy, with flags, and other ſuch weeds, which betoken a cold and damp ground, are leſs fit for corn, though other things may ſucceed on it. Where plants appear blaſted, ſhrubby, and curled, theſe are diſtempers in them occaſioned by ſudden changes of wet and cold, and a dry heat. All theſe lands are, by their natural produce, to be judged leſs fruitful than the others. Blackiſh, dun, or yellow ſand, and very hot ſtony gravel, are generally eſteemed very unfruitful. Chalky lands are naturally cold, and therefore they require warm compoſts; and this is the reaſon why chalk itſelf is ſo good a manure for hot and dry lands. Sandy land, well manured with marl, will bear turneps, or white or blue peaſe, to great advantage. *Mortimer*'s Huſbandry, p. 68.

The very greateſt article, in the culture of plants, trees, *&c.* is the *ſoil*; and in many caſes it is not ſufficient to have found a *ſoil*, which once tried proves convenient, to ſuppoſe that it will always continue ſo. In track of time the *ſoil*, which was once proper for the nouriſhment of ſome peculiar vegetable, loſes its virtue; and this ſooner in ſome lands, and later in others. All who are converſant in huſbandry, are well acquainted with this. If a good piece of ground be choſen for the ſowing of wheat, and it produces very well the firſt year, it will not for ever continue to do ſo; the ſecond year's crop will be perhaps good, and the third and fourth tolerable: all this while the land is in heart, as the farmers expreſs it, but after this it becomes improper, and very little wheat will be raiſed if ſown upon it; yet when it refuſes to produce wheat, it will, without any alteration, produce barley in ſufficient plenty for ſome years; when it will yield no more good crops of barley, it may be ſtill ſowed with oats, and will produce that grain as well as freſh land; and when it has been worn out with all theſe, it will produce peaſe. After this it is made quite barren, and can be of no farther uſe to the farmer, the vegetative quality of it being worn off by theſe ſucceſſive crops, each ſort of grain taking off that part which is more peculiarly fitted for its own nouriſhment; the wheat firſt, and the reſt in their order. While one of theſe plants is taking up what belongs to its particular nature, the reſt all remain quiet and undiſturbed; and theſe are afterwards carried away by ſucceſſive changes of plants, which require them; and at length, by the whole, all the vegetable matter is carried away, and the lands ſo drained of it, that there muſt be a ſupply of ſomething in its room, before any thing more of any kind can be raiſed from it. Philoſ. Tranſact. N° 253. p. 217.

The ſupply of freſh vegetable matter, in the place of that which was drained away by the ſucceſſive growths of plants, is done by ſeveral ways, but by none ſo well, as by letting it lie fallow for ſome time; in this caſe the rain falling upon it, the vegetable earth, which this water contains, is depoſited in ſufficient quantity, and this is alone ſufficient to give nutriment to new crops; and it is proved by this, that the rain water, as well as other water, does contain ſuch earth as is neceſſary to vegetation. The other means of giving a ſupply to the exhauſted earth are the manures laid on it by the farmer, and theſe are, all of them, ſome animal or vegetable remains, and their uſe is to drain into the earth thoſe particles from themſelves, which may be again received into the bodies of new productions of the ſame kinds. Blood, urine, the excrements of animals, with their ſeveral parts, as horns, hoofs, hair, feathers, calcined ſhells, and vegetable bodies in an altered ſtate, ſuch as lees of wine and beer, aſhes of burnt vegetables, leaves, ſtraw, roots, ſtubble, and the like, when in a decaying ſtate, turned under the earth again by plowing, there become diſunited into their component parts, and theſe again are carried up into other new plants.

If we take off our thoughts from the fields, and look among the gardens, we there meet with farther confirmations of the ſame thing: the trees, ſhrubs, and herbs cultivated in theſe, after they have continued in one ſtation, till they have derived thence the greater part of the matter fitted for their encreaſe and nouriſhment, will either decay, or degenerate, unleſs they have a new ſupply of manure added to the earth about their roots, or are themſelves tranſlated into other earth, not ſo drained of that particular matter out of which they are to be fed.

The older trees have ſome more ſupplies of fit matter than the younger, by means of the length of their roots, which, when they have drained one ſpot of ground, uſually are carried much farther into another, and reach a very great way; but at laſt they can reach no farther, and all fails, unleſs ſuch a ſupply of manure, or the being removed into freſh earth, ſupply that nouriſhment they can no longer have where they ſtand. The gardiners, when they tranſplant trees, cut off theſe long roots; but though they only do this to prevent the trouble of opening a larger hole than neceſſary for their reception, yet there is in nature this good reaſon for it, that they have, when brought to a freſh *ſoil*, no occaſion for thoſe long roots to draw nouriſhment from afar off, when there is enough of it every where about them. What is to be learned from the whole of this, is, that the modern ſyſtem is erroneous, which ſays that water is the only thing that gives nouriſhment and encreaſe to plants; ſince, if this was the caſe, there could be no need of manures, nor any need of altering the crop, in order to its ſucceeding, or of tranſplanting trees to make them thrive. It is plain that ſome ſort of terreſtrial matter, taken from among the *ſoil*, is what gives encreaſe and bulk to plants; for were it only water, the rain falling in all places alike, all would alike be at all times ſuited to produce all plants; and if the earth, according to Lord Bacon's ſyſtem, ſerved to no other purpoſe to plants and trees, but to keep their roots firm, and to defend them from over-heat, and over-cold, one earth would do as well for theſe uſes as another, and the ſame earth would do as well for the ſame plant as a different earth. Philoſoph. Tranſact. N° 253. p. 219.

Mr. Tull thinks, that the only difference of *ſoil*, except the richneſs, is the different degree of heat and moiſture it has; the earth is equally proper, of whatever kind it be, and if theſe additions be properly adjuſted, any *ſoil* will nouriſh any plant. Let a bed of thyme and a bunch of ruſhes be removed into each other's place, without any farther care, and both will die: but let them change their ſoil, by removing the earth wherein the thyme grew, from the dry hill down into the watery bottom, and plant ruſhes therein; and carry the moiſt earth, in which the ruſhes grew, out of its wet place, up the hill, and ſet the thyme in it, it will be found, that the ſame quantity of unchanged earth will ſerve for either: the ruſhes will grow in the earth of the hill when carried into the bogg, and the thyme will grow in the earth of the bottom where the ruſhes before grew, as ſoon as it is carried up the hill. So that while the earth is the ſame, it is only the accidental addition of more or leſs water that makes it fit for the growing of thyme, or the growing of ruſhes.

Earth is the true food of all plants, it is that alone which gives them their encreaſe, and any earth will do for any plant, with the addition of the other acceſſories in due proportion; that is, an acceſſory to vegetation, as water is, but then it does no more than that to give the matter of encreaſe to the plant. The earth of England, when a proper degree of heat is given it in a ſtove, will nouriſh the plants of the Indies; and, on the other hand, the earth of the Indies, when expoſed to the natural cold of the Engliſh climate, will nouriſh Engliſh plants. There is no need, in conſidering the nature of a *ſoil* for plants, to have recourſe to tranſmutation; for whether air or water, or both of them, be, or be not transformed into earth, the thing is the ſame in regard to the plant, if it be earth, when it is taken up by its roots: and it is very certain, from experiments, that neither air alone, nor water alone, as ſuch, can nouriſh plants. Theſe kind of metamorphoſes may properly enough be conſidered in diſſertations purely concerning matter, and to diſcover what the component particles of earth are; but they are not at all neceſſary to be known, in order to the maintaining of plants. *Tull*'s Horſehoeing Huſbandry, p. 14.

Brickiſh SOIL, a term uſed by our farmers to expreſs a kind of hazely earth, or land, with a reddiſh caſt. It is frequent in Eſſex, and ſome other counties, and approaches to the nature of a loam. It has no ſtones in it, and does not bind after wet as clay does, but lets all the water in that comes, and has no ſtones in it; whereas all clays hold the water till the ſun exhales, and after rain with a froſt moulder into duſt.

Theſe loams are an excellent mixture for other earths, being a happy medium between two extremes, uniting what is too looſe, cooling what is too hot, and entertaining a moderate ſhare of moiſture.

The beſt produce of the brick earth is rye; if well dunged it will bear white oats, turneps, barley, wheat, buckwheat, and peaſe. The natural produce, in weeds, is broom, fern, quick-graſs, and the like. If it be well dunged, it will produce large crops of clover, but it ſoon wears out of it, and ſhould therefore be ſowed mixed with rye-graſs. The beſt manure for theſe lands is chalk, mixed with coal-aſhes:

marl makes a great improvement in them, and there is a ſtiff yellow kind of clay, that moulders with the froſt, that anſwers the ſame purpoſe. Whatever amendment is beſtowed upon this ſort of land by dung, and other enriching things, that do not abſolutely alter the nature of the earth, laſts but a little while. Theſe lands bind very much after rain, and turn whiter; no froſt will diſſolve the clod, and if they are newly plowed up, and never ſo much rain comes on them, people may walk or ride over them almoſt as firm as over gravel. If they are not frequently plowed, they are very ſubject to worms, which deſtroy the winter corn. They yield but poor crops in wet years; the weeds are generally very rank, and the wheat runs all into ſtraw. Plowing is a great improvement of them, they always grow well the year after it. Theſe lands are to be ordered for corn in the ſame manner with the clay land, only as they are rank, and carry the crop much into ſtraw, it is beſt to dung them on the etch crop, and to ſow them with barley, and never to dung the fallows. Where the farmer has not a mind to plow them, but keep them for graſs, they ſhould be mowed one year, and then kept ſhort fed with ſheep, which will in time ſweeten them very much. The red ſandy lands in Northamptonſhire are of this kind; they will not hold manure, ſo they plow but once for the year's crop, which is juſt before the ſowing-time, and manure juſt before they plow it; for if they plow it oftener, and manure it ſooner, they find a great quantity of the beſt mould waſhed away below the ſurface, and out of the reach of the roots of the corn.

In Oxfordſhire they have a ſort of red land, which they begin fallowing as ſoon in the year as they can, before the ſun is too high: if it is moderately moiſt, when fallowed, they eſteem it the better, but it ſhould not be too wet. They ſeldom give it a ſecond ſtirring, and they reckon that if it is too fine and light, it runs to weeds. *Mortimer*'s Huſbandry, p. 73.

SOIL, in ſome parts of England, is uſed as the name for the *phoca*, or ſea-calf. See PHOCA.

This creature, in Cornwall, they frequently find ſleeping on the ſhore, and kill him; ſometimes by ſhooting, ſometimes by ſtriking over the head with long poles. He defends himſelf, when on ſhore, by throwing ſtones backward with great violence. *Ray*'s Engliſh Words, p. 107.

SOJOURNERS, among the Athenians, were permitted to dwell in the city, and follow their own buſineſs, without diſturbance, provided they obſerved all the laws and cuſtoms of the country; but were allowed no ſhare in the government. However, they were not allowed to act any thing, or manage any buſineſs in their own names, but were obliged to chooſe out of the citizens one, to whoſe care and protection they would commit themſelves, whoſe duty it was to defend them from all violence and oppreſſion. He was called *proſtates*. *Potter*, Archæol. Græc. l. 1. c. 10. Tom. I. p. 55. See the article PROSTATES.

SOKE (*Cycl.*)—SOKE-*reeve*, in our old writers, the lord's rent-gatherer in the *ſoke*, or *ſoken*. *Fleta*, *Blount*.

SOKHIO, in the materia medica, a name uſed by ſome authors for a peculiar ſpecies, if it may be ſo called, of the lignum aloes.

It is of a greyiſh colour, and ſeems to have been the blea, or outer part of the wood next the bark. *Camell.* Syll. p. 87.

SOLÆUS, in anatomy, a large fleſhy flat muſcle, nearly of an oval figure, and thicker in the middle than at the edges. It has its name, from its ſuppoſed likeneſs to a ſole. It is ſituated on the backſide of the leg, lower down than the gaſtrocnemii, by which it is covered, and with which it forms the calf of the leg. It is fixed below, partly to the tibia, and partly to the fibula: it is fixed to above one third of the upper part of the backſide of the fibula, and a little to the articular ligament of the head of this bone. It is likewiſe fixed to the backſide of the tibia from the oblique line, or impreſſion, which terminates the inſertion of the poplitæus, down to the middle of the internal angle of the bone; afterwards leaving theſe two bones, it ends in a broad ſtrong tendon, which, together with that of the gaſtrocnemii, forms what is called the *tendo Achillis*. This ſtrong tendon contracts a little in its paſſage to the os calcis, and then expanding a little, it is inſerted obliquely in the backſide of that bone all the way to the tuberoſity. The fleſhy body of the *ſolæus* ſeems to conſiſt of, at leaſt, two planes of fleſhy fibres, that on the backſide of the muſcle being the moſt ſimple, and the other, or that next the bone, penniform. This muſcle, with the two gaſtrocnemii, form what anatomiſts call a *true triceps*. *Winſlow*'s Anatomy, p. 219.

SOLAND, or SOLEN-*goose*, in zoology. See the article GOOSE.

SOLANUM, *night-ſhade*, in botany, the name of a genus of plants, the characters of which are theſe. The flower conſiſts of one leaf, and is of a rotated form, and divided into ſeveral ſegments. The piſtil ariſes from the cup, and is fixed in the manner of a nail to the middle part of the flower, and finally changes into a roundiſh or oval berry, or ſoft ſucculent fruit, which contains many ſeeds, uſually of a flatted form. *Tourn.* Inſt. p. 148.

The ſpecies of *ſolanum*, enumerated by Mr. Tournefort, are theſe, 1. The common *night-ſhade* with black berries. 2. The common *night-ſhade* with red berries. 3. The common *night-ſhade* with yellow berries. 4. The common *night-ſhade* with greeniſh yellow berries. 5. The berry-bearing African *night-ſhade* with frequent and deeply indented leaves. 6. The great Surinam *night-ſhade*, reſembling the common *night-ſhade* in leaves, &c. 7. The perennial Portugal *night-ſhade* with large indented leaves, and red fruit. 8. The common climbing *night-ſhade*, or bitter-ſweet. 9. The white-flowered climbing *night-ſhade*. 10. The double-flowered climbing *night-ſhade*. 11. The climbing *night-ſhade* with variegated leaves. 12. The ſea-*night-ſhade*, or dulcamara. 13. The common berry-bearing ſhrubby *night-ſhade*, called *ſtrychno dendron*, and *pſeudo capſicum*. 14. The tuberoſe eſculent *night-ſhade*, or potatoes. 15. The white-flowered *potatoes*. 16. The prickly African large-fruited ſhrubby *night-ſhade* with deeply indented leaves, and flowers like thoſe of borrage. 17. Black annual Virginian thorny *night-ſhade*, ſpreading very far, and bearing white flowers. 18. The thorny American ſhrubby *night-ſhade* with fire-coloured ſpines. 19. The red-fruited Indian ſhrubby *night-ſhade*. 20. The borrage-flowered Indian thorny *night-ſhade*. 21. The thorny and deeply woolly *night-ſhade*. 22. The leſs thorny woolly *night-ſhade* of China with ſmall flowers, diſpoſed in a ſort of umbels. 23. The Indian *night-ſhade* with indented leaves, and purpliſh black prickles. 24. The ſmooth American *night-ſhade* with yellow nerves to the leaves, and yellow thorns, and with large fruit. 25. The thorny American *night-ſhade* with leaves like thoſe of the mad-apple, or melongena, and large fruit. 26. The ſhrubby acanthus-leaved American *night-ſhade*. 27. The prickly peach-leaved American *night-ſhade*. 28. The prickly bay-leaved ſhrub American *night-ſhade*. 29. The woolly-leaved climbing American *night-ſhade*. 30. The woolly mullein-leaved American *night-ſhade* with ſmall yellow fruit. 31. The American ſhrubby *night-ſhade* with the common *night-ſhade* leaves, and ſmall red fruit. 32. The tree American *night-ſhade* with undulated almond-like leaves, and large white flowers and red fruit. 33. The ſingle ſeeded ſhrubby American *night-ſhade* with polycanthus leaves. 34. The prickly climbing American *night-ſhade* with henbane leaves, and flowers, purple without, and white within. *Tourn.* Inſt. p. 149.

SOLANUM *pomiferum*, *apple-bearing night-ſhade*, a name given by writers to the *night-ſhades*, and plants of ſeveral genera, allied to thoſe, and bearing large fruits. See the articles MELONGENA and LYCOPERSICON.

SOLANUM *ſomniferum*, *ſleepy night-ſhade*, a name given by Caſpar Bauhine, and ſome others, to a ſpecies of winter-cherry, the whorled alkekengi with ſmall fruit. See the article ALKEKENGI.

SOLAR (*Cycl.*)—SOLAR *comet*. See the article DISCUS.

SOLATRUM, in botany, a name given by many authors to the common night-ſhade. *Ger. Emac. Ind.* 2.

SOLDANELLA, *ſea bind-weed*, in botany, the name of a genus of plants, the characters of which are theſe. The flower conſiſts of one leaf, formed into the ſhape of a bell, and jagged or fimbriated at the edges in moſt ſpecies; from the cup of this flower riſes a piſtil, which perforates the bottom of the flower, and is fixed like a nail to its hinder part; this afterwards ripens into a cylindric fruit, which opens at the top, and is filled with ſeeds fixed to a placenta.

There are only three known ſpecies of this plant. 1. The common round-leaved kind. 2. The white-flowered round-leaved Alpine kind. 3. The Alpine kind with leſs rounded leaves. *Tourn.* Inſt. p. 82.

In the Linnæan ſyſtem of botany, the characters of this genus are theſe. The cup is an erect perianthum, divided into five pointed ſegments, and remaining when the flower is fallen. The flower conſiſts of one petal, in the ſhape of a bell, widening by degrees to the mouth, where it is notched and jagged. The ſtamina are five tapering filaments. The antheræ are ſimple. The germen of the piſtil is roundiſh. The ſtyle is ſlender, of the length of the flower, and remains when that is fallen. The ſtigma is obtuſe. The fruit is an oblong cylindric capſule, obliquely ſtriated, containing only one cell, opening, and having ten indentings on the top. The ſeeds are very numerous, extremely ſmall, and pointed, and their receptacle is columnar in figure, and looſe. *Linnæi* Gen. Plant. p. 64.

SOLDANELLA is alſo a name very improperly given by many authors to ſome of the proper and genuine ſpecies of bind-weeds; as the purging ſea-bind-weed with roundiſh leaves and purpliſh flowers, the great Italian ſea-bind-weeds with ſinuated leaves, and the common round-leaved ſea kind. See the article CONVOLVULUS.

SOLDER (*Cycl.*)—*Silver*-SOLDER. Though ſpelter *ſolder* be much cheaper than *ſilver-ſolder*, yet workmen in many caſes prefer the latter. And Mr. Boyle [b] informs us, that he has found it to run with ſo moderate a heat, as not much to endanger

endanger the melting of the delicate parts of the work to be *ſoldered*; and if well made, this *ſilver-ſolder* will lie even upon the ordinary kind itſelf; and ſo fill up thoſe little cavities, that may chance to be left in the firſt operation, which is not eaſily done without a *ſolder* more eaſily fuſible than the firſt made uſe of.—[b Works Abridged, Vol. I. p. 135.]

SOLDIDO, a name given to the *tamoato*. See TAMOATO.

SOLDIER (*Cycl.*)—The profits attending the profeſſion of a *ſoldier*, among the Romans, were very conſiderable. 1. Booty and plunder, with which they frequently returned home loaded, eſpecially after taking any cities or towns; for theſe were generally given up to be plundered. 2. The ſubdued countries, which were often divided among the *ſoldiers*. 3. Their pay. 4. Cloaths. 5. Proviſions. 6. Farms and houſes in provinces were alſo given them. 7. Many privileges and immunities, as that none could touch his goods in his abſence in the camp. 8. Legacies, which the emperors left to be diſtributed among them. 9. Donatives. 10. Promotions to military honours lay open to every brave man, though of the meaneſt birth. *Pitiſc.* in voc.

SOLEÆ, among the Romans, were a kind of ſandals or ſlippers, which covered only the ſole of the feet, and were bound on with thongs of leather; inſtead of which the women, and effeminate perſons of the other ſex, tied them on with purple-coloured ribbands, or ſuch as were variouſly adorned with gold and ſilver. *Pitiſc.* in voc.

SOLEN, the *razor-fiſh*, in natural hiſtory, the name of a genus of ſhell-fiſh, the characters of which are theſe. They have bivalve ſhells with an oblong body, and are open at both ends. They are uſually ſtrait, but in ſome ſpecies crooked. It had its name *ſolen* from the Greek, in which language that word expreſſes a pipe or tube; this fiſh, when the ſhells are cloſed, very aptly reſembling a tube. The Latin writers have called it *unguis*, from its reſemblance in colour and conſiſtence to the human nail. The common people, in many parts of France, call it *coutelier*, and in Italy it is commonly called *cannolichio*.

Rondeletius obſerves that there are, among the *ſolens* of the ſame ſpecies, males and females, which are eaſily diſtinguiſhable from one another; and that the females are larger, have no variegations on the ſhells, and are much better taſted than the males. Rumphius has deſcribed a very remarkable ſpecies of *ſolen*, which always remains buried in ſand, and which is not properly a bivalve, conſiſting only of one piece, though of the ſhape of the *ſolen*; he calls this *ſolen arenarius*. Liſter has called the crooked ſpecies *ſolenes curvi*, and ſome call them the *ſcymitar ſolens*.

We have ſeveral ſpecies of the ſtrait *ſolens*, though but few of the crooked ones. Of the firſt kind are, 1. the common white *ſolen*. 2. The red American *ſolen*. 3. The variegated *ſolen*. 4. The zoned *ſolen*, called the *onyx-ſhell*. 5. The brown *ſolen*. 6. The large duſky *ſolen*. 7. The *unguis*, properly ſo called. This exactly, in texture and appearance, reſembles the human nail. 8. The finger *ſolen*, called *dactylus* by the antients. 9. The flute or pipe *ſolen*. 10. The reed *ſolen*. 11. The long brown *ſolen* with a thick black muſcle at the cardo. See Tab. of Shells, N° 23.

Of the crooked *ſolens* the following two are the only known ſpecies. 1. The ſcymitar *ſolen*. 2. The *ſolen arenarius*, always found in ſand.

The ſhell of this fiſh is compoſed of two pieces, which are the two halves of a hollow cylinder with an elliptic baſe, divided in a longitudinal direction. Theſe two pieces are faſtened together near one end by a ligament, like that which joins the ſhells of the muſcle or the oiſter. From the place where this ligament is fixed, quite to the other end of the ſhell, there is a membrane faſtened to each edge of the ſhells, and this encreaſes in breadth in proportion to its diſtance from the place of its origin; ſo that viewed externally, it forms a ſort of iſoſceles triangle, the baſe of which has about two lines in breadth. The colour and conſiſtence of this membrane give it very much the appearance of a piece of parchment; it has a conſiderable ſpring in it, and ſerves on occaſion to open, or draw together the two ſides of the ſhell.

There is another membrane, of the ſame kind with this, faſtened to the other ſide of the fiſh, there adhering to each ſhell, but this is of an equal breadth all the way down: this ſerves alſo to ſhut or open the edges of the ſhell. When the *ſolen* ſhuts its ſhell, it folds itſelf into ſeveral longitudinal wrinkles, which open again when the ſides of the ſhells ſeparate.

Hence it is to be obſerved, that though this ſhell has a power of opening and ſhutting, yet the body of the fiſh is always ſecured, and is no more expoſed to ſight at one time than at another, and there is no part where the fiſh can be ſeen but at the ends.

This fiſh lives in the ſand on the ſea-ſhore, where it buries itſelf often a foot and a half, or two feet deep; the length of the ſhell is, at this time, nearly in a vertical poſition, and the fiſh has a power of raiſing itſelf at pleaſure up to the ſurface, and ſinking down again, while the ſhell remains all the time buried in its place. Almoſt all other animals have an horizontal motion, and the ſhell-fiſh of the ſea crawl along upon its bottom under water, as the common land animals do on dry ground; but this creature's progreſſive motion is only vertical, and that confined to a very ſmall compaſs, all that it is able to do for itſelf, being only to raiſe itſelf higher or lower, and ſink deeper or riſe higher in the ſand, within the narrow compaſs of about two feet at the utmoſt, as the going beyond that muſt occaſion its deſtruction. Where theſe ſhell-fiſh are buried in the ſand, there is a hole reaching from every one of them to the ſurface, by means of which they have a free communication with the water: theſe holes generally are placed in great numbers near one another, and are eaſily diſtinguiſhed at a time when the tide has left the ſhore uncovered. They are not round, but oblong, and ſomewhat reſemble the key-hole of a lock, but that they have a roundneſs at each end, whereas that uſually is rounded only at one. When the winds are violent, they blow the ſand about, and ſtop up theſe holes, otherwiſe, whenever there are any of theſe fiſh, they are eaſily diſcovered. When the ſea is down, theſe fiſh uſually run deep into the ſand, and to bring them up, the common cuſtom is to throw a little ſalt into the holes, on which the fiſh raiſes itſelf, and in a few minutes appears at the mouth of its hole. When half the ſhell is diſcovered, the fiſherman has nothing more to do than to take hold of it with his fingers and draw it out, but he muſt be cautious not to loſe the occaſion; for the creature does not continue a moment in that ſtate, and if by any means the fiſherman has touched it, and let it ſlip away, it is gone for ever, for it will not be decoyed again out of its hole by ſalt; ſo that there is then no way of getting it but by digging under it, and throwing it up with the ſand. This fiſh has two pipes, each compoſed of four or five rings or portions of a hollow cylinder, of unequal lengths, joined one to another, and the places where they join are marked by a number of fine ſtreaks or rays. Now the reaſon why the ſalt makes theſe creatures come up out of their holes, is, that it gives them violent pain, and even corrodes theſe pipes: this is ſomewhat ſtrange, as the creature is nouriſhed by means of ſalt water; but it is very evident, in that if a little ſalt be ſtrewed upon theſe pipes in a fiſh taken out of its habitation, it will corrode the joinings of the rings, and often make one or more joints drop off: the creature, to avoid this miſchief, ariſes out of its hole, and throws off the ſalt, and then retires back again. The uſe of theſe pipes to the animal, is the ſame with that of many other pipes of a like kind in other ſhell-fiſh, they all ſerve to take in water; they are only a continuation of the outer membrane of the fiſh, and ſerve indifferently for the taking in and throwing out the water, one receiving, and the other diſcharging it, and either anſwering equally well to their purpoſe.

When one of theſe fiſh is taken out of its hole, and laid upon the ſand, if any thing touches it, it immediately gets in order for its progreſſive motion. It throws out a long cylindric part, of half the length of the ſhell, and of the ſhape of a clapper of a bell; this is ſuſpended to the middle of the animal by a ligament, but in all other parts it is looſe; this ſerves as a leg to the creature: as it lies upon the ſand, it extends this about an inch from the end of the ſhell, and changes its cylindric figure to a flat one, which terminates in a point, flat and ſharp at the edges; with this it opens its paſſage into the ſand. When the opening is made, it extends this part ſtill farther, and buries it deeper, and after this bends it back again in ſuch a manner, that its point turns up towards the ſhell; thus it gives this part a figure of a hook, and by this hook it draws its whole body and ſhell down. In this attempt it brings the edges of the ſhells every where cloſe together, and inſtead of lying flat upon the ſand, it now by degrees gets into a vertical poſition, and then there remains nothing to do, but to draw it deeper into the ſand. To effect this, it now again extends its leg, which it eaſily paſſes into the ſand in its flatted ſhape, and when it has thus pierced to its utmoſt length, the creature inflates, and extends it by degrees to the ſize of the ſhell, and to a round or cylindric figure; the conſequence of which is, that there is now a hole made of the ſhape of the ſhell, and equal to its diameter, into which it can eaſily ſink: to facilitate this, however, the creature ſwells out the extremity of the leg into a ſort of button, which holding faſt in its place, nothing more is neceſſary than to contract the reſt of the leg, in order to pull down the ſhell after it. This operation is repeated as often as is neceſſary, and the creature, at every movement of this kind, getting down half the length of its ſhell, or thereabouts, is very ſoon plunged as deep as its occaſions require.

When it has occaſion to aſcend out of its hole, the ſame leg ſerves for that purpoſe; nothing more being required, than the putting out the end of the leg, ſwelling it, and thus thruſting itſelf up to the length of that leg; then retracting it into the ſhell again, and thruſting out, and inflating its end for a ſecond movement of the ſame kind. Theſe motions may be all perceived in the creature when out of the ſand, particularly that by which it buries itſelf; for if held up in the fingers, it thruſts out the leg, and performs all the motions as if in the ſand, making a fruitleſs attempt to

ſave itſelf in its old way. Mem. Acad. Par. 1712. See the article DACTYLUS.

Klein, and ſome others, have given the name *ſolen* to the ſeveral ſpecies of *tubuli marini*.

The word is derived from the Greek, σωλην, tubulus. Of theſe there are ſeveral genera, diſtinguiſhed by their proper characters.

1. *Solen lignorum*, the wood tubule. This is a *tubulus marinus*, or ſhelly caſe of a ſea-worm, of a white colour, not cut, of the thickneſs of a gooſe-quill, more or leſs, and very irregularly bent and contorted.

2. *Solen arenarius*, the ſand tubule. This is defined to be a *tubulus marinus*, in form of a very long tube, which is thick, jointed, and gradually tapering from one end to the other, and divided into new pipes of the ſame kind. *Klein*, de Tub. Mar. p. 12.

3. The *ſolen anguinus*, or ſnake tubule. This is defined to be a *tubulus marinus*, which is variouſly bent and waved, in the manner of a ſnake. Of theſe there are ſeveral ſubdiviſions; ſome are ſmooth, and terminate in a beautifully twiſted end; others are variouſly and very elegantly folded, and others are of a triangular form, and are triangular tubes terminated at one end with a number of ſlight obtuſe notches or teeth, as they are called by ſome; and finally, ſome are found with a fiſſure running down their whole length, and regularly marking the middle of all their ſnail-like volutions. *Klein*, de Tub. p. 3.

4. The *ſolen vermicularis*, or worm tubule. Theſe are diſtinguiſhed from the others by being very long, and folded like our large earth-worms. Of theſe alſo there are ſeveral kinds; ſome deſcribed by Rondeletius, Johnſon, and other authors, under the name of worms hiding themſelves in tubes, *vermes in tubulis delitescentes*. Theſe are of a cylindric figure, white, rough on the outſide, but very ſmooth within, and are ſometimes perfectly ſtrait, ſometimes crooked and folded. Within theſe ſhells the exuviæ of the animal-inhabitant may be often diſtinguiſhed. *Klein*, de Tub. p. 4.

Others of theſe are of an angular figure, often trigonal, and not unfrequently theſe are found twiſted into beautiful ſpiral lines.

Others, from their ſimilitude to the inteſtines of ſmall fiſh, have been called *viſcera piſcium* by authors. Theſe are uſually ſomewhat rough, and lie hid in the mud, under and among the rocks: they are commonly of an earth colour, or duſky brown.

Others are ſo tough and ſoft as to be flexile; theſe reſemble an earth-worm, or the gut of ſome ſmall animal in form, and are of a rough ſandy conſtruction, and often are found above a foot long.

Others are ſmall, lightly ſtriated, or cancellated, and uſually of a reddiſh colour; and finally, others are very ſmall, perfectly white, and often turned like a nautilus: theſe are very common on almoſt all marine bodies, being ſometimes found adhering to the leaves of the ſea-fucuſes, often to ſhells of various kinds, and very frequently to the claws of lobſters, &c.

5. The *ſolen corallorum*, or coral tubule. This is a very capacious tubule, reſembling parts of the thicker and larger inteſtines, whether empty or ſtuffed; and are at one end affixed to the rocks, particularly to thoſe on which the corals are found, and open at the other. Of theſe there are two principal kinds, the one ſmooth, the other corrugated or wrinkled. Of the ſmooth ones ſome reſemble a boot in figure, and have been called *ocreati*, and *boot-ſhells*; others are low and vaulted, and reſemble the hollow of an oven; theſe alſo, for this caſe, have been called *clibaniformes*. *Klein*, de Tub. p. 5.

6. The *ſolen phalloides*, or tubule reſembling in figure the membrum virile. This is a large, white, and ſmooth tubule, much reſembling in figure the part from which it has its name. It frequently reſembles a ſort of thick root, and at its lower end there ſtands out a ſort of ſiphunculus, which is perforated. Liſter has deſcribed this under the name of *phallus*. *Klein*, de Tub. p. 6.

7. The *ſolen fragilis*, or brittle tubule. This is diſtinguiſhed from the reſt by its fragility, being compoſed, in a manner, only of looſe ſand, and always falling to pieces with a ſlight touch. Of theſe ſome are of a finger's length, rough on the outſide, and ſmooth within, ſlender, and uſually found full of water; others have a great deal of ſand in their compoſition, but are ſo contrived, that they are ſmooth both within and without, and pellucid. *Klein*, de Tub. p. 7.

SOLE, in the manege, is a nail or ſort of horn under a horſe's foot, which is much more tender than the other horn that incompaſſes the foot, and by reaſon of its hardneſs is properly called the *horn*, or *hoof*. A horſe's ſhoe ought to be ſo ſet upon the hoof, as not to bear upon the *ſole*; for otherwiſe the *ſole* would be hurt, and not only make the horſe lame, but corrupt the fleſh that ſeparates it from the coffin-bone.

To take out the *ſole*, is to do it without touching the horn of the hoof; for if you take off the horn, you make a *hoof-caſt*. We take out the *ſole* for ſeveral infirmities, as may be ſeen in Mr. Solleyſel's Compleat Horſeman. A horſe that is *unſoled*, may recover in leſs than a month.

High-ſoled, called in French *pied comble*, is ſaid of a horſe whoſe *ſole* is round underneath, ſo that it is higher than the hoof, and oftentimes makes the horſe halt, and hinders the ſhoeing of him, unleſs the ſhoe be vaulted.

SOLEA, the *ſoal-fiſh*, a well known fiſh, and much eſteemed at table.

It is diſtinguiſhed from the fiſh of the plaiſe-kind, in that it is of a longer and narrower ſhape. Its upper part is of a blackiſh grey, its under, or belly, white. It is covered with ſmall ſcales, armed at their extremities with a ſort of ſhort prickles. The fins that ſurround the body are all inclined from the head toward the tail. The eyes are ſmall, and covered with a looſe ſkin. The pupils are of a fine bright green. It is a firmer fiſh, by much, than the plaiſe. It is common in the Mediterranean, Engliſh, and German ſeas. *Willughby*, Hiſt. Piſc. p. 100.

SOLFEGGIAMENTO, in the Italian muſic, compoſitions, of which the ſyllable *ut*, or *do*, *re*, *mi*, *fa*, &c. are the ſubject. See SOLFEGGIARE.

SOLFEGGIARE, SOLFIZARE, or SOLMIZARE, in the Italian muſic, is the uſing the ſyllables *do*, *re*, *mi*, *fa*, &c. in learning to ſing, otherwiſe called *ſolfaing*. See the article SOLFAING, *Cycl.*

From this muſicians have made what is called a *ſolfeggiamento*, which properly intimates no more than the practice abovementioned; but the name is more particularly applied to certain compoſitions, be they fugues, or others, of which theſe ſyllables are the ſubject. Several very fine pieces of this kind are extant. *Broſſard.*

SOLFIZARE, in the Italian muſic. See the article SOLFEGGIARE.

SOLID *body in geometry*, that which has three dimenſions, length, breadth, and thickneſs. *Ozan.* Dict. Math. p. 117. *Wolf*, Elem. Geom. ſect. 421.

Such are priſms, cubes, ſpheres, parallelopipeds, cylinders, cones, pyramids, &c. *Wolf*, lib. cit. cap. 2. p. 186. See each under its proper article, PRISM, CUBE, CYLINDER, &c. *Cycl.*

For the ratio of geometrical *ſolids*, all priſms, parallelopipeds, cylinders, pyramids, and cones, are in a compound ratio of their baſes and altitudes: ſo that if the baſes be equal, they are in the ſimple ratio of the altitudes; or, if the altitudes be equal, of the baſes. And as the baſes of cylinders and cones are circles, and circles are in the duplicate ratio of their diameters, it follows that all cones and cylinders are in a ratio compounded of the direct ratio of their altitudes, and the duplicate one of their diameters. *Wolf*, Elem. Geom. ſect. 510, ſeq. Ejuſd. Elem. Anal. ſect. 106.

Regular SOLID. See the Cyclopædia.

Irregular SOLID, a *ſolid* which is not terminated, or contained under equal and ſimilar ſurfaces. *Wolf*, lib. cit. ſect. 428. *Ozan.* Dict. Math. p. 120.

The *ſolidity* of a regular body is eaſily found from principles of geometry [c]; for that of irregular bodies, mechanical methods are uſed: one is by putting the body in a hollow parallelopiped, and filling up the remaining ſpace with water or ſand; then taking out the body, and obſerving the heighth to which the water or ſand riſe alone [d]. This gives us a parallelopiped, equal to the given body, whoſe ſolidity is eaſily found.—[c *Wolf*, lib. cit. ſect. 497. d Ibid. ſect. 498.] See the article PARALLELOPIPED.

SOLID *root*, among botaniſts, expreſſes the whole *root* to be one uniform lump of matter. See the article ROOT.

SOLEIL *de mer*, in zoology, a name given by the French writers, and by Rondeletius, to a peculiar ſpecies of ſtar-fiſh, of a ſmall ſize, the legs of which reſemble very much the tails of lizards, and are very brittle.

Geſner deſcribes alſo a ſpecies under the name of the ſea-moon, *luna marina*, which he ſays is remarkably fragile, and which, from what elſe he has ſaid of it in its deſcription, appears alſo to be the ſame creature. The great character, however, of the creature's legs reſembling, both in colour and figure, the end of the common brown land-newt's tail, is ſo expreſſive, that it cannot but be always known by it.

Theſe rays are ſo extremely friable, that it is ſcarce poſſible to touch them without their breaking, and they are not beſet with points in the manner of the common rays of the creatures of this kind: their upper ſurface is rounded, and covered with a ſort of circular ſcales; the under ſurface is, in the ſame manner, covered with ſcales, but it is flat: theſe ſcales alſo differ in figure, being only ſegments of circles, whereas the others are compleat rings; thoſe on the underſide are beautifully arranged, in an alternate order, of two and one all the way along the rays.

The other rays of ſtar-fiſhes being furniſhed with many hundred legs, and theſe wanting them entirely, it follows, that in this ſpecies the rays themſelves muſt ſupply the place of legs, and aſſiſt the creature in walking; and thence its manner of walking muſt neceſſarily be different from that of any other kind. Theſe rays are five in number, and are inſerted very near the mouth of the creature, which is always placed in the center of the ſtar: the part where this aperture is ſituated, and which may be called the body of

the

the animal, is of a roundiſh figure; the diameter of it is about a third part of the length of the rays; its under ſurface is flat, and its upper convex; and it is covered, both above and below, with ſcales, but they are arranged in different manners. At the inſertion of each of the rays, there is placed a triangular membrane, terminating in a ſharp point; and theſe membranes only appear, when the creature is immerſed in water, and moves itſelf about.

The common habitation of the ſea-ſtars, on the rough ſhores of the ſea, is no place for theſe tender creatures, every daſh of a wave againſt a ſtone, if they were in the way, would break off their limbs; they have the caution, therefore, to fix their reſidence only in calm places, and where the ſhore is covered entirely with a deep ſmooth ſand. They are often buried in the ſand, and often, when the water has forſaken them, are ſeen walking ſlowly on the ſhore; and in this caſe they uſe their rays as ſo many legs. As they divide the body of the fiſh into equal parts, there is no ray before or behind any where, ſo that the creature goes with equal eaſe to any ſide that it likes. The beſt motion they are able to make is, however, very ſlow, and the ground on which they march ought to be very even; for if they attempt to haſten their pace, or if they find any thing uneven in their paſſage, one or more of their legs uſually breaks; and this is the reaſon why this ſpecies is ſeldom found with its rays perfect. They never bury themſelves deep in the ſand, but juſt get under it, ſo as to be covered; and this they do by advancing two of the rays together, and burrowing carefully with them, and then following them with the reſt of the rays and the body. Mem. Acad. Par. 1712.

SOLIFUGA, in natural hiſtory. See SOLIPUGA.

SOLIPUGA, in natural hiſtory, that name given by the Romans to a ſmall venomous inſect of the ſpider-kind, called by the Greeks *heliocentros*, both words ſignifying an animal which ſtings moſt in the country and ſeaſons where the ſun is moſt hot.

Solinus makes this creature peculiar to Sardinia; but this is contrary to all the accounts given us by the antients. Pliny tells us of its being common in Ethiopia, and that in ſome places there the inhabitants had been all killed by the ſerpents and *ſolipugæ*; and Lucan gives the hiſtory of it among the poiſonous reptiles of Africa.

Almoſt all the hot countries produce this venomous little creature. It lies under the ſand, to ſeize other inſects as they go by; and if it can meet with any uncovered part of a man, will bite him, and the wound will prove very painful and envenomed. It is ſaid that the bite is abſolutely mortal, but probably this is not true. Solinus writes the word *ſolifuga*, and ſo do many others, erroneouſly deriving the name from its flying from the ſun's rays, and burying itſelf in the ſand.

Pliny ſays that it was an ant of the ſhape of a ſmall ſpider, but his accounts of this kind are too confuſed to be much depended on. Some of the old commentators wander yet farther from the truth, and call it a kind of fly; but the deſcriptions of it, by thoſe moſt to be truſted, make it a ſpider, and it ſeems to be that called by Ariſtotle *phalangium dectícum*, the deadly ſpider. It is plain that even Pliny, in ſome part of his works, has underſtood the creature to be this phalangium; for where he has tranſlated the old Greek writers on the ſubject of the phalangium, he has very frequently rendered the word not phalangium, but *ſolipuga*: ſo that it is wonderful he ſhould, in other places, treat of the phalangium, without any mention of the *ſolipuga*, and of the *ſolipuga*, in a different part, as not at all allied to the phalangium. It appears from this, and a great many like things, that Pliny wrote his book at different times, and tranſcribed his accounts from different authors; ſo that he ſometimes forgot what he had before written on the ſame ſubject under a different name.

SOLLECITO, in the Italian muſic, is ſometimes uſed to expreſs that a piece is to be played in a mournful manner, fit to enforce grief upon the hearer; at other times, that it ought to be done carefully and with exactneſs. *Broſſard.*

SOLMIZARE, in the Italian muſic. See SOLFEGGIARE.

SOLO, in the Italian muſic, is frequently uſed in pieces conſiſting of ſeveral parts, to mark thoſe that are to perform alone; as *fiauto ſolo*, *violino ſolo*.

It is alſo uſed for *ſonatas* compoſed for one violin, one German flute, or other inſtrument, and a baſs: thus we ſay, *Coralli*'s *ſolos*, *Geminiani*'s *ſolos*, &c.

When two, or three parts, play or ſing ſeparately from the grand chorus, they are called a *doi ſoli*, a *tre ſoli*, &c.

Solo is ſometimes denoted by *S*.

SOLOMON's *ſeal*, a plant, called by authors *polygonatum*. See the article POLYGONATUM.

SOLSEQUIUM, a word uſed by ſome chemical writers as a name for ſulphur.

SOLOS, σολος, in antiquity, an inſtrument with which the exerciſe of the quoit was performed, which ſome will have to be diſtinguiſhed from the diſcus, becauſe that was of iron, this of ſtone: but others, with more reaſon, report that the difference conſiſted in this, *viz.* that the σολος was of a ſpherical figure, and the diſcus broad. *Potter*, Archæol. Græc. Tom. I. p. 443.

SOLVENTS (*Cycl.*)—Among the ſeveral liquors, which are called *ſolvents* of the metals, there are ſome which entirely diſſolve them, others which diſſolve only a part of them. Common water is the moſt general of all *ſolvents*; it diſſolves all metals by attrition alone. Mercury does not eaſily diſſolve iron, but it readily enough diſſolves all other metals. Acids in general alſo diſſolve them all; but theſe acids being of different natures, ſome of them diſſolve ſome particular metals, and do not touch the reſt. The general diviſion of the acid *ſolvents* is into two kinds, thoſe of the nature of aqua fortis, and thoſe of the nature of aqua regia. The laſt are either the ſpirit of ſea-ſalt alone, or any of the other acids, with the addition of ſea-ſalt, or its diſtilled ſpirit; and the firſt are ſpirit of nitre, and all other mixed menſtruums, in which ſpirit of nitre makes a part, provided there be no ſpirit of ſea-ſalt, or of that ſalt in ſubſtance in them. There is alſo a third claſs, beſide theſe, of what are called the ſimple acids; theſe are ſuch acid liquors as contain neither nitre nor ſea-ſalt, nor any preparation of them; and of theſe ſome are obtained from the animal, ſome from the vegetable, and ſome from the mineral kingdom.

All the *ſolvents* of the aqua regia claſs diſſolve gold, without diſſolving ſilver, and all thoſe of the aqua fortis claſs diſſolve ſilver, without touching gold: but the other acid ſpirits, and the aquæ regales, and aquæ fortes, all equally diſſolve the leſſer metals, if made of a proper degree of ſtrength for each metal. It was long ſuppoſed, that mercury was only ſoluble in the aqua fortis claſs, but Mr. Homberg has proved that the aquæ regales will alſo diſſolve it; and the ſame accurate chemiſt has alſo advanced another fact, which more than this contradicts the received opinions: this is, that ſilver is alſo ſoluble in aqua regia, if proper circumſtances are obſerved. The occaſion of his advancing this, was the following obſervation. He often made his aqua regia, by diſtilling together two parts of ſalt-petre, three parts of vitriol, and five parts of ſea-ſalt; in the diſtillation he uſed to ſeparate the phlegm which roſe firſt, and keep it in a vial by itſelf, and the ſpirit that followed in another.

One day having ſome gold to diſſolve, he by miſtake took down the vial which contained the phlegm of the aqua regia, inſtead of that which contained the ſtrong ſpirit; he poured on a quantity of this phlegm to the gold, and ſet it in a proper heat for two hours, when taking it out, the liquor was found to be tinged yellow, but the gold was not diſſolved. Not recollecting the miſtake, he ſuppoſed he had taken aqua fortis inſtead of the aqua regia, and taking out the gold he weighed it, and found it had not loſt a grain. On this he put in a piece of ſilver to the liquor, and placing it again in the ſame heat, this metal was ſoon diſſolved into a ſort of black mud. In this ſolution there appeared nothing of that ebullition, which always attends the diſſolving ſilver in aqua fortis; and Mr. Homberg, ſurpriſed at this, was for repeating the operation; when pouring the liquor upon ſome freſh ſilver, it did not appear to diſſolve it at all: in enquiring into the cauſe of this, he found that the liquor he had taken was not aqua fortis, but the phlegm of aqua regia. On this the event ſeemed much more remarkable than before, and he repeated the proceſs ſeveral times, and always with the ſame ſucceſs; but trying it a year afterwards, he found the event exactly contrary, the ſame liquor then diſſolving gold, and not touching ſilver: after this making ſome of the phlegm afreſh, he found it would diſſolve ſilver, and not gold, as in the firſt experiment; and this, when it had been kept a year, again changed its nature, and would then diſſolve gold, and not ſilver. So that, from the whole, there appear three neceſſary circumſtances for the making aqua regia diſſolve ſilver; the firſt, that it be very weak; the ſecond, that it have before had gold in it; and the third, that it be freſh diſtilled.

This phlegm of aqua regia is pellucid, and colourleſs as water, before it has been poured upon the gold; after this it becomes lightly tinged with yellow, and when after this it is powered upon the ſilver, it becomes as black as ink. The ſolution of ſilver, in this menſtruum, is very different from that in aqua fortis; in the laſt it is made with great ebullition, and the ſolution, when perfected, is limpid as water; in the other there is no ebullition, and the ſolution appears rather a diſunion of the parts, for the whole becomes black and turbid, and differs much from a clear ſolution. Mem. Acad. Par. 1706.

SOLUTION (*Cycl.*)—*Chemical* SOLUTION. The great Boerhaave has ſummed up the doctrine of *chemical ſolution*, by its ſeveral agents, in the following ſuccinct manner.

1. *Solution* is performed by water, by diluting, infuſing, boiling, diſtilling, mixing, fermenting, putrefying, and ſeparating.

2. With oil, by diluting, infuſing, boiling, diſtilling, mixing, ſeparating, but not by fermenting, or by putrefying.

3. With fire, by calcining, roaſting, burning, melting, ſubliming, mixing, ſeparating, and by the promoting ſeveral other operations.

4. With the assistance of air, by fermenting, putrifying, agitating, exciting, and adding other parts capable of dissolving.
5. With fermented spirits, by diluting, infusing, boiling, distilling, mixing, and making oils thinner.
6. With alkaline salts, by calcining, torrefying, burning, melting, mixing, and separating, according to the various force of a dry fire employed.
7. By volatile alkaline salts, by subliming in the dry way, and by diluting, distilling, and digesting in the moist way.
8. With fixed alkali salts, assisted and moved by water and fire, by digesting, boiling, diluting, separating, and mixing.
9. With fixed acid salts, as those of alum, sulphur, and vitriol; either separately in a liquid form, or in their calxes, by diluting, boiling, distilling, digesting; or in a dry form, by calcining, roasting, burning, and distilling.
10. With volatile acid salts, by diluting, digesting, distilling, and insinuating.
11. With compound salts and soaps, by calcining, subliming, distilling, and digesting, either in a dry or a liquid form.
And 12. with metals, by fusion and amalgamation.
This seems an accurate and perfect table of the whole work of *solution*, and will easily be understood in every article, on recollecting the several chemical processes. *Boerh.* Chem. Part. 2. p. 338. See MENSTRUUM, *Cycl.* and *Suppl.*
No phænomenon in nature is more universally known, than the *solution* of salts in common water, but the world has not yet attended to all that might be learned from the observations on it.
Mr. Lemery, who examined into this point with great assiduity, has observed, 1. That the first effect of water upon a salt, is the reducing it into an inexpressibly fine powder. 2. That it is merely the consequence of this pulverisation carried greatly farther, that every particle of salt which, while in larger moleculæ, subsided to the bottom of the water, according to the known laws of hydrostatics, becomes capable of being elevated and suspended in the water, though in itself greatly heavier than that fluid; that while in a proper state of separation in this manner, they remain imperceptible in all the water, and when by certain accidents they again approach one another, they form concretions like their original ones, and again subside in that fluid, in which they floated while in form of this imperceptible powder.
In the *solutions* of salts, the same author observes, that all the particles of water do not serve to the same purpose; some officiating only in the keeping the saline particles suspended, others in the keeping them asunder, and, as barriers, preventing their reunion.
The quantity of water, necessary to sustain the particles of all salts in solution, is the same, but the quantity, required to keep those particles from joining again, is different, in regard to every salt. Hence though a quantity of water, equal to the weight of the salt, be sufficient to the suspension of its particles, yet every salt requires its own appropriated quantity of water to keep it in a state of solution; that is, to keep its particles from cohering together again. In such salts, the particles of which are not subject to form hard concretions, such as the fixed salt of tartar, and the like, there requires no more water for a *solution* than is necessary to suspend the particles of the salt; but in those which readily form solid concretions, such as common salt, nitre, borax, and the rest, there requires a large quantity beside to act as a barrier.
The more the particles of any salt are disposed to reunite, the more water they require to keep them in a state of *solution*; and hence follows a very remarkable phænomenon, which is the *solution* of several salts successively in the same water: this is known to be possible, and the reason of the whole is this, that when a given salt, requiring a large quantity of water for its *solution*, is dissolved in that water; the greater part of that water, which in this *solution* serves only to the second purpose of keeping the particles of the salt asunder, is still at full liberty to act as water upon another salt that shall be thrown into it.
This, however, can be only the case in regard to salts which do not naturally ferment with one another, because the whole process is disturbed by such a fermentation, and, in consequence of it, there is a third salt formed, which is not the same with either of the two; and the consequence of the formation of this salt, is the precipitation of the metallic, or earthy matter, which was the base of one of the other salts. Thus an alkaline salt, added to a *solution* of alum, or saccharum saturni, takes up the acid of either of these salts, and becomes, by its mixture with that acid, a new concrete salt, and at the same time throws down, in precipitation, the terrestrial base of the alum, and the metallic one of the salt of lead.
To return to those salts which excite no fermentation with one another. In regard to these, when a quantity of water has dissolved as much as it can retain of one, it will readily take in and dissolve a second; and the particles of this not fermenting with those of the salt first dissolved, will remain suspended, and the water which dissolves them, and which in the first *solution* served only as an intermedium to keep the particles of that salt asunder, serve as well to that purpose, now they are impregnated with this new salt, as they did before.
The reason hitherto given for this phænomenon was, that the particles of different salts, though suspended in such manner in the same fluid, that they were every moment coming into contact with one another, yet had no tendency from nature to cohere, or precipitate one another; but that whenever, by future accidents, they should be brought to concrete, they would do it separately, each in its own pure state; but this reason, though true, is an imperfect one. In these successive *solutions* of salts in the same water, the second salt produces a remarkable effect, which no body, till Mr. Lemery, seems to have taken notice of; which is, that while this is dissolved in a liquor, which before served as an intermedium to keep the particles of another salt asunder, it encreases by its whole quantity the quantity of that intermedium, and becomes itself a sort of intermedium to the particles of the first dissolved salt; and by this means the liquor, which had before dissolved as much as it could contain of the first salt, now becomes able to take up some more of it, and will, in reality, perfectly dissolve an additional quantity: this was an experiment well known, but never understood before.
It is well known that salt of tartar does not ferment with salt petre, nor does it take any thing from this salt, or at all alter by being mixed with it, which is quite different from the effect on mixing it, as before observed, with alum, or saccharum saturni; on this principle, and on the known property of salt of tartar being dissolved in a smaller quantity of water than any other salt; or, in other words, of water's dissolving more salt of tartar than of any other salt, Mr. Lemery resolved on the trial, whether water, which had already dissolved as much nitre as it could contain, would not, on the addition of salt of tartar, dissolve a larger quantity of fresh nitre, than on the addition of sal armoniac, or any other salt: but what appeared very strange was, that after two days standing of a *solution* of nitre, with about a fourth part of the quantity of salt of tartar added, there was found a white powder at the bottom. The liquor being examined on this, was found to be a lixivium of salt of tartar, and the powder at the bottom, salt petre.
On adding fresh quantities of salt of tartar, new precipitations were afterwards formed, and, in fine, all the salt petre which had been dissolved was separated. The salt petre being examined, by all trials proved true salt petre, as pure and unmixed as when put in; and the liquor being evaporated, the salt of tartar was found equally pure. Salt of tartar tried afterwards in the same manner with *solutions* of other salts, with which it does not raise any fermentation, was found to have the same effect, precipitating all equally out of the *solution*.
In the common precipitations of salts, such as alum and sugar of lead, by means of an alkali, the alkali seizes upon the acid of those salts, and by that means effects the thing, and therefore itself becomes changed into another salt, and the precipitate, robbed of that acid, is no longer the salt it was, but merely its base: but here the salts, both alkali and neutral, remain the same they were before, both pure and unmixed, and the whole process seems only one of them taking the place of the other.
The salts which are capable of successive *solutions* in the same water, and of remaining suspended together in it, must be all of the neutral kind; that is, they must be salts composed of acids, engaged in such manner in the pores of their bases, as to fill the whole, and leave no void spaces for the penetration of other acids. But this is by no means the case with salt of tartar, which being wholly spunge-like in its structure, readily admits all sorts of acids, and ferments with them; and therefore is very capable of divesting other salts of that, on the presence of which their natural state, as salts of a particular kind, depends.
Every alkali salt is, as it were, an essential salt, in part decompounded; that is, it is the earthy part of such salt, the acid parts of which have been driven off by fire, and when there is only so much left, as may give the whole a saline form; for if all the acids were to be driven off, the remainder would not be an alkali, nor yet a salt, but a mere simple earth; as is the case in the caput mortuum of spirit of nitre distilled by a retort, the residuum from this distillation being a mere dead earth, indissoluble in water, and altogether different from the fixed alkali produced by burning the same nitre with charcoal. What proves, also, that these alkalis are only the matrix of the compound salts divested of their acids, is, that if spirit of nitre be poured upon the alkali salt of nitre made with charcoal, true nitre is regenerated. Mem. Acad. Par. 1724.
When *solutions* of salts are congealed, the ice often affords very pretty figures; but it is to be observed, that the same salt does not always give the same figures. Thus the same *solution* of verdigrease, frozen by means of snow and salt, affords

affords a different figure, from what is produced by the natural cold of the air. And the former ice being thawed, and left to freeze in the same vial, did not give the same figures as at first. See *Boyle*'s Works Abridged, Vol. I. p. 168.

SOLUTION, in metallurgy, is distinguished into dry and moist. The dry *solution* is the blending imperceptibly a small quantity of a metal, or mineral, with a very large one of some other body, dry, hard, and not fluid when cold. The moist *solution* is the distributing a body through the very minutest parts of an aqueous, or in great part aqueous fluid, in such manner, that both may turn into a fluid, to appearance, homogeneous, which goes through all filters, without being detained or separated by them, and the smallest part of which contains in it a proportionable quantity of both the menstruum or dissolvent, and of the dissolved body. The *solution* of gold in aqua regia, and of silver in aqua fortis, as also that of any of the salts in water, are *solutions* of this kind. *Cramer*'s Art of Assaying, p. 194.

In the making the several *metallic solutions*, for the necessary processes in chemistry, the operator is subject to great danger in his health, from the noxious vapours. This has been an accident complained of indeed by many, but scarce attempted to be remedied or obviated by any, in a rational way, till Mr. Geoffroy, whose experiments subjected him greatly to the mischief, employed his thoughts for his own sake, as well as that of the world in general, to the effectual preventing it.

The dissolutions of the metals, in the corrosive acid spirits, are those which send out the most copious and most dangerous vapours. The exhalations of quicksilver, of antimony, and of lead and copper, are all in themselves greatly hurtful, as well as the fiery vapours of spirit of nitre, sea-salt, or vitriol; and if either of these is singly so, how pernicious must they need be in those cases, where two of them are joined together in such a manner, as that this union sends up infinitely more vapours than would otherwise arise? in this case, the utmost care is necessary to prevent the chemist from falling a sacrifice to his zeal for his discoveries.

The common way of avoiding this danger, is by making the *solution* either abroad in the open air, or in a chimney; but sometimes these cautions cannot be used, and under some circumstances they are ineffectual. This gave occasion to Mr. Geoffroy to use a method, which he afterwards proposes to the public, of stopping the rise of the vapours entirely, or at least of diminishing them so greatly, that they shall be harmless and unperceived. All that was necessary to this, seemed to him to be the contriving to cover the surface of the fluid with some body, capable of retaining those vapours, yet not capable of disturbing the operation of the menstruum on the metal; and the common expressed oils of fruits, as the oil of olives, almonds, or the like, were found capable of happily performing this effect; and that particularly, as they would easily receive into themselves the acid salts which arise in the conflict. The thing which gave this gentleman the hint of the discovery was, that in the boiling of sugars, honey, or the like substances, when there is any danger of their boiling over the vessel, the pouring in a little oil stops the swelling. In the *metallic solutions* it has the same effect; and that heightened by this good consequence, that by keeping in the fiery vapours of the acid, it returns them back upon the metal, and by this means does, in effect, add greatly to the power of the menstruum.

This method of using oil has indeed three advantages, 1. The preserving the operator from the injuries from the vapours. 2. The greatly moderating that violent rarefaction which is often of ill consequence. And 3. the same quantity of the menstruum, by this means, dissolves more of the metal.

The best method of making *solutions* with this advantage is this: first wet the surface of the metal to be dissolved with water, or spirit of wine; then pour a little water, or spirit of wine, into the glass in which the *solution* is to be made, this will prevent the oil from sticking to the surfaces of either; then put the metal into the glass, and pour in the oil upon it; last of all, pour on the menstruum: this being greatly heavier than the oil, will sink to the bottom and work upon the metal, while the oil perfectly covers the whole surface. There is no need to be exact as to the quantity of the oil, but more or less is to be used, in proportion to the greater or less ebullition which the mixture is expected to make.

The air-bubbles, which arise to the surface with great impetuosity in the making of these *solutions*, are here seen to break by degrees as they enter the covering of oil, and generally are quite dissipated before they arise to the surface of it. The few of them which retain their figure till they arrive at the surface, there burst and give a slight exhalation; and one may continually see the drops of the menstruum falling back again out of the oil into it, after being deserted by the bubbles of air which had raised them so far. On the contrary, in the common way of making *solutions*, the air-bubbles push one another up to the surface, where they form a sort of skum, which continually thickens by their fresh rising and supporting one another, till it often rises over the top of the vessel. These bubbles of air seem to be formed of small parcels of air extremely condensed in the pores of the metal, which, when the particles of it are separated for *solution*, find themselves at liberty to dilate and expand, and arise to the surface in their proper form.

If it be thought necessary, in any *solution* which raises a more than ordinary quantity of vapours, to prevent the flying off of that small quantity which may escape through the oil, there is nothing more necessary than to pour a little spirit of wine upon the oil; for the acid vapours which pass the oil will then be received in the spirit, and will be dulcified in it, and instead of a disagreeable odour, will yield only a very sweet and safe one. Spirit of wine alone, used instead of oil, and poured gently on the *solution*, has very great effects; insomuch, that if used to the *solutions* in spirit of nitre, which usually send up very noxious and coarse red vapours, they by this means are made to send up only very fine light white ones, and those of a very agreeable smell: the bubbles raised in this case are very small, and usually burst before they arrive at the surface of the spirit. The only objection to this method, is, that the spirit of wine soon mixes itself with the menstruum, and there are some cases in which this may be of ill consequence to the process. Mem. Acad. Par. 1719.

SONCHUS, *sowthistle*, in botany, the name of a genus of plants, the characters of which are these. The flower is of the semiflosculous kind, being composed of a number of semifloscules, each standing upon an embryo seed, and all contained in a general cup, which is considerably thick, and becomes of a conic figure when ripe. The embryos finally become seeds, winged with down, and affixed to the thalamus. See Tab. 1. of Botany, Class 13.

The species of *sonchus*, enumerated by Mr. Tournefort, are these. 1. The prickly *sonchus* with undivided leaves. 2. The prickly *sonchus* with leaves jagged in the manner of those of dandelion. 3. The prickly *sonchus* with undivided leaves, in shape resembling those of the lettuce, or of dipsacus. 4. The Cretic jagged prickly *sonchus*. 5. The great tree prickly *sonchus*. 6. The great creeping *sonchus*, called by many the *great creeping hawk-weed*. 7. The smooth *sonchus* with broad jagged leaves. 8. The white-flowered broad-leaved jagged smooth *sonchus*. 9. The smooth *sonchus* with leaves divided into numerous fine segments. 10. The lesser smooth *sonchus* with less jagged leaves. 11. The smooth narrow-leaved *sonchus*. 12. The narrow-leaved sea-*sonchus*. 13. The smooth *sonchus* with poppy leaves. *Tourn.* Inst. p. 474.

The common *sowthistle* is greatly recommended by authors as a refrigerant and attenuant. It is prescribed by many of the old physicians in stranguries, and other disorders of the urinary passages; and is ordered externally, in cataplasms, in all kind of inflammations.

SONTAGE, in our old writers, a tax of forty shillings laid upon every knight's fee, according to Stow, p. 284. *Blount*, *Cowel*.

SOOT *(Cycl.)*—This is an excellent manure, particularly for cold lands, which have been long over-run with moss; but sea-coal-*soot* is much better for this purpose than wood-*soot*. They usually allow forty bushels to an acre, but some lands require more. It produces an extremely fine and sweet grass, and destroys weeds of all kinds. *Mortimer*'s Husbandry.

The chemical analysis of *soot* shews us, that it is composed of several parts; 1. a fetid, oily, bitter spirit. 2. Water. 3. A sharp volatile alkaline oily salt. 4. A sharp alkaline fat oily spirit. 5. A fetid black bitter inflammable, and almost caustic oil, mixed with an oily salt. 6. A true sal armoniac. And 7. a black fixed earth.

Wood-SOOT has been long known as a good medicine in many cases, but the principles upon which it acted as such were never well understood, till Boerhaave gave a regular analysis of it. The directions he gives for the process are these.

Choose the blackest and driest *wood-soot* from the chimney of an oven, where nothing is baked but bread, and nothing burnt but vegetables; gather this in a dry day, and fill with it a glass retort almost up to the neck; clean the neck of the retort, and luting on a receiver, give a fire of a hundred and fifty degrees, and keep it up equably, a large quantity of transparent water will come over with considerable violence. When no more water will come over, cleanse the receiver, and raising the fire to a little above two hundred degrees, there will then come over a whitish fat liquor; this also comes over with great violence, and the fire must be gradually encreased, till no more of this will come. Change the receiver, and raise the fire to a yet greater degree, and a yellow, copious, volatile salt will come over, and stick all over the sides of the new receiver. When no more of this salt will arise, encrease the fire to the utmost that sand can give, and with a heat of suppression there will arise a black thick oil; when this is all come over, and the vessels cooled, there will be found in the neck of the retort a salt, which could be raised no higher, even by that violent fire; and in the

the bottom of the retort there remains a black feculent matter, the upper ſurface of which is covered with a white ſaline cruſt, which, both in figure, colour, and the ſtructure of its ſtriæ, reſembles the common ſal armoniac. If the milky liquor be rectified, it affords a very penetrating volatile ſpirit, and ſome ſharp volatile ſalt.

Here we are taught what the agitation of an open fire can move, change, expel, and drive through the air by burning; firſt in the form of ſmoak, then of flame, and laſtly of exhalation, and how high it is able to carry them; for a chimney is a kind of ſtill-head, converging in an open top, and *ſoot* is often carried up thirty or forty feet, or more, to the top of theſe, and after this a black ſmoak is diſcharged out of the orifice, which diſperſes in the air, and finally ſeems to vaniſh.

This ſmoak and *ſoot* conſiſt of ſeveral parts; as 1. a fetid, oily, unpleaſant bitter ſpirit, reſiding in the water that firſt comes over, and is afterwards found diſperſed alſo through all its other parts; this ſpirit ſeems to be the oily and more ſubtile part of the vegetable, acted on by the force of fire. 2. A water, which is here contained in great plenty in this ſpirit; in the firſt limpid, and in the ſecond milky liquor, as alſo in the ſaline ſpirit, and the volatile ſalt itſelf, and even in ſome degree in the oil. This water can ſcarce be ſeparated pure by any art, being always impregnated with the bitter taſte and nauſeous ſmell of the ſpirit. 3. A ſharp volatile alkaline oily ſalt, which firſt comes over, and ſticks to the ſides of the receiver. From this principle we are well aſſured, that ſuch a volatile alkaline ſalt always ſtrongly impregnates the whole air, where wood fuel is burnt. 4. A ſharp alkaline fat ſpirit, conſiſting of the ſalt juſt now mentioned diſſolved in water, and ſo reſembling ſpirit in fluidity, pungency, volatility, and the other qualities. 5. A fetid black bitter nauſeous, and almoſt cauſtic oil, mixed with an oily ſalt. 6. A true ſal armoniac, raiſed to the neck of the retort, and covering the ſurface of the black matter left at its bottom. If this ſalt be carefully collected and ſeparated from the alkaline kind, it proves to be a perfect and genuine ſal armoniac; it is of a whitiſh colour, ſomewhat tranſparent, and makes no efferveſcence with acids, and if mixed with fixed alkalis, it eaſily yields a volatile ſalt, wholly agreeing with that from the commom ſal armoniac; whence by the by it is evident, that all ſal armoniac owes its origin to *ſoot*. 7. The laſt ſubſtance found in *ſoot*, is the remaining black earth left at the bottom of the retort: this has an oil which tenaciouſly adheres to it, and when this is driven off in a ſtrong open fire, there remains a white calx.

By this accurate analyſis of *wood-ſoot*, we learn what parts of vegetables are volatile, and fly off by an open fire, and what are fixed and remain behind, and finally, what fire throws off from vegetables into the air; and hence, among other things, we may learn that even earth, which appears ſo very fixed in the fire when ſeparated from the other principles, yet when mixed with them is, by the force of fire, thrown up to the height of forty feet, and more, in the air; whence it aſcends to yet greater heights, and finally diſperſes in form of a thin cloud.

Hence we may alſo learn that *ſoot*, which contains ſo many active principles, muſt be qualified for a powerful medicine. Pills of dry *ſoot* are found very beneficial in all cold diſtempers; the volatile ſalt of *ſoot* poſſeſſes the virtues of the volatile ſalts of animals. The ſalt which riſes laſt is recommended greatly by Hartman for giving relief in cancers; and this is very probable, ſince ſal armoniac of the common kind, properly applied, is known to be of great uſe in caſes of running cancers. *Soot* of different fuels is not to be ſuppoſed all to poſſeſs the ſame virtues; that of pit-coal is found to be a ſubſtance of a very different kind from that of wood, and that of the common turf, or peat, and of the oak wood, have alſo been found, on experiment, to be very different. Boerhaave very juſtly obſerves, that the *ſoot* from kitchen-chimneys, where the ſmoak muſt have been impregnated with the effluvia of the victuals, muſt be very different from pure *wood-ſoot*. *Boerhaave*'s Chemiſtry.

The tincture of *ſoot* is in uſe; and Dr. Cheyne recommends it as a great and ſudden relief in vapours. Nat. Meth. of curing Diſeaſes.

SOPHORA, in botany, the name given by Linnæus to a genus of plants called by Dillenius, in his Hortus Elthamenſis, *ervi ſpecies*; the characters are theſe. The perianthium is ſhort and campanulated; it conſiſts of one leaf, divided into five obtuſe ſegments at the end. The flower is of the five-leaved papilionaceous kind. The vexillum is oblong and ſtrait; it grows broader as it approaches the apex, and is bent back at the edges. The alæ are two; they are oblong, of the length of the vexillum, and appendiculated at the baſe. The carina conſiſts of two petals, of the ſize of the alæ, the under edges of which ſtand near together, ſo that they form a ſort of boat. The ſtamina are ten diſtinct parallel ſubulated filaments; they are of the ſame length with the flower, and are hid in its carina. The antheræ are ſmall and aſſurgent; the germen of the piſtil is oblong and cylindric; the ſtyle is of the length and ſituation of the ſtamina; and the ſtigma is obtuſe. The fruit is an extremely long and ſlender pod, it contains only one cell, and is marked with protuberances where the ſeeds are contained. The ſeeds are numerous, and of a roundiſh figure. This genus of plants agrees with the other papilionaceous and diadelphous genera, except that in this the ſtamina are diſtinct and ſeparate. *Dillen.* Hort. Elth. p. 112. *Linnæi* Gen. Plant. p. 177.

SOPHRONISTÆ, σωφρονισται, among the Athenians, were ten officers appointed to take care that the young men behaved themſelves with ſobriety and moderation. *Potter*, Archæol. Græc. l. 1. c. 15. Tom. I. p. 84.

SOPHRONISTERIUM, σωφρονιστηριον, among the Athenians, a houſe of correction like our Bridewell. *Potter*, Archæol. Græc. l. 1. c. 25. Tom. I. p. 130.

SOPIO, a name uſed by ſome of the old writers for opium, from its ſoporific virtue.

SOPORARIÆ *arteriæ*, a name given by ſome authors to the carotid arteries.

SOPOROUS (*Cycl.*)—SOPOROUS *diſeaſes*, a term by which medical writers expreſs the *lethargy* and *coma*, and ſome others even the *carus* and *apoplexy*.

The firſt of theſe, the lethargy, is an idiopathic affection, depending on a congeſtion of blood about the head, whence there ſoon ariſes a ſtaſis both of that and the other humors; the conſequence of which is an univerſal oblivion, or forgetfulneſs of all things. The coma is a ſymptomatic *ſoporous* affection, uſually complicated with deliriums, and taking its origin from a reſtriction of the fluids about the head in acute fevers. This is the generally received ſenſe of the moderns, as to theſe diſeaſes, though ſome invert the meaning of the words, and make lethargy ſignify a ſymptomatic affection attending perſons in fevers; and the coma to be the idiopathic diſeaſe, particularly the ſleeping coma. To theſe ſome alſo add the carus, which they ſay is a ſlighter kind of lethargy; while others will have that diſeaſe to be a more violent diſorder than the lethargy, and of a middle nature between that and the apoplexy, or little better than the laſt. *Junker*'s Conſp. Med. p. 666.

Signs of them. A lethargy is uſually preſaged by an univerſal laſſitude and inaptitude to motion, and a vertigo, or tremor in the head, or an intenſe pain in its hinder part; by a continual inclination and deſire to go to ſleep, and ſleeping more ſound than uſual; and finally, by a ringing in the ears, and a general hebetude or dulneſs of the ſenſes. When preſent, it is known by the patient's falling into a particularly ſound ſleep, out of which it is very difficult to wake him, and when awaked he is wholly forgetful, both of himſelf, and of every thing about him, and has an immediate propenſity to ſleep again; the pulſe, reſpiration, colour, and heat of the body, are all the while nearly the ſame as in health; and when there is a fever attendant on it, it is ever a very ſlow, and ſcarce ſenſible one. The coma is of two kinds, the ſleepy and the waking, or *coma vigil*. In the ſomnolent, or ſleepy coma, the patients fall into a long and ſound ſleep, but that not ſo profound as in the lethargy; for in this caſe, though they be immoveable, yet they are much more eaſily waked than in lethargies, and are not ſo perfectly forgetful of all things when waked, as they are in that diſeaſe. In the coma vigil, or wakeful coma, the patient has an eternal propenſity and deſire to ſleep, but cannot really get to ſleep; with this he is uſually delirious, and commonly keeps his eyes ſhut, but is all the time very quick of hearing whatever is ſpoken in the room, and opens his eyes immediately on being touched; and ſometimes their delirium proceeds ſo far, that they endeavour to get out of the bed, and to do ſeveral mad actions.

Perſons ſubject to them. Lethargies principally affect fat people, who are of a ſanguineo-phlegmatic habit, and particularly ſuch as are advanced in years, and live upon rich and moiſt diets, and have accuſtomed themſelves to ſleeping after dinner. Old people alſo, who have been ſubject to catarrhs, whether of the head or breaſt, and ſuch as have been long uſed to have iſſues, and have cloſed them up, or to regular cuppings at certain ſeaſons of the year, but have omitted them, on account of their advanced age, uſually fall into it. Thoſe alſo who have been much uſed to tobacco, whether ſmoaked or taken in ſnuff, and have ſuddenly left it off, very often alſo fall into this diſeaſe, or into apoplexies. There are alſo many other cauſes, from which old men are ſubject to lethargies, ſuch as long waking, cares and troubles upon the ſpirits, the uſe of narcotic medicines, drunkenneſs, contuſions, or heavy blows upon the head, and, as ſome affirm, the being for a long time together expoſed to the rays of the moon. Infants alſo, which are fat, are ſubject to the ſame diſeaſe, from the ſtriking back of any watery humor.

Comas uſually happen to people in acute malignant fevers, and are preceded by violent pains in the head, and raging deliriums, and are very often owing to the improper uſe of opiates, and ſtupifying medicines. *Junker*'s Conſp. Med. p. 670.

Prognoſtics in them. Old perſons, who are ſubject to frequent ſleepineſs, unleſs they change their courſe of life, and uſe a

coarſer diet and more exerciſe, uſually fall into fatal lethargies. In perfect lethargies, in which the patients cannot be wakened at all, they uſually die between the fourth and the ſeventh day, unleſs an eruption of ſome matter from the noſe or ears happen; which is not unfrequently the caſe in perſons who fall into this diſeaſe, after violent blows on the head. The coma is much the ſame in its prognoſtics as the lethargy; but in this a cold ſweat uſually preſages immediately approaching death. It is much better that a phrenitis ſhould happen to perſons in a lethargy, than that a lethargy ſhould happen to thoſe in a phrenitis.

Method of cure. In a lethargy the ſenſes are to be rouſed, and the humors deduced from the head to the lower parts by ſtimulating glyſters, and acrid ſuppoſitories, by ligatures on the oppoſite parts, by frictions, bliſters, and ſinapiſms, or ſuch cataplaſms as bring on heat and redneſs of the parts, applied to the ſoles of the feet and the palms of the hands; as alſo by twitching off the hairs in very ſenſible parts, by applying volatile ſalts to the noſe, by pricking with a needle, and by loud calling: and in plethoric habits, immediately after the clyſter, a vein ſhould be opened, and after that leeches applied to the temples; and internally, powders of nitre and cinnabar, with the gentle alexipharmics, are to be given; and all ſorts of camphorated medicines are proper to be applied externally, after ſhaving the head. In many caſes, crudities in the primæ viæ have a great ſhare in bringing on theſe diſeaſes, and in ſuch vomits and briſk purges are very proper.

In a coma, whether it be of the ſomnolent, or wakeful kind, the fever, which is the primary diſeaſe, is firſt to be regarded; but with the antifebrific medicines, the nitrous and cinnabarine ſhould be joined, and the camphorated ones uſed externally.

Preſervatives againſt them. Every preſervative muſt tend to the taking off what may prove the cauſes of theſe diſorders. For this purpoſe, in old perſons of mucous habits, the matter muſt be by all poſſible means derived from the head, and carried off by ſome ſafe way. In this intention, briſk purges of jalap and colocynth, and for thoſe of very ſanguine habits, of black hellebore, are to be given every quarter of a year. To theſe ſhould be added the bitters, and ſulphureous medicines, with the gum reſins, in form of pills: theſe ſhould be taken regularly at the equinoxes; and a proper diet muſt be obſerved, namely, drier foods muſt be principally eaten, and the ſpices frequently uſed, and the patient adviſed not to eat too heartily. Roaſted meats, in general, are better than boiled; and wine ſhould be drank in moderation, and ſome of it impregnated with bitters. *Junker*'s Conſ. Med. p. 678.

SOPRANO, in the Italian muſic, ſignifies the treble.

SORA, in botany, the name given by the people of Guinea to a kind of ſhrub which they uſe in medicine, boiling it in water, and giving the decoction in caſes of pain of any kind.

The leaves of this ſhrub are of the ſize and ſhape of thoſe of ſena; they ſtand upon ſhort footſtalks, and are woolly underneath. Philoſ. Tranſ. N° 231.

SORBUS, the *ſervice-tree*, in botany, the name of a genus of trees, the characters of which are theſe. The flower and fruit reſemble thoſe of the cratægus, but differing, in that the leaves are winged as thoſe of the aſh.

The ſpecies of *ſorbus*, enumerated by Mr. Tournefort, are theſe. 1. The common *ſervice*. 2. The cultivated *ſervice* with a large red fruit of a turbinated form. 3. The cultivated *ſervice* with large turbinated pale-red fruit. 4. The cultivated *ſervice* with a reddiſh middle-ſized turbinated fruit. 5. The cultivated *ſervice* with a reddiſh middle-ſized oval fruit. 6. The cultivated *ſervice* with a ſmall reddiſh turbinated late-ripening fruit. 7. The cultivated *ſervice* with ſmall turbinated fruit. And 8. the wild *ſervice*, or *ſorbus aucuparia*. *Tourn.* Inſt. p. 633.

SORE, among ſportſmen, denotes a buck of the fourth year.

SOREL, in the language of ſportſmen, a buck of the third year. See the article BUCK.

SOREL, in botany. See SORREL.

SOREX, in zoology, the name of a ſpecies of wild or field-mouſe, called the *dormouſe*, or *ſleeper*. There are two kinds of this creature, a larger and a ſmaller.

The larger *dormouſe* is nearly of the ſize of the common rat. Its colour is a browniſh grey, like that of the common mouſe, but variegated with ſomewhat of a reddiſh caſt on the ſides, and on the head. The ears are large and ſmooth; the belly is white; and the inner part of the legs, and the lower part of the tail, eſpecially toward the extremity, are of the ſame colour. The noſtrils and the feet are red; the tail is all over hairy, and is terminated by a thick tuft of white fur. The eyes are large and prominent, and of a fine jetty ſhining black. The beard is partly white, and partly black. Round about the eyes, and round the ears, there is a fine blackneſs; the upper part of the tail is alſo black. The ſmell of this creature is the ſame with that of the mouſe, and its dung is of the ſame kind. It lives in caverns underground, and ſleeps all the winter, as ſome affirm. It feeds on vegetables, and is particularly fond of hazel-nuts, which it uſually hoards up, when ripe, for a ſcarcer ſeaſon. *Ray*'s Syn. Quad. p. 219.

The ſmaller kind is much more common than the larger one. This is of the ſize of the common mouſe, and in different countries varies much in colour. In Italy Mr. Ray obſerved it all over of a reddiſh tawney on the upper part, except the end of the tail, and all its under part white, the tail only excepted; the tail covered with long and thick-ſet hairs, and looking ſomewhat like a ſquirrel's. The eyes are very black and prominent. Thoſe which the ſame author obſerved in England were leſs of the reddiſh hue on the back, and were not white under the belly, but only on the throat; neither had they the white tip at the end of the tail. Poſſibly the Italian and Engliſh may be really diſtinct ſpecies. This creature feeds on nuts and other ſuch fruits. It retires into caves in winter, and ſleeps much, but not through the whole winter, as has been ſuppoſed, for it lays up its winter-proviſion in its hole in autumn, and feeds on it at that time. *Ray*'s Syn. Quad. p. 220.

The *ſorex*, according to the Linnæan ſyſtem, makes a diſtinct genus of animals; the diſtinguiſhing character of which, is, that its dentes inciſores, or cutting-teeth, are two in number, and are ſerrated, or notched on each ſide. *Linnæi* Syſt. Nat. p. 40.

SORGLUM, in the materia medica, the name of the grain of the *milium arundinaceum*, called *Indian millet*. *Dale*'s Pharm. p. 262.

SORNI, a name given by ſome of the chemical writers to iron. *Caſt.* Lex. Med.

SORRANCE (*Cycl.*)—SORRANCE-*water*, a name given by our farriers to a ſolution of vitriol and ſome other ingredients in vinegar, a medicine much eſteemed in many of the diſeaſes of horſes: it is prepared in the following manner.

Take Roman-vitriol and roach-alum of each an ounce and half, verdigreaſe an ounce, copperas two ounces; reduce all theſe to powder together, and put them into a two-quart bottle, into which pour a quart of the ſtrongeſt and beſt wine-vinegar; this is to be ſet in balneo mariæ. The ſhort way of doing which by the farrier, is this: he puts a wiſp of hay into the bottom of a kettle, and then tying ſome pieces of lead or iron about the neck of the bottle, to make it heavy enough to ſink in water, it is ſet upon the hay ſo, as to ſtand very upright; then three notches are cut lengthwiſe in the cork to give paſſage to ſome of the vapours when the bottle is heated, that it may not burſt. When every thing is thus prepared, ſo much cold water is to be put into the kettle, that the neck of the bottle may ſtand two or three inches above it; the kettle is then to be ſet over the fire, and the water is to be made to boil, and kept boiling about half an hour, the bottle being at times taken out, and thoroughly ſhaken. When the ſalts are thus thoroughly diſſolved in the vinegar, the whole is to be kept for uſe.

The method in which they uſe it is this. Take an earthen pan, which will hold about twelve quarts, let this be filled with urine that has been made by ſound, healthy, and young perſons; the ſtaler the urine is, the better it is for uſe, and it ought indeed always to ſtand, at leaſt, three weeks before it is uſed. It is proper for the farrier, therefore, always to keep a quantity of this ready, and when the *water* is to be uſed, half a pint of it is to be mixed with a quart of the urine, or if it be required ſtronger, more of the *water* is to be added: theſe are to be thoroughly mixed together, and the legs, or other affected part of the horſe, bathed with it with ſoft rags twice a day.

The virtues of this *water* are highly extolled; it is ſaid to cure the malanders in two, or three times dreſſing; it is alſo a ſovereign remedy for the mange, either dry or wet, and for the rat-tails, ſcratches, gourded, or ſwelled legs and heels; and it alſo cures horſes when the greaſe is fallen into their heels, as the farriers expreſs it. The farcy is alſo ſaid to be often cured by a long continuance in the uſe of it, purging the horſe two or three times, at different diſtances of time, during the time of his being under cure by the *water*. They alſo find it a good cleanſer and healer of foul ulcers, and that it prevents the breeding of proud-fleſh and worms in wounds, and drives away a flux of humours that were falling upon any part. They uſe it alſo in clefts and cracks of the heels, and in windgalls, eſpecially in the prevention of the laſt by its repellent qualities. The green *water* alone is an excellent remedy for fiſtulas, cankers, and the galled backs of horſes; diſpoſing ſuch *ſorrances*, as they are called, not to feſter, rot, and grow worſe, as all greaſy and oily medicines do, but cleanſing them, and laying the way to a very ſound and ſtanding cure.

SORREL, *acetoſa*, the name of a genus of plants, the characters of which are theſe. The flower is of the ſtamineous kind, being compoſed of a number of ſtamina ariſing from a ſix-leaved cup. The piſtil, which is ſurrounded by theſe, finally becomes a triangular ſeed, wrapt round in a cup: this is compoſed of three of the ſix leaves of the cup, the other three withering away.

The ſpecies of *ſorrel*, enumerated by Mr. Tournefort, are theſe. 1. The common meadow-*ſorrel*. 2. The white-

flowered meadow-*sorrel*. 3. The meadow-*sorrel* with curled leaves. 4. The great mountain-*sorrel*. 5. The Pyrenean *sorrel* with very long and narrow leaves. 6. The mountain-*sorrel* with a broad and roundiſh leaf, ſomewhat reſembling that of arum. 7. The mountain-*sorrel* with leaves like thoſe of the lemon-tree, and with branched twigs. 8. The mountain-*sorrel* with undulated leaves, and not branched twigs. 9. The dwarf mountain-*sorrel* with the fagopyrum leaf. 10. The mountain-*sorrel* with knotty points. 11. The tuberoſe-rooted *sorrel*. 12. The *sorrel* with pale green ariſarum leaves. 13. The mountain-*sorrel* with narrow arrow-headed leaves. 14. The marygold-leaved *sorrel*. 15. The atriplex-leaved ſhining *sorrel*. 16. The great Italian *sorrel* with round glomerated ſeeds. 17. The lanceolated field-*sorrel*. 18. The tall narrow-leaved lanceolated, or ſheep's *sorrel*. 19. The narrow-leaved creeping lanceolated *sorrel*. 20. The ſmall *sorrel* with leaves not lanceolated. 21. The Cretic *sorrel* with prickly ſeeds. 22. The ſmall Cretic *sorrel* with utriculated ſeeds. 23. The baſil-leaved *sorrel*. 24. The American *sorrel* with leaves ſtanding on very long foot-ſtalks. 25. The roundiſh-leaved tree-*sorrel*. 26. The round-leaved garden-*sorrel*. 27. The round-leaved Alpine *sorrel*. 28. The round-leaved creeping Yorkſhire *sorrel* with leaves ſinuated in the middle. 29. The creeping ſhielded-*sorrel*. 30. The little erect *sorrel* with multifid leaves. 31. The trifid-leaved Indian *sorrel*. *Tourn.* Inſt. p. 502.

Sorrel ſeeds are found to contain a vaſtly larger proportion of the active principles this plant abounds with, than either the leaves or the roots. They are eſteemed aſtringent, and good in diarrhœas, dyſenteries, and hæmorrhages.

We much neglect this plant, becauſe it is common; yet this plant alone has very often proved a remedy for the ſcurvy. Mr. Morin, of the Academy of Paris, who in the Hotel Dieu had many hundred ſcorbutic patients, cured the greater part of them only by *sorrel* boiled and eaten with eggs.

Wood-SORREL, *lujula*, in medicine, is a very grateful acid; in fevers it quenches thirſt, and takes off the heat of the ſtomach. It is recommended in fevers of all kinds, and the ſcurvy; alſo in obſtructions of the liver and of the viſcera. It is ſometimes given in decoction in fevers, and the expreſſed juice is mixed with the juices of the other antiſcorbutic plants againſt the ſcurvy.

Externally, it is extolled againſt inflammatory eruptions of all kinds in decoction, which is to be uſed by way of fomentation. There uſed to be a ſyrup, but, at preſent, only a conſerve of this plant is retained in the ſhops.

SORREL, in the manege, is uſed for a reddiſh colour. The mane ought to be red, or white, in a horſe of this colour. It is diſtinguiſhed, according to the degrees of its deepneſs, into a *burnt sorrel*, and a *bright*, or *light sorrel*. Generally ſpeaking, it is a ſign of a good horſe.

SORY, in natural hiſtory, the name of a foſſile ſubſtance, much ſpoken of by the antients, but ſuppoſed to be now loſt: this, however, proves to be an error, for it is plentifully produced in the eaſtern parts of the world, and is in common uſe there, only under another name; neither indeed is it peculiar to that part of the world, though the inaccuracy of the late writers of foſſils has made them overlook or miſtake it.

It is a firm and not brittle ſubſtance, though of a ſpungy and cavernous ſtructure, and is conſiderably heavy. It is found in maſſes of no regular ſhape or ſize, ſome being roundiſh, others angular or flatted, and ſome of the ſize of a wallnut, others of many pounds weight. It feels very harſh and rough to the touch, and is covered with no inveſtient coat or cruſt, but ſhews its natural ſurface, which is always corrugated or wrinkled, and uſually full of ſmall protuberances and cavities, and when broken, is found to be of a rugged and ſpungy ſtructure within.

Its natural colour is a ruſty black, but it is ſometimes reddiſh, and ſometimes bluiſh; and is commonly ſtained, in different places, with ſpots of a bluiſh or ruſt colour, when black; and of a greeniſh hue, when it is of a reddiſh colour: in the places where it is free from theſe, it is uſually ſomewhat bright and ſparkling. It is of an acrid and diſagreeable taſte, and of a ſtrong and nauſeous ſmell: put into the fire it burns to a deep purple, and if boiled in water a great part of it becomes diſſolved in it; and this may again be ſeparated from the water by evaporation and cryſtallization, and then appears in the form of pure blue vitriol, forming regular rhomboidal cryſtals, and tinging iron to a copper colour, on being firſt wetted, and then rubbed upon it. *Hill*'s Hiſt. of Foſſ. p. 606.

It is found in many parts of the Turkiſh dominions, particularly in Gallo-Græcia; as alſo in ſome parts of Germany. In this country it is boiled for the blue vitriol it contains. In Turky it is mixed with lime, and made into a paſte with water, which is laid on ſuch parts of the body as they would eradicate the hair from, and effects that purpoſe in a very few minutes. In the eaſtern nations, where it is thus uſed, it is known by the name *ruſma*.

The antients uſed it externally to take off pimples, and put a piece of it into a hollow tooth, as a remedy for the tooth-ach. There can be no doubt of their *sory* being the ſame ſubſtance with this; ſince Dioſcorides has deſcribed it to be blackiſh in colour, full of ſmall cavities, moiſt on the ſurface (as ours always is in moiſt weather) and of a diſagreeable taſte and ſmell.

This ſubſtance, as alſo the chalcitis, miſy, and melanteria, are all properly ores of vitriol, the particles of thoſe ſalts being ſo perfectly blended in them, as not to be at all diſtinguiſhable to the naked eye, yet being always regularly ſeparable from them by water, which is to the ſaline ores what fire is to thoſe of the metalline kind. *Hill*'s Hiſt. of Foſſ. p. 607.

SOSPIRO, in the Italian muſic, a pauſe or reſt, equal to the time of a crotchet. See the articles PAUSE, REST, CHARACTER, *Cycl.*

Canone al SOSPIRO. See CANONE *al ſoſpiro*.

SOSTENUTO, in the Italian muſic, denotes that the ſound is to be held out in an equal and ſteady manner for the whole time of the note. Thus they ſay *arcate ſoſtenute*. See *Corelli*, Concerto 8.

SOTIRELLA, a name given by ſome to a compound medicine, in form of a hard maſs, and conſiſting of opium and ſome other narcotics, with camphor, wood-ſoot, and nutmeg. It is deſcribed in the Auguſtan Diſpenſatory, and is intended to be put into hollow teeth, as a remedy for the tooth-ach.

SOUGH, otherwiſe called an *addit*, in mineralogy, is a paſſage like a vault cut out under the earth, to drain the water from the mines. *Houghton*'s Compl. Miner in the Explan. of the Terms.

SOUL (*Cycl.*)—SOUL-*ſcot*, a certain fee paid by our Saxon anceſtors to the prieſt on opening a grave. See the article BURIAL.

SOUL-*trees*, in mining. See the article STOWS.

SOUND (*Cycl.*)—Mr. Euler [b] is of opinion, that no *ſound* making fewer vibrations than 30, or more than 7520 in a ſecond, is diſtinguiſhable by the human ear. According to this doctrine, the limits of our hearing, as to acute and grave, is an interval of eight octaves.—[b Tentam. Nov. Theor. Muſ. cap. 1. ſect. 13.]

SOUND, in the manege. A horſe is ſaid to be *ſound* that does not halt. When a jockey ſells a horſe, he warrants him *ſound* hot and cold; that is, that he does not halt either when you mount him, or when he is heated, nor yet after alighting, when he ſtands and cools.

SOUNDING (*Cycl.*)—SOUNDING *the pump*, at ſea, is done by letting fall a ſmall line, with ſome weight at the end, down into the pump, to know what depth of water there is in it.

SOUR *land*, in agriculture, a term uſed by the farmers to expreſs a cold and ſomewhat wet clayey ſoil.

This muſt have its tilth according to its ſtate and condition, when they ſet about it. If it have a ſtrong ſwarth upon it, then they give it a fallow, by turning it up when the ſun is in Cancer: this they call a ſcalding fallow, and eſteem it of great uſe, becauſe it kills the graſs roots, and makes the land fine; but if it be light, and have but a thin ſwarth, they leave it for a cooler tillage, and plow it early in the year, when their clay is fallowed.

Pigeon's dung and malt-duſt are the moſt proper manures for this ſoil. The malt-duſt is to be ſown with the winter-corn, and plowed in with it, for then it lies warm at the roots of the corn all winter. *Plot*'s Oxfordſhire, p. 246.

SOURDON, in zoology, the name of a bivalve ſhell-fiſh found on the coaſt of Poitou, and other places. It is a ſmall fiſh, its length being little more than an inch, and its breadth about three quarters of an inch. Its ſhells are both conſiderably convex, the outer ſurface is deeply furrowed, but the inſide is perfectly ſmooth. The fiſh buries itſelf lightly in the ſand, and has a pipe of communication, which it raiſes to the ſurface; but as this creature never buries itſelf deep, the pipe is neceſſarily very ſhort; but they are cut into ſeveral ſegments at the extremity, and appear as if were fringed, and have ſeveral hairs growing from theſe ſegments. The *ſourdon* is capable of a progreſſive motion by means of a limb, ſomewhat reſembling that of the other chamæ; but more than any approaching to the nature of a leg, as it in ſome meaſure repreſents, in miniature, a human leg with a clumſy boot upon it: by means of this limb the creature can eaſily bury itſelf in the ſand, or riſe up out of it, or move horizontally on the ſurface, and that as well backwards as forwards, and that with more ſwiftneſs than could be well ſuppoſed. Mem. Acad. Par. 1710.

SOURIS, in the manege, is a cartilage in the noſtrils of a horſe, by means of which he ſnorts. See SNORT.

The cutting of this cartilage is called in French *eſſouriſſer*.

SOUTHERNWOOD, *abrotanum*, in botany, the name of a genus of plants, the characters of which are wholly the ſame with thoſe of wormwood, and the plants are only to be diſtinguiſhed by their very different general face and appearance.

The ſpecies of *ſouthernwood*, enumerated by Mr. Tournefort, are theſe. 1. The broad-leaved ſcentleſs *abrotanum*. 2. The great narrow-leaved male *abrotanum*. 3. The greateſt narrow-

narrow-leaved male *abrotanum*. 4. The leſſer narrow-leaved male *abrotanum*. 5. The field-*abrotanum* with white ſtalks. 6. The broader-leaved field-*abrotanum*. 7. The field-*abrotanum* with red ſtalks. 8. The hoary field-*abrotanum* with the carline ſmell. 9. The low *abrotanum* with very large yellow tufts of flowers. 10. The ſweet-ſcented flax-leaved *abrotanum*. 11. The Spaniſh *abrotanum* with pontic wormwood leaves. 12. The ſea Spaniſh *abrotanum* with thick ſhining and rigid leaves. 13. The lightly hoary male *abrotanum* of Surinam. And 14. the tall hoary *abrotanum* with very thick-ſet leaves. *Tourn.* Inſt. p. 458.

Southernwood is an attenuant, and recommended by ſome in ſuppreſſions of urine, a drachm of it in powder being the doſe. Its decoction is good for recovering the hair when fallen off; and its juice is ſaid to cleanſe and heal old ulcers. The leaves of this plant dried and powdered, or given in a ſtrong infuſion, are good in all obſtructions of the liver and ſpleen; they are alſo of conſiderable virtue as antihyſterics, and are given in nephritic caſes. The good women give the expreſſed juice, of the tender tops of the plant, as a remedy againſt worms, and that with ſucceſs. There are accounts of perſons being cured of jaundices ſolely by the ſame medicine. Matthiolus recommends the leaves dried, and taken in powder, as a remedy for the fluor albus.

Female SOUTHERNWOOD. See the article SANTOLINA.

SOUTHING, in navigation, the difference of latitude a ſhip makes in ſailing to the ſouthward.

SOW, in the iron works, the name of the block or lump of metal they work at once in the iron-furnace. The ſize of theſe *ſows* of iron is very different, even from the ſame workmen, and the ſame furnace. Theſe furnaces having ſandſtone for their hearths and ſides, up to the height of a yard, and the reſt being made of brick, the hearth, by the force of the fire, is continually growing wider; ſo that if it at firſt contains as much metal as will make a *ſow* of ſix or ſeven hundred weight, at laſt it will contain as much as will make a *ſow* of two thouſand weight. *Ray*'s Engliſh Words, p. 126.

Sow, in zoology. See the articles HOG and SUS.

Sow-*bread*. See the article CYCLAMEN.

Sow-*thiſtle*, in botany. See SONCHUS.

SOWING (*Cycl.*)—One very great article in *ſowing* to advantage, is to know exactly at what depth the ſeed may be planted, without danger of burying it. Seed is ſaid to be buried, when it is laid at a depth below what it is able to come up at. Different ſorts of ſeeds come up at different depths, ſome ſix inches, or more, and others will not bear to be buried at more than half an inch. The way to come at an accurate knowledge of the depth, at which every ſeed will come up beſt from the *ſowing*, is by making gages in the following manner. Saw off twelve ſticks of about three inches diameter, bore a hole in the end of each ſtick, and drive into each a taper peg; let the peg in the firſt ſtick be half an inch long, the next an inch, and ſo on, every peg being half an inch longer than the other, till the laſt is ſix inches long: then in that ſort of ground, in which you intend to plant, make a row of twenty holes with the half-inch gage, put therein twenty good ſeeds, cover them up, and then ſtick the gage at the end of that row. Proceed in the ſame manner with the eleven other gages, making the holes in the ſame row all with the ſame gage, and ſticking it at the end of the row: when the ſeeds begin to appear, it will be eaſy to ſee at what depth they come up beſt, by obſerving the moſt flouriſhing row, and taking up the gage at the end, and ſeeing what is its length.

By this means we not only know what is the depth in that ſort of ground, at which this ſort of ſeed will come up beſt, but alſo we are able to judge of the nature of the ſeed; for by obſerving how many of the twenty ſeeds that were *ſown* come up, and how many fail, it is eaſy to calculate how much bad ſeed there is among any given quantity, and to allow properly for it in the *ſowing*, that the field may be neither overſtocked with plants, nor too bare of them. The farmer often ſuſtains great loſſes by *ſowing* bad ſeed, or by burying good ſeed, and both might be effectually prevented, by making theſe eaſy trials. One caution is to be obſerved in this, that it is not proper to *ſow* the ſeeds of all plants at the greateſt depths at which they will come up, becauſe in wheat, and ſome other grain, a moiſt ground will rot the roots at this depth, Experience alone, added to theſe rules, can perfectly inſtruct the farmer in the certain way of ſucceeding; the nature of the land, the manner how it is laid, either flat or in ridges, and the ſeaſon of planting, muſt all be conſidered.

The quantity of ſeed is to be different alſo, according to the manner of the *ſowing*. The proper quantity to be drilled into an acre, is much leſs than muſt be *ſown* in the common way; not becauſe the hoeing will not maintain as many plants as the other way, for, on the contrary, it will maintain many more, but the difference is upon many other accounts, as that it is impoſſible to *ſow* it ſo evenly by hand as the drill will do. For let the hand ſpread it never ſo exactly, which yet is difficult enough to do with ſome ſeeds in windy weather, yet the unevenneſs of the ground will alter the ſituation of the ſeeds, the greateſt part of them rebounding into holes, and the loweſt places, or elſe the harrows, in covering, drawing them down thither; ſo that theſe low places may have ten times too much ſeed, and the higheſt may have much too little, or even none of it, and this inequality leſſens in effect the quantity of the ſeed, becauſe fifty ſeeds, in the room of one, will not produce ſo much as one will do; and where they are too thick, without being in theſe cluſters, they cannot well be nouriſhed, their roots not ſpreading to near their natural extent, for want of hoeing to open the earth, and give them way. In the common way of *ſowing*, ſome of the ſeeds are buried out of all hope of ever coming up again, and ſome others are left naked upon the ſurface, where they become the food of birds, and of vermin: as ſo many muſt, therefore, periſh in the common way of *ſowing*, and ſo few can be loſt in the way by drilling, there is plain reaſon why the ſeed, neceſſary to *ſow* any given quantity of ground, ſhould be much leſs for the drill-way, than for the other. The farmers, in general, know nothing of the proper depth at which they ſhould *ſow* their ſeed, nor of the difference in quantity that is to be obſerved in different circumſtances; they allow the ſame quantity to an acre of rough ground, as they do to an acre of fine, and forget that what is too little for one, may yet be too much for the other; it is all mere chance-work, and they put their confidence in good ground, and a large quantity of dung to cover their errors.

The farmers in Wiltſhire allow more corn for the *ſowing*, than in any other part of England; they uſe ſometimes eight buſhels of barley to an acre, ſo that if it produce four quarters for an acre, there is but four grains for one encreaſe. This is ſown on land plowed once, and double dunged, the ſeed only harrowed into the hard and ſtale ground, ſo that it is very probable that not ſo much as two buſhels out of the eight take place, or come to any thing. Sometimes, in a very dry ſeaſon, an acre ſcarce produces four buſhels at the harveſt.

Inſtead of all this uncertainty and loſs in the common way, in drilling all the ſeed lies juſt at the ſame depth, not one grain of it being placed deeper or ſhallower than the reſt. As none of the ſeeds, therefore, can be loſt by being buried, or by being expoſed on the ſurface to vermin, no allowance is to be made for theſe accidents; all that is to be allowed for in the *ſowing*, is the miſchief that may happen from the worm, the froſt, or the like unavoidable accidents, common to all ſeeds.

When a man has (by the uſe of the gages, and the growth of the ſeeds planted in the rows marked by them) proved the goodneſs of the ſeed, and found the depth it is to be planted at, he is to calculate what number of ſeeds a buſhel, or any other weight or meaſure, contains; for one buſhel, or one pound of ſmall ſeed, may contain double the number of ſeeds of a buſhel, or a pound of large ſeed of the ſame ſpecies. This calculation is made by weighing an ounce, and then calculating the number of ſeeds this ounce is compoſed of; then weighing a buſhel, and multiplying the number of ſeeds in an ounce by the number of ounces in the buſhel, and the product will give the number of ſeeds in the buſhel with ſufficient exactneſs. When this is known, the ſeeds are to be proportioned by the Rule of Three to the ſquare feet in an acre; or elſe it may be done, by dividing the ſeeds of the buſhel by the ſquare feet in an acre, and the quotient will give the number of ſeeds for every foot. Then the farmer is to conſider how near he intends to plant the rows, and whether ſingle, double, treble, or quadruple; for the more numerous the rows are, the more ſeed will be required. The narrow ſpaces between double, triple, or quadruple rows, ſuppoſe ſeven inches, the double having one, the treble two, and the quadruple three, are called *partitions*. The wide ſpace, ſuppoſe of five feet, between any two of theſe double, treble, or quadruple rows, is called an *interval*.

Examine next what is the produce of one middle ſized plant of the annual, but the produce of the beſt and largeſt of the perennial ſort, becauſe that, by hoeing, will be brought to its utmoſt perfection; proportion the ſeed of both to the reaſonable product, and when it is worth while adjuſt the plants to their competent number with the hand-hoe after they are up, and plant perennials generally in ſingle rows. Laſtly, plant ſome rows of the annual thicker than others, which will ſoon give experience, preferable to all the rules in the world, for the quantity of ſeed neceſſary for the drilling.

The diſtances of the rows is one extremely material point in the obtaining a good crop; but as a much larger diſtance is to be allowed in theſe, than common practice has been uſed to, it is very difficult to perſuade the farmer to venture a trial at ſuch diſtances as he may have experience from. There is a method of planting the rows by the drill at very near diſtances, and in this work one horſe may draw a drill with eleven ſhares, making the rows at three inches and a half diſtance from each other, and at the ſame time *ſowing* in them three different ſorts of ſeeds, which do not mix, and theſe at different depths. Thus the barley-rows may

be

be ſeven inches aſunder, and the barley four inches deep; a little more than three inches above that, in the ſame channels, clover-ſeed; and betwixt every two of theſe rows, a row of ſaint foin ſeed covered half an inch deep.

Mr. Tull, who tried this method, obtained the firſt year a very good crop of barley, the next year two crops of broad clover, where that was *ſown*; and where hop-clover was *ſown*, a mixture of that and of ſaint foin, and every year afterwards a crop of ſaint foin. But the ſame gentleman was afterwards ſo fully convinced of the folly of theſe, or any other mixed crops, and of *ſowing* with theſe narrow ſpaces, that he never practiſed it afterwards.

Every row of vegetables to be horſehoed, ought to have an empty ſpace, or interval, of thirty inches, on one ſide of it at leaſt, and of near five feet in all ſorts of corn: this will ſeem a monſtrous allowance to thoſe who have not experienced the good effects of it, but all who have will readily come into the practice of it ever afterwards. The line of corn is called one row, though it be double, triple, or quadruple, becauſe when four of theſe rows grow up in the ſpring, they unite, and ſeem to be all one row. Wide intervals are neceſſary for perfect horſehoeing, and the largeſt vegetables have generally the greateſt benefit by them, though ſmall plants may have conſiderable benefit from much narrower intervals than thoſe of five feet.

In handhoeing there is always leſs ſeed, fewer plants, and a greater crop, *cæteris paribus*, than in the common *ſowing*; yet there the rows muſt be much nearer than in horſehoeing, becauſe as the hand moves many times leſs earth than the horſe, the roots will be ſent out in a like ſmaller proportion; and if the ſpaces, or intervals, where the broad hoe only ſcratches a little of the ſurface, ſhould be wide, they would be ſo hard and ſtale underneath, that the roots of perennial plants would be a great while in running through them, and the roots of annual plants would not be able to do it at all. The advantage of the horſehoeing is principally owing to the depth to which it ſtirs the ground, and familiar inſtances have proved, that the ſtirring it to a like depth, by whatever inſtrument, is of the utmoſt advantage to whatever plants are ſet in the place. A poor fellow in Wiltſhire was obſerved to have always his cabbages much larger and finer than his neighbours, though his ground was no better, and he could afford leſs dung; but the reaſon was, that inſtead of clearing away the weeds between them with a handhoe, he uſed to dig between with a ſpade, which goes as deep as a horſehoe, and comes the neareſt anſwering its purpoſes of any inſtrument whatever. *Tull*'s Horſehoeing Huſbandry. See the article INTERVALS.

Man has found out many advantageous ways of propagating, whether by *ſowing* or planting ſuch trees and herbs as he beſt knows the uſes of, but nature as much excels him in this article as in all the reſt, when any compariſon can be made; and it appears evident to the naturaliſt, that ſhe has taken more care to propagate and *ſow* the moſt trivial weeds, as we eſteem them, than we can employ in regard to the choiceſt plant. It is owing to this care, that no one ſpecies of plant has ever been loſt, notwithſtanding all the accidents they are daily ſubject to.

There is not, perhaps, a more eminent inſtance of this care of nature, than in that plant, commonly known in America under the name of the *wild pine*, and called by botaniſts *viſcum caryophylloides*. This is a large plant with leaves like the pine-apple, and it grows on the boughs of other trees, as miſletoe does with us, but that its roots do not pierce into the ſubſtance of the wood, as is the caſe in this plant, but only ſpread themſelves upon the ſurface. The ſeeds of this plant are ſmall and light, and they have a very long and fine down adhering to them, by means of which, as ſoon as they are diſlodged from the capſules, they are taken up by the winds, and ſupported in the air till they ſtrike againſt ſome branch of a tree which is proper to give them a place of growth: here the downy fibres become of a ſecond uſe, in that they hold faſt the ſeed, and will not let it drop down, but it remains thus ſupported till the time of its ſtriking root, which it does from many points at once, and conſequently a number of roots are immediately propagated, in different directions, over the ſurface of the bark. Philoſ. Tranſact. N° 251. p. 116.

It is neceſſary, to the ſupport of this plant, that it ſhould always have a quantity of water within itſelf to ſupply its juices. This water is retained in the center of the leaves, which are hollow within, and form a ſort of bulb for this purpoſe; but as it cannot be preſerved, unleſs the plant ſtands erect, and as the ſeeds, in their various flight before the wind, are as often ſtruck againſt the lower, or ſide parts, as againſt the upper ſurface of a bough, ſo the plant generally begins to ſhoot in a wrong direction; but ſo provident is nature, that it immediately turns itſelf up, whether from the ſide, or from the very bottom of the branch. This reſervatory is not only of uſe to the plant, but ſerves alſo to the birds, and to ſeveral ſmall animals, who, in times of ſcarcity of water, go to it, and ſeldom fail of finding enough there: nay, Dampier tells us that himſelf and his ſailors, when on ſhore in ſome of the American iſlands, and in diſtreſs for water, have been often relieved by it; for that, on ſtriking in a knife a little above the root, the water always came out in large quantities, and they uſed to catch it in their hats, and drink as much as they had occaſion for.

The faſtening of the ſeeds of this plant to the branches of trees, on which they are to grow, is not a ſingle inſtance of the providence of nature in propagating vegetables: we ſee in the ſea fucuſes ſomething of a like kind. The proper place of growth of theſe is on rocks and ſtones, and accordingly, as the ſeeds of the viſcum are made light, that they may fly in the air, and aſcend to the places where they are to grow, ſo thoſe of the fucuſes are made heavy, that they may deſcend even in water, and fall upon the ſtones that are to give them ſupport. This peculiar gravity is given to the ſeeds of the ſea plants, by means of a glutinous jelly with which they are ſurrounded while in the capſule, and which falls out with them; and is not only of uſe in carrying them to the bottom, but alſo in faſtening them to the ſtones on which they alight, otherwiſe they would eaſily roll off again, and be toſſed about, and loſt among this immenſe bed of waters; but by means of this jelly they are firmly kept in their place, till they have made ſuch ſhoots as are ſufficient to ſupport them againſt the waſhing of the waves; then the jelly dries away, and leaves the water free acceſs to them, to nouriſh them.

The moſſes have been by former ages ſuppoſed to have no ſeeds at all; but it has of late been found that they have immenſe numbers, and thoſe of the only kind that could be of ſervice to their propagation; that is, ſuch as are extremely ſmall and light. It is neceſſary that the ſeeds of theſe minute plants ſhould often be carried upward, in order to their being placed on trees, walls, and other eminences: this is eaſily performed by the winds, when the ſeeds are ſo ſmall, that, on being diſlodged, they look like ſmoak, not like any ſolid ſubſtance; but it could not have been ſo well executed, had they been larger. The common cup-ſeeding muſhroom produces, on the contrary, large and ſolid ſeeds; theſe cannot grow in any ſeaſon but a very moiſt one, and nature providing for this, has ſo ordained it, that the cup remains cloſed, and the ſeeds firm in its bottom, in dry weather; but as ſoon as a ſhower of rain falls the cup opens, and the ſeeds are waſhed out and thrown upon the wet ground, where they immediately grow. Philoſ. Tranſ. N° 251. p. 118.

Many of thoſe plants, whoſe ſeeds ſtrike well from the ſurface, and do not require to be buried as others do, are furniſhed with a downy ſubſtance to every ſeed, which makes the whole ſo light, that it floats in the air, and is carried to great diſtances; by this means every ſeed is carried a vaſt diſtance its own way, and if one falls on an improper ſoil, another ſucceeds better. We have a very remarkable late inſtance of the ſpreading of plants, from this proceſs of nature, in the ſmall Canada fleabane with toad-flax leaves. This plant was, ſome years after the ſettlement of the French in America, brought into Europe, and firſt *ſown* in the gardens of France, and then in thoſe of England; out of both which its downy ſeeds were wafted by the winds into the fields, and there produced the plant, which thence became a wild inhabitant, both of France and England, and continues ſo to this day, thriving as well with us as in its native ſoil.

Other plants, which are deſtined to grow at ſome ſmall diſtances from one another, have been provided by nature with elaſtic, or ſpringy ſeed-veſſels, which throw their ſeeds to a diſtance, without the help of man. The yellow arſmart, and ſome of the cardamines, called for this reaſon *noli me tangere*, are of this kind, as alſo our wild wood-ſorrel, and many others. In all theſe plants, as ſoon as the ſeed is perfectly ripe, and fit for *ſowing*, the ſeed-veſſel burſts at the firſt rude ſhock of wind, and toſſes out its ſeeds to three feet diſtance in ſome caſes. This diſtance is alſo encreaſed by the action of the wind, which burſts the capſule, and the ſeparated ſeeds are often carried thus to five, ſix, or ſeven feet diſtance from the mother plant, and ſcattered different ways, ſome falling by the way, and the reſt ſpreading abroad as they go along.

There is one remarkable inſtance of the care of nature of one plant in this way, which is the *ſpirit weed* of Jamaica. The ſeeds of this plant can only grow in a wet ſeaſon; and in conſequence of this it is ſo provided, that the pods containing them can only open in wet weather; they will remain ever ſo long whole upon the plant in a dry time, but as the firſt ſhower falls, the ſeed-veſſels being wetted, burſt open, and ſcatter their ſeeds ſeveral ways, and every one immediately ſtrikes root and grows.

The lychniſes, poppies, and ſnapdragons, all have their ſeed-veſſels open at the top only, and in theſe the ſeeds lie ſecurely till a windy ſeaſon happens, then they are diſlodged; and do not fall all together, as they otherwiſe would, in one ſpot, raiſing a cluſter of young plants to ſtarve and ſpoil one another; but they are, according to the ſame great intent of nature, ſcattered to ſuch diſtances, that every one may produce

a plant in such circumstances as it may thrive under. Philos. Trans. N°251. p. 120.

SPA (*Cycl.*)—Spa-*water*. The contents of this *water*, by means of which it is able to do such great things in many chronical cases, are understood by the following experiments and observations.

1. When the *Spa-water* is carried to any distant place, though ever so well stopped down, they always, after a time, will precipitate a small quantity of a yellow ochreous earth.

2. If a single grain of galls be put into an ounce of *Spa-water*, it tinges the whole with a beautiful purple; but if the *water* be heated before the galls are put in, there will not be the least change of colour produced in it.

3. Mixed with milk they do not coagulate it, but when mixed with wine they make a great ebullition, and throw up a large quantity of air-bubbles with a peculiarly pleasing smell.

4. The *waters* drank at the spring cause a sort of drunkenness, but it does not last above a quarter of an hour.

5. A small vial being filled up to a certain height with *Spa-water*, and afterwards exactly to the same height with pure distilled water, and weighed, when filled with each, in a nice balance, was found, when the *Spa-water* was in it, to weigh three ounces, four drachms, and forty grains, and with the other, three ounces, four drachms, and forty one grains; so that the *Spa-water*, notwithstanding its mineral particles, is somewhat lighter than the purest common water.

6. And finally, a pint of the *Spa-water* evaporated over a very gentle fire, leaves behind only a grain and half of a white powder.

Hence it appears, that the *Spa-waters* are the lightest and most subtle of all the mineral waters; and the small quantity of earth, and large portion of subtle mineral spirit they contain, bespeak their possessing the most exalted virtues of all the mineral waters.

One very remarkable virtue of this *water* is, that it greatly relieves in all disorders of the kidneys, ureters, and bladder, whether occasioned by stone, gravel, or ulcerations. It possesses, beside, all the virtues of the other mineral waters, and is of the greatest service in edulcorating sharp, and dividing viscous humours, and removing all diseases arising from these causes, by disposing them to pass off by the proper emunctories.

SPADE, (*Cycl.*) is an instrument for digging up the ground; the handle, or shaft, is about three feet long; the head of it is all of iron, the upper part being flat, for the workman to set his foot on to force it into the ground; the length of the head is a foot, or fifteen inches, and the breadth six or eight.

SPADO, among the Romans, differed from an eunuch only in this, that the latter was deprived both of the penis and testes, but the *spado* of the testes only. *Hofm.* Lex. univ. in voc. See Eunuch, *Cycl.*

SPAGIRIC *art*, *ars spagirica*, a name given by authors to that species of chemistry which works on the metals, and is employed in the search of the philosopher's stone.

SPAGNUOLA, in the Italian music, denotes a guitar.

SPANIEL. This sort of dog is of great use, but subject to many distempers; among these the mange is a very frequent one, and is the most pernicious of all others to his quiet and his beauty, and is very apt, when one dog has it, to spread to others that come in its way. The best cure is a decoction of a large quantity of brimstone, with some common salt and wood-ashes, in water and urine, of each equal quantities; this is to be used three or four times a day, washing the creature well with it before the fire, or in the warm sun. If this is not strong enough, the same ingredients, with the addition of a considerable quantity of wood-soot, are to be boiled in strong vinegar, and the liquor used in the same manner; but this must never be used in cold weather, as it would then endanger the creature's life.

When this disease is not in a violent degree, it may be cured by the herb agrimony internally taken. The method is to pound the roots, leaves, and seeds of this plant in a mortar, and mix them with a large quantity of wheaten-bran; they are to be then made into dough in the common way, and baked in an oven; the dog is to have no other bread but this for some time, but he is to eat of this as often, and as much as he will: this, without any farther care, has cured many.

Another very troublesome disorder in this creature, is what is called the *formica:* this infests only the ears, and is caused by flies, and by the dog's scratching for them. The best medicine for the cure of these is this: take a quantity of pure and clean gum tragacanth, infuse it in white-wine vinegar; let as much vinegar be used as will serve to soften it, and when it has lain a week in it, let it be taken out and ground on a marble, as the painters grind their colours, adding to it roach-alum and galls, reduced to powder, of each two ounces; all this is to be well mixed together, and the matter, if it grows too stiff in the grinding, is to be moistened with some of the vinegar in which the gum was soaked: when all is thoroughly mixed, and ground fine, it is to be put by in a gallypot, and a small quantity of it applied to the creature's ear every night till the complaint is removed.

The swelling of the throat is another disease very common to *spaniels*, but the cure of this is easy, there needs only to bath it well with oil of camomile, and afterwards wash it with a mixture of vinegar and salt; this done night and morning will, in a few days, wholly remove the complaint. *Spaniels* will sometimes, when they have much rest and good food, lose their sense of smelling, but this is recovered by a brisk purge and repeated airings; a very common dose, on this occasion, is a drachm of jalap, and two drachms of sal gem, mixed up into a bolus with oxymel of squills: this is to be rubbed over with some butter, and will be got down in that manner pretty easily, and will work briskly.

SPAR, (*Cycl.*) in natural history. *Spars* are defined to be fossils not inflammable, nor soluble in water. When pure, pellucid and colourless, and emulating the appearance of crystal, but wanting its distinguishing characters; composed of plane and equable plates, not flexile nor elastic; not giving fire with steel; readily calcining in a small fire, and fermenting violently with acids, and wholly soluble in them.

Of this class of bodies there are ten orders, and under those twenty one genera, many of which, from their accidental admixtures, deviate greatly in appearance from the natural state of pure *spar*.

Of the first order are the pellucid crystalliform and perfect *spars*, composed of a column terminated at each end by a pyramid.

Of the second are those composed of two pyramids joined base to base, without any intermediate column.

Of the third are the crystalliform columnar *spars*, adhering by one end to some solid body, and terminated at the other by a pyramid.

Of the fourth are the pyramidal crystalliform *spars* without columns.

Of the fifth are the *spars* of a parallellopiped form.

Of the sixth are the *spars* externally of no regular form, but breaking into rhomboidal masses.

Of the seventh order are the crustaceous *spars*. These are of a crystallino-terrene structure, or debased from their native pellucidity by an admixture of earth, and formed into plates or crusts of a striated figure within.

The eighth order comprehends the crustaceous terrene *spars*; bodies so highly debased with earth, as to appear merely earthy, of an irregular structure, and not striated within. These often encrust fissures of stone, and sometimes vegetable and other extraneous bodies in springs.

Of the ninth order are the *spars* formed into oblong cylindric bodies, known by the name of *stalactitæ*, or stony icicles.

And the tenth comprehends those formed into small round figures, composed of various crusts enclosing one another, and generally known by the name *stalagmitæ*; and adding to these the *spars*, influenced in their figures by metalline particles, we have the whole series of these bodies. These are, 1. the *cubic*, owing their figure to lead. 2. The *pyramidal* with four planes, owing their figure to tin. 3. The *rhomboidal*, consisting of six planes, owing their figure to iron. *Hill*'s Hist. of Fossils, p. 201.

The genera of these several orders are these.

Of the first there are three. 1. The *triexahedria*, those which are composed of a hexangular column, terminated at each end by a hexangular pyramid. 2. The *tripentahedria*, those composed of a pentangular column, terminated at each end by a pentangular pyramid. And 3. the *enneahedria*, which are composed of a trigonal column, terminated at each end by a trigonal pyramid.

Of the second order there are three genera. 1. The *dioctahedria*, *spars* composed of two octangular pyramids joined base to base. 2. The *diexahedria*, composed of two hexangular pyramids joined base to base. And 3. the *ditrihedria*, which are composed of two trigonal pyramids joined base to base.

Of the third order there are also three genera. 1. The *hexaedrostyla*, which are hexangular columns, terminated by hexangular pyramids. 2. The *pentaedrostyla*, composed of a pentangular column, terminated by a pentangular pyramid. And 3. the *triedrostyla*, composed of a trigonal column, terminated by a trigonal pyramid.

Of the fourth order there are only two genera. 1. The *hexapyramides*, *spars* in form of hexangular pyramids without columns. And 2. *tripyramides*, those in form of trigonal pyramids without columns.

Of the fifth order there is only one known genus, the *parallellopipedia*, *spars* of a regular parallellopiped figure, as well in their whole masses, as in their constituent particles.

Of the sixth order there is also only one known genus, the *anomorhomboidia*, *spars* of no regular external figures, but breaking into rhomboidal masses.

Of the seventh order there are two known genera. 1. The *placagnodiaugia*, semipellucid, and of a striated texture within, and

and of cruſtaceous external figures. And 2. the *placagnoſcuria*, opake cruſtaceous *ſpars* of an irregular ſtructure within.

Of the eighth order there are two genera. 1. The *cibdeloſtracia*, terrene *ſpars*, found in form of thin plates on the ſurfaces of fiſſures in ſtone quarries. And 2. *cibdeloplacia*, terrene *ſpars*, uſually found coating over vegetable, or other extraneous matter in ſprings, *&c.*

Of the ninth order there are two genera. 1. The *ſtalactagnia*, cryſtalline *ſparry* ſtalactitæ. And 2. *ſtalacto-cibdela*, cryſtallino-terrene, *ſparry* ſtalactitæ.

And of the tenth order there are alſo two genera. 1. The *ſtalagmodiaugia*, or pellucid *ſparry* ſtalagmitæ. 2. *Stalagmoſcieria*, dull and opake *ſparry* ſtalagmitæ. *Hill*'s Hiſt. of Foſſils, p. 203.

The obſervation that *ſpar* is continually formed at this time in caves and grottos under ground, has given birth to many different conjectures as to the origin of that ſubſtance. We have accounts from Swiſſerland, and other places, that the ſnow by long lying on the earth, and being ſubject to repeated freezing, is at length hardened into *ſpar*: this is much of the nature of that opinion of the antients concerning cryſtal, that it was water frozen by ſevere colds to a ſort of ice, much harder than the common kind; both are equally erroneous and abſurd. But more rational conjectures, as to its origin, are, that it is produced either by effluvia alone, or by the joint force of effluvia iſſuing up from the depths of the earth, and mixing with water ouzing out of rocks into their cracks and cavities, or by the ſame water or effluvia paſſing through beds of this *ſparry* matter contained in clay. In the firſt place we are to obſerve, that *ſpar* is capable of being diſſolved either by water or vapour, and ſuſpended imperceptibly in either; and that though it remains ſuſpended a long time, yet there are occaſions of its ſeparating itſelf from either of theſe vehicles, ſuch are long ſtanding ſtill, and evaporation. What is called the growth and formation of *ſpar*, therefore, is properly perhaps only the change of place in this ſubſtance, and all that theſe agents, water and vapours, do, is only to waſh it out of the ſtrata of earth or ſtone, in which it lay in ſcattered particles, and bring it together into the cracks and crevices of ſtones, where it may again ſeparate itſelf, and become more pure and perfect. The operation of nature, in this caſe, is very like that of art in the extracting of ſalts from the various bodies they are mixed with; and *ſpar* in its two ſtates, when blended in the ſtrata of ſtone, *&c.* and when pure, and in form of cryſtals in the cracks, may be compared to alum, for inſtance, in its bed, and when purified. The alum in the common ſtones, from which it is made, is not perceptible to the eye, but lies in ſcattered particles; water being added to this takes up the ſalt, and when it has been managed by evaporation and reſt, yields it again purified and alone, and it forms ſuch cryſtals on the ſides of the veſſel as the other does on the ſides of the fiſſures of ſtone, which are the veſſels where the water, out of which it was formed, was ſet to evaporate, and to reſt a proper time. That ſome *ſpars* grow from vapours alone, is evident from the *ſtalactitæ*, or ſtony icicles, hanging down from the roofs of our caverns, which, though they grow downwards, yet have many times little plants of the ſame ſubſtance growing out at their ſides, and ſtanding upwards, contrary to the growth of the other, and evidently formed of the matter ſeparated from the vapours in their aſcent, as the ſtalactitæ themſelves are from ſuch as have aſcended to the roof, and there been condenſed into water, and ſent down again in drops. Nor is the *ſparry* matter alone thus raiſed in vapour, for even the metals, and other bodies, as little likely as thoſe to be thus raiſed, yet are found to form ſtalactitæ. The mundics in general, though they never form regular ſtalactitæ, yet often are found adhering to the ſides of them, and the metals, particularly iron and lead, form regular ſtalactitæ; the iron ones very common, and very perfect; the lead leſs perfect, and more rare; and Dr. Brown gives us abundant inſtances, of *ſpars* growing entirely from vapours in the baths of Buda in Hungary. Phil. Tranſ. N° 129.

Mr. Beaumont [b] is of opinion, that earth by degrees will ripen into *ſpar*; but this is an error. He founds his opinion on certain ſtalactitæ, and ſtalagmitæ, found in caverns, partly earth and partly *ſpar*, and ſuppoſes, that the whole would in time become *ſpar*; but there is nothing in nature to warrant this conjecture.—[b Phil. Tranſ. ibid.]

Mr. de Juſſieu has given us, in the Memoirs of the Paris Academy, a very remarkable account of the recryſtallization, or reproduction of the parts of *ſpar*, after ſolution, in the following inſtance.

There are found in the mines near St. Bell, where they dig copper-ore, a ſort of ſtones, which uſually cover the vein of the ore; theſe are compoſed of ſeveral flat plates laid evenly on one another, as our rhomboidal and parallellopiped *ſpars*, and theſe, as the diſtinctions of foſſils were not at that time eſtabliſhed, the author called, from their eaſy calcination, a ſort of gypſum, which he diſtinguiſhed from the reſt by their plated ſtructure. They are white on their outſide, and greyiſh within; and their internal part being heavy, and full of ſparkling points, they were ſuppoſed to contain ſome copper, and were thrown into the furnace uſed for roaſting the other ſtones in which copper was lodged. The calcination reduced theſe ſtones into a ſort of plaſter, or gypſum: After this theſe calcined ſtones, which were now as red as colcothar of vitriol, were thrown into tubs, and large quantities of water were poured on them; this took up their cupreous, their vitriolic, and their *ſparry* particles. From theſe tubs the impregnated liquor was let out into a baſon, in the midſt of which were placed ſeveral pieces of iron; theſe were all immediately changed in appearance into copper by the liquor. The liquor ſent up all this while a thick white vapour, which covered all its ſurface, and aroſe to the height of a foot above the edge of the baſon. This vapour by degrees diſſipated itſelf into air; but where it had touched, not only the ſides of the baſon that were above the ſurface of the liquor, but alſo the earth about the edges, were covered with ſmall regular cryſtals, of a figure approaching to a parallellopiped, and of an inſipid taſte, in ſome degree tranſparent, and very thin and flat in proportion to their breadth or length. Theſe were the ſingle cryſtals, but the continual formation of them, one upon another, at length formed of them concrete maſſes, reſembling large cakes of tartar. Theſe were like the other a true *ſpar*, being indiſſoluble in water, and eaſily calcining in the fire, and having all the other qualities of the ſtones from which they were originally obtained. This proceſs is the more ſingular, as calcination is a very ſtrange method of procuring the cryſtals of a body, and in this ſubſtance ſeems entirely to deſtroy them in their original ſtate; ſo that chance alone could have diſcovered a property of their riſing in vapour from this, and again aſſuming their proper form; but it would deſerve a trial whether the common *ſpars*, which will recryſtallize after ſolution in the acid menſtrua, will alſo do it after calcination. Mem. Acad. Par. 1719.

SPARS, in medicine, have from the earlieſt times been recommended in nephritic complaints. Some have uſed one kind, ſome another, as the *lapis judaicus*, the *ſparry* incruſtations of caverns, petrified oyſter-ſhells, and water in which large quantities of *ſpar* are ſuſtained. After all, the nephritic virtues of *ſpar* want ſufficient proof; ſome even ſuſpect its uſe to be more hurtful than beneficial. See CRYSTAL.

It were to be wiſhed, that whoever attempts to aſcertain this point, would chooſe for the experiment ſome determinate kind of *ſpar* in its natural form, rather than under appearances, whereby its efficacy may be confounded with that of other bodies. See the articles BELEMNITES and OSTRACITES.

SPARAGUS, or ASPARAGUS, *ſperage*, in botany. See the articles ASPARAGUS and SPERAGE.

SPARGANOSIS, a word uſed by ſome to expreſs a milk-tumor in women's breaſts.

SPARGUS, in ichthyology, a name given by Gaza to the common ſparus, which he calls alſo *fluta*.

Artedi calls it the plain yellow *ſparus* with an annular ſpot near the tail. See SPARUS.

SPARLING-*fowl*, in zoology, a name given in ſome places by the country people to the female merganſer, called more uſually the *dundiver*. This ſo much differs from the male of the ſame ſpecies, as to have deceived the generality of authors into thinking it a different bird.

SPARRING, or SPARING, among cock-fighters, a term uſed to ſignify the fighting of a cock with another to breathe him; in which fights they put hotts on their ſpurs, that they may not hurt one another. Sportſm. Dict. in voc. See the article HOTTS.

SPARROW, in zoology. See the article PASSER.

SPARROW-*graſs*, in botany, *&c.* See ASPARAGUS.

SPARSE-*leaves*, *ſparſa folia*, among botaniſts. See LEAF.

SPARTIUM, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the papilionaceous kind; the piſtil, which ariſes from the cup, finally becomes a ſhort roundiſh turgid pod, which uſually contains a kidney-ſhaped ſeed.

The ſpecies of *ſpartium*, enumerated by Mr. Tournefort, are theſe. 1. The yellow-flowered *ſpartium* with a kidney-ſhaped ſeed. 2. The white-flowered Spaniſh *ſpartium*. 3. The prickly ebony-like purſelain-leaved American *ſpartium*. And 4. the climbing citron-leaved American *ſpartium* with white flowers growing in cluſters at the joints. *Tourn.* Inſt. p. 645.

SPARTOPOLIAS *lapis*, in natural hiſtory, a name given by ſome authors to a whitiſh agate, variegated with long and ſlender ſtreaks of grey diſpoſed in a variouſly undulated order, and reſembling grey hairs.

SPARUS, in the Linnæan ſyſtem of zoology, the name of a genus of fiſhes of the general order of the acanthopterygii, the characters of which are, that the opercula of the gills are ſcaly, and the mouth is furniſhed with grinders covered with lips. Of this genus are the ſargus, cantharus, melanurus, *&c.* *Linnæi* Syſt. Nat. p. 54.

In the Artedian ſyſtem of ichthyology, the characters of this genus of fiſhes are theſe. The coverings of the gills are ſcaly. The teeth are covered with lips, as in quadrupeds.

The teeth in the jaws reſemble the dentes canini of men. The molares, or grinders, are like thoſe of quadrupeds. The teeth are placed only in the jaws and fauces, their palate and tongue being ſmooth. There is but one back fin. The eyes are covered with a lax ſkin, and the tail in moſt of the ſpecies is forked. The inteſtines are long, and they are twiſted in ſpiral forms, and often fixed to the meſentery. The appendices to the pylorus are large, and few in number, from three to ſeven being the uſual numbers.

Of the *ſpari* ſome have acute and cylindric teeth; of theſe the following are the ſpecies of them. 1. The *ſparus* with a very acute back, and an arched yellow ſpire between the eyes. This is the *aurata*, or gilt-head. 2. The ſilver-eyed *ſparus* with yellow parallel longitudinal lines on each ſide. 3. The red *ſparus* with ſilver eyes. This is the *rubellio* of authors. 4. The reddiſh *ſparus* with the ſkin formed into a ſinus at the root of the back fin and the pinna ani. This is called the *brama marina*, or ſea-bream. The tail is forked, and the mouth has granulous tubercles in it. 5. The variegated *ſparus* with an acute back, and with four large teeth. This is the *dentex* and *ſynodon* of authors. 6. The *ſparus* with four longitudinal parallel lines, of a golden and ſilvery colour. This is the *boops* of authors. 7. The variegated *ſparus* with a black ſpot in the middle of each ſide, and with four large teeth. This is the *mana* of authors. 8. The *ſparus* with a black ſpot on each ſide, and with the pectoral fins and the tail red. 9. The *ſparus* with the upper jaw longeſt, and with two tranſverſe black lines on each ſide. 10. The *ſparus* with the ſecond bone of the belly fins extended into a long hair. This is the *chromis* of authors. 11. The variegated *ſparus* with an equal tail, and a black ſpot in it near the end. This is the *orphus* of authors. Its head is reddiſh. 12. The yellowiſh *ſparus* with a ſingle annular ſpot in the tail. This is the *ſparus* of authors, Artedi only having uſed the name in this extenſive generical ſenſe. 13. The *ſparus* variegated with yellow tranſverſe lines, with a large and remarkable ſpot at the tail. This is the *ſargus* of authors. 14. The *ſparus* variegated with longitudinal lines, with a black ſpot on each ſide of the tail. This is the *melanurus* of authors. 15. The *ſparus* with eleven lines on each ſide, which are gold coloured, and run longitudinally and parallel to one another. This is the *ſalpa* of authors. Thus have the ſeveral fiſhes, which are only ſo many ſpecies of the ſame natural genus, been treated of under almoſt as many generical names, to the great confuſion of thoſe who apply to this ſtudy. *Artedi*, Gen. Piſc. p. 28.

The *ſparus* is common in the Adriatic, and ſome other ſeas, and eſteemed a very delicate fiſh. *Aldrovand.* de Piſc. lib. 2. cap. 18. *Geſner*, Paralip. p. 1056.

The name *ſparus* is of Greek origin, being derived from the verb σπαιρειν, to palpitate, or tremble; and was given to this fiſh from its remarkable quality of trembling or palpitating all over the body, as ſoon as taken out of the water.

SPARUS, among the Romans, a kind of ruſtic weapon, bent backwards like the foot. It was likewiſe uſed for a ſmall dart, or miſſive weapon. *Pitiſc.* in voc.

SPASM (*Cycl.*)—A *ſpaſm* may be either univerſal, extending itſelf over the whole body, which is a very rare caſe; or partial, occupying only ſome one part of the body: theſe are very frequent, and ſeize at times on every part, from the head to the foot.

Of the nature of the univerſal *ſpaſms* are, 1. the *tetanus*, which ſeizes upon the whole body, and makes it ſtiff and rigid in every part. 2. The *emproſthotonos*, which bends the body forwards, ſo that the head is brought to meet the knees. 3. The *opiſthotonos*; this enclines the whole body forcibly backwards. And 4. the *catalepſis*, which ſeizes the whole ſyſtem in a moment, and fixes it rigidly and unalterably in that poſture in which it finds it; ſo that the poſition of every limb, and the very turn of the countenance, and look of the eyes, is the ſame as when the patient was ſeized. This is a very rare caſe.

To the claſs of particular and partial *ſpaſms* belong 1. many of the arthritic complaints. 2. The *incubus*, or nightmare, which is a *ſpaſm* of the breaſt. 3. The *convulſive aſthma*. 4. The *cynic ſpaſm*, which is a peculiar diſtortion of the face, reſembling that of a perſon while laughing. This endures uſually many hours, and is often of very fatal conſequence, frequently terminating in an apoplexy, or in the moſt terrible convulſions. 5. The *ſardonic laugh*, which only differs from the former in that it is attended with an abſolute delirium, which is not the caſe in the other. 6. The *priapiſm*, which is an involuntary and painful erection of the penis. 7. The ſpaſtic contraction of the colon in flatulent colics. 8. The *fixt ſpaſms* of Paracelſus, which the author deſcribes as often afflicting podagric and arthritic patients. *Junker*'s Conſp. Med. p. 608.

Spaſms in general, beſide theſe diſtinctions, are divided by authors into the ſudden, or inſtantaneous, which ſeize upon any muſcle in a moment, and keep it for a conſiderable time in a painful ſtate of contraction, and the ſlow ones.

The *ſlow ſpaſms* are alſo divided into two kinds. 1. The *muſcular* and *tendinous*. And 2. the *fibrillary*. In the firſt of theſe the whole muſcle is affected with tenſive pains, and the limb becomes finally contracted. In the other, the ſeparate fibres in the muſcle are only affected. This is uſually the caſe in *ſpaſms* in arthritic caſes, which ſeize a few fibres only at firſt, but finally faſten upon more, and extend themſelves over the whole muſcle, in which caſe the pain uſually becomes leſs. A tenſive pain in the neck, occaſioned by ſitting or lying in an uneaſy poſture, uſually called a *crick in the neck*, is alſo to be enumerated among the partial *ſpaſms*; and finally, theſe affections are not reſtrained wholly to the external parts, but often ſeize alſo upon the internal, as the œſophagus, the ſtomach, the bladder, &c.

It is a common error to confound the word *ſpaſm* with *convulſion*; their difference is evident, the one being ſtationary and immoveable, the other erratic, and flying from one part of a muſcle to another, and from one muſcle to another; the convulſion alſo uſually extends itſelf farther than the *ſpaſm*, and is greater in degree; and finally, the *ſpaſm* is a much leſs dangerous complaint than the convulſion. Men are more ſubject to *ſpaſms* in general than women, and among them, ſuch as are of a ſanguine and plethoric habit, are moſt of all ſubject to them. The general cauſe of *ſpaſms* is an abundance of blood in a body where the veſſels are ſmall, and nature is endeavouring to throw off the load of the plethora from veſſels, where it is troubleſome to her, by this means; which, though an erroneous one, is therefore not without its end.

Prognoſtics in SPASMS. The univerſal *ſpaſms* are greatly the moſt dangerous, as they are frequently attended with internal inflammations; and the partial *ſpaſms* too often degenerate into convulſions. If *ſpaſms* are very frequent in young people, they are to be ſuſpected of threatening arthritic complaints in old age; and when perſons have been free from *ſpaſms* in their youth, and become ſubject to them when old, it is much to be feared that they portend apoplexies, palſies, and ſuffocative catarrhs: and in general all *ſpaſms*, as they are in reality no other than the incomplete attempts of nature to free herſelf of ſomewhat that offends her in particular parts, portend ſome worſe miſchief, when they are obſerved to return frequently, and with violence. *Spaſms* happening in acute diſeaſes, and from wounds, are all very dangerous ſymptoms, and threaten convulſions, and other miſchiefs.

Method of cure. The means to be uſed, when the fits are off, are bleeding in any manner, by the lancet, by leeches, or by cupping, as may be moſt proper in regard to the part principally affected, and other circumſtances; after this the primæ viæ are to be cleared by purges from any foulneſſes that may adhere to them; and finally, ſuch medicines are to be given, as are known to attenuate the blood; and with all this, gentle exerciſe is of great ſervice. In the time of the fit, lenient and paregoric medicines of this kind are amber, and the ſpirit of hartſhorn: to theſe are to be added the acrid vegetables, ſuch as the more temperate carminatives, and the emulſive diluent medicines, with nitre and cinnabar. This laſt drug is famous alone in all theſe caſes, and indeed in all emotions of the blood; but neither this, nor any of the others, will take effect till after bleeding, if the *ſpaſm* be violent. The volatile alkalis alſo ſucceed beſt when mixed with a fixed one; ſuch as the ſpirit of hartſhorn with the tincture of ſalt of tartar, or of antimony. *Junker*'s Conſp. Med. p. 612. See CONVULSION, *Appendix*.

SPATAGOIDES, in natural hiſtory, the name of a genus of the *echini marini*, the characters of which are; that it has the aperture for the anus on one ſide of the upper ſurface, and has a large furrow on the back, which makes it of a cordated form; but has no furrows on the vertex, but only four or five ſmooth rays, made of a number of ſlight tranſverſe ſtriæ. See Tab. of Teſtaceous Animals, N° 14.

SPATANGI, in natural hiſtory, the name of a genus of the *echini marini*, including all thoſe which are marked in the ſhape of a heart, and have the aperture for the anus in one of the ſides of the upper ſuperficies. Theſe have all a remarkable furrow on the back; their baſe is nearly flat, and they have ſeveral furrows on the vertex. By theſe characters they are diſtinguiſhed from the briſſi, with which they have in common the marks of two lips to their mouth, and want the teeth the other kinds have. See Tab. of Teſtaceous Animals, N° 11. *Klein*'s Echin. p. 35.

SPATHA, is a word uſed by different authors in various ſenſes; ſome expreſs by it a rib; others the inſtrument called by ſurgeons a *ſpatula*, and uſed for ſpreading ointments and plaſters; and Celſus calls a ſort of inciſion-knife by this name. It is alſo uſed for the external covering of the fruit of the palm-tree, and by others for a ſword. This laſt is indeed its proper ſignification, and all the others are only metaphorical applications of it to different things, which bear ſome reſemblance to a ſword.

SPATHA, among botaniſts, expreſſes that ſort of cup which conſiſts of a ſimple membrane growing from the ſtalk. This kind of cup is of various figures; often diphyllous, or divided into two parts; often ſimple; ſometimes more divided: it incloſes ſometimes a ſingle flower, ſometimes ſeveral

flowers together, and these have often no perianthium. The *spatha* is of very different texture, and consistence, in different plants.

SPATHA, among the Romans, is sometimes taken for a broad sword, sometimes for a sort of ladle used by cooks, and also for a surgeon's instrument. *Pitisc.* in voc.

SPATHALIUM, among the Romans, an ornament which the women wore about their hands, not unlike the coral ones of the moderns. *Pitisc.* in voc.

SPATHESTER, the name of a chirurgical instrument used to draw the prepuce over the glands.

SPATHINUS, in natural history, a name given by the Greeks to the stag, or deer, when in its second year.

In the first it was called *nebrus*; in the third year *dicratus*; and after this *cerastes* as long as it lived.

SPATHOMELE, a word used by some to express the spatula, and by apothecaries and surgeons in mixing and spreading ointments and plasters.

SPATLING-*poppy*, a name given to the common field-lychnis, from the white froth found on it in the spring. See the article FROTH-*spit*.

SPATULA, (*Cycl.*)—The use of the *spatula* is to depress the tongue, in order to examine the state of the tonsils, uvula, and fauces, when they are affected with any disorders. It is also used to suspend the tongue, when the frænum is to be divided; for which purpose it has a fissure at its extremity, and should rather be made of silver than of any other metal.

These *spatulæ* are made of different shapes. Vid. *Heister*'s Surg. Introd. sect. 36. and Plate I. P. Q. R.

SPAX, a name given by some authors to the common tænia, a small fish of the anguilliform-kind, frequent on the shores of Italy. *Rondelet.* de Pisc. p. 112.

SPEAR, in the manege. The feather of a horse, called the *stroke of the spear*, is a mark in the neck, or near the shoulder of some Barbs, and some Turky and Spanish horses, representing the blow or cut of a *spear* in those places, with some resemblance of a scar. This feather is an infallible sign of a good horse.

SPEAR-*hand*, or *sword-hand* of a horseman, is his right hand.

SPEAR-*foot*, of a horse, is the far-foot behind. See the article FAR, *Appendix*.

SPEARWORT, the English name of the *ranunculus flammeus*. See the article RANUNCULUS.

This is with us generally esteemed a poison, but the Scotch use it as a medicine. They beat it, and squeeze out the juice, which they take as a purge, drinking a little melted butter or oil before and after it, to prevent its taking the skin off from the throat. It operates very violently, but with their robust constitutions it does very well.

They use it also externally in cases of pain in the head, or any other part of the body. They bruise the leaves to a sort of paste, and apply them to the part; they soon raise a blister, and a large quantity of water is discharged, after which the pain goes off. This is a short way of blistering, and answers as safely, and as well as ours by the cantharides: but it is a wonder that people, who see this quality in the plant, should dare to take it into their mouths and stomachs.

SPECIES (*Cycl.*)—It has been generally allowed to be true, that no *species* of animal, once created, ever became extinct, or ever will be: but though this may be true in general, yet it does not follow, but that a whole species of animals may be extinct in some particular place by various accidents.

This seems to have been the case with the great moose-deer, now found only in America, which was certainly once an inhabitant of Ireland, though now extinct there, and that so long ago, that no historian mentions its ever having lived there.

There are many animals, as well as trees and plants, common to America and to Ireland. The horns of the moose-deer are found with the bones of the head, and sometimes with other bones, in immense quantities, to this day, in that kingdom, buried in strata of marl at great depths. The writers of fossils, who are fond of resolving every thing into the effects of the deluge, affirm, that these horns were brought from some other country by the waters of the flood; but they seem to be as improbable things to be brought by the sea, and left uninjured in other countries, as can well be conceived; and they are too little altered, and too well preserved, to suffer an unprejudiced observer to agree to this account.

We find numerous instances of the surface of the earth altering, in length of time, in many parts of this kingdom; and it is no forced judgment to determine, that the soil, in which these horns are now found buried, was once the surface of the country, though other substances have been since piled upon it, and made a surface over it. The creatures, whose horns we find buried, probably lived on the island when this was the surface; and as they live in herds, so dying in herds, or at least several together, their bodies were left in heaps upon the surface, where they were afterwards consumed and wasted, only the tough substance of the horns preserving them, they have remained, and being covered with the superadded strata, are now found in this fossile state. In countenance of this opinion it is to be observed, that the deer-kind in general are subject to contagious diseases, which often carry off great numbers of them. The rein-deer in Lapland are sometimes almost all destroyed by these diseases; and it is not impossible that such a distemper, raging longer and more violently than ordinary, might destroy the whole *species* in this place. The inhabitants might also promote the destruction by their hunting; for we see by the destruction of the wolves, once so frequent in this kingdom, that this cause alone may be sufficient to extirpate, or extinguish the race of an animal in one kingdom. Phil. Trans. N° 27. p. 501.

What the accurate Artedi has given, as the definition of the *species* in ichthyology, is not confined to fishes alone, but, with proper regulations, may be made the basis of real distinctions of *species* in all other natural bodies. Every fish, which differs from all the other fishes of the same genus in some external part, whether that difference be in excess or defect, in number or in proportion, or even in colour, provided that the difference be fixed and invariable, is properly to be called a distinct *species*. *Artedi*'s Ichthyolog.

The specific differences of fishes are to be drawn from these circumstances; but it is not to be supposed that every *species* differs in all of them, sometimes only one, sometimes more, occasion the variation. See SPECIFIC *names*.

If any one fish, in regard to all the others of the same genus, is found to be possessed of some external part which they all want; as for example, if it have cirri, tubercles in the shape of horns on the head, spines or prickles in the head, or on any other part of the body, the fish is then to be esteemed a distinct *species*. If one fish differs from the others of the same genus in the number of any parts, as fins, spines, or tubercles, it is then also a distinct *species*. If one fish differs from another in the proportion of any essential part, as in the having longer jaws, longer teeth, or the like, it is also to be esteemed a truly different *species*. If one fish differs from another in the figure of some essential part, as of the snout, the back, the teeth, or the tail, or the lineæ laterales, it is to be esteemed a distinct *species*. If one fish differs from another of the same genus in the excess of parts, having some part that is deficient in the other; or if in the number, proportion, or figure of some of the essential parts; the distinction will be the more evident as the greater number of parts differ, and the *species* will easily be found to be truly distinct. *Artedi*'s Ichthyolog.

If a fish differs from all the others of the same genus in colour, while it has no other distinction from some of them, then it is to be examined whether the colour is always permanent and invariable; if not, there is no distinction of *species* to be founded upon it; but if it be, it remains a matter of doubt whether it may be esteemed a specific difference, colour being one of the least essential characters, and, according to Linnæus, what no distinction of *species* can be founded on. As the colour of fishes is very apt to vary, even in the same *species*, and to be sometimes more intense, sometimes more remiss, this is to be considered in a due light, before any judgment is formed on it; and it is to be observed whether the colour, that makes the difference, be wholly of another nature, or only different in degree. The *perca fluviatilis* of Bellonius will be sometimes pale yellow, sometimes deeper, and sometimes even black, according as the water is clear or more muddy; and thus whatever differences are only in degree of the same colour, or in the changes from that degree toward black, without the intermixture of any other colour, are not to be at all depended upon. *Linnæi* Fund. Bot. 27.

We are not to expect the same precision in the differences of the truly distinct *species* of all the genera of fishes: in some they are found so obvious, and so great, that the first look distinguishes them; but there are some other genera, in which the several *species* are so alike one to the other, in the essential characters, that though there is a general external face, in which they all vary, yet it is not easy to say in what the distinction between *species* and *species* consists. Thus, among the several *species* of salmons, the number and figure of the essential parts is the same in all, and their proportion, in regard to the bulk of the fish, differs but little; the jaws are in some indeed wider, and in others longer, but it is not much. The colours and spots vary indeed greatly, in the different *species*, but then it must be allowed, that they also differ in the several individuals of the same *species*: so that, upon the whole, there is no genus of fish, in which the *species* are so difficultly distinguished. The very bones of the fins, which differ in the several *species* of the same genus, in almost all other fishes, are the same in these. The number of the vertebræ is almost the only mark in which the real difference of these consists: this is a troublesome thing to count, but in the boiled fish it is best done, and is always certain, the number being the same in all of the same *species*, of whatever size, and the several *species* all differing as to this number. Great care is to be taken in the counting of these, and by that means the smallest fish and the largest will be found to have the same number, if of the same

ſame *ſpecies*. There are ſome few inſtances of the different *ſpecies* of the ſame genus having the ſame number of vertebræ, but this is very rare. Artedi tells us that he never obſerved it but in a few of the cyprini; and thoſe which have no diſtinction in this character, he obſerves, have ſuch very remarkable external differences, that it is not needful to look for others.

SPECIES *aromaticæ*, a new name given in the late London Diſpenſatory to the compoſition uſually called *ſpecies diambræ*. The College obſerved, that the intention of this medicine was beſt anſwered, by compoſing it of ſuch ſpices as the daily experience of the table ſhews were moſt grateful to the ſtomach, and by avoiding all ingredients which, though of the aromatic kind, are accompanied with any thing nauſeous and diſguſtful in their flavour; and therefore have ordered it to be now made in the following manner. Take cinnamon two ounces, cardamom ſeeds, ginger, and long pepper, of each an ounce; make all together into a fine powder. *Pemberton*'s Lond. Diſp. p. 318.

SPECIES *e ſcordio*, the ingredients of the diaſcordium electuary in a dry form. The recipe is ſomething altered in the late London Pharmacopœia, and ſtands thus: take bole armenic four ounces, ſcordium two ounces, cinnamon an ounce and half, ſtorax, roots of tormentil, biſtort, gentian, dittany of Crete, galbanum, and gum arabic and red roſes each an ounce, long pepper and ginger each half an ounce, opium three drachms; this may be left out at pleaſure; and all are to be beat to a fine powder. *Pemberton*'s Lond. Diſp. p. 319.

SPECIES, in muſic. Here, as in other arts, *ſpecies* denotes the ſubdiviſions of the genus. The antients had three genera, the *enharmonic*, *chromatic*, and *diatonic*. The *enharmonic* had no ſubordinate *ſpecies*. The *chromatic* genus was divided into three *ſpecies*, viz. the *molle*, *ſeſquialterum*, and *toniæum*; or, as others call them, *molle*, *hemiolium*, and *toniçum* [c]. And laſtly, the *diatonic* genus was ſubdivided into the *molle*, and the *intenſum*; ſo that the antients had ſix *ſpecies*, or diviſions of the fourth in uſe. Some of theſe are alſo in uſe among the moderns, but others are unknown, as yet, in theory or practice [d].—[[c] *Wallis*'s Append. Ptolem. Harm. p. 164. [d] Vid. Phil. Tranſ. N° 481. p. 271, ſeq.] See the articles ENHARMONIC, CHROMATIC, and DIATONIC. See alſo GENUS.

SPECIES is alſo applied, in antient muſicians, to the different diſpoſitions of the tones and ſemitones in a fourth, fifth, or octave. Hence they ſay there are three ſpecies of fourths, four of fifths, ſeven of octaves. *Wallis*'s Append. Ptolem. Harm. p. 171.

The Grecians expreſſed this ſenſe of the term *ſpecies* by εἶδος, or by σχημα [e]. The Latin word, *figura* [f], has alſo been taken in the ſame ſenſe.—[[e] *Ariſtox.* p. 6, 74. Ed. Meib. [f] *Wallis*, ibid. p. 170.]

Change of SPECIES. The *change of ſpecies* is a term uſed in huſbandry to expreſs an expedient the farmer often has recourſe to, in order to procure good crops: this is the ſowing firſt one kind of plant, then another, and then a third, and ſo on, upon the ſame land: by this means the moſt is made of the ſoil; and it is found, when it will no longer give a good crop of the firſt corn planted on it, it will ſtill give a good one of ſome other *ſpecies*; and finally, of peaſe after all. After this laſt *change of ſpecies*, it is found neceſſary, in the common method of huſbandry, to renew the land with fallowing and manure, in order to its producing any thing again. See SOIL.

This *change of ſpecies* has been a practice of the farmers of all times, and is recommended, and judged neceſſary, by moſt of the writers on this ſubject; but Tull, in his New Syſtem of Horſehoeing Huſbandry, proves, that it is not neceſſary, and that the land only wants proper tillage, when exhauſted by one ſort of corn, to enable it to produce as good crops of the ſame corn again. The three fundamental propoſitions he lays down to prove this, are, 1. That plants of the moſt different nature feed on the ſame ſorts of food. 2. That there is no plant but what muſt rob every other plant, within its reach, of a part of its nouriſhment. And 3. that a ſoil, which is once proper for any kind of vegetable, will continue to be always proper for it, in reſpect to the ſort of food it gives. If only any one of theſe propoſitions were true, it would follow, that there is no need of a *change of ſpecies* from year to year; and as they are all ſo, this truth is yet the more inconteſtible, and experience proves it yet more evidently, for the ſame land will produce crops of wheat every year, without any change, only by the practice of the horſehoeing huſbandry, inſtead of the common. *Tull*'s Huſbandry. See the articles FOOD *of plants* and HUSBANDRY.

SPECIFIC (*Cycl.*)—SPECIFIC *operation of medicines*. Dr. Martin endeavours to defend the doctrine of the *ſpecific operations* of cathartic medicines, from the different nature of the drugs, and by an appeal to experience. See his Eſſ. Phyſ. and Medic.

SPECIFIC *gravity of metals*. See METALS.

SPECIFIC *names*, in natural hiſtory, are thoſe epithets compoſed each of one or more terms, and placed after the generical name, in the denomination of any ſpecies of plant, animal, or mineral, expreſſing thoſe characters by which it differs from all the other ſpecies of that genus.

The more accurate of the modern naturaliſts have, in their ſeveral provinces, ſet about the reformation of the *ſpecific* names of things. They firſt obſerve, that many of the *ſpecific* names of the antients no way anſwered the intent of their formation, but expreſſed the more trivial diſtinctions, or accidents, while they omitted the realities, and more eſſential grounds of diſtinction. On this foundation the critical writers of our times diſtinguiſh the old *ſpecific* names into the genuine, or true, and the ſpurious, or falſe ones.

The genuine names are thoſe which expreſs thoſe characters, by means of which the thing becomes a different ſpecies; theſe are invariable, and by theſe names the thing is, in ſome ſort, deſcribed. The falſe ones are thoſe *ſpecific* names which do not, nor cannot diſtinguiſh the ſpecies, called by them, from the others of the ſame genus, which may as well belong to ſome other ſpecies as to that, and which therefore are of no uſe to the ſtudent. The true formation of theſe names is on the real characters of the body to be named; but inſtead of this theſe falſe ones are formed, from the following accidental, or variable diſtinctions.

1. From the fiſh being common, or ſcarce. On this difference are founded the diſtinctions of fiſh, for inſtance, in their *ſpecific* names, into *vulgaris* and *rara*; and thus authors abound with *acus vulgaris*, *lupus vulgaris*, *boops rara*, and the like. Names are meant to convey ſome idea of the nature of the thing, but what do theſe convey? or how is the perſon, who is ſhewn a fiſh he does not know, to find out whether it be ſcarce or common?

2. From the number of the ſpecies of ſome genus. Thus we find *acus prima*, and *acus altera*, and the *aſellus primus*, *ſecundus*, *tertius*, and ſo on, in many other genera: theſe convey even leſs than the former.

3. Some of the *ſpecific* names of the antients are formed of the place, or habitation of the creatures. Of this nature are the *alburnus lacuſtris*, the *apua phalerica*, the *brama marina*, the *lampetra fluviatilis*, and a thouſand others; either alluding to the nature of the water, or peculiar place where the fiſh firſt met with, of this genus, chanced to be found.

4. Some are formed on the value or baſeneſs of the fiſh. Of this kind are the *ſalmo nobilis*, the *albula lauta*, the *aſellus luſcus*, the *ſalmo ſpurius*, ſo called, from its not having the fine flavour of the other, and ſo on.

5. The different bigneſs is another foundation of theſe names: thus we have the *acus major*, *albula parva*, *bugloſſus maximus*, *harengus minor*, and the like.

6. The colour, though very variable, or only confined to one part of the fiſh, has given occaſion to others; and in theſe it has been expreſſed, as if generally diffuſed over the fiſh. Thus the *albula cærulea* has only a part blue, though the name ſeems to expreſs that the whole is ſo: the *aſellus flaveſcens*, and *vireſcens*, are names of the ſame kind, the yellow and green expreſſed in them not being general, but only partial: the *torpedo maculoſa*, and *non maculoſa*, ſeem to expreſs two ſpecies different only in the ſpots, whereas theſe ſpots appear and diſappear at times in the ſame *ſpecies*.

All theſe, and many hundred others, founded on the ſame principles with theſe, are falſe and ſpurious, and not at all anſwering the intent of *ſpecific* names, nor diſtinguiſhing the fiſhes one from another. An unknown fiſh carries no figures of 1, 2, 3, &c. marked on it, to ſay whether it be the firſt, ſecond, or third of the author who deſcribes it; nor can it be known, at ſight, whether it be a native of ſalt or of freſh water, whether it lives in rivers or in ponds, and whether it be of American, Aſiatic, or European origin; neither can the taſte, the nature, or the manner of life of the fiſh, be ſeen on the outſide of its body: all theſe, therefore, are to be baniſhed from the names, though they make a proper part of the hiſtory of the ſpecies. On firſt meeting with a fiſh, can any man judge whether it be the greateſt, the middle, or the ſmalleſt of its kind, or ſay whether it is longer or broader than the reſt, before he knows them? nor can the mention of a colour ſignify any thing, when it is not ſaid what part of the fiſh is tinged with it. As the properties, on which theſe *ſpecific* names are founded, cannot be known till the fiſh is well known, and as the uſe of the name is the leading the perſon, yet ignorant, to know it, it follows that all theſe names are falſe, frivolous, and abſurd, and yet theſe are the names by which almoſt all the old authors have called them.

The true, and genuine *ſpecific* name, on the other hand, is that which diſtinguiſhes the fiſh called by it, at firſt ſight, from all the others of the ſame genus; or which, if it require thought and deliberation, yet requires no perſon's knowledge of the fiſh.

Theſe *ſpecific* names are to be taken from ſome external part, which in that peculiar ſpecies differs from thoſe of all the others, either in regard to exceſs, defect, number, proportion, or invariable colour.

The *ſpecific* names, taken from the exceſs of the parts, or from ſome particular parts which that ſpecies has, and which the others want, are preferable to all others. The principal parts, which ſometimes are in exceſs, ſometimes are deficient, and therefore give the proper origin to theſe names, are theſe. The *cirri*, or long-ſhaped fleſhy filaments hanging from the mouth; the tubercles, which in the heads of ſome fiſhes imitate horns; the prickles which are on the heads, and other parts; and the prominences, and other ſoft apophyſes; and other ſuch remarkable things, in whatever part of the body. Inſtances of proper *ſpecific* names, founded on the exceſs or defect of theſe parts, are theſe. *Gadus ore cirrato*, and *gadus cirris carens*. *Cottus cornubus quatuor in capite*. *Cottus cornubus capitis carens*, &c.

After theſe, the beſt names are thoſe which are taken from the number of certain parts differing in exceſs, or ſmall numbers, in the ſeveral ſpecies. The fins, and their bones, and the prickles of them, are parts which give theſe names, as alſo the ſpines on the heads and bodies of ſome fiſhes, and the *lineæ laterales*, or ſide lines, and the teeth.

Of this kind are thoſe expreſſive *ſpecific* names of the *gadus dorſo dipterygio*, *gadus dorſo tripterygio*, *gaſteroſteus aculeis decem*, &c.

Others of theſe names are taken from the proportion of ſome two parts one to another. The difference of this kind is generally in regard to length; and the parts alluded to, are the jaws, the teeth, &c. Of this ſort are the *clupea mandibula ſuperiore longiore*, and the like. In the ſquali, and ſome other cartilaginous fiſhes, the upper part of the tail is always longer than the under part; but as this holds in all the genus, there can be no uſe made of it as a *ſpecific* character.

Others of theſe names are made from the figure of ſome particular part, different from the reſt of the genus. The parts alluded to in theſe names are generally theſe; the ſnout, the back and belly, the tail, the lateral line, and the fixed ſpots and colours. The ſnout of any ſpecies, when different from that of the others of the ſame genus, in being conic, depreſſed, or compreſſed, or long and cylindric, gives great opportunity of good names of this kind. Thus we have the names of *coregonus roſtro conico*, and *coregonus roſtro depreſſo*, and the like. The back and belly, when plane ridged, or carinated, give occaſion to *ſpecific* names in the ſame manner; the cyprini in particular give us inſtances of this. The tail gives alſo occaſion to many names, as it is cuſpidated, rounded, ſtrait, lightly hollowed, or forked; and the lateral lines give the ſame occaſions of names, as they are ſtrait, crooked, ſingle, double, &c. The ſpots, provided they are permanent, are good for the baſis of *ſpecific* names, expreſſing whether they are round or long, large or ſmall, ſtrait, or tranſverſe. The ſituation of the fins, and other parts, is generally ſo regular in all the ſpecies of the ſame genus, when that genus is naturally eſtabliſhed, that very little can be done in the making names from them as *ſpecific* ones; but this ſituation of the parts is of the utmoſt uſe in the generical diſtinctions.

All *ſpecific* names, founded on theſe characters, are genuine and proper, and ſupply real notes for the diſtinguiſhing the ſpecies; and whoever will examine together all the ſpecies of any one genus, however badly named by the old authors, will find, in all the really diſtinct ſpecies, marks ſufficient for the making ſuch names as are here preſcribed. No fiſh can want theſe, ſince its being a diſtinct ſpecies from the reſt conſiſts in ſome of the articles, on the deſcription and diſtinction of which that name is to be formed. *Artedi*'s Ichthyology.

SPECTABILES, among the Romans, a title of honour given to the ſecond rank or degree of nobility under the Roman emperors, being unknown in the time of the republic. There were other two degrees; the firſt had the title of *illuſtres*, and the third that of *clariſſimi*. *Pitiſc.* in voc.

SPECTER, in conchyliology, a name given by the French naturaliſts to a ſpecies of *voluta*, on which there are ſeveral reddiſh broad bands, compoſed of looſe and irregular figures; the ground colour is a fine white. They are called by Latin writers *concha ſpectrorum*. See CONCHA.

SPECTRORUM *candela*, in natural hiſtory, a name by which ſome have called the belemnites. See the article BELEMNITES.

SPECULA, among the Romans, were places whence a good view might be had of what was doing at a diſtance. The word is particularly uſed to ſignify watch-towers and beacons. *Pitiſc.* in voc.

SPECULARES, in natural hiſtory, the name of a genus of foſſils of the claſs of the talcs.

The word is derived from the Latin, *ſpeculum*, a looking-glaſs; the bodies of this kind being naturally of bright gloſſy and poliſhed ſurfaces, and in the thicker maſſes not tranſparent, but reflecting the images of things.

The *ſpeculares* are talcs, compoſed of viſibly ſeparate plates of extreme thinneſs, and each fiſſile again into a number of others yet finer. See Tab. of Foſſils, Claſs 1.

The bodies of this genus are the common Muſcovy talc; the *ſpecularis lucida fuſca*, or brown talc, a ſpecies little inferior to the former in beauty, and found in Germany and England; and the *ſpecularis amethyſtina*, called *talc rouge*, or red talc, by the French. This is found in Muſcovy and Perſia, and no where elſe, as far as is yet known, and is often imported into France in maſſes, which are of a beautiful purple: we have of it brought into England, but only in thin flakes, fit for the covering miniature pictures. In theſe flakes it has none of the redneſs natural to it in the lump, but is the fineſt and moſt tranſparent of all the talcs. *Hill*'s Hiſt. of Foſſils, p. 71. 74.

Pliny, and other of the antient writers, as well as ſeveral of the moderns, uſe the term *ſpecularis lapis* for that ſpecies of talc, commonly known by the name of *iſinglaſs*, or *Muſcovy glaſs*.

This has been a ſubſtance in great uſe among mechanics, from the earlieſt times we have any accounts of. It is found in broad flat maſſes of ten or twelve inches in breadth, and from half an inch to three inches in thickneſs; and is compoſed in theſe of an almoſt infinite number of broad and beautifully even plates, or flakes, laid with a perfect regularity on one another, and ſeldom parting naturally from each other, though by art they may be divided, almoſt without end, into broad and extremely thin laminæ. Theſe are very flexile and elaſtic, and make no efferveſcence with aqua fortis. By the laſt of theſe properties they are diſtinguiſhed from the plated ſpars which ſome have confounded with them, and by their elaſticity from all other foſſile bodies.

It is found in many parts of the world. The iſland of Cyprus abounds with it. It is very common alſo in Ruſſia, and has of late been diſcovered to abound in the Alps, the Apennines, and many of the mountains of Germany. It is imported in large quantities into England, and is uſed by the lanthorn-makers inſtead of horn, in their nicer works; by the painters to cover miniature pictures; and by the microſcope-makers to preſerve ſmall objects for viewing by glaſſes. The antients uſed it inſtead of glaſs in their windows. *Hill*'s Hiſt. of Foſſils, p. 72.

SPECULARIA, among the Romans, a kind of window-caſements, which were uſed before glaſs was introduced for this purpoſe. They conſiſted of tranſparent ſtones, called *lapides ſpeculares*. *Pitiſc.* in voc. See SPECULARIS *lapis*, *Cycl.* and *Suppl.*

SPECULARIS *lapis*. See SPECULARES, ſupra.

SPECULATION (*Cycl.*)—SPECULATION-*ſhell*, in natural hiſtory, a name given by the French writers to a very beautiful ſpecies of the *voluta*, uſually called by us the *Guinea-ſhell*, from its being brought from that part of the world. See the article VOLUTA.

SPECULATIVE (*Cycl.*)—SPECULATIVE *muſic*, called by the Italians *muſica ſpeculativa*, or *theorica*, that which treats only of the ſounds, examines their natures, properties, and effects, without regard to the executive part.

SPECULUM (*Cycl.*)—SPECULUM *linguæ*, a chirurgical inſtrument. See GLOSSOSPATHA.

SPECULUM *indicum*, an affected term uſed by ſome chemical writers to expreſs filings of iron.

SPEEDWELL, *veronica*, in botany. See the article VERONICA.

We have ſeveral of the exotic kinds of this plant propagated in the gardens of the curious. They may all be raiſed from ſeeds, but their roots encreaſe ſo faſt, that they are uſually propagated by parting them. The beſt ſeaſon for doing this is in September, and the ſummer following they will produce their flowers in full perfection. They will grow in any ſituation, but they thrive beſt in a freſh ſoil, that is not too wet. They require no care but the being kept clear from weeds, and having their roots parted every autumn, otherwiſe they multiply too faſt, and both choak up themſelves, and injure whatever is near them. *Miller*'s Gard. Dict.

SPEISSE, in mineralogy, a name given by the Germans, and other workers on cobalt, to a ſort of impure regulus of biſmuth, ſometimes occurring in their proceſſes.

It is not uncommon for ores of biſmuth to be mixed with the cobalt in the ſmalt-works. Both this ore and the cobalt yield the blue vitrifiable earth of which ſmalt is made, but in one of them it is blended with arſenic, and in the other with the biſmuth. The ſeparating it from theſe two minerals requires different proceſſes, and the workmen therefore ſeparate the two minerals, and work each by itſelf; but it ſometimes happens that the ore of biſmuth is ſo like to the true cobalt, that it cannot be diſtinguiſhed by the eye, and ſo intimately mixed with it, that it cannot be ſeparated from it; in this caſe the whole is expoſed to the fire together, and after the arſenic is ſublimed in form of meal, there remains a coarſe and impure regulus of biſmuth, which having mixed itſelf with the earth of the cobalt, and other extraneous ſubſtances, is of a reddiſh white colour, and very impure and friable. This gives them the trouble of a ſecond operation, by which they ſeparate the pure regulus of biſmuth, and the remainder being a mixture of its earth and that of the cobalt, is run together into the blue glaſs, called *ſmalt*, the earth of biſmuth ore being of the ſame nature with that of cobalt. Philoſ. Tranſ. N° 396. p. 199.

SPELTA, in the materia medica, a name uſed for the grain of the zea dicoccos, commonly called *ſpelt corn*. *Dale*'s Pharm. p. 261.

SPELTER (*Cycl.*)—This mineral has been applied lately to ſo large a work as the cylinder of a fire-engine, by Mr. Ford of Colebrook Dale in Shropſhire: it runs eaſier, and caſts as true as braſs, and bores full as well, or better, when warmed a little. While cold it is as brittle as glaſs, but the warmth of the hand will make it ſo pliant, that a ſhaving of it may be wrapt round the finger like a bit of paper. This metal never ruſts, and therefore works better than iron; the ruſt of which, upon the leaſt intermiſſion of working, reſiſts the motion of the piſton. Philoſ. Tranſ. N° 482. ſect. 6.

SPENT, at ſea. The ſeamen ſay a ſhip hath *ſpent* any maſt, or yard, when it is broken down by foul weather, or any ſuch accident; but if it be done by an enemy's ſhot in a fight, they ſay, *ſuch a yard*, or *maſt*, *was ſhot by the board*.

SPERAGE, *aſparagus*, in botany. See ASPARAGUS.

The propagation of this uſeful plant is from ſeed; and as much of the ſucceſs depends upon the goodneſs of the ſeed, it is much better to ſave it than to buy it at the ſhops. The manner of ſaving it is this: mark with a ſtick ſome of the faireſt buds, and when they are run to berry, and the ſtalks begin to dry and wither, cut them up; rub off the berries into a tub, and pouring water upon them, rub them about with your hands, the huſks will break and let out the ſeed, and will ſwim away with the water in pouring it off; ſo that in repeating this two or three times, the ſeeds will be clean waſhed, and found at the bottom of the tub. Theſe muſt be ſpread on a mat to dry, and in the beginning of February muſt be ſown on a bed of rich earth: they muſt not be ſown too thick, and muſt be trod into the ground, and the earth raked over them ſmooth; the bed is to be kept clear of weeds all the ſummer, and in October, when the ſtalks are withered and dry, a little rotten dung muſt be ſpread half an inch thick over the whole ſurface of the bed.

The ſpring following the plants will be fit to plant out for good; the ground muſt therefore be prepared for them by trenching it well, and burying a large quantity of rotten dung in the trenches, ſo that it may lie at leaſt ſix inches below the ſurface of the ground: when this is done, level the whole plot exactly, taking out all the looſe ſtones; this is to be done juſt at the time when the *aſparagus* is to be planted out, which muſt be in the beginning of March, if the ſoil is dry, and the ſeaſon forward; but in a wet ſoil, it is better to wait till the beginning of April, which is about the ſeaſon that the plants are beginning to ſhoot.

The ſeaſon being now come, the roots muſt be carefully taken up with a narrow-pronged dung-fork, ſhaking them out of the earth, and ſeparating them from each other, and obſerving to lay all their heads even, for the more convenient planting them, which muſt be done in this manner.

Lines muſt be drawn, at a foot diſtance each, ſtrait acroſs the bed, theſe muſt be dug into ſmall trenches of ſix inches deep, into which the roots muſt be laid, placing them againſt the ſides of the trench with their buds in a right poſition upwards, and ſo, that when the earth is raked over them, they may be two inches under the ſurface of the ground. Between every four rows a ſpace of two feet and a half ſhould be left for walking in, to cut the *aſparagus*. When the *aſparagus* is thus planted, a crop of onions may be ſown on the ground, which will not at all hurt it.

A month after this the *aſparagus* will come up, the crop of onions muſt then be thinned, and the weeds carefully cleared away. About Auguſt the onions will be fit to pull up. In October following cut off the ſhoots of the *aſparagus* within two inches of the ground, clear well all weeds away, and throw up the earth upon the beds, ſo as to leave them five inches above the level of the alleys. A row of colworts may be planted in the middle of the alleys, but nothing muſt be now ſown on the beds. In the ſpring the weeds muſt be houghed up, and all the ſummer the beds kept clear of weeds. In October they muſt be turned up, and earthed again, as the preceding ſeaſon.

The ſecond ſpring after planting, ſome of the young *aſparagus* may be cut for the table. The larger ſhoots ſhould only be taken, and theſe ſhould be cut at two inches under ground, and the beds every year managed as in the ſecond year. *Miller*'s Gard. Dict.

SPERMACOCE, the name of a plant which, according to the Linnæan ſyſtem of botany, makes a diſtinct genus, the characters of which are; that the calyx is a very ſmall perianthium, divided by four notches at its extremity, placed on the germen, and remaining when the flower is fallen. The flower conſiſts of one leaf, which forms a tube longer than the flower, with its extremity divided into four ſegments, ſomewhat bent back, and obtuſe. The ſtamina are four pointed filaments, ſhorter than the flower. The antheræ are ſimple. The germen of the piſtil is roundiſh, flatted, and ſituated below the receptacle. The ſtyle is ſingle, but bifid at the top. The ſtigmata are obtuſe. The fruit is compoſed of two oblong capſules growing together, convex on one ſide, and flat on the other, obtuſe, and each furniſhed with two horns. The ſeeds are ſingle and roundiſh. *Linnæi* Gen. Plant. p. 25.

SPERMATOPŒA, a name given to ſuch medicines as are ſuppoſed to encreaſe the ſemen.

SPERVERIUS, in zoology, a name by which Bellonius, and ſome other authors, have called the ſparrow-hawk, more commonly known by the names of *niſus*, and *accipiter fringillarius*. *Ray*'s Ornitholog. p. 52. See the article FRINGILLARIUS *accipiter*.

SPHACELUS (*Cycl.*)—In caſes of a perfect *ſphacelus*, or mortification, where the parts are become abſolutely dead, and wholly without ſenſe, and ſoft, ſo as to retain the impreſſions of one's fingers ends, and are plainly fetid and corrupted, all the medicines in the world will be ineffectual to reſtore the part to its life and ſenſe again; and all that remains to be done, is the one miſerable remedy of preſerving the reſt of the body, by cutting off that part, to prevent the mortification from ſpreading farther. A different method is to be taken, however, in this operation, according to the degree of the ſymptoms, and nature of the part affected.

If only ſome extremity of the foot, tarſus, metatarſus, or inſtep, or only the bare ſkin and fat are *ſphacelated*, which is ſometimes the caſe, the whole foot is not to be amputated in that caſe, but preſerving the limb entire, the ſurgeon is only to remove that part which is vitiated; and that is frequently beſt of all done by ſuppuration, or if not to be effected by that means, may be attempted by the cauſtic. When it is to be done by ſuppuration, that is to be brought on as faſt as poſſible, and when it is done, the cruſt or eſchar of the ulcer is to be ſeparated from the ſound parts with proper caution.

To haſten effectually a ſuppuration in theſe caſes, nothing is ſo ſerviceable as the making numerous long and deep ſcarifications near the ſound parts; and afterwards the inciſed parts are to be well anointed with the common digeſtive ointment, and after that treated with the balſamic cataplaſms and fomentations, in common uſe on the like occaſions.

A fomentation, alſo very ſerviceable in theſe caſes, is made by mixing, in a quart of a decoction of ſcordium, or of barley-water, vinegar of rue ſix ounces, ſpirit of wine with Venice treacle four ounces, and an ounce, or two ounces of common ſalt: this is to be applied hot with compreſſes to the part, and frequently repeated, till it is ſeen that the diſorder ſpreads no farther; which is known to be the caſe, when we ſee the tumor of the vitiated parts ſubſide, and the edges of the ſound parts become tumid all round; and on the ſecond or third day after this a ſuppuration is uſually formed, and the ſound parts gradually become ſeparated from the vitiated. After this, to ſoften and promote a ſpeedy ſeparation of the eſchar, the following cataplaſm is always found highly ſerviceable. Take of ſcordium two handfuls, mallows, marſhmallows, and henbane, of each one handful, lavender-flowers half a handful; let theſe be boiled to the conſiſtence of a cataplaſm in vinegar, or oxycrate, and when in that ſtate add to them three ounces of flour of linſeed, one ounce of linſeed oil, and two ounces of ſal armoniac. This is to be applied warm over the whole, and retained in a proper degree of heat, as long as ſhall be found neceſſary, by means of a brick boiled in water, and applied wrapped in a linnen cloth, or ſome other like means. After theſe methods have been uſed, and the whole ſurrounding ſkin is gently tumefied with redneſs, a cruſt, or eſchar is then formed by degrees, and the ſound fleſh begins to ſeparate from the reſt: by this we know that the diſorder has done ſpreading, and that an entire ſeparation of the vitiated parts will very ſhortly follow.

When this ſeparation ſhews itſelf beginning, it muſt be promoted as much as poſſible, by dreſſing the part with the common digeſtive, either alone, or mixed with Venice treacle, which muſt be retained on between the ſound and dead parts. To make way for this, it is ſometimes neceſſary to divide them a little by the lancet; and when that is done, and the dreſſing has been applied, the before deſcribed cataplaſm ſhould be again laid on warm; and in all the ſucceeding dreſſings, whatever is found looſe of the dead part muſt be carefully removed. And if it be neceſſary, from the adheſion of the vitiated parts to the ſound, to uſe the ſciſſors, or ſcalpel, to divide them, this is always to be done with very little, either of pain or of danger; it will then be proper to dreſs the part with the digeſtive, and a plaſter of diachylon, or the like, over it, till the corrupted parts are entirely caſt off, and the ulcer appears perfectly well cleanſed, and then the cure is eaſily perfected in the common way.

This is the gentler, and more common method; ſome ſurgeons, however, from the tedioufneſs of it, have recourſe directly, in theſe caſes, to the cauſtic. They anoint either the edges only, or elſe the whole of the corrupted part, every day, with butter of antimony, or the cauſtic ſtone liquefied, till the living parts are ſurrounded by a ſort of eſchar, applying afterwards the cataplaſms before deſcribed, or

others of the ſame kind, to prevent the diſorder from ſpreading; and to make the corrupted parts ſeparate from the ſound, the corroſive lixivium of Boerhaave is greatly in repute, and much uſed on theſe occaſions. It is made of three ounces of very ſtrong quick-lime, mixed with nine ounces of pot-aſhes, firſt ground ſeparately to powder, and afterwards mixed, adding a little water, they are then to be put into a glaſs veſſel, and ſet in a cellar to run by deliquium.

As ſoon as they are found to become fluid, the matter muſt be put into a filtre of coarſe paper, and the clear liquor that runs through muſt be kept for uſe. It is to be uſed by dipping a bruſh or feather into it, and rubbing it over the part affected once or twice a day; or fine linnen-rags may be wetted with it, and applied all over the part; not forgetting, however, at the ſame time, the uſe of the before ordered cataplaſm: this application is to be continued till the corrupted part begins to caſt off in cruſts or ſcales; and when this is the caſe, it muſt be dreſſed with the common digeſtive, and when perfectly cleanſed, healed with a vulnerary balſam.

Another cauſtic, highly commended by Belloſte in theſe caſes, is made by diſſolving one part of crude mercury in two parts, either of ſpirit of nitre, or of aqua fortis. This is to be rubbed over the parts as the former, and will occaſion a ſpeedy ſeparation. Several great authors, however, adviſe the uſing the knife, and actual cautery in theſe caſes, dividing and burning down to the ſound parts; but the cruelty of this method, and the pain, and ſometimes danger that attend it, make the methods of cure by ſuppuratives, and mild cauſtics, much to be preferred: indeed, the ſurgeons in general are not now ſo fond of calling in the actual cautery as formerly.

Finally, when the *ſphacelus* is ſo deeply affixed in any part of the upper or lower extremity, that it has penetrated thro' the muſcles as far as the bone, and has either reſiſted the force of all medicines, or the proper time for the applying them has been neglected; in this caſe, to preſerve the reſt of the body, the injured part muſt be amputated. *Heiſter*'s Surgery, p. 217.

SPHÆCULÆ, among the Romans, were tickets of wood, *teſſeræ ligneæ*, by which the emperors ſcattered their preſents to people of both ſexes in the theatre, or *circus*. *Pitiſc.* Lex. Ant. in voc.

SPHÆROMACHIA, Σφαιρομαχια, in antiquity, a particular kind of boxing, wherein the combatants had balls of ſtone or lead in their hands, which were called σφαῖραι. *Potter*, Archæol. Græc. lib. 2. cap. 21. Tom. I. p. 448. See the article BOXING.

SPHAGITIDES, a name given by ſome authors to the jugular veins.

SPHAGNUM, in botany, the name of a genus of moſſes, the characters of which are theſe. They produce heads or capſules only of one kind, which differ alſo from thoſe of all the other moſſes, in that they have no calyptra, or other covering: theſe ſtand on very ſhort pedicles, and are therefore ſo guarded by the leaves, as not to need any other covering. The *ſphagna* are divided into two orders, the one comprehending the branched kinds, and the other the unbranched ones: theſe are diſtinguiſhed by ſome by the terms *cauliferous* and *acaulous*. See Tab. of Moſſes, N° 8. *Dillen.* Hiſt. Muſc. p. 242.

Of the firſt order there are nine known ſpecies. 1. The larger ſoft and hollow-leaved bog-*ſphagnum*. This grows in wet places in vaſt beds, and riſes to a foot high, with cluſters of leaves at the heads of all the branches. 2. The ſoft bog-*ſphagnum* with finer leaves. This is as tall, or more ſo, than the former, but is much ſlenderer, and the leaves much ſmaller and finer. The firſt is uſually of a dead white, and this laſt of a ſomewhat reddiſh hue. 3. The bright green-pointed *ſphagnum* with oval heads. This grows in large tufts in the boggy places on the Welch mountains. 4. The rough *ſphagnum* with red heads. The ſtalks of this are not above an inch long, and not branched, but folded, and interwoven one with another into thick tufts. It uſually grows upon rocks, but ſometimes on the ſtumps of old trees. 5. The hoary nodoſe *ſphagnum*. This is all over hairy, the ſtalks are ſomewhat longer than thoſe of the former kind, and the heads are ripe in December. This uſually grows on the ſtumps of old trees. 6. The *ſphagnum* with numerous heads, all bending one way. This is very common on the ſtumps of old trees, and produces its heads in November. It is of a very lively and pleaſant green. 7. The plain-feathered *ſphagnum*. This is an elegant ſpecies, and grows on the bodies of old trees in Patagonia. 8. The wavy-feathered *ſphagnum* with hairy heads. This is of the ſame country with the former, and grows to three or four inches in length. 9. The wavy-feathered *ſphagnum* with ſcaly heads. This is found on the trunks of trees in the woods of Germany. *Dillen.* Hiſt. Muſc. p. 253.

Of the *ſphagna* of the ſecond order, or thoſe which have no branched ſtalks, there are only four known ſpecies. 1. The dwarf hair-leaved *ſphagnum*. This is the ſmalleſt and fineſt of all the plants of this claſs, and is common in ſmall tufts about way-ſides in many places. 2. The larger dwarf bulbous *ſphagnum*. This grows only to the height of a few lines, and is compoſed of numerous leaves, ſurrounding one another ſo, as to form ſeveral bulbs. The heads are eaſier to be diſtinguiſhed by the touch than the ſight, for they lie hid between the leaves, and are ſmaller than poppy-ſeeds. 3. The leſſer dwarf bulbous *ſphagnum*. The leaves of this are much ſmaller than thoſe of the preceding kind. 4. The largeſt dwarf *ſphagnum* with briſtles. The capſules of this ſpecies, as well as the leaves, are much larger than thoſe of any other of the acaulous kinds, and the middle rib of every leaf runs out into a kind of briſtle.

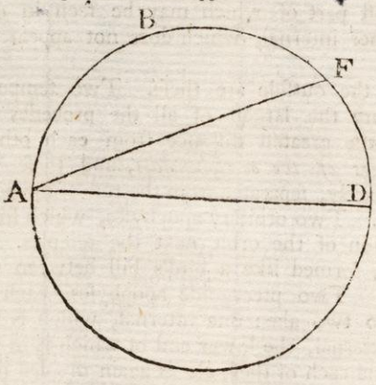
SPHENOIDES (*Cycl.*)—The *ſphenoidal*, or cuneiform bone, is ſituated in the lower part of the cranium, a little toward its forepart, making the middle or baſis of the ſkull, and thence taking its name of *os baſilare*.

It is of a very odd figure, its greateſt extent is tranſverſe, and it may in ſome manner be ſaid to repreſent a bat with its wings extended. Its poſterior, or thickeſt part, by which it is joined to the apophyſis of the os occipitis, may be called its body; the reſt of it is wholly made up of eminences and cavities. And in order to examine theſe methodically, the bone muſt be divided into two ſides, the one external, the greateſt part of which may be ſeen in one entire ſkull, the other internal, which does not appear till the ſkull is opened.

The eminences on the outſide are theſe. Two temporal apophyſes, which are the largeſt of all the proceſſes of this bone, and at the greateſt diſtance from each other, called *the great wings of the os ſphenoides*, and theſe are ſometimes, though rarely, ſeparated from the reſt of the bone by tranſverſe ſutures. Two orbitary apophyſes, which form a conſiderable portion of the orbit next the temples. A ſmall ſharp proceſs, formed like a bird's bill between the orbitary apophyſes. Two pterygoide apophyſes, each of which is divided into two alæ: one internal, which is the largeſt, the other external, the lower end of which is in the ſhape of a hook; and each of theſe alæ is again divided into two ſides, the one internal toward the palate, the other external toward the temples. Two ſpinal apophyſes. A little anterior eminence above the ſharp proceſs, for the articulation of this bone with the os ethmoides; but in ſome ſubjects, inſtead of this eminence, there is only a little notch.

The external cavities of this bone are two portions of the temporal foſſæ; two pterygoide foſſæ; the lower ends of theſe are divided by a little notch, or ſlit, of an irregular figure, which may be called the *fiſſura palatina*: a little oblong foſſula at the root of the internal ala; two ſuperior orbitary, or *ſphenoidal* fiſſures; a little notch at the end of each of theſe fiſſures, for the paſſage of an artery of the dura mater; two temporal notches; two maxillary notches, the edges of which help to form the two inferior orbitary fiſſures, which may be called *fiſſuræ ſpheno-maxillares*: two holes for the ſuperior maxillary nerves; two other holes on one ſide of the former, called *pterygoide*, which, in an entire ſkull, are hid by the other bones: two oval holes, for the inferior maxillary nerves; two little ſpinal holes, each of which tranſmits an artery of the dura mater, but ſometimes theſe are only notches; a little hole between the two maxillary holes; and a little groove on one ſide of the ſpinal apophyſis, which forms part of the euſtachian tube.

The internal eminences are two thin ſharp tranſverſe apophyſes, which form the ſuperior orbitary fiſſures, called *the little wings of the ſphenoidal bone*; a little proceſs, in ſome ſubjects, between theſe two thin apophyſes, for the articulation with the os ethmoides, which in ſome other ſubjects is a notch. Four clynoide apophyſes, two anterior, two poſterior; which laſt are ſometimes united in one, and ſometimes run forward all the way to the anterior proceſſes, forming a kind of bridge, under which the internal carotid artery paſſes at its laſt curvature. This paſſage has alſo ſometimes been found divided into two by a thin bony ſeptum, beſide other varieties; one or two ſmall productions where the internal carotid enters the cranium; two little ſtyloide proceſſes, or hooks, which in ſome ſubjects join the extremity of the os occipitis, before the perfect union of theſe bones.



The internal cavities are two portions of the large middle foſſæ of the baſis cranii; two ſuperior, orbitary or *ſphenoidal* proceſſes; two optic holes; a ſmall ſuperior, orbitary hole, near the end of each *ſphenoidal* fiſſure, which is often no more than a notch; a ſmall groove at the extremities of the ſame fiſſures; a depreſſion between the clynoide apophyſes, called *ſella ſphenoidalis*, *ſella turcica*, and *foſſa pituitaria*. Here are alſo ſeen almoſt all the holes mentioned on its outſide, and it appears that the ſuperior maxillary hole ought more juſtly to be called a ſhort canal. Beſide theſe, there are alſo two very conſiderable cavities, called the *ſphenoidal ſinuſes*, ſituated in the thick portion of this bone, under the anterior part of the ſella turcica, and middle ſpace between the two optic holes, reaching as far as the ſharp proceſs, or bill, already deſcribed; theſe are commonly divided by a bony ſeptum, and they open before on each ſide of the ſharp

proceſs, juſt behind the ſuperior conchæ of the noſe, or oſſa convoluta ſuperiora.

The figure, ſize, openings, and ſeptum of theſe vary greatly; ſometimes one is wanting, ſometimes both are ſo; ſometimes there are ſeveral cells without any ſeptum, and ſometimes the ſeptum is placed more on one ſide than the other. The ſubſtance of this bone is for the moſt part compact, having very little diploe; and what there is of this lies in diſtinct parts of the bone, *viz.* in the thick portion behind the ſella turcica, toward the ſymphyſis with the occipital bone, and in the orbitary apophyſes in a ſmall quantity. It is articulated with all the other bones of the cranium, with the oſſa malarum, oſſa maxillaria, oſſa palati and vomer. *Winſlow*'s Anatomy, p. 26.

SPHERE *(Cycl.)*—A *ſphere* is equal to four times the cone, the baſe of which is equal to the generating circle, and the height of which is equal to the radius. Or a hemiſphere is equal to twice the cone of the ſame baſe and height. And a cylinder, of the ſame height and baſe, being triple of the cone, it follows, that the hemiſphere is two thirds of the cylinder, and conſequently the whole *ſphere* two thirds of the circumſcribing cylinder. *Archim.* de Sph. et Cyl.

The portion of a *ſpherical* ſurface, generated by the revolution of an arch A B F, about the diameter A D of a circle, is equal to the area of a circle deſcribed with a radius equal to the chord A F.

The ſurfaces therefore generated by arches, terminated at A, are as the ſquares of their chords, or as their verſed ſines.

Hence parallel planes, which divide the diameter of a *ſphere* into equal parts, divide the ſurface of the *ſphere* into equal parts at the ſame time. *Archim.* de Sph. et Cyl.

SPHERICAL *(Cycl.)*—SPHERICAL *numbers*. See CIRCULAR *numbers*, *Cycl.*

SPHEROID *(Cycl.)*—Dr. Halley has demonſtrated, that in a ſphere Mercator's nautical meridian line is a ſcale of logarithmic tangents of the half complements of the latitudes[b]. But as the earth has been found to be a *ſpheroid*, this figure will make ſome alteration in the numbers reſulting from Dr. Halley's theorem. Mr. Mac Laurin has therefore given us a rule, whereby the meridional parts to any *ſpheroid* may be found with the ſame exactneſs as in a ſphere. We have alſo an ingenious treatiſe of Mr. Murdoch's on the ſame ſubject.—[b See Phil. Tranſ. N° 219. Mr. Cotes has alſo demonſtrated the ſame propoſition, Harm. Menſ. p. 20, 21.] A ſphere, whoſe diameter is equal to the great axis of a *ſpheroid*, is to that *ſpheroid* in the duplicate ratio of the axis to its conjugate. Hence the *ſpheroid* is quadruple of a cone, the height of which is the ſemi-axis, and the baſe of which is equal to a circle deſcribed upon the conjugate axis as its diameter. *Mac Laurin*'s Fluxions Introd. p. 16.

SPHINCTER *(Cycl.)*—SPHINCTER *cutanea*, in anatomy, a name given by Laurence, and ſome others, to the muſcle of the anus, called by Albinus and Winſlow *ſphincter internus ani*.

SPHINCTER *inteſtinalis*. See INTESTINALIS *ſphincter*.

SPHINCTER *labiorum*, in anatomy, a name given by Douglas, and ſome others, to the muſcle of the mouth, called by Riolanus and Albinus *orbicularis*, and *orbicularis oris*, and by Cowper *conſtrictor labiorum*.

SPHINCTER *palpebrarum*, in anatomy, a name given by Molinet, and ſome others, to the muſcle of the eyelids, called by Winſlow and Albinus the *orbicularis palpebrarum*, and *orbicularis*. See the article ORBICULARIS.

SPHINX, *(Cycl.)* in the hiſtory of inſects, a name given by Mr. Reaumur to a very ſingular ſpecies of caterpillar deſcribed in the ſecond volume of his hiſtory of inſects.

The reaſon of the author's having given it that name, is, that when it is not eating it erects its head, and with it more than a third part of its body, into a perpendicular ſituation upon the leaf on which it was before laid all along; it keeps itſelf a long time in this ſituation, looking around it with a ſeeming air of fierceneſs. There are alſo a ſeries of broad belts upon the body, which contribute ſomething towards its reſemblance to the figure of that imaginary monſter.

This caterpillar has a horn on the hinder part of its body, which ſeems to be of no ſort of uſe, but merely a trouble to the creature. It is hollow, and encloſes, in the manner of a ſheath, the new horn which is to appear when the creature changes its ſkin. This the author found to be the caſe by cutting it ſeveral times, and always finding within it the new horn cut off alſo at the ſame place, and had often obſerved the great difficulty the animal had in changing its ſkin, when it came to the horn. *Reaumur*, Hiſt. Inſect. Tom. 2.

SPHONDYLIUM, *cow-parſnep*, in botany, the name of a genus of plants, the characters of which are theſe. The flowers are diſpoſed in umbels, and are of the roſaceous kind, being compoſed of ſeveral petals of a heart-faſhioned ſhape, irregular in ſize, and diſpoſed in a circular order round a cup, which afterwards becomes a fruit, compoſed of two large, flat, oval ſeeds, ſtriated, and uſually marginated at the end, and which frequently depoſit their covering, and are marked with black ſpots on the ſides where they touch one another.

The ſpecies of *ſphondylium*, enumerated by Mr. Tournefort, are theſe. 1. The common hairy *ſphondylium*. 2. The hairy *ſphondylium* with purple flowers. 3. The great *ſphondylium*, called by authors *panax Heracleum*, or Hercules's all-heal. 4. The curled-leaved *ſphondylium*. 5. The hairy *ſphondylium* with narrower leaves. 6. The narrow-leaved *ſphondylium* with blackiſh purple flowers. 7. The little Alpine *ſphondylium*. 8. The ſmooth Alpine *ſphondylium*. *Tourn.* Inſt. p. 319.

The common *cow-parſnep*, which is frequent in our meadows and paſtures, and flowers in July and Auguſt, is recommended by Dr. Willis, and many others, as one of the beſt nervous ſimples our nation produces, and it is pity that it is not brought more into practice. The ſeed is the part in which its virtues are contained in greateſt perfection, and is a very good medicine in hyſteric caſes, given in powder or infuſion.

SPHONDYLUS, in ichthyology, a name given by Pliny, and others of the old authors, to a peculiar ſpecies of the ſyngnathus, or *acus Ariſtotelis*. It is the ſpecies, called by Artedi *ſyngnathus corpore medio hexagono cauda pinnata*; and by other authors the *acus ſecunda ſpecies*; and by Bellonius and Geſner *typhle marina*. *Pliny*, lib. 32. cap. 11.

SPHONDYLUS is alſo uſed by ſome authors, for the ſtones or bones found in the head of a mullet.

SPHRAGIS, the ſeal-ſtone, a name given by ſome authors to the ſingle joints of the aſteriæ, when found looſe, not joined into a column. See the article ASTERIA.

SPHRAGIS is alſo uſed by ſome of the old Greek naturaliſts, to expreſs the ſpots on the back and ſides of a panther.

The ſkin of this creature is of a pale colour, and theſe ſpots are all dark and round, and look like ſo many regular impreſſions of a ſeal, whence the name *ſphragis*. The Romans called any thing, that was variegated in this manner, *pantherina*; and we meet with the phraſe *menſæ pantherinæ*, uſed to expreſs tables found of ſome wood, which was variegated with round ſpots, in the manner of thoſe *ſphrages* on the back of the panther.

SPHYGMICA, in medicine, a term uſed by ſome for that part of the judgment of the phyſician, which regards the differences of the pulſe.

SPHYRÆNA, in zoology, a name by which ſome authors have called the *ſudis*, or *lucius marinus*, the ſea-pike. *Willughby*, Hiſt. Piſc. p. 273. See the article SUDIS.

SPHYRÆNA *altera*, in ichthyology, a name given by Appian, and ſome other of the old Greek writers, to the *eſox*, or common pike. See the articles ESOX and LUCIUS.

SPICCATO, in the Italian muſic, ſignifies that every note ſhould be well ſeparated from others, and diſtinctly ſounded. It is particularly uſed with regard to inſtruments played with a bow; and denotes that every note muſt have a diſtinct bow from that preceding, or ſucceeding.

SPICULUM, in Roman antiquity, a kind of weapon which ſome will have to be the ſame with the haſta, or ſparus. *Hofm.* Lex. in voc.

SPIDER, *araneus*, in zoology, an inſect of which we have a great number of ſpecies common among us, which all agree in the general marks and characters.

They all have weapons iſſuing out of the mouth, but theſe are of two kinds, according to the two principal diſtinctions of the *ſpiders*. They conſiſt, in ſome, of two ſpiculæ, in the manner of a forked hook: this is their ſtructure in all the kinds which have eight eyes. In others they are compoſed of two forcipated arms, or are divided into two claws, in the manner of the legs of a crab: theſe are the weapons of all thoſe *ſpiders* which have only two eyes.

The bodies of all *ſpiders* are covered with a ſort of cruſtaceous coat, but it is tender and brittle; and in the males of all the ſpecies, the forceps, or weapons at the mouth, are larger and ſtronger than in the females.

All *ſpiders* have two antennæ, placed in the forepart of the head over the mouth: theſe are compoſed like the legs of a number of joints. The head of a *ſpider* is not ſeparated from the ſhoulders by any inciſure, but remains fixed to them as all of one piece.

The eyes of the *ſpider* differ greatly in number, ſituation and figure, in the different ſpecies; and ſometimes the different eyes of the ſame *ſpider* are of different ſizes.

All *ſpiders* have eight legs, which are all inſerted into the breaſt, but in the length and figure of theſe there is as much variety as in the eyes in the different ſpecies of *ſpiders*:

they have all three joints in each leg, but in ſome the foremoſt pair are the longeſt, in others the hinder pair are ſo, and in others ſome of the intermediate pairs.

The belly of the *ſpider* is remarkably divided from the head and ſhoulders, ſo as to adhere only by a thread: this is the caſe in all, except the two-eyed kinds, and in the different ſpecies the body is variouſly painted. The appendages near the anus are very obſervable, they ſerve to ſpin the threads out at. Among the many ſpecies of theſe inſects, ſome are ſmooth, others are hairy, and ſome have a harder, ſome a tenderer ſkin. *Ray*'s Hiſt. Inſect. p. 12.

Among the great number of ſpecies of this inſect, theſe are the principal diſtinctions among thoſe which have eight eyes. Some ſpin webs for the catching of flies of a rounded figure; theſe have all their eyes of the ſame ſize and figure; they have four middle ones placed in a quadrangular figure, and the other four beſide theſe, but ſtanding ſomewhat obliquely. The firſt pair of legs of theſe *ſpiders* are always the longeſt, the ſecond pair are the longeſt next to theſe, then the fourth pair, the third being much the ſhorteſt of all. Theſe *ſpiders* are always ſmooth, or nearly ſo, and are elegantly figured on the buttocks. Of theſe ſome always live in the center of the web, others have their habitation in a neighbouring corner. Of the firſt of theſe ſorts we have five ſpecies. 1. The yellowiſh *ſpider* with white back and ſides, and a white head with large pellucid black eyes. This is of a middle ſize, and its legs are variegated with brown and white. The males in this ſpecies are ſlenderer than the females, and of a more reddiſh colour; and in both ſexes the head and ſhoulders are ſomewhat pellucid. 2. The hazel *ſpider* with a croſs on its back, and tubercles on the belly. This ſpecies ſpins very large nets. 3. The ſlender green and gold ſpider with a long body. This is of a middle ſize, and its fore-legs are extremely long. 4. The grey wood-*ſpider* with the body terminating in a three-cornered point. This is a ſmall ſpecies, but it ſpins very large webs. Its belly is black.

Of the ſecond kind of *ſpiders*, which ſpin round webs, and have their habitation at a corner of the web, not in its center, there are five principal ſpecies. Theſe are, 1. the grey full-bodied *ſpider* with various delineations on the back. This is a very large kind; its ſhoulders are hoary, its legs thick, not long and ſpotted. 2. The ſmooth black croſs *ſpider* with an oval body. This is of a middle ſize, its legs are ſhort and ſpotted. It is very common among ruſhes and water plants. 3. The yellow *ſpider* with four great white ſpots, and many ſmall ones. This is one of the largeſt *ſpiders*, and generally builds its habitation on the tops of plants. This is called by Mouffet, and ſome others, the *Colcheſter ſpider:* and there are two other ſpecies which much reſemble it; the one diſtinguiſhed by having a cheſnut-coloured head, and a black belly; the other, by a large brown ſtreak running from the ſhoulders to the tail. 4. The black *ſpider* with figures like oak leaves upon its buttocks. It is a very large *ſpider*. 5. The grey round-headed *ſpider* with foliaceous lines on the buttocks, undulated at the edges. This is a middle-ſized one, and is common about houſes. *Ray*'s Hiſt. Inſect. p. 24.

Another genus of *ſpiders* are diſtinguiſhed by their building conglobated webs; theſe are all ſmall, and have the fore-legs longeſt of all, next theſe the hinder pair, and then the ſecond, the third being the ſmalleſt of all.

Of theſe there are ſix principal kinds. 1. The black ſmooth houſe-*ſpider*. This is the largeſt of this genus, and has elevated ſhoulders. 2. The white *ſpider* with an oval body, ſurrounded with a ſcarlet ring. 3. The brown *ſpider* with a round body, ornamented with foliaceous figures. 4. The reddiſh brown wood-*ſpider* with a round body, marked with the figure of a ſtar. 5. The ſmall grey *ſpider* with a black ſpot upon its buttocks. And 6. the ſmall livid *ſpider* with denticulated figures on the rump. This uſually erects its conglobated nets on the top of the branches of furze buſhes.

A third genus of *ſpiders* are diſtinguiſhed by the thickneſs and cloſeneſs of the webs; ſome of theſe inhabit the bottom, or funnel-end of their webs, others live near them, but not in them. Of the firſt genus there are two remarkable ſpecies. 1. The yellowiſh hairy long-legged houſe-*ſpider*. This is of a middle ſize, and its eyes are very black and ſparkling. 2. The great grey *ſpider* with the appendices of the anus very remarkably prominent. This is a very large kind, and is of a livid colour.

Of the ſecond kind of theſe, which live at a diſtance from their webs, there are alſo two principal kinds. 1. The ſmooth cheſnut-coloured, or blackiſh *ſpider* with elegant ſnow-white ſpots. This is of a middle ſize, and has long and ſlender legs. 2. The black *ſpider* with white ſhoulders, and a denticulated white mark upon the back. This is of the middle ſize. Its legs are hairy.

To theſe is to be added the cave-*ſpider* of Mouffet. This is a large black *ſpider* with a very large ſpot, of a deeper and more ſhining black upon the ſhoulders.

A fourth genus of *ſpiders*, is diſtinguiſhed by the ſmallneſs of the webs they build: theſe are, however, of a very cloſe texture, and the creature always lives within them. Of the *ſpiders* of this kind there are three principal ſpecies. 1. The grey woolly *ſpider* with a broad black ſpot on the belly. 2. The plain livid, or yellowiſh *ſpider*. This is ſometimes of the one, and ſometimes of the other of theſe colours, but never has any variegations. 3. The yellowiſh cylindric-bodied *ſpider*. This is a large *ſpider*, and has ſix eyes. This has a long ſeries, or chain of ſpots on the back, and a yellowiſh line or ſtreak on each ſide. *Ray*'s Hiſt. Inſect. p. 30. See the articles LUPUS and PHALANGIUM.

The *ſpider* affords to the ſagacious obſerver, as well without as with the aſſiſtance of glaſſes, a great many extremely curious particulars. As the fly (which is the *ſpider*'s natural prey) is an animal extremely cautious and nimble, and uſually comes from above, it was neceſſary the *ſpider* ſhould be furniſhed with a quick ſight, and an ability of looking upwards, forwards, and ſideways, at the ſame time; and the microſcrope ſhews, that the number, ſtructure, and diſpoſition of its eyes, are wonderfully adapted to the ſerving all theſe purpoſes.

Moſt *ſpiders* have eight eyes: two on the top of the head or body, for there is no diviſion between them, the *ſpider* having no neck; theſe look directly upwards: there are two more in front, placed a little below theſe, and diſcovering all that paſſes forwards, and on each ſide: a couple more, one whereof points ſideways forward, and the other ſideways backward; ſo that it can ſee almoſt quite round it. All kinds of *ſpiders* have not, however, this exact proviſion; for in ſome we find ten, and in others only ſix, or four. The eyes of the *ſpider* are not pearled; and the field-*ſpiders*, or long-legs, have no more than two eyes.

Whatever be the number of the *ſpider*'s eyes, they are however all immoveable and tranſparent, and are ſituated in a moſt curious manner. The beſt way of viewing them with the microſcope, is to cut off the legs and tail, and leave only the head for examination.

All *ſpiders* have eight legs, which they employ in walking, and two ſhorter, called *arms*, which they uſe in ſeizing their prey. All the legs are thickly beſet with hairs; each has ſix joints, and ends with two hooked claws, which are ſerrated on their inſide; by means of theſe teeth, or jags in their claws, they ſeize very faſt hold of any thing, and behind theſe there is a ſort of ſpur, which is perfectly ſmooth. Beſide theſe, nature has allotted to this creature, for the ſeizing its prey, a pair of ſharp crooked claws, or forceps, in the forepart of its head. Theſe ſtand horizontally, and when not exerted for uſe, are concealed in two caſes contrived for their reception, in which they fold like a claſp-knife, and there lie between two rows of teeth, which are likewiſe employed to hold faſt the prey.

Each of theſe claws, or pincers, has a ſmall ſlit near its point, according to Lewenhoek, like that in a viper's tooth, through which he ſuppoſes that a poiſonous juice is, in like manner, thrown out. But Dr. Mead, in his Eſſay on Poiſons, diſſents wholly from this opinion, having never been able, on repeated examinations, to diſcover any ſuch opening, not even in the claws of the great American *ſpider*; which being above fifty times bigger than any of the European *ſpiders*, would more eaſily have diſcovered this opening, if nature had allotted any to this part of the animal. Beſides, repeated obſervations alſo convinced him that nothing dropped out of the claws, which were always dry, while the *ſpider* bit any thing, but that a ſhort white proboſcis was, at the ſame inſtant, thruſt out of the mouth, which inſtilled a liquor into the wound. And the ſame author obſerves, that the quantity of liquor, emitted by our common *ſpiders* when they kill their prey, is viſibly ſo great, and the wounding weapons ſo minute, that they could contain but a very inconſiderable portion thereof, if it were to be diſcharged that way. *Baker*'s Microſcope, p. 196.

Spiders frequently caſt their ſkins, which may be found in their webs perfectly dry and tranſparent; and from ſuch ſkins the forceps, or claws, for they are always ſhed with the ſkins, may eaſier be ſeparated, and examined with much greater exactneſs, than in the common *ſpider* while living.

The *ſpider*'s manner of weaving its web is very wonderful. The creature has five little teats, or nipples, near the extremity of the tail; from theſe there proceeds a gummy liquor, which adheres to every thing it is preſſed againſt, and being drawn out, hardens inſtantly in the air, and becomes a ſtring, or thread, ſtrong enough to bear five or ſix times the weight of the *ſpider*'s body. This thread is compoſed of ſeveral finer ones, which are drawn out ſeparately, but unite together at two or three hairs breadth diſtance from the creature's body. Theſe threads are finer or coarſer, according to the bigneſs of the *ſpider* that ſpins them. Mr. Lewenhoek has computed, that a hundred of the ſingle threads of a full grown *ſpider* are not equal to the diameter of the hair of his beard; and conſequently, if the threads and hair be both round, ten thouſand ſuch threads are not bigger than ſuch a hair. He calculates farther, that when young *ſpiders* firſt begin to ſpin, four hundred of them are not larger than one which is of a full growth; allowing

which, four millions of a young *ſpider*'s threads are not ſo big as the ſingle hair of a man's beard.

The eggs of ſome *ſpiders* are a very pleaſing microſcopic object; they are round at one end, and flattiſh at the other, with a depreſſion in the center of the flattiſh end, and a yellowiſh circle round it. The colour of theſe eggs is a pearly or bluiſh white, and when the young *ſpiders* hatch, they come out in their perfect form, and run about very nimbly. The female *ſpider* depoſits her eggs, to the number of five or ſix hundred, in a bag compoſed of her own web, which ſhe either carries under her belly, or hides in ſome very ſafe receſs. Philoſ. Tranſ. N° 272.

The young *ſpiders* are always very beautiful objects for the microſcope. The current of the blood may be eaſily diſcovered in their legs, and part of their bodies; and many other curious particulars occur in their diſſection.

There are two or three ſpecies of this animal, peculiarly worthy the attention of the curious in microſcopic diſcoveries. 1. A little white field-*ſpider* with ſhort legs. This is found plentifully among new hay, and its body appears like white amber with black knobs, out of which grow ſhort but ſharp prickles. The eyes of theſe may be very diſtinctly ſeen, being very briſk and lively, and ſome have ſix, ſome eight of them: each eye has a pupil of a violet blue, which is beautifully clear and tranſparent, and is ſurrounded by a circle of pale yellow. 2. The wandering, or hunting *ſpider*, that ſpins no webs, but runs and leaps by fits. This has two tufts of feathers fixed to its fore-paws, which make a very beautiful appearance before the microſcope. The variety and beauty of colouring alſo, all over this little creature, afford a very pleaſing ſight. 3. The *long-legs*, or ſhepherd-*ſpider*. This is a moſt wonderful creature: it has two fore-claws at a great diſtance from the head, tipped with black like thoſe of a crab, and opening and ſhutting like the ſcorpions; theſe are ſerrated or indented on their inſide. When all the legs are cut from this *ſpider*, and it is examined by the microſcope, it will be ſeen that the protuberance on the top of its back is furniſhed with two fine black eyes. *Power*'s Microſ. Obſ. p. 13. *Hook*'s Microgr. p. 200.

The venom of many kind of *ſpiders* is greater than uſually ſuppoſed: we have, in the Philoſophical Tranſactions, an account of a perſon in New-England who was bitten by a ſmall *ſpider* a little above his ankle; he perceived the creature biting, and cruſhed it to death upon the wound, between his ſtocking and his leg; in half an hour he felt a pain in that leg, which in another half hour extended itſelf to the groin, and at the ſame time he had a creeping pain in the calf of his other leg; and in a quarter of an hour after this it affected his ſtomach, his back, and his head. The pains were not conſtant and fixed, but erratic, and very acute, and his pulſe was extremely low and heavy. He was relieved, by taking internally ſpirit and ſalt of hartſhorn in viper-wine, and applying a cataplaſm of garlick to the part, and in three or four days wholly recovered.

Boccone mentions a ſpecies of large *ſpider*, common in the iſland of Sardinia, whoſe bite proves mortal within the ſpace of a few hours; the whole body uſually ſwells almoſt immediately, in conſequence of this bite. The cure is performed by oil of olives, in which the creature is infuſed over the heat of a ſtove. This is a medicine they always keep ready in the houſe, and while they uſe this externally, they give large doſes of Venice-treacle inwardly, diſſolved in ſtrong wine: but many die of this bite, either from the want of power in the remedies, or from their being uſed too late. *Boccon.* Muſ. de Fiſ.

When *ſpiders* aſcend and deſcend by their thread, they do not ſpin a new one at every deſcent; but whenever they aſcend, they wind the thread with their feet into a ſort of coil, and when they deſcend, they only unravel it again. Phil. Tranſ. N° 482. ſect. 16.

Some think the white matter, we often find floating in the a irtowards the end of the ſummer, is produced by *ſpiders*. Ibid. See the articles *Air*-THREADS, OPILIO, PHALANGIUM, *&c.*

SPIDER-*wort*, in botany. See PHALANGIUM.

SPIEI, in the glaſs trade, an iron inſtrument, hooked at the end and pointed, with which the workmen take the metal up out of the melting-pots for proofs or eſſays, to ſee whether it be fit to work. *Neri*'s Art of Glaſs, p. 241.

SPIGNEL, in the materia medica, *&c.* the Engliſh name of the plant called by botaniſts *meum*. See MEUM.

SPIGOLA, in ichthyology, a name given by Paulus Jovius, and ſome others, to that ſpecies of pearch which is generally called the *lupus marinus*. See the article LUPUS.

It is a genuine pearch, and is diſtinguiſhed from the others by Artedi, by the name of the *pearch* with the thirteen rays in the ſecond back fin, and fourteen in the pinna ani. Authors have called two different fiſh by this name *lupus marinus*, which conveying no diſtinct idea of the characters of the fiſh, was applicable to either as much as the other; but this name of Artedi admits of no equivocation, and muſt always diſtinguiſh the fiſh.

SPIKE, or *Oil of* SPIKE, a name given by our druggiſts to an eſſential oil, much uſed by the varniſh-makers and the painters in enamel; and of ſome uſe in medicine.

This *oil*, when genuine, is brought from Provence, and ſome other parts of France, and is there made of lavender. This plant is called in Provence *aſpic*, and thence came the name *oil of aſpic*, which afterwards degenerated into *oil of ſpike*.

The manner of making the *oil* upon the ſpot is this: when the flowers are perfectly ripe, they put them into an alembic with a great quantity of water, and this they diſtil after ſeveral days maceration: there ariſes with the water a large quantity of an oil of a fine pale amber colour, and this ſeparated from the water, is the true and genuine *oil of ſpike*.

The flower of this plant is the part which yields the largeſt quantity of oil; as is the caſe with all the plants with galeated flowers, of which the huſk or flower-cup uſually contains almoſt all the oil of the plant. The aromatic plants, in general, yield indeed but a ſmall quantity of oil, but the vaſt abundance of this plant, in theſe places, makes the expence of gathering it ſo ſmall, that the *oil* is very cheap. The quantity required on ſeveral occaſions is, however, much greater than what all the lavender of the country can yield; and the price it is expected to be ſold at is ſo ſmall, that it is not to be wondered that there are ſeveral common adulterations of it.

The moſt uſual ways of ſophiſticating it, however, are two; the one with the ſpirit of wine, which is eſteemed the leaſt hurtful, and the *oil* thus ſophiſticated is often called the very beſt of the country. The method Mr. Geoffroy took to diſcover the cheat was this: he procured a long and narrow vial, of an equal diameter all the way up, into this he firſt put an ounce of fair water, and to this he added an ounce of the *oil*; he marked the height of the water in the vial, then ſhook the two liquors together, and they became milky, and heated on the mixture, which alone would have been a ſufficient proof that there was ſpirit of wine in the *oil*. After ſome ſtanding the liquor became clear, and the *oil* floated at the top, but in a much ſmaller quantity than might have been expected, there being not more than a quarter of an ounce of it, the reſt having been ſpirit of wine, which mixed with the water, and thus left all the true *oil*, which was only one fourth of the quantity, to float alone on the water, which was greatly encreaſed in height in the vial. A pint of this *oil of ſpike*, therefore, contains only four ounces of the genuine *oil*, and twelve ounces of plain ſpirit of wine.

The ſecond method of adulterating this *oil*, which the ſame gentleman had ſuſpected, was eaſily diſcovered next: for on mixing this quarter of an ounce of pure *oil of ſpike* with three quarters of an ounce of oil of turpentine, there was produced an ounce of a liquor, which appeared wholly the ſame with the *oil of ſpike* commonly ſold in the druggiſts ſhops. And indeed, much of what is uſually ſold is worſe than this, being no other than oil of turpentine ſcented with a ſmall quantity of the true *oil of ſpike*.

The ready way of diſcovering the *oil*, counterfeited with oil of turpentine, is to wet a paper in it, and ſet it on fire; the turpentine will here be diſcovered by the thick ſmoak it yields, it being, of all vegetable oils, that which yields greatly the thickeſt cloud in burning: and, on the contrary, that which has been adulterated with ſpirit of wine, will be diſtinguiſhed by the ſame trial, by its yielding a much finer and thinner ſmoak, and burning with a bright blue flame. If they be tried by firing them in a ſpoon, that which is adulterated with ſpirit of wine will burn very bright, and yield no fume at firſt; but as it grows near the bottom, it will ſmoak a little, and finally will leave no reſiduum, except that it varniſhes over the inſide of the ſpoon: that adulterated with the oil of turpentine will burn more vehemently, ſmoak more, and leave a coarſer varniſh upon the ſpoon; and if it be of the coarſeſt kind, that is, if it have been adulterated with badly-rectified oil of turpentine, the fume will be the more abundant, and there will be left in the ſpoon a fetid matter, reſembling melted pitch.

Mr. Geoffroy tried whether, in the buſineſs of varniſhing, the oil of turpentine alone might not do as well as the *oil of ſpike*; he found that it dried perfectly well, but that it left a ſtinking ſmell upon the work, which never went off; whereas the mixture of this oil, with that of *ſpike*, makes a ſmell like neither, and which ſoon goes off.

An ounce of oil of turpentine, with only twenty drops, either of our common oil of lavender, or the pure *oil of ſpike*, makes a liquor tolerably well ſcented, and which ſerves for the purpoſes of *oil of ſpike*. If two drachms of our oil of lavender be added to ſix drachms of ſpirit of wine, they immediately mix, and this afterwards mixed in a ſmall proportion with oil of turpentine, makes a ſort of *oil of ſpike*. The moſt regular method, however, that the artificer can uſe, if he can get the genuine *oil of ſpike*, is to mix one ounce of it with three of oil of turpentine, which perfectly fits it for his purpoſe, and makes it the ſame with that in common uſe. The method of making this perfectly pure, is to rediſtil it in a balneum mariæ; there will thus be procured

cured an oil highly rectified, and pellucid as water, which will dry away as ſoon as touched on any thing. The great diſadvantage attending the *oil of ſpike* adulterated with ſpirit of wine, is, that it will not readily mix with all the ſorts of varniſh.

Having gone through the properties of *oil of ſpike*, in regard to varniſh, it remains to enquire into them in regard to its other great uſe in enamel, and to conſider the effects of the two uſual methods of adulterating it in this work.

The *oil of ſpike* which wants body, is not at all fit for enamelling, becauſe it dries too ſuddenly, and does not at all aſſiſt the natural dryneſs of the enamel, which is only a ſort of powder of glaſs; and the particles of this powder, with a fluid of too little body, are not manageable by the artiſts, ſo that the colour never is brought to a due conſiſtence: and when the *oil* has too much body, the mixture becomes too tenacious, and is as unmanageable in that extreme as in the other; and this fault is attended with another very great miſchief, which is, that the ſume raiſed by this *oil*, when heated, is often ſo groſs, as to deſtroy the beauty of the colours. In ſhort, thick oil of turpentine is always deſtructive of enamels by its ſmoak.

The true compoſition for enamelling is *oil of ſpike* mixed with ſpirit of wine, but the proportions muſt be nicely regulated from repeated trials: for if the quantity of the ſpirit be too large, it is apt to ſeparate itſelf from the *oil* and colour in the drying, and this always ſpoils the gloſs and beauty of the work. Artificers obſerve, that *oil of ſpike* does beſt for their purpoſes, after it has been kept two or three years. But this is only owing to the *oil*'s being adulterated with ſpirit of wine, and uſually containing too large a proportion of the ſpirit when firſt ſent over, it becomes better for uſe when a part of that ſpirit has had time to evaporate in the keeping. It would be a better way for theſe curious works, to procure the *oil* pure, and then occaſionally mix it with ſuch a proportion of ſpirit of wine, as experience ſhews to be the moſt proper. Mem. Acad. Par. 1716.

SPIKENARD, in botany. See the article NARDUS.

Ointment of SPIKENARD. See NARDINUM *unguentum*.

SPIKES, or, as the ſeamen call them, SPEEKS, in a ſhip, are large long iron nails with flat heads. They are of divers lengths, ſome a foot, or two long, and ſome are jagged, ſo that they cannot be drawn out again. They are uſed to faſten the planks and timbers. They call alſo a kind of ſmall fidd, which ſerves them to open and ſplice ſmall ropes, a *marling ſpike*.

SPINA (*Cycl.*)—SPINA *bifida*, in anatomy, a parting of the *ſpinal* proceſſes into two rows. The exiſtence of ſuch a caſe is doubted. See SPINE.

SPINA *burgi*, in botany, a name uſed by ſome authors for the *alaternus*, or ever-green privet, a garden ſhrub, the fruit of which is a mild aſtringent. *Park.* Theatr. p. 1445.

SPINA *ventoſa*, is properly a ſpecies of corruption of the bones, which takes its riſe in their internal parts, and by degrees enlarges the bone, and raiſes it into a tumor.

The antients were ſtrangers to this name for this diſorder, and called it *ſideratio*, *gangræna*, or *cancer oſſis*, and ſometimes expreſſed it by the word *teredo*. Some among the French call it alſo an *exoſtoſis*, though this is a term more properly denoting certain eminences, or preternatural acuminated excreſcences in the bones, which happen after fracture, or other accident, and are ſome.imes attended with a caries.

The name of the diſorder ſeems to have been borrowed from *ſpina*, a thorn, from the reſemblance the eminences of the bone in this caſe bear to thorns, continually pricking the fleſh, and producing the moſt grievous pains; and the epithet *ventoſa* is added, becauſe the tumor ſeems, to the touch, to be filled with air, though this is very rarely the caſe. This ſeems to have been the origin of the name *ſpina ventoſa*, which ſome after-writers barbarouſly diſtorted into *ſpinæ ventoſitas*. When this diſorder happens to children, Severinus, and many others, call it *pædarthrocaces*.

In the *ſpina ventoſa* the caries, or eroſion of the bone, is occaſioned by a depravity of the contained fluids, and generally ariſes ſpontaneouſly, or without any external cauſe, and does not begin upon the ſurface of the bone, but between its lamellæ, or elſe in its internal cavity; from whence extending itſelf by degrees to the external parts, it at length either affects the whole bone, or a greater or ſmaller part of it, expanding itſelf to different widths, and riſing to a tumor, which is ſometimes hard, and without pain, and at others feels as if it were filled with wind, and is attended with a greater or leſſer degree of pain, pricking and ſhooting, and at laſt grows red, and is attended with other bad ſymptoms, till the diſordered bone being by degrees corroded, the common integuments, and other ſofter parts that lay over it, remaining at firſt entire, but at laſt partaking of the diſorder, foul ulcers of a very terrible ſort break out. When tumors of the bone are hard, and the ſoft parts about them not inflated, and are free from redneſs, inflammation, and pain, as is very frequently the caſe in ricketty diſorders, the bad ſymptoms juſt deſcribed ſeldom come on. This is properly the pædarthrocaces, but the painful, red, inflated tumors happening equally to children, and to adults, are properly the *ſpina ventoſa*.

It differs from a caries by being attended with a tumor, and from the rickets by its being accompanied with pain and eroſion. It generally begins about the heads, or epiphyſes of the larger bones, where they are moſt tender and ſpungy, and where the noxious matter may not only have ſufficient room to lodge in the cellular ſubſtance, but where it will alſo meet with the leaſt reſiſtance in ſoftening and expanding the parts. Sometimes, however, it alſo ariſes in the middle of the bones, between their lamellæ, eſpecially in the tibia. The os frontis is alſo ſubject to diſorders of this kind in venereal caſes, and it is frequently ſituated in the bones of the face, neck and breaſt; though thoſe of the arms, legs, fingers, carpus, meta-carpus, tarſus, and meta-tarſus, are more frequently the ſubjects of it.

Though this diſorder uſually ariſes from internal, yet it is ſometimes found to be owing to external cauſes; eſpecially in perſons conſtitutionally addicted to a diſorder of this kind, when the veſſels between the lamellæ of the bone, or in the medulla itſelf, are by a blow, fall, or other external violence, injured, or torn, and their fluids extravaſated, and by degrees putrefy, corrupt, and deſtroy the medulla, and ſoften the very ſubſtance of the bone, and corrode it; whence proceed pain, tumors, ulcers, and fiſtulas of the bone, and adjacent parts, and all the ſame train of miſchiefs which attend theſe diſorders, when begun ſpontaneouſly from internal cauſes.

The proximate cauſe of this diſorder is a collection, or congeſtion, either of a viſcid and thick, or of an acrimonious and corroding humor, or an inflammation ariſing in the medulla, or in the cellular ſubſtance of the bone, degenerating into an abſceſs, and forming matter, or ichor. As theſe ſtagnating fluids can find no diſcharge from the bones, eſpecially from their cavities, they continue confined there till they putrefy, and become acrimonious, and corrode and deſtroy the neighbouring parts, converting them, particularly the medulla, into a kind of ſanies; and at length they attack the bone and deſtroy it. The collection of viſcid and pituitous humors, and the expanſion of the bones, ſometimes happens without pain, as in ricketty caſes, but the eroſion of the parts can never happen without the moſt acute pains.

When the internal parts of the bones only are affected by this diſorder, the pain does not encreaſe upon external preſſure; when the pain encreaſes upon external preſſure, the external parts are brought into conſent; and when this happens, the perioſteum, and parts which ſurround it, with the ſubſtance of the bone and tunica cellularis, enlarge, from whence a ſenſation frequently ariſes, as if the parts were filled with air, or wind. But when the tumor is opened, either ſpontaneouſly, or by the knife, the bone, if it lies bare, is found full of ſmall eroſions, reſembling a ſpunge or pumice-ſtone.

Of this terrible diſorder there are properly three degrees: the firſt is, when the patient complains of a continual grievous pain in the bone, which ſeems to him to proceed from the marrow, and torments him ſo, that he can have no ſleep, and all this while there is no external pain or tumor; in this caſe the diſeaſe is confined to the internal part of the bone. The ſecond degree is when a tumor appears to be ariſen on the ſurface of the bone, and is attended with external pain, more or leſs. The third degree is when, after the former ſymptoms, an ulcer is formed in the tumor, which diſcharges a fetid ichor, or purulent matter, ſmelling like rank butter or lard.

There are two methods of treating this diſorder, one ſuited to the milder, the other to the more violent ſtate of it, in which the bones, and the parts ſurrounding them, are entirely corroded and deſtroyed. In the milder ſtages, the acrimony of the blood muſt be endeavoured to be corrected by large draughts of the decoctions of the woods, with the China and ſarſaparilla roots. The parts affected ſhould alſo be fumigated with the ſteam of decoctions of aromatic herbs, and twice a day, in the intermediate times, the part may be rubbed over with a mercurial ointment, and afterwards covered with the common mercurial plaſter. Mercurial medicines ſhould alſo be given internally, according to the ſtrength of the patient, and ſometimes a ſalivation is neceſſary.

Mercurial remedies ſeem indeed ſo peculiarly appropriated to this caſe, that nothing is to be done without them; and it hence looks very ſuſpicious, that ſomething venereal is always in the caſe, or elſe that the diſorder is of itſelf very much akin to that diſeaſe. By diligently purſuing this method for ſome weeks, the firſt and ſecond ſtages of this diſeaſe may be cured even where there are bony tumors formed; and the tumors may either be reduced, or at leaſt brought to that ſtate, that they will remain as they are without farther encreaſe, or without pain, or any farther inconveniency.

But when theſe tumors are ſo far advanced, as to be out of the reach of the remedies, the pain and tumors encreaſing, and abſceſſes forming; as there is great reaſon to fear the

the entire deſtruction of the bone, if the abſceſs does not burſt of itſelf, the ſurgeon ſhould not ſtay for its maturation, but lay the bone bare in the loweſt, or in the moſt painful part. When the abſceſs is already burſt, if the opening be too ſmall, it muſt be enlarged with a knife, or if the patient too much dreads the knife, the cauſtic may ſupply its place; and after this ſeveral ſmall holes muſt be made in the bone with a ſmall piercer, perforating it into the medulla, to give way for the diſcharge of the confined matter; and when theſe ſmall holes are not ſufficient, a larger muſt be made by the trepan, if the bone will admit it: this will not only make more way for the diſcharge of the matter, but will alſo give room for the proper application of remedies better than any other method.

While this is under cure, the patient muſt uſe internally the decoctions of the woods, and mild mercurial, and antimonial medicines; and externally the wound muſt be treated with cleanſing, and balſamic remedies, ſuch as decoctions of agrimony, ſanicle, St. John's wort, or birthwort, and eſſence of myrrh and aloes. Theſe ſhould be injected warm with a ſyringe twice every day, as may alſo a ſolution of mercurius dulcis made in plantane-water, or in lime-water. Honey of roſes ſhould be added in a ſmall quantity to either of the decoctions, uſed as eſſences; and after the uſe of them, the wound ſhould be dreſſed with the before-mentioned eſſences, or with thoſe of maſtich or amber, ſpread upon lint, and covered with a mercurial, or other plaſter: this method is to be continued till the parts are healed. The actual cautery is ſometimes neceſſary to root out the diſorder, eſpecially when it is only between the lamellæ of the bone, for in other caſes there is no getting to the bottom with it.

But when all theſe methods are unſucceſsful, and the part is already too much corroded and deſtroyed, there is no hope of ſaving it, nor indeed of ſaving the life of the patient, by any other means than the taking off the limb. When the diſorder is ſituated, however, in ſome ſmall bone, as on the carpus, tarſus, meta-carpus, or meta-tarſus, or fingers, it will not always be neceſſary to take off the whole limb, that is to ſay, the finger, foot, or hand, but it will frequently ſuffice to remove the corrupted bone alone. In larger bones, where the whole bone is not affected, but only a part of its external ſurface is diſordered by either a caries, or *ſpina ventoſa*, the whole limb is by no means to be taken off, but the diſeaſed part of the bone only removed: but when a large bone, as the os humeri, tibia, or femur, or an entire joint of the arm, knee, or foot, is diſeaſed, there is no remedy but amputating it in the ſound parts juſt above. *Heiſter*'s Surgery, p. 264.

Dr. Schlichting affirms, that the *ſpina ventoſa* may be cured by rubbing the tumor twice a day with ung. Neapolit. preventing ſalivation by gentle cathartics. Phil. Tranſ. N° 466. ſect. 10.

It appears likewiſe, from a caſe related in the Philoſophical Tranſactions, that amputation of the limb is not always neceſſary. Vid. Phil. Tranſ. N° 480.

SPINACHIA, *ſpinach*, in botany, the name of a genus of plants, the characters of which are theſe. The flowers are of the apetalous kind, conſiſting only of a number of ſtamina. Theſe flowers are alſo barren, and the embryo ſeeds are found on ſuch parts, or different plants of *ſpinach*, as have no flowers. Theſe finally become ſeeds of a turbinated form, and are contained either in a capſule of the ſame figure, or elſe in a cornuted or angular one.

The ſpecies of *ſpinach*, enumerated by Mr. Tournefort, are theſe. 1. The common *ſpinach* with prickly ſeed-veſſels. 2. The common barren *ſpinach*. 3. The procumbent Cretic *ſpinach* with echinated capſules. And 4. the common *ſpinach* with ſmooth capſules. *Tourn.* Inſt. p. 533.

The common *ſpinach*, intended for winter uſe, ſhould be ſown on an open ſpot of ground in the latter end of July, obſerving to do it, if poſſible, when the weather is rainy. When the young plants are come up, the weeds muſt be deſtroyed, and the plants left at about five inches aſunder. The ground being kept clear of weeds, the *ſpinach* will be fit for uſe in October. The way of gathering it to advantage, is only to take off the longeſt leaves, leaving thoſe in the center to grow bigger; and at this rate a bed of *ſpinach* will furniſh the table for the whole winter, till the *ſpinach* ſown in ſpring is become fit for uſe, which is common in April. *Miller*'s Gard. Dict.

SPINACHIA, in zoology, a name given by ſome authors to our common ſtickleback, or barnſtickle, more uſually known among writers by the names *pugnitius*, or *aculeatus piſciculus*. *Geſner*, de Aquatil. See the article PUGNITIUS.

SPINALIS (*Cycl.*)—SPINALIS *cervicis*, in anatomy, a name given by Albinus to a muſcle of the neck, called by Fallopius the *tertium par muſculorum dorſi*, and by Cowper and Morgagni *ſpinalis colli*.

This is the muſcle which the French anatomiſts call *les vertebraux externes du demi-epineux, ou le tranſverſaire epineux du col.* See TRANSVERSALIS, *&c.*

SPINALES *colli minores*, muſcles lying between the ſix *ſpinal* apophyſes of the neck, and between the laſt of the neck and firſt of the back; being inſerted in theſe apophyſes by both extremities on one ſide of the poſterior cervical ligament, which parts them from thoſe of the other ſide. They are likewiſe termed *interſpinales*. Vid. *Winſlow*'s Anat. p. 244.

SPINALIS *dorſi*, in anatomy, a name given by Albinus to a muſcle of the back, figured by Euſtachius Tab. 37. and called by Fallopius *quintiparis dorſi muſculorum pars implantata in ſpinas vertebrarum thoracis*.

Others, as Spigelius, have called it a part of the *ſemiſpinatus*, and others a part of the *longiſſimus dorſi*. The French have named it *le grand epineux de dos*. See the articles SEMISPINATUS and LONGISSIMUS *dorſi*.

SPINALIS *dorſi major*, a pretty long and ſlender muſcle, lying upon the lateral part of the extremities of the *ſpinal* apophyſes of the back. It is compoſed of ſeveral muſcular faſciculi of different lengths, which croſſing each other, are inſerted laterally by ſmall tendons in the *ſpinal* apophyſes from the ſecond, third, or fourth vertebræ of the back; and ſometimes, though ſeldom, from the laſt of the neck, or firſt of the back, all the way to the firſt or ſecond vertebra of the loins, with ſeveral irregular decuſſations, which vary in different ſubjects. The longeſt faſciculi are all a little incurvated, and the whole muſcle terminates in points at its ends, but is conſiderably broad in the middle. It communicates by ſome fibres with the longiſſimus dorſi, and *ſemiſpinalis*, and ſends off faſciculi to ſeveral tranſverſe apophyſes of the back, from the fourth to the eleventh. It is called by ſome *ſemiſpinalis*, but very improperly. *Winſlow*'s Anatomy, p. 247.

SPINALES *dorſi minores*. Theſe muſcles are of two kinds; ſome go laterally from the extremity of one *ſpinal* apophyſis to another, being often mixed with the ſhort faſciculi of the *ſpinalis* major; the reſt lie directly between the extremities of two neighbouring *ſpinal* apophyſes, being ſeparated from thoſe on the other ſide by the *ſpinal* ligament. Theſe are ſmaller and thinner than thoſe of the neck, and are properly enough termed *interſpinales*. *Winſlow*'s Anatomy, p. 248.

SPINALES *et tranſverſales lumborum*. There are ſome faſciculi which run up from the ſuperior falſe *ſpines* of the os ſacrum to the lower *ſpinal* apophyſes of the loins, which may be looked upon as ſo many *ſpinales lumborum majores*; and there are alſo ſome *ſpinales lumborum minores* between the *ſpinal* apophyſes of the loins, and *tranſverſales minores* between the tranſverſe apophyſes, which are ſometimes of a conſiderable breadth. *Winſlow*'s Anatomy, p. 249.

SPINARELLA, in ichthyology, a name given by Bellonius, and ſome other authors, to the little fiſh called by us the *leſſer ſtickleback*, and diſtinguiſhed by Artedi by the name of the *gaſteroſteus* with ten ſpines on the back. See the article GASTEROSTEUS.

The ſize is an uncertain mark, but this number of the ſpines wholly determines the ſpecies, the common *gaſteroſteus*, or ſtickleback, having only three.

SPINATUS, in anatomy, a name given by Riolanus, and others, to a muſcle of the neck, called by Albinus *ſpinalis colli*, and by Winſlow, and the other French writers, *les vertebraux externes du demi-epineux, ou tranſverſaire epineux du col.* See the articles SPINALIS and TRANSVERSALIS.

SPINDLE (*Cycl.*)—SPINDLE, in mining, is a piece of wood faſtened into either ſtow-blade. *Houghton*'s Compleat Miner in the Explan. of the Terms. See the article STOWS.

Theſe ſtows give a miner, or any other perſon that owns them, as good a right to a meer or meers of ground, (ſo that every meer have a pair of ſtows ſet on them) as a deed of conveyance doth to any purchaſer. *Houghton*, ibid.

SPINDLE, in ſhip-building, a part of the capſtan. See the article CAPSTAN, *Cycl.* and *Suppl.*

SPINE (*Cycl.*)—This takes in all that order of bones which follow one another without interruption, from the os occipitis downward along the poſterior part of the trunk.

It repreſents a very compound folding pillar, round on the foreſide, and on the backſide ſtuck full of prickles or points, repreſenting ſo many *ſpines*. It has a canal in the middle through its whole length, into which a great number of holes open on each ſide. When it is viewed directly on the foreſide or backſide, it appears ſtrait, and to be made up of different portions of pyramids, in a contrary ſituation to one another; but viewed ſideways, it preſents ſeveral different curvatures. The pieces which compoſe the *ſpine* are of two kinds, one ſimple, the other compound; the ſingle pieces are generally twenty four in number, called by the name of *vertebræ*; the compound pieces are two, the os ſacrum and os coccygis. The ſingle ſpecies are alſo called *true vertebræ*, to diſtinguiſh them from the portions which compoſe the other two, which are called *falſe vertebræ*. The true vertebræ are divided into three claſſes, *viz.* ſeven of the neck, twelve of the back, and five of the loins; and to theſe are given the names *cervical*, *dorſal*, and *lumbar*. *Winſlow*'s Anatomy, p. 53.

This bone, when felt through the integuments, ſeems ſometimes divided, and has given riſe to the notion of a *ſpina bifida*, or bifurcation of the *ſpine*. But ſome doubt of the exiſtence

exiſtence of ſuch a caſe, as a perfect *ſpina bifida*, ſuppoſes the very canal and *ſpinal* marrow to divide into two branches, and the *ſpinal* proceſſes to divaricate into two rows. We have a caſe in the Philoſophical Tranſactions, where the *ſpinal* marrow of an infant was found bare, without any bony covering, and which was taken for a *ſpina bifida*. See Phil. Tranſ. N° 472. ſect. 2. and N° 366. p. 98.

See, in the Mem. de l'Acad. Royale des Sciences anno 1730, ſome curious obſervations, by Mr. Winſlow, on the motions of the *ſpine*.

Cartilages of the SPINE. The cartilages of all the vertebræ in general are of two kinds, one proper to each vertebra, the other common to two vertebræ which lie next one another; the firſt may be termed the *cartilages of articulation*, the latter the *cartilages of ſymphyſis*.

The proper articular cartilages of each vertebra of the whole *ſpine* are thoſe four which cover the ſurfaces of the four ſmall articular apophyſes. In the natural ſtate they are very white and ſmooth, and much thicker than in the dried bones. Their circumference is the ſame with that of the articulated ſides of the apophyſes, except in thoſe places where there are ſmall ſuperficial notches. The vertebræ of the back, beſide the four cartilages of their ſmall apophyſes, have others which do not belong to their articulations with one another, *viz.* thoſe which cover the lateral foſſulæ in the bodies of theſe vertebræ, and the foſſulæ in their tranſverſe apophyſes, by both of which they are articulated with the ribs.

The cartilages of the ſymphyſis lie between the bodies of the vertebræ, one of them being contained between, and cloſely joined to the lower ſurface of one vertebra, and to the upper ſurface of the next under it; the breadth and circumference of theſe anſwer exactly to thoſe of the ſurfaces between which they are contained, but their height, or thickneſs, is different in each claſs of the vertebræ. In the vertebræ of the loins they are, according to the ſtature of the ſubject, a quarter or a third of an inch thick, in thoſe of the neck they are not ſo thick, and thinneſt of all in thoſe of the back. Neither are they of equal thickneſs in all their parts, thoſe of the neck and loins appear to be thickeſt on the foreſide, and thoſe of the back rather thickeſt on the contrary part; but theſe differences are moſt remarkable in the vertebræ that lie near the middle of each claſs.

The internal ſtructure of theſe cartilages is different from that of all the other cartilages of the body, and indeed they reſemble the reſt in nothing but in whiteneſs and in elaſticity. When we view their circumferences only, they appear to be one uniform maſs like the reſt, but when divided by an inciſion, parallel to the ſurface of the vertebræ, we ſee that they are made up of a great number of concentric cartilaginous rings, contained within each other, with a ſmall ſpace left between them. Theſe are cloſeſt and thinneſt near the center, and about the middle ſeem to degenerate into another ſofter kind of ſubſtance. Theſe rings do not form an entire circumference, being turned inward on the backſide, anſwerably to the poſterior ſlope in the body of each vertebra. They lie horizontally, one edge being fixed to the lower ſide of one vertebra, and the other to the upper ſide of the vertebra next below the former.

The interſtices between the rings are filled with a mucilaginous ſubſtance, leſs fluid than that of the joints, and their breadth, or heighth, is proportionable to the diſtance of the vertebræ between which they lie.

Each cartilaginous lamina taken ſeparately is very pliable, according to its length, but taken all together they are not ſo eaſily bent, partly becauſe of their circular figure, and partly becauſe of their proximity and multiplicity. They yield, however, in the inflexions of the *ſpine*, and without any inflexion to the weight of the head and upper extremities; but this is done by very ſmall degrees, and moſt of all, when the upper part of the body is loaded with any foreign weight. After theſe compreſſions they reſtore themſelves, merely by being freed from the preſſure; ſo that a man is really taller after lying ſome time, than after he has carried a burthen for a great while. Theſe ſingular obſervations of the different heights of the ſame perſon, at different times, which were firſt made in England, and afterwards confirmed at Paris by Mr. Morand, are moſt naturally and eaſily accounted for, merely by the different ſtate of the intervertebral cartilages.

The intervertebral cartilages of the neck lying, for the moſt part, between the convex ſide of one vertebra, and the concave ſide of another, are of a greater extent, in proportion to the ſize of thoſe vertebræ, than thoſe of the back and loins. The os ſacrum has no cartilage, except that between the upper ſide of the firſt falſe vertebra, and the laſt vertebra of the loins; and thoſe by which it is connected to the oſſa innominata, already deſcribed as the cartilages of that bone. The cartilages, which join the different portions of the os coccygis, are preſerved in ſome ſubjects to a very great age, but in others they very ſoon become entirely bony. *Winſlow*'s Anatomy, p. 145.

Ligaments of the SPINE. The vertebræ are ſtrongly connected to each other by three kinds of ligaments. Each vertebra is connected to thoſe above and below it by a great number of very ſhort and ſtrong ligaments, which croſs each other obliquely, and are fixed round the edges of the body of each vertebra. Theſe crucial ligaments cover the circumference of the intervertebral cartilages, and adhere cloſely to them.

The bodies of all the vertebræ, from the ſecond of the neck to the os ſacrum, are covered by ligamentary half vaginæ on the convex ſide, in which theſe vaginæ are fixed, ſurrounding all the crucial ligaments, and made up of ligamentary filaments partly oblique, but for the moſt part longitudinal. All the vertebræ are likewiſe ſtrongly connected by a ligamentary tube, which lines the inner ſurface of the medullary canal from the occipital hole to the os ſacrum; it repreſents a long flexible funnel, its cavity at the upper part being equal to that of the occipital foramen, and ending in a point at the os ſacrum. The firſt vertebra is fixed to the os occipitis beſide this, by a diſtinct and very ſtrong ligamentary covering; the ſecond has two ligaments peculiar to it, one which connects the apophyſis dentiformis to the os occipitis, and another tranſverſe, which confines this apophyſis within the anterior portion of the cavity of the firſt vertebra. The firſt may be called the occipital, and the ſecond the tranſverſe ligament of the odontoide apophyſis. Along the whole bony canal of the *ſpine*, between the baſes of each *ſpinal* apophyſis, lies a flat and very elaſtic ligament, of a yellowiſh colour, which fills up the poſterior great notches of the vertebræ, adhering to their edges, and to the neighbouring portions of the inner ligamentary tube.

Between the extremities, or apices of the *ſpinal* apophyſes, are ſmall ligamentary ropes, which go from one *ſpine* to the next, which are all really double, though they appear ſo only in the neck, being there fixed ſeparately to the forked extremities of the *ſpines*. Between all the *ſpinal* apophyſes, from their apices to the middle of their baſes, lies a ligamentary membrane, going between each two; and there is a ligament of a like kind between the two tranſverſe apophyſes in all.

The articular ligaments of the *ſpina* dorſi are thoſe which tie the glenoide cavities of the firſt vertebra to the condyles of the os occipitis; thoſe that join the cartilaginous ſurface of the apophyſis dentiformis to the anterior cavity of the firſt vertebra, and thoſe by which all the oblique, or articular apophyſes, are connected together. Theſe are all ſmall, ſhort, and ſtrong. The vertebral ligaments of the ribs, or thoſe which connect the ribs to the vertebræ, are of the ſame kind, and are inſerted round the cartilaginous foſſulæ in the body, and apophyſes of each vertebra. Beſide all theſe ligaments of the *ſpine*, there is one which goes in form of a membrane from the os occipitis, all the way to the laſt two vertebræ of the neck: this is a true intermuſcular ligament, and may be properly called the *ligamentum cervicale poſterius*. There are alſo two lateral ligaments of the ſame kind, fixed to the tranſverſe apophyſes of the vertebræ of the neck. *Winſlow*'s Anatomy, p. 147.

SPINES *of echini*, in natural hiſtory. Theſe in their foſſile ſtate make a great appearance in the cabinets of the curious, and in the works of the learned, and are of an almoſt infinite variety of kinds; and many of them are of the ſame figures and dimenſions with thoſe of the echini now living in our own and other ſeas, and well known to us. But beſide theſe there are an almoſt infinite variety of others, which though allowed on all hands to be truly *ſpines* of ſome echini or other, yet evidently differ from thoſe of all the known recent fiſh of that name, and have certainly belonged to ſpecies of it which we have not yet the leaſt knowledge of. Theſe, however different in ſhape from one another, yet all agree in their texture and conſtituent matter, both with one another, and with the foſſile remains that ſupply the places of the ſhells of the other ſpecies ſo common in our chalk-pits, all being compoſed of a plated, or tabulated ſpar. Both theſe ſhells and the *ſpines*, though they retain every outer lineament of the bodies they owe their form to, yet have they nothing of their interior texture, nor any the leaſt reſemblance of it, but are compoſed of plates ſet edgewiſe, or aſlant, in the ſhells, and in the *ſpines* always obliquely to the axis of the body; ſo that all the foſſile *ſpines of echini* break regularly in an oblique direction, and always ſhew on each part a perfectly ſmooth and gloſſy ſlanting ſurface.

Of the foſſile *ſpines of echini* ſome are long and ſlender, tapering from a broader baſis to a fine point, and ſometimes from a thick part, at or near the middle, to an obtuſe point at each end: theſe are uſually ſtriated, ridged, or furrowed, and often elegantly granulated, though ſometimes they are ſmooth. Theſe moſt reſemble the *ſpines* of the more common ſpecies of recent or living echini we are acquainted with; others of them are of very different and very ſtrange figures; ſome are of the ſame length with the common long ones, but are very flat, and are ridged more or leſs high, or covered with tubercles of different ſhapes; others are ragged, and variouſly jagged, and knotted like a rough branch

branch of fir ſtript of its leaves, or that ſort of fucus called the *ſea ragged ſtaff*. Another very common kind in ſome parts of the world, eſpecially in Syria, but leſs frequent with us, is the body called by authors *lapis judaicus*: theſe are ſuppoſed, in ſome ſort, to reſemble an olive, ſwelling from a ſhort ſtalk to a large thick and ſhort body of an oval figure, and marked very elegantly with longitudinal furrows, and in the different ſpecies with very differently ſhaped tubercles. Of this ſhape there are alſo ſome perfectly ſmooth.

We have alſo with us great numbers of a kind approaching to theſe, but having longer ſtalks and ſmaller bodies, and theſe we meet with of all ſizes, from three inches in length down to the bigneſs of a barley-corn; and there are at times found ſome of all the intermediate figures, between theſe tumid ones and the long and ſlender ſort.

We have numbers alſo of various lengths, and variouſly ſurrounded with granulæ of a ſhape nearly cylindric, and beſide the bodies themſelves, we meet with impreſſions of all the kinds on our flints in gravel-pits. The *ſpines* themſelves are uſually bedded in the ſtrata of chalk, though ſometimes they are found in the ſtone-quarries, and ſometimes, but that moſt rarely, bedded in clay, or looſe among gravel. *Hill*'s Hiſt. of Foſſ. p. 652.

SPINNING (*Cycl.*)—The art of *ſpinning*, which nature has given to many animals of different kinds for their preſervation and other purpoſes, is not confined to the inhabitants of the earth or air alone, but is even extended to thoſe of the ſea. Mr. Reaumur has ſhewn, by a ſeries of curious experiments, that the common muſcle, and ſome other ſhell-fiſh of the ſea, poſſeſs it in a great degree of perfection. See the article MUSCLE.

But he obſerves, that though the workmanſhip is the ſame, the manner of producing it is very different. Spiders, caterpillars, and the like, make threads of any length that they pleaſe, by making the viſcous liquor, of which they are formed, paſs through a fine perforation in the organ appointed for this *ſpinning*: but the way in which the muſcles form their threads is very different, as the former reſembles the work of the wire-drawer, ſo this does that of the founder, who caſts metals in a mould. The canal of the organ, deſtined for the muſcle's *ſpinning*, which from its ſhape is commonly called its tongue, is the mould in which its thread is caſt, and gives it its determinate length. Mem. Acad. Par. 1711.

SPINOSA, in zoology, the name by which the Italians call the porcupine. See the article HISTRIX.

SPINOSE-*leaf*, among botaniſts. See the article LEAF.

SPINOSI *piſces*, in zoology, ſuch fiſhes as have ſome of the rays of their backfins running out into thorns or prickles, as the pearch, *&c.* *Willughby*, Hiſt. Piſc. p. 271.

SPINOZISM (*Cycl.*)—We have an examination of *Spinoziſm*, and of Mr. Bayle's objections againſt this ſyſtem, by Monſ. de Jariges, in the Mem. de l'Acad. de Berlin, Tom. I. p. 121. and Tom. II. p. 295. Wolfius has alſo given a refutation of *Spinoza*, in his Theol. Nat. Part 2.

SPINTHER, among the Romans, a kind of bracelet which the women, in the firſt ages of Rome, uſed to wear on the upper part of their left arm.

SPINUS, in the natural hiſtory of the antients, the name of a foſſile body of a very remarkable quality; for according to the accounts of Theophraſtus, and other authors of the greateſt credit, if broke to pieces, and thrown in an heap expoſed to the ſun, it took fire and burnt, and that the more, if moiſtened or ſprinkled with water.

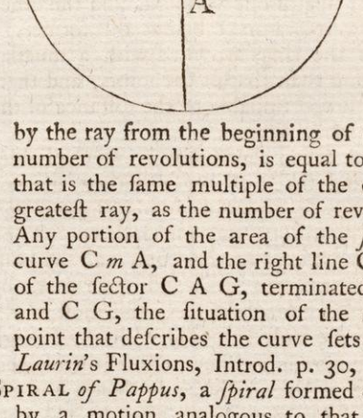
It ſeems to have been a ſubſtance nearly allied to what they called the *lapis thracius*, but with this remarkable quality, both of them ſeem to have been of the claſs of the harder bitumens, and are wholly unknown to us. Some late writers have imagined, that the common black ſlate-ſtone, ſo frequent with us in the coal-pits, was the ſubſtance called by Theophraſtus, and the antients, by this name, but it has none of the qualities attributed to the *ſpinus*. *Hill*'s Theophraſtus, p. 35.

SPINUS, in zoology, the name of a ſmall bird, called by ſome *ligurinus*, and in Engliſh the *ſiſkin*. Its head is black, and its neck and back green. The neck, however, has ſome ſlight admixture of a blackiſh tinge, and the roots of the backfeathers have alſo ſome blackiſhneſs. Its rump is of a greeniſh yellow, as are alſo its breaſt and throat. Its belly is white, and its tail is yellow underneath, with ſome browniſh ſpots. The female is paler coloured than the male, and its throat, and its ſides, under the wings, are whitiſh, with ſtreaks of brown. It is common in Germany and England, and is kept in cages for its ſinging. In winter theſe birds fly in large flocks. *Ray*'s Ornitholog. p. 192.

SPIPOLA, in zoology, the name of a ſmall bird of the lark kind, of which there are, according to Aldrovand, three ſpecies, ſuſpected by Mr. Ray to be only varieties of the *ſpipoletta*, or *tordino* of the Venetians. *Aldrovand.* de Avib. lib. 17. cap. 26. See the next article.

SPIPOLETTA, in zoology, the name of a ſmall bird of the lark kind, called *tordino* by the Venetians, and ſeeming to be the *ſtopparola*, as alſo the *griſola*, and *ſpipola* of Aldrovandus. It is ſmaller than the common lark; its head, neck, ſhoulders, and back, are of a greyiſh colour, with an admixture of green; its breaſt and belly white, and its throat ſpotted. The female differs from the male, in that her belly is yellow. The wing-feathers are of a duſky brown, with whitiſh or yellowiſh edges. Its tail is moderately long, and part of the feathers are ſnow-white, the reſt brown or blackiſh. The length of the heel diſtinguiſhes this bird from all others, except the lark kind, and it differs from all the ſpecies of larks in the colour of its beak and legs, which are black. It is common in the markets of Venice and other places. *Ray*'s Ornitholog. p. 153.

SPIRÆA, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the roſaceous kind, being compoſed of ſeveral petals arranged in a circular form. The piſtil ariſes from the cup, and finally becomes a fruit compoſed of ſeveral ſmall pods, containing oblong ſeeds.



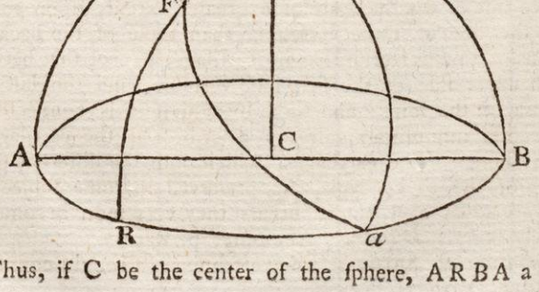
The ſpecies of *ſpiræa*, enumerated by Mr. Tournefort, are theſe. 1. The willow-leaved *ſpiræa*. 2. The opulus-leaved *ſpiræa*. 3. The *ſpiræa* with hypericum leaves, not indented. And 4. the Spaniſh *ſpiræa* with crenated leaves, reſembling thoſe of the hypericum. *Tourn.* Inſt. p. 618.

The ſeveral ſpecies of this plant are very common in our gardens, and make a very beautiful figure. They are propagated either by ſuckers, which they produce in great abundance, or by laying down the tender branches of the old plants. When they have taken root, they ſhould be removed into the nurſery for two or three years, and will then be fit for tranſplanting in the places where they are to remain. *Miller*'s Gard. Dict.

SPIRAL (*Cycl.*)—As a curve may approach continually to a right line, or to another curve, while they are both produced, and yet never meet it, ſo a *ſpiral* line may approach continually to a certain point, and not reach it in any number of revolutions, how great ſoever, that can be aſſigned. This happens in the logarithmic, or logiſtic *ſpiral*, and in ſeveral others. See *Mac Laurin*'s Fluxions, Book 1. p. 283, ſeq.

Some of theſe *ſpirals*, after having made an infinite number of revolutions, is ſaid, in the modern ſtile, to reach that certain point, and yet the length of the *ſpiral* may be finite, or equal to an aſſignable line. Propoſitions, expreſſed in this manner, ſeem the moſt myſterious of paradoxes; but the wonder diſappears, when we know it amounts to no more than that a line may continually increaſe, and yet the increments acquired may decreaſe in ſuch a manner, that it ſhall never amount to a given line.

SPIRAL *of Archimedes*. The *ſpiral* area CABDE, is equal to one third part of the circle, deſcribed with the radius CE.



In like manner, the whole *ſpiral* area, generated by the ray drawn from the point C to the curve, when it makes two revolutions, is the third part of a ſpace double of the circle deſcribed with the radius 2 CE; and the whole area, generated by the ray from the beginning of the motion, till after any number of revolutions, is equal to the third part of a ſpace that is the ſame multiple of the circle deſcribed with the greateſt ray, as the number of revolutions is of unit.

Any portion of the area of the *ſpiral*, terminated by the curve C *m* A, and the right line C A, is equal to one third of the ſector C A G, terminated by the right line C A, and C G, the ſituation of the revolving ray, when the point that deſcribes the curve ſets out from C. See *Mac Laurin*'s Fluxions, Introd. p. 30, 31.

SPIRAL *of Pappus*, a *ſpiral* formed on the ſurface of a ſphere, by a motion analogous to that by which the *ſpiral* of Archimedes is deſcribed in plano. See the article SPIRAL, *Cycl.*

This *ſpiral* is ſo called from its inventor Pappus. Collect. Mathem. lib. 4. prop. 30.

Thus, if C be the center of the ſphere, ARBA a great circle,

circle, P its pole; and while the quadrant P M A revolves about the pole P with an uniform motion, if a point proceeding from P move with a given velocity along the quadrant, it will trace upon the ſpherical ſurface the *ſpiral* P F *a*.

Now if we ſuppoſe the quadrant P M A to make a compleat revolution in the ſame time that the point, which traces the *ſpiral* on the ſurface of the ſphere, deſcribes the quadrant, which is the caſe conſidered by Pappus; then the portion of the ſpherical ſurface, terminated by the whole *ſpiral*, the circle A R B A, and the quadrant P M A, will be equal to the ſquare of A B. In any other caſe, the area P M A *a* F P is to the ſquare of the diameter A B, in the ſame proportion as the arch A *a* is to the whole circumference A R B A. And this area is always to the ſpherical triangle P A *a*, as the inſcribed ſquare is to the circle. See *Mac Laurin*'s Fluxions, Introd. p. 31—33.

The portion of the ſpherical ſurface, terminated by the quadrant P M A, the arches A R, F R, and the *ſpiral* P Z F, admits of a perfect quadrature, when the ratio of the arch A *a* to the whole circumference can be aſſigned. See *Mac Laurin*, ibid. p. 33.

SPIRINCHUS, a name by which ſome authors have called the ſmelt. *Willughby*, Hiſt. Piſc. p. 202. See the article EPERLANUS.

SPIRITS (*Cycl.*)—*Brandy* SPIRITS. *Brandy* differs from wine *ſpirit*, in that the former is drawn from the poorer and thinner ſorts of wines, the latter from the richer and fuller bodied wines. *Shaw*'s Eſſ. on Diſtil. p. 128.

Brandy alſo differs from *ſpirit* of wine, as the former is only what they call proof high, or half pure *ſpirit*, half phlegm; whereas *ſpirit* of wine is raiſed higher, or carried by rectification to a further degree of purity.

Brandy alſo differs from ſtrong waters, as the latter is a compound, whereof the former, or pure *ſpirit* of wine, is only one ingredient.

The Portugueze are lately come into the way of making *brandy* [b]. The Greek *brandies* are the worſt, though made of the beſt wines [c].—[[b] Atlas Marit. p. 154. [c] *Tournf.* Voyag. du Levant, Tom. I. let. 2. p. 35.]

The Spaniſh *brandies* are much coarſer than the French, though ſometimes made to paſs for them in Holland, and other places of great traffic [d]. Some prefer Rheniſh *brandy* to that of France; and in Holland particularly, it ſells for double the price. It is indeed a fine *ſpirit*, but the Engliſh know little of it farther, than that a daſh thereof ſerves to fill up a caſk of French [e]. Some tell us of frozen *brandy*, of which Mr. Boyle gives an inſtance in Ruſſia; but it is only the watery part that is capable of congelation. All the effect of the moſt intenſe cold on *brandy*, is to make a ſeparation between its *ſpirit* and phlegm; the former retires to the center in form of pure alcohol, while the latter inveſts it with a circumference of ice [f].—[[d] *Shaw*'s Eſſ. on Diſtil. ſect. 5. p. 139. [e] Id. ibid. p. 141, ſeq. [f] *Boyle*'s Works Abr. Tom. I. p. 594.]

Brandies always differ, according to the different ſpecies and growth of the grapes. We have various kinds of French *ſpirits*, having each their particular flavours, by which the connoiſeurs readily diſtinguiſh one ſort from another; though the vulgar call them all indiſcriminately by the name of *French brandy*. An ordinary judgment may eaſily diſtinguiſh Languedoc *brandy* from that of the iſles of St. Martin and Oleron; or Bourdeaux from Cognac. Nor would the ſimilitude between the ſeveral ſpecies of French *brandies* be ſo great as it is found, but that only the weakeſt and loweſt flavoured wines are diſtilled for this purpoſe; or ſuch as are unfit for other uſes. When out of curioſity, or good huſbandry, the French diſtil the bottoms, or refuſe parcels of the groſſer bodied and fuller taſted wines, the *brandy* got from them is what we in England rather call a wine *ſpirit*, than a *brandy*. Every kind of grape, as it affords a wine, ſo does it alſo a *brandy* of its own peculiar flavour. *Shaw*'s Eſſ. on Diſtil. ſect. 5. p. 130, ſeq.

The too free and frequent uſe of *brandy* is attended with ill effects, as it attenuates the body, and impairs the ſtrength, and ſtupifies the brain. In perſons who have died hereof, the blood has been found thick and coagulated; the pancreas dried; the liver ſchirrous, and almoſt petrified; the glands tumefied beyond their natural bulk [g], *&c.* But what ſhall we ſay to the Pariſian woman, who was burnt to aſhes with a fire only kindled from the *brandy* in her body [h]? Conringius even attributes the degeneracy of the modern from the antient Germans, to the prevelancy of drinking this liquor [i].—[[g] Hiſt. Acad. Scienc. Anno 1706. p. 29. *Barth.* Act. Med. Tom. V. Obſ. 118. p. 313. [h] Philoſ. Tranſ. N° 97. p. 6138. *Barth.* l. c. Tom. I. Obſ. 118. p. 211. [i] *Conring.* de Habit. Corp. Germ. p. 99, ſeq.]

In the hot climates of America, they are ſaid to make clyſters of *brandy*. A perſon who had experienced the uſe of one of theſe fiery enemata, made of a pint of *brandy*, aſſures us, it not only made him dead drunk, but raving mad. Phil. Tranſ. N° 37. p. 721.

Brandy is alſo applied, in a leſs proper ſenſe, to all *ſpirituous* inflammable liquors, drawn from vegetables by diſtillation. In which ſenſe *brandy* includes all ardent, or inflammable *ſpirits*, uſed in the way of beverage. Dr. Shaw adds a further limitation to *brandy ſpirits*, *viz.* that they be proof high, or conſiſt of equal quantities of water and alcohol. On which footing, *ſpirits*, either above or below proof, do not come under the appellation of *brandies* [k]. But in the popular uſe this diſtinction is not kept to.—[[k] *Shaw*'s Eſſ. on Diſtil. ſect. 5. p. 130.]

Arrac, rum, malt and melaſſes *ſpirits*, in this ſenſe, are *brandies*, though under another denomination.

In the iſland of Andros they make brandies from the fruits of the arbutus and mulberry trees. Atlas Marit. p. 176.

A patent was ſome time ago obtained for making *brandy* from carrots and parſneps; the latter of which is ſaid to have nearly reſembled French *brandy* [l]. Of late we meet with frequent advertiſements of raiſin-*brandy*, which, if really made of that fruit, is neareſt akin to wine-*brandy*.—[[l] *Hought.* Collect. Tom. II. p. 382. 461.]

Apple, or cider-*brandy*, is alſo praiſed by ſome.

Cider is found to yield an eighth part of good *ſpirits*, and if cloſe kept a year or two in a cool place, much more. Dict. Ruſt. Tom. I. in voc.

Brandy is alſo uſed to denote certain compound liquors, whereof *brandies* are the baſis.

Such are raſpberry-*brandy*, cherry-*brandy*, gooſeberry-*brandy*, &c.

Cherry-*brandy* is uſually made with black cherries, by filling a bottle half full with them, and adding *brandy* thereto till the bottle be full; this being ſhaken from time to time, within a month will be ready to drink.

If the like quantity of gooſeberries, inſtead of cherries, be put in, it makes a good *brandy*. To dulcify it, and give it a fine flavour, they alſo put in ſugar with raſpberries. Dict. Ruſt. Tom. I. in voc. *cherry-brandy*.

The French method of diſtilling *brandies* is the ſame with that practiſed by our diſtillers, in working from waſh or wines; only that the former throws a little of the natural lee into the ſtill along with the wine, which gives the *ſpirit* a flavour, on which a great part of its merit depends. *Shaw*, lib. cit. p. 132.

When *brandies* prove foul, ſeedy, or retain the taſte of certain weeds apt to grow among the vines, they draw them over again, in order to cleanſe them of that adventitious flavour: in which operation they leave out the faints, or rather change the receiver, as ſoon as the ſtream begins to run proof. Then mixing together all that run off before, they call it *trois cinque*, that is, *brandy* conſiſting of five parts alcohol, and three of flegm; beyond which the French *bruleurs*, or common diſtillers, rarely go.

The yearly export of *brandies* from France is ſaid to amount to 25000 tuns; an article of itſelf ſufficient to enrich a moderate country [m]. While the duty on French *brandy* continued at 9*l.* the tun, the Engliſh alone took 10 or 11000 tuns off their hands [n]; but now that the duty is raiſed to 52*l.* the tun, the importation is greatly reduced, to the advantage of the Engliſh Diſtillery, except that ſmuggling ſtill intervenes.—[[m] Atlas Marit. p. 146. [n] Compl. Engl. Trad. Tom. II. p. 89. Atlas Marit. p. 107. *Hought.* Collect. Tom. II. N° 387. p. 470.]

Divers reaſons may be alledged for the great fecundity of *brandies* in France. All thoſe poor grapes, which prove unfit for wine, are uſually firſt gathered, preſſed, and their juice fermented, and directly diſtilled: this rids their hands of their poor wines at once, and leaves their caſks empty for the reception of better. It is a rule with them to diſtil no wines that will fetch any price as wines, for in this ſtate the profit on them is vaſtly greater, than when reduced to *brandies*. This large ſtock of ſmall wines, wherewith they are almoſt over-run in France, ſhews one great reaſon of their making ſuch vaſt quantities of *brandy*, more than other countries, which lie warmer and better for grapes. But this is not the only fund of their *brandies*; for all the wine that pricks, or turns eager upon their hands, is alſo condemned to the ſtill; and, in ſhort, all that they can neither export, nor conſume at home, which amounts to a large quantity, ſince much of the wine, laid in for their family proviſion, is ſo poor, as not to keep the ſpending. *Shaw*'s Eſſ. on Diſtil. ſect. 5. p. 131, ſeq.

The colour of their *brandies* is acquired from the caſk, and the length of time they uſually lie therein, which is ſometimes twelve or eighteen months, and often two or three years; during which, it is no wonder if they acquire a yellow or browniſh caſt. Their lying thus long, as it were, in a ſtate of ſlow digeſtion, wonderfully takes off from that hot, acrid, and foul taſte, peculiar to all *ſpirits*, or *brandies*, newly diſtilled; and gives them a coolneſs and a ſoftneſs, not eaſily introduced by art. And on theſe properties are founded ſeveral methods of trying their goodneſs, or diſcovering whether they are debaſed or adulterated by the admixture of coarſer *ſpirits*. Phil. Tranſ. N° 391. p. 398, ſeq. *Shaw*'s Eſſ. on Diſtil. ſect. 5. p. 134.

Brandies are rarely adulterated in France, where they have no cheaper *ſpirits* to debaſe them withal; and the like holds, in great meaſure, in favour of the Dutch, though otherwiſe

wiſe ſuſpected to be great adulterators. The chief temptations for adulterating are in England, where the duties are high, and where there are various kinds of *ſpirits* in plenty to mix with them, as malt, melaſſes, cyder, and ſugar *ſpirits*, with all which they are often ſophiſticated, and ſo dextrouſly, as frequently to eſcape all the ways of detection.

Rules for diſtilling brandy SPIRITS. *Brandy*, whether made from wine, malt, ſugar, or whatever elſe, is a compound conſiſting of four different parts, which are inflammable *ſpirit*, eſſential oil, acid and water.

As theſe ſeveral parts do not differ greatly in their ſpecific gravity, or degree of volatility, a ſtrong tumultuary boiling heat will drive them all over promiſcuouſly together. As at the beginning of the operation there uſually ariſes more totally inflammable *ſpirit* than water, ſo after ſome time the ſtream contains more water than *ſpirit*. This gives the foundation for what the diſtillers call *low-wines*, *proof-ſpirits*, and *faints*.

The *low-wines* are the whole quantity of *ſpirit*, ſtrong and ſmall, mixed together; *proof-ſpirit*, a mixture of about equal parts of totally inflammable *ſpirit* and water; and *faints* are what runs after the proof is come off, which is always a mixture of more water than *ſpirit*.

The low-wines are commonly rediſtilled, to get rid of the ſuperfluous aqueous part, and are thus reduced to *brandies*, or proof-*ſpirits*. The faints may alſo be ſerved in the ſame manner; and by this means the produce of the diſtillery, which in the ſtate of faints, or low-wines, could not be judged of, as to its intrinſic value, is reduced to a certain ſtandard, and marketable ſtrength.

In the diſtilling the fermented liquor, when once the ſtream falls from the ſtrength of proof-*ſpirit*, there immediately begins to riſe with it a coarſe and nauſeous oil, which, though not ſo communicative as the firſt, never fails to impregnate the whole ſtream with its flavour. Hence all common *ſpirits*, or *brandies*, are what the chemiſts call dilute quinteſſences; that is, they are mixtures of the ardent *ſpirit* and eſſential oil of the concrete, only here let down to proof with water, and impregnated with a ſmall proportion of a volatile acid. As ſoon as the proof falls off, the liquor grows milky; that is, the oil, which before remained diſſolved in the ſtrong *ſpirit* is let looſe by an over proportion of water, and may be commodiouſly ſeparated by the chemical glaſs made for that purpoſe.

The common cuſtom of the diſtillers is to continue the diſtillation, as long as the liquor that runs off will take flame at a candle applied to the vapour of a ſmall quantity thrown on the hot head of the ſtill; and indeed there is a certain point of time, after which the *ſpirit* that comes will not pay for the fire and labour, as not more than from a twelfth to a twenty fourth part of the *ſpirit* will come over in the water. With other views, however, ſuch as the obtaining a more fixed vegetable acid, and a groſſer eſſential oil, the operation may be continued till the danger of an empyreuma comes on.

The matter remaining in the ſtill, after the operation is ended, has ſeveral uſes, and may in particular be made to afford Mr. Boyle's acid *ſpirit* of wine.

When by repeated diſtillation, without addition, any *ſpirit* is entirely freed from its aqueous part, it is then called *alcohol*, *totally inflammable ſpirit*, *rectified ſpirit*, or, in the vulgar phraſe, *ſpirit of wine*. On theſe general obſervations, it will be eaſy to form ſome new practical methods for the improvement of diſtillation, as uſed in the way of making inflammable *ſpirits*, or *brandies* for ſale.

As the fermented liquor affords different parcels of matter of different degrees of ſpecific gravity, and of volatility, when a pure ſeparation of the lighteſt part is intended, the fire ſhould never be raiſed to a boiling heat, which jumbles and confounds all the parts together, rather than ſeparates them.

In the chemical way this rule may be practiſed to great advantage, but great difficulties will attend the obſervance of it in the common buſineſs of diſtillation. To render it more commodiouſly practicable, theſe two methods may be propoſed. 1. The encreaſing the height of the ſtill above the liquor. And 2. the working by a balneum mariæ, inſtead of a naked fire.

As to the firſt method it has been expected, that by raiſing the ſtill-head to the height of two or three yards above the liquor, a boiling heat would carry up the pure inflammable *ſpirit*, without any conſiderable mixture of phlegm, and yet continue to run in a full ſtream from the noſe of the worm: but this does not anſwer to expectation in all particulars, but all the attempts that have been made towards it ſhew, that the method is ſtill improveable. The ſerpentine-pipe, uſed in this ſort of diſtillation by Lemery, and ſome others, though it occaſions the *ſpirit*, as it creeps up, to depoſit a great part of its phlegm, yet has this great objection attending it, that the *ſpirit* itſelf will not riſe in it without a boiling heat, which never ſhould be uſed in a ſimple ſeparatory diſtillation, becauſe it throws up ſo much oil, as to foul at leaſt the breaſt and head of the ſtill, and bottom of the pipe, whence it infects the ſubſequent *ſpirit* that waſhes them.

It is evident that this method may be brought to a greater perfection than it yet has been, but the other method, by the balneum mariæ, is preferable on ſo many accounts, that it is better to bend our thoughts this way in attempting the improvements ſo much wanted, and which would be ſo beneficial.

By a proper regulation of the balneum mariæ, we may hope for a pure *ſpirit* almoſt at the firſt extraction. Such an expectation will not appear unreaſonable to any one, who will compare the *ſpirit* drawn in the common method by the balneum mariæ, where the water is made to boil violently all the time, with another parcel of the *ſpirit* prepared from the ſame fermented liquor by the hot ſtill. The difficulties of working from waſh, in this way of the balneum mariæ, are indeed very conſiderable, eſpecially in regard to the common malt-diſtillers, with whom cheapneſs and diſpatch are the only things in view; for to work at the ſame time both quick and perfect, is an art not yet learned in the diſtilling trade.

The whole application of the balneum mariæ, in this matter, depends on a ſuitable engine and apparatus, and perhaps a large and long rectangular boiler might be commodiouſly turned into the ſort of balneum we are recommending; and this might be fitted with a great number of low alembics, which would work day and night with a very little fire, and ſtill leſs attendance. The contrivance in general is obvious; but the great art would be the avoiding encumbrance and loſs. A large number of ſtills are abſolutely neceſſary, but no worms or refrigeratories are required to them, and by an eaſy apparatus, the large number of theſe ſmaller ſtills may be charged with as much eaſe as one great one. When the operation proceeds ſo ſlow, as not to anſwer the coſts, the bottoms of all theſe ſtills may be emptied into one large common ſtill, and worked off in the uſual way for a coarſer commodity, that may afterwards be rectified.

In order to procure the *ſpirit* from the ſmaller ſtills perfectly pure, the water of the balneum is to be not quite ſcalding hot.

By this means, when tried in little, a ſurpriſingly cool and almoſt inſipid *ſpirit* has been obtained at the very firſt extraction, though mixed with a conſiderable proportion of phlegm, ſo that it required no manner of rectification to fit it even for the nicer uſes. The method is curious and uſeful, though it were found worth while thus only in ſmall; but will become greatly beneficial to the large dealer, if it could be reduced in the ſame methods to practice.

In the common method of ſimple diſtillations, all means ſhould be uſed to prevent the groſſer eſſential oil from getting into the *ſpirit*.

Theſe means have regard to the preparation of the fermented liquor, the regulation of the fire in diſtilling, the uſe of percolation, and the keeping out the faints.

As to the manner of preparing the fermented liquor, and clearing it of its groſs oleaginous fæces, before it is committed to the ſtill, the beſt method is to let it ſtand ſome time after the fermentation is wholly over, that it may depoſit all that it can, and become as thin and limpid as may be; and one great means of arriving at a perfection in this reſpect, is the making the liquor ſufficiently thin; if it be too thick and rich of the ingredient, the *ſpirit* muſt be coarſe. The liquor thus prepared, muſt never fill above two thirds, at the utmoſt, of the ſtill. A boiling heat is neceſſary in this operation; but then care muſt be taken that this be not carried too far, and that the whole proceeds uniformly and regularly. The fire muſt be kept as even as poſſible, and never raiſed by ſtarts; for that never fails to throw over the coarſe oil, and foul the *ſpirit*; ſo that, if poſſible, the operation ſhould begin and end with the ſame uniform and invariable degree of heat.

Another method of keeping the groſſer oil, at leaſt in ſome degree, from mixing itſelf with the *ſpirit*, is by ſtretching a piece of very thick and woolly flannel over the mouth of the ſtill, or by ſuffering the ſteams to paſs through the ſame ſort of flannel ſeveral times doubled, and placed at the noſe of the worm. It is ſurpriſing what a large quantity of groſs fetid, offenſive, and unctuous matter will be thus collected, eſpecially in the diſtilling of malt *ſpirits*.

The faints ſhould never be ſuffered to run among the finer *ſpirits*, on account of the large quantity of this groſs oil, or greaſy matter, they contain; eſpecially if the fire be encreaſed, as it uſually is, in order to bring them over. Some of the larger dealers, who value proof more than purity, will always have a doſe of this to give their goods a face, and keep up a head a proper time. This prevailing fondneſs for a ſtrong proof, however abſurd in itſelf, is one great reaſon why the generality of malt *ſpirits* are no clearer. This caution of keeping out the faints ſhould alſo extend to the keeping out a little of the firſt running, which alſo, in this operation, is a kind of faints, as containing largely of the oil of the concrete, though much more ſubtle than that in the proper faints. A farther regard muſt alſo be had to the ſtill-head and worm, through which the faints have once paſſed, as theſe depoſit in the head, and along the whole

length of the worm, a coarſe and nauſeous oil, which will give a diſagreeable flavour to a very large quantity of pure *ſpirit*.

When the worm is once infected with this oil, it penetrates ſo deep into the pores of the metal, that a ſimple waſhing will not get it out, but rather it ought to be filled with a lixivium boiling hot, or elſe ſome pure and highly-rectified *ſpirit* ſhould be put into it, and left in it a whole night, to imbibe and carry off with it the oil. Theſe are cautions that may ſeem trifling, but they are in reality of ſo much conſequence, that if rightly attended to, a much purer *ſpirit* will be drawn off this way, than by any other common method. *Shaw*'s Eſſay on Diſtillery.

Proof SPIRITS, or *common ſaleable goods*, are *ſpirits* of any kind of a determinate ſtrength, being the ſame with that of good brandy, and the malt and ſugar *ſpirits* of the diſtillery, as they are uſually ſold; containing equal quantities of rectified *ſpirit* and water.

The common method of examining whether *ſpirits* have this due degree of ſtrength is this. Take a long vial, fill it half way with the common malt *ſpirit*, and give it a ſmart ſtroak by its bottom againſt the palm of the hand, there will then appear on the ſurface a chaplet, or crown of bubbles, which will go off again in a ſtrong manner; that is, firſt remaining a while, and then going off by degrees without breaking into ſmaller bubbles, or ſwelling into larger.

By this experiment all the traders in *ſpirits* judge of the ſtrength of the goods they purchaſe, yet this is a mere fallacy and deception; for if only a little vinous, or ſaccharine matter, as treacle, ſyrup, muſt, rob of fruits, or the like, be added to a quantity of highly-rectified *ſpirit* of wine, this ſlight addition will give a brandy proof to that *ſpirit*.

Whether there be any ſecret for making weaker *ſpirits* ſhew this proof, as well as brandies, *&c.* is not certainly known, but the thing is certainly practicable, ſince arrack, which is but of half the ſtrength of brandy, gives as fair a proof this way; and if a drop or two of any eſſential oil be added to a pint of brandy, it takes off its proof, and makes it appear much weaker than it is. The true ſtrength may, however, always be known, by carefully burning away a meaſured quantity of brandy, *&c.* ſince if it leaves one half water, it is right, if more or leſs, it is too ſtrong, or too weak.

But beſide the falſe method of judging of brandies by what is called *proof*, there is another not leſs fallacious one of judging of their goodneſs, though kept as a great ſecret in the hands of ſome dealers, and imagined a certain criterion to determine whether foreign brandies are mixed with corn *ſpirits*. Theſe diſtillers are provided with a certain yellow liquor, a few drops of which being poured into a glaſs of right French brandy gives it a beautiful blue colour, and by the ſtrength, and goodneſs of this colour, they judge and buy; but if common malt *ſpirit* were tinged with oak, it would give this colour equally with French brandy, and might be purchaſed as ſuch. This proof-tincture is expeditiouſly made, by diſſolving a little green vitriol, firſt calcined to a redneſs in a weak *ſpirit* of ſea-ſalt, which thus becomes a yellow liquor, a ſingle drop or two of which being added to a glaſs of any inflammable *ſpirit*, coloured yellow or brown with oak, or with long remaining in the caſk, will inſtantly turn it of a bright and beautiful blue.

The beſt way of judging in theſe caſes is by the noſe and palate. Dilute a quantity of brandy conſiderably with water, and you will perceive the malt-taſte, if mixed with malt *ſpirits*; or burn a little in a ſpoon, and by the ſmell and taſte of the water it leaves, you will eaſily judge whether there be malt in it. *Shaw*'s Lectures, p. 125, 126.

Proof ſpirits may be diſtinguiſhed into three kinds, *perfect proof*, *more than perfect proof*, and *leſs than perfect proof*. By *perfect proof* is uſually underſtood that crown of bubbles, before mentioned, of a certain ſize, ariſing as a head upon a ſmall quantity of a well-qualified *ſpirit* ſhook in a ſlender vial.

Proof more than perfect, is that in which the bubbles, raiſed by ſhaking the *ſpirit*, are larger than thoſe on the common or perfect proof, and go off more ſuddenly; that is, according as the *ſpirit* is higher, or approaches more to the nature of rectified *ſpirit*, or, as it is uſually called, *ſpirit of wine*.

Proof leſs than perfect, is that wherein the bubbles are ſmaller, and go off quicker and fainter than in perfect proof; the *ſpirit*, in this caſe, being mixed with more than its own quantity of phlegm, or is too poor for ſale.

In commerce, with regard to *ſpirits*, it would certainly be a much better method to aboliſh ſuch uncertain proofs, and to make all the goods of the ſtrength of what we call *ſpirits of wine*; that is, a totally inflammable *ſpirit*, whoſe purity is much greater, whoſe ſtrength may always be found out with exactneſs, and whoſe bulk, ſtowage, carriage, and encumbrance, would be only half, in regard to that of *brandy* or *proof ſpirit*; and it might at all times, as occaſion called for it, be mixed into a great variety of extemporaneous liquors, and the exact degree of ſtrength would be always preciſely known. See the article *Rectified* SPIRITS, infra.

This operation indeed, in the common way, proves ſo tedious and expenſive, and, after all, ſo ſhort of expectation, and ſo generally unſatisfactory, that it is not to be expected that the common diſtillers, till they have fallen into a better manner of working, ſhould come into the propoſal. But if, inſtead of the common way of rectifying by the hot-ſtill, they would try the uſing a large balneum mariæ, made of a large rectangular boiler, and a ſet of tall conical veſſels, they will find that little fire, and little attendance, and conſequently very little expence, will, in this manner, furniſh them with *ſpirits* reduced at once to this ſtandard, and greatly ſuperior, in all reſpects, to the common ones of the ſame ſtrength. In this caſe there would be no need of any addition of ſalts; but the diſtiller may work more perfectly, and more expeditiouſly without them, and thus preſerve the fine eſſential vinoſity of the *ſpirit*, which in the common way of working they conſtantly loſe.

The advantage of this method would be yet greater to the apothecaries, and the makers of compound cordial waters, who want only a pure *ſpirit* of ſuch a ſtrength, and ſuffer greatly in the fineneſs and perfection of their commodities, by the *ſpirit* they are obliged to uſe having in it a fulſome and nauſeous oil of its own, which will always mix itſelf with their compoſitions, and the oils of the aromatics, *&c.* which they add to it. If *ſpirits* were brought to this ſtandard for the market, there would be no poſſibility of deceit, and no farther examination need be made of it by the buyer, than its burning perfectly dry in a ſpoon. *Shaw*'s Eſſay on Diſtillery. See the article STRENGTH.

It is however to be obſerved, that though the burning *ſpirits* away in a ſpoon may ſerve the trader in the common way, yet Mr. Geoffroy has obſerved that they are no proofs for the philoſopher, or the chemiſt, being not at all determinate or exact, though commonly ſuppoſed ſo.

From what has been ſaid, it appears that brandy is much more inflammable than wine, and *ſpirit* of wine much more ſo than brandy, and ought to burn away without leaving any remainder. Hence it is vulgarly ſuppoſed, that ſuch *ſpirit* of wine as burns wholly away contains no phlegm, and that if two parcels of *ſpirit* both burn wholly away in this manner, they muſt be the ſame in ſtrength, and in all their qualities; but Mr. Geoffroy has proved by experiment, that ſuch *ſpirit* as burns wholly away, does yet contain a great deal of water, and that two parcels both may burn thus away, and yet be very different; and that this trial is not determined by the entire abſence of the phlegm, but by its proportion to the oil.

If the ſame *ſpirit* of wine, which in the common way of burning leaves no water, be again tried, by burning it in a hollow veſſel ſet to float in a large quantity of cold water, it will then leave a conſiderable quantity of water; nay, all that is rectified only in the common way leaves a large portion of phlegm on this experiment. The plain reaſon of which is, that this is the only fair trial, the other in the common way being fallacious. In this there is no more water left than was in the *ſpirit*; but in the other, the veſſel becoming heated by the burning of the *ſpirit*, that heat gradually evaporates the water, as the *ſpirit* burns away; ſo that the one is as ſoon gone as the other. But keeping the veſſel cool by external water, prevents that evaporation, and conſequently retains and diſcovers all that cannot burn of the *ſpirit*.

The quantity of water thus diſcovered in *ſpirit* of wine is very great, and it has always been found, that in proportion as the experiment has been made more and more perfect, the *ſpirit* has always appeared proportionably leſs and leſs ſo.

The quality of the phlegm that is left, is alſo of uſe to judge of the *ſpirit* by; if that were perfectly fine, this ought to be perfectly limpid and clear, and without taſte or ſmell: as it wants either of theſe properties, it is a proof of the want of perfection of the *ſpirit* it is obtained from; but the greateſt of all its defects, is its having a coarſe oil ſwimming upon it, and giving the colours of the rainbow in different lights. Mem. Acad. Par. 1718.

Rectified SPIRIT, or *alcohol*. A perfectly *rectified ſpirit* of wine, or ſuch as is entirely freed from water, is a thing of frequent and neceſſary uſe in the nice operations of chemiſtry.

It had uſed to be prepared, either by often diſtilling the *ſpirit*, and every time drawing over only half of it, and repeating this till the half remaining in the cucurbit appeared as ſtrong as that drawn over; or elſe by raiſing it to a great height from the body of the veſſel, and this in a very gentle heat, ſo that *ſpirit* alone could riſe, the water not being capable of being driven ſo far by that degree of heat.

But the accurate Boerhaave always found upon trial, that there was ſtill remaining ſome water in theſe *ſpirits*, whether prepared by the firſt or ſecond proceſs, or both. *Boerhaave*'s Chem. Part 2. p. 124.

The method he therefore invented is this: fill a ſtill half full with the *ſpirit* prepared for *alcohol* in one or the other of theſe ways, add to it half a pound of pure decrepitated, and perfectly dried ſea-ſalt; put this in hot, then place on the head, and carefully lute the junctures; leave this for twelve hours in a heat ſo ſmall, as not to make the *alcohol* boil, then diſtil off the *ſpirit*; keep the firſt two ounces apart, becauſe ſome aqueous vapour may have happened to lodge in the head, or worm of the ſtill, which this certainly waſhes off; after this receive two thirds of the following *alcohol* into a pure dry glaſs-veſſel, and keep it perfectly ſtopped; then draw off the remainder, and keep that by itſelf: there will remain a moiſt ſalt in the ſtill, which has attracted the aqueous matter of the *alcohol*, and held it ſo down, that it could not riſe by the heat of boiling water, which is all that muſt be uſed in this diſtillation; and the ſalt having been firſt decrepitated, never makes any change in the *alcohol*, by adding any thing thereto. By this means an *alcohol* is prepared perfectly pure, and fit for all the uſes of chemiſtry.

The *alcohol* thus perfected is the lighteſt of all fluids next to air; it is extremely pellucid, thin, and ſimple, and is totally inflammable, burning without ſmoak, and without leaving any fæces behind. It has no diſagreeable ſmell in the burning, remains the ſame after diſtillation, is very expanſive with heat, eaſily boils over the fire, is of a grateful odour, and agreeable taſte. This fluid inſtantly coagulates all the juices of the body, except pure water and urine; it hardens the ſolid parts of the body, and preſerves both the ſolids and fluids from putrefaction, or ſpontaneous reſolution; it preſerves the bodies of birds, fiſhes, inſects, and other animals ſuſpended in it, perfect for ages. It mixes almoſt uniformly with water, vinegar, any acid liquors, oils, and pure volatile alkaline ſalts; and diſſolves gummy and reſinous bodies. Hence we are acquainted with no liquor, either natural, or produced by chemiſtry, which will mix with more bodies.

It is in particular an excellent vehicle for the preſiding *ſpirit* of vegetables, as by means of it that *ſpirit* may be commodiouſly extracted from its own body, and fitted for medicinal purpoſes. In the living human body it wonderfully raiſes, gratefully affects, and ſtirs the animal, natural, and vital *ſpirits*, whence it gives encreaſe to the ſtrength, ſenſes, and agility; but by its power of coagulating the blood, ſerum, and other juices, it may kill by being imprudently taken. It inſtantly ſtops bleeding, by at once contracting the veſſels, and coagulating that blood which it touches at the mouths of them; and hence it is a ſudden and powerful remedy in theſe caſes.

If the parts of animals, or vegetables, ſuſpended in *alcohol*, contain any thing oily in them, the *alcohol* immediately extracts it from the matter, which thence becomes ſhrunk, wrinkled, and withered; but ſmall birds with their feathers on, and fiſh that are well covered with ſcales, remain perfectly preſerved in their recent form, by being plunged in hot *alcohol*. When they have been long enough in the *ſpirit* to be perfectly penetrated by it, they may be taken out and dried in a ſlack oven, and afterwards put up in empty glaſſes well ſtopped, where they will remain beautiful ſpecimens for ages. *Boerh.* Chem. Part 2. p. 126.

Alcohol being required on many occaſions to be perfectly pure, and free from the leaſt drop of water, it may be proper to add here the true and infallible rules of judging when it is ſo. Theſe are the following.

1. If any oil be contained in the *alcohol*, it turns milky on being mixed with water.

2. If it contains any acid; when a little of it is mixed with *ſpirit* of ſal armoniac, there will be an effervеſcence, otherwiſe there will be only a ſimple coagulation; and if any thing alkaline be contained in it, this will be diſcovered by the mixing it with acids; as for the other ſalts, they are ſcarce ever contained in the *alcohol*.

Theſe are the teſts of ſuch admixtures, but they are the leaſt common; water is the moſt frequent, and moſt to be ſuſpected in it, and this is the moſt difficult to be diſcovered. To this purpoſe a little of it is to be fired in a ſpoon in a ſtill place, where there is no wind moving, and if no water be left in the ſpoon, this is a fair ſtep toward its anſwering expectation: this, however, alone is by no means to be depended upon. Gunpowder alſo put into a ſpoon, and covered with *alcohol*, if when the whole is burnt away it takes fire, gives another proof that there is but little water contained in it; but this does not prove, any more than the former, that there is none. After theſe trials, the ſureſt is this: take a round chemical vial, capable of holding four or ſix ounces, and having a long neck; fill two thirds of this with *alcohol*, and add to it a drachm of pure ſalt of tartar well dried, and heated very hot; ſhake them well together, and hold them over the fire to make them juſt ſo hot, as that the *alcohol* does not quite boil. If after this the ſalt of tartar is perfectly dry, we may be aſſured that the *alcohol* contains no water, or if any, not to be diſcovered by any experiment hitherto known, unleſs by the water collected from its flame when perfectly burnt.

If after the ſalt of tartar has remained dry ever ſo long at the bottom of this pure *alcohol*, only a drop or two of water be added to it, the ſalt immediately becomes moiſt, and hangs about the bottom and ſides of the veſſel. To this it is to be added, that this pure *alcohol*, when diſtilled, gives no appearance of itſelf, either in the head or neck of the alembic, nor on the ſides of the receiver; neither appearing like the aqueous fluids in moiſt drops, nor like good *ſpirit* of wine, running in veins, but remaining inviſible to the eye, except at the bottom of the receiver. This property of *alcohol* was known to the antient chemiſts, as appears by their writings. *Boerhaave*'s Chemiſtry, Part 2. p. 127.

Water is a ſolvent to *alcohol*, or *ſpirit* of wine, in certain circumſtances, but not ſpontaneouſly, or in all mixtures. If water be gently poured into it, it does not diſſolve it, or mix itſelf with it, but falls through it, and collects itſelf into a ſeparate body at the bottom of the veſſel; as ſoon, however, as they are ſhook together, the *alcohol* begins to blend with the water, though at firſt, or with a little ſhaking, it only is diſperſed in form of unctuous veins through the body of the water, but by continued ſhaking, they perfectly unite. As *alcohol*, therefore, is a pure vegetable oil, produced by a perfect fermentation, its nature is thus perfected, ſo as not only to burn in the fire, but to mix perfectly and eaſily with water: but water impregnated with ſalts will not diſſolve *alcohol*, for a ſtrong ſolution of ſalt of tartar in water, will not be brought to mix with *alcohol* by any ſhaking, nor even by boiling together; but as ſoon as the mixture has ſtood a little, the *ſpirit* gets to the top, and remains perfectly unmixed with the water. Salt of tartar unites itſelf more intimately than many other ſalts to water; and if another ſalt, which more eaſily ſeparates from water, ſuch as Epſom ſalt, be, in the place of ſalt of tartar, diſſolved in water, though the ſolution be ever ſo ſtrong, the liquor will diſſolve *alcohol*; and on their being mixed together, the whole will become turbid and white, and the ſalt will be precipitated in cryſtals. *Boerhaave*'s Chem. Part 1. p. 452.

Water has alſo this remarkable quality, that if mixed with *alcohol*, in which any eſſential oil has been diſſolved, it ſeparates the oil from the *alcohol*. Thus if oil of cinnamon be diſſolved in pure *alcohol*, and water be let fall into this ſolution, the mixture preſently becomes white and opake, though it was perfectly pellucid before; and the oil ſeparates itſelf from the *alcohol*, and gathers into a body. Hence it appears, that *alcohol* is diſqualified by water for the diſſolving of theſe oils; that it alſo more eaſily and readily unites with water than with them; and finally, that theſe eſſential oils, while they appear to be wholly diſſolved in the *alcohol*, and no longer look like oils, but like *ſpirit*, yet are really oils, and eaſily ſeparable in their true form. *Boerh.* Chem. Part 1. p. 453.

Proof *ſpirit* cannot be uſed for burning in lamps, for diſſolving roſins, for making varniſh, and there are a great number of tinctures, ſolutions, and mixtures, for which it cannot ſerve; but *alcohol*, beſide its ready uſe in the medicinal way, may, when the *ſpirit* is of a proper kind, be made into punch, and all other mixtures, with more purity, and a great deal more certainty and exactneſs in point of ſtrength. *Shaw*'s Eſſay on Diſtillery.

Colouring of SPIRITS. The art of giving to diſtilled liquors a colour, which takes off their watery appearance, and gives them a reſemblance of the foreign brandies, *&c.*

The colouring is not only neceſſary on this account, but as we uſually eſteem the *ſpirits* by the proof of the crown of bubbles, it is found that the clean rectified *ſpirit* will not afford this proof till it has received its doſe of the colour. The diſtillers diſpenſe this colour in any proportion that they find convenient or neceſſary: it is always yellow, but according to the degree differs extremely in deepneſs, from the paleſt ſtraw colour to the deepeſt orange. This art of colouring was firſt introduced, from obſerving that all the fine and ſoft foreign brandies, that had the mellowneſs neceſſary to their perfection to the taſte, had alſo a yellow colour. The colour, in this caſe, has indeed nothing to do with the flavour; but that being kept in caſks the ſame age that was neceſſary to give them this mellowneſs, would alſo give them a colour from the wood. It was hence ſuppoſed, that the particular excellence of the foreign brandies depended on the woody colour, and accordingly have been taken to give the ſame colour to our *ſpirits*, by various methods.

The way of obtaining it, by many years ſtanding in the caſk, proved too tedious for our haſty workmen, and accordingly they provided means of giving it extempore by ſtrong tinctures of ſeveral ingredients; the chief of which are logwood, ſaffron, Japan earth, treacle, burnt ſugar, and oak chips: the three former of theſe have but little to recommend them, but the others are found very ready, and very proper for the uſe.

Treacle gives a fine colour, not much unlike that of the foreign brandies, and being neceſſarily uſed in a large quantity, as its colour is but dilute, it not only mends the bubble,

or bead proof, impaired by the rectification, but alſo gives it a fullneſs in the mouth; both which properties are very agreeable to the vulgar, who are the chief retail conſumers of theſe coarſe goods.

Burnt ſugar, that is, ſugar diſſolved in a little water, and ſcorched over the fire till it turns black, goes much farther in the colouring than treacle, and at the ſame time gives no ſweetneſs, but rather an agreeable bitterneſs; and thus recommends itſelf to the nicer palates, that are not for a luſcious *ſpirit*. Indeed ſugar, thus treated, tinges to a great perfection, and that without loſs of time, and with as much cheapneſs as can well be deſired.

The laſt article mentioned, namely, oak chips, is of all others the moſt natural for the imitating the dye of foreign *ſpirits*, as it is the very wood whereof the caſks they come over in are made, and from which they take that colour we are ſo fond of. The colouring with oak has alſo this farther advantage, in *ſpirits* meant as ſophiſtications of the foreign ones, that it will ſtand ſome teſts uſually had recourſe to on the occaſion, which the others will not ſtand.

Common *ſpirit* poured on oak chips, and digeſted in a moderate heat, eaſily fetches out this reſinous part of the wood, on which the colouring depends; but then it does not go near ſo far as the burnt ſugar; a large quantity of oak being required to colour a ſmall parcel of brandy, or *ſpirits*. It is adviſeable not to make the tincture every time, but to have recourſe to an extract of this wood in a liquid form: this extract is beſt made in two menſtruums, alcohol and water, and may be evaporated to any ſtrength, ſo that a very ſmall doſe of it will tinge a great quantity of liquor. The two liquid extracts muſt be mixed together, and as they will be apt to ſeparate in ſtanding, it will be proper to add to them, when newly made, a quantity of fine ſugar; this will give a body to the whole, and it will keep better from mouldineſs than it would without it. *Shaw*'s Eſſay on Diſtillery.

Convertibility of SPIRITS. This is a doctrine that has obtained among many of the moſt curious experimenters, and indeed the moſt intelligent of our chemiſts have always allowed, that provided proper care were taken in the getting together the materials, one *ſpirit* may always be changed into another, as brandy into rum, malt *ſpirit* into brandy, and brandy into malt *ſpirit*. The principles on which this is believed are theſe.

All ſimple *ſpirits* (as they are called) conſiſt of four parts, water, oil, phlegm, and alcohol: the laſt of theſe is the eſſential part, and is what conſtitutes the whole a *ſpirit*. In reducing *ſpirits*, therefore, to their utmoſt degree of ſimplicity and purity, it is evident that the three ſuperfluous parts are to be got rid of, and the fourth left alone; by this means the alcohol is procured diſtinct, and is a liquor *ſui generis* of many peculiar qualities, not to be found in any other fluid.

Among others it has theſe remarkable properties. 1. When abſolutely purified, it is an uniform and homogene liquor, capable of no farther ſeparation, without loſs or deſtruction of ſome of its homogeneous parts. 2. It is totally inflammable, having no ſoot, nor any moiſture behind. 3. It has no peculiar taſte or flavour, any more than pure water, except what is owing to its nature as alcohol, or perfectly pure *ſpirit*. 4. It is an unctuous and criſpy fluid, running veiny in the diſtillation, and its drops rolling on the ſurface of any other fluid, like peaſe upon a table, before they unite. 5. It appears to be the eſſential oil of the body it is obtained from, broken very fine, and intimately and ſtrongly mixed with an aqueous fluid, which is aſſimilated, or changed in its nature in the operation. 6. And laſtly, it ſeems to be a kind of univerſal fluid, producible with the ſame properties from every vegetable ſubject; but to produce it thus, requires ſome care in the operation.

On theſe principles is founded the opinion, that all *ſpirits* may be reduced to a perfect ſimilarity, or ſameneſs, from whatever ſubject they were procured, and on this depends their convertibility into one another; for when once they are brought to this ſtandard of ſimplicity, there needs nothing more than to add the oil of ſuch of the finer *ſpirits* as is required to convert the *ſpirit* into that particular kind. By this means the ſame taſteleſs *ſpirit*, whether obtained from malt, ſugar, or grapes, may be made into either malt *ſpirit*, brandy, or rum, by adding the eſſential oil of the grape, ſugar, or malt; and thus what was once malt *ſpirit*, ſhall become brandy, or whatever elſe the operator pleaſes.

Many methods have been attempted to obtain the firſt point, that is, the reducing the *ſpirit* to perfect and pure alcohol. The moſt practicable means ſeem to be long digeſtion, and the repeated diſtillation from water into water, where the eſſential oil will at once be left upon two ſurfaces, and the acid imbibed. The ſhorter ways are thoſe by rectifying from neutral abſorbent ſalts and earths; ſuch are ſugar, chalk, and the like. And laſtly, the uſe of fixed alkalies may be tried, for theſe very forcibly keep down both the phlegm and oil; inſomuch that this laſt method promiſes to be the ſhorteſt of all, if the art were known of utterly aboliſhing the alkaline flavour, which the alcohol is apt to acquire in this operation, and which, for this purpoſe, is by no means ſuitable, as abſolutely deſtroying all vinoſity, which univerſally conſiſts in a fine volatile, pungent acidity. The diſtillers are the only people, whoſe buſineſs would lead them to make the experiment. This method of converting one *ſpirit* into another, would be of immenſe profit to them if they could perfectly ſucceed in it; but as it would require time and ſlow proceſſes to bring it about, there is but little hope of its ever being brought to bear among them, while they are in their preſent ſcheme of doing every thing with diſpatch and hurry.

Dr. Shaw has ſaid a vaſt deal in the praiſe of a taſteleſs *ſpirit*, which is producible from a vegetable ſubſtance, only overlooked, as he tells us, becauſe it is too common, with which all the foreign *ſpirits* might be imitated to the utmoſt perfection by means of their eſſential oils, all thin fine wines raiſed to any due degree of ſtrength, without giving them the brandy flavour, and many other things of great uſe performed; but he has not told us what the vegetable ſubſtance is from which we are to obtain this. *Shaw*'s Eſſay on Diſtillery.

SPIRITS, in medicine, are of uſe, in external applications, to wounds and ſores. They ſtimulate ſores, reſiſt putrefaction, harden the fibres, coagulate the liquors, hinder ſuppuration, and quicken the pulſe when abſorbed.

Tinctures of abſorbent and aromatic powders are often made with the ſame intention, and partake of the nature of their ingredients, but principally of the *ſpirit*. Med. Eſſ. Edinb. Vol. 5. Art. 24. See the articles ABSORBENTS and AROMATICS.

The power of brandy, or any thing of this kind, in killing worms, is evident from this, that the children of the people in the northern iſlands of Scotland, who are accuſtomed from their infancy to drink that coarſe ſort of brandy which they call *aqua vitæ*, never are troubled with worms. It is a dangerous practice to uſe brandy in this general manner, but on ſome occaſions it may be very ſerviceable. Philoſ. Tranſ. N° 233.

The danger of the frequent and immoderate uſe of *ſpirits* is too well known from experience, and acknowledged by phyſicians; but a late ingenious writer thinks it not improbable that many, eſpecially ladies, are led gradually to the uſe of thoſe poiſons by a certain complaiſant pharmacy, too much uſed in the modern practice: thus palſy-drops, poppy-cordial, plague-water, and ſuch like, which being in truth nothing but drams diſguiſed, yet coming from the apothecaries, are conſidered only as medicines. He therefore recommends to them the uſe of tar-water, a cordial not only ſafe and innocent, but giving health and *ſpirit* as ſurely as other cordials deſtroy them. See TAR-*water*.

The *ſpirits* of wine, or other fermented liquors, produce irregular motions, and ſubſequent depreſſions in the animal *ſpirits*; whereas the *ſpirit*, lodged and detained in the native balſam of pines and firs, is of a nature ſo mild and benign, and proportioned to the human conſtitution, as to warm without heating, to cheer, but not inebriate, and to produce a calm and ſteady joy, without that ſinking of *ſpirits* which is a ſubſequent effect of all fermented cordials.

Acid SPIRITS. *Acid ſpirits* extracted from foſſils, and applied to animal bodies, coagulate the liquids, and mortify the ſolids; by being diluted with water, they approach to vinegar.

By diſſolving metallic ſubſtances in theſe *ſpirits*, their corroding ſphacelating power is increaſed, and ſome of them give ſuch pain, as to bring on convulſions. Med. Eſſ. Edinb. Vol. 5. Art. 2.

Ætherial SPIRIT *of Frobenius*, *ſpiritus ætherius Frobenii*, a name given by Frobenius, and others, to a liquor famous for its extreme volatility, and many other qualities, and prepared by him in this manner. Take four pounds of the beſt oil of vitriol, and the ſame weight of rectified *ſpirit* of wine: firſt pour the *ſpirit* of wine into a glaſs retort, and then pour to it, by little and little, an ounce of the oil of vitriol, ſhake the retort till the two liquors are thoroughly mixed; the veſſel will then begin to grow warm; then pour in more of the oil of vitriol, ſhaking it again, and ſo on, putting in an ounce of the oil of vitriol at a time, and allowing about an hour's time for making the whole mixture, leaſt the ſudden violent heat they excite ſhould burſt the veſſel. When the whole quantity is perfectly mixed, place the retort in a ſand-furnace, the heat of which is as near as poſſible the ſame with that of the veſſel, which will be at this time very conſiderable; take out ſome of the hot ſand, and place the retort in the center of the reſt; then adding more of the hot ſand round it, apply a large receiver to the noſe of the retort; let this receiver be placed on a veſſel of cold water, and covered with a double flannel wetted with cold water; raiſe the fire gradually, till the drops fall ſo faſt, that you may count five or ſix between each; and beſide theſe drops, the upper hemiſphere of the receiver appears filled with a white vapour. This heat is to be continued ſo long as the *ſpirit* ſmells like ſweet marjoram; as ſoon as this aromatic flavour goes off, and the

ſmell

ſmell becomes acid and ſuffocating, like that of brimſtone; take away the receiver, and put out the fire, for all that ariſes after this period is only a gas of ſulphur, and is of no uſe.

The greateſt precaution muſt be uſed in this whole diſtillation, otherwiſe the liquors in the retort will run over into the receiver; the fire muſt ceaſe, as ſoon as the *ætherial ſpirits* are gone over, for there remains behind an oleum vini, which is extracted out of the *ſpirit* by the force of the acid, and will ariſe in the retort, and often runs over, or cauſes exploſions. On the ſecond day, when the retort is cold, pour on the matter that remains in it half as much alcohol, or rectified *ſpirit*, as at firſt, that is two pounds by weight; and then repeating the whole proceſs of the diſtillation, exactly as before, there will come over half as much as at firſt of the *ætherial ſpirit*. On the third day after this proceed in the ſame manner, and you will have ſo much more. In this manner the operations are to be repeated, till no more *ætherial ſpirit* can be raiſed, and all turns to a carbo. Then ſeparate it, and alkaliſe it with *ſpirit* of ſal armoniac, made without *ſpirit* of wine, till all effervescence ceaſes; then diſtil it once more in a balneum mariæ, and it is fit for experiments.

There are more products to be got out of the proceſs. 1. A balſamic oil. 2. A terra-foliata tartari, which is of a glittering hue, and is not fuſible as the common one, prepared with vinegar and the fixed ſalt, is. This is very uſeful in medicine. And 3. a purple earth is to be extracted out of the caput mortuum. Phil. Tranſ. N° 461. p. 870.

The properties of the *ætherial ſpirit* are, 1. That it is ſo extremely volatile, that it evaporates immediately, and does not appear to wet the finger which is dipped in it. 2. That it is ſo extremely inflammable, that it will take fire at a very great diſtance from any flame. 3. That it is of a very pleaſant and aromatic ſmell. And 4. that it does not mix with water.

We have ſeveral curious obſervations on this *æther of Frobenius* by Mr. Groſſe, in the Memoirs of the Academy of Sciences. This Gentleman had obſerved, that in diſtilling *ſpirit* of wine from a ſolution of alum, there was produced a liquor of an agreeable aromatic ſmell, not unlike that of the *æther*; and on this principle he conceived an opinion, that this *æther* was not to be ſought in the common oils of plants, but in ſome mixture of *ſpirit* of wine with a vitriolic acid: and Mr. Geoffroy's papers affording ſome hints alſo to the ſame purpoſe, Mr. Du Hamel, in concert with Mr. Groſſe, determined to attempt the diſcovery with the utmoſt pains on this baſis, and after many unſucceſsful trials, Mr. Groſſe found out three different methods of making it, of which he gives the following account.

Take a pound of pure, uncoloured, and well-rectified oil of vitriol, and two pounds of well-rectified *ſpirit* of wine. The oil of vitriol muſt be firſt put into a retort, and the *ſpirit* of wine afterwards added by a little at a time. There ariſes a very violent heat on the mixing theſe liquors, and the mouth of the retort is to be ſtopt when they are mixed, and the veſſel ſet by for two or three days; in which time the mixture aſſumes a reddiſh colour. After this the retort is to be placed in a ſand-heat, and the diſtillation being made, there firſt ariſes a ſmall quantity of very ſweet ſcented *ſpirit* of wine; after this there ariſes another liquor in white clouds; and after this, on continuing the diſtillation, there comes over another, which is very ſulphureous and volatile, and very ſtrongly affects the noſe, and would indeed ſuffocate a perſon, if its vapours were received in large quantities. After this there ariſes an acid phlegm, and what remains in the retort is a black maſs.

It appeared very plainly by the ſmell, that the *æther* was contained in theſe diſtilled liquors, the manner of ſeparating it was the only difficulty; and after ſeveral tedious experiments with ſal armoniac, and other things, Mr. Groſſe happily thought of trying common water, as the moſt ſimple and eaſy of all methods, to weaken both the ſulphureous acid and the *ſpirit* of wine, which he judged the only obſtacles to the *æther* from ſhewing itſelf in its true form; and this was founded on that remarkable property of the *æther*, of not mixing with water, though blending itſelf very readily with *ſpirit* of wine. On pouring a large quantity of water on theſe diſtilled liquors, the *æther* immediately ſeparated itſelf from the reſt, and by reaſon of its extreme lightneſs roſe all at once to the ſurface of the water. This did not, however, yield it perfectly pure; but adding a little ſalt of tartar to this, the remainder of the acid ſulphureous *ſpirit* was abſorbed, and the *æther* obtained perfectly pure and fine, as that made by Frobenius himſelf.

As the *æther* had been by this means ſeparated from the whole diſtilled matter, it did not clearly appear which of the ſeveral different matters, that ſucceeded one another in the diſtillation, contained it, the reſt ſeeming only a load to the proceſs: with this thought Mr. Groſſe, to try by the ſmell which was moſt likely to contain it, in a ſucceeding diſtillation pricked the bladder, that luted the junctures of the retort and receiver, with a pin, and judging of the ſeveral liquors, as they ſucceeded one another, by their ſmell, he determined that the firſt was only a very highly-rectified *ſpirit* of wine; the ſecond, which came over in white clouds, ſmelt very ſtrongly, and perfectly like the *æther*: this ſeemed indeed the whole matter of the *æther*, the reſt ſerving only to abſorb it. The third liquor had a very penetrating and ſuffocating ſmell of ſulphur.

From theſe obſervations this gentleman attempted the making the *æther* in this ſecond manner. All being prepared as before, he diſtilled off the *ſpirit* of wine, or firſt liquor, and as ſoon as the white vapours began to appear in the retort, he took off the fire, for there was no doubt but the remaining heat was ſufficient for the diſtillation of ſo very volatile a liquor as the *æther*. This ſucceeded accordingly, and the clouds all coming over, and the remaining *ſpirit*, or third liquor, remaining behind in the retort, the *æther* was now found in the receiver, mixed only with a ſmall quantity of *ſpirit* of wine, or with a very ſmall portion, at the utmoſt, of the ſucceeding *ſpirit*. An addition of water ſeparates the *æther* from the *ſpirit*, as in the former proceſs, and if it be not ſufficiently dry and clean when thus procured, it may be diſtilled over again with a gentle heat; and it is remarkable, that if it be diſtilled this ſecond time, without previouſly adding any water, it comes over firſt into the receiver; though the *ſpirit* of wine comes firſt in the common, or primary operation.

Theſe are very ſimple and eaſy ways of making this famous *ſpirit*; but though they uſually ſucceed, yet they have ſometimes failed, even in the hands of the inventor, and that though all the circumſtances of the proceſs have been the ſame, the failure being owing to ſome imperceptible difference, either in the oil of vitriol, or in the *ſpirit* of wine; though this, however, has ſometimes made the proceſs fail in the two former ways, Mr. Groſſe adds a third, in which he obſerves that it always ſucceeded with him.

By this method the *æther* is procured perfectly dry and pure, without the mixture of water, or of the alkaline ſalts. For the ſeparation, or purification of it, the method is this: when the white vapours have appeared, the whole matter in the receiver is to be poured into a ſmall retort, which being placed over a lamp, the *æther* will immediately riſe, and diſtil into the recipient; when half the liquor is come over, or, at the utmoſt, two thirds of it, the lamp is to be taken away, that the *ſpirit* may not riſe, and make a new mixture. Thus the pure *æther* is, without farther trouble, found in the receiver. Mem. Acad. Par. 1734.

Coal-SPIRIT. See the article COAL-*ſpirit*.

Fœtid SPIRIT, *ſpiritus fœtidus*, a new medicine introduced into the practice of phyſic, and directed to be made of any fixed alkaline ſalt a pound and half, ſal armoniac a pound, aſſa fœtida four ounces, and proof-*ſpirit* three quarts, diſtilling off five pints with a gentle heat. *Pemberton*'s Lond. Diſp. p. 205.

Foreign SPIRITS, a general name by which our dealers in theſe things call brandy, rum, and arrack.

It is hard to purchaſe any of theſe genuine and pure, unleſs at the firſt hand, and in large quantities. The dealers generally mix our own *ſpirits* with them. When we had little other *ſpirit* but that of malt made with us, this cheat was eaſily diſcovered, for a nice palate would diſtinguiſh the mixture of only a tenth part of this foul *ſpirit* among the foreign clean ones; but ſince we have the melaſſes *ſpirit* ſo common, and rectified to ſo great a perfection, the deceit is not eaſily found out, though a larger proportion is uſed.

All *foreign ſpirits* are to be ſuſpected of this adulteration, which have not an uniform taſte, and grateful odour. But one of the beſt ways of diſcovering the mixture, is to burn away all that is inflammable in a ſmall quantity by way of trial, and then examine the phlegm.

The great art of this ſophiſtication conſiſts in the purity, and well rectified ſtate of the *ſpirit*; and when the diſtiller can furniſh himſelf with ſuch a *ſpirit* as will not be found out, though mixed in a large quantity with brandy or rum, he is very near the art of making brandy and rum himſelf. *Shaw*'s Eſſay on Diſtillery.

SPIRIT *of lavender*, a form of medicine, which has been uſed to be compounded of a vaſt number of ingredients; but the late London Diſpenſatory has greatly ſhortened the catalogue of them, by ordering this to be made only of lavender flowers and roſemary tops, or the ſimple *ſpirit* of each; and the addition of cinnamon and nutmeg, of each half an ounce, and red ſanders three drachms to two quarts of the *ſpirit*. The ſimple *ſpirits* are to be mixed in the proportion of three parts lavender, and one part roſemary, or elſe the ingredients proportioned in the ſame manner. *Pemberton*'s Lond. Diſp. p. 248.

Malt-SPIRIT. See the article MALT-*ſpirit*.

SPIRIT *of melaſſes*. See MELASSES-*ſpirit*.

Glauber's SPIRIT *of nitre*, *ſpiritus nitri Glauberi*, in pharmacy, a form of medicine made thus: take of nitre three pounds, and of the ſtrong *ſpirit* of vitriol one pound; let them be mixed with caution, and gradually, under a chimney; and afterwards let them be diſtilled, firſt with a gentle heat, and then with a ſtronger. *Pemberton*'s Lond. Diſpenſ. p. 191.

Dulcified SPIRIT *of nitre*, *ſpiritus nitri dulcis*, a form of medicine ordered to be made thus: take of rectified *ſpirit* of wine one quart, and of Glauber's *ſpirit of nitre* half a pound; mix them by pouring the *ſpirit of nitre* on the other, and diſtil the mixture with a gentle heat, as long as what comes off will not raiſe any fermentation with a lixivial ſalt. *Pembert.* ibid. p. 198.

This is much uſed by our diſtillers to give a vinoſity to thoſe *ſpirits*, whoſe natural flavour of that kind they have deſtroyed by the improper uſe of alkaline ſalts in the rectifications. Nothing can be more proper for this purpoſe than this *ſpirit*, as it really gives the brandy flavour, and is not at all prejudicial to health, but very well falls in with the nature of the *ſpirit*, and promotes its medicinal properties as a diuretic, deobſtruent, and lithontriptic.

In order to bring the uſe of this *ſpirit* to a greater certainty and perfection, it is to be obſerved, 1. that there is a great difference in *ſpiritus nitri dulcis*, according to the manner of its preparation; ſuch of it being moſt apt to fly off from the *ſpirit* as had leaſt pains taken about its incorporation by digeſtion, or repeated diſtillation.

2. Any rectified clean *ſpirit*, impregnated with a proper doſe of *ſpiritus nitri dulcis*, and kept in a ſound glaſs veſſel cloſe ſtopt, will a long time retain that vinoſity it obtains from it, and which it would otherwiſe have loſt in a very ſhort time.

3. The caſks long uſed to receive rectified *ſpirits*, impregnated with this acid, uſually appear yellow and rotten, or corroded within like the bottom of a cork, which ſtops a vial of *ſpirit of nitre*. It hence appears no wonder that the vinous taſte, given by this addition, is ſooner loſt in the caſk than in a bottle.

4. When the inflammable *ſpirit* has been rectified with fixed alkalies, it always requires a much larger proportion of the *ſpiritus nitri dulcis*, to give it this vinoſity, than when rectified only by repeated diſtillation; and this vinoſity given by the acid is ſooner loſt, as the *ſpirit* was more impregnated by the alkalies uſed in the rectification. This is the reaſon of that odd obſervation, that melaſſes *ſpirit* retains the vinoſity given it by *ſpiritus nitri dulcis* much longer than malt *ſpirit*; the former having had little, if any, of the alkaline ſalt uſed in the rectifying it, of which the latter, by reaſon of its natural foulneſs, has had a great deal.

5. The beſt way of making this volatile acid, whether with or without external heat, is not uſually practiſed, *viz.* ſo as to render it a perfectly homogeneous and uninflammable liquor, whence it proves much more volatile than it ought to be. Thus when perfect alcohol, and a well rectified ſtrong *ſpirit of nitre*, are by degrees put together for the making of this vinous acid; one half of the mixture evaporates in the conflict, or may be made to diſtil away ſo, as to leave the other half more fixed. The method of making it is alſo improveable, by uſing in the preparation a *ſpirit* of wine impregnated with ſome fine flavoured ingredient, which has not much oil, for acids do not readily mix where there is much oil.

In the preparation of this *dulcified ſpirit of nitre*, the longer it ſtands in digeſtion with the *ſpirit* of wine, the milder it grows; and by the ſame means, alſo, the violently corroſive oil of vitriol may be ſo blunted, as to be rendered ſcarce perceptible to the taſte. In fine, a *ſpiritus nitri dulcis* may be made by a ſlow digeſtion, greatly ſuperior to that commonly uſed, and of ſo fixed a nature, that it will not be ſubject to have its flavour fly off from the *ſpirit* it is mixed with, any ſooner than the native vinoſity of brandy will of itſelf fly off from that *ſpirit*, as it always will in time. A proper care in the preparation of this acid might free the diſtillers from that troubleſome neceſſity they are under of adding their *ſpirit of nitre*, juſt before they ſend their goods away, for fear the flavour ſhould be loſt before the *ſpirit* is all uſed, and ſo the ſophiſtication be found out. There is no fixing any certain proportion, in which the acid is to be mixed with the *ſpirit*, but in general it is beſt not to overdo it; for though it will give an agreeable vinoſity to any tolerably clean *ſpirit*, the perſon will be much deceived, who attempts to drown the bad flavour of a foul one by it. *Shaw*'s Eſſ. on Diſtillery.

SPIRIT *of ſalt*. See the article SALT.

Strength of SPIRITS. See the article STRENGTH.

SPIRIT *of ſulphur*, the ſame as oil of ſulphur. See the article SULPHUR.

SPIRITO, in the Italian muſic, is uſed to ſignify that a performer ſhould ſing or play with vigour, life, and *ſpirit*. Hence we meet with *con ſpirito* in cantatas and ſonatas.

SPIRITUS *rector of vegetables*. See the article ARCHÆUS.

SPIRITUS *tartari*, the name of a medicine very famous in Germany, and probably in the greater eſteem, becauſe of the difficulty of preparing it. It is the *ſpirit* of ſalt of tartar volatilized; and is ordered by Langelot to be made in this manner: let two or three pounds of crude tartar be burnt to a blackneſs, in order to have what is moſt neceſſary, a ferment to ferment the tartar with; put this into a large pot, and pour to it ſo much water as will ſerve to ſtand an inch above it; make this mixture luke-warm, and then pour into it half a handful of crude tartar powdered, bubbles of air will ariſe upon this, and will continue ſome time; when they ſeem to decreaſe, more powdered tartar is to be added from time to time, to keep up this fermentation. The bubbles will be large, and riſe in cluſters, and reſemble bunches of grapes in all but colour. The fire all this time muſt be carefully managed, and the tartar put in gradually, that the fermentation do not become too great, or the pot run over.

After this the matter is to be put together into an iron retort, and a very gentle fire kept under it for ſome time, and gradually heightened, ſo as to force up all the ſalt; this being done, the volatilized ſalt is to be carefully ſeparated, and it is remarkable, that the ſalt is ſo wholly volatilized by this fermentation, that there ſcarce remains any fixed ſalts in the caput mortuum in the retort.

The liquor in the receiver is to be rectified by another diſtillation, the water, neceſſarily uſed in the fermentation, rendering it too weak. When it is rectified ſo far, that it appears whitiſh, it is known to be of a due ſtrength, and it is then the famous *ſpirit of tartar*, not only celebrated for its medicinal virtues, but famous for extracting tinctures that can be obtained from no other menſtruum. *Langelot*, de Digeſt. et Ferm.

SPIRITUS *volatilis aromaticus*, a name given of late to what uſed to be called *ſal volatile oleoſum*. The modern way of making it is this: take eſſence of lemons, and oil of nutmegs, of each two drachms, oil of cloves half a drachm, dulcified *ſpirit* of ſal armoniac a quart; diſtil the whole with a very gentle heat. *Pemberton*'s London Diſpenſatory, p. 205.

SPISSUM, in the antient muſic, was uſed to ſignify thoſe two ſmaller conjunct intervals of a tetrachord, which taken together, were leſs than the third. *Wallis*'s Append. Ptolem. Harm. p. 165.

The Greek term for this was πυκνον. This happened in the enharmonic, and the three chromatic genera; in each of which the interval, between the hypate and the lichanos, was leſs than the interval between the lichanos and the nete. To the *ſpiſſum* was oppoſed the *non-ſpiſſum*, απυκνον, or *rarum*, as Martianus Capella tranſlates it. The απυκνον happened in the two diatonic genera, where the two ſmalleſt intervals were equal to, or greater than the third. They were ſuppoſed equal in the diatonicum molle, and greater in the intenſum. *Wallis*, ibid. See the article GENUS.

SPIZA, in zoology, a name by which the antient naturaliſts called the chaffinch. See the article FRINGILLA.

SPLANCHNICA, a name given to medicines appropriated to diſeaſes of the bowels.

SPLEEN (*Cycl.*)—Mr. du Vernoi has added one opinion more to the many already given, concerning the uſe of the *ſpleen*. From obſerving a large empty ſpace near the *ſpleen*, in the abdomen of a dead body, the proportional largeneſs of its blood-veſſels, and the ſtructure of the *ſpleen* analogous to that of the penis, he concludes the *ſpleen* in a living perſon to be ſubject to inflations like a bellows: but how it is thus to be moved, or to what purpoſe, he does not tell us. See Comment. Acad. Petrop. Tom. 4. p. 156. ſeq.

Mr. Lieutaud argues for the *ſpleen*'s being larger by a greater quantity of blood in it, when the ſtomach is empty, and that this blood is preſſed out, when the ſtomach is full, to increaſe the ſecretion of bile. Hiſt. de l'Acad. des Scienc. 1733.

We have an account, in the Philoſophical Tranſactions, N° 451. of the extirpation of part of the *ſpleen* of a man, which had begun to mortify; notwithſtanding which, the man recovered.

The *ſpleen* has been cut out of dogs without any damage. Mr. Boyle mentions his having ſeen the experiment tried on a young ſetter, who recovered in a fortnight. Works Abridg. Vol. 1. p. 27.

Dr. Pozzi relates the phænomena he remarked in diſſecting a dog, whoſe *ſpeen* was cut out when he was young. The liver, which was larger and more heavy than ordinary, was alſo more brittle; the vena portarum was enlarged; the gall-bladder was full of bile, more acrid than it is commonly. From theſe appearances he thinks the uſe of the *ſpleen* to be for ſeparating a liquor like to ſpittle, which may dilute the bile, and prevent its too great acrimony. Med. Eſſ. Edinb.

The uncertainty we are in, as to the real uſe of the *ſpleen*, has given ground, perhaps, to the notion that men might live without the *ſpleen*; and that, in many caſes, it might contribute much to health to cut out this uſeleſs viſcus. In the Journal des Savans, there is an account of a method of deſtroying it, without the terrors of the operation of opening the body.

This was done by a perſon who applied a wooden knife to the ſurface of the body where the *ſpleen* is lodged, and ſtriking forcibly on it with a mallet, told the patient that he had broken the ſubſtance of the *ſpleen*; and that after this it required only the taking certain medicines which he prepared, utterly to deſtroy and carry it out of the body.

The folly of a pretence of this kind, one would think, ſhould have

have been alone ſufficient to have laughed it out of the world; but numbers of people ſubmitted to the operation, till a youth in Peterſburg unhappily being killed by a blow of the kind here mentioned; and his belly ſwelling greatly, excited the curioſity of his relations to have it opened. The cauſe of his death was found to be an hæmorrhage, which had filled the cavity of the abdomen, and which proceeded from the *ſpleen*'s having been burſt by the blow. This convinced them, that attempts to wound the *ſpleen* were no longer to be looked upon as the means of health. Act. Petrop. Vol. 1. p. 381.

Infarction of the SPLEEN, *infarctus lienis*, a diſeaſe conſiſting in an inflation of this lax and celluloſe viſcus, owing its origin to a reſtriction of the blood toward the *ſplenic* branch, in which nature ſeems to have intended the relieving herſelf from the load of a plethora, by the diſcharging a part of the maſs through the vaſa brevia. *Junker*'s Conſp. Med. p. 194.

The *infarctus lienis* differs from an obſtruction of the *ſpleen*, in that this laſt is a total ſuppreſſion of the blood in it, this only a partial one. It is too often confounded with nephritic complaints, and is indeed, in general, of the claſs of hypocondriac maladies, but only ariſes from a ſpecial and peculiar derivation of the blood to that one viſcus, not to any other of the circumjacent parts.

Signs of it. An *infarction of the ſpleen* is diſcovered by an inflation of the left ſide, a little below the ſpurious ribs, attended with permanent pains, but theſe not very acute, or violent: theſe complaints have frequent remiſſions, ſeldom continuing above a day or two in the ſame ſtate. During the time of the ſymptoms being worſt, there is a difficulty of breathing, and an anxiety of the præcordia, and generally a lowneſs of ſpirits: to theſe it may be added, that there is uſually a dry cough, and frequent belchings.

Perſons ſubject to it. Men are in general much more ſubject to this diſeaſe than women, unleſs at the middle and more advanced periods of life, when they are more ſubject to it than the men. People of a melancholic habit alſo are moſt afflicted with it, and ſuch as have before had hypocondriac complaints, and have been injudiciouſly treated with aſtringents; and all perſons of a ſedentary and ſtudious life, or who employ much time in thinking.

Cauſes of it. Theſe are a ſedentary life, and a diet of too heavy and thick a kind; an omiſſion of habitual bleedings, or other evacuations, or a ſuppreſſion of the menſtrual or hæmorrhoidal diſcharges; an injudicious treatment of intermittent fevers with aſtringents, or of acute ones with too cooling medicines, and an habitual coſtiveneſs: and to theſe may be added an hereditary diſpoſition.

Prognoſtics in it. This is a diſeaſe of no immediate danger to the patient, and the more recent it is when taken in hand, the eaſier it is cured; if left to itſelf it becomes habitual, and brings no danger of death with it, but if improperly treated, it frequently becomes the baſis of the moſt obſtinate kind of quartans, or degenerates into a ſcirrhus, which may be a long time ſuffered without any danger of life; but finally, the whole too often ends in ſlow hectic fevers, and œdematous and aſcitic ſwellings. In women it often terminates in a vomiting of blood; and ſometimes, but very rarely, an inflammatory and ſuppurating ſtaſis ſupervenes, and a black, fetid, and purulent matter is voided by ſtool or by vomiting.

Method of cure. The plethoric habit, which gives riſe to this complaint, is to be taken down by copious bleedings in the right foot, and then ſhould be repeated every ſpring and autumn; and the menſes muſt be brought to a proper regularity in the uſual way, as muſt alſo the hæmorrhoids in the other ſex, by the application of leeches to the part. The ſpiſſitude of the blood is to be amended by decoctions of elecampane, hyſſop, and the like; and by moderate and repeated doſes of tartarum vitriolatum, gum ammoniacum, &c. and gentle doſes of rhubarb and ſena in infuſion muſt be taken at times. To theſe may be added the external uſe of reſolvents and ſtrengthners, ſuch as ointment of marſhmallows, the plaiſter of gum ammoniacum, and the like; and finally, the preparations of ſteel are to be given: to theſe ſome add a number of things eſteemed ſpecifics, ſuch are madder and caper roots, dodder, yarrow, white maidenhair, and ſpleenwort, and the bark of the aſh-tree, and wood of the tamariſk. *Junker*'s Conſp. Med. p. 197.

Scirrhus of the SPLEEN. This is an indurated tumor of the *ſpleen*, cauſed by a ſtagnation and inſpiſſation of the humors from the exhalation of their thinner parts. This complaint is ſometimes compleat, and ſometimes incompleat; but in the moſt favourable caſes it is a greatly more dangerous complaint than an infarction of the *ſpleen*, and more difficult of cure. *Junker*'s Conſp. Med. p. 201.

Signs of it. Theſe are a ſenſible and palpable hardneſs under the ribs on the left ſide, extending toward the loins, with a ſenſe of a weight, as it were, hanging in this part; and hence the lying on the right ſide is always very painful and uneaſy. The face has dull deadneſs in the look, which ſometimes is communicated alſo to the ſkin of the whole body, and there is uſually a blackneſs about the orbits of the eyes; there is alſo a ſenſation of a narrowneſs in the breaſt, with ſome difficulty of breathing, and a dry cough. The appetite is uſually voracious, but ſometimes it is affected with nauſeas, without any apparent cauſe. The bowels are uſually ſomewhat coſtive, but irregularly ſo. The mind alſo ſeems affected, and a gloomy moroſeneſs, ſilence, and anxiety, oppreſs the perſon, without any viſible cauſe. Finally, there uſually is a ſwelling in the right foot, which by degrees extends itſelf farther, and is ſeldom regarded at firſt.

Perſons of both ſexes are equally ſubject to this diſorder, but it is not, however, very common. Men who have long been ſubject to hypocondriac diſorders, and women ſubject to hyſteric complaints, are moſt ſubject to it; and to theſe may be added, perſons of an indolent, ſpeculative, and ſedentary life, and thoſe who have been imprudently treated with aſtringents in intermittent caſes.

Cauſes of it. Beſide thoſe before mentioned, a ſcirrhus is ſometimes brought on in the *ſpleen* by a violent blow, or other external injury; a too thick diet may alſo be very inſtrumental in laying the foundation for it; and not a little may be added to all theſe caſes, by violent paſſions of the mind.

Prognoſtics in it. In recent *ſcirrhuſes*, and ſuch as are yet incompleat, there is ſome hope of ſucceeding in the attempt of a cure; and on the contrary, in old caſes and compleat *ſcirrhuſes*, there is indeed very little hope: but there is this comfort for the patient, that even ſuch a one, when wholly left to itſelf, will remain many years without endangering life.

There is in a *ſcirrhus* an eternal tendency to corruption, but this is rather to be expected from ſphacelation, than from an inflammatory ſuppuration; but when emollients are uſed, there is great and imminent danger: for as theſe are nearly allied to the maturating remedies, they may produce their effect; and it is certain, that no laudable ſuppuration is ever to be expected in this caſe.

Method of treatment. This caſe is to be treated in the ſame general manner with the infarctions of the *ſpleen*, already mentioned; but the more powerful reſolvents are to be uſed in this, as the more ſtubborn caſe. Gentian, bryony, and arum root, with the fine aperient roots, and the capillary herbs, with the powerful gums, as galbanum, ſagapenum, ammoniacum, and the reſt. Bleeding muſt alſo be ordered, as ſoon as the primæ viæ have been cleanſed; and externally the plaiſter of cicuta, with ammoniacum, may be applied: but if the caſe is fixed and obſtinate, it is better to let all applications alone, and leave nature to do the beſt for herſelf. *Junker*'s Conſp. Med. p. 202.

SPLEEN, in ichthyology. The *ſpleen* in fiſhes is uſually ſituated near the ſtomach, in the left ſide of the abdomen. Its figure is generally triangular, ſometimes oblong. Its colour is always more duſky and obſcure than that of the liver.

SPLEEN-*wort*. See the article LONCHITES.

SPLENECTOMIA, the name given to the chirurgical operation of cutting out the ſpleen. Many have thought that the ſpleen was an uſeleſs part of the human body, and even noxious; but this ſeems to be a very raſh opinion.

SPLENIA, a word uſed by ſurgeons to expreſs compreſſes, or rags ſeveral times doubled, applied to wounds over the plaiſters, or other dreſſings.

SPLENII *inferior*, in anatomy, a name given by Cowper to a muſcle, called by Albinus *ſplenicus colli*, and by Winſlow, and others, *maſtoidæus poſterior*, and *portio inferior ſplenii*. See the article SPLENIUS.

SPLENITIS, in medicine, the name of a ſpecies of fever, in which the blood is powerfully directed toward the ſpleen by nature, in order to break and diſſolve congeſtions formed there. The *ſplenitis* differs from what authors call an *infarctus lienis* in degree, as in this the blood only ſtagnates in ſome degree, and is not wholly obſtructed; and as there is no acute inflammatory fever here, as there is in the *ſplenitis*.

The *ſplenitis* is very various in degree; in ſome caſes the whole parenchymatous ſubſtance of the ſpleen being affected, in others only its membranaceous and ſuperficial parts. It is eaſy to conceive that the former caſe is greatly the more dangerous of the two.

Signs of it. This diſeaſe always firſt attacks people with a very remarkable ſhivering and coldneſs; this is ſucceeded by a very terrible heat, and intolerable thirſt; and there is a preſſive pain, and a ſenſible ſwelling in the left hypocondrium. If the patients expoſe themſelves a little to the open air, the extremities grow cold almoſt immediately; if a hæmorrhage happens, it is always from the left noſtril: and finally, the urine is reddiſh and turbid, and after the fourth day depoſits a roſe-coloured ſediment, which has ſomewhat of the appearance of matter. Plethoric perſons are more than all others ſubject to this diſeaſe.

Cauſes of it. The general cauſe is a plethora joined with a thickneſs of the blood, which forms ſtaſes, and fixed coagulations in the ſpleen; and the fever itſelf is no other, than the attempt of nature to break through thoſe ſtaſes, by the additional velocity of the motion of the blood. The uſual accidents that bring on this bad ſtate of the blood,

are the omiſſion of habitual bleedings, or the ſuppreſſion of the natural diſcharges of the menſes or hæmorrhoids; and the occaſional accidents that immediately bring on the diſeaſe in this ſtate of the blood are, violent commotions of the mind, ſudden chilling of the body when very hot, as by drinking cold water immediately after violent exerciſe, the taking violently aſtringent medicines in fevers, and an improper uſe of cooling external remedies in diſorders of the ſpleen, as the infarctions of it, and the like. *Junker*'s Conſp. Med. p. 292.

Prognoſtics in it. It is always a very dangerous diſeaſe, though not ſo fatal as the hepatitis, or a like inflammatory ſtate of the liver; but it is remarkable, that as the vomiting a black matter in the hepatitis is always a fatal ſymptom, ſo in this diſeaſe the ſame matter is frequently voided, but it is here ſalutary, and frequently carries off the diſeaſe. The appearance of the hæmorrhoids has alſo been frequently obſerved to have the ſame good effect. When the inflammation lies deep, it is moſt frequently fatal; when it is ſuperficial, it is often carried off: but when it ſeems cured, it ſometimes is found afterwards to have degenerated into an incurable ſcirrhus of the part.

Method of cure. The firſt thing to be done, is to open the bowels by a clyſter, and they are afterwards to be kept from becoming coſtive, by a repetition of the ſame means. Bleeding is uſually neceſſary, and may be performed once or more in the beginning of the diſeaſe; then gentle diaphoretics are to be given with juleps ſlightly acidulated. Theſe are the proper medicines for the morning; and in the afternoon powders of nitre, vitriolated tartar, and crabs eyes, ſated with lemon juice, are to be given with the cooling emulſions; and if the pains be very violent, they may be mitigated, by giving ſmall doſes of a gentle anodyne, ſuch as the ſtorax pill, with the beforementioned powders. If the ſuppreſſion of the habitual hæmorroidal evacuations are ſuſpected to be the cauſe of the diſeaſe, leeches muſt be applied to the parts, and no wine, or any other ſtrong liquor, muſt be allowed, till the decline of the diſeaſe. *Junker*'s Conſp. Med. p. 293.

SPLENITIS is alſo uſed by ſome authors to expreſs a tumor or inflammation of the ſpleen.

Splenitis is alſo uſed as the name of a vein in the left hand, the ſame as the *ſalvatella*. The vein of this kind in the right hand is called *jecoraria*.

SPLENIUS, called alſo *maſtoidæus poſterior*, in anatomy, a flat, broad, oblong muſcle, ſituated obliquely between the back part of the ear, and the poſterior and lower part of the neck.

It is partly ſingle, and partly made up of two portions, one ſuperior, the other inferior. Theſe two portions are cloſely united backward, making only one plain, but they are divided above.

The ſuperior portion is fixed to the extremities of the three or four loweſt ſpinal apophyſes of the neck, and of the firſt, and ſometimes the firſt and ſecond of the back. It is not fixed immediately to the apophyſes of the neck, which are above the laſt, but only by the intervention of the poſterior cervical ligament. It is likewiſe fixed to the edge of the interſpinal ligaments of the other vertebræ; from thence it runs obliquely toward the maſtoide apophyſis, and is inſerted in its upper part, and along the neighbouring curve portion of the tranſverſe ridge of the os occipitis.

The inferior portion of the *ſplenius* is fixed to three or four ſpinal apophyſes of the back, beginning by the ſecond or third, and afterwards running up till it reaches the ſuperior and lateral part of the neck. It is inſerted in the tranſverſe apophyſes of the three or four ſuperior vertebræ of the neck, by the ſame number of extremities a little tendinous; theſe, however, are ſometimes only two in number. The two *ſplenii* repreſent a great Roman V, and the *ſplenius*, and ſterno-maſtoidæus of the ſame ſide, form a figure like a Roman A, or the legs of a pair of compaſſes, the points of which are in an horizontal plane. *Winſlow*'s Anatomy, p. 239.

SPLENIUS *capitis*, in anatomy, a name given by Albinus to a muſcle, called by Winſlow, and others, the *maſtoidæus ſuperior*, or upper portion of the *ſplenius*. Riolanus, and others, call it the *triangularis ſplenii*.

SPLENIUS *colli*, in anatomy, a name given by Albinus to a muſcle, called by Winſlow, and others, *maſtoidæus poſterior*, or the lower portion of the *ſplenius*; and by Cowper the *muſculus inferior ſplenii*. See SPLENIUS, ſupra.

SPLICE (*Cycl.*)—*Cut*-SPLICE, in a ſhip, is when a rope is let into another with as much diſtance as one pleaſes, ſo as to have it undone at any time, and yet be ſtrong enough.

Round-SPLICE, is when a rope's end is ſo let into another, that they ſhall be as firm as if they were but one rope.

SPLINTERS *of bone*, in fractures. In caſes of fractures the ſurgeon is frequently troubled with *ſplinters of the bone* in the way, which vellicate and prick the neighbouring parts, and render the proper execution of his office very difficult. If theſe *ſplinters* are looſe, and have no connection with the bone, they muſt be carefully lifted out of the wound; if they hang to the bone in ſome part by the perioſteum, that muſt be cut off with the ſciſſors; but if they adhere pretty firmly to the neighbouring parts, and do not hinder the reduction of the bone, it is beſt to replace the bone, and leave them either to looſen, and come out of themſelves by the ſuppuration of the parts, or to grow again, as they ſometimes will ſafely and firmly do, to the reſt of the bone. When they adhere pretty firmly to the principal parts of the bone, they ſhould never be extracted by force, but replaced with the greateſt exactneſs: for when this is properly performed, they will frequently unite to the reſt of the bone.

When the points of *ſplinters of bone* ſtick ſo far out, that they are a great hindrance to the reduction of the bone, you are diligently to conſider whether you can, by any means, contrive their reunion to the bone, which may be determined, by obſerving at what diſtance they are from the large bone, and what quantity of fleſh there is intervening: when they cannot be reduced, or reunited to the bone, they muſt be removed with a pair of ſtrong forceps, or, if they ſtick very firmly, with a fine ſaw. If the *ſplinters* are buried under the ſkin, and cannot be got at with hands, it is proper firſt to try if they can be reduced to their natural ſituation; and if they cannot, an inciſion muſt be made through the ſkin, that they may be taken out. *Heiſter*'s Surg. p. 109.

SPLIT, in botany, a name given by ſome authors to the great *fumaria bulboſa*, or hollow root. *Rupp.* Flor. Sen. p. 216.

SPLIT, at ſea. When a ſail is blown to pieces, the ſeamen ſay it is *ſplit*.

SPLITTING. To *ſplit* a thin piece of metal, as an old ſilver groat, place the metal on the heads of three pins ſtuck up triangularly, and let a heap of flower of brimſtone burn out upon it; then throwing it hard againſt the floor, the upper part will ſeparate from the lower. *Boyle*'s Works Abr. Vol. I. p. 134.

SPOLIARIUM, among the antient Romans, the third part of the bath, uſed for undreſſing and dreſſing in. *Pitiſc.* Lex. Ant. in voc.

Spoliarium was likewiſe a part of the gladiatorial ſchools, where their cloths and ornaments were laid, and where the wounded and killed were carried. *Pitiſc.* l. c.

SPONDIAS, in botany, the name given by Linnæus to the genus of plants, called by Plumier *monbin*; the characters are theſe. The perianthium is plain and permanent, and conſiſts of one leaf, divided into five ſegments at the edge. The flower is compoſed of five oval and expanded petals. The ſtamina are nine filaments, five of which are placed in a circle, the others are of the ſame length with theſe, which is that of the cup. The antheræ are ſimple. The germen of the piſtil is oval. The ſtyle is very ſmall, and is terminated by three obtuſe and permanent ſtigmata. The fruit is an oval berry in every cell, of which there are contained four nuts. *Linnæi* Gen. Plant. p. 175. *Plumier*, Gen. 22.

SPONDYLI, Σπονδυλοι, in antiquity, pellets of braſs uſed in giving ſentence, before the κυαμοι, or beans, came into uſe. *Potter*, Archæol. Græc. Tom. I. p. 119.

SPONDYLOLITHOS, a name given by authors to a ſtone found in the country of Tyrol, and elſewhere, reſembling the vertebræ of an animal. It is in reality no other than the vertebræ of ſome ſea-fiſh petrified, as is common with us.

SPONDYLUS, in natural hiſtory, a name given by authors to a kind of oiſter of an oblong and umbonated form, of which there are ſeveral ſpecies. See OSTREA.

SPONGIA, *ſpunge*, in botany, the name of a genus of plants, the characters of which are theſe: that it is ſoft and elaſtic, naturally growing under water, and pervious by multitudes of holes.

The ſpecies of *ſpunge*, enumerated by Mr. Tournefort, are theſe. 1. The fineſt *ſpunge* with very ſmall cavities. 2. The great flatted *ſpunge*. 3. The globular, or round *ſpunge*. 4. The funnel-faſhioned *ſpunge*. 5. The cup-like *ſpunge*, divided into ſegments at the edges. 6. The branched *ſpunge*. 7. The conic-ſhaped branched *ſpunge*. 8. The ſhrubby-branched *ſpunge*. 9. The branched river-*ſpunge*. 10. The hairy *ſpunge*. 11. The ſail *ſpunge*. 12. The tubular long American *ſpunge*. 13. The very long-branched rope-like American *ſpunge*. 14. The headed and fingered American *ſpunge*. 15. The American honeycomb *ſpunge*. 16. The flatted and elegantly punctuated American *ſpunge*. *Tourn.* Inſt. p. 575.

Burnt *ſpunge* is much recommended as a ſweetner of the blood, and a diuretic. Some have pretended to cure the leproſy with it, and others extol it againſt the bite of a mad-dog; but theſe are virtues not univerſally received.

SPONGIOLI, a word uſed by ſome authors to expreſs the ſmall button muſhrooms, which are gathered before they expand or open their heads.

SPONSUS, one of the many names given by the chemiſts to mercury.

SPORADIC *diſeaſes*, diſtempers which ſeize particular perſons at any time or ſeaſon, or in any place. They are thus called, in contra-diſtinction to the epidemic diſeaſes, which are peculiar to certain times and ſeaſons, or to peculiar places.

SPORTS, in the cuſtoms of Flanders, were in great vogue through Flanders and the Low-Countries, ſome centuries ago. Every city had a ſolemnity of this kind peculiar to itſelf: thus Bruges had that called the *Foreſter*; Valenciennes the *Prince of Pleaſantry*, and the *Prince of the Horſe-comb*; Cambray the *King of Ribaldry*; and Bouchain the *Provoſt of Sots*. Liſle, one of the richeſt towns in Flanders, was not behind hand with its neighbours in celebrating *ſports*, by the magnificence and diverſions whereof, to draw together a vaſt concourſe of people from all parts. One of the chief of theſe divertiſements was called the *King of the Spinet*, *Roy d'Epinette*; which was celebrated with a great deal of pomp and ſhew. See Hiſt. Acad. Inſcript. Tom. 4. p. 452, ſeq.

SPOT (*Cycl.*)—SPOT, in ornithology, the name of a particular ſpecies of pigeon, called by Moore the *columba maculata*. It is of the ſize of a ſmall common pigeon, and was brought over to England from Holland. This ſpecies has always a *ſpot* upon its head, juſt above its beak, from whence it has its name. The feathers of the tail are always of the ſame colour with this *ſpot*, and the reſt of the body is all white. The *ſpot* and tail are black in ſome, red in others, and yellow in others. They look very beautiful when they ſpread their tails and fly, and are a diſtinct ſpecies, as they always produce young ones of their own marks. *Moore*'s Columb. p. 44.

SPRING, (*Cycl.*) in mecanics, is uſed to ſignify a body of any ſhape, perfectly elaſtic.

Length of a SPRING may, according to its etymology, ſignify the length of any elaſtic body, but it is particularly uſed by Dr. Jurin to ſignify the greateſt length to which a *ſpring* can be forced inwards, or drawn outwards, without prejudice to its elaſticity. He obſerves this would be the whole length, were the *ſpring* conſidered as a mathematical line; but in a material *ſpring*, is the difference between the whole length, when the *ſpring* is in its natural ſituation, or the ſituation it will reſt in when not diſturbed by any external force, and the length or ſpace it takes up when wholly compreſſed and cloſed, or when drawn out.

Strength, or *force of a* SPRING, is uſed for the leaſt force or weight, which, when the *ſpring* is wholly compreſſed or cloſed, will reſtrain it from unbending itſelf. Hence alſo the force of a *ſpring* bent, or partly cloſed, is uſed for the leaſt force or weight, which, when the *ſpring* is bent thro' any ſpace leſs than its whole length, will confine it to the ſtate it is then in, without ſuffering it to unbend any farther.

The theory of *ſprings* is founded on this principle, *ut tenſio, ſic vis*; that is, if a *ſpring* be forced or bent inwards, or drawn outwards, or any way removed from its natural ſituation, its reſiſtance is proportional to the ſpace by which it is removed from that ſituation.

This principle was verified by the experiments of Dr. Hook [b], and ſince him by thoſe of others, particularly by the accurate hand of Mr. George Graham.—[b Lectures *de potentia reſtitutiva*, 1678.]

For the better in elligence of this principle, on which the whole theory of *ſprings* depends, ſuppoſe a *ſpring* C L reſting with the end L againſt any immoveable ſupport, but otherwiſe lying in its natural ſituation, and at full liberty; then if this *ſpring* be preſſed inwards by any force p, or from C towards L, through the ſpace of one inch, and can be there detained by that force p, the reſiſtance of the *ſpring*, and the force p, exactly counterballancing one another; then will the force $2p$ bend the *ſpring* through the ſpace of two inches, $3p$ through three inches, $4p$ through four inches, &c. The ſpace C l (Fig. 2.) through which the *ſpring* is bent, or by which its end C is removed from its natural ſituation, being always proportional to the force which will bend it ſo far, and will detain it ſo bent.

Fig. 1.

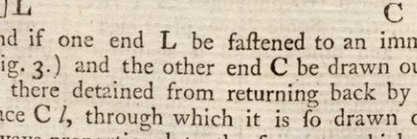


Fig. 2.

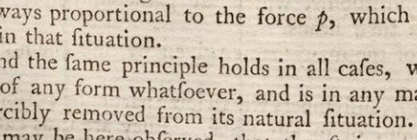

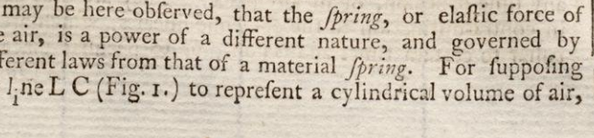

Fig. 3.

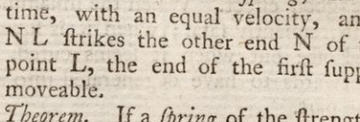
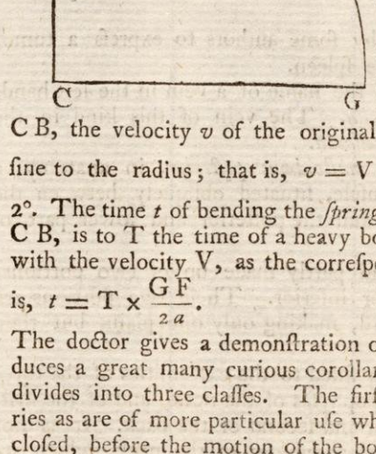


And if one end L be faſtened to an immoveable ſupport, (Fig. 3.) and the other end C be drawn outwards to l, and be there detained from returning back by any force p, the ſpace C l, through which it is ſo drawn outwards, will be always proportional to the force p, which is able to detain it in that ſituation.



And the ſame principle holds in all caſes, where the *ſpring* is of any form whatſoever, and is in any manner whatſoever forcibly removed from its natural ſituation.

It may be here obſerved, that the *ſpring*, or elaſtic force of the air, is a power of a different nature, and governed by different laws from that of a material *ſpring*. For ſuppoſing the line L C (Fig. 1.) to repreſent a cylindrical volume of air, which by compreſſion is reduced to L l, (Fig. 2.) or by dilatation is extended to L l, (Fig. 3.) its elaſtic force will be reciprocally as L l; whereas the force, or reſiſtance of a *ſpring*, will be directly as C l.

This principle being premiſed, Dr. Jurin gives us a general theorem concerning the action of a body ſtriking on one end of a *ſpring*, while the other end is ſuppoſed to reſt againſt an immoveable ſupport. And leſt any objection ſhould be formed againſt the poſſibility of an immoveable ſupport, ſince any body, how great ſoever, may be moved out of its place by the leaſt force, he obſerves, that the objection may eaſily be removed. Thus, if the *ſpring* L M be ſuppoſed continued to N, ſo that L N = L M, if a body M, with any velocity in the direction M L, ſtrikes one end of the *ſpring*, and a body N, at the ſame time, with an equal velocity, and a contrary direction, N L ſtrikes the other end N of the continued *ſpring*, the point L, the end of the firſt ſuppoſed *ſpring* will be immoveable.

Theorem. If a *ſpring* of the ſtrength P, and the length C L, lying at full liberty upon an horizontal plane, reſt with one end L againſt an immoveable ſupport; and a body of the weight M, moving with the velocity V, in the direction of the axis of the *ſpring*, ſtrike directly on the other end C, and thereby force the *ſpring* inwards, or bend it through any ſpace C B; and a middle proportional C G be taken between the line $CL \times \frac{M}{P}$, and $2a$, a being the height to which a heavy body would aſcend in vacuo with the velocity V; and upon the radius R = C G be erected the quadrant of a circle G F A: then,

1°. When the *ſpring* is bent through any right line of that quadrant, as the body M, is to be C B, the velocity v of the original velocity V, as the coſine to the radius; that is, $v = V \times \frac{BF}{R}$.

2°. The time t of bending the *ſpring* through the ſame ſine C B, is to T the time of a heavy body's aſcending in vacuo with the velocity V, as the correſponding arch to $2a$; that is, $t = T \times \frac{GF}{2a}$.

The doctor gives a demonſtration of this theorem, and deduces a great many curious corollaries from it. Theſe he divides into three claſſes. The firſt contains ſuch corollaries as are of more particular uſe when the *ſpring* is wholly cloſed, before the motion of the body ceaſes.

The ſecond comprehends thoſe relating to the caſe, when the motion of the body ceaſes before the *ſpring* is wholly cloſed. And

The third, in caſe the motion of the body ceaſes at the inſtant that the *ſpring* is wholly cloſed.

We ſhall mention ſome of the laſt claſs, as the moſt ſimple; having firſt premiſed, that P = ſtrength of the *ſpring*, L = its length, V = the initial velocity of the body cloſing the *ſpring*, M = its maſs, t = time ſpent by the body in cloſing the *ſpring*, A = height from which a heavy body will fall in vacuo in a ſecond of time, a = the height to which a body would aſcend in vacuo with the velocity V, C = the velocity gained by the fall, m = the circumference of a circle, whoſe diameter is 1. Then,

1°. If the motion of the body ſtriking the *ſpring* ceaſe, when it is wholly cloſed, the initial velocity V is equal to $C\sqrt{\frac{PL}{2MA}}$.

2°. The initial velocity V is proportional to $\sqrt{\frac{PL}{M}}$.

3°. If P L be given, either in the ſame or in different *ſprings*, the initial velocity V is reciprocally as $\sqrt{M}$.

4°. The product of the initial velocity, and the time ſpent in cloſing the *ſpring*, or V t is equal to $1'' \times \frac{m\,CL}{4A}$; and is proportional to L the length of the *ſpring*.

5°. The initial quantity of motion, or M V, is equal to $C\sqrt{\frac{PLM}{2A}}$.

6°. M V is proportional to $\sqrt{PLM}$, or to P t. And if P L be given, either in the ſame or different *ſprings*, M V is as $\sqrt{M}$.

7°. If $\frac{P}{L}$ be given, either in the ſame or in different *ſprings*, the initial quantity of motion is as the length of the *ſpring* into the time of bending it.

8°. If a quantity of motion M V bend a *ſpring* through its whole length, and be conſumed thereby, no other

quantity of motion equal to the former, as $n\,M \times \frac{V}{n}$, will close the same *spring*, and be wholly consumed thereby.

9°. But a quantity of motion, less or greater than M V, in any given ratio, may close the same *spring*, and be wholly consumed in closing it; and the time spent in closing the *spring* will be respectively less or greater, in the same given ratio.

10°. The initial *vis viva*, or $M\,V^2$, is equal to $\frac{C^2\,P\,L}{2\,A}$; and $2\,a\,M = P\,L$.

11°. The initial *vis viva* is as the rectangle under the strength and length of the *spring*; that is M V V is as P L.

12°. If $\frac{P}{L}$ be given, the initial *vis viva* is as P^2, or as L^2.

13°. If the *vis viva* $M\,V^2$ bend a *spring* through its whole length, and be consumed in closing it; any other *vis viva*, equal to the former, as $n\,n\,M \times \frac{V^2}{n\,n}$ will close the same *spring*, and be consumed thereby.

14°. But the time of closing the *spring* by the *vis viva* $n\,n\,M \times \frac{V^2}{n\,n}$, will be to the time of closing it by the *vis viva* $M\,V^2$, as *n* to 1.

15°. If the *vis viva* $M\,V^2$ be wholly consumed in closing a *spring* of the strength P, and length L; then the *vis viva* $n\,n\,M\,V^2$ will be sufficient to close, 1°. either a *spring* of the strength $n\,n\,P$, and length L. 2°. Or a *spring* of the strength *n* P, and length *n* L. 3°. Or of the strength P, and length $n\,n\,L$. 4°. Or if *n* be a whole number, the number $n\,n$ of *springs*, each of the strength P, and length L, one after another. We may add, that it appears from hence that the number of similar and equal *springs* a given body in motion can wholly close, is always proportional to the squares of the velocity of that body. And it is from this principle that the chief argument, to prove the force of a body in motion to be as the square of its velocity, is deduced. See FORCE, *Appendix*.

The theorem abovementioned, and its corollaries, will hold equally, if the *spring* be supposed to have been at first bent through a certain space, and by unbending itself, to pass upon a body at rest, and thereby to drive that body before it, during the time of its expansion: only V, instead of being the initial velocity with which the body struck the *spring*, will now be the final velocity, with which the body parts from the *spring* when totally expanded.

It is also to be observed, that the theorem, &c. will hold equally good, if the *spring*, instead of being pressed inward, be drawn outwards by the action of the body. The like may be said, if the *spring* be supposed to have been already drawn outwards to a certain length, and in restoring itself draw the body after it. And lastly, the theorem extends to *springs* of any form whatever, provided L be the greatest length it can be extended to from its natural situation, and P the force which will confine it to the length. See Phil. Transf. N° 472. sect. 10.

SPRING, in natural history. Nothing is more certain, than that some *springs* wholly owe their origin to rains, though this is not the case with others. Those intermitting *springs*, which flow very largely after great rains, and then are gradually dried up, are owing wholly and entirely to rains; but those are not the only ones, but some of the perennial *springs*, which run in summer as well as winter, and in dry as well as wet seasons, are owing also to rains or vapours of a like kind: thus those *springs*, found at the tops of mountains, seem to be owing to the thick mists which we every day see hanging about the top of those mountains.

Though some *springs* are thus evidently owing to rain and vapours, yet others are plainly of some very different origin. The temporary *springs*, or irregular fountains we find in many parts of the world, cannot come from rains or dews, much less can those regular periodic fountains, of the nature of the Zirchnitzer sea in Carniola, and the fountain of Loire in France, and that of Lambsbourne in England: and it is yet less possible, that such vast perennial *springs*, as those of Wellowbridge in our kingdom, and of the Sorgue in France, can come from rains; for all the water that falls in the whole country about these places, in rains and dews, is not nearly so much as that which issues from them. *Plot*, de Origin. Font.

It is said [b] that in the diocese of Paderborn, in Westphalia, there is a *spring* which disappears twice in twenty four hours, and always returns at the end of six hours with a great noise, and with so much force, as to turn three mills not far from its source. It is called the *bolder-born*, or boisterous *spring*.—[b Philos. Transf. N° 7. p. 127.]

Burning, or *Boiling* SPRINGS. The *burning spring* near Grenoble in Dauphine is famous: St. Augustin speaks of it as extinguishing lamps which are lighted, and lighting those which are extinct [c]. But it is now cold like others; only near it is a spot of ground, which still emits a light flame; over which some imagine it might antiently have passed [d].

—[c *August.* de Civ. Dei, lib. 21. cap. 7. & 11. Mem. Acad. Inscipt. Tom. 9. p. 565. d Mem. Acad. Scien. An. 1699. p. 26.]

At Bosely, near Wenlock in Shropshire, there is a famous boiling well, which was discovered, in June 1711, by an uncommon noise in the night, so great, that it awakened several people, who being desirous to find what it was owing to, at length found a boggy place under a little hill, not far from the Severn; and perceiving a great shaking of the earth, and a little boiling up of water through the grass, they took a spade, and digging up some part of the earth, the water flew to a great height, and was set on fire by a candle. This water was for some time afterwards constantly found to take fire, and burn like spirit of wine; and after it was set on fire, it would boil the water in a vessel sooner than any artificial fire, and yet the *spring* itself was as cold as any whatever. Phil. Transf. N° 334.

This well was at length lost for many years, and not recovered till May 1746, when by a rumbling noise under ground, like to what the former well made, it was hit upon again, though in a lower situation, and thirty yards nearer the river.

The well is four or five feet deep, and six or seven wide; within that is another less hole of like depth, dug in the clay, in the bottom whereof is placed a cylindric earthen vessel, of about four or five inches diameter at the mouth, having the bottom taken off, and the sides well fixed in the clay, rammed close about it. Within the pot is a brown water, thick as puddle, continually forced up by a violent motion, beyond that of boiling water, and a rumbling hollow noise, rising and falling by fits five or six inches. It may be fired by a candle at a quarter of a yard distance; and it darts and flashes in a violent manner, about half a yard high. It has been left burning forty eight hours, without any sensible diminution. It may be extinguished by putting a wet mop upon it, which must be kept there a small time. On the removal of the mop there succeeds a sulphureous smoke, lasting about a minute, and yet the water is very cold to the touch. Phil. Transf. N° 482. sect. 6.

Lancarim SPRING. See the article LANCARIM.

SPRING-*arbor*, in a watch, that part in the middle of the *spring*-box, about which the *spring* is wound or turned, and to which it is hooked at one end.

SPRING-*box*, in a watch, the cylindrical case, or frame, that contains within it the *spring* of the watch.

SPRINGER, in ichthyology, a name given by authors to the grampus, or arca.

SPRINGES, (*Cycl.*) a sort of horsehair nooses, made so as to run very easy, and planted in the places where birds run in some particular path, to take them as they pass.

Those birds that frequent the waters, or love to paddle and feed in wet and plashy places, are the most easily taken by these *snares*.

The sportsmen who would use them to advantage, must first carefully search out the haunts and places where the fowls come in flocks, or in couples, and feed in the morning and evening hours. The furrows and water-tracks in these places are principally to be regarded; and wherever the several furrows, or water-courses, meet in one, and afterwards divide into several others, these places are to be remarked above the rest: the places which have most marks of the birds feet, give also the surest of all proofs, that they are well frequented. When these places are found, there should be placed a number of small and short sticks cross-wise overthwart all the other passages, one stick being placed about half an inch from another, and making together a kind of fence, guarding every way, except that one through which it is intended the fowls should pass. This being done, a good stiff stick is to be provided, cut flat on each side; both ends of this stick are to be planted under water, so that the upper part of the flat side may only be upon a level with the surface; then a bow is to be made of a hazel, or willow, in the form of a pear, broad and round at one end, and narrow at the other, and at least a foot long, and five or six inches wide; at the narrow end of this there is to be a nick or dent. Then a stiff young grown plant of hazel, elm, or withy, is to be chosen, being bushy and clear, and without knots, three or four inches about at the bottom, and about an inch at the top. Having made the bottom end of this sharp, at the top of it there must be fastened a very strong loop, made of about an hundred horsehairs, platted very fast together with strong packthread, and made to slip any way with great ease. This noose or loop should be just of the dimensions of the pear-fashioned loop before mentioned. Then hard by this loop, and within an inch of the end of the plant, there is to be fastened with strong horsehair a broad and thin trigger, made sharp at both ends. Then the bigger sharp end of the plant being made fast in the ground, just by the edge of the water; the smaller end, with the loop and the trigger, must be brought down just to the first bridge; and the pear-fashioned hoop being set upon the bridge, one end of the trigger must be set upon the nick in the hoop, and the other end on the

nick made on the ſmall end of the plate, which by the violence and bend of the plant will make them all ſtick together till the hoop be removed. This done, the loop is to be laid upon the hoop in ſuch faſhion as the hoop is proportioned: then from each ſide of the hoop little ſticks are to be pricked, as before directed, making as it were a kind of impaled path-way, widening it all the way as it goes farther from the hoop, and making it ſo conſiderably wide at the end, that any fowl that chances to come that way may be entered a conſiderable way in, before ſhe perceives the fence; by this means the bird will be enticed to go ſtrait on to the *ſpringe*, and as ſoon as ſhe touches it, either with head or feet, ſhe will be certainly caught; and thus if the plant be ſtrong enough, the largeſt bird may be caught as eaſily as the leaſt.

When the ſmaller fowls, that frequent watery places, are to be taken by this engine, it is to be made only a great deal ſlighter. When it is intended for ſnipes, woodcocks, or the like, the main plant may be of willow, hazel, or grown ozier, or any other pliant wood that will eaſily bend, and will recover its ſtraitneſs again. The uſe of this engine is limited to the winter-ſeaſon, and to times when there is much wet upon the ground. If there happen any great froſts, ſo that there is no advantage to be made of the wet places firſt deſcribed, then the ſportſman is to look for ſome place where there is a conſiderable fall, and where the current is not frozen, and in this place the *ſpringes* are to be ſet; and the greater the froſts are in this caſe, the more birds there will be taken.

There is another uſe of *ſpringes* for birds, which is the taking, by means of them, certain birds on the boughs of trees and in hedges, which is often attended with very great ſucceſs. The ſportſman, for this purpoſe, muſt firſt mark ſome tree where the birds very much reſort; then fix on ſome particular branch that is tolerably ſtrait, and cutting off all the twigs to within a foot or two of the top, he is there to bore a hole through the branch with a piercer or wimble, large enough to admit a gooſe-quill. Then another branch is to be pitched upon, at about a foot diſtance from the firſt, and all its boughs are to be pared away up to a certain height. There is to be fixed to this branch a packthread of half a foot long, and at the end of this is to be tied a nooſe of plated horſehair. The branch to which the packthread is faſtened, is then to be ſtooped ſo far, that the nooſe may be brought through the hole in the other branch, and faſtened there by means of a little ſtick four fingers long, and hooked at the end, juſt fitting the hole, and ſo brought into it, as juſt to ſtop the flying back of the other branch. Then there is to be placed beyond the nooſe ſome bait of a fruit, or inſect, as a cherry, a pear, or a worm, or any other thing which the bird, intended to be taken, is known to be fond of: this is to be ſet in ſuch a manner, that the bird can no way get at it but by ſetting its feet on the ſmall ſtick which ſupports the nooſe, and ſtops the hole. The weight of the bird will throw down the ſtick, and the bird will then be caught by the legs, and tied faſt to the branch where the hole is, by the flying back of the other branch where the packthread is faſtened.

There is yet another method in uſe for the taking many kinds of birds, from the partridge or pheaſant to the blackbird. This is made in the following manner, and is to be placed either on the ground, or on a tree, buſh, or hedge, according to the nature of the bird intended to be taken by it. A ſtrait and even piece of willow, or ſallow, is to be choſen, of about ſix feet long, and of the thickneſs of a walking cane; this is to be ſharpened at one end, and ſtuck down into the ground, and at the other end there is to be faſtened a ſmall crook; then two holes are to be made in the ſtick, the one big enough to admit a gooſe-quill, the other ſmaller; and a piece of ſtick is to be choſen, which being bent will ſpring back to its ſtraitneſs again, ſuch as holly, or the like: this ſhould be about three feet long, and the larger end of it is to be fixed in the larger hole of the firſt ſtick; the ſmaller end muſt have faſtened to it a packthread, at the end of which there is a nooſe of horſehair: this is to be brought through the ſmaller hole, and be pegged in ſo ſlightly, as juſt to prevent its flying back of itſelf. Then the *ſpringe*, or nooſe, is to be ſpread on the peg, and a bait, proper for the bird intended to be taken, is to be placed at a proper diſtance; ſo that the bird cannot come at it but by treading on the peg, which will give way under its weight, and the ſtick, to which the packthread is faſtened, will fly back, and the bird will be conſequently caught in the nooſe, and have its legs drawn cloſe to the other ſtick.

SPRINGING *a leak*, at ſea, is ſaid of a ſhip that begins to leak. See the article LEAK.

SPROD, among the fiſhermen of many parts of England, a name given to the ſalmon while in its ſecond year's growth. *Willughby*, Hiſt. Piſc. p. 189. See the article SALMON.

SPULLERS *of yarn*, in our old writers, perſons that work at the *ſpole*, or wheel. It alſo denotes triers of yarn, to ſee if it be well ſpun, and fit for the loom. *Blount*.

SPUN-*hay*, in the military art, hay twiſted in ropes, very hard, for an expedition in the winter-time; each trooper carrying as much as he can behind him.

SPUNGE, (*Cycl.*) *ſpongia*, in botany. See the article SPONGIA.

This ſpecies of ſea plant, when burnt, yields the ſame ſmell with hair or horns, or other parts of animal bodies.

A pound of *ſpunge* when weighed in a humid ſeaſon, on drying carefully in a ſtove without injuring its texture, will be reduced to eleven ounces. This quantity being diſtilled by the retort in the common way, and the principles ſeparated, and the ſalt and ſpirit rectified, there will be found an ounce and half of a reddiſh phlegm, or a ſpirit ſo weak, as ſcarce to afford any ſmell or taſte; an ounce and half of a volatile urinous ſpirit; and an ounce, four drachms and a half of a volatile urinous ſalt; half an ounce of a fetid thick oil; half an ounce of a fix'd ſalt, which, beſide the common lixivial alkali, contains ſome ſea ſalt; and five ounces of a caput mortuum, in which the magnet diſcovers ſome particles of iron.

The weight of all theſe amounts to that of the dried *ſpunge* put in, within three drachms, which is a moderate loſs from evaporation, and from ſome little remains which will always ſtick to the veſſels. By this analyſis we find, that *ſpunge* gives nearly as much volatile ſalt as raw ſilk, which yields the moſt of any known animal ſubſtance; and the difference between the quantity, yielded by that ſubſtance and this, is not more than four grains from the ounce. Mem. Acad. Par. 1706.

A wet *ſpunge* applied to bleeding-veſſels, has been found a very ſucceſsful method of ſtopping the effuſion of blood. Vid. Phil. Tranſ. N° 478. p. 33.

Cotton-SPUNGE, a name given by ſome writers to a ſpecies of ſea *ſpunge* very fine and light, and reſembling cotton in its texture. It is found at conſiderable depths, growing on the rocks in form of a coarſely-branched ſhrub; it is of a greyiſh colour, and very flexile; but it is often rendred coarſe and rigid, by being covered in certain parts with that ſort of tartarous, or cruſtaceous ſubſtance, which ſome of the antients have deſcribed under the name of an *alcyonium*, and others of an *adarce*, and which the druggiſts of the late ages have taught us to call *lapis ſpongiæ*, the *ſpunge*-ſtone. It is formed itſelf of bundles of fibres, and though it has the appearance of a very open texture, yet it admits the water but very badly, and does not imbibe it in any thing like the quantity that the common *ſpunge* does, nor is it, when imbibed, ſo eaſily preſſed out again.

When examined by the microſcope, this plant appears not at all of the ſtructure of the common *ſpunge*, but ſeems a mere aſſemblage of oblong and ſlender fibres, like thoſe of cotton or wool, not hollow, and very cloſely amaſſed together: theſe are not capable of imbibing any other moiſture than the little that can get between their interſtices in the maſs, and the yet much ſmaller quantity that can enter the ſubſtance of the filaments themſelves. Hence it is no wonder, that this plant will not imbibe water ſo readily as the common *ſpunge*, or retain it ſo well when imbibed, and yet will not yield ſo to the preſſure of a hand, as to part with it as that does.

The *ſpunge*-ſtone, or tartarous incruſtation on this plant, when examined by the microſcope, is found to be very like the incruſtations of ſtony or ſparry matter upon ſticks and ſhells, in ſome of thoſe waters which we call *petrifying ſprings*, for the whole thickneſs of it is compoſed of ſeveral thin laminæ; but then, as in thoſe incruſtations, each of theſe laminæ is of one ſimple piece, and generally of a tranſverſely ſtriated texture. In the *ſpunge*-ſtone each lamina is not thus ſtriated, nor is indeed of one piece, but is a congeries of numbers of ſimple ſmall cakes, reſembling the ſcales of fiſhes. *Marſigli*, Hiſt. Phyſ. de la Mer.

Loaf-SPUNGE, in natural hiſtory, a name given by authors to a peculiar ſpecies of *ſpunge* of the marine kind. It is called by the French *eponge en mie de pain*.

It grows at conſiderable depths to the rocks among coral, and other ſea plants. Its ſhape is uſually that of a common loaf, and its texture very much reſembles that of the crumb of bread. It is very various in colour at different times, being uſually of a fine ſcarlet; ſometimes, however, it is purple, ſometimes of a violet colour, and ſometimes ſnow white, but this more rarely than of any other colour. It is the ſofteſt and lighteſt of all the *ſpunge*-kind, being better ſuited to imbibe the water than any other. It would be greatly eſteemed for the common uſes of *ſpunge*, if it were produced in plenty enough to be had on the common occaſions, but it is ſcarce. When examined by the microſcope, it is found to be compoſed of an almoſt infinite number of cavities and protuberances, and is compoſed of an infinite ſucceſſion of ſmall fibres, which are arranged in a very beautiful manner, and ſeem held together by a ſort of glutinous matter. *Marſigli*, Hiſt. Phyſ. de la Mer.

SPUNGE, in the manege, is the extremity, or point of a horſe's ſhoe that anſwers to the heel of his foot; upon it the calkins are made. Thick *ſpunge* ruins the horſe's heels, and therefore ought never to be uſed.

SPURGE, in botany, the Engliſh name of the *tithymalus*. See the article TITHYMALUS.

This plant abounds in a thin and ſharp milky juice. On being wounded, it throws this out freely. It is clammy between the fingers, and though perfectly white when firſt let out, it turns bluiſh, on being held a while upon a knife or lancet, and has the colour and conſiſtence of blue ſkimmed milk. If it be made up into cakes with flower, it ſeems greaſy or oily, and never dries. Moſt of the milky juices of plants, as thoſe of the wild lettuce, throatwort, and the like, readily break into curds and whey on being expoſed to the air; and in the firſt of theſe, the whey is of a fine purple colour. The *ſpurge* juice requires a long time ſtanding before it breaks, but at length it ſeparates, and the curd is tough and firm, and the whey clear as rock water. The whole is very corrupt and ſtinking at this time, and if the cake of curd be dried, it ſeems a ſort of reſin, and will break and burn like reſin at a candle.

SPURGE-*laurel*. See the article LAUREOLA.

SPURGE-*root*, in the materia medica. See the article ESULÆ *radix*.

SPURKETS, in a ſhip, the ſpaces in her ſide betwixt the upper and lower futtocks, or betwixt the rungs fore and aft.

SPURRE, in zoology, a name given by many to the bird more commonly called the *ſea-ſwallow*, and by authors *ſtema*. *Ray*'s Ornitholog. p. 269. See the article STEMA.

SPURRY, in Latin *ſpergula*, is ſown in the Low-Countries twice in a ſummer. The firſt ſowing is in May; theſe plants flower in June and July, and the ſeed is ripe in Auguſt. The ſecond time of ſowing it is after the rye-harveſt; they uſually plow up the rye-grounds, and ſow them with this ſeed to ſerve the cows in winter, when the other ſorts of graſs are low or dead. The cows that feed on this plant are found to yield better milk, and finer butter is made from it, than from that of cows feeding on any other paſture. Poultry alſo are very fond of eating this plant, and the farmers in ſome places have an opinion, that it makes them lay the more eggs. *Mortimer*'s Huſbandry, p. 43.

SPYRUS, the *dung of goats*. This is uſually found in ſmall round maſſes, and is recommended by Hippocrates as a fumigation in diſeaſes of the womb.

SQUACCO, in zoology, the name of a large bird of the heron kind. Its head and neck are variegated with black, white, and yellow, and it has on the back part of its head a cruſt of the ſame colour. Its back is of a ferrugineous yellow; its breaſt and belly are white, as are alſo its wings and tail, at leaſt in great part; and its legs are green. It is a bold and fierce bird. *Aldrovand.* de Avib. p. 400.

SQUAIOTTA, in botany, the name of a bird of the heron kind. Its beak is yellow, but blackiſh at the extremity; its legs are green; its head is variegated with grey and black; and its back very elegantly with white and red. It ſeems to have had its name from its note, which it often repeats in flying. *Aldrovand.* de Avibus.

SQUALIUS, in ichthyology, a name given by Pliny to the chub. Varro, and others of the old writers, have called it *cephalus* and *ſqualus*, and the Italians at this time call it *ſquaglio*; it is wrong, however, to adapt any generical name to a fiſh, which is itſelf but a genuine ſpecies of an already eſtabliſhed genus. This is properly a ſpecies of the cyprini, and is mentioned as ſuch by Artedi.

SQUALLEY, a note of faultineſs in the making of cloth. 43 Eliz. cap. 10. *Blount*, *Cowel*. See REWEY.

SQUALUS, in the Linnæan ſyſtem of zoology, the name of a diſtinct genus of fiſhes, of the general order of the chondropterygii. The characters of this are, that the body is oblong, and the apertures of the gills are five on each ſide. Of this genus are the galeus, lamia, zygæna, *&c.* *Linnæi* Syſt. Nat. p. 52.

The characters of this genus, according to Artedi, are theſe. The foramina, or apertures of the bronchia, are five on each ſide, and they are placed longitudinally from the head to the pectoral fins; the head is depreſſed; the body oblong, and either rounded, or longiſh and angular; the ſkin is rough; the eyes are placed at the ſides of the head; and the upper part of the tail is longer than the under. The mouth in moſt of the ſpecies is placed in the under part of the head, and opens tranſverſely. The ſpecies of this genus are theſe.

Of thoſe which have granulous teeth are the following. 1. The *ſqualus* with a long-pointed and bony ſnout, flatted and denticulated at each ſide. This is the *priſtis*, or ſaw-fiſh. 2. The ſmooth *ſqualus* with granulous teeth. This is the *galeus lævis*, or ſmooth hound-fiſh.

Of thoſe which have ſharp teeth, and a prickly back, the following are the ſpecies. 1. The *ſqualus* with no pinna ani, and with a rounded body. This is the *galeus acantheus* of authors, or the prickly dog-fiſh. It has three rows of teeth on each ſide. 2. The *ſqualus* with no pinna ani, with the noſtrils placed at the extremity of the ſnout. The back of this is flat, and the belly rough and brown. 3. The *ſqualus* with no pinna ani, and with a triangulate body. This is the *centrine* of authors. This has three rows of teeth in the upper jaw, and only one row in the under. 4. The *ſqualus* with no pinna ani, and with the mouth placed at the end of the head. This is the *ſquatina* of authors, the monk-fiſh, or angel-fiſh, by ſome called the *mermaid*. It has three rows of teeth in each jaw, the whole number amounting to one hundred and eighty, or thereabout.

Of thoſe *ſquali* which want the pinna dorſi, the following are the ſpecies. 1. The *ſqualus* with a broad and tranſverſe head, ſhaped like a hammer. This is the *zygæna* of authors, the balance-fiſh, or hammer-headed ſhark. This has three or four rows of teeth in the jaws, and oblong holes near the eyes. 2. The *ſqualus* with a tail longer than the whole body. This is the fiſh called by authors the *vulpes marinus*. The tail is falcated, and reſembles a ſword in ſome degree. 3. The *ſqualus* with the noſtrils placed near the mouth, and with two ſmall foramina near the eyes. This is the *galeus canis* of authors. It is called in Cornwall a *tope*. It grows to five feet long, and weighs an hundred pounds. 4. The *ſqualus* of a reddiſh variegated colour, with the pinna ani at a middle diſtance between the anus and the fin of the tail. This is called the *catulus major*, and in England the *bounce*. 5. The *ſqualus* with the variegated back, and with the belly fins growing together. This is the *catulus minor* of authors, and is called the *rough hound*, or the *mergay*. 6. The grey *ſqualus* with the ventral fins not joined together. This is the *catulus maximus* of authors. 7. The *ſqualus* with a triangular hollow in the extremity of the back, and no foramina about the eyes. This is the *galeus glaucus* of authors, or the new ſhark. 8. The *ſqualus* with a flat back, and with numerous teeth ſerrated at the edges. This is the *canis carcharias*, or common ſhark. It is the largeſt of all the *ſquali*, often growing to ſuch a ſize, as to weigh a thouſand pounds. The ſnout is long. The teeth are for the moſt part ſerrated, and there are ſix rows of them above, and as many below, though ſometimes they are fewer. The two backfins are placed, one in the middle of the back, the other very near the tail. The ſkin is rough. *Artedi* Gen. Piſc. p. 44.

SQUALUS is alſo a name given by Varro, Columella, Salvian, and others, to a ſpecies of the cyprinus, diſtinguiſhed by Artedi by the name of the oblong *cyprinus* with long ſcales, and with the pinna ani containing eleven rays, and commonly known with us under the name of the *chub*, or *chevin*. The generality of authors call it *capito* and *cephalus*, but it is very improper to give diſtinct generical names to fiſh, which are genuine ſpecies of other genera.

The name *ſqualus* is originally Latin; it is uſed by Pliny, and many other of the old Roman authors, and is derived from the word *ſqualor*, becauſe this fiſh is found to delight in impure and dirty places.

SQUAMIS, in ichthyology, a name given by Albertus, and others, to the fiſh called by us the *monk*, or *angel-fiſh*, by the generality of authors *ſquatina*, and by the old Greek writers *rhine*.

It is a ſpecies of the ſqualus, and is diſtinguiſhed by Artedi by the name of the *ſqualus* with the mouth at the end of the ſnout. See SQUATINA.

SQUAMMOSE-*culm*. See the article STALK.

SQUAMMOSE-*root*, among botaniſts, one compoſed of, or covered with leſſer flakes. See ROOT.

SQUARE (*Cycl.*)—SQUARE, in glaſs-making, an inſtrument with which the conciator, or founder, ſtirs and mixes together the metal when in fuſion in the melting-pots. When this inſtrument is grown red-hot, it is always to be quenched in a pail of water, otherwiſe the metal will ſtick to it. *Neri*'s Art of Glaſs, p. 240.

SQUARE, in the manege, is uſed for working in a *ſquare*. The piſte or tread of a volt, inſtead of being always circular, and traced upon a circumference round a center, ought to be imagined as if it formed four ſtraight equal lines laid in a *ſquare*, and equally removed from the center, or the pillar, which repreſents it in the middle of the manege-ground; ſo that to work in a *ſquare*, is to ride along each of theſe four lines, turning the hand at every corner, and ſo paſſing from one line to another.

SQUARE, in the ſea language, is to ſet even. Thus they ſay, *ſquare the yards*; that is, ſet them right acroſs the ſhip. See the article YARD.

SQUARTIA, in ichthyology, a ſpecies of fiſh found in the Eaſt-Indies, the ſkin of which makes the ſhagreen. *Hofm.* Lex. in voc. See SHAGREEN.

SQUATAROLA, in zoology, a name given by the Venetians to the grey plover, or *pluvialis cinerea*. See the article PLUVIALIS.

SQUATINATORIA, in zoology, a name by which ſome authors have called the rhinobatus, a ſea fiſh of a ſort of middle nature between the monk-fiſh, or angel-fiſh, and the ray. *Willughby*, Hiſt. Piſc. p. 79. See the article RHINOBATUS.

SQUATINA, the *monk-fiſh*, called alſo in Italian the *peſce angelo*, and thence in Engliſh the *angel-fiſh*.

It is of a middle ſhape, between the long and flat cartilagineous fiſhes, being much broader than the galei, and rounder

rounder than the rays. It grows to a very large ſize, ſometimes to four, five, or ſix feet long. It is covered all over with a mucous ſubſtance, but under it the ſkin is harſh, and rough enough to ſerve for the poliſhing wood and ivory. It is of a browniſh grey on the back and ſides, and white under the belly. The head is flatted and roundiſh, and the mouth large, and opening at the extremity of the ſnout, not, as in other of the fiſhes of this claſs, under the head. It has three rows of teeth, eighteen in a row. Its eyes are large, and placed near its mouth, and ſeem as if meant for looking ſideway, rather than up or down. Its upper pair of fins very much reſemble wings, from whence it has its name of the *angel-fiſh*, and at the extremities of theſe are a number of ſharp hooked thorns. It has alſo a row of ſhort prickles on its back. See Tab. of Fiſhes, N° 7.

It is common in the Engliſh ſeas, and is not unfrequently caught in Cornwall. *Johnſon*, de Piſc. p. 23.

SQUATT, in mineralogy, a term given by the Engliſh miners to a peculiar ſort of bed of ore, leſs valuable than a load or vein, becauſe of its reaching but a little way.

Though the ore of the *ſquatts* is generally very rich and good, not inferior in quality to the beſt vein-ore, the miners are often terribly diſappointed, on finding theſe *ſquatts* inſtead of the right veins, after a long ſearch. In the tin countries, the way of ſearching for mines is by looking after the ſhoad-ſtones; that is, certain metalline ſtones which contain ſome ore, and which have originally made the upper part of the vein of ore, reaching up to the day, or the ſurface of the earth. See SHOAD.

In the time of the deluge theſe upper parts of the veins have been waſhed off, and carried down the ſides of the hills, in which the mines uſually lie, into the flat country, but they always lie in a regular and continued train, from the orifice of the mine to the fartheſt part of the train; ſo that when but one ſtone of this kind is found, the miners are certain of coming to the bed of metal, on tracing it up to its head by the train. This is a laborious and expenſive work, becauſe the ſtones never lie on the ſurface, but at the different depths of one to ten feet, or any depth between theſe. The *ſquatts* have their trains of ſhoad-ſtones as well as the regular veins, and when theſe are traced to the orifice, there is the appearance of a rich load, which the proprietor is not thoroughly undeceived in, till the diggers come to the end of it.

The *ſquatt* is a bed of ore from three to ten fathom long, and uſually is about half as broad as it is long; few are larger than this ſtandard, but many much leſs. This is always flat, and thence has its name; the round collections of ore of the ſame kind being called *bonnies*. The *ſquatt* communicates with no other load or vein, but is entire of itſelf, and its extremities terminate at once, without running into ſeveral little ſtrings, in the manner of thoſe of the right veins. It does not lie within walls, as the loads or veins always do, though it is always depoſited in the ſhelf, or faſt ground; that is, in ſtrata that have not been moved by the flood. Phil. Tranſ. N° 69.

SQUATUS, in ichthyology, a name uſed by Pliny, and other of the old Roman authors, to expreſs the fiſh called by the old Grecian writers *rhine*, and by the moderns *ſquatina*.

It is a ſpecies of the ſqualus, and is diſtinguiſhed by Artedi under the name of the *ſqualus* with no pinna ani, and with the mouth in the top of the ſnout. See SQUATINA.

SQUILL, SCILLA, or *ſquilla*. See SCILLA, *Cycl.*

Wagner recommends the powder of *ſquills*, given with nitre, in hydropical ſwellings, and in a nephritis, and mentions ſeveral examples of cures which he performed, by giving patients from four to ten grains with a double quantity of nitre. He ſays it almoſt always operates as a diuretic, ſometimes vomits or purges. Medic. Eſſ. Edinb.

Dr. Heſs ſays, he has made cures of the aſthma with the powder of *ſquills*. The efficacy of this powder of *ſquills*, from four to twelve grains, in curing the aſthma, is atteſted by ſeveral. Med. Eſſ. ibid. from Commerc. Norimb. 1737, & 1739.

SQUILACHI, in zoology, the name by which the modern Greeks call the *jackall*, or *lupus aureus* of authors. *Bellon.* lib. 2. cap. 107. See JACKALL.

SQUILLA *aquæ dulcis*, the *freſh-water ſhrimp*. Few people are aware of the vaſt deſtruction made by this little inſect among the ſmall fry of fiſh. This inſect is commonly very plentiful in ſtanding waters, and particularly in breeding-ponds, where they always have their prey in plenty before them; and often ſuffer none, or ſcarce any of the numerous young fry, hatched from the ſpawn of carp and tench, to live to grow up. They may be obſerved following the ſhoals of the young fry, and ſeizing multitudes one after another; and at other times lurking among the weeds, to ſeize ſuch as ſtraggle by themſelves. If one of theſe inſects be put into a baſon of water with a dozen or two of theſe young fiſh, though as big as himſelf, he will very ſoon deſtroy them all. They kill numbers that they cannot eat, but leave them to rot.

SQUIRREL, *ſciurus*, in zoology. See the article SCIURUS.

There is great diverſion in the hunting this little creature, and its fleſh is very delicate and well taſted. The only ſeaſon for hunting it is in autumn, and the beginning of winter, at which time the creature is fat; and the leaves being off the trees, it may be ſeen as it leaps from bough to bough, which when purſued it does with a ſurpriſing agility.

In the ſummer they build their neſts, which the ſportſmen call *drays*, very artificially in the tops of trees, with ſticks, moſs, and ſuch other things as the woods afford; they fill this lodging, during the ſeaſon, with nuts and other fruits, which are to ſerve them in the ſevere weather, when the trees afford nothing. They ſleep in the midſt of this proviſion a great part of the winter, and that ſo ſound, that they will not be waked by ever ſo loud a noiſe made juſt under their drays; though at other times they fly out immediately on hearing any noiſe, even at a conſiderable diſtance.

The tail of the *ſquirrel*, which is as large as the body, though compoſed almoſt entirely of hair, ſerves the creature, in ſome ſort, inſtead of wings; for by means of it the body is kept ſuſpended in the air, without any viſible ſinking, while the creature throws itſelf from the boughs of one tree to thoſe of another of equal height. But the more general leaps the *ſquirrel* takes, are from the outermoſt branches of a high tree to another ſomewhat lower at a diſtance; it is wonderful to ſee how far it will be carried in theſe leaps; and if it miſſes the tree it aims at, and by that means falls from the top of ever ſo high a tree to the ground, the tail ſupports it ſo well, that it comes ſoftly down, and receives no harm. The hunting of the *ſquirrel* is moſt agreeably performed in woods of a young growth, the trees of which may be ſhaken by the hand; and it is neceſſary to take out ſome means of diſlodging them from the clefts of trees, in which they will take refuge, and from which they will never be removed by mere noiſe.

Many people uſually go together on this expedition, and ſometimes they carry bows and arrows for the diſlodging the prey from theſe places; ſometimes bludgeons, or ſhort and thick ſtaves, loaded at one end with lead, to prevent their lodging in the trees, when they are thrown up. The *ſquirrel* which in her fright has taken refuge in any part of a tree, and is not to be diſlodged either by hollooing or ſhaking the tree, will always quit the place as ſoon as an arrow, or bludgeon, has been well aimed at her, and will give a farther chaſe.

The *ſquirrel* is always fond of a large oak in time of danger, and runs to the neareſt ſhe can find as ſoon as ſhe ſees herſelf purſued: in ſome part of the upper boughs of this tree ſhe ſits ſecure from the men and dogs, and as it is too troubleſome to the ſportſmen to climb every tree, the only method is to ſhoot arrows, and throw bludgeons at her; ſhe is very ſeldom hurt by theſe, unleſs hit juſt upon the head, for her backbone is ſo ſtrong, that ſhe will bear very nearly as hard a blow as a dog without danger of hurt. So long as the ſtrength and ſpirits of the creature laſt, ſhe always keeps in the tops of the higheſt trees, but when ſhe grows weary ſhe comes down, and takes ſhelter in the hedges; ſhe then ſoon becomes a prey to the dogs, or is very often killed upon the ground, in attempting to gain the hedge in places where there is no continued chain of trees by which ſhe can come at it.

The common *ſquirrel*, when it would croſs a water, is often ſeen to get upon ſome light piece of wood, and ſail over by means of her tail.

Flying-SQUIRREL. The *flying-ſquirrel* is a creature famous in hiſtory for being one of thoſe few animals which ſhew, that nature has given to ſome quadrupeds a power of flying.

This however is an obſervation not ſo well verified in this creature as in the bat, which is truly a quadruped, its fore feet being only expanded into wings, and webbed, and which truly flies; whereas all that is called flying in this *ſquirrel*, is only its ſuſpending itſelf in the long leaps it makes by means of a membrane on each ſide of the body, attached to the fore legs, and reaching to the hinder ones, only growing narrower all the way.

This creature is found in ſeveral parts of America, and in many places on the confines of Ruſſia toward Tartary. It lives in hollow trees, and covers itſelf carefully up with moſs. It ſeldom ſtirs abroad in the day-time, but toward evening goes out in ſearch of food. When kept within doors it ſleeps the whole winter, but revives in ſpring. The manner in which they catch them in Ruſſia is this: they tie a net over the hole in a tree where they ſuſpect any of theſe creatures to lie hid, then they kindle a fire of ſtraw, or light buſhes about the foot of the tree, and as ſoon as this begins to ſmoak pretty much, the creatures come out of the holes, and are taken in the net. Their ſkin is extremely ſoft, and the hair is ſhort, and of a blackiſh grey. Philoſ. Tranſ. N° 427. p. 37.

STABILES, in the antient muſic, was a name given to the extreme chords of a tetrachord.

They were ſo called, becauſe they remained the ſame throughout all the genera and ſpecies of muſic[c]. One of theſe chords was the hypate, and the other the nete. They are

ſometimes alſo called *ſtantes*, *immobiles*, or *quieſcentes*; and by the Greeks ἑστῶτες, ἀκίνητοι, ἠρεμοῦντες [f].—[e Vid. Philoſ. Tranſact. N° 481. f *Wallis*'s Append. ad Ptolem. Harm. p. 159.]

STABLE. Nothing conduces more to the health of a horſe, than the having a good and wholſome *ſtable*. The ſituation of a *ſtable* ſhould always be in a good air, and on a firm, dry, and hard ground, that in winter the horſe may come in and go out clean. It ſhould always be built ſomewhat on an aſcent, that the urine, and other foulneſſes, may be eaſily conveyed away by means of drains or ſinks cut for that purpoſe.

As there is no animal that delights more in cleanlineſs than the horſe, or that more abominates bad ſmells, care ſhould be taken that there be no hog-ſtie, hen-rooſt, or neceſſary-houſe near the place where the *ſtable* is to be built; for the ſwallowing of feathers, which is very apt to happen when hen-rooſts are near, often proves mortal to horſes, and the ſteams of a hog-houſe, or hog's dung, will breed many diſtempers; and particularly, they will bring on the farcy and blindneſs in many horſes. It is much better to build the walls of a *ſtable* of brick than of ſtone, for the former is always dry, the other often ſweats, and is very apt to be damp, and to cauſe rheums and catarrhs to horſes that are ſet in the *ſtable* in damp weather.

The walls ought therefore to be of brick, and to be made of a moderate thickneſs, two bricks, or a brick and half at the leaſt, both for the ſake of ſafety and warmth in winter, and to keep off the heat of the ſun in the midſt of ſummer, which would ſpoil the horſe's appetite, and ſink his ſpirits. The windows ſhould be made on the eaſt and north ſides of the building, that the north air may be let in to cool the *ſtables* in ſummer, and the riſing ſun all the year round, eſpecially in winter.

The windows ſhould either be ſaſhed, or have large caſements, for the ſake of letting in air enough; and there ſhould always be cloſe wooden ſhutters, that the light may be ſhut out at pleaſure; by which means the horſe will be brought to ſleep in the middle of the day, as well as in the night, when it is judged proper that he ſhould do ſo.

Many pave the whole *ſtable* with ſtone, but it is much better to have that part, which the horſe is to lie upon, boarded with oak planks; for it will be not only eaſier, but more warm and comfortable to the creature.

The boards muſt be laid as even as poſſible, for this is the way to make the creature lie moſt at his eaſe, and in the moſt healthful poſture. The dealers in horſes generally indeed make the boards be laid higher toward the top, and ſlanting down: this ſhews a horſe to more advantage as he lies, but it is very uncomfortable to the creature, and his hinder parts are always ſlipping down, and the hind legs are often made ſubject to ſwellings by it.

The planks ſhould be laid croſswiſe, not lengthwiſe, and there are to be ſeveral holes bored through them to receive the urine, and carry it off underneath the floor into ſome drain, or common receptacle. The ground behind ſhould be raiſed to a level with the planks, that the horſe may always ſtand even, and the floor behind ſhould be paved with ſmall pebbles, and the place where the rack ſtands ſhould be well wainſcotted. There are to be two rings placed on each ſide of the ſtall, for the horſe's halter to run through, and a logger is to be fixed to the end of this, ſufficient to poiſe it perpendicularly, but not ſo heavy as to tire the horſe, or to hinder him from eating. The beſt place for him to eat his corn in is a drawer, or locker, made in the wainſcot partition; this need not be large, and conſequently need not take up much room, ſo that it may be eaſily fixed, and taken out to clean at pleaſure: by this means, the common dirtineſs of a fixed manger is to be avoided.

Many people are againſt having a rack in their *ſtables*; they give the horſe his hay ſprinkled upon his litter, and if they think he treads it too much, or too ſoon, they only nail up three or four boards, by way of a trough, to give it to him in. The reaſon of this is, that the continual lifting up the head to feed out of the rack is an unnatural poſture for a horſe, which was intended to take his food up from the ground, and makes him, as they expreſs it, withy-cragged. In the way of ſprinkling the hay on the litter, or laying it in a trough even with the ground, he not only takes it up as if from the earth in a natural way, but can eat as he lies, which is a piece of indulgence that a horſe takes great pleaſure in.

When there is *ſtable*-room enough, partitions are to be made for ſeveral horſes to ſtand in; theſe ſhould always allow room enough for the horſe to turn about, and lie down conveniently in, and they ſhould be boarded up ſo high toward the head, that the horſes placed in ſeparate ſtalls may not be able to ſmell at one another, nor moleſt each other any way. One of theſe ſtalls ought to be covered in, and made convenient for the groom to lie in, in caſe of a great match, or the ſickneſs of a valuable horſe. Behind the horſes there ſhould be a row of pegs, to hang up ſaddles, bridles, and other neceſſary utenſils; and ſome ſhelves for the hanging up bruſhes, &c. and the ſtanding of pots of ointment and other preparations.

The *ſtables* of the nobility are often incommoded by bins for oats placed in them, which take up a great deal of room with very little advantage. Dr. Plot has given us, in his hiſtory of Oxfordſhire, a very convenient method, uſed by a gentleman of that county, to prevent this. It is done by making a conveniency to let the oats down from above, out of a veſſel like the hopper of a mill, whence they fall into a ſquare pipe of about four inches diameter, let into the wall, which comes down into a cupboard alſo let into the wall, but with its mouth ſo near the bottom, that there ſhall never be more than about a gallon in the cupboard at a time; which being taken out, and given to the horſes, another gallon immediately ſucceeds it from above, without any trouble to the groom or any body elſe. By this means there is not an inch of room loſt in the lower part of the *ſtable* where the horſes ſtand; and there is this great conveniency beſide, that the oats are always kept ſweet by it; for every gallon that is taken away puts the whole quantity above in motion, by the running down of the gallon that ſupplies its place, and no muſtineſs ever comes, where there is this continual airing and motion. There may eaſily be contrived two of theſe, the one for the oats, the other for ſplit beans; and both of theſe may be let into the range of preſſes, the oats and beans being ſeparated above by partitions. The other requiſites for a *ſtable* are a dung-yard, a pump, and a conduit; and if ſome pond or running river be near, it is greatly the better.

STACCATO, or STOCCATO, in the Italian muſic, intimates that every note ſhould be divided and ſeparated from the next in a very plain and diſtinct manner, and is much the ſame with *ſpiccato*. *Broſſard*.

STACHYS, in botany, the name of a genus of plants, the characters of which are theſe. The flower conſiſts of one leaf, and is of the labiated kind. The upper lip is ſomewhat arched, and ſtands erect, the lower is divided into three ſegments, of which the lower is conſiderably the largeſt. The piſtil ariſes from the cup, and is fixed in the manner of a nail to the hinder part of the flower, and ſurrounded with four embryos, which afterwards become ſo many ſeeds, and ripen in the cup of the flower into a roundiſh ſhape. To theſe marks it may be added, that the leaves are hoary, as Dioſcorides deſcribes thoſe of *ſtachys* to be.

The ſpecies of *ſtachys*, enumerated by Mr. Tournefort, are theſe. 1. The great German *ſtachys*. 2. The great German *ſtachys* with paler flowers. 3. The broad-leaved Cretic *ſtachys*. 4. The narrow-leaved Cretic *ſtachys*, called *baſtard ſtachys*. 5. The leſſer Italian *ſtachys*. 6. The mullein-leaved ſhrub American *ſtachys*. *Tourn.* Inſt. p. 186.

STÆBE, in botany, a word uſed by the Greeks as the name of ſeveral plants, very different one from another.

Dioſcorides frequently calls the hippophaes by this name *ſtæbe*; Theophraſtus alſo calls his hippopheos and pheos by the ſame name; and what Hippocrates ſays of the fruit of the hippopheos, is by the modern Greeks interpreted the ſeed of the *ſtæbe*. The pheos and hippopheos were thorny plants of the ſhrub kind, growing on the ſea-coaſts of Crete and other places, and are ſtill called by the inhabitants *ſtæbis*. But beſide theſe there was a ſmall plant, called by the old Greek writers *phleos*. This was a ſmall ſoft herb, growing in damp places, and uſed to ſtuff beds with, and to other ſuch purpoſes. This alſo was called by the ſame authors *ſtæbe*. See the next article.

STÆBIS, in botany, a name given by the modern Greeks to a plant growing very plentifully in the iſland of Crete, and ſeeming to be the ſame with the *ſtæbe* of the antient Greeks, when uſed as the name of the pheos or hippopheos; for the antients uſed it alſo as the name of a low plant of the gnaphalium kind, growing in marſhy places, and uſed to ſtuff beds, &c. with.

It is evident that Dioſcorides calls the pheos and hippopheos, or, as he writes it, hippophaës, by the name *ſtæbe*; and Neophytus tells us, that the *ſtæbe* of Dioſcorides was called in his time, in the vulgar Greek, *ſtæbion*, and *ſtæbis*.

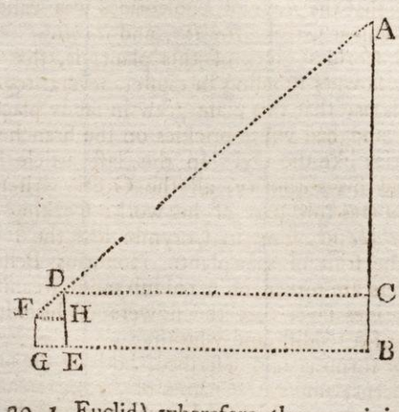
The deſcription Dioſcorides gives of this plant, is, that it had ſmall and fleſhy flowers ſtanding in cluſters ſeveral together; and Pliny tells us, that this plant grew in ſandy places near the ſea-ſhores, and had white prickles on the branches, and cluſters of berries like the ivy. In this laſt article he ſeems to go beyond his authority, all the Greek writers, from whom he tranſlates this part of his work, ſpeaking of the flowers of the *ſtæbe* growing in Corymbi like the ivy, but not giving it the fruit of that plant. Honorius Bellus ſays, that the flowers are mixed of a reddiſh and greeniſh colour; and Dioſcorides ſays, that the flowers of his hippopheos are mixed of a reddiſh and whitiſh.

The whole plant or ſhrub is alſo deſcribed, both by the antients and the moderns, under the names of *hippopheos* and *ſtæbis*, in the ſame manner: they ſay it grew to about three feet high, ſpreading its branches, ſo as to form a round buſh, and that the prickles or thorns grew under the leaves. They were both put to the ſame uſe alſo, and all the in-

terpreters of the old Greeks have agreed in looking upon them as ſynonymous terms. The fruit of the hippopheos, mentioned by Hippocrates, is rendered the ſeed of the *ſtæbis*.

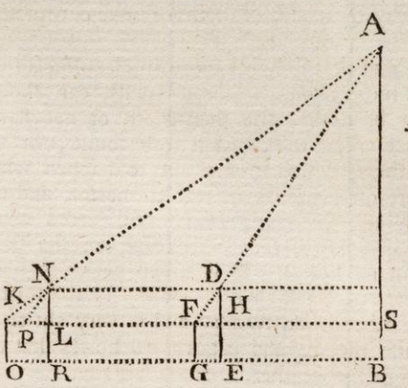
STÆBIUM, in botany, a name given by the modern Greeks to the plant called *hippophaes* by Dioſcorides; that author alſo ſometimes called it *ſtæbe*. See the articles STÆBE and STÆBIS.

STÆCHAS, in botany, the name of a genus of plants, the characters of which are theſe. The flower conſiſts of one leaf, and is of the labiated kind. The upper lip is erect and bifid, and the lower divided into three ſegments, the whole ſo diſpoſed, that the flower has, at firſt ſight, no appearance of a labiated one, but appears meerly a plain flower of five ſegments. The piſtil ariſes from the cup, and is fixed in the manner of a nail to the hinder part of the flower: this is ſurrounded by four embryos, which ripen into as many ſeeds, contained in the cup of the flower. To theſe marks it is to be added, that the flowers of the *ſtæchaſes* are diſpoſed in various ſeries in a ſort of ſcaly heads, from the ſummits of which there grow certain beautiful-coloured leaves, which Cluſius calls their membranaceous ligulæ. See Tab. 1. of Botany, Claſs 4.



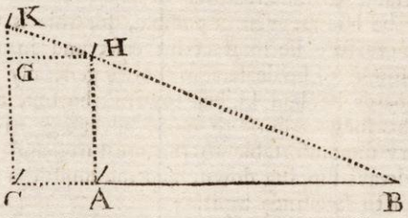
The ſpecies of *ſtæchas*, enumerated by Mr. Tournefort, are theſe. 1. The common purple *ſtæchas*, vulgarly called *Arabian ſtæchas*. 2. The naked-ſtalked *ſtæchas* with longer ligulæ. 3. The broad-leaved *ſtæchas* with white flowers. 4. The Portugal *ſtæchas* with large ligulæ, variegated with roſe colour and purple. 5. The Portugal *ſtæchas* with green hairy leaves. *Tourn.* Inſt. p. 201.

The flowers of the *ſtæchas* are much uſed in medicine, in diſeaſes of the head and nerves, eſpecially in ſuch as are ſuppoſed to ariſe from cold cauſes. They alſo promote the evacuation by urine, and by the menſes, and in ſome places are eſteemed one of the greateſt antidotes, and given in large doſes againſt the effect of poiſons, and the bites of venomous animals. Meſue, and the Arabians in general, ſpeak of it as a purge, and particularly as good in caſes where phlegm was to be evacuated; though they ſay it did this but ſlowly and weakly. At preſent we do not acknowledge any purging quality in it. There is a very fragrant oil drawn from the flowers and tops of this plant, in the ſame manner as that from lavender; but it is not much in uſe with us. The flowers are an ingredient in the Venice treacle, mithridate, and ſome other of the officinal compoſitions.



It is to be obſerved that there is another plant, called *ſtæchas*, in the ſhops; and by the writers on the materia medica, this has the epithet *citrina*, for its diſtinction from the *ſtæchas* we have been treating of, which is either called *ſtæchas* without any addition, or *ſtæchas Arabica*. The *citrine ſtæchas* has none of the virtues of this kind, nor is it of the ſame genus of plants, but of the elichryſum kind. See the article ELICHRYSUM.

The ſeveral ſpecies of *ſtæchas* are propagated by ſowing the ſeeds in March, in a bed of dry light earth; when the young plants are about three inches high, they muſt be removed into other beds, and placed at about ſix inches diſtance, watering and ſhading them till they have taken root. They muſt after this be kept clear from weeds, and ſheltered from the ſeverity of the winter by mats, or a light covering of peas, haulm, or other ſuch matter; and in March, or the beginning of April, they may be removed into the places where they are to remain. The poorer the ſoil is, in which they are planted, the better they will ſtand the winter, and the more fragant will be their flowers. They may be propagated by cuttings planted in ſpring, but the ſeeds ripening very well with us, the raiſing them from thoſe is the much better way. *Miller's* Gard. Dict.



STAFF (*Cycl.*)—This is uſed as an inſtrument for taking acceſſible, or inacceſſible heights. The manner of operation, in taking the height of an acceſſible object, is as follows. Let there be placed perpendicularly in the ground a longer *ſtaff* DE, likewiſe a ſhorter one FG, ſo as the obſervator may ſee A, the top of the height to be meaſured, over the ends D, F of the two *ſtaves*; let FH and DC, parallel to the horizon, meet DE and AB in H and C, then the triangle FHD, DCA, ſhall be æquiangular; for the angles at C and H are right ones, likewiſe the angle A is equal to the angle FDH (by 29. 1. Euclid) wherefore the remaining angles DFH, and ADC, are alſo equal; and FH : HD :: DC : CA, *i. e.* as the diſtance of the ſtaves, to the exceſs of the longer *ſtaff* above the ſhorter; ſo is the diſtance of the longer *ſtaff* from the object, to the exceſs of the height of the object above the longer *ſtaff*. Hence CA may be found by the Rule of Three; to which if DE, the length of the longer *ſtaff*, be added, you will have the whole height of the object. Tr. Pract. Geom. p. 19, ſeq.

Inacceſſible heights may likewiſe be taken by means of two *ſtaves*. This muſt be done at two ſtations in a right line from the object, at each of which the *ſtaves* are to be placed in ſuch a manner, that the ſummit, or top of the height, may be ſeen along their tops in the ſame right line. Thus, ſuppoſe A the ſummit of the object whoſe height is to be meaſured, DE, FG, the two *ſtaves* at the firſt ſtation; and RN, KO, the ſame *ſtaves* at the ſecond, ſo placed, that the points FDA, KNA, are in the ſame right line. Through the point N let there be drawn the right line NP, parallel to FA: wherefore in the triangles KNP, KAF, the angles KNP, KAF, are equal; alſo the angle AKF is common to both; conſequently the remaining angles KPN, KFA, are equal. And PN : FA :: KP : KF. But the triangles PNL, FAS, are ſimilar; therefore PN : FA :: NL : SA. Thence alternately KP : NL :: KF : SA; *i. e.* as the exceſs of the diſtance of the *ſtaves* at the ſecond ſtation above their diſtance at the firſt, to the difference of their lengths; ſo the diſtance of the two ſtations of the ſhorter *ſtaff*, to the exceſs of the height ſought above the height of the ſhorter *ſtaff*. Wherefore SA may be found by the Rule of Three; to which add the height of the ſhorter *ſtaff*, and the ſum will give the whole inacceſſible height AB. Tr. Pract. Geom. p. 22. See the articles HEIGHT and ALTITUDE, *Cycl.*

Staves may be uſed for meaſuring any diſtance, ſuppoſe AB, to one of whoſe extremities we have acceſs. Let there be a *ſtaff* fixed at the point A, then going back to ſome ſenſible diſtance, in the ſame right line; let another be fixed in C, ſo that both the points A and B may be covered or hid by the *ſtaff* C. Likewiſe going off in a perpendicular, from the right line CB at the point A, let there be placed another *ſtaff* at H; and in the right line CGK, perpendicular to the ſame CB at the point C, and at ſuch a point of it K, that the points K, H and B, may be in the ſame right line, let there be fixed a fourth *ſtaff*. Let there be drawn, or ſuppoſed to be drawn a right line HG parallel to CA. The triangles KHG, HAB, will be equiangular: wherefore KG : GH (=CA) :: AH : AB; *i. e.* as the exceſs of CK above AH is to the diſtance betwixt the firſt and ſecond *ſtaff*; ſo is the diſtance betwixt the firſt and third *ſtaff* to the diſtance ſought. Tr. Pract. Geom. p. 25.

STAFF, or *Catheter*, in ſurgery. The proceſs of cutting for the ſtone, called the *high operation*, having been attended with ſome inconveniencies, which occaſioned its being haſtily left off, Mr. Cleland has attempted to remedy thoſe inconveniencies, by means of a *catheter* of a peculiar ſtructure, which he is of opinion, had it been known at that time when this operation was ſet on foot and miſcarried, would have turned the advantage of the methods to the ſide of the high operation, and made it allowed much preferable to any other method hitherto practiſed, and hopes that it will be yet brought into uſe, and revive that method.

The *catheter* is to be made either of ſilver or ſteel, and may be of different ſizes to ſuit different ages. It has the outward appearance of the common *catheter*, and will anſwer all the ſame uſes; but in reſpect of this operation it differs from the common one, in that it is compoſed of two legs with blunt points, a long tube, a ſliding bolt, and a handle, which ſerves to open and ſhut the legs. The bolt, which is fixed to the extremity of the tube, goes into two holes fixed in the plate of the handle; the one ſerves to keep the legs cloſe during the time it is to be introduced into the bladder, and the other to extend them to the diſtance of an inch or more, during the time that the operation is performing. The ſtructure of this *catheter* is well expreſſed by ſome figures given in N°401 of the Philoſophical Tranſactions, and the manner of uſing it is this: after having taken the neceſſary precautions, and filled the bladder, the *catheter* is to be introduced into the bladder with its points ſhut; then unbolt it at the handle, and by holding the tube in one hand, and the handle that moves the legs in the other, turn or open the legs till the bolt becomes oppoſite to the ſecond

hole upon the plate, into which it muſt be thruſt; then by preſſing gently downward the handle between the patient's legs, the two blunt points will be eaſily felt above the os pubis, in the protuberance made by the injection into the bladder. The advantages propoſed by uſing this *catheter* are theſe: firſt, it is a director to the operator, ſhewing the place in which the puncture is to be made into the bladder; it alſo ſerves as a ſupport to the bladder when the water is run out, and keeps it from ſubſiding during the time of the operation, or till the ſtone is extracted. It ſerves alſo to reſiſt the preſſure of the abdominal muſcles and the peritonæum, and hinders the inteſtines from being forced down upon the knife, keeping the orifice ſufficiently open, till the ſtone or ſtones are taken out. And finally, it may always be diſcovered, by the help of this inſtrument, whether the bladder be become ſcirrhous.

The method of performing the operation with this *catheter* is thus: after the *catheter* is introduced, and fixed with its legs open, the two points are to be felt for above the os pubis; when theſe are found, the finger and thumb are to be placed gently upon them, and the handle is to be held by an aſſiſtant, to keep it firmly in that poſition; then with a knife in the other hand a puncture is to be made immediately into the bladder, directly in the middle between the two points; but for the more ſecurity, it may be made ſomewhat lower, nearer the os pubis: when the knife is thus introduced, a large inciſion is to be made downward, inclining under the arch of the pubis, in proportion to the bigneſs of the ſtone, taking care not to wound the cartilage that joins the bones together when the knife is withdrawn. The bladder being thus ſupported, the ſtone may be taken out either with the fingers, or with a pair of tenets, there being little danger of breaking it in this method. When the operation is finiſhed, the handle of the *catheter* is to be raiſed; it is to be unbolted and ſhut cloſe, then fixed in this poſition and drawn out, and the patient dreſſed in the uſual way. Philoſ. Tranſ. N° 401. p. 786.

Flag-STAFF, in a ſhip, the long *ſtaff*, or piece of wood, whereto the flag is made faſt, and along which it is hoiſed up.

Station-STAFF, in ſurveying, an inſtrument conſiſting of two rulers that ſlide to ten feet, divided into feet and inches, with a moveable vane or ſight, two of which are uſed with a level; and on the edges there are the links of Gunter's chain divided. Its chief uſe is for the eaſy taking off-ſets.

STAG, *cervus*, in zoology. See CERVUS.

STAG-*evil*, in the manege. See the article HART.

STAG-*worms*, in natural hiſtory, a name given to a ſpecies of worms produced of the eggs of a fly, and lodged in a very ſtrange place behind, and under the palate of the *ſtag*, or deer's mouth.

They are always found in great numbers together, and are contained in fleſhy bags, which are placed as the almonds of the ears in the human ſpecies. The huntſmen are well acquainted with theſe *worms*, and are of opinion that they are the cauſe of the falling off of the creature's horns; they eat their way to theſe, according to their opinion, through the proper parts of the head, and then gnawing them round at the roots, they are forced to fall like a tree that is ſawed off at the bottom. This however is a vulgar error. Mr. Reaumur has abundantly proved, that theſe *worms* never attempt ſo ſtrange a paſſage; they always remain where they are firſt found till they are in a ſtate to change into the flies, to whoſe eggs they owe their origin, and whoſe forms they are at length to aſſume. *Reaumur*'s Hiſt. Inſect. Vol. 9. p. 8.

STAGGERS (*Cycl.*)—The moſt approved remedy for this diſtemper, which ſhews itſelf in horſes in a giddineſs, and reeling about, in waterineſs of the eyes, and a variety of odd motions of the head, is the following method. The creature is firſt to be blooded largely, then a glyſter is to be given him, compoſed of two quarts of emetic wine, and four ounces of the unguentum populneum. When he has repoſed an hour or two after voiding this glyſter, let another be given him, made of two ounces of the ſcoriæ of the liver of antimony finely powdered, boiled a little while in five pints of beer, and with the addition of four ounces of the ſame ointment, or of ointment of roſes. This laſt glyſter is to be frequently repeated, and his legs are to be all the while rubbed ſtrongly with whiſps of hay, wetted in warm water, to make a revulſion. His food ſhould be bran and white bread, and he ſhould be walked from time to time in ſome temperate place. If theſe methods do not ſucceed, let an ounce of Venice treacle be diſſolved in a quart of ſome cordial waters, and given him; and after this let the following glyſter be given warm: take Venice treacle and ſal polycreſtum, of each two ounces; diſſolve them in two quarts of a decoction of mallows and camomile flowers; add a quarter of a pint of oil of rue. This repeated two or three times after bleeding, and the other methods, will often cure the worſt ſtages of this diſeaſe.

Mr. Boyle mentions a cure of this diſeaſe in horſes, by rubbing their gums with the coach whip till they bleed. Works Abr. Vol. 1. p. 88.

STAGONIAS, a word uſed by the old authors to expreſs that ſort of male frankincence which is in round drops, and very clear and fine.

STAGONIUS, a name ſometimes given to ſtorax. See the article STORAX.

STAINING, or COLOURING *of porcelain*. The Chineſe, for a great many ages, uſed only white porcelain. The firſt *colour* they employed was blue, and after that they came into the uſe of all the reſt. Their antient blues was prepared by themſelves from a kind of a lapis lazuli; but we now ſupply them with the ſmalt ſo much cheaper, that it is no longer worth their while to make it themſelves. They uſed to prepare this only by giving a gentle calcination to the ſtone, and then beating it to powder, and grinding it to the utmoſt fineneſs in mortars of unglazed porcelain-ware, with peſtles of the ſame. The red, which the Chineſe uſe, is made of our green vitriol, or common copperas. They put about a pound of this into a crucible, and lute on this another crucible inverted: this laſt has a hole cut in the top, which they keep covered or open at pleaſure. They ſet this crucible in a furnace of bricks, ſo contrived, as to throw all the flame upon the lower veſſel, in the way of our chemiſts reverberatory furnaces. They make a large fire of charcoal all round it, and obſerve the hole at the top; for ſo long as there aſcend thick black fumes through that, the matter is not ſufficiently calcined. They watch the going off of this fume, and when there appears in the place of it a fine and thin cloud, they take away the crucible, the matter being then ſufficiently burnt. They try this, however, by taking a little out, and examining the colour; if it is not ſufficiently red, they let it remain longer in the fire. When they find that it is of a good colour, they take away the fire, and leave the veſſels to cool; this done, they find a cake of red matter at the bottom of the crucible, and a quantity of a finer powder about its ſides. They keep theſe ſeparate, the latter being the pureſt, the fineſt, and the brighteſt colour.

One pound of copperas affords about four ounces of this colour, and this is the red which they manage in different ſhades, and vary ſo much.

The Chineſe have alſo a white colour, which they uſe in their figures painted on the China: the ware itſelf is naturally white, and the varniſh, or oil of ſtone, is a great addition to its whiteneſs all over. But they have yet a way of making a much brighter and finer white than theſe, as may be ſeen in moſt of the fine China-ware where there is any white in the figures. This white is made in the following manner: they collect on the ſhores of their rivers a ſort of agate, which is of a whitiſh hue without veins, and tolerably tranſparent. It approaches very much to the nature of cryſtal, and probably cryſtal may be found to ſupply its place with us. They calcine this ſtone to a white powder, and to every ounce of this, when ground in their porcelain mortars to an impalpable fineneſs, they add two ounces of ceruſs in fine powder: this they mix with the varniſh, and lay on in the common way of other colours.

This white mixture ſerves not only for the colouring white, but it is the baſis of ſeveral other of thoſe beautiful colours which we ſee on the China-ware, and which our manufacturers have been often perplexed what to make of. Their green colour is made of copper ruſted with acid; and their fine deep violet colour is made of this green, by adding to it a due proportion of this white. It is not to be ſuppoſed that this effect is produced according to the common laws of mixing colours among our painters, for then the white and green would only make a paler green. But copper being a metal that as well gives a fine blue, as a fine green, according to the nature of the ſubſtances it is mixed with, the white in this caſe alters the very nature of the green, and converts it into that fine and deep violet blue, which we may draw from copper by means of any of the volatile alkalis; ſuch as ſpirit of ſal armoniac, ſpirit of hartſhorn, ſpirit of urine, or any the like liquor. The workmen know how to bring this blue to any degree, by putting in different proportions of the two colours. There is not any admixture of them, that will not produce a blue of ſome kind; but always the more of the green colour is uſed, the deeper the blue will be, and the leſs the paler. The yellow is made by an admixture of ſeven drachms of this white, and three drachms of copperas, or more, if they deſire the colour to be deeper.

Theſe colours are laid on upon the veſſels when they have been once baked, but they do not appear till the ſecond baking is over in their proper ſhades or tinges, and ſometimes ſcarce at all.

The black China is much eſteemed in the Eaſt, and particularly when it is ornamented with gold; this colour looking better with that ornament than any other. The black is always laid on when the porcelain is firſt dried, and is prepared by mixing three ounces of the fine deep blue with ſeven ounces of that fine varniſh, which they call *oil of ſtones*. This admixture gives a fine deep black. When the colour is thoroughly dry, the veſſels are baked, and when this is done the gold is laid on, and the whole is baked again in a particular furnace made for this purpoſe. If they would

have

have the black degenerate into blue, they need only add leſs of the blue, and a little of the ceruſs and agate white before deſcribed. They have two peculiar ways of applying the red, beſide the common one, both which require a nice workman, and make the ware come very dear. They call the one of theſe *oils red*, and the other *blown red*. Obſerv. ſur les Coutumes de l'Aſie. See *Blown* RED.

There are many things practiſed by the Chineſe in their *colouring* and forming the ſeveral kinds of porcelain, which may be well brought into uſe among us, and give a new value to our own wares, even though we ſhould never arrive at their art of making the thing itſelf. One kind of *colouring* eaſily introduced among us, would be what they call *hoan ton hoan*. This produces veſſels of great beauty and price, and is done in this manner. The matter, of which the veſſels are made, for this purpoſe, need not be fine; they uſually take any of the common veſſels baked, without having been varniſhed, and conſequently ſimply white, and without luſtre. When theſe are intended to be of one ſimple *colour*, they need only be plunged into a liquid varniſh or oil, as the workmen there call it, *coloured* with ſuch ingredients as will ſtrike the moſt lively tinges: but if it is to be *coloured* in compartments, as is uſually the cuſtom with this ſort of China, it is to be done by the pencil. The uſual way is to paint theſe in pannels, one green, another blue, and ſo on, and they make a very agreeable appearance. There requires no more to this, than the laying on the *colours* tolerably thick with a large pencil; but if the pictures of animals, and plants are to be given, they are to be done with the moſt permanent *colours*, and the veſſel being again well baked, becomes very beautiful. Obſerv. ſur les Coutumes de l'Aſie, p. 320.

The Chineſe, who are deceivers in every thing, find the way of cheating very much in regard to this ſort of China-ware. They paint the flowers of plants, and ſome parts of the birds, *&c.* in very bright colours, after the veſſel has been baked. Vermilion is a fine *colour*, which they often add on this occaſion; but they cannot uſe this before the baking, becauſe it would be deſtroyed by the fire. Theſe *colours* which are laid on afterwards cannot laſt, but ſoon rub off in the wiping, or uſing the things; the others laſt for ever; for they are laid on with the greateſt heat of all, the veſſels being put into the ſame furnaces to lay on theſe, as the other things are baked in for the firſt time.

Salt petre, and powder of flints, are generally the things added to the *colours* thus laid on, to make them penetrate, and run properly. Thus for the fine deep violet colour, which makes the greateſt figure of all others on this ware, they mix together equal quantities of the fine azure, the powder of flints and ſalt petre, all firſt powdered ſeparately till perfectly fine; this is tempered with water, and then laid on with the pencil, and though it looks rough at firſt, it comes out of the furnace of as beautiful a gloſſy hue as any thing can be conceived. The yellow is made by mixing together three ounces of ceruſs, and three ounces of powdered flints, and adding three, four, or more drachms of the red copperas, till the whole is of the proper degree of *colour*. The white is compoſed only of powder of flints and ceruſs, with a ſmall admixture of the ſalt petre, or it will ſucceed tolerably well without. Theſe are all the particulars neceſſary to be obſerved for the making a ſort of porcelain of great beauty, in which the nature of the ware itſelf is not concerned; ſo that it ſeems eaſy to imitate it with any of our own wares.

In the baking of this, or any other kind of *coloured* China, the ſecond time, there is, however, ſome caution to be uſed in the placing the pieces. The Chineſe are very artful in their diſpoſition of theſe, arranging them in the moſt compact manner, and putting the little ones within the great ones; but great care is alſo neceſſary, that the veſſels do not touch one another in the parts where they are painted, for the conſequence of that would be the ſpoiling of both veſſels, as the *colours* would run together. The bottom of one veſſel may generally be placed on the bottom of another, though both are painted, becauſe the rims are not painted, and they keep the painted parts from touching one another. High and narrow veſſels, ſuch as chocolate-cups, and the like, are very troubleſome on this occaſion. The method the Chineſe workmen take with them, is this: they place a range of them, ſo as to cover the whole bottom of the furnace, and they cover this with a thin bed of broken China-ware, over which they place another row of the cups, and ſo on to the top, where they lay on no covering: they never bake any thing elſe with theſe cups, when they are of this kind of twice-baked porcelain. Obſervat. ſur les Coutumes de l'Aſie, p. 321.

STAINING *of ſtones*. The art of *ſtaining* the gems and hard ſtones, could it be brought to perfection, would be a very elegant and uſeful one; but it is loaded with ſo many difficulties, that many, who have worked largely in the attempt, have given it up as impoſſible to be carried to any degree of perfection. The heat, neceſſary to be given to the ſtones in the common way of attempting this operation, ſpoils the ſtone, in order to give it the colour. It is true, that ſomething is to be done with ſolutions of ſilver, and the other metals, in acid menſtrua without fire, and ſomething may be done with a moderate heat alone, without the uſe of any thing elſe; but chance has diſcovered another way, by which, without heat, it may be done in a very eaſy manner. This was diſcovered by Mr. Muller, who grinding ſome aurum fulminans, made by diſſolving gold in aqua regia, and precipitating it with ſalt of tartar, together with ſome red glaſs powdered, and a little water added, found that this mixture ſtained the onyx, or chalcedony, of which the mortar was made. He was rubbing this mixture together to make an enamel colour, and leaving it three or four days in this little mortar, he found, that not only where it had been rubbed againſt the bottom of the mortar, but where it had accidentally ſplaſhed againſt the ſides of it, and on the ſurface of the peſtle, it had tinged them both very deeply to a fine red, leaving the intermediate parts of a true onyx, or chalcedony colour, wholly unaltered. The poliſh of the ſtone was not injured in the places where it was thus *ſtained*, nor could any art get out the colour, though it was tried with alkalis, and other ſharp liquors. This colour was not given to theſe parts of the ſtone of the mortar in ſimple blotches, but formed itſelf into regular lines, as we ſee the natural colours of ſtones do; but this not in the ſame degree of colour, but ſome of the lines were deeper, others paler.

This experiment was repeated in ſeveral other mortars of the ſame ſtone, but without ſucceſs; on which the ſtones, of which they were compoſed, were examined with the help of glaſſes, and it was found that this mortar chanced to be made of a more flaky chalcedony than any of the others, though it appeared equally ſolid and beautiful to the naked eye, and bore a poliſh no way inferior to them. It may be worth while, on this occaſion, ſtrictly to examine ſtones of this chalcedony kind, and on meeting with a plate of one of them of this flaky kind, to cover it with this mixture, and by that means give it a ſeries of lineations, which muſt make it a very beautiful and valuable ſtone. The poliſh will not be injured by this, or if it ſhould, the adding a new poliſh will not at all affect the colours. In the ſame manner the texture of ſtones, intended for any other experiments in *ſtaining*, ſhould be conſidered, and the chooſing proper ones may make this proceſs ſucceed on them. Phil. Tranſ. N° 179.

STAJOLUS, among the Romans, a meaſure of length uſed in ſurveying land; it was equal to five palms and three fourths of a palm. *Pitiſc.* in voc.

STAKE, the name of a ſmall anvil uſed by ſmiths; ſometimes it ſtands on a broad iron foot, on the work-bench, to be moved up and down occaſionally; and ſometimes it hath a ſtrong iron ſpike at the bottom, by which it is fixed to ſome place on the work-bench. Its uſe is to ſet ſmall and cold work ſtrait, by hammering it on the *ſtake*, or to cut or punch upon with the cold chiſel, or cold punch.

STAKE *of a plough*. The *ſtake* is an upright piece of wood, paſſing at its bottom through that link of the tow-chain which paſſes through the box of the plough, and at its upper end receiving the end of what is called the *bridle-chain*, which ties it to the crow-ſtaff, or if it be not long enough, a wyth, or cord, is uſed to tie it: it is alſo tied to it again, a little below the pillow of the plough, by another wyth or cord. *Tull*'s Huſbandry. See the articles PLOUGH, PILLOW, CROWSTAVES, *&c.*

STAL-*boat*, a kind of fiſhing-boat, mentioned 27 Eliz. c. 21. *Blount*.

STALACTAGNIA, in natural hiſtory, the name of a genus of ſpars. The word is derived from the Greek σταλακτὸς, ſtillatitious, or formed by dropping, and ἁγνὸς, pure.

The bodies of this genus are formed by the dropping of water from the roofs of ſubterranean caverns, and are the purer ſort of what are called by authors *ſtalactitæ*. They are cryſtalline ſparry bodies, formed into oblong conical figures, compoſed of various cruſts, and uſually found in form of icicles. Of this genus there are three known ſpecies. 1. A hard and white one. This is a very beautiful body, and is found in many parts of England, as well as other countries. 2. A white ſhattery one, found in the ſame places. And 3. a yellow ſhattery one, common with us in Yorkſhire, Devonſhire, and Derbyſhire; as alſo in many other parts of the world. *Hill*'s Hiſt. of Foſſ. p. 363.

STALACTOCIBDELA, in natural hiſtory, the name of a genus of ſpars. The word is derived from the Greek σταλακτὸς, ſtillatitious, or formed by the dropping of water, and κιβδηλος, impure.

The bodies of this genus are formed by the dropping of water from the roofs of ſubterranean caverns, and are the coarſer kinds of what authors have called *ſtalactitæ*. They are cryſtallino-terrene ſpars, formed into oblong bodies, and found hanging from the roofs of caverns and grottos.

Of this genus there are only two known ſpecies. 1. A browniſh friable one, common in our ſubterranean caverns, and even on the inſides of new-built ſtone arches, as thoſe of the New Bridge at Weſtminſter. And 2. a ſnow-white friable one, found in ſubterranean caverns in England and Germany,

Germany, and even on modern-built brick arches, as has of late been found on opening the vault under the terrace at Windſor. This, and the preceding inſtance, give us unqueſtionable evidence of the preſent, and daily formation of theſe bodies. *Hill*'s Hiſt. of Foſſ. p. 367.

STALAGMITÆ. See the article STALAGMOSCIERIA.

STALAGMODIAUGIA, in natural hiſtory, the name of a genus of ſpars. The word is derived from the Greek σταλαγμὸς, a drop, and διαυγὴς, pellucid. The bodies of this genus are the purer kinds of what authors call *ſtalagmitæ*, or drop-ſtones.

They are ſpars found in form of ſmall balls, each compoſed of numerous cruſts, and conſiderably pellucid and cryſtalline. Of this genus there are three known ſpecies. 1. A white one with numerous thin cruſts, and a ſmooth ſurface, found in many parts of Germany, and in England. 2. A greyiſh white one with thicker cruſts, and a rougher ſurface. And 3. a yellow thin-cruſted one with an echinated ſurface. Theſe are both found in the ſubterranean caverns of England, and many other places, and the former of them is the *confetti di Tivoli* of the Italians. *Hill*'s Hiſt. of Foſſ. p. 370.

STALAGMOS, a term uſed by authors to expreſs a diſtillation of rheum from the head.

STALAGMOSCIERIA, in natural hiſtory, the name of a genus of ſpars. The word is derived from the Greek σταλαγμὸς, a drop, and σκιερὸς, opake, and expreſſes an opake ſpar, which has received its form from the dropping of water.

The bodies of this genus are the coarſer kinds of what are called by authors *ſtalagmitæ*, and are ſmall round maſſes, compoſed of numerous thin cruſts, and of an opake and coarſe ſtructure.

Of this genus we have only two known ſpecies. 1. A ſmall browniſh white one with a ſmooth coat, found in Saxony, and ſome parts of England. And 2. a ſmall browniſh white one with thin cruſts, and a large nucleus. This is found in ſmall maſſes in Yorkſhire, and is the ſubſtance of which the famous Ketton-ſtone of Rutland is compoſed. *Hill*'s Hiſt. of Foſſ. p. 373.

Scotland affords a vaſt variety of the *ſtalagmitæ*. One cave, about eight miles diſtant from Aberdeen, on the ſea-ſide, has its whole roof cruſted over with *ſtalactitæ*, of a foot in length, hanging down like the fringe of a bed. The floor alſo is as deep covered with congeries of *ſtalagmitæ*. The upper coat, both of theſe and the *ſtalactites*, is of a ſea-colour, but the inner parts are as white as ſal prunellæ. The water which drops from theſe is of a very peculiar nature, for it is ſo acrimonious, that if it touch the ſkin but ever ſo ſlightly, it makes it ſmart. Near this cave there is another hollow rock, in which the *ſtalactitæ* make a very beautiful figure: they are all formed into long and thick columns, and ſtand perpendicularly, ſo that they repreſent the pipes of an organ; when broken, they are all found to be hollow within. The rock, and all the ſtone thereabouts, is of the limeſtone kind.

STALK, among botaniſts, that part of a plant which riſes immediately from the root, and which uſually ſupports the leaves, the flowers, and the fruit.

The term *ſtalk* is uſed on all occaſions; but in ſpeaking of the graſſes, and gramineous plants, where the word *culm* is uſed in its place, to diſtinguiſh that peculiar kind of *ſtalk* which is general to all theſe plants, and is not found in any others. See the article PLANT.

The terms uſed in deſcribing the *ſtalks* of plants, are; a *ſimple ſtalk*, one which runs up undivided from the root to the top.

Naked ſtalk, one that has no leaves.

Folioſe ſtalk, one with leaves on it.

Ramoſe ſtalk, that which ſends out branches.

Erect ſtalk, that which riſes ſtrait up.

Oblique ſtalk, that which is ſlanting.

Voluble ſtalk, that which twiſts round other things.

Flexuous ſtalk, that which bends.

Reclinate ſtalk, that which ſtoops towards the ground.

Procumbent ſtalk, that which lies on the ground.

Creeping, or *ſarmentous ſtalk*, that which emits roots as it runs along.

If the *ſtalk* be rounded in ſhape, it is called *round*; if it make two angles, *ancipital*; if three, *trigonal*; if four, *ſquare*; if more, *polygonal*.

If the *ſtalk* be lightly ridged and furrowed on the ſurface, it is ſaid to be *ſtriated*; if more deeply, *canaliculate*; if full of protuberances, *ſcabrous*; if lightly hairy, *villoſe*; if more roughly, *hiſpid*.

In the *branched ſtalk*, if the branches riſe erect, it is expreſſed by *aſcendant*; if they ſpread, by *diffuſe*; if they are very large, it is called *branchiated*.

If the *ſtalk* divaricate, or, inſtead of ſending out branches, it divide into them, it is called a *compoſite ſtalk*. If theſe divarications proceed by pairs, or if every branch be divided only into two others, it is called *dichotomous*; if it part into two ſeries of branches, it is expreſſed by the term *diſtichous*; if it part into a multitude of ramifications, is called *ſubdivided*.

All theſe terms are uſed alſo in expreſſing the different ſtates of the *culm*, which having no articulations, is called *equal*; when ſcaly, *ſquammoſe*.

STALK, or *ſtalking*, among the ſportſmen, a term uſed to expreſs the manner of making approaches to their game behind ſome animal, or the reſemblance of ſome animal, or other object, which may be more familiar, or leſs terrible to the creature than the body of a man would be.

The beſt, of all methods for *ſtalking*, is by means of a real living horſe, trained for the purpoſe. This horſe ſhould be choſen of the talleſt and largeſt kind; no matter how old he is, but he muſt be well trained, and ready at command. And as there is much art required to the reclaiming a horſe that is by nature wild, and apt to be frighted by noiſe and fire, as is the caſe when the gun is fired over him, the firſt attempt toward the training him muſt be the chaining up his head to a tree, and firing the gun ſeveral times very near him: at firſt he will be frighted, and kick and caper about, but after this has been practiſed many days together, he will by degrees become ſo tame, that a gun may be fired under his neck without ſtarting, or taking any notice of it.

When he is thus taught to bear the noiſe of a gun, one great matter is obtained; what remains, is the teaching him to go in a proper manner, moving gently, and feeding as he goes, and to ſtand ſtill and feed when the ſportſman would have him: this is only to be done by much practice, and by his obſerving the motions and checks given him as ſignals on this occaſion. The horſe muſt be always naked for this ſport, for the ſight of a ſaddle and bridle on a horſe give the birds an alarm, and they will riſe and take wing, when they would otherwiſe have ſtood perfectly quiet: he muſt therefore only have a little ſlip tied about his lower chap, by means of which he may be guided as the ſportſman ſees occaſion; and the perſon who uſes him, muſt always take care to go juſt upon a level with his ſhoulders, and to guide his own feet by his. Some take their aim under the *ſtalking* horſe's belly, but this expoſes them too much to the ſight of the birds, who often fly away before they can take aim; but the better way is to take the level before the creature's breaſt, where the whole body of the man remains as much concealed, as it was before the taking the aim.

The horſe being properly trained, will walk ſlowly along in any ſort of ground, as ſtubble-fields, mooriſh places, or the banks of rivers, and will always feed, or pretend to feed, as he is directed. The ſportſman is to conceal himſelf and his gun behind the horſe's fore ſhoulder, bending his body low by his ſide, and keeping the whole body of the horſe always full between the fowl and himſelf. When by this means the ſportſman is come ſo near to the birds, that the gun will reach them with ſtrength to kill, he is never to attempt advancing any nearer, that they may not be diſturbed. Some recommend the ſhooting over the horſe's buttocks, and ſome over his neck, but the beſt way is under the neck, and before the breaſt; for by this means the body of the ſportſman is covered by the ſhoulder, and his legs by the legs of the horſe. It is proper alſo to take out a ſpaniel, but he muſt be one that is well trained to the ſport, and that will lie ſtill and cloſe behind his maſter's heels, for if he is ſeen, the birds will immediately be gone. When the birds are ſhot, the dog will bring them to his maſter, and as they often fall in places where a man cannot come at them, this creature is of very neceſſary ſervice.

This is the beſt of all methods of *ſtalking*, but as ſuch a horſe is difficult to train, and chargeable to keep, and is not always to be had, there are many other contrivances introduced to ſupply the place of it; among theſe the principal are the *ſtalking* wheelbarrow, the *ſtalking* buſh, and the *ſtalking* hedge. The firſt of theſe is to be thus contrived: take a wheelbarrow, made on purpoſe of light fir, and ſet round about it boughs and buſhes in ſuch a manner, that you may ſit in it, and not be diſcovered by the fowl, and drive it along without giving them diſturbance. The ſportſman is always to take a ſpaniel well trained to the ſport along with him on this occaſion, and when he knows the haunts of the birds, he is to level through the boughs that are placed about it, and ſend out his ſpaniel for the birds he kills.

The *ſtalking* buſh is to be contrived of ſeveral buſhes well platted together, with all their leaves on; it is to be faſtened to a ſtake, which is to have an iron point at the end: the whole is to be of the height of a man, and thickſet with boughs all the way, from top to bottom. When the ſportſman ſees his game before him, he is to advance ſlowly with this artificial buſh between him and them; when he is come within a proper diſtance, he is to fix the buſh into the ground, by running in the iron ſpike, and then to ſhoot through the boughs.

The *ſtalking* hedge is generally made about nine feet long, and a yard and half high: it is to be made of ſmall wands, ſo woven together, as to give room for the placing of green boughs among them, that it may reſemble a great growing hedge. This is to be carried before the ſportſman, and, in

the manner of the buſh, it is to be faſtened down, when near enough for the gun to kill from it.

As birds however are apt to have ſome apprehenſion of terror from ſeeing a tree or hedge move, theſe machines are to be carried on very ſlowly; and the reſemblance of a real animal, as a horſe or cow, are better for the purpoſe: theſe may be made of canvas, ſupported on a ſlight frame, and with tails of hair. For pheaſants, woodcocks, and the like fooliſh birds, the common flat figure of a horſe will do; but the water fowl are generally much more ſhy, and it is neceſſary, for the getting near them, to have the body made hollow, and ſtuffed with hay, or ſome other matter, to keep it out. The proper time to uſe theſe engines is either early in the morning, or late in the evening; for the ſunſhine in the middle of the day very ſoon diſcovers to the fowl the imperfection of the engine.

STALKER, in brick-making. See the article BRICK.

STALKERS, in our old writers, a kind of fiſhing-nets. Stat. 13 Rich. II. cap. 20. *Blount.*

STALLAGE, *ſtallagium*, in our old writers, the liberty, or right of pitching and erecting *ſtalls* in fairs or markets, or the money paid for the ſame. *Kenn.* Gloſſ. Terms of Law. *Blount*, *Cowel.*

STALLION, in the manege, in French *etalon*, a ſtone-horſe kept to breed. See the articles HORSE and MARE.

STAMINA, (*Cycl.*) among botaniſts, the male organs of generation in flowers. They conſiſt of two parts, a filament and anthera; though ſometimes the latter ſtands alone. The filament is a ſlender body, ſupporting a tumid one, which is the anthera, on its head or top. The anthera is the great male organ of generation, is hollow, and contains in it a fine powder, called *farina fœcundans*. See GENERATION and FARINA.

STAMINEOUS, (*Cycl.*) in botany, a term uſed by authors for thoſe flowers of plants which have no petals, or flower-leaves, but conſiſt only of a number of *ſtamina* and piſtils placed in a cup. This cup is ſometimes miſtaken for a flower, and its leaves thought to be true petals; but they remain when the *ſtamina* are fallen, and become the capſules containing the ſeed, which is the true character of a cup, not of a flower. *Tourn.* Inſt. p. 501.

STAMNOS, an urn, or veſſel, for holding water. Some authors have made it ſignify the bucket-head, as it is called, of thoſe alembics which have no worm, but are cooled about the head by this means.

STAMPS, in metallurgy, a ſort of large peſtles lifted up by water-wheels, and ſerving to beat to powder the ores, and refuſe of ores of metals. *Ray*'s Engliſh Words, p. 116.

STANCH, or STAUNCH, a name given by the country people of Northamptonſhire, and ſome other counties, to a ſpecies of foſſil called *ſelenites*, from its ſuppoſed virtue in ſtopping fluxes of blood. *Hill*'s Hiſt. of Foſſ. p. 129. See the article PACHODECARHOMBIS.

STANCHION (*Cycl.*)—STANCHIONS, in a ſhip, thoſe pillars, which being ſet up pillarwiſe, do ſupport and ſtrengthen the waſte trees.

STAND (*Cycl.*)—STAND, in commerce, a weight from two hundred and a half to three hundred of pitch. Merch. Dict.

STANDARD (*Cycl.*)—For the Roman *ſtandards*, ſee the article SIGNA.

STANDEL, in our old writers, denotes a young ſtore oak-tree, which in time may make timber; and twelve ſuch young trees are to be left ſtanding in every acre of wood, at the felling thereof. 35 Hen. VIII. cap. 17. 13 Eliz. cap. 25. *Blount.*

STANDING-*coin*. See the article COIN.

STANDING-*marriage*, in the law of Scotland, is uſed to expreſs one actually ſubſiſting, though perhaps reducible for adultery, or liable to be declared void for impotency, or conſtingency of blood; that is, conſanguinity. *Bayne*'s Crim. Law.

STANDING *part of the ſheat*, in a ſhip, that part of it which is made faſt to a ring at the ſhip's quarter. When they ſay *overhale the ſheat*, they mean, *hale upon the ſtanding part*; but when they ſay *hale the ſheat* barely, they intend only of the running part.

STANDING *part of a tackle*, aboard a ſhip, is the end of the rope where the block is ſeized or faſtened; as the other, which is haled, is called *fall.*

STANDING-*ropes*, in a ſhip, thoſe ropes which do not run in any blocks, but are ſet taught, or let ſlack, as occaſion ſerves; as the ſheat-ſtays, back-ſtays, and the like.

STANNEL, in zoology, an Engliſh name of a ſpecies of hawk, more commonly known by the names of the *keſtrel*, or the *windhover*; and called by Latin authors *tinnunculus* and *cenchris*. *Ray*'s Ornitholog. p. 50. See the article TINNUNCULUS.

STANNUM, *tin*. See the article TIN.

STAPEDIUM, in anatomy, a name given by Albinus to the muſcle of the ſtapes in the ear, called by others *ſtapidis muſculus*, and *ſtapidanus muſculus*.

STAPES (*Cycl.*)—This bone is very well denominated from its reſemblance to a ſtirrup; it is divided by anatomiſts into its head, legs, and baſis. The head is placed upon a ſhort flatted neck, the top of it being ſometimes flat, ſometimes a little hollow. The two legs, taken together, form an arch like that of a ſtirrup, in the concave ſide of which is a groove, which runs through their whole length; one of the legs is longer, more bent, and a little broader than the other.

The baſis reſembles that of a ſtirrup, both in its oval ſhape, and union with the legs, except that it is not perforated, as the ſtirrups now are, but ſolid, like thoſe of the antients. Round its circumference, next the legs, is a little border, which makes that ſide of the baſis appear a little hollow; the other ſide is pretty ſmooth, and one half of the circumference is ſomething more curve than the other. The ſubject being in an erect poſture, the *ſtapes* is to be conſidered as lying on its ſide with the head turned downward, near the extremity of the leg of the incus; the baſis inward being fixed in the feneſtra ovalis, the longeſt leg backward, the ſhorteſt forward, and both in the ſame place. By this ſituation it is eaſy to know the *ſtapes* of each ear. *Winſlow*'s Anatomy, p. 49.

STAPHYLE, a word uſed by the old Greek writers, ſometimes to expreſs a grape; and ſometimes a diſorder of the uvula, which conſiſts in an extenuation of its ſuperior part, and a tumor of the inferior, whence it hangs down in the ſhape of a grape. The uvula, or gargareon, is alſo thus called by ſome writers.

STAPHYLEPARTES, the name of a chirurgical inſtrument, in uſe among the antients for elevating the uvula. It is mentioned by Paulus Ægineta.

STAPHYLINUS, in botany, a name given by ſome authors to the common *daucus ſylveſtris*, wild carrot, or bird's neſt. *Dillen.* Cat. Giſſ. 150.

STAPHYLIS, a name given by ſome authors to a ſort of cup or boat, made for feeding young children, and contrived with a ſpout in form of a grape or nipple.

STAPHYLODENDRON, the *bladder-nut*, in botany, the name of a genus of trees, the characters of which are theſe. The flower is of the roſaceous kind, being compoſed of a number of leaves diſpoſed in a circular form. The cup is compoſed of one leaf, divided into many ſegments at the edge; and from this ariſes the piſtil, which finally becomes a membranaceous fruit, inflated in the manner of a bladder, and containing hard ſeeds. See Tab. 1. of Botany, Claſs 21. The ſpecies of *ſtaphylodendron*, enumerated by Mr. Tournefort, are theſe. 1. The common *ſtaphylodendron*, or *bladder-nut*. 2. The trifoliate Virginian *ſtaphylodendron*, called by ſome the *wild piſtacia*, or the *trefoil Virginian piſtacia*. *Tourn.* Inſt. p. 616.

STAPHYLOMA, in ſurgery, the name of a diſtemperature of the eye, which is of two kinds: in one the cornea is more than uſually protuberant; and in the other the uvea breaks forth, and forms an unſightly tumor on the cornea, either from internal cauſes, or from ſome wounding inſtrument forced through the coat; in which laſt caſe, the ſight of the eye is uſually deſtroyed.

This is a very dangerous diſorder, as it not only deforms the face, and deſtroys the ſight of the eye, but very often it induces violent inflammations, headachs, reſtleſneſs, abſceſſes, and ſometimes a cancer in theſe parts. In the cure of this diſorder, the tumor and deformity are to be relieved by the application of compreſſes dipped in alum-water, together with a plate of lead and a bandage, or ſome proper inſtrument. If the uvea protrudes itſelf through a wound in the cornea, it ſhould be returned with a probe, and the patient muſt be ordered to lie in a ſupine poſture, and the wound muſt conſtantly be dreſſed with the white of an egg, and a mucilage of quince-ſeeds, till it is healed; and by this means the ſight is often reſtored.

If this diſorder is become inveterate and inflexible to all remedies, a needle, armed with a double thread, muſt be paſſed through the middle of the tumor, and the two ends of the thread are then to be tied on a knot, firſt on one ſide, and then on the other, by which means the tumor will gradually wither, and fall off along with the threads; but as this method occaſions a continued pain, and from thence ſometimes ariſe inflammations, it is better ſtill to cut off the tumor with a ſcalpel, or ſciſſors. *Heiſter*'s Surgery, p. 423.

STAPIDACEUS *muſculus*, in anatomy, a name given by Duverney, Douglaſs, and many others, to the muſcle of the ſtapes of the ear, called by others *ſtapedis muſculus*, and by Albinus *ſtapedium*. See the article EAR.

STAR (*Cycl.*)—Mr. Flamſtead had obſerved different diſtances of the pole-*ſtar* from the pole at different times of the year; and theſe obſervations were, through miſtake, looked upon by ſome as a proof of the annual parallax of the fixed *ſtars*. On the whole, Mr. Flamſtead concluded that the pole-*ſtar* was 35″, 40‴, or 45′ nearer the pole in December, than in May or July.

Dr. Hook had alſo communicated ſeveral obſervations on the apparent motions of the fixed *ſtars*; and as this was a matter of great importance in aſtronomy, ſeveral of the learned were deſirous of verifying and confirming his obſervations. An inſtrument was accordingly contrived by Mr. George

George Graham, and executed with ſurpriſing exactneſs. With this inſtrument the *ſtar* γ, in the conſtellation Draco, was frequently obſerved by Meſſrs. Molyneux, Bradley, and Graham, in the years 1725, 1726; and the obſervations were afterwards repeated by Mr. Bradley, with an inſtrument contrived by the ſame ingenious perſon, Mr. Graham, and ſo exact, that it might be depended on to half a ſecond. The reſult of theſe obſervations was, that the *ſtar* did not always appear in the ſame place, but that its diſtance from the zenith varied, and that the difference of the apparent places of Themis, the third ſatellite of Jupiter, amounted to 21 or 22 ſeconds. Similar obſervations were made on other *ſtars*, and a like apparent motion was found in them, proportional to the latitude of the *ſtar*. This motion was by no means ſuch as was to have been expected, as the effect of a parallax; and it was ſome time before any way could be found of accounting for this new phænomenon. At length Mr. Bradley reſolved all its variety, in a ſatisfactory manner, by the motion of light and the motion of the earth compounded together. See LIGHT.

STAR, *ſtarrum*, in our old writers. All the deeds, obligations, *&c.* of the Jews, were called *ſtars*, and writ for the moſt part in Hebrew alone, or in Hebrew and Latin; one of which yet remains in the Treaſury of the Exchequer, written in Hebrew without points, the ſubſtance whereof is expreſſed in Latin juſt under it, like an Engliſh condition under a Latin obligation: this bears date in the reign of King John; and many *ſtars*, as well of grant and releaſe, as obligatory, and by way of mortgage, are pleaded and recited at large in the Plea Rolls. Paſch. 9 Edw. I. *Blount.*

The word *ſtar* is a contraction from the Hebrew *ſchetar*, a deed or contract.

STAR *of the earth*, in botany, the name of a plant famous for its virtues in curing the bite of a mad-dog: but unhappily there has been a very great miſunderſtanding among authors about the plant properly ſignified by this name; ſome calling by it the *coronopus*, or buckſhorn-plantain, an herb common every where, and others a ſpecies of *lychnis*, or catch-fly, which is a very ſcarce plant. The original account of its nature and virtues ſeems to be this: King James ſent to the Royal Society a dried ſpecimen of a plant, which had been ſent to him as the plant with which his dogs had been cured when bitten by a mad-dog, and the name, by which this was called, was *ſtar of the earth.*

The plant was ſo ill dried, that it was not eaſily diſtinguiſhed, but at length Mr. Ray found it to be the *ſeſamoides ſalamanticum magnum.* It does not ſeem, however, clear, that this was the plant vulgarly known by that name, but rather that it was gathered by ſome ignorant perſon; neither the name *ſtar of the earth* at all agreeing with it, nor any account having been given before of its having ſuch virtues. Dr. Grey, in his Compleat Farrier, greatly recommends the *ſtar of the earth* in the cure of this bite, and the plant he means is plainly the *coronopus*, or buckſhorn-plantane: and, upon the whole, it ſeems that this laſt mentioned is the plant properly called by this name, as its virtues have always been celebrated even in this caſe, and its leaves always are diſpoſed on the earth in the form of the rays of a *ſtar*. It is to be added to this, that the Counteſs of Suffolk's powder, ſo famous in many places for this terrible diſeaſe, and by which ſeveral perſons have been known to be cured, is principally compoſed of this plant. Philoſ. Tranſ. N° 450. p. 455.

STAR-*fiſh*. There are many ſpecies of the *ſtar-fiſh*, and thoſe extremely different one from another: they have different numbers of rays, but the moſt common kind has five. Their upper ſurface, or that to which the legs are not faſtened, is covered with a firm and hard ſkin, which is full of little eminences of a harder matter, approaching to the nature of that of the ſhells of the echini marini, and the like. This ſkin is of different colours in the different ſpecies; moſt uſually it is red, ſometimes it is green, in ſome blue, and in others yellow, and of all the degrees of theſe colours, or the mixtures that may be produced from them. This colour does not extend to the under ſurface, that is covered all over with legs and with points, like the eminences of the upper ſide, only longer; theſe are all either whitiſh, or yellowiſh. In the center of the *fiſh* there may be ſeen a mouth or ſucker, by means of which the creature draws its nouriſhment from the ſhell-fiſh, on which it feeds. There are five teeth placed round this ſucker, or perhaps they may be more properly called *five bony forceps*; by means of which it ſeizes and holds faſt the creature, while the ſucker does its office, in draining out the juices; and probably it is by means of theſe that they open the bivalve ſhells, when they feed on the fiſh in them.

Every ray of the *ſtar-fiſh* is furniſhed with ſo very large a number of legs, that they cover the whole ſurface: they are diſpoſed in four ranges, each of which contains about 74; ſo that the whole ray contains 304, and conſequently the *fiſh* has, upon all five of its rays, no leſs than 1520 legs. With all this numerous train of legs, however, the animal moves but very ſlowly; and indeed they are ſo ſoft and feeble, that they ſcarce deſerve the name of legs, and, more properly ſpeaking, they are only a ſort of horns, like thoſe of our garden-ſnails, but they ſerve the animal to walk with, and are therefore called legs. It is not only in their ſoftneſs that they reſemble the horns of ſnails, but their figure is alſo perfectly like them, ſo as that the compariſon gives a ſufficient deſcription of them. They are capable of being contracted or ſhortened alſo, in the ſame manner with the horns of ſnails, and it is only in the time of the creature's moving that they are ſeen of their full length; at other times no part of them is ſeen but the extremity of each, which is formed like a ſort of button, being ſomewhat larger than the reſt of the horn. If one of the rays of this *fiſh* be turned the lower part upwards, and attentively viewed, the mechaniſm by which it extends its legs will be eaſily underſtood. If the ray be cut tranſverſely in two, it is found compoſed of two bodies, divided from one another by a cartilaginous hard ſubſtance. This body ſeems compoſed of a vaſt number of vertebræ, and along it there run a great number of ſpherical, or oblong tubercles, very bright and tranſparent. There are four ranges of theſe, on each ſide two; they are formed of a fine thin tranſparent membrane, filled with a perfectly clear and pellucid fluid, like water. It is not difficult to conceive, that theſe little bladders ſerve to the lengthening and contracting of the legs of the animal; it is ſoon perceived that they are of the ſame number with the legs, and are ranged in the ſame order, ſo that each bladder correſponds to one leg: but the whole is perfectly explained, when on preſſing one of theſe bladders the liquor is ſeen to flow out of it into the leg which it belongs to, and that the leg is extended and lengthened by this means; and that when this preſſure is taken off, the fluid runs back again of itſelf from the leg to the bladder, and that on this the leg gradually ſhortens again: there is, therefore, nothing more neceſſary for the lengthening and contracting of the legs, than that the animal ſhould have a power of preſſing theſe bladders; that would always perform the firſt motion, and the mere ceaſing to preſs them would perform the other.

When the under part of the rays is viewed, and the creature in motion, it is ſeen that the legs are elongated, and again contracted, merely by the ingreſs and egreſs of a fluid; and that the creature does not uſe all the legs of the ſame ray to walk with, but ſometimes one part of them, and ſometimes another, and this with great irregularity. They ſeize on any part of the rock, in the creature's moving, in an acute angle, and in conſequence, when they ſet themſelves ſtrait upright again the body of the fiſh, muſt be ſo far pulled forward, as is the ſpace of that angle from the perpendicular. They march with equal eaſe when thus inverted, and when in their natural poſition, and as well on ſand as ſtones, and if in the dry, or if covered with water; but in all caſes they move very ſlowly.

If a *ſtar-fiſh* is taken up when full of water, it throws it out at different parts of its body by a vaſt number of little, and almoſt imperceptible apertures, in ſo many ſmall ſtreams or threads; and when it has diſcharged thus all that it will naturally, it may be made to throw out more by preſſing or ſqueezing the rays, and by this means the pipe, by which it is thrown out, may be forced out of the body, and is then ſeen to be white, and of a triangular, not round figure. Theſe are diſpoſed in great numbers over the rays. Mem. Acad. Par. 1710.

The amazing property of reproducing the eſſential parts, when loſt, is not confined to the polype, and ſome few others of the inſect world, but is extended to the *ſtar-fiſh*, and to the urticæ marinæ of various kinds, and probably to many others, in which we at preſent have no expectation of finding it. Mr. Reaumur, on the diſcovery of this property in the polype, obſerved theſe other animals, as they lay on the ſhores of Poictou, and other places, and often found that ſpecies of *ſtar-fiſh*, which is very commonly known, and which has naturally five rays or arms, with only three or four, one or two being wanting; and on taking up and examining theſe mutilated ones, nature was always found reproducing the limb that was wanting; and on cutting and breaking other *ſtar-fiſh* into ſeveral parts, it was but a very little while before the broken parts cicatriſed, and every part remained alive; and by the appearances of things there remained no doubt, but that theſe living pieces will all, in time, reproduce their wanting parts.

Mr. Reaumur could not ſtay long enough on the ſpot to ſee this, but Mr. de Villars, on the coaſt of Rochelle, ſaw the whole proceſs very frequently in the urticæ marinæ, which he cut to pieces on purpoſe for the experiment, and which always reproduced the parts he had cut off; and the common fiſhermen of the coaſts, where Mr. Reaumur was in company with Mr. Juſſieu, ſeeing them making their experiments on the *ſtar-fiſhes*, appeared to be well acquainted with their nature, and told them that they might cut and tear them as much as they pleaſed, but they would not be able to kill them: ſo familiarly was this piece of natural hiſtory known among theſe people, though unknown to thoſe who had employed their lives in the ſearches after ſuch things.

Mr.

Mr. Reaumur was very ſenſible of the advantages that water inſects, and animals, have over others, as to the healing of their wounds, but was reſolved to try the experiment on ſome land animals. The creature he firſt choſe for theſe experiments was the earth-worm; and on cutting theſe creatures aſunder, though many of the pieces dried, yet he had the pleaſure of ſeeing ſome ſucceed ſo perfectly, that the tail part, which wanted not only the head, but alſo the organs of generation of both ſexes (which in theſe animals are always both contained in the ſame individual) has been ſeen to reproduce both theſe organs and the head, and become as perfect a worm as the whole was. Philoſ. Tranſ. N° 464. Append.

STAR-*gazer*, in ichthyology, the Engliſh name of the uranoſcopus. See the article URANOSCOPUS.

STAR-*ſhot*, the common name of a gelatinous ſubſtance often found lying on the ſurface of the earth, and called by ſome *ſtar-jelly*, and *ſtar-fallen*.

The vulgar have been always of opinion, that this was produced from that meteor which they call a *falling-ſtar*; others have imagined it a vegetable ſubſtance, and ſuppoſed it grew out of the earth: neither of theſe however appear, upon a cloſe examination, to be the caſe, but that it is really the half-digeſted food of herons, bitterns, crows, ſea-mews, and coddy-moddies, principally when they have fed upon frogs or earth-worms.

The heads of frogs have been found whole in maſſes of this matter, as have alſo parts of worms; and theſe birds, when ſhot, have been found, when dying, to diſgorge a ſubſtance of the ſame kind.

It is a gelatinous ſubſtance, reſembling a thick mucilage of gum tragacanth, and is cold to the touch. There are often yellow ſpecks, and ſmall clots, like grumous blood, in it. It ſtinks like putrid fleſh when kept, and is principally found in miſty mornings, and in wet weather in autumn, winter, and ſpring. *Moreton*'s Northampt. p. 353.

Mr. Boyle ſays, he has ſeen this jelly reſolved by digeſtion only into a permanent liquor; and that a phyſician of his acquaintance extolled it as a ſpecific, outwardly applied, to wens. Works Abr. Vol. 1. p. 310.

STAR-*ſtone*, *aſteria*, in natural hiſtory, the name of a kind of extraneous foſſil, of a very regular figure and ſtructure, and approaching very much to the nature of the entrochi, having the ſame ſubſtance and inner ſtructure, and being much of the ſame ſize, though different in form: and as thoſe foſſils have fragments of ſhelly bodies, to which they are ſometimes found affixed, and appendages like branches, or the rudiments of ſuch, growing from them, ſo theſe have both the one and the other; the firſt called *aſteropodia*, and the others the *appendiculæ*, or wires of the *aſteriæ*.

The *aſteropodia*, in ſubſtance and inner ſtructure, agree perfectly with the ſhells of the echinitæ, found in our chalk-pits, and with the *aſteriæ* and entrochi; theſe bodies being all compoſed of obliquely-arranged plates of a tabulated ſpar: they are uſually compoſed of ſeveral joints, but they are only very imperfect fragments of the body of the animal the *aſteriæ* have once been a part of; the ſeveral parts of which they are compoſed are all convex on one ſide, and concave on the other, but they are of very different ſhapes, being ſometimes roundiſh, ſometimes oblong, often quadrangular, and not unfrequently of different numbers of angles. They have frequently two, ſometimes more ridges running acroſs them, and ſometimes they have tubercles, or ſmall protuberances, ſtanding either on their upper or under ſide: they are ſometimes found ſingle, but more frequently compound, or arranged into ſmaller or larger parcels, being placed one over another in the manner of the tiles of a houſe, and ſeem truly to have been originally part of an imbricated ſhell, or cruſt of ſome yet unknown ſpecies of ſea-fiſh. They are in theſe compound maſſes even very evidently fragments, and are uſually of irregularly broken figures, though ſometimes they reſemble, in ſome degree, parts of the rays of one or other of the kinds of *ſtar*-fiſh. They are uſually found looſe from the *aſteriæ*, though lying among them; but ſometimes the *aſteriæ* are regularly fixed on them, juſt as the entrochi on the modioli, and are plainly ſeen to have originally grown out of them.

The *encrinos* of authors is one kind of *aſteropodium*, and has been affirmed by ſome perfectly to agree in figure with a ray of the magellanic *ſtar*-fiſh. This is, however, ſeldom found in ſuch a compound ſtate; it uſually is met with in ſingle joints, and then is what authors call the *aſteropodium minus*, or ſmall *aſteropodium*. *Hill*'s Hiſt. of Foſſ. p. 653.

Theſe bodies are uſually of a pale bluiſh grey, or aſh colour; ſometimes they are whitiſh, and ſometimes, though more rarely, yellowiſh, or reddiſh.

Having thus far deſcribed the *aſteropodia*, which ſeem properly the baſes of the *aſteriæ*, we ſhall be more intelligible in the account of the *aſteriæ* themſelves, which are to be treated of merely as branches of them; though, from their being much more frequent than theſe their baſes, they are much more familiarly known, and uſually more regarded.

The *aſteriæ* are ſhort, and commonly ſomewhat crooked angular columns, compoſed of ſeveral joints, each reſembling the figure of a radiated *ſtar*, with a greater or ſmaller number of rays in the different ſpecies: they are uſually found of about an inch in length, and of the thickneſs of a gooſe-quill. Some of them have five angles, or rays, and others only four, and in ſome the angles are equi-diſtant, while in others they are irregularly ſo; in ſome alſo they are ſhort and blunt, while in others they are long, narrow, and pointed; and ſome have their angles ſo very ſhort and obtuſe, that at firſt ſight they might be taken for *entrocho-aſteriæ*. The ſeveral joints in the ſame ſpecimen are uſually all of the ſame thickneſs; this however is not always the caſe, but in ſome they are larger at one end, and in others at the middle, than in any other part of the body; and ſome ſpecies have one of the rays bifid, ſo as to emulate the appearance of a ſix-rayed kind.

All the *aſteriæ* are naturally ſulcated between the angles, but this in a very different degree; ſome are very little ſo, while others are cut ſo deeply, that the ſingle joints of them reſemble the rowels of a ſpur. One end of the column is frequently found finely engraved along the edges of the angles, or rays, while the other end is ſmooth, or nearly ſo; and the ſame is often the caſe alſo in the ſingle joints. Not unfrequently, alſo, one end of a column is indented, and the other has five ſtriæ, running from a hollow center to the ſulci between the rays.

They are found of various bigneſſes and colours; the longeſt ſeldom arrive, however, at two inches, and they are found of all the intermediate bigneſs from this down to the length of a barley-corn: they are not unfrequently found, alſo, compreſſed and flatted, as is common to the foſſils that have been formed in animal moulds.

They are uſually found bedded in the ſtrata of clay, though not unfrequently in thoſe of a lax ſort of quarry-ſtone, and ſometimes in a harder, but that leſs frequently. They uſually have ſea-ſhells, and other marine remains, lying about them; and ſometimes theſe ſhells adhere to the *aſteriæ*, and when ſeparated from them do no injury to the *aſteriæ*, but themſelves ſhew a mark of the figure of the body, or part of the column, when a part has been always wanting in the ſhell. Had theſe ſhells been ſtuck into the bodies of the *aſteriæ*, it would have been a proof that theſe ſhells were the bodies firſt formed, and that the matter of the *aſteriæ* had been formed, or had gathered about them afterwards; but as it is, we have by it abundant proof on the other ſide of the queſtion, and may plainly diſcover that theſe *aſteriæ* are really of marine origin; and that however they may be altered in their matter or ſtructure, ſince they were depoſited in the earth, yet that they were really exiſting in this their proper form in thoſe ſeas, when the ſhells that are found adhering to them acquired their growth.

From the columns of the *aſteriæ* there are ſometimes propagated certain ſmall branches, like thoſe of the entrochi; theſe are called by authors *appendiculæ aſteriarum*, or the wires of the *aſteriæ*.

They are compoſed of ſeveral ſhort cylindric joints, with obliquely-truncated ends, and each hollowed to the middle, where there ſtands a ſmall tubercle. Theſe branches are ſometimes two inches long, and the largeſt or thickeſt joint always adheres to the *aſteria*, all the ſucceeding ones growing ſmaller, and the branch taperer toward the end. In their natural ſituation on the *aſteria*, they ſtand in regular circles at different diſtances, one above another: there is always one wire in each of the ſulci, or channels of the body, and theſe ſtand evenly againſt one another.

Theſe wires, or *appendiculæ*, are very ſeldom, however, found in this their native ſtate, or fixed to the bodies of the *aſteriæ*; they are commonly found broken off, and lying looſe among them, and the rudiments only of them remaining on the *aſteriæ*, and very rarely even theſe. The wires themſelves are more frequently found wholly ſeparate from them, and either in fragments of different lengths, or in ſingle joints, immerſed in ſtone, or lying among the ſtrata of clay. *Hill*'s Hiſt. of Foſſ. p. 654.

The *aſteria* is alſo denominated *aſtrites*, *aſtroites*, *aſtrobulus*, and *aſteriſcus*; by Geſner *ſphragis aſteros*, *ſigillum ſtellæ*, in Engliſh the *ſtarry-ſtone*.

The *aſteriæ* may be reduced to two kinds; the firſt, thoſe whoſe whole bodies make the form of a *ſtar*; the ſecond, thoſe which in the whole are irregular, but which are adorned, as it were, with conſtellations in the parts.

Dr. Liſter, for diſtinction's ſake, only gives the name *aſteria* to the former ſort, diſtinguiſhing the latter by the appellation of *aſtroites*; the other naturaliſts generally uſe the two indiſcriminately [b]. The *aſteria*, ſpoken of by the antients, appears to be this latter kind [g].—[b] *Plott*, Nat. Hiſt. Oxfordſh. cap. 5. ſect. 16. ſeq. [g] Mercat. Metalloth. arm. 9. cap. 10.]

Some antient writers indeed ſpeak of another more extraordinary ſpecies of *aſteria*, or *aſterites*, which the ſun's rays would ſet on fire, and which on that account came into uſe for the compoſition of philtres for kindling love. *Bail.* Dict. Crit. in voc. Eſope, n. (A).

The quality of moving in vinegar, as if animated, is ſcarce perceivable in the *aſtroites*, but is ſignal in the *aſteria*.

The former muſt be broken in ſmall pieces before it will move; but the latter will move, not only in a whole joint, but in two or three knit together. *Plott*, Nat. Hiſt. Oxfordſh. ſect. 26, ſeq.

STAR-*wort*, *after*, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the radiated kind. Its diſk is compoſed of floſcules, and its border of ſemifloſcules: theſe all ſtand on the embryo ſeeds, and are contained in one common ſquammoſe cup. The embryos finally ripen into ſeeds, which are winged with down, and fixed to the thalamus of the flower.

The ſpecies of *after*, enumerated by Mr. Tournefort, are theſe. 1. The common blue Attic *ſtar-wort*. 2. The Attic *after* with white flowers. 3. The round-leaved hairy Auſtrian *ſtar-wort* with large blue flowers. 4. The long-leaved mountain *ſtar-wort* with large blue flowers. 5. The purple-flowered Alpine *after*. 6. The blue-flowered dwarf mountain *ſtar-wort*. 7. The blue-flowered Alpine Attic *ſtar-wort*. 8. The purple tripolium-flowered *after*. 9. The broader-leaved *after* with tripolium flowers. 10. The common acrid blue-flowered *after*, called the *blue fleabane*. 11. The great blue Attic *ſtar-wort*. 12. The leſſer blue Attic *ſtar-wort*, called the *blue Alpine fleabane*. 13. The blue-flowered willow-leaved ſea *ſtar-wort*, called *tripolium*. 14. The leſſer *tripolium*. 15. The ſmall white-flowered *tripolium*. 16. The early Pyrenean *after* with large blue flowers. 17. The autumnal Pyrenean *after* with ſmaller blue flowers. 18. The broad-leaved American *after* with pale blue umbellated flowers. 19. The tall hairy New England *after* with very large violet-purple flowers. 20. The late-flowering hairy willow-leaved American *after* with blue flowers. 21. The tall-branched, wild daiſy-leaved, late-flowering *after*. 22. The branched late-flowering purple *after*. 23. The broad-leaved paniculated *after* with deep violet-coloured flowers. 24. The blue-flowered hyſſop-leaved branched African *after*. 25. The white-flowered branched hyſſop-leaved African *after*. 26. The annual Canada branched *after*, called by ſome the *branched daiſy*. 27. The African *after* with helichryſum leaves. 28. The hairy yellow mountain *after atticus* with very large flowers. 29. The ſmooth mountain *after* with large yellow flowers. 30. The yellow-flowered *after* with ſweet-ſcented roots. 31. The fleabane-leaved autumnal meadow *after*, commonly called the *middle fleabane*. 32. The meadow Alpine *after* with gold-yellow flowers. 33. The yellow-flowered woolly Dutch *after*. 34. The very hairy and woolly Alpine *after*. 35. The hairy mullein-leaved *after*. 36. The rock *ſtar-wort* with viſcous, hairy, and ſtrong-ſcented leaves. 37. The long-leaved mountain yellow *after*. 38. The yellow marſh *after* with long woolly leaves. 39. The ſea *after* with a thick cylindric, and three-pointed leaf. 40. The yellow jagged-leaved marſh *after*, called the *jagged-leaved marſh fleabane*. 41. The marſh *after* with ſmall globoſe flowers. 42. The yellow-flowered tuberous-rooted ſea *after*, called *ſea-fleabane*. 43. The mountain willow-leaved *after* with yellow flowers. 44. The yellow ſweet-ſcented *fleabane* like *after*. 45. The fleabane-leaved yellow Alpine *after*. 46. The mullein-leaved *after* with yellow flowers. 47. The primroſe-leaved American *after* with yellow flowers, and a thick large cup. 48. The American primroſe-leaved *after* with a ſingle purple flower. 49. The ſhrubby yellow ſtœchas-leaved American *after* with umbellated yellow flowers. 50. The American *after* with large ragwort leaves, hairy underneath. 51. The yellow-flowered ſtœchas-leaved Æthiopian *after*. 52. The great *after*, commonly called *elecampane*. *Tourn.* Inſt. p. 481.

All the ſpecies of this plant are propagated by parting their roots early in ſpring, and they will grow in almoſt any ſoil or ſituation; and the larger ſorts encreaſe ſo faſt, that if not prevented, they will in a little time over-run a large ſpace of ground. They grow beſt in the ſhade. But the lower kinds do not run ſo much at the root, but ſhould be taken up and tranſplanted every other year, which will make them produce much fairer flowers. *Miller*'s Gard. Dict.

Golden STAR-*wort*. See the article ASTER *Atticus*.

STAR *of Bethlehem*. See the article ORNITHOGALUM.

STARAPHAXAT, a name uſed by ſome of the old writers for any medicine that reſtrains fluxions upon the eyes, noſe, or fauces.

STARTING, in the manege. A horſe is ſaid to be *ſtarting*, ſkittiſh, or timorous, that takes every object he ſees to be otherwiſe than it is; upon which he ſtops, flies out, and ſtarts ſuddenly to one ſide, inſomuch that the rider can't make him come near the place where the object is. This fault is more common to geldings than ſtone-horſes. Such horſes alſo as have bad eyes are moſt ſubject to it, as well as thoſe that have been kept a long time in a ſtable without airing; but theſe laſt are eaſily cured of it. When you have a ſkittiſh horſe, never beat him in his conſternation, but make him advance gently, and with ſoft means, to the ſcarecrow that alarms him, till he recovers it, and gains aſſurance.

STARVING *to death*, a kind of puniſhment uſed by the people of Arragon ſome ages ago; and it is reported by Tavernier, that the chief ladies in the kingdom of Tunquin are at this day ſtarved to death for adultery.

STASIS, a word uſed by phyſicians to expreſs a ſtagnation of the humors.

STATELY, in the manege. A horſe is ſaid to be *ſtately*, that goes with a proud, ſtrutting gate.

STATER, the name of a weight among the antients, equal to four drachms.

STATHEUSIS, a word uſed by the old writers to expreſs the torrefaction, or roaſting of ſome medicines before a ſlow fire, as is done frequently at preſent with rhubarb, *&c.*

STATICAL, (*Cycl.*) is ſometimes applied in a peculiar ſenſe to the experiments made as to the quantity of perſpiration, and other excretions of the human body.

We have a very particular account of ſome experiments of this kind in the Philoſophical Tranſactions, N° 470, made by Dr. John Lining of Charles-Town, in South-Carolina.

STATICAL *hygroſcope*. See the article HYGROSCOPE.

STATICE, *thrift*, in botany, the name of a genus of plants, the characters of which are theſe. The flowers are collected into a head of a ſort of globular form, which is ſurrounded by a common ſcaly cup. The head is compoſed of a number of caryophylleous flowers, compoſed of ſeveral petals, and each ariſing from its own proper tubular cup. The piſtil ariſes alſo from the ſame cup, and finally becomes an oblong fruit, covered by the cup.

The ſpecies of *ſtatice*, enumerated by Mr. Tournefort, are theſe. 1. The larger *ſtatice*, *thrift*, or *ſea July flower*. 2. The ſmaller *ſtatice*. 3. The large white-flowered Alpine *ſtatice*. 4. The ſmalleſt mountain *ſtatice*. 5. The Portugal *ſtatice* with ſcorzonera leaves. 6. The large ſhrubby Portugal ſea *ſtatice* with great flowers. 7. The great Portugal *ſtatice* with capillaceous leaves. 8. The ſmalleſt Portugal *ſtatice* with capillaceous leaves. And 9. the low ſea *ſtatice* with rigid capillaceous leaves. *Tourn.* Inſt. p. 340, ſeq.

STATICULA, among the Romans, thoſe little figures with which it was uſual to adorn their drinking-cups, called *ſcyphi*. *Pitiſc.* in voc.

STATICULI, among the Romans, a kind of dancing pantomimes. *Pitiſc.* in voc. See PANTOMIME.

STATION (*Cycl.*)—We have a method of meaſuring diſtances at one *ſtation*, in the Philoſophical Tranſactions, N° 7, by means of a teleſcope. But the practice of this method does not anſwer to the theory.

STATION, *ſtatio*, στασις, in the antient muſic, was ſometimes uſed for any fixed pitch, or degree of ſound, whether produced by intention or remiſſion. Vid. *Wallis*, Append. ad Ptolem. Harmon. p. 154.

STATION-*line*, in ſurveying. See the articles LINE and SURVEYING, *Cycl.*

STATIONARY (*Cycl.*)—STATIONARY *fevers*, a term uſed by Sydenham to expreſs a peculiar kind of fever, adapted, and owing to ſome general conſtitution of the air and ſeaſons. There are certain general conſtitutions of years, which owe their origin neither to heat, cold, dryneſs, nor moiſture, but rather depend upon a certain ſecret, and inexplicable alteration in the bowels of the earth, whence the air becomes impregnated with ſuch kinds of effluvia, as ſubject the human body to peculiar diſtempers, ſo long as that kind of conſtitution prevails, which after a certain courſe of years declines, and gives way to another. Each of theſe general conſtitutions is attended with its own proper and peculiar kind of fever, which never appears in any other; and this is thence called a *ſtationary fever*.

STATIVA, among the Romans, a ſtanding camp kept for the defence of the frontiers of the empire. Theſe camps gave riſe to a great many towns, which took their names from the legion ſtationed there. *Pitiſc.* in voc.

STATORES, among the Romans, made a part of the emperor's life-guard. *Pitiſc.* in voc.

STATUARY (*Cycl.*)—STATUARY *marble*, among our artificers, the name of the ſofter white marble uſually wrought into *ſtatues*, the ſame with the Parian marble of the antients.

STATUTE (*Cycl.*)—The king's royal aſſent to a bill by his letters patent under his great ſeal, and ſigned with his hand, and declared and notified in his abſence to the lords ſpiritual and temporal, and to the commons, aſſembled together in the high houſe, is as effectual as if the king was preſent. Stat. 33 Hen. VIII. cap. 21.

Statutes were antiently proclaimed by the ſheriff, but upon the invention of printing, this method was diſcontinued. Every body is obliged to take notice of an Act of Parliament at his peril. 4 Inſt. 26.

STATUTE-*ſeſſions*, in law, a meeting in every hundred of conſtables and houſholders, by cuſtom, for the ordering of ſervants, and the debating of differences between the maſters and the ſervants, rating of ſervants wages, *&c.* 1 Eliz. cap. 4. *Cowel.*

STATUTO *mercatorio*, a writ for the impriſoning him that has forfeited a *ſtatute merchant* bond, until the debt is ſatisfied: and of theſe writs there is one againſt lay-perſons, and another againſt perſons eccleſiaſtical. Reg. Orig. 146, 148. *Cowel.*

STATUTO *ſtapulæ*, a writ that lies to take the body to priſon, and ſeize upon the lands and goods of one who hath forfeited the bond called *ſtatute ſtaple*. Reg. Orig. 151. *Blount*, *Cowel*.

STATUTUM *de laborariis*, an antient writ for the apprehending ſuch labourers as refuſe to work according to the *ſtatute*. Reg. Judic. 27. *Blount*, *Cowel*.

STAVESACRE, *ſtaphiſagria*, in botany. See the article STAPHISAGRIA.

Staveſacre grows in Provence, Languedoc, and many other parts of Europe. The leaves are large and finger'd, the flower blue, and ſomewhat like that of the larkſpur. The ſeed, which is the only part of the plant uſed in medicine, is of a duſky brown, and very rough on the outſide, and of a pale yellow within, and of a bitter, diſagreeable, and very acrid taſte. The ſeed ſhould be choſen new, clean, and plump. Taken inwardly they are a violent purge and vomit, in a very ſmall doſe, and are never preſcribed; but outwardly they have always been famous for deſtroying lice in children's heads. Some take it into their mouths alſo for the tooth-ach, and others have ventured to uſe gargariſms of it to cure phlegm, and as an errhine, ſnuffing it up the noſtrils. It is alſo commended for the cleanſing old ulcers. *Lemery*'s Dict. de Drog.

The chief uſe of *ſtaveſacre*, as a medicine, is the deſtroying vermin in children's heads: to this end it is powdered and mixed with *cocculus indicus*, and ſeldom fails of ſucceſs. It is a violent purgative, and therefore ſeldom uſed at preſent.

STAUROPHORI, Σταυροφοροι, in church-hiſtory, certain eccleſiaſtics, whoſe buſineſs it was to carry the croſs in proceſſions. *Hofm.* Lex. in voc.

The word is compounded of σαυρος, a croſs, and φερω, I carry.

STAUROPHYLAX, Σταυροφυλαξ, in church-hiſtory, a dignified officer in the church of Conſtantinople, to whoſe care the keeping of the croſs, found by Helena, was committed. *Hofm.* Lex. univ. in voc.

The word is derived from σαυρος, a croſs, and φυλασσω, I keep.

STAXIS, a word uſed by the antient phyſicians to expreſs a diſtillation of blood in drops from the noſe.

A *ſtaxis*, in the doctrine of criſes, is juſtly condemned as indicating a weakneſs and decay of ſtrength in nature; whereas, on the contrary, free and copious diſcharges of blood from the noſe are eſteemed good indications, and often make happy criſes.

STAY (*Cycl.*)—STAY, in the manege. To *ſtay*, or ſuſtain your horſe, is to hold the bridle firm and high. We likewiſe *ſtay* or ſuſtain a horſe with the in-leg, or in-heel, when he makes his croupe go before his ſhoulders upon volts: as alſo when we hinder him to traverſe, and ride him equally, keeping him always ſubject, ſo that his croupe can't ſlip out, and he can't loſe either his cadence, or his ground, but marks all his times equal.

STEAMS. Subterranean *ſteams* often affect the ſurface of the earth in a very remarkable manner, and influence or prevent vegetation more than any thing elſe. The ſurface of ſome ground is ſo hollow and light, and ſo ſwoln by a warm and continually working ferment, that it muſt needs ſend up a warming *ſteam*; and that it does ſo, even in the coldeſt weather, is evident from the immediate melting of the ſnow that falls on it: nay, in many places, the effect of this *ſteam* is ſo great, that it melts the ſnow before it reaches the ground, ſo that it falls on it in form of rain.

Some ſtones alſo, and ſome waters, impregnate the earth by their innate warmth, ſending up a continual ſucceſſion of warm effluvia from all parts of their ſurfaces; and other ſtones have exactly a contrary effect, rendering the places where they lie barren and cold. Streams of water, which have in their ſubterranean courſe run through beds of limeſtone, marl, or chalk, are always enriched, and warmed by the *ſteams* iſſuing from thoſe ſubſtances, and mixing with them as they paſs, and conſequently theſe waters enrich the ground wherever they run; and, on the contrary, ſome waters are uliginous, or corroſive, from the *ſteams* they have received in their channels from the veins of pyrites, or beds of metalline ores. It is even reported, that the very ſubſtances of metals and minerals are thus raiſed in *ſteams*, and that the juices of plants are found loaded with them; thus we are told, that in Italy crude quickſilver is found in the juices, and at the roots of plants; and that in Moravia, Hungary, and Peru, the ſubſtances of the metals are found in the bodies of plants, particularly lead and ſilver. The Miſcellanea Curioſa of Leipſick ſpeak of wonderful appearances of gold in the form of plants, which, if true, muſt be owing to that metal's having been raiſed in *ſteams*, and carried into the veſſels of the plants in ſuch quantity, as in fine to deſtroy the vegetable appearance, and leave the figure of the plant in metal. Phil. Tranſ. N° 110.

STEATITES, in the hiſtory of foſſils, a name given by late authors to a ſubſtance called in Engliſh *ſoap-earth*, and which, though the authors on theſe ſubjects had not taken notice of that circumſtance, was the very ſubſtance called *Cimolia purpuraſcens*, or purple earth of Cimolus, by the antients. The later ages finding the purple Cimolian earth of the old writers to be wholly different from their white kind, have given that name (though it is not eaſy to gueſs why) to the common fuller's earth, which has no tinge of purple in its whole ſubſtance.

This earth however, called by us *ſoap-earth*, and *ſteatites*, is well worth enquiring after, as a ſubſtance for imitating the fine porcelain ware of China. Dr. Woodward much recommends it on this account, and repeated trials have been made of it ſince his time, and ſome of them very lately; in all which it has afforded the fineſt earthen-ware ever made with us, and promiſes fair, with good management, for the equaling any in the world.

It is dug in many parts of Devonſhire and Cornwall, and the neighbouring counties; the cliff of the Lizard point is almoſt wholly compoſed of it, and the adjacent little iſlands abound with it; and from all theſe places it might be brought, at ſmall expence, in any quantities. It is known from all other earths by theſe characters. It is compoſed of extremely fine particles, and is of a firm, equal, and regular texture, and great weight. It is very firm and hard as it lies in the earth, but when it has been ſome time expoſed to the air, it becomes almoſt of a ſtony hardneſs. It is of a perfectly fine, ſmooth, and gloſſy ſurface, ſofter to the touch than any other ſpecies of earth, and does not at all adhere to the tongue, or ſtain the fingers in handling; but drawn along a rough ſurface, as a piece of cloth, or the like, it marks it with a fine and even white line. In colour it is a clear white, veined and variegated very beautifully with purple of different degrees of deepneſs; and is of ſo fine a ſtructure of parts, that when cut into thin pieces it is in ſome degree tranſparent. It makes no efferveſcence with acids, and burns to a pure white, even in its purple parts. *Hill*'s Hiſt. of Foſſ. p. 22. See TERRA *Cimolia*.

STEATOCELE, a term uſed by the antients to expreſs a ſort of rupture, occaſioned by a large quantity of fat or ſuety matter lodged in the ſcrotum.

STEEL (*Cycl.*)—The difference between *ſteel* and iron is, that *ſteel* being much the harder, will not yield to the hammer, but is brittle, inſtead of being ductile, and reſiſts the file. Malleable iron grows rigid by being ſimply extinguiſhed in cold water, but it yet retains a conſiderable degree of ductility in the cold, and may be extended in all dimenſions with the hammer.

Steel, however, if heated again, and cooled by ſlow degrees, may be filed, and extended more or leſs by the hammer. But there are many degrees in the hardening of *ſteel*; for if it has been made extremely red-hot, and is then quenched in cold water in motion, it becomes greatly harder than if it had been but moderately red-hot, and had been quenched in warm water.

Steel is alſo of a darker colour than iron, and the ſurface of it, when broken, appears to conſiſt of ſmaller granulated, or even ſtriated particles, than the iron it was made of. This appears moſt diſtinctly, when *ſteel* is welded to the ſame iron of which it was made, and the maſs made red-hot, and well incorporated by hammering. If then you harden it again, by extinguiſhing it in cold water, and poliſh it, the veins of iron are eaſily diſtinguiſhable from thoſe of the *ſteel*; the iron ones being whitiſh, and of a ſilver-like hue, the *ſteel* ones blackiſh, or like water; and when broken, the ſize of the particles is found extremely different. *Cramer*'s Art of Aſſaying, p. 346.

The manner of making iron into *ſteel* had remained very long a ſecret, but many authors of late date have given the proceſs, though it does not appear the ſame in all, and in many is encumbered with circumſtances, intended only to diſguiſe it. Mr. Reaumur has taken greater pains, than almoſt any man, to come at the truth; but to be rightly informed of his reaſons, we ought to begin where he did, that is, at the origin of the iron in its pure metallic ſtate.

The ores of this metal are mixed bodies, compoſed of ſome particles truly metallic, and of others ſulphureous, ſaline, and terrene; this compound maſs is put in fuſion by the fire, and on this operation the metallic parts being heavieſt, ſubſide to the bottom of the veſſel, or furnace, and are then eaſily ſeparated from the lighter ſubſtances which float at the top. This ſeparation, however, is not ſuppoſed to be perfect, but the metal, after this its firſt fuſion, retains many heterogene particles, which prevent it from being malleable. It is after this to be refined, that is, to be melted again, and that ever ſo often performed, the metal becomes yet more and more pure and perfect, ſome heterogene matter being every time depoſited, or thrown off, and this is uſually much leſs after every fuſion.

The metal, when thus purified by melting, yet remains hard and brittle: theſe are two qualities which we do not want in iron, and this hardneſs and friability are no incompatible qualities, ſince their origin is this, that the iron in this ſtate is compoſed of a multitude of ſmall granules, every one of which is very firm and compact in its own texture, though they

they cohere but ſlightly one with another. The knife, or the file, cannot eaſily cut any one of theſe granules, but a blow of a hammer eaſily ſeparates large parcels of them from thoſe to which they were joined: this caſt iron is therefore uſed only for ſuch purpoſes as requires a ſubſtance poſſeſſed of theſe qualities; purpoſes where hardneſs is required, and where no blows are to be met with. Thus backs of grates, iron pots, and the like, are made of it.

One of the general properties of metals is, that they are malleable; that is, their ſeveral particles cohere ſo well together, that they are ductile and extenſible under the hammer, and will ſuffer the whole maſs to bend any way without breaking, that is, without their ſeparating from one another. In the words of the artizans, ſuch ſuppleneſs and pliability is called *body* in a metal, and the caſt iron, which wants this, is ſaid to have no body, and is what they call *no ſoft metal.* It is therefore no way fit for ſuch works as require faſhioning by the hammer or the file, nor of ſuch as are to ſtand any violent blows; but as it is eaſily fuſible, it ſerves for caſt works where there is no great delicacy in the figuring, ſince it does not run ſo thin as to adapt itſelf to every lineament of a fine figure, nor is qualified to be repaired by inſtruments.

The ill qualities of caſt iron are, in a great degree, remedied in the forged or wrought iron, taken from the ſame quantity, and the ſame fuſion. The forging of iron is only the placing it over the fire till heated to a certain degree, and then beating it out with large hammers till it becomes ſoft. When it has been ſufficiently forged, it becomes ſoft and malleable, even when cold, and when heated, is eaſily wrought into any figures, which it retains always afterwards; and it is eaſily cut by the file when cold, and is not brittle on being ſtruck, as is the caſt iron.

While it gains theſe properties by the forging, it loſes, however, another by the ſame means, which is its fuſibility. It will no longer melt in the fire, but when the workmen give it the ſtrongeſt heat they can, it is only reduced to a ſort of ſoft paſte, and *ſweats* a little, as they expreſs it; that is, ſome few drops of truly melted iron fall from it.

It is very certain, that both the caſt and the forged iron are mixtures of metalline, ſaline, and ſulphureous particles; and the different arrangement of theſe, in their mere ſimple running together in the fuſion, and their being driven intimately into, and among one another, by the hammering, makes the fuſibility different in the two ſtates.

If the forged iron differ greatly from the caſt, there is however a third ſtate into which it is reducible by art, which is yet different from both, this is what we call *ſteel*; and the quality of iron on receiving this change is not one of its leaſt valuable ones, ſince from this we have all our inſtruments for cutting, ſawing, boring, and the like purpoſes, the value of which to us is almoſt infinite. The German *ſteel* has always been in great repute, and though ſeveral other nations have made it, yet the Germans have kept their method a ſacred myſtery, to keep up their trade in it.

Steel is conſiderably harder than forged iron, and ſo it is neceſſary that it ſhould be, in order to many of the purpoſes it is employed in. Shears of *ſteel*, which are intended to cut iron, muſt be harder than iron, otherwiſe their edge will turn, and they will not cut; whereas, if the metal is too hard, then the granules will fly off, and the edge break away in ſmall fragments. This is the caſe with all edged tools; and hence it is that good *ſteel* is ſo nice and difficult a thing to make, ſince there is required ſuch a degree of hardneſs, and no more.

It is very well known, that *ſteel* acquires its hardneſs from the plunging it into water; it is to be heated to a certain degree, and then immediately plunged, while the fiery particles yet remain in it, into water perfectly cold; it is then to be ſpeedily drawn out of the water, and thus the whole operation is finiſhed. It acquires its hardneſs in degrees, proportionate to its heat when plunged into the water; and this hardneſs, or temper, remains with it only till it is heated as high again; for after that, if it is left to cool leiſurely, and not thrown into water, it is loſt. All the maſſes of *ſteel* which are ſold are thus tempered; nevertheleſs, when they are wrought into tools, their temper is loſt, and is to be renewed by plunging them again into cold water, when they have been forged into the ſhape of which they are to be.

Mr. Reaumur affirms, that *ſteel* differs in nothing from forged iron, except that it contains more ſulphurs, and more ſalts. Hence it follows, that caſt iron ſhould be *ſteel*, ſince it evidently differs from forged iron in the ſame manner, and by the ſame properties; and in effect, caſt iron is *ſteel*, ſuch as it is, eſpecially the white ſort, which is more pure, and more perfectly diveſted of its earth, than the browner ſorts; and this white kind may be accordingly brought to all the hardneſs of *ſteel*, by repeated heating and quenching in cold water. It follows alſo, that in order to convert iron into *ſteel*, we are to give it new ſalts, and new ſulphurs. It may be aſked, where is the neceſſity of giving again that, which the mere caſt iron poſſeſſes? To which the anſwer is, that *ſteel* is required to be malleable in ſome degree, which the mere caſt iron is not; and it is to be added to this, that it may be poſſible for us to give to forged iron ſuch ſalts and ſulphurs as are more proper for the *ſteel*, than thoſe which the caſt iron naturally poſſeſſes.

We have great variety of ſalts and ſulphurs, out of which to chuſe for this purpoſe, and Mr. Reaumur made many trials to find which would ſucceed beſt; and the reſult of all was, that for ſulphurs, powdered charcoal and common ſoot; and for ſalts, ſea-ſalt alone ſucceeded beſt, and that theſe were properly to be mixed with aſhes, by way of an intermediate ſubſtance. Theſe ſubſtances muſt alſo have their allotted doſe; that is, there muſt not only be a certain proportion of the ſeveral ingredients one to another, which however need not be very preciſe or exact, but there muſt alſo be a proportional quantity of the whole employed to the quantity of iron that is to be wrought upon; and in this alſo regard muſt be had to the ſeveral ſorts of ores from which the iron was obtained, ſince the iron of ſome ores is much ſooner convertible into *ſteel* than that of others, and makes alſo a better *ſteel.*

The manner of beſt introducing theſe ſalts and ſulphurs into the body of the iron, was found by this author a matter of great difficulty to determine. He ſoon perceived, that fire was the only agent that could convey theſe bodies into the metal; and in contriving how this might be done moſt eaſily, and with leaſt expence, he found out, after many trials, a new ſort of furnace, which effected this purpoſe with great eaſe, and which was not ſubject to the inconveniences of other furnaces.

As *ſteel* is iron with an admixture of heterogene particles, it follows that it muſt be leſs metallic, that is, leſs malleable, or more brittle; and it is alſo neceſſary that it muſt be, in ſome degree, malleable for the purpoſes it is required for; and it is eaſy to conceive that theſe properties cannot be given it, in a proper degree, but by means of a very accurate operation; and even when all the parts of the proceſs are the ſame, there is yet much depending on the iron itſelf, which can never be perfectly known but by trial. Something, however, may be judged of the iron by breaking bars of it: the ſeveral ſorts of iron, when broken, ſhew ſome of them only granules, others flakes, and others fibres; ſome alſo ſhew all three of theſe moleculæ at once, and others two of them; but it is eaſy, in either of theſe caſes, to ſee which ſort is in the greateſt number. The laminated and the fibrous iron are the two extremes; the firſt is very brittle, the latter very malleable. The laminated iron is ever the worſt of all kinds for making into *ſteel*; and of this kind ſuch pieces are worſt of all, the laminæ of which are very white and ſhining, and are large and irregularly diſpoſed, and arranged in different inclinations. Mr. Reaumur began to reckon from theſe an arrangement of all the kinds of iron, which coming, each by degrees, to have the laminæ ſtill ſmaller and ſmaller, and at the ſame time leſs glittering, and placed more evenly together, ſunk at laſt into the irons of the granulated kind. It is eaſy to conceive how many differences there muſt be between theſe; and from theſe the fibroſe ones may be deduced, owing their texture merely to the granulæ, which in theſe are diſpoſed into long ſtrings or ſtreaks. Tho' in this arrangement of the irons, the firſt are, of all others, the leaſt proper for making *ſteel*, it does not follow that the laſt are the moſt ſo: theſe indeed uſually make a very ſoft and pliant ſort of *ſteel*, which has what the workmen call the *greateſt body* of all the kinds of *ſteel*, and is therefore moſt proper of all for certain purpoſes, as the making watch-ſprings, and the like; but the want of hardneſs makes it very unfit for cutting tools of all kinds, from the razor to the ax. The granulated iron always makes the fineſt and hardeſt *ſteel*; and of theſe ſuch ſucceed beſt, whoſe granules are ſmalleſt.

One thing remarkable is, that all *ſteel*, though made of iron of the granulated or ſtriated kind, yet is, before it has been hammered, of a flaky, or a ſort of laminated ſtructure; but this ſeems owing to the fire's having melted ſome of the granules in the operation, and run ſeveral numbers of them together into theſe plates. The ſmallneſs of theſe flakes in *ſteel*, which has not been worked, are a proof of its being but of a bad kind.

A bar of iron, when converted into *ſteel*, is not equally ſo converted in all its parts; the fire has always acted more ſtrongly upon its ſurface than on its central parts, and it is therefore more perfect *ſteel* there than in its inner parts; but a perfection in the operation is not neceſſary to the *ſteel's* being good and uſeful, and the whole bar is often very good *ſteel*, as are alſo many bars made at the ſame time, yet all perhaps ſomewhat differently affected.

If the compoſition, which is to convert the iron into *ſteel*, be too ſtrong, or if the fire be too violent, or the matter continued too long in it, in all theſe caſes the *ſteel* will be over made; that is, there will be an over proportion of ſaline and ſulphureous parts added to the iron: theſe will therefore too far ſeparate the particles of the metal aſunder, and the conſequence will be, that the *ſteel* will be too brittle to bear hammering, and will be of great loſs to the proprietor in the great quantities that will be broken, beſide the loſs he will

will ſuſtain from the abundance of ſcales which will fly off in the working. The way to meliorate ſuch *ſteel* as this, muſt be to diveſt it of part of its ſalts and its ſulphurs, but peculiarly of the laſt; and Mr. Reaumur found, that the burying the bars of ſuch *ſteel* in lime, or any other alkaline ſubſtance that would readily abſorb the ſulphurs, and placing it for a proper time in the fire, it would be in a manner decompoſed again, and come out a very good and perfect *ſteel*; and this is no trivial proof, that the account given of the manner of iron's becoming *ſteel* is the true one.

By this management *ſteel* may again be converted, or reduced to its primitive iron, and a body of any middle degree, between *ſteel* and iron, may be produced, by ſtopping this proceſs at different points of time, or continuing it till all the adventitious ſalts and ſulphurs are drawn off or abſorbed. Hardneſs and flexibility are the two great points in this operation, and what the metal gets of the one of theſe, it aſſuredly loſes of the other. The greater hardneſs is from the greater quantity of the adventitious ſalts and ſulphurs; and the greater flexibility, or, as the workmen call it, the *greater body*, is from the greater quantity of the metallic; and he who is able to calculate properly the quantities of his ſalt, charcoal, and ſoot, and to regulate exactly the degree of fire, is capable to make *ſteel* of what degree of temper or perfection he pleaſes.

Iron, impregnated with new ſalts and new ſulphurs, is not however perfectly reduced to the ſtate of what the workman expects in *ſteel*; there wants yet the quenching it while hot in cold water, to compleat the operation. The *ſteel* penetrated every way by the particles of fire, and at that inſtant plunged into water, is by that quenching ſtopt in the very ſtate in which it was, and is not ſuffered to exhale the igneous bodies, as it would otherwiſe have done. It was, while in the fire, rarified and dilated, and this quenching continues it in that ſtate, and it is found, on meaſuring, conſiderably thicker and larger than it was while unheated. It might be ſuppoſed from hence, that the particles of fire, which were lodged in the *ſteel* while red-hot, were thus detained and impriſoned in it, and ſo wrought the change, as they are known to remain in many calcined bodies, though they have not been ſo ſuddenly quenched; but if this were the caſe, the *ſteel* muſt be encreaſed in weight as well as bigneſs, as many calcined bodies are, but this is not found to be ſo in fact.

Recourſe muſt be had therefore to ſome other operation on the *ſteel*, and this appears, in reality, to be no other than the change of its texture, or internal ſtructure. If a body be naturally compoſed of a number of particles, which are in themſelves hard and compact, but between which there are certain ſpaces; if one take from thoſe hard and compact particles ſomewhat to fill up thoſe voids, it muſt appear very evidently, that though by this the proper particles are rendered leſs hard, yet the whole body muſt be made harder than it was before.

In the converting of iron into *ſteel*, Mr. Reaumur conceives that the particles of iron, being naturally very covetous of ſalts and ſulphurs, have imbibed great quantities of theſe adventitious bodies, while the ſpaces between them have been able to retain very few. This being then the firſt ſtate of the *ſteel*, when it is afterwards heated, in order to its being tempered by quenching, the fire drives theſe ſulphureous and ſaline particles, ſo abundant in the iron, out of its granules, and diſperſes them throughout the ſpaces between theſe granules; and that it is to this equal and regular diſtribution of theſe ſalts and ſulphurs, fixed in that ſtate by the immediate quenching, that the hardneſs, and other qualities of *ſteel* are owing.

To the advantage the metal gets by this means, there is however always joined a diſadvantage, which is, that its grain naturally and neceſſarily becomes coarſer by it, and the *ſteel* has the leſs body. The hardeſt *ſteel* always muſt neceſſarily have the leaſt body; but according to the rules laid down by Mr. Reaumur, one may diſpoſe the hardneſs in what degree one pleaſes, and conſequently all the other properties are in the direction of the ſame laws.

If the oppoſition of the qualities of *ſteel* be nicely conſidered, we ſhall find, that inſtead of being hurtful, they are truly what ſhould be moſt wiſhed for, and are productive of the moſt deſirable conſequences. It may appear ſomewhat ſtrange, that hardneſs and flexibility in *ſteel* ſhould be ſuch directly oppoſite and contradictory principles, and that the quenching, which makes *ſteel* more powerful to reſiſt preſſure or rubbing, ſhould at the ſame time make it more feeble in action; but this is plainly the caſe, and a piece of *ſteel* wire, which, before it is tempered by quenching, will, when hung vertically, ſuſpend a certain weight, will not ſuſtain the ſame weight when tempered, but will be broken even by a leſs; and that if the trial be made by tempering it up to one certain part, and no farther, the wire will aſſuredly break at that very part where the tempered and untempered portions meet. The encreaſe of ſize in every grain of *ſteel*, from the quenching, gives the plain ſolution of this phænomenon. The rupture of any body whatever, that is, the ſeparation of its parts, by whatever means it is done, muſt be more difficult, the more intimately thoſe parts touch, or the more points they touch in. The granules of *ſteel* are theſe touching parts, and it is very evident that theſe granules becoming larger on the quenching, muſt after this touch in fewer points, in the whole combination of the maſs; and on the other hand, as they are larger, they alſo muſt mutually touch each other in a larger ſpace. Here are two contrary principles, which conſtitute the facility and the difficulty of the rupture by different means; and it cannot be, but that the one of theſe conſtructions muſt give the greater force to reſiſt preſſure or friction, and the other to reſiſt drawing or traction.

It has been already obſerved that *ſteel* is the harder, according as it was more or leſs hot at the time when it was plunged into the water; and it muſt be added to this, that it alſo is the more ſo, the more cold the water is into which it is plunged. The degree of heat in the *ſteel* is eaſily known by its colour, and the diſtinctions in it are familiar to the workmen. Several perſons have thought there was great virtue to be communicated to the water by means of different ingredients; this Mr. Reaumur carefully tried, and the reſult was, that he found common cold water the beſt, and moſt uſeful of all liquors: it is true, that vinegar and verjuice harden the *ſteel* ſomewhat more, and aqua fortis greatly ſo, but the latter of theſe renders it too hard for ſervice; and repeated trials have evinced, that common water alone will give *ſteel* all the hardneſs it can be wiſhed to have, provided only that it be plunged into it at a time when it is ſufficiently hot.

If *ſteel*, after the tempering, be found too hard, there is a very familiar way of bringing it back to what ſtate one pleaſes, between that and iron, which is only the heating it in the fire; for it may be kept in the fire ſo long, as to be reduced wholly to iron again. It is eaſy to infer from hence, what was before obſerved, that caſt iron is *ſteel* of a peculiar kind; its properties plainly evince, that it is *ſteel* with an over proportion of all that makes it ſo, and conſequently of all its properties. It is not malleable, is very brittle, and too hard for the file, or any other tool, to cut. Theſe are the qualities of *ſteel* which is over tempered, or, as it may be called, too much *ſteel*: it owes theſe qualities to its being overcharged with thoſe ſulphurs and ſalts, which in a due proportion makes *ſteel* of iron. The method of reducing this to the ſtate of wrought iron, is the ſame with what we have before obſerved is to be uſed to untemper too high tempered *ſteel*, that is, keeping it in the fire till part of its ſalts and ſulphurs are driven off; and if the fire alone be thought too difficult, or too tedious a method, Mr. Reaumur has found that thoſe alkaline ſubſtances, which naturally abſorb ſulphurs, will aſſiſt the reducing this to the ſtate of wrought iron, as they do to the untempering of *ſteel*, and that the very ſame ſubſtances of this kind, which have been found beſt in the untempering *ſteel*, ſucceed beſt in the rendering this malleable; ſuch are lime, chalk, and the like.

Caſt iron may be taken for theſe operations in two ſtates; the one, that of ſimply melted iron in its firſt fuſion, the other that of the iron, which has been run into the mould. When a caſt piece of iron, in a certain form, is heated again with the calx of animal bones, which is one common way, this being a ſubſtance extremely diveſted of ſalts and ſulphurs, it abſorbs thoſe of the metal too greedily, and diveſts it of too great a quantity of them; ſo that when the piece comes afterwards to be filed, the fragments fly off in large ſcales, and the beauty of the caſt figure muſt be loſt: to remedy this difficulty, ſome powdered ſulphur is to be added in the heating; for this being a ſulphureous and ſaline body, checks and moderates the effects of the calx of bone.

Chalk in the ſame manner can only be employed with certain regulations; it ſucceeds very well, if the fire be not too violent, or too long continued, but if it be exceſſive in either of theſe particulars, the chalk throws into the body of the iron ſalts and ſulphurs of its own, which lay hid in its ſtructure, and which would not have been diſlodged by a ſmaller fire; but which being diſlodged, and thrown into the iron, act upon it, and render the ſucceſs of the operation quite different from what was intended, the iron becoming more hard and more brittle by it.

One great nicety in all theſe operations, is the underſtanding the ſigns by which it is known at what time caſt iron is ſufficiently ſoftened, or over tempered *ſteel* is ſufficiently reduced toward the ſtate of iron again; but this is only to be acquired by nice obſervation, and on this depends the whole certainty of the proceſſes, ſince every minute's continuance in the fire gives the operation a different turn in degree.

Mr. Reaumur, in one of his experiments in the ſoftening a piece of caſt iron of a beautiful figure, found, on taking it out, that it had loſt prodigiouſly of its weight, and coming to a nicer examination, he found that it was hollow; its outer cruſt having been ſooner converted into malleable, that is unfuſible, iron than the reſt, and the violence of the fire afterwards having melted away the inner part, which was not yet ſo changed. This accident led him to experiments, by which he found that he could, at any time, melt out

the central part of a thick ſquare bar of caſt iron, the outer part changing firſt into the condition of malleable iron, and ſerving as a crucible for the fuſion of the yet unaltered fuſible iron within. By a proper management of this diſcovery, it will be eaſy to take off the unwieldy weight of many works of caſt iron, which do not require ſo much ſtrength as that of the ſolid contained in their circumference. Mem. Acad. Scienc. Par. 1722.

Mr. Cramer obſerves, that the method of making *ſteel* out of iron, is either by fuſion, or by cementation. That by cementation may be performed in the following manner: chooſe ſome bars of pure iron, not too thick, prepare a cement of charcoal-duſt, moderately pulverized, one part, and wood-aſhes half a part; or of charcoal-duſt two parts, bones, horns, leather, or hair of animals, burnt to a blackneſs in a cloſe veſſel, and in a gentle fire, and afterwards reduced to powder, one part, wood-aſhes half a part; mix them together. Prepare a cylindrical earthen veſſel, two or three inches higher than the bars are long; put into the bottom of this veſſel the cement, prepared as before directed, ſo that being gently preſſed down, it may cover the bottom of the veſſel an inch and half deep; place then the iron bars perpendicularly, ſo that they may be every where an inch diſtant from the ſides of the veſſel, and from each other; fill the interſtices with the cement, and cover the bars with it, that the veſſel may be quite full, cover it with a tile, and ſtop the joints with a lute; put this veſſel into a furnace, and keep it moderately, but equally red-hot, for ſix or ten hours. When this is over, take the red-hot bars out, and dip them in cold water, they will then be brittle, and turned to *ſteel*. *Cramer*'s Art of Aſſaying, p. 344.

The method of making *ſteel* by fuſion is this: take of iron ore, or of unmalleable iron of the firſt fuſion, divide it into ſmall parcels, and put them into a bed made of charcoal-duſt in a ſmith's forge; let the quantity of the iron be but ſmall for the experiment; put to it, as a defenſitive menſtruum, ſome of the vitreſcent ſcoriæ of ſand, or ſtones of the ſame nature; then put upon them a quantity of charcoal, light this, and admit only a ſmall blaſt of the bellows, that the ſcoriæ and metal may both melt regularly: when this has been ſome time kept in fuſion, take it out, divide it into two parts, which make red-hot, and hammer into long bars; finally, heat them red-hot, and plunge them into cold water, and they will then be found to be *ſteel*, ſo very hard, as not to be filable, and ſo brittle, as to break aſunder when ſtruck with conſiderable force. *Cramer*'s Art of Aſſaying, p. 348.

Mr. Lemery ſhews a ſimple method of reducing *ſteel* to a very fine powder, without ruſting it: pour water on filings of *ſteel* in an earthen veſſel, till it is four inches above the filings; ſtir it well every day, ſupplying more water, as that in the veſſel ſubſides, ſo that the *ſteel* is always covered: continue this operation till the *ſteel* falls into an impalpable black powder, then dry it for uſe. Mem. de l'Acad. des Scienc. 1736.

Mr. Boyle tells us of his having opened the body of *ſteel*, by a highly rectified ſpirit of urine made *per ſe*, and poured upon new filings of the *ſteel*. This being put into a warm place, the menſtruum diſſolved a conſiderable part of the metal. See his Works Abr. Vol. I. p. 77.

Annealing, or *nealing of* STEEL, is by ſome uſed for the ſoftening it, in order to make it work eaſier; which is uſually done by giving it a blood-red heat in the fire, and then taking it out, and letting it cool of itſelf. *Mox*. Mechan. Exerc. p. 60.

Some have pretended to ſecrets in annealing, by which they could bring down iron or *ſteel* to the temper of lead: this was to be done by often heating the metal in melting lead, and letting it cool again out of the lead. But this method is found by Moxon to have no other effect than what is had from the former. *Hought*. Collect. N° 276.

Steel may indeed be made a little ſofter than in the common way, by covering it with coarſe powder of cow-horn, or hoofs; thus incloſing it in a loam, heating the whole in a wood fire till it be red-hot, and then leaving the fire to go out of itſelf, and then the *ſteel* to cool. *Mox*. loc. cit.

STEEL *glaſſes*, a name given by ſome authors to the metalline ſpheres uſed in optics. Theſe, according to Cardan, are made of three parts of braſs, one part of tin, and one of ſilver, with an eighteenth part of antimony; but moſt either totally leave out the ſilver, or add only a twenty-fourth part, to ſave the expence. There are many other methods, directed by ſeveral authors, but moſt uſe arſenic and tartar, mixed with the metals. Theſe are afterwards to be poliſhed with emery, rotten-ſtone, putty, and the like. *Merret*'s Notes on Neri, p. 342.

STEEL-*ore*, is uſed to ſignify a particular kind of lead-ore. See LEAD-*ore*.

STEEL-*waters*. See the article *Mineral* WATERS.

STEELING, in cutlery, the laying on a piece of *ſteel* upon a larger maſs of iron, to make that part which is to receive the edge harder than the reſt. The body of an ax may very well be of iron, as it never comes into uſe to cut with, and perhaps is ſtronger, and leſs liable to break, than if of *ſteel*; but it muſt have a quantity of *ſteel* at that part where the edge is to be made.

STEELYARD (*Cycl.*)—*Chineſe* STEELYARD. The people of China carry this ſtatera about them to weigh their gems, and other things of value. The beam, or *yard*, is made of wood, and is round, and a quarter of an inch over, and about a foot in length; upon this are three rules of meaſure, made of a fine ſilver-ſtudded work, as in a watch-caſe. One of theſe rules is divided into inches, and every inch into 25 parts; the other two are divided alſo into equal parts, but not into inches. They all begin from the end of the beam, whence the firſt is extended 8 inches, the ſecond 6 and $\frac{1}{2}$, the third 8 and $\frac{1}{2}$. The firſt is the European meaſure, the other two ſeem to be China meaſure, and that of ſome other nation trading with them. At the other end of the *yard* hangs a round ſcale, marked with China characters, and at three ſeveral diſtances from this end are faſtened ſo many ſlender ſtrings; the firſt diſtance makes $\frac{3}{5}$ of an inch, the ſecond is double to the firſt, and the third 4 inches and $\frac{4}{5}$. When they weigh any thing, they hold up the *yard* by ſome of theſe ſtrings, and hang a ſealed weight, of about an ounce and $\frac{1}{4}$ troy weight, upon ſome point of the rule, as the thing requires. *Grew*'s Muſeum, p. 369.

STEELYARD-*ſwing*. In the Philoſophical Tranſactions we have an account of a *ſteelyard-ſwing*, propoſed as a mechanical method for aſſiſting children labouring under deformities, owing to the contraction of the muſcles on one ſide of the body. The crooked perſon is ſuſpended with cords under his arm, and theſe are placed at equal diſtances from the center of the beam. It is ſuppoſed that the gravity of the body will affect the contracted ſide, ſo as to put the muſcles upon the ſtretch; and hence by degrees the defect may be remedied. See N° 462. ſect. 7.

STEEVE, aboard a ſhip. The ſeamen ſay that the bow-ſprit, or the beak-head of a ſhip *ſteeves*, when it ſtands too upright, and not ſtrait enough forwards.

STEEVING, in merchant ſhips, is uſed for the ſtowing of cotton, or wool, by means of ſcrews, to force it cloſe together.

STEINBIZA, in ichthyology, a name given by Hildegard, and ſome other writers, to that ſmall ſpecies of cobitis, called by others *cobitis aculeatus*, and *tænia cornuta*. It is the *cobitis* with a forked ſpine under each eye, deſcribed by Artedi. *Hildegard*, lib. 4. p. 1. See COBITIS.

STEINHUN, *ſtone-hen*, a name given by the Germans to a bird of the lagopus kind, more commonly known by the name of *otomo*, and in ſome places by that of *colmeſtre*.

It ſeems not to differ from the lagopus in any thing but colour, and that bird being known to change its colour in the ſummer months, it is probably no other *ſpecies*. *Ray*'s Ornitholog. p. 127. See the articles LAGOPUS and OTOMO.

STELE, Στηλη, in antiquity, a kind of puniſhment, being a pillar whereon a criminal was expoſed, and on which was engraven an account of his crime.

The perſons, thus expoſed to the laughter and reproaches of the people, were called *ſtelitæ*. *Potter*, Archæol. Græc. lib. 1. cap. 25. Tom. I. p. 130.

STELECHEIA, a word uſed by ſome authors to expreſs the vena portæ.

STELECHITES, in the materia medica, a name given by Dioſcorides, and ſome other of the Greek writers, to a peculiarly fine kind of ſtorax. It was the ſame with the calamite, only that this name was given to the larger, and the name *calamite* to the ſmaller or ſlenderer pieces. Pliny, Strabo, and many others, join in telling us, that the wood of the ſtorax-tree was the moſt ſubject to be eaten by worms, of that of any tree in the world.

The ſoftneſs, and ſweet taſte it had, probably rendered it liable to theſe injuries. When the worms attacked a branch, they generally eat away all the wood, and left an empty caſe of the bark, ſo that inſtead of a ſtick, there was a hollow tube like a reed: all the while that the worms were eating, the wounded veſſels poured out their balſam, and covered at length the whole ſurface with their fine pellucid yellowiſh balſam. This was doing without, while the vermin were at work within, and in conſequence, the whole ſtick, or twig, became a hollow tube, covered over with the moſt pure and fine ſtorax. This was eſteemed beyond any other ſtorax for medicinal uſes; and when in ſmall twigs, it was called *calamites*, or *calamita*, and when on larger ſticks, it was called *ſtelechites ſtorax*. When the worms attacked the body of the tree, the duſt they made by their eroſion formed a hillock or heap round the tree, or at its foot, and the extravaſated balſam running among this duſt, made a maſs that was called the *cymatius ſtorax* at that time, and was the ſame with the common ſtorax now in uſe.

STELECHITES *ſtibii facie*, in natural hiſtory, a very uncouth name given by Aldrovandus, and ſome others, to the entrochi. He gave them this name from the reſemblance of ſome of the longeſt pieces to fragments of the trunks of trees, the arms parting out from the ſides of theſe main branches, the rudiments of which are very frequent in many of

of the entrochi, paſſing for the remains of boughs, and the hollow in the middle, for the cavity where the pith of the tree was. The addition of *ſtibii facie*, was only from the obſerving that the top and bottom were radiated, or ſtriated, from the central hole to the circumference, in the manner of antimony. Theſe are truly no vegetable remains, but parts of the arms of that ſtrange fiſh called *ſtella arboreſcens*.

They are all fragments, or ſhort pieces, broken from larger; the longeſt pieces we meet with ſeldom exceed two inches in length, and we find from theſe down to ſingle joints, as thin as a ſixpence: theſe ſingle joints are diſtinguiſhed by authors from the compound bodies, or entrochi, by the name *trochitæ*. The largeſt that we find meaſure two inches in circumference, but we have from this ſize to the thickneſs of the fineſt pin; about a quarter of an inch in diameter is, however, the moſt frequent ſize. The longeſt pieces conſiſt of from twenty to thirty joints, and are very various in their thickneſs. Theſe bodies are found ſometimes in clay, and ſometimes in marble. The Derbyſhire marble, of late come ſo much into eſteem, owes all its beauty to the great quantity of them it contains; and they in ſome places make up all the ſubſtance of the maſſes of rock, only with a very ſlender portion of ſtone to join them.

They are uſually found thrown in irregular directions, and often ſhew that they have ſuffered injuries by accident. In ſome the joints they are compoſed of are diſlocated, and thruſt out of their place; in others the whole ſubſtance is cruſhed flat, as if a hollow cane were trod upon, and ſqueezed to flatneſs; and in this caſe, the cracks occaſioned by the injury are always manifeſt. Theſe injuries muſt have happened to the entrochi, while their matter was yet ſoft; for at this time they are ſo brittle, that the force employed to diſlocate, or cruſh them, would only ſhatter them to pieces, not take that regular effect. In ſome the whole ſeries of joints are diſlocated, and the entrochus reſembles a pile of crown pieces placed on a table, and then puſhed aſide, ſo as not to break the pile, but force all the ſeveral crowns, or joints of it, to hang over one way. Some of them are found twiſted like a cord, and ſome have the taints evenly arranged, but ſtuffed full of extraneous matter, as bricks are laid in mortar. The joints of the entrochi vary in thickneſs, from the thickneſs of a ſixpence to a quarter of an inch; but this is not proportioned by their ſize, for there are ſome of them as ſmall as pins, which yet conſiſt of very thick joints.

The outermoſt joint is in ſome more deeply, and in others more ſlightly furrowed; and the outer circle of the points, though generally ſmooth, is ſometimes radiated. The rudiments of branches from the entrochi are ſmall knobs, evidently broken off: they are always placed in the middle of a thick joint, between future and future, and ſometimes are ſingle; but ſometimes there is a whole circle of them round the body of the entrochus in that joint; and ſometimes, beſide a regular circle of knots, there are other ſmaller eminences, like warts, which ſtand irregularly above and below them, and give the whole a very irregular figure. Sometimes the entrochi with thinner joints are found thus knotted, and theſe ſeem to have been all over covered with joints of ſmaller branches; and in the living ſtate of the animal, when they were perfect, muſt have made a very remarkable figure. Some joints have three regular rows of knots on them, each perfectly encompaſſing the entrochus; the middle row, or circle, conſiſts of large knots, and the upper and lower one of ſmall ones. Some of the joints, inſtead of having a circle of knots, riſe up regularly into a circular ſharp ridge between future and future; and in ſome of thoſe which have no rudiment of a knot on any part, the joints all riſe thus regularly into ſharp ridges in the middle, but that alternately, and in a very beautiful order; the one joint having a high and large ridge, and the other a ſmall and low one all the way. In others there is the ſame ſort of difference in the joints alternately, but the one ridge is blunt, and the other ſharp, and edged all the way: in theſe the joints alſo are alternately larger and ſmaller, one than another. In ſome the alternate edges are knotted, and in ſome there is a double edge in the middle of every joint: theſe have the appearance of being compoſed of a very great number of extremely thin joints, but this is not in reality the caſe. Some of theſe laſt have the double edge in the center of the joint knotted at intervals, and have the appearance of ſerrate edges.

Moſt of the entrochi have had branches, in greater or ſmaller number, iſſuing from them; in all they are inſerted deep into the ſtem, and often, when they have been diſplaced, leave deep holes in it. The ſtriature of the branches runs tranſverſely to the ſtriature of the main ſtem: theſe branches are of various thickneſſes, and ſometimes very thin ones grow upon very thick ſtems; but the more general rule is, that the thicker the ſtem, the thicker are the branches from it. Some of the branches from the largeſt ſtems are found to be branched again, but this is very rare. The pieces of entrochus which we find, however large, are uſually of a cylindric figure, as thick at one end as at the other; but there are ſome few found which ſwell out in the middle, and grow gradually taper to each end. Theſe Agricola has deſcribed, and eſteems them a diſtinct kind; but theſe never terminate regularly, in the manner of perfect bodies, at the ends, but are all fragments as the others are. Phil. Tranſ. N° 100.

STELENCHIS, a ſtrigil, or an inſtrument uſed in the baths to rub off the ſweat from the ſkin.

STELITÆ, Στηλῖται, in antiquity, perſons who had undergone the puniſhment called *ſtele*. See STELE.

STELLA (*Cycl.*)—STELLA *crinita*, in natural hiſtory, a name given by Linkius to a genus of *ſtar-fiſh*, the characters of which are theſe; that they have more than five rays, and from theſe have ſeveral other lateral proceſſes, which are covered with a fine down or hair.

STELLA *lapis*, in the materia medica, the name of a ſtone which has been very differently interpreted by different writers. Some have ſuppoſed it the *aſteria* of Pliny, and ſome the common *corolloide aſtroites*; but Meſue explains it to be the *lapis lazuli*.

This ſtone, and the ſapphire, being both blue gems, have been very ſubject to be confounded together; and the ſapphire of the antients was indeed no other than a kind of lapis lazuli; but this author has always diſtinguiſhed between the modern ſapphire and the lapis lazuli, by calling the latter *ſtella lapis*, and the former *zemphyrus*. This word has been by ſome written *zephyrus*, and its meaning much doubted of, but it is plainly the name of the ſapphire; and this word is only formed on the Arabian name of the ſame gem, which is *ſemphir*. See the articles ZEMPHYRUS and SEMPHIR.

STELLA *lumbricalis*, in natural hiſtory, a name given by Linkius, and others, to a kind of *ſtar-fiſh* with an undivided body, and with five vermiform rays.

STELLA *marina*, in natural hiſtory, a genus of animals, the characters of which are theſe. It is a ſoft animal divided into many parts, or compoſed of many ſegments, or lobes, running out from a central part, and reſembling the radii of a circle, or the rays of a *ſtar*, as it is vulgarly painted. The central part is the body, and has always a mouth in its lower ſide; and the rays, commonly called *arms*, and by ſome very improperly *legs*, all ſtand at equal diſtances from one another. The upper part of the central nucleus of this animal is called the back, and the lower the belly, but in both theſe the ſtructure is very different in the ſeveral diſtinct ſpecies of the creature.

The ſkeleton of the *ſtar-fiſh* examined, ſhews the body to be made up of joints, very different in number and figure; and in ſome, this articulated ſubſtance is made up of very ſmall, and in others of very large pieces; in ſome alſo it is covered with a very thick ſkin, and in others with a very thin one; this however, in the firmeſt ſtate, never approaches to a ſhelly hardneſs, and is rather callous than teſtaceous, or cruſtaceous, as ſome have called it. The parts, of which all theſe fiſh are invariably compoſed, are the trunk or body, and the lobes: theſe are of no determinate figure, nor have any thing certain, but that there is a mouth, or aperture, for the taking of food, in ſome part of the under plane of the trunk; and the only apparent ſenſation the animal has, is that of touch or feeling. The common poſition of the mouth is in the center of the body, and the conformation of it is this: the under part of each lobe runs toward a point with the reſt at the center of the body, and theſe ſeveral productions of the lobes make a ſort of lips, the ends of each of which are armed with a number of ſharp teeth, which ſerve to take and convey the food into the body. From this mouth there goes a ſeparate canal to all, or many of the lobes, which runs through their whole length, and becomes gradually narrower, as it approaches the extremity: theſe things are conſtant in all the ſpecies, all their other properties differ in the different ones.

Some genera of the *ſtellæ marinæ* have their body multifid, and have juſt as many canals in their belly as there are lobes or arms, one conſtantly and regularly running to each; while others have ſeveral cylindric rays or lobes, which are not perforated with any canal: hence the general number of them are divided into the whole, and the multifid kinds. In the multifid kinds the lobes, or rays, are uſually five in number, though ſometimes they are more, ſometimes fewer: hence authors have eſtabliſhed a triple diſtinction of theſe creatures. 1. Thoſe which have juſt five rays. 2. Thoſe which have more than five. And 3. thoſe which have a ſmaller number than that. The whole bodied ones are alſo arranged into their ſeveral genera in the ſame manner.

The moſt frequent kind of *ſtar-fiſh* is that which has five rays, which iſſue in the manner of ſo many vermiform, or worm-like proceſſes: theſe therefore are called *ſtellæ vermiformes*, or the worm-like *ſtar-fiſh*. Another kind, nearly approaching to the nature of theſe, has more than five rays, and from the ſides of theſe other tranſverſe proceſſes being produced, which are covered with an extremely fine kind of down, or hairyneſs: theſe are called the *hairy ſtar-fiſh*. A third kind is called the *aſtrophyta*, or plant-like *ſtar-fiſh*: this is compoſed of a body from whence there ariſe a great

number

number of branches, which divaricating more and more, are at length encreaſed, or divided into a prodigious number; and theſe being cylindric in figure, reſemble very much the branches of plants.

This general diſtinction being eſtabliſhed, the general and particular arrangements are naturally deduced from the ſubordinate diſtinctions: from the moſt remarkable differences in each ſeries of *ſtellæ* of every claſs are conſtituted the genera; from the leſs remarkable difference among each genus, the ſubordinate diſtinctions, and from the minuter diſtinctions among theſe, the ſpecies are diſtinctly ſeparated from one another. The accurate Linkius has hence eſtabliſhed a very regular method of theſe animals, calling them by names expreſſive of their differences, as *oligactis*, for ſuch of the firſt general diviſion as have leſs than five lobes, or rays, and the like. Several of the ſpecies of the *ſtar-fiſh* are eatable, and ſome of them afford a very good nouriſhment. Some are preſcribed by phyſicians as ingredients in plaiſters.

The foſſile world has been greatly enriched by the fragments and remains of the ſeveral kinds of *ſtar-fiſh* which have been converted into ſtone, and have been variouſly gueſſed at in that ſtate, as to their origin. The aſteriæ are by many affirmed to be the foſſile radii of the *ſtar-fiſh* of the decempede, or ten-rayed kind; and others have thought it evident, that ſome ſpecies of them have been the remains of the common coriaceous kinds. The encrinos, or *lilium lapideum*, ſeems to be a part of one of the ten-rayed kinds; and the trochitæ, and entrochi, are plainly owing to the fragments of ſeveral of theſe kinds. *Linkius*, de Stellis Marin.

STELLA *arboreſcens*. See ARBORESCENT and BASKET-*fiſh*.

STELLA *occidens*, a word uſed by ſome of the chemical writers to expreſs ſal armoniac.

STELLA *ſcolopendroides*, in natural hiſtory, a name given by Linkius to a kind of *ſtar-fiſh* with an undivided body, and five rays, reſembling the bodies of the ſcolopendræ, as thoſe of the more uſual kind, called *ſtella lumbricalis*, do the bodies of common earth-worms. See the article STELLA *marina*, ſupra.

STELLA *vermiformis*, in natural hiſtory, a name given by Linkius, and other authors, to a common kind of *ſtar-fiſh*, which has five rays parting from the body, each ſomewhat reſembling the body of a large worm. See the article STELLA *marina*, ſupra.

STELLARIA, in botany, a name uſed by ſome authors for the *carduus ſtellatus*, or *ſtar*-thiſtle. *Ger.* Emac. Ind. 2.

STELLARIS *lapis*, a name given by many authors to the various ſpecies of *aſtroites*. See the articles ASTROITES and STAR-*ſtone*.

The near alliance between this name and the *aſteria*, though they are the names of two foſſils of an extremely different kind, has been the occaſion of great errors. Authors, not converſant in foſſils, have too haſtily attributed to one of them the properties of the other.

Cambden tells us, that about Bevor-Caſtle there are found *aſtroitæ*, which he very well deſcribes, as conſiſting of the repreſentation of ſeveral *ſtars* fixed together by a flinty, or other extraneous matter.

STELLATE *leaf*, among botaniſts. See LEAF.

STELLIO, in zoology, the name by which authors call the ſwift, or ſpotted lizard. The ſpots which diſtinguiſh this kind are not, however, ſtellated, as might be ſuppoſed from the name, but round; ſome ſmall, and ſcattered irregularly all over the body; and others larger, and diſpoſed in thirteen zones, or ſemicircles. The ſpots are much more diſtinct and clear on the back than on the belly. It is common in Syria, and ſome other places.

STELLIO *aduſta*, an affected term uſed by ſome chemical writers for cinnabar.

STELLITES, in natural hiſtory, a name given by ſome writers on foſſils to a kind of white ſtone found on Mount Libanus, and in ſome other parts of Syria, containing the lineaments of the ſtar-fiſh compleat.

The ſame ſtones frequently contain the lineaments of other fiſhes, principally of the bones, or ſkeletons of them; and it is very certain, that the real bodies of theſe ſtar-fiſhes, and the bones of other fiſh, after the fleſh and ſkin had been corrupted and worn off, have been received into this ſtone while yet ſoft, and afterwards retained in it after its concretion: our own coal-ſlates ſhew us innumerable inſtances of leaves of plants; and the black ſlate of iſleb ſhews us, fiſhes thus preſerved.

STEM (*Cycl.*)—*Falſe* STEM, in a ſhip, that fixed before the right one. When a ſhip's *ſtem* is too flat, ſo that ſhe cannot keep a wind well, they uſe to put a *falſe ſtem* above, which makes her rid more way, and bear a better ſail.

STEMPHYLA, a word uſed by the antients to expreſs the huſks of grapes, or the remains of the preſſings of wine. The ſame word is alſo uſed by ſome to expreſs the remaining maſs of the olives, after the oil is preſſed out.

STEMPHYLITES, a name given by the antients to a ſort of wine preſſed hard from the huſks.

STEMPLES, in mining, croſs bars of wood in the ſhafts which are ſunk to mines.

In many places the way is to ſink a perpendicular hole, or ſhaft, the ſides of which they ſtrengthen from top to bottom with wood-work, to prevent the earth from falling in: the tranſverſe pieces of wood, uſed to this purpoſe, they call *ſtemples*, and by means of theſe the miners in ſome places deſcend, without uſing any rope, catching hold of theſe with their hands and feet. *Ray*'s Engl. Words, p. 118.

STENO's *duct*, a name given from its diſcoverer to the ſuperior ſalival duct. See SALIVAL, *Cycl.*

Several anatomiſts, particularly Heiſter and Palfyn, have diſputed whether *Steno's duct* is pervious in recent ſubjects, as well as in the ſkeleton. Dr. Kulm affirms, he has demonſtrated it to ſeveral to be pervious in deer, bears, wild goats, hares, calves, and in the human ſubjects; and mentions the manner of tracing it. See Med. Eſſ. Edinb. Abridg. Vol. 2. p. 421.

STENOMARGA, in natural hiſtory, a name uſed by ſome authors for a light marly earth, more uſually called *agaricus mineralis*, and *lac lunæ* by the later writers, and *terra*, or *creta Seleneuſiaca*, by Dioſcorides and Galen. *Agricola*, de re Metal. p. 378.

STENTATO, in the Italian muſic, is uſed to ſignify that the voice ſhould be forced in ſome part of a ſong, or on ſome particular ſound, to expreſs an extraordinary emotion.

STEP (*Cycl.*)—STEP, in a ſhip, that piece of timber whereon the maſts or capſtans do ſtand at bottom, is called the *ſtep* of the maſt or capſtan.

STEPHANITÆ, Στεφανῖται, in antiquity, an epithet given to games and exerciſes, where the prize was only a garland. *Potter*, Archælog. Græc. Tom. I. p. 451.

STEPHANOPHORUS, Στεφανοφόρος, in antiquity, the chief prieſt of Pallas, who preſided over the reſt. It was uſual for every God to have a chief prieſt; that of Pallas was the *ſtephanophorus*, juſt mentioned, and that of Hercules was called *dadouchus*. *Potter*, Archæol. Græc. Tom. I. p. 206. See DADOUCHUS.

STEPHANOPHORUS was alſo a prieſt that aſſiſted the women in the celebration of the feſtival Theſmophoria. Id. Tom. I. p. 403. See THESMOPHORIA.

STEPHENS's *medicine for the ſtone* (*Cycl.*)—Mrs. *Stephens* having ſold medicines for the ſtone in the bladder or kidneys, Dr. Hartley publiſhed ſeveral caſes of their ſucceſs; and ſo much was ſaid of them, that the parliament appointed truſtees to examine into the truth of what was alledged in their favour. The report of theſe truſtees being favourable, ſhe had five thouſand pounds ſterling ordered her for publiſhing the receipt. Dr. Hartley leaving out the ſuperfluous part of Mrs. *Stephens*'s preſcription, reduces her receipt to a more ſimple form; to wit, to two ounces and an half of ſoap, and ſeven ſcruples and an half of egg-ſhell powder, as the mean doſe of the medicines to be taken. Dr. Hales, after ſeveral trials on the different ingredients, found that the diſſolving power of them lay in the lime, which Dr. Rutty confirmed; and Dr. Jurin having taken ſoap-lees, the ingredients of which are pot-aſhes and lime, beginning with a few drops, and increaſing the quantity till he took an ounce, or an ounce and an half every day, in a proper vehicle, was cured of bloody urine, pain, &c. and paſſed ſeveral ſmall ſtones; after which he had no uneaſineſs.

STERA, in anatomy, a word uſed by ſome of the barbarous writers to expreſs the uterus. It ſeems to have been only a corruption of the word *hyſtera*.

STERCORARIUS *piſcis*, the *dung-fiſh*, the name of an Eaſt-Indian fiſh; ſo called, from its frequenting neceſſary-houſes which are over the water, and other places, where the like naſtineſs is to be found. It is for this reaſon ſuppoſed unwholeſome by ſome, but is really a very well-taſted fiſh, and eaten by moſt people where it is to be had. It is a broad and thin fiſh, of about ſix or ſeven inches long, and nearly as much in breadth. Its back is variegated with ſpots of deep brown; its belly is bluiſh. *Ray*'s Ichthyogr. Append. p. 2.

STERCUMEZEFF, an affected word uſed by ſome of the chemical writers for litharge.

STEREO-*ſtatics*, is uſed by ſome for the *ſtatics*, or ſcience of the equilibrium of ſolid bodies. *Curtel.* Math. Univ. p. 79.

STERN (*Cycl.*)—STERN-*faſt*, aboard a ſhip, ſome faſtenings of ropes, &c. behind the *ſtern* of a ſhip, to which a cable or hawſer may be brought, or fixed, in order to hold her *ſtern* to a wharf, &c.

STERN-*poſts*, in a ſhip, a great timber let into the keel at the *ſtern* of a ſhip, ſomewhat ſloping, into which are faſtened the after-planks; and on this poſt, by its pintle and gudgeons, hangs the rudder.

STERNA, in zoology, a name by which Turner, and ſome others, have called a bird, known among authors by the name of the *hirundo marina*, or ſea-ſwallow.

It is of the ſmaller kind of *lari*, or gulls, and has a forked tail. It is called the *ſea-ſwallow*, from its having very long wings, very ſhort legs, and a forked tail, and its being almoſt always on the wing. Its uſual weight is about five ounces. Its body is of a long and ſlender ſhape, the upper part of its head is black, but it has a white line ſurrounding it; the belly, and under part of the wings, are white, the

breaſt a little greyiſh; the rump is alſo white, but the back and wings of a blackiſh grey; its beak is ſomewhat long and ſtrait, and its legs are red. It is very common on our weſtern coaſts. It feeds on fiſh, and flies uſually in large flocks. *Ray*'s Ornitholog. p. 269.

STERNOCOSTALES, commonly called the *muſculi triangulares ſterni*, are five pairs of fleſhy planes, diſpoſed more or leſs obliquely on each ſide the ſternum, on the inſides of the cartilages of the ſecond, third, fourth, fifth, and ſixth true ribs. They are inſerted by one extremity in the edges of the inſide of all the lower half of the ſternum; from thence the firſt muſcle on each ſide runs up obliquely, and is fixed in the cartilage of the ſecond rib. The ſecond runs leſs obliquely to its inſertion in the cartilage of the third rib; and the reſt are inſerted, in the ſame manner, in the cartilages of the following ribs; their obliquity decreaſing, and their length encreaſing, in proportion as they are ſituated lower down, ſo that the loweſt of all is almoſt tranſverſe. This laſt muſcle, which is fixed by one extremity in the cartilage of the ſixth true rib near the bone, ſeems to paſs the appendix enſiformis, immediately above the inſertion of the diaphragm in that appendix, and to join the muſcle on the other ſide. *Winſlow*'s Anatomy, p. 233.

The *ſternocoſtalis* was called by ſome of the older anatomiſts *ſextus thoracis*; and by Riolanus, and ſome others of the later writers, *pectoralis internus*.

STERNODACTYLÆUS, in anatomy, a name given by Riolanus, and ſome others, to a muſcle of the foot, called by Albinus the *flexor brevis digitorum pedis*, and by others the *ſublimis flexor*, or *perforatus pedis*.

STERNOHYOIDÆUS, a long, thin, flat muſcle, called by ſome *ſterno-cleido-hyoidæus*.

It is broader at the lower than at the upper part, and is ſituated, together with its fellow, on the foreſide of the throat; from whence ſome have very improperly named it *muſculus bronchialis*. It is fixed by its lower extremity in the ſuperior and lateral part of the inner, or poſterior ſide of the ſternum, in the poſterior part of the ſternal extremity of the clavicula, in the tranſverſe ligament which connects thoſe two bones, and in the inner, or backſide of the cartilage of the firſt rib. All theſe other inſertions are more conſiderable than that in the ſternum, which is ſometimes ſcarce perceivable. From hence it runs up to the foreſide of the aſpera arteria, joined to its fellow by a membrane which forms a ſort of linea alba, and is inſerted laterally in the lower edge of the baſis of the os hyoides. There is ſometimes a tranſverſe tendinous line about the middle of the backſide of this muſcle. *Winſlow*'s Anatomy, p. 256.

STERNOMANTIS, Στερνομαντις, in antiquity, a deſignation given to the delphian prieſteſs, more uſually called *pythia*. *Potter*, Archæol. Græc. Tom. I. p. 278. See the article PYTHIA, *Cycl.*

STERNOMANTIS is alſo uſed for any one that had a propheſying demon within him. *Potter*, Archæol. Græc. Tom. I. p. 300, ſeq.

STERNOMASTOIDÆUS, a muſcle, called alſo ſimply *maſtoideus*, and *maſtoidæus anterior*, or *externus*. It is long and narrow, pretty thick, and moſtly fleſhy, and is ſituated obliquely between the back part of the ear, and the lower part of the throat. It is in a manner compoſed of two muſcles, united at the upper part through their whole breadth, and ſeparated at the lower. It has two inſertions below both of them, flat, and a little tendinous; the firſt is in the upper edge of the ſternum, near the articulation of the clavicula; and the other in the clavicula, at a ſmall diſtance from the ſternum. Theſe two portions run up obliquely, and unite together at about an inch above their lower inſertions, the triangular ſpace left between them being filled by a membrane. The ſternal portion riſes foremoſt, and covers the clavicular, both forming one body, or belly, which running in the ſame oblique direction to the apophyſis maſtoidæus, is inſerted in the upper and back part of that proceſs, over which it likewiſe ſends off a very broad aponeuroſis, which covers the ſplenius, and is inſerted in the os occipitis. The two anterior maſtoidæi repreſent a great Roman V, the angle being at the lower part of the throat, and the two crura running up behind the ears. *Winſlow*'s Anatomy, p. 234.

STERNUM (*Cycl.*)—This is a long flat bone, not all of the ſame breadth, but repreſenting a kind of dagger. It is generally made up of three principal pieces; the firſt broad and ſhort, the ſecond longer and narrower, and the third a ſort of ſmall appendix, called by the Greeks *xyphoides*, from its reſemblance to the point of a broad ſword.

The firſt, or uppermoſt piece, is broad and thick at the top, but thinner and narrower below, being nearly of the figure of a triangle with the three angles cut off, or of a very irregular ſquare. The ſecond is much longer than the firſt, and is flat on both ſides, whereas the outſide of the upper is unequally convex, and the inner a little concave. This is broader alſo toward the lower, than toward the upper part, and has ſometimes ſeveral tranſverſe lines, eſpecially on its outſide, which point out the places where the pieces, of which it is made up in children, are joined together. The two lateral edges of this bone have each one cartilaginous half notch, and five cartilaginous whole notches; the half notches are at the upper part of the lateral edges, and the five entire notches come nearer to each other, in proportion as they are lower, and part of the laſt properly belongs to the third piece.

The third piece, commonly called *cartilago enſiformis*, and *xyphoides*, is entirely cartilaginous in infants, and young ſubjects, but in an advanced age it generally oſſifies, either wholly, or in part. This piece is joined to the lower extremity of the ſecond, between the cartilages of the laſt true ribs, and is often more or leſs notched on each ſide, to form part of the articular notches of the *ſternum*. Its figure and ſize vary, and in ſome ſubjects it is forked, and in others perforated. Sometimes alſo it is very large, and at others very ſmall, hardly exceeding in ſome ſubjects the third part of an inch. The inner ſubſtance of the *ſternum* is almoſt all cellulous, and very tender; it is covered with a thin, but compact lamina. The *ſternum* compleats the fore part of the cavity of the thorax, and ſuſtains the anterior extremities of the ribs; being ſufficiently fixed to reſiſt compreſſions, and other outward accidents, and yet moveable enough, by means of its articulation with the cartilages of the ribs, not to obſtruct the motions neceſſary to reſpiration. It ſerves alſo for the inſertion of ſeveral muſcles, and to ſupport the mediaſtinum. *Winſlow*'s Anatomy, p. 67.

We owe to Mr. Hunauld a very judicious account of the perforation which is ſometimes found in the lower part of the *ſternum*.

This perforation is ſometimes larger, ſometimes ſmaller; and a certain German author has found a very ſingular uſe for it, ſuppoſing that it gives paſſage to the mamillary veins and arteries; but Mr. Hunauld, though he had often found the *ſternum* thus perforated, never could obſerve any veſſels paſſing it, but always found it filled up with a cartilaginous ſubſtance. The German author does not poſitively affirm that he ſaw the veſſels paſſing through this perforation, and Mr. Hunauld ſuppoſes it to have been but a conjecture, that this might be its uſe. Its origin and formation, however, may be more rationally accounted for on much ſounder principles.

The *ſternum* is in its firſt ſtate wholly cartilaginous, and the oſſification begins afterwards in ſeveral different parts of it: the number of theſe oſſifying ſpots is wholly uncertain, but as they encreaſe they unite, ſooner or later, into three pieces, and afterwards theſe three pieces unite themſelves, ſo as to form only one. If therefore, when theſe different oſſifications begin to unite, there be ſome place where the oſſification has been impeded, this place, or ſpot, muſt remain only of a cartilaginous ſubſtance, and in making the ſkeleton, this cartilage will be ſeparated from the bones, and will conſequently leave a perforation in the *ſternum*; and what makes this the more probable, is, that this perforation, which is ſo commonly ſeen in ſkeletons, is never found in diſſecting the recent body. It may alſo have happened, that the three pieces of bone, which conſtitute the *ſternum*, by uniting at their edges, may, in acquiring their growth and ſolidity, have naturally left a vacancy between them. We never find a perforation of this kind in the upper part of the *ſternum*, which is probably owing to that part of it being only one piece in the earlier times, and not oſſifying in different places and ſpots at the ſame time; as is always the caſe in regard to this lower part of the *ſternum*, where the perforation is always found. Mem. Acad. Par. 1740.

Cartilages of the STERNUM. The *ſternum* of an adult ſubject has commonly ſixteen cartilages; fourteen of the number are articular, the other two are ſymphyſes. Of the former, two belong to the articulations of the clavicle, and twelve to thoſe of the true ribs, from the ſecond to the ſeventh incluſively; and the two ſymphyſes are both between the *ſternum*, and the firſt rib on each ſide. There is likewiſe another ſymphyſis, by which the upper portion of the *ſternum* is connected to the lower; but the cartilage of this is often obliterated in advanced age. The apophyſis enſiformis is often long toward the *ſternum*, and more or leſs cartilaginous toward the other end. This has, in very aged perſons, been ſometimes found entirely oſſified, and ſometimes wholly cartilaginous even in adults. *Winſlow*'s Anatomy, p. 149.

Ligaments of the STERNUM. The *ſternum* has ſeveral ligaments, by which it is connected to the clavicles and ribs. It is joined to the clavicles by ſtrong ſhort ligaments, fixed by one extremity round the edges of its two ſuperior notches, and by the other in the extremity of each clavicle, and by the middle to the inter-articular cartilages, ſurrounding the particular ligaments which go between the edges of theſe cartilages and the *ſternum*. *Winſlow*'s Anatomy, p. 149.

STERNUM *fractured*. The *ſternum* is equally ſubject to depreſſions and fractures, from falls and blows, with the reſt of the bones. When either of theſe accidents happen to it, the part is not only uneven and painful, but the ſubjacent arteries and veins are alſo contuſed and ruptured; whence ariſe pains in the breaſt, difficulty of breathing, violent coughs, ſpitting of blood, or elſe extravaſations of it in the

præcordia, or between the duplicatures of the mediaſtinum, with many bad ſymptoms of the like nature. The ſigns of a *fractured ſternum* will therefore be very evident by theſe, and by its being moveable to the touch, eſpecially when one part of it grates againſt another, and when there is a cavity and inequality very remarkably viſible there.

In order to reduce a fracture of this bone, the patient muſt be laid on his back on a bed, or hard even place, as a table, putting a hard pillow, a large parcel of cloth rolled up, or ſome other ſuch body, under his back, and preſſing down his ſhoulders, by which means the *fractured ſternum* will be elevated and extended; and to facilitate the reduction, the ſurgeon muſt preſs the bones of the *ſternum* together, and ſhake them very ſtrongly. But when this method is impracticable, or not proper, the ſkin muſt be divided, and the depreſſed part of the *ſternum* lifted up into its place, by means of an elevator, or elſe of a ſcrew gently wormed into the part, and afterwards pulled upwards; and when it has regained its natural ſituation, it muſt be kept in it by the proper bandages. If after the reduction violent pains continue under the *ſternum*, and if blood ſhould gather, and ſuppurate internally, between the duplicature of the mediaſtinum, the lower part of the *ſternum* ought to be trepanned, as the cranium on the like occaſions; and when the putrid matter is diſcharged, and the wound cleanſed, it muſt be healed with vulnerary balſams; and if any blood ſhould be found diſcharged into the cavity of the thorax, the cure muſt entirely depend on the evacuating that by the paracenteſis, in the manner of wounds of the thorax. *Heiſter*, p. 122.

STHENIA, Σθενια, in antiquity, a feſtival of Argos, ſuppoſed to be kept in honour of Minerva, ſurnamed Σθενιας from σθενος, ſtrength. *Potter*, Archæol. Græc. Tom. I. p. 430.

STIÆ, a word uſed by ſome of the old authors for pebbles found on the ſea-ſhore.

STIBIALIA, a term uſed by ſome to expreſs the antimonial medicines.

STIBADIUM, among the Romans, a low kind of table-couch, or bed of a circular form, which ſucceeded to the triclinia, and was of different ſizes, according to the number of gueſts they were deſigned for. They were called *hexaclina*, *octaclina*, or *enneaclina*, according as they held ſix, eight, or nine gueſts, and ſo of any other number.

STIBINUS *color*, a term uſed by St. Jerom, and others, to expreſs the falſe black colour which the antient Jews, and other Eaſtern people, gave to their eye-brows with *ſtibium*, or antimony.

STIBIUM, *antimonium*, antimony. See ANTIMONY, *Cycl.*

This is a mineral never found native in its perfect ſtate, but always intimately mixed with, and penetrated by ſulphur, and other extraneous matter, and by it reduced to the ſtate of an ore. In this condition it is ever found in the earth, and according to the different proportions of ſulphur, or other matter, it contains, it aſſumes very different appearances.

It is moſt commonly found in form of a very hard and heavy lead-coloured ſubſtance, compoſed of a number of extremely ſmall granules, all very bright and ſparkling, and giving it the appearance of a lump of the pureſt ſteel when freſh broken. This is what is commonly underſtood by the name *antimony ore*, and is what is ſold under that title in the German ſhops.

Not unfrequently, however, it appears of a ſomewhat more lax texture, leſs heavy, but much more bright, and compoſed of ſmall, but viſibly broad and flat particles, of a very pale whitiſh lead colour, and glittering appearance, like that of many of the lead ores. This is called *broad-grained antimony ore*.

Sometimes alſo, but leſs frequently, *antimony* appears in form of bright maſſes, made up of multitudes of parallel ſlender filaments, of a bright ſteel colour, and more glittering hue than in either of the former ſtates: theſe filaments are of different breadths and thickneſſes in the ſeveral maſſes. Theſe are generally known by the name of *ſtriated*, or *plumoſe antimony ore*.

Theſe are the moſt natural and ſimple appearances of this foſſil, but beſide theſe it is liable to a multitude of other very different ones, as it ſometimes contains iron mixed among its own matter, and very frequently ſilver; theſe may naturally be ſuppoſed to give it ſome differences in its appearance: but beſide theſe it is ſubject to much greater, from its admixtures with the common marcaſites and pyritæ; theſe often tinge the whole body of the ore to a ſilvery white, or to a golden yellow.

Antimony ores are found in fiſſures and veins at different depths, and often very near the ſurface, and is variouſly accompanied with ſpars, cryſtals, ſulphurs, and other ſubſtances. Sometimes the veins of it are every way ſurrounded by a tolerably pure yellow native ſulphur; ſometimes with a more debaſed matter, made of a mixture of ſulphurs, earth and ſpar, differing according to the different diſpoſition and admixture of theſe bodies.

Antimony is found in great abundance in England and Germany; we have ſeveral mines of it in Cornwall; and Germany, Hungary, and many other parts of the world, afford it in very great abundance.

To reduce it to a ſtate fit for uſe, it is to be ſeparated from its ore by the force of fire, and by the aſſiſtance of ſuch ingredients as break the mutual connection between the ſulphureous and the reguline part, which mutually diſſolving each other, keep the concrete in the ſtate of ore. The addition of iron is able to do this; and that of ſilver, copper, and other metals, has alſo the ſame effect.

There have not been wanting perſons, who have pretended to extract a mere running mercury from *antimony*, and Mr. Boyle believed it might be done: but this is one of the many great things pretended to by chemiſtry, of which we have yet no ſufficient proof.

Antimony, when ſeparated from its ore, is very eaſily fuſible, and runs the thinneſt of all the bodies of this kind. It greatly promotes the fuſion of other foſſils, but it makes every thing brittle that it is mixed with. It is of great uſe in medicine, chemiſtry, and mechanics, and in its ſeveral preparations is diaphoretic, cathartic, and emetic. The chemiſts uſe it greatly in their operations on other metals, and it is an ingredient in pewter, bell-metal, and the mixt metal, of which types are made for printing. *Hill*'s Hiſt. of Foſſ. p. 623.

Mr. Geoffroy has been the inventor of a new method of treating this mineral, by which it yields much more regulus than according to thoſe preſcribed by Kunkel and Stahl, and is purified without the addition of ſalts, and with very little loſs.

It is generally ſuppoſed, that the vapours of *antimony* are poiſonous when raiſed by fire, but it appears otherwiſe from the operations this gentleman made on it; the ſame operator having once gone through ſixty calcinations of twelve ounces of *antimony*, without receiving any harm from it: whence it is very evident, that the common opinion of the fumes of *antimony* containing an arſenical ſulphur is an erroneous one; and it may be added, that one great mark of *antimony*'s being good, is, that it loſes a great deal of its weight in calcination. It has more ſulphur in this caſe, which the fire raiſes in a vapour, and leſs of the terreſtrial matter or ſpar, which are uſually very abundant in it. It has been proved by experiment, that the ſulphur of *antimony* is a neceſſary and eſſential part of its conſtruction, ſince without this it is no longer emetic; but this ſulphur is only neceſſary in a certain proportion; for it is found, that when it is more abundant in the *antimony*, the whole loſes in proportion of its emetic quality; and Mr. Geoffroy has found by repeated experiment, that to give this virtue in its greateſt degree, the *antimony* is firſt to be diveſted of its native ſulphur, much of which is of no uſe as to this intention, and is then to be melted with a gentle fire in a crucible with a quantity of ſoap, made from a ſtrong lixivium of pot-aſhes, quick-lime, and oil, united by boiling into a ſolid maſs.

The *antimony* melted with this, after a ſufficient previous calcination, affords a ſort of glaſſy cruſt of ſcoriæ, which covers a quantity of compact regulus lying at the bottom of the crucible. Theſe ſcoriæ are a ſort of blackiſh glaſs, which melts in the flame of a candle, but does not run on being expoſed to the air. This is plainly compoſed of the burnt oil of the ſoap, united with the acid of ſulphur of *antimony*, and a vitrification made with ſome earthy particles, and the ſalts of the ſoap; this vitrification is what preſerves the fatty matter from being liquified by the air. When theſe ſcoriæ are ſeparated from the reguline matter, if that be again melted, with an addition of an alkali ſalt and of the powder of white cryſtal glaſs, there is produced a purer regulus than can be obtained by any other known method, and in a larger quantity, by two ounces from the pound, than ever Stahl, or Kunkel, were able to procure. Mr. Geoffroy, by theſe nice obſervations and experiments, diſcovered that *antimony* contained much leſs common ſulphur than had been generally ſuppoſed, ſince it can be made to loſe, at the utmoſt, only three ounces and five drachms in the pound in calcination. The emetic quality of the regulus proves, however, that it yet contains a very large ſhare of ſulphur, though of another kind: this Mr. Geoffroy diſtinguiſhes from the common ſulphur, by the name of the *metallic ſulphur*. Mem. Acad. Scienc. Par. 1736.

Acid of ANTIMONY. Mr. Charras was the firſt author who gave the world a ſuccinct method of drawing an acid liquor from *antimony*. He did it thus: he mixed crude *antimony* ore in powder with three times its weight of ſand, this he diſtilled in a large retort into a capacious receiver, filled half full of river water, and on rectifying this, the acid liquor was to be produced. Himſelf acknowledges, however, that this, though a ſuccinct, is not always a certain method, for that ſometimes the acid liquor was produced, and ſometimes not: this, however, he attributes wholly to the management of the fire, which he ſays will always afford the acid, if conducted regularly through its ſeveral degrees. But Mr. Homberg trying this experiment ſeveral times, and finding it ſometimes ſucceed, and at other times not, though the ſame cautions were uſed, diſcovered at length that this va-

riation, in the ſucceſs of the proceſs, was not occaſioned by any difference in the fire, but by the different nature of the matter employed. The crude ore of *antimony* ſometimes being mixed with a white argillaceous earth, and ſometimes free from this admixture; he found, that when it had this white earth in any great proportion, it never failed to yield this acid liquor; and that when it had none of it, it never could be made to yield a drop of acid; and conſequently, that this was not an acid extracted from *antimony*, but merely from the earth, as common pipe-clay, or any of our argillaceous earths, will yield an acid by means of a ſtrong fire.

This liquor had therefore been very improperly called the *vinegar of antimony*; and it is evident, that whatever acid *antimony* contains, muſt be of the nature of ſpirit of ſulphur, ſince ſulphur ſo greatly abounds in the compoſition of that mineral, and its ſulphur is wholly the ſame with the common brimſtone. Whatever acid, therefore, of this kind could be produced, muſt be of the nature of that collected from the fumes of burning ſulphur; and, even though it were produced from *antimony*, could have nothing of the nature of *antimony* in it, ſince it would be wholly the produce of the common ſulphur in that mineral, and not of the reguline part, which alone is properly *antimony*. Experiment alſo proves the truth of this opinion, the *acid of antimony*, truly ſeparated from it, being no way different, in any particular, from that of crude ſulphur.

There are ſeveral ways by which it may be made, but the following ſeems the eaſieſt and moſt familiar. Powder crude *antimony* very fine, lay it in an earthen diſh not glazed, and of a conſiderable width at the top; cover this diſh with an earthen pot, with the bottom taken out, and fit to this three earthen aludels, and cover the mouth of the uppermoſt aludel with a large glaſs bell; the edges of which muſt be ſuſtained about a quarter of an inch above a veſſel of water, kept ſo hot, as to fumigate the inſide of the bell; the water that runs down from the bell, will be received again into the veſſel of water. In the middle of the earthen pot, which covers the diſh of *antimony*, there muſt be a hole, large enough to admit the handle of an iron ladle, or ſome ſuch other inſtrument, to ſtir about the *antimony*. The fire being made under the earthen diſh, and continued a proper time, there will be found the flowers of *antimony* in the aludels, a little acid liquor in the water of the veſſel kept under the bell, and the *antimony* will be found calcined in the diſh.

It is but little acid that can be obtained in this manner, but then it is aſſuredly the pure acid of the ſulphur of *antimony*. Sometimes this method furniſhes alſo little or no acid, but this depends on the care of the operator, and the temperature of the air; for the colder and moiſter the ſeaſon is, the more acid will be obtained, and the hotter and drier it is, the leſs. The operation, whenever ſo perfect, is however of little value, the acid being every way the ſame with that of common ſulphur. Mem. Acad. Par. 1700.

Infuſion of ANTIMONY. Mr. Homberg being well aſſured, that water was a menſtruum capable of diſſolving all the metals, if properly applied, uſed it, in ſeveral different manners, in his analyſis of *antimony*. He made an *infuſion of antimony* in water, putting into ſeveral glaſs veſſels crude *antimony*, coarſely powdered, five pounds into each veſſel, and to each of theſe quantities he added two pints of rain water; after the *antimony* had ſtood thus for ſix months, the ſeveral parcels were uſed on different occaſions, one only excepted, which had been forgotten, and had at length ſtood two winters and a ſummer: having at length found this veſſel, he obſerved that its inſide was every where coated over with configurations of leaves; he at firſt ſuppoſed this to be owing to ſome ſalts of the *antimony*, which had been diſſolved in the water, and had afterwards cryſtallized themſelves in this manner, as the butter of *antimony* is ſometimes known to do in ſublimation; but on rubbing the ſides of the veſſel with a finger, and afterwards ſcraping them with a knife, he found that they were covered with a yellowiſh pellicle, without the leaſt appearance of ſalt, and that the configurations of the leaves were not raiſed upon this pellicle, but ſunk, as if graved by a tool. The water taſted ſomewhat acid, and being tried on turnſol, and on different metallic ſolutions, it turned the turnſol to a light red, and turned a ſolution of ſilver white; whence it appeared to be an acid, and of the nature of that of ſea-ſalt. The ſunſhine had turned this water ſower, had made it act upon the *antimony*, and take up a part of its ſalt. This ſalt, in the winter, was probably afterwards concreted into the figures of leaves, formed upon the mud depoſited by the water on the ſides of the veſſel; and theſe ſalts being afterwards diſſolved again in ſome hotter weather, had eaten their way into this ſediment of mud, in the form of the leaves, *&c.* in which they had concreted. Mem. Acad. Par. 1693.

Texture of STIBIUM. Monſieur de Reaumur gives the following account of the contexture of *antimony*, or *ſtibium*.

Nothing is more common, than to obſerve on the ſurface of broken *antimony* long and ſhining needles, as it were; and that *antimony*, on which theſe are moſt diſtinct and viſible, is eſteemed the beſt. Sometimes theſe ſtreaks are ranged with ſo much order, and branch out ſo regularly in certain directions, that thoſe who are ever ſo converſant with it, cannot but admire its beauty. The figures of the conſtituent molecules of this mineral may poſſibly contribute ſomething to the formation of theſe needles, but the texture, and configuration of the conſtituent parts, will not alone account for the diſpoſition of theſe ſtreaks, and their arrangements, in regard to one another; ſince upon breaking different lumps of the ſame *antimony*, and thoſe of the ſame ſhape, we frequently obſerve quite different configurations of the needles. Let us take, for inſtance, equal maſſes of *antimony* of a regular conic figure, theſe being moſt frequent, from the ſhape of the veſſel they cool in, which reſembles a funnel, or inverted cone; let ſeveral of theſe conical maſſes be broken into different parts, and we ſhall ſee the needles in very different directions in theſe ſeveral parts.

In one of theſe maſſes, from a certain height, we may obſerve all theſe needles directed to the point of the cone; in a piece taken from a little higher, the needles ſhall be horizontal, or nearly perpendicular to the former; above theſe we ſhall find others, which ſometimes direct themſelves toward ſome point in the baſe of the cone, and ſometimes form themſelves into different cones with their ſeveral ſummits.

In another of theſe maſſes we ſhall not find the needles diſpoſed into a horizontal direction, but running into ſmall conical parcels, in directions quite reverſe one to another; that is, ſome of them ſhall have their ſummits toward the baſe of the cone, and others toward its apex. In ſome lumps alſo we ſhall diſcover needles every where, and in others no where at all; and often the needles are found in one part of the lump, with no appearance of them in the others. Sometimes alſo we ſhall find the inſide of a maſs regularly diſpoſed into cones, though the outſide is of no ſuch figure, for the internal cones have no dependance upon the external figure of the maſs; and ſometimes the needles are diſpoſed along the ſides of the cone, and their direction ſeems to follow the ſides of the veſſel in which they were fixed. Notwithſtanding, however, all theſe varieties in form, the cauſe of all the appearances is wholly the ſame, and is no other than that refrigeration, by which the maſs is changed from a fluid into a ſolid ſtate; and to the progreſs of this the needles plainly owe their different directions.

All melted metals cool firſt at the tops and ſides, and thence by degrees through the whole body of the maſs: the particles at the ſides and top, which firſt cool, becoming fixt to thoſe which are neareſt them, affix thoſe, and they are the next that cool, and ſo on, in ſucceſſive order; now moleculæ, of whatever ſhape, thus affixed ſucceſſively to each other, form a kind of threads or needles, the ſeveral directions of which ſhew the order in which the refrigeration has been carried on.

If the crucible, or other veſſel, in which the melted *antimony* is ſuffered to cool, were in the ſhape of a hollow bowl; if its ſides were every where equally thick, and equally warm, and acted equally upon by an air equally cold; and if the melted ſubſtance were of the ſame uniform nature, alſo, in all its parts, all the needles or fibres would be then ſo many rays, terminating in the center of the bowl; and if the ſubſtance were ſuch, that its fixed particles were naturally all of a length, we ſhould find ſo many concentrical beds of needles, formed by parcels of each ray, and lying at equal diſtances from the center.

But ſo many regular circumſtances do not concur in the cooling of melted *antimony*; and hence the beforementioned irregularities muſt neceſſarily ariſe. In melting *antimony* in conical crucibles, and ſuffering it to cool in them, the needles may be determined ſeveral ways, to any directions one may chooſe.

If, when the crucible is taken from the fire, it be ſet to cool upon ſome cold body, the conſequence is, that the bottom and top of the *antimony* muſt cool firſt, and the needles will be found diſpoſed into two cones, the one having its baſe at the apex, and the other at the baſe of the large, or general cone: but if the crucible be ſet on burning coals, and the ſurface of the *antimony* covered with more coals, then the ſides muſt cool firſt, and the needles will be found running horizontally, or forming themſelves into horizontal cones: the touching the ſides of the crucible alſo, at times, with a wet cloth, and by that means forcing the melted matter to cool firſt in ſuch particular places, will give cones of needles directed horizontally, and having their baſes at thoſe ſpots of the crucible ſo forcibly cooled.

Not unfrequently there is found a hollow in the midſt of a conical maſs of *antimony*, and in that caſe there are ever found needles proceeding in different directions from the ſides of that cavity inwards, as they, when cooled, became of the ſame nature with the ſides of the veſſel, and acted on the encloſed maſs in the very ſame manner.

To procure the needles perfect and fine, the *antimony* muſt be ſuffered to cool gradually, for if it cool too faſt, one molecula becomes fixed before it can be adapted to the end of another, and the whole is a confuſed maſs; and the ſame happens alſo if it cool too ſlowly; for then the particles of

fire get out ſo very regularly and inſenſibly, that the moleculæ cooling equally all together, form no arrangements. This is found by letting a crucible of melted *antimony* ſtand on ſome burning coals, and gradually cool as their heat burns away and decreaſes; in which caſe the maſs will have perhaps no needles at all, or if any, then but very few.

It may be objected to this, that if the refrigeration of the maſs is the only cauſe of the needles in *antimony*, all melted metals ought to afford the ſame appearance alſo, if cooled in the ſame manner: and poſſibly indeed all do ſo; we ſee them eaſily in *antimony*, becauſe it breaks with a ſlight blow, without diſordering the configuration of its parts, the combinations of its molecules into needles being more firm than that of the needles to one another; but in metals which require more force to break them, the needles may perhaps rather break than ſeparate, and by more force muſt be more diſordered; and all the parts may be as regularly arranged in a ductile maſs, as in a brittle one, though we are not able to diſcover that arrangement.

Lead, when hot to a proper degree, ceaſes to be ductile, and is brittle, and lead broken at this juncture is found to be granulated, appearing like broken ſteel; there is no reaſon to doubt but that this is alſo the caſe, when that metal is perfectly cold, but that the force required to ſeparate, or break it, deſtroys its proper ſtructure.

Mr. Reaumur melted lead in a conical crucible, and ſuffering it to cool to a certain degree only, he broke the maſs into ſeveral large lumps by a ſmart blow of a hammer, and in theſe found the ſame needles as in *antimony*, the granules having cohered in long trains, juſt as the moleculæ of the *antimony*; and the diſpoſitions of the ſeveral groupes of needles in the lead, in regard to the ſides and bottom of the crucible, were the very ſame with thoſe of *antimony*. But there is this manifeſt difference between the needles of lead, and thoſe of *antimony*, that whereas the latter are flat and extremely gloſſy, the former are viſibly round, and much leſs bright. Mem. Acad. Scienc. Par. 1724.

Ore of ANTIMONY. The way of running down *antimony* out of its ore by the aſſayers, is as follows. Take a crucible that will hold ſome pounds of *antimony* ore, broken into pieces of the ſize of a hazel-nut, and bore at the bottom of it a few ſmall holes with a common gimblet; place this bottom in the mouth of another ſmaller crucible, put in the ore, and cover the orifice with a tile; then lute all the junctures, and place this on the pavement of the hearth, making a circle of ſtones all round it, at ſix inches diſtance; fill this intermediate ſpace with aſhes, ſo high, that the lower pot may be covered up to its rim, then put freſh burning coals upon the whole, and blow the fire ſtrongly with a pair of hand-bellows, to make the upper veſſel red-hot: when it has been ſo a quarter of an hour, take away the fire, and when the veſſels are cold, open them, and the *antimony* will be found in form of a regulus in the under veſſel. *Cramer*'s Art of Aſſaying, p. 356.

The moſt ready method of fuſing *antimony*, yet known, is by means of that mineral ſubſtance called *cawk*. A lump of this, of the bigneſs of a wallnut, thrown red-hot into a pound of *antimony* in fuſion, converts almoſt the whole ſubſtance of it into glaſs, fifteen ounces of clean and fine glaſs being thus produced; and what is very remarkable, the cawk itſelf never melts in the metal.

The purification of gold, by means of *antimony*, is performed in this manner. Before you enter on the proceſs, it is neceſſary to gueſs, as nearly as may be, at the allay of the gold, by the touch-needles, or otherwiſe. If the quantity of gold in the maſs is not leſs than three quarters, that is, eighteen carats, the maſs muſt be melted in a wind-furnace, and the crucible muſt be covered, to prevent coals falling in; this done, put into it, at ſeveral times, double the quantity of crude *antimony* in fine powder, as ſoon as one portion of the *antimony* is melted, putting in another: let the whole continue in fuſion a few minutes, then pour it into a melting cone, warmed, and rubbed with tallow, and ſtrike with a hammer on the floor, near where the cone ſtands, that the heavier part may ſink to the bottom. When all is cold, invert the cone, and ſtrike it, and a maſs will fall out, having at bottom a regulus, more or leſs yellow, according to the quantity of the gold in the mixture; this may with a few blows be ſeparated from the ſulphureous cruſt, which is at top. Melt in a ſmaller fire this regulus, and when in fuſion add to it a double quantity of crude *antimony* in powder, and pour it out into the cone again a little after; ſeparate the regulus from the *antimony* at top, and then repeat this operation once more. When this is done, put the ſeparated regulus into a thick good teſt, place this in the furnace immediately before the bellows, put coals round it, and one or two pieces of wood upon them, and make a middling fire, ſuch as is ſufficient to melt the regulus, the reguline part of the *antimony* will vaniſh in a thick ſmoak; then encreaſe the fire, and keep it ſo, till the fumes are over, and the ſurface of the gold is of a fine green; and afterwards give the gold another fuſion with borax and nitre, and it will be perfectly pure.

When the gold to be purified by this proceſs is impure to an allay of eight carats, it is not proper to perform the precipitation by *antimony* alone, but there ſhould be added as many times two carats of common ſulphur, as the allay of the gold is ſo many carats leſs than eighteen. *Cramer*'s Art of Aſſaying, p. 276.

STIBIUM, in medicine, *&c.* is not only given in ſubſtance, but many preparations of it are alſo uſed; which are either emetic, cathartic, diaphoretic, or ſudorific. Crude *antimony* in powder is found good for diſſolving viſcidities, in cutaneous diſeaſes, and, as ſome very confidently aſſert, in convulſions and epilepſies. Externally, in ointments, it is commended for drying up ulcers, curing the itch, and in plaiſters for reſolving of tumors.

There appears no reaſon for people's being afraid of giving crude *antimony* internally, experience ſhews it to be a ſafe medicine, unleſs by accident the acid of the ſtomach ſhould prove ſtrong enough to be a menſtruum to it.

The preparations of *antimony* are, 1. *ſulphur præcipitatum antimonii*. 2. *Crocus antimonii*, called alſo *crocus metallorum*. 3. *Crocus antimonii lotus*. 4. *Calx antimonii*, called *antimonium diaphoreticum*. 5. *Tartarum emeticum*. 6. *Cauſticum antimoniale*. 7. *Cinnabaris antimonii*. 8. *Regulus antimonii martialis*. 9. *Tinctura antimonii*. 10. The *Kermes* mineral, or Carthuſian powder. See the articles SULPHUR, CROCUS, CALX, *&c. Cycl.* and *Suppl.*

The virtues of *antimony*, in the diſeaſes of animals, are very great, and very evident on any trial. Pigs that have the meaſles are at all times recovered by it, which proves it a great purifier of the blood. Horſes who have running heels, that cannot be cured by the common methods uſed by the farriers, will generally be cured by this medicine in a little time. The manner of uſing it is this: mix one drachm with every feeding of oats which the horſe has in a morning; it is beſt put together in one place, buried under a few oats, and the horſe's head being with-held a little, and then let go juſt againſt that place, he will take it all in at a mouthful. Some horſes do not diſlike it, others obſtinately refuſe it, but to theſe it may eaſily be given in balls. The virtues of this drug, in fattening of cattle, has by many been thought imaginary, but experiment proves it to be a real truth. A horſe that is lean and ſcabby, and not to be fatted by any other means, will become fat on taking a doſe of *antimony* every morning, for two months together. A boar fed for brawn, and having an ounce of *antimony* given him every morning, will become fat a fortnight ſooner than others put into the ſtye at the ſame time, and fed in the ſame manner, but without the *antimony*. Philoſoph. Tranſ. N° 39.

Crude *antimony* is recommended in palſies, pains, and numbneſs, which come on after a ſalivation, and is ſaid to have cured ſeveral who were paralytic from other cauſes. The method of giving it, is to begin with three grains, increaſing the doſe with three grains every day, to half a drachm; after which the doſe is diminiſhed three grains every day, till it comes down to the quantity of the firſt doſe. Commerc. Liter. Norimb. ap. Medic. Eſſ. Edinb.

Antimony, before the twelfth age, was of ſervice only in the compoſition of paint. Scripture deſcribes it to us as a ſort of paint, with which the women blackened their eyebrows. Jezabel underſtanding that Jehu was to enter Samaria, painted her eyes with *antimony*, or, according to the Hebrew, put her eyes in *antimony*.

As large black eyes were thought the fineſt, they of both ſexes, who were careful of their beauty, rubbed their eyes, eyelids, and round the eyes, with a needle dipped in a box of paint made of *antimony*, with a deſign of blackening them.

At this day the women of Syria, Arabia, and Babylonia, anoint and blacken themſelves about the eyes; and both men and women put black upon their eyes in the deſert, to preſerve them from the heat of the ſun, and the piercing of its rays. M. Darvieux tells us, that the Arabian women border their eyes with a black colour made of tutty, which the Arabians call *rehel*. They draw a line of this kind of blacking without the corner of their eyes, to make them appear larger. Iſaiah, in his enumeration of the ſeveral ornaments belonging to the daughters of Sion, has not forgot the needles which they made uſe of in painting their eyes and eyelids; nor has this practice eſcaped the laſh of Juvenal [b].

Ille ſupercilium madida fuligine tinctum
Obliqua producit acu, pingitque trementes
Attollens oculos.

Ezekiel, diſcovering the irregularities of the Jewiſh nation under the idea of a debauched woman, ſays, that ſhe bathed, perfumed herſelf, and that ſhe anointed her eyes with *antimony*. Job ſhews ſufficiently how much *antimony* was in eſteem, by calling one of his daughters a veſſel of *antimony*, or a box to put paint in, *cornu ſtibii*. Tertullian and St. Cyprian have declaimed very warmly againſt this cuſtom of painting their eyes and eyebrows [c].—[b *Juv.* Sat. 2. c *Calmet*'s Dictionary.]

STIBIUM *ceratum*. See the article VITRUM *antimonii ceratum*.

STICA, a name given by ſome authors to all external aſtringents uſed in hæmorrhages.

STICA, in our old writers, a braſs Saxon coin, of the value of half a farthing, four of them making an helfing. *Blount*.

STICHOMANTIA, Στιχομαντεια, in antiquity, a ſort of divination by verſes, (commonly thoſe of the Sibylline oracles) which being wrote on little pieces of paper, and thrown into a veſſel, the firſt drawn out was ſuppoſed to contain the will of the Gods. *Potter*, Archæol. Græc. Tom. I. p. 333. See SORTES, *Cycl.*

STICHOS, a name given by the old writers to a pectoral confection, the principal ingredient of which was the herb *marrubium*, or hore-hound.

STICKLEBACK, in ichthyology, a name given by us to that ſmall fiſh, called by authors by the ſeveral names of *ſpinachia*, *ſpinax*, and *pugnitius piſcis*; as alſo *piſciculus aſper*, *piſciculus aculeatus*, and the like; and finally, by Artedi, by the much more expreſſive name of *gaſteroſteus*, expreſſing that great ſingularity it has in the bony ſtructure of its belly. The common *ſtickleback* is diſtinguiſhed by Artedi by the name of the *gaſteroſteus* with three ſpines on the back; and by this character it differs from two other ſpecies, the one the *ſpinarella* of authors, a ſmall ſpecies with ten prickles in the back; and the other a long ſea kind with fifteen ſpines on its back, called by Willughby, and others, the *pugnitius marinus longus*. See the article GASTEROSTEUS.

As contemptible a fiſh as this may ſeem, its miſchief in eating the young fry in ponds is not greater than its value. In a ſort of manufacture carried on at Boſton, and ſome other parts of Lincolnſhire, they have fallen into a way of making oil of it, and have made annually a hundred tun, or more, to their very great advantage. All the waters thereabout ſwarm with this little fiſh, and doubtleſs a ſufficient quantity might be found in other places for the ſame ſort of uſe. They grow in the Boſton river to an inch and half in length, and about half an inch in breadth, and are taken out at a buſhel a draught. Eight chalder of them make a barrel of oil; their barrel is a hogſhead; they are obliged to uſe them very freſh, elſe the oil runs from them to waſte, and they uſually boil every night what they have caught by day. It is a wonder that this quality of this little fiſh was not found out ſooner, for in frying them in the common way for eating, they all run into an oil in the pan. Philoſ. Tranſ. N° 223.

STICKLER, in our old writers, an inferior officer, who cut wood within the king's parks of Clarendon. Rot. Parl. 1 Hen. VI. *Blount*.

STICKS *of eels*, a quantity, or meaſure of twenty five. A bind of eels contains ten *ſticks*, and each *ſtick* twenty five eels. Stat. Weights and Meaſures. *Blount*.

STIFFLE, or GREAT *muſcle*, in the manege, is the part of the hind leg of a horſe which advances towards his belly. This is a moſt dangerous part to receive a blow upon.

STIGMA, among botaniſts. See the article PISTIL.

STIGMATA, in natural hiſtory, the apertures in different parts of the bodies of inſects communicating with the tracheæ, or air veſſels, and ſerving for the office of reſpiration. *Reaumur*, Hiſt. Inſect. paſſim.

Nature has given to theſe minute animals a much larger number of tracheæ and bronchia, than to us. We have the ramifications of the trachea reaching no farther than into the breaſt, whereas, in the bodies of theſe inſects, we find them extended through the whole, and finely and admirably interlaced one with another. We have but one mouth to reſpire by; and the organization of the parts, inſervient to reſpiration, is very admirable in us; but in the inſect claſs, the mouths, or openings to breathe at, are much more numerous, and the organization much more complex.

All the two-winged and four-winged flies, which have a ſingle or undivided corcelet, to which their legs are all fixed, have alſo four *ſtigmata* in that corcelet, two on each ſide. They have them alſo on the rings of their body, but thoſe on the corcelet are the moſt conſiderable.

Of the four on the corcelet, the two anterior ones are uſually the largeſt. The beſt way to find them, in the generality of flies, is to examine them firſt in the larger ſpecies of the libellæ, where they are very diſtinct and plain, and after their ſituation is well known in that ſpecies, they will be much the more readily found in the reſt.

Theſe *ſtigmata* of the corcelet, as well the anterior as the poſterior, are oblong, and placed obliquely to the length of the body; that end of them next the head is more elevated than the other, and their ſize is ſufficiently large to render them viſible, eſpecially the firſt pair. Each of theſe ſeems not a little to reſemble a ſea-muſcle with its ſhells a little open, or is ſomewhat like the opening of an eye. It is alſo ſurrounded by two eyelids, proportionably thick; and beſide theſe, which make its outer circumference, one may diſcover two others within, which are bordered with hairs, and which, when cloſed, often quite ſhut up the opening.

The colour of the *ſtigmata* often is ſome help alſo to us for the diſcovering them; they are very frequently different in colour from the corcelet; ſome are yellowiſh, others of a coffee colour, or ſome degree of a fallow colour, in flies whoſe corcelet is brown, or black, or bluiſh.

Flies have, beſide theſe, ſeveral *ſtigmata* alſo in the rings of their bodies, perhaps in every one of them, though commonly thoſe in the two or three firſt are only to be diſtinguiſhed: theſe are not like thoſe of the corcelet, but are round, uſually a little eminent above the reſt of the ſurface, and reſembling pin's heads; they are not eaſily diſcovered, becauſe they are not only ſmall, but uſually hid by the folds, or commiſſures of the rings. They are uſually two on each ring, placed on the two oppoſite ſides, and partly under the belly. *Reaumur*, Hiſt. Inſ. Vol. 4. p. 248.

STIGMATICI, among the Romans, were ſervants marked in the face for ſome crime. *Pitiſc.* in voc.

STIGMATIZING, among the antients, was inflicted upon ſlaves as a puniſhment, but more frequently as a mark to know them by; in which caſe, it was done by applying a red-hot iron, marked with certain letters, to their foreheads, till a fair impreſſion was made, and then pouring ink into the furrows, that the inſcription might be the more conſpicuous. *Potter*, Archæol. Græc. Tom. I. p. 64.

STIGMATIZING, among ſome nations, was looked upon as a diſtinguiſhing mark of honour and nobility. *Potter*, loc. cit. p. 65.

STIL *de grain*, in the colour trade, the name of a compoſition uſed for painting in oil or water, and is made of a decoction of the lycium, or Avignon berry, in alum-water, which is mixed with whiting into a paſte, and formed into twiſted ſticks. It ought to be choſen of a fine gold yellow, very fine, tender, and friable, and free from dirt. *Pomet*'s Hiſt. of Drugs, p. 14.

STILE (*Cycl.*)—In a philoſophical *ſtile*, the only end is accurately to explain our thoughts to others; thence the particular rules to be obſerved by a philoſopher, in delivering his doctrines, naturally follow: ſuch as,

1°. Not to deviate from the received ſignifications of terms.

2°. That the ſame terms be always taken in the ſame ſenſe.

3°. To fix the meaning of ſuch words as have only a vague ſenſe.

4°. To ſignify objects, eſſentially different, by different names.

From theſe rules, the uſe and neceſſity of terms of art appear, and ſhews with how little reaſon they are vulgarly condemned.

5°. The philoſopher ought always to make uſe of proper expreſſions, and uſe no more words than what are preciſely neceſſary to eſtabliſh the truth of his doctrines. *Wolf*, Diſc. Prælim. Logic. cap. 5.

STILL-*bottoms*, in the diſtillery, a name given by the traders to what remains in the *ſtill* after the working the waſh into low wines.

Theſe *bottoms* are procured in the greateſt quantity from the malt waſh, and are of ſo much value to the diſtiller in the fattening of hogs, &c. that he often finds them one of the moſt valuable articles of the buſineſs. They might alſo be put to other uſes, ſuch as the affording a large proportion of an acid ſpirit, an oil, a fuel, and a fixed ſalt; and with ſome addreſs, and good management, a vinegar, and a tartar. Another very advantageous uſe of them, is the adding them to the next brewing of the malt for more ſpirit: the encreaſe of the produce from this, is more than could eaſily be conceived. It alſo more readily diſpoſes the new waſh to ferment, and gives the ſpirit a vinoſity that it cannot have without it; the proportion, in this caſe, muſt never exceed that of a fifth, or ſixth part of the whole quantity of liquor employed.

The liquor left behind in the *ſtill*, after the rectifying the low wines into proof ſpirit, is alſo called by ſome by the name of *ſtill-bottoms*; but this is little more than mere phlegm, or water impregnated with a few acid, and ſome oily parts, not worth ſeparating, unleſs for curioſity. The liquor left in the *ſtill*, after the rectifying the proof ſpirit into alcohol, is alſo of the ſame kind.

The *bottoms* of melaſſes ſpirits ſeem calculated for many uſes. It is very probable that the vinegar-makers would find their account in the trying them, and the ſtrong, and laſting yellow colour, with which they tinge the hands, may recommend them to the dyers. A ſmall proportion of them added to the new treacle to be fermented, greatly promotes the operation, and encreaſes the quantity of ſpirit.

The *bottoms* of the wine ſpirit, that is the remainder, after diſtilling the ſpirituous part from damaged wines, or wine lees, may be brought to afford Mr. Boyle's acid ſpirit of wine, and that ſubſtance called by Becher the *media ſubſtantia vini*. A parcel of tartar may alſo be procured in very great perfection; and the laſt remainder may be converted into excellent and genuine ſalt of tartar. The liquor may otherwiſe be ſerviceable in making vinegar and white lead. *Shaw*'s Eſſay on Diſtillery.

STILL-*houſe*. The Dutch have much the advantage of us in the ſtructure of their *ſtill-houſes*, and have every thing in

great readineſs and neatneſs. The general rules, in building theſe *houſes*, ſhould be theſe.

The firſt caution is to lay the floor aſlope, not flat, where any wet work is to be performed; it ſhould alſo be well flagged with broad ſtones, ſo that no wet be detained in the crevices, but all may run off, and be let out at the drains made at the bottom and ſides.

The *ſtills* ſhould be placed abreaſt on that ſide of the *ſtill-houſe* to which the floor has its current. The largeſt *ſtills* in Holland, for their greateſt works, are never of that monſtrous ſize that we ſee them of in England, but much more manageable and handy, as ſeldom containing more than ſix or eight hogſheads; and with ſuch *ſtills*, a ſingle hand will perform much more buſineſs than with one of a much larger ſize. Fronting the *ſtills*, and adjoining to the back wall, ſhould be a ſtage for holding the fermenting backs, and theſe being placed at a proper height, may empty themſelves, by means of a cock and a canal, into the *ſtills*, which are thus charged with very little trouble.

Near this ſet of fermenting backs ſhould be placed a pump or two, that may readily ſupply them with water by means of a trunk, or canal, leading to each back. Under the pavement, adjoining to the *ſtills*, ſhould be a kind of cellar, wherein to lodge the receivers, each of which ſhould be furniſhed with its pump, to raiſe the low wines into the *ſtill* for rectification; and through this cellar the refuſe waſh, or *ſtill*-bottoms, ſhould be diſcharged by means of a hoſe, or other contrivance. Theſe are the principal things to be regarded in the erecting a *ſtill-houſe* for the original production of ſpirits, and if theſe rules are well obſerved, malt ſpirit will be made with little more trouble than melaſſes; for by this means the buſineſs of brewing and cooling the waſh, which, according to the method generally practiſed in England, takes up ſo much time and trouble, is entirely ſaved, fermentation is carried on to a much greater advantage, and the quantity of ſpirit encreaſed. *Shaw*'s Eſſay on Diſtillery.

STINT, in zoology, the name of a ſmall bird common about the ſea ſhores in many counties of England, and ſeeming to be the ſame with the *cinclus prior* of Aldrovand, and the *ſchæniclos*, or *junco* of Bellonius, called by the French *alouette de mer*, the *ſea-lark*.

It is ſomewhat ſmaller than the common lark, and in ſhape reſembles the ſmaller ſnipe. Its beak is black, ſlender, and ſtrait; its feet of a greeniſh, or browniſh black; its back is a grey, variegated with oblong black ſpots, and its wings ſomewhat of a reddiſh brown; its neck is grey, and its head variegated with black and a reddiſh brown; its wings are long, and when folded reach beyond the end of the tail; and its rump is ſomewhat reddiſh with black ſtreaks. *Ray*'s Ornitholog. p. 226.

STIP *viſch*, in zoology, a name given by the Dutch in the Eaſt-Indies to a fiſh of the claſs of our European ones which have two back fins, the anterior of which is prickly, the hinder not ſo. Its ſkin is ſpotted, and its fleſh very delicate, and well taſted. It is generally caught by hooks. *Ray*'s Ichthyogr. Append. p. 8.

STIRRUP, (*Cycl.*) in the manege. To looſe one's *ſtirrups*, is to ſuffer them to ſlip from the foot.

The *ſtirrup-foot* is the near, or left foot before.

Stirrup-leather is a thong of leather, deſcending from the ſaddle down by the horſe's ribs, upon which the *ſtirrups* hang.

Stirrup-bearer, called in French *porte etrier*, is an end of leather made faſt to the end of the ſaddle, to truſs up the *ſtirrup* when the rider is alighted, and the horſe ſent to the ſtable.

STIRRUP *of a ſhip*, a piece of timber put upon a ſhip's keel, when ſome of her keel happens to be beaten off, and they cannot come conveniently to put, or fit in a new piece; then they patch in a piece of timber, and bind it on with an iron, which goes under the ſhip's keel, and comes up on each ſide of the ſhip, where it is nailed ſtrongly with ſpikes; and this they call a *ſtirrup*.

STOÆ, Στοαι, in antiquity, the porticos at Athens. Theſe were full of exedræ, ἐξέδραι, and ſide-buildings, furniſhed with ſeats fit for ſtudy or diſcourſe. Here it is probable philoſophers, and their ſcholars, uſed to meet. *Potter*, Archæol. Græc. lib. 1. cap. 8. Tom. I. p. 38. See the article EXEDRÆ, *Cycl.*

STOAKED, in a ſhip. When the water in the bottom cannot come to the well of the pump, they ſay, *the ſhip is a-ſtoak*, or *ſtoaked:* ſo they ſay alſo, *the limber holes are ſtoaked*, when the water cannot paſs through them; and that *the pump is ſtoaked*, when ſomething is got into it which choaks it up, ſo that it will not work.

STOAT, in zoology, the name uſed by many for the animal whoſe ſkin is the ermin. See the article ERMINEUM *animal*.

STOC *and ſtovel*, in our old writers, a forfeiture where any one is taken carrying *ſtipites* and *pabulum* out of the woods; for *ſtoc* ſignifies ſticks, and *ſtovel* pabulum. Antiq. Chart. ap. *Blount*.

STOCK *of an anchor*. See the article ANCHOR.

STOCK-*bricks*. See BRICK-*making*.

STOCK-*fiſh*, in the fiſh trade, a name given to the common cod-fiſh when cured in a particular manner, which makes it neceſſary to beat it with ſticks before it is fit for dreſſing. *Willughby*'s Hiſt. Piſc. p. 166. See COD-*fiſh*.

STOCK-*July-flower*. See the article LEUCOIUM.

STOCKER, in ichthyology, a name given by the Germans to the *ſaurus* of the antients, the *trachurus* of the later writers. It is a ſpecies of the *ſcomber*, known among us under the name of the *horſe-mackrel*; and is diſtinguiſhed from the reſt by Artedi, by the name of the *ſcomber* with the lateral line prickly, and with thirty rays in the pinna ani.

STOCKS (*Cycl.*)—STOCKS, among ſhip-carpenters, a frame of timber and great poſts, made aſhore to build pinnaces, ketches, boats, and ſuch ſmall craft, and ſometimes ſmall frigates. Hence we ſay, *a ſhip is on the ſtocks*, when ſhe is a building.

STOCKS, *cippus*, a wooden machine to put the legs of offenders in, for the ſecuring of diſorderly perſons, and by the way of puniſhment in divers caſes ordained by ſtatute, *&c.* And it is ſaid that every vill, within the precinct of a torn, is indictable for not having a pair of *ſtocks*, and ſhall forfeit 5*l.* Kitch. 13.

STOMACACE, a word uſed by ſome authors to expreſs a ſymptom of the ſcurvy, which is a fœtor of the mouth, with a ſoreneſs and bleeding of the gums.

STOMACH (*Cycl.*)—In order to underſtand the action of the *ſtomach*, in turning the aliments into chyle, we are firſt to thoroughly conſider its form. It is eaſy to obſerve, that the two orifices of the *ſtomach*, the œſophagus, and pylorus, are not ſituated exactly over-againſt one another; but that if the *ſtomach* be regularly divided longitudinally into two halves, the œſophagus will be found wholly in the anterior half, and the pylorus, in great part, in the poſterior. Near the inſertion of the œſophagus there are two planes of muſcles, the one is placed near the bottom of the *ſtomach*, and encompaſſes all that part of the œſophagus that is neareſt that part. This muſcle throws off obliquely ſeveral bundles of fibres, which run to the middle, both of the anterior and poſterior ſides of the *ſtomach*, and many of theſe extending even to the lower part of it, make what are there called *the oblique fibres of the ſtomach*. The other muſcular plane encloſes, in the ſame manner, the other part of the mouth of the œſophagus, or that which lies toward the pylorus; this terminates on each ſide near the bottom of the *ſtomach*. Theſe two planes of fibres are, as it were, two fleſhy bands about the mouth of the œſophagus, which croſs one another both on the upper and under part of the *ſtomach*.

The longitudinal fibres are very ſlender, and appear about an inch from the pylorus, extending themſelves along both the anterior and the poſterior ſides of the *ſtomach*, quite to the orifice of the œſophagus; and finally, they are inſerted round about the pylorus by two ligamentary bands, which authors have generally paſſed over without obſerving. Theſe bands are much like thoſe of the colon, and occupy all the length of the neck, and may be eaſily diſtinguiſhed by the touch, and are not difficult to be ſeen on bending the part in an inflated *ſtomach*.

The fibres of the bottom of the *ſtomach*, when nicely examined, are found to be circular, all compoſing ſeveral ſmall concentric circles, each ſeries of which is independent of all the reſt. There is one of theſe circles placed juſt in the center of the bottom of the *ſtomach*, and from this the other circles ſpread, being of ſeveral different diameters, according to the places where they ſtand, and reaching to near the orifices where the fleſhy fibres take another courſe, as before obſerved. The bodies, called *circular fibres of the ſtomach*, and ſuppoſed to part from the upper part of the *ſtomach*, cloſe to one another, and taking the round of the *ſtomach* to return thither again, are truly a number of ſmall muſcles, or bundles of fibres, placed at ſmall diſtances from one another, no one of which ever reaches perfectly round the *ſtomach:* from theſe ſeveral ſmaller fibres are propagated in an irregular manner, which fill up the interſtices of the circular directions of theſe, and form a ſort of net-like plexus, between the fibres of which the nervous membrane of the *ſtomach* is eaſily ſeen. Theſe interſtices, in general, are of a ſort of lozenge ſhape, and the whole of theſe fibres may be ſaid to conſtitute a ſort of muſcular net, enveloping the whole *ſtomach*. All thoſe bundles of fibres, or ſmall muſcles, which are ſituated below the upper orifice of the *ſtomach*, or near about it, form together a plan, or ſeries, which runs in a ſtrait line from the upper to the lower extremity of the *ſtomach*; whereas, on the contrary, thoſe which are placed about the middle of the *ſtomach* ſeem to turn about, and form parts of circles, the convex part of all which ſtands toward the bottom of the *ſtomach:* and finally, thoſe which are placed about the neck of the *ſtomach* are much bent, and their bending is always the greater, as they approach nearer to the pylorus. This appears to be the true figure and arrangement of the fibres of the *ſtomach*; and as this is very different in many particulars, from the common accounts of anatomical authors, it was neceſſary to give this at large, in order to underſtand and explain the action of this part in the

the great work of digeſtion; and according to this account, the offices of every part will be very eaſily underſtood.

The circular bands of muſcular fibres, placed round the orifice of the œſophagus, are deſigned to prevent the upper orifice of the *ſtomach* from being too much diſtended, whether by our careleſsly ſwallowing too large morſels, or by the action of vomiting. The uſe of the muſcular circles, at the bottom of the *ſtomach*, is as eaſily ſeen: the aliments received into this part of the *ſtomach*, were it not for theſe circular arrangements of fibres, would remain there, and have no tendency given them to go out of the *ſtomach*; but by this wonderful ſtructure, the whole bottom of the *ſtomach* can at once be put into a ſafe and eaſy, though a powerful contraction, by means of which the aliments are naturally ſent toward the pylorus for their diſcharge. Theſe circles give the firſt principle of the periſtaltic motion of the *ſtomach*, which is much the ſame with that of the inteſtines.

When the aliments have been thrown off from theſe circles, they are not immediately, however, diſcharged into the pylorus, but are thrown upon thoſe bundles of fibres, or ſmall muſcles, which make what has been before called the *reticular coat of the ſtomach*. That part of this coat which immediately receives them, is that compoſed of ſegments of circles, the convex parts of which are all placed toward the bottom of the *ſtomach*; and as theſe afterwards form their contractions, their middle naturally elevates, and throws off the aliment ſtill toward the pylorus, and this is done with the more force, as the action of theſe fibres is ſtrengthened by the longitudinal ones; and, in fine, thoſe longitudinal fibres, which are attached to the bands that ſurround the pylorus, when they act, contract, or pull the other parts of the *ſtomach* toward their inſertions; ſo that every thing tends to help the throwing the food upon the pylorus.

The reticular coat of the *ſtomach* has alſo other great advantages; it is eaſily capable of extenſion, and conſequently gives the *ſtomach* a capacity of enlarging, ſo as to hold a larger quantity of aliments than it otherwiſe could; and when they act, ſo as to be approaching toward their natural ſtate again after ſuch diſtention, this action, which is no other than their contraction, neceſſarily throws the aliments toward the pylorus: this contraction is always ſucceeded by a ſmall dilatation again, and that by another contraction, and theſe alternately ſucceeding one another, ſo long as any of the aliments continue in the *ſtomach*, conſtitute what authors call its periſtaltic motion. Although this motion is very ſlight, and only a kind of vermicular undulation, which is ſcarce ſenſible, yet there have not been wanting very great men, who have thought it ſufficient for the great work of digeſtion. Theſe authors ſet aſide the uſe of any liquors, or juices of the *ſtomach*, mixing themſelves with the aliments, and give the whole to this motion, which they call a kind of trituration, which they ſay breaks the aliments into ſmall and fine parts, by rubbing them againſt one another, and that theſe fine broken particles make what is called chyle; but it is ſcarce conſonant to reaſon, that ſo weak a cauſe ſhould be productive of ſuch great effects.

This motion is no ſtronger than the periſtaltic motion of the inteſtines, and that is never ſuppoſed to have any ſuch effects on their contents, but only to puſh them forward. The liquor prepared from the food is known alſo to be grey at its paſſing out of the *ſtomach*, and only to acquire its white colour in the duodenum; and how is this accountable for on the plan of trituration only? And finally, if that were all that was required to digeſtion, to what purpoſe did nature, which does nothing in vain, ordain ſuch an abundance of fluids to be preſent in all places, where the aliments were deſtined to undergo any change? To know the abundant quantity of theſe, we need only follow the courſe of the food from the time of its being taken into the mouth to that of its being changed into chyle.

All the time that the teeth are chewing the food, the parotid glands afford a prodigious quantity of ſaliva, which runs into the mouth, mixes with it, and paſſes with it into the *ſtomach*; beſide theſe, alſo, there are many other ſources of the ſaliva, which all diſcharge it at the ſame time, but the quantity from theſe alone is not eaſily conceived. A ſoldier had, by a wound in the cheek, one of the parotids cut in two, and had the wound cloſed within, but not without; it was obſerved, that whenever he uſed his jaws in chewing, this one wounded gland alone diſcharged a quantity of lymph enough to wet ſeveral napkins; what then muſt be the quantity at every meal diſcharged from both, and from all the other ſources together? Though this is all carried down into the *ſtomach*, yet there freſh juices are added to it. Wepfer diſcovered multitudes of glands in the human *ſtomach*, the orifices of which were very ſenſible; and beſide theſe, Mr. Ruyſch diſcovered ſeveral other eminences, which, by their reſemblance to thoſe in the ſecond *ſtomach* of an ox, ſeem to be only caſes encloſing cluſters of minute glands, all deſtined, with the others, to pour out their contents on the maſs of aliments. All theſe fluids, however, only change the food into a thick greyiſh liquor, which is too coarſe to be received into the lacteals, and needs a farther elaboration. This elaboration changes it into a white liquor, which we call chyle; and this is only performed in the duodenum, where there can be no trituration, but where there is a very remarkable aſſemblage of different liquors to effect it: for beſide the common ones, the liver and gall-bladder diſcharge into this inteſtine a great quantity of bile by the ductus choledocus; and the pancreas ſends thither alſo a great deal of its lympth. Brunderus has obſerved alſo, in this inteſtine, a vaſt number of glands, which, according to him, make a ſort of ſecond pancreas: theſe all furniſh, alſo, a great quantity of liquors to the duodenum, where this great change is made in the matter of the aliment; and it is very natural to conclude from the whole, that it is by means of theſe liquors that this change is effected; and if it appear, that the laſt change of the greyiſh liquor of the *ſtomach* into chyle be wrought by theſe fluids, why ſhould it be doubted but that nature, which is alike in all its works, has uſed the ſame means in the firſt change, and by the liquors, mixt with the aliments in the *ſtomach*, has wrought them into that grey liquor they are found there changed into? Trituration does not at all ſeem the buſineſs of the *ſtomach*, nature we ſee has appointed another part, the mouth, for that office, and has furniſhed that with hard bodies, capable of tearing and grinding things to pieces. The moſt natural opinion, on the whole, ſeems therefore, that the office of the mouth was thus to rend and tear in pieces the aliments before their paſſage into the *ſtomach*, that there the juices might act more ſtrongly upon them; in the ſame manner as the chemiſt beats and breaks to pieces the ſubſtances, which he is going to throw into proper liquors, to extract their tincture. Mem. Acad. Par. 1719.

The digeſtive power of the *ſtomach* of ſome fowls is vaſtly greater than that in men, or any other animals. Cryſtal bullets, ſome hollow, and others ſolid, have been crammed down the throats of hens, and have been found afterwards ſtrangely eroded, and eaten by the juices there. Hollow bullets of glaſs have been alſo crammed down by the members of the Florentine Academy, and have been found afterwards not only eroded on their ſurface, but filled within with a whitiſh liquor like cream, which ſeemed to prey upon their ſubſtance. It is probable hence, that the ſtrong digeſtion of theſe fowls may be in ſome meaſure owing to a powerful menſtruum in their *ſtomach*; glaſs and cryſtal are two things wholly indiſſoluble by any menſtruums we are acquainted with, and yet they are corroded here.

This menſtruum in the *ſtomach* of theſe animals, aſſiſted by what the gravel-ſtones, which they ſwallow, are able to do in the manner of teeth, may very well deſtroy, and reduce ſubſtances of ſuch denſe texture, as we ſcarce know how to manage. The glaſs drops with long tails, called *Prince Rupert's drops*, having been in the ſame manner forced down the throats of capons, were found entire in the *ſtomach* after many days, and burſt as uſual on breaking off the tail. Theſe loſt ſomewhat of their weight by remaining in the *ſtomach* ſome time, but the ſame ſort of drops, when untempered by heating in the fire, loſt a great deal in a very ſhort time. One of them, with which Redi made his experiments, loſt four grains of its weight in four days, and giving it to another fowl, it, in ſix days time, loſt nine grains more. This is an argument, not only of the vaſt power of digeſtion in the *ſtomach* of theſe fowls, but of the great difference of hardneſs there is between the ſame glaſs when tempered, by being dropped hot into water, and when untempered again by fire.

Experiments were alſo made, by giving diamonds, topazes, leaden bullets, jaſpers, and porphyry, to the ſame animals, and others of like kinds. The diamond loſt nothing of its weight; the topaz almoſt nothing, the loſs being ſcarce diſcernible with nice ſcales; other ſtones ſcarce loſt any thing, but the leaden bullets loſt conſiderably. Hence it is eaſy to conclude, that the ſmall gravel-ſtones, which they pick up to ſerve for grinding the food in their *ſtomachs*, do their office without parting with almoſt any thing from themſelves: theſe little ſtones, though leſs beautiful, yet approaching in their nature to the gems. There is great difference, however, between theſe and pearls; for it was found that four pearls given to a pigeon loſt one third of their weight in twenty four hours, and eight ſmall pearls given to another pigeon loſt two thirds of their weight in two days. *Redi*, Eſperienz.

STOMACH *of fiſhes*. The *ſtomach of fiſhes* is very different in the various kinds, in reſpect of ſize, thickneſs, and its ſeveral properties and qualities; but its ſituation is generally longitudinal, and it is ſingle in all the known fiſhes, except in the *ſtromateus* of Rondeletius, in which it is ſaid to be double.

The *ſtomach* in living fiſh is cold to the touch, but this is only a proof that it is leſs hot than our own fleſh. That there is heat in it, is evident enough from the digeſtion which is ſo powerful in it, the *ſtomachs* of many fiſh digeſting ſubſtances which ours could not at all effect; ſuch are the ſhells of ſhell-fiſh. It is not eaſy to ſuppoſe this could be performed without ſome degree of heat in the part, but at the ſame time we are informed by this how ſmall a

degree

degree of heat is neceſſary for working theſe effects, and how much may be done by the continual attrition of the fibres, and by a proper fluid. *Artedi*, Ichthyolog.

STOMACH *of flies*. In examining with care the bodies of theſe little animals one may perceive, that when the paſſage of the aliments is got beyond the lungs, and below the place where they form a ſort of diaphragm, one finds the canal, that ſerved for this paſſage, forming a large, though ſhort body, the diameter of which three or four times exceeds that of the canal itſelf. This body is compoſed of three fleſhy lobes, and is unqueſtionably the *ſtomach* of the animal. The inteſtine goes out of it, very nearly from the ſame part where the other paſſage is admitted into it; the inteſtine then directs itſelf toward the anus, and afterwards runs upward again toward the diaphragm, or bottom of the lungs; and thence, after many convolutions, many times running backward and forward, it terminates in the anus.

In caterpillars and butterflies, the canal from the mouth to the anus is only one ſtrait inteſtine, but it is much otherwiſe in theſe creatures, the inteſtines, both in the fly, and in the worm it is produced from, always making a number of contortions and convolutions.

STOMACH-*bruſh*. See EXCUTIA *ventriculi*.

STOMACHICA *febris*, the *ſtomachic fever*, a name given by Heiſter, and ſome others, to a ſpecies of fever, called by others a *meſenteric fever*, and by our Sydenham *nova febris* in a peculiar treatiſe. See INTESTINAL *fever*.

STOMATICA, a term uſed by ſome for all medicines uſed in diſorders of the mouth.

STONE (*Cycl.*)—Some look upon *ſtones* as unorganized vegetables, and that they grow by the accretion of ſalts, which often ſhoot into angular and regular figures. This, it is ſaid, appears in the formation of cryſtals on the Alps; and that *ſtones* are formed by the ſimple attraction and accretion of ſalts, appears by the tartar on the inſide of a claret veſſel, and eſpecially by the formation of a *ſtone* in the human body. Dr. *Berkeley*, Biſhop of Cloyne, in Philoſ. Tranſ. N° 481. p. 326.

Stones are often corroded, and conſumed by the air. Ibid.

Naturaliſts vulgarly define *ſtone* a foſſil incapable of fuſion, yet *ſtone* has been known to be melted, and when cold to become *ſtone* again. Philoſ. Tranſ. N° 481. p. 327. See the article SCIARRI.

Hence it ſhould ſeem not impoſſible for *ſtone* to be caſt, or run into the ſhape of columns, vaſes, ſtatues, or relievos; which experiment may perhaps, ſome time or other, be attempted by the curious, who following where nature has ſhewn the way, may poſſibly, by the aid of certain ſalts and minerals, arrive at a method for melting and running *ſtone*, both to their own profit, and that of the public. Phil. Tranſ. N° cit. p. 328.

Formed STONES, among naturaliſts, mineral, or *ſtony* matter, caſt in the cavities of certain ſea-ſhells, or other parts of marine animals.

Of theſe ſome are found quite naked and bare; others have the remainder of the ſhell about them: and among theſe there are alſo found many real ſhells, ſcarce at all altered from their recent ſtate, buried at great depths in the earth, far from ſeas, and even on the tops of mountains.

This is by moſt ſuppoſed an effect of the general deluge, and by many is thought a convincing proof of the truth of that hiſtory; but there have been many who have aſſerted, that theſe bodies can convey no ſuch proof, ſince, as they affirm, they are not, nor ever were marine bodies, or owed their form to ſuch, but mere *luſus naturæ*, *ſtones* formed in the places where they are found, having no relation to animals of any kind, but only accidentally reſembling them. But the aſſertors of the former opinion have plainly the better ſide of the argument. See MARINE *remains*.

It ſeems indeed contrary to the great wiſdom of nature, which is found, in all its works and productions, to deſign every thing to ſome determinate end, that theſe bodies ſhould have been ſo nicely formed by a mere plaſtic virtue in the earth, or endued with all the characters and neceſſary parts of animal coverings, &c. for no other end but merely to exhibit ſuch a form, without having any relation to the uſes theſe particulars are appropriated to in the animal. See the article FIGURED *ſtones*.

But if the origin of the *ſtones*, found in the ſhape of ſhells, be doubtful, yet the real ſhells, found in the earth, ſurely cannot be ſuppoſed to have been formed there; yet theſe are found at as great diſtances from the ſea, and that not only in the lower grounds and hillocks, but in the higheſt parts of the loftieſt mountains, and that without the leaſt particle of *ſtony* matter about them; mere ſhells, unpetrified, and uncorrupted, and of the exact figure, ſtructure, and conſiſtence with the ſea-ſhells, which are now living, of the ſame ſpecies.

Mentzel ſays that the mount near Bologna, where the Bononian *ſtone* is found, abounds with theſe *formed ſtones*: they lie in beds with ſtrata of ſand, of a yard thick, between them, and are not lodged in *ſtone*, or any cementitious matter, as we often find them in England, but are all looſe and ſeparate: and Fabius Columna tells us, that the hills about Andria, in Apulia, abound with ſea-ſhells not at all petrified, but whole and uncorrupt, and ſeeming to have undergone no change. The mountains about Genoa have alſo been found full of them; and we have in our own kingdom numerous inſtances of them in all their ſtates, ſome ſeeming mere *ſtone*, and others perfect and unaltered ſhells; ſome looſe, and others bedded in marble, in *ſtone*, or in indurated earth.

That nature ſhould form real ſhells, without ever intending them for the covering of an animal, ſeems no way probable; and indeed, were it true, would give great ſtrength to the atheiſt's opinion, that all things exiſted by mere chance, and were intended for no end or uſe. Nor are the ſhells the only inſtances of theſe foſſile bodies perfectly reſembling animal ones, but we find with them other parts of animals, as the teeth of fiſhes and land animals; which, though met with buried in earth, or on the tops of mountains, are plainly the ſame with the ſubſtances produced by the fiſhes, &c. Of this kind are the teeth of the ſeveral ſpecies of ſharks, called *gloſſopetræ*; thoſe of the wolf-fiſh, called *bufonitæ*; the vertebræ of ſeveral fiſh, and the like.

The very inſpection is abundantly ſufficient to prove, that theſe were once parts of animals; but were that inſufficient, they have not, even in this their foſſile ſtate, ſo far diveſted themſelves of their animal nature, but that they carry proofs of it; and Columna has evidently proved their true origin from theſe. He obſerves, that all animal and vegetable ſubſtances, whether of a woody, bony, or fleſhy nature, by burning, are changed firſt into a coal, before they go into a calx or aſhes; whereas *ſtony* ſubſtances, on the contrary, do not burn into a coal, but are reduced at once into their calx or lime, or elſe into glaſs. But theſe teeth, ſuppoſed by ſome mere productions of the earth, all burn firſt to a coal, while the *ſtony* matter adhering to them does not; whence alone it is ſufficiently plain, that they and that ſubſtance are of very different kinds, and that they are truly of a bony, not a *ſtony* matter. It is alſo repugnant to that great maxim, that nature does nothing in vain, to ſuppoſe theſe teeth formed in the earth where they are now found, ſince they could there have no uſe as teeth, nor the vertebræ, or other bones, as bones. It is very certain, that nature never made teeth without a jaw, nor ſhells without an animal inhabitant, nor bones without the reſt of the body they belong to; theſe things are not made in this ſeparate and uſeleſs ſtate in the element to which they naturally belong, much leſs in a foreign one.

Their very ſubſtance and place alſo evince plainly, that they were not formed where they are now depoſited; for they are uſually lodged in *ſtone*, and *ſtones* contain not the matter of which they are made; and as to their place, they muſt be ſuppoſed to have been lodged there either when formed, which proves our aſſertion, or elſe they muſt have been at ſome time either generated all of a ſudden there, or have grown from a ſmall origin, encreaſing by little and little, as the animal ſubſtances which they imitate do. Now if the *ſtone*, in which they lie, was formed before them, and they were formed all of a ſudden in it, how came the cavity there juſt correſponding to their ſize? and if they grew by little and little, how could they force a cavity in the *ſtone*, without burſting or cracking it?

Things that grow, expanding themſelves leiſurely and ſlowly, may indeed by degrees lift up great weights, and dilate the chinks or cracks of *ſtones*; but then they are ſubject to various contortions and alterations in their ſhape, as we daily ſee in the roots of trees, which make their way through the cracks of *ſtones*, and in common plants, whoſe roots meet with hard matter in their way, receding from the form they would have in a looſe open ſoil, and conforming to that of the body that ſtands in their way: thus, if foſſile ſhells and teeth were generated, and grew in *ſtone*, they muſt be liable to contortions and alterations in their ſhape and figure, from the ſhape of the cavities they found, or the hardneſs of the different matter they meet with in their progreſs; but nothing of this kind appears, and it is plain they were generated elſewhere, and then buried in the ſtrata of our fields, becauſe they are all of the ſame exact and regular ſhape, whether found looſe on the ploughed lands, buried in clay or marl, or lodged in beds of marble, or hard *ſtone*. All of the ſame ſpecies are, in theſe ſeveral matrixes, of the ſame exact form; whence it evidently appears, not only that they were not produced where they are now found, but even that the ſtrata were not hardened at the time when they received them.

It is alſo no ſmall proof of theſe teeth being of marine or animal origin; that they are not regularly ſhaped at the baſe, but are all broken, and that in various manners; which proves very plainly, that there has been no vegetation in the caſe, becauſe in all other figured foſſils it is obſerved, that they are never found mutilous, or imperfect. It cannot, with any ſhew of reaſon, be ſuppoſed, that theſe teeth were thus broken within the body of the *ſtone* where they now lie, but is plain that they were lodged in the *ſtone* at a time when it was ſoft, and were before that broken off from the jaw of the creature in this irregular manner.

It is likewiſe no weak argument, that theſe bodies are not formed at this time in the *ſtone*, that they are all found perfectly alike; for were they continually encreaſing, either in ſize or number, it is probable that the new-formed ones would be ſome way different from thoſe which were of older date; nor can any thing be more abſurd, than to think that were they mere *ſtones*, they would have been formed as we ſee they are, not only with the external ſhape and appearance, but with the whole inner ſtructure of teeth; theſe foſſile teeth being not like *ſtones*, one homogeneous body, but compounded of various parts of a different conſtitution, there muſt, in the formation of it, have been made a various election of humors; one for the root, another for the inner part, and a third for the enamel, or ſuperficial coat. The variety of ſpecies in the gloſſopetræ alone may evince, that they have belonged to the animal we attribute them to, ſince they are of extremely different kinds; ſome being ſtrait, ſome crooked, ſome bent inwards, ſome outwards, ſome to one, and others to the other ſide, ſome plain, others ſerrated at their edges, others undulated, and others beſet all about with ſmaller teeth, and ſome ſtrait and flatted, or cylindrical, others triangular, ſome plain, and others tricuſpidate, or having a ſmall point on each ſide the great one, or main body of the tooth; and all theſe varieties, and no more than theſe, are found in the teeth of ſharks of various kinds, and at various ages, and in the different parts of the mouth. The firſt row of teeth in theſe animals hanging out of the mouth, bend forward and downward, the ſecond row are ſtrait, eſpecially towards the ſides of the mouth, where they are triangular and broad, and the other rows bend downward toward the inner part of the mouth. *Columna*, de Gloſſopetra.

If the *formed ſtones* be original productions of nature, merely reſembling theſe marine bodies in form, why are we to ſuppoſe that nature ſtopt here, or confined her formations of this ſort merely to the reſemblance of fiſhes, and parts of them? why might not other natural bodies as well be imitated, and *formed ſtones* found in the ſhape of the horns and hoofs of animals? for if we deny them their origin from animals, is it yet explained how, or in what manner they are formed? They cannot ſhoot in the manner of ſalts, ſince then the ſeveral ſpecies, which are of the ſame ſubſtance, ought to be alſo of the ſame ſhape, which is not found to be the caſe; but, on the contrary, we meet with the ſame ſpecies of ſhell in ſeveral kinds of matter, and compoſed of every various ſpecies of *ſtone*; nay, and of the pyrites, a ſalino-ſulphureous matter, wholly different from common *ſtone*, and which could not, by any principle in nature, be made to ſhoot as a ſalt into the ſame form with ſo different a ſubſtance as limeſtone; whereas, if, as we obſerve, theſe bodies are really formed from ſhells, *&c.* they muſt retain the forms of thoſe bodies, of whatever foſſile matter they be compoſed; neither could it be ſuppoſed, that if a ſalt ſhould ſhoot into the figure of a ſhell, it ſhould alſo ſhoot into all the natural differences of the upper and under valve in bivalves, the one hollow, the other flat, as is neceſſary in many ſpecies, for the preſervation and well-being of the animal; and as theſe foſſile bodies are found wholly correſponding to the moſt minute particulars of the recent ſhells of the ſame ſpecies, there ſeems no reaſon to doubt their having been actually formed from them.

The perfection of the figures of theſe bodies is a farther proof of their origin from animals which they repreſent, ſince in all cryſtallizations there are many imperfect and mutilated figures, nay more than perfect ones. The hexaedral figure of common cryſtal, the cubes of marcaſites, and the cryſtals of ſalts in chemical operations, are all much more regular and ordinate in themſelves, than the figures of ſcallops, cockles, and other ſea-ſhells; yet in theſe ſimple bodies we find great defects and imperfections; often the top is cut off, and ſometimes one of the ſolid angles; and not unfrequently numbers of theſe concretions are found adhering one to another, and injuring one another's form: ſometimes, alſo, their planes greatly differ from one another in ſize and ſituation, and often they differ, or recede other ways, from their natural and perfect figure. Since this is the caſe in the cryſtallizations of bodies of ſo ſimple a figure as cubes and columns, terminated by pyramids, how much greater muſt have naturally been the varieties and imperfections, in ſuch variouſly figured bodies as the *formed ſtones*, which reſemble the ſhells of ſea-fiſhes, had they been formed like theſe by mere cryſtallization? but no ſuch defects or irregularities appear in theſe.

As there are, therefore, none of thoſe defects in theſe compound bodies, to which other much more ſimple ones are found ſubject, and that there are no irregularities obſerved in them, the like of which are not alſo found in the living animals which they repreſent; and as in whatever country they are found, and in whatever matter they are lodged, and whatever ſubſtance they are compoſed of, they are ever found alike among themſelves, and perfectly reſembling the parts of animals, it is not to be conceived that they ſhould have ſhot into theſe forms merely in the manner of ſalts, but evident that they were parts of animals; the ſimilitude of conformation in their pores, their ſtriæ, hinges, teeth, prominences, *&c.* neceſſarily inferring a ſimilitude of original, and being a ſtrong argument of the government of ſome principle ſuperior to matter figured and moved in their formations. Nor is it any ſmall argument againſt their ariſing from the ſhooting of ſalts, that in all the experiments made with the different ſalts and minerals by chemiſtry, no one ſimilar cryſtallization, no reſemblance indeed, even to the meaneſt of them, was ever produced. *Steno*, de Solido intra Solidum.

To all this it may alſo be added, as an unanſwerable proof of the foſſile ſhells having been once marine, and having lived in the ſea, that they are found with injuries which could have been no way elſe received. The purpura, and ſome other ſhell-fiſhes, have bony tongues, with which they bore regular holes through the ſhells of ſhell-fiſh of other kinds, in order to make their way in, and prey upon their fleſh. Theſe holes are always eaſily known by their regularity and ſhape; and ſhells bored through in this manner are not only frequent on our ſhores, but there are ſuch alſo found foſſile, bedded in the ſtrata of earth or *ſtone*; and ſurely, if ſalts could be allowed to have ſhot into the figures of ſea-ſhells, they could never be ſuppoſed able to ſhoot into the figures of ſuch wounds, as a few of thoſe ſhells have received in their recent ſtate from other animals.

The general opinion is, that the deluge brought all theſe ſhells into the places where we ſee them; but this ſeems not eaſily conceived; and as there is no argument ſo good, but that being carried too far it will make againſt its purpoſe, ſo the laying too much to the effects of the general deluge, has made many believe it has done nothing at all.

Theſe *formed ſtones* and real ſhells are both found in vaſt ſtrata on the tops of the higheſt mountains, the Alps, Apennines, and others in different parts of the world. The deluge laſted only ten months, and probably the tops of mountains were not covered half that time; and theſe immenſe quantities of ſhells cannot be ſuppoſed either to have bred there in that time, or to have been carried ſo high in ſuch prodigious numbers. It is more probable that theſe tops of mountains were once not ſuch, but bottoms of the ſea. The hiſtory of the marine bodies they contain is then very plain, and earthquakes may have raiſed them, or they may indeed not be ſo high above the level of the ſea, as we at firſt ſight ſuppoſe. If indeed we ſtick to the letter of the text, in the ſcripture hiſtory of the creation, we can find no account for theſe bodies from that time; for if the creation of fiſhes ſucceeded the ſeparation of the land from the water in all parts of the globe, they could not be then depoſited there; but it is poſſible, that at the creation the whole earth was not all at once uncovered, but only thoſe parts where Adam and the animals were created, and the reſt gradually afterwards, perhaps not in many years, as there ſeems no neceſſity of underſtanding the account of the creation to have been in ſix natural days. If we may thus underſtand, and conjecture in this reſpect, it is not difficult to conceive, that during the years in which the earth remained covered with ſea-water, ſhell-fiſh might breed and multiply abundantly all over its bottom; and this bottom being afterwards elevated, deſerted by the ſea, and made dry land, theſe ſhells muſt be elevated with it, and retained in thoſe ſtrata, which afterwards hardened into the various kinds of earth and *ſtone*: and ſomething of this kind ſeems to have been the caſe, much rather than, according to Dr. Woodward, that all *ſtony* matter ſhould have been diſſolved by the deluge, and afterwards have concreted again. *Ray*'s Phyſicotheological Diſcourſes.

Solution and colours of STONES. The various beauties of the form and colour of the ſeveral more precious *ſtones*, cannot but have been always the admiration of the curious part of the world, and the wits of the ableſt chemiſts have been tried, in attempting to counterfeit them; and much may be gathered even from their attempts, which have not ſucceeded, toward the learning the true nature and hiſtory of theſe beautiful bodies.

The beautiful figures of the Florentine marble, whoſe veins repreſent trees, rivers, and ruins of buildings, are well known; as are alſo the delineations of trees and ſhrubs in thoſe ſpecies of white agates, called *Mocoa ſtones*. All the *ſtones* of this kind are natural, for art has not yet been able to come up to any counterfeit of them; but it is not ſo in regard to thoſe agates which repreſent regular figures of beaſts, *&c.* theſe are all aſſiſted by art, and that by a very ſimple and eaſy proceſs; and Mr. Du Fay, in the Memoirs of the Paris Academy, has given at one view the ſeveral ways, then known, to penetrate into the ſubſtance of agate, marble, *&c.* and to lodge figures in them.

The *ſtones* ſubject to be tinged he divides into two claſſes, the harder and the ſofter. Of the harder kind are thoſe which reſiſt the force of acids, even of the moſt powerful kind; and of this claſs are agates, onyxes, and all that are vulgarly comprehended under the general name of the gems, or precious *ſtones*, with cryſtal, porphyry, granite. Theſe, and the like *ſtones*, are not ſoluble in any of the known acids, yet theſe ſame acids, impregnated with the ſolutions

of metals, are capable of penetrating very deeply into them, and tinging them with different colours. The ſimple agates and jaſpers, and other *ſtones* of the like uniform ſtructure, are eaſily coloured in an uniform manner; but thoſe which are variegated with veins are compoſed of ſeveral different ſorts of matter, and therefore are leſs eaſily, and leſs evenly ſtained. As the tinging matter does not penetrate the ſeveral beds, or veins, in the ſame manner, therefore all that can be done to theſe, is to add ſpots and veins to their natural ones, but they cannot be tinged throughout to one uniform colour, as the chalcedony, or white agate may.

If a ſmall quantity of a ſolution of ſilver, in ſpirit of nitre, be poured upon one of theſe agates, and the *ſtone* expoſed to the ſun, it will in a few hours be tinged to a reddiſh brown colour; and if more of the ſame ſolution be added, and it be again expoſed, the colour will become ſtronger, and will penetrate deeper into the body of the *ſtone*; and if the *ſtone* be not too thick, and the ſolution be rubbed on both ſides, it will tinge it throughout. Nor is this all the effect, for it will give it ſeveral veins and lineations, which were not diſtinguiſhable in it before; the reaſon of which is, that in all theſe *ſtones* there are ſome parts harder than the reſt, and conſequently more difficultly coloured, and theſe remaining, therefore, paler than the reſt of the maſs, make the lines and veins in it.

If there be added to the ſolution of ſilver, uſed for this purpoſe, a fourth part of its quantity of ſoot, and as much ſalt of tartar, the colour becomes grey; and if, inſtead of this ſoot and tartar, the ſame quantity of plumoſe alum be uſed, the *ſtone* will be tinged to a deep violet colour, tending to black.

A ſolution of gold gives agate only a pale brown colour, and that penetrates but a little way into it; and a ſolution of biſmuth gives a colour, which appears white when the light falls directly upon it, but brown when it is held againſt the ſunſhine, or a candle; and all the metallic and mineral ſolutions, employed in the ſame manner, affect the *ſtone* more or leſs in the ſame way.

The expoſing the *ſtones* to the ſun is a very neceſſary article in the proceſs, ſince without that the tinge is but very faint, and penetrates but to a very little depth. To trace in the chalcedony, or white agate, figures of any determinate kind, the uſual method is this: before the agate is poliſhed, mark out the intended figure with the point of a fine needle, and afterwards with a bruſh, or a pen, follow thoſe lines with a very ſtrong ſolution of ſilver. One would imagine that the dendritæ, or delineations of trees in Mocoa *ſtones*, might be imitated in this manner; but it is difficult to give the due blackneſs of colour, and to mark the figures with a like preciſion and exactneſs. If any *ſtone* ſhould, however, be ſuſpected to be adulterated, or counterfeited in this manner, it is eaſily brought to the trial; for if it be thus made, a ſmall heat over the fire will almoſt entirely diveſt it of its colour, and the rubbing a little ſpirit of nitre, or aqua fortis over it, will have the ſame effect. In both caſes the *ſtone* may, however, be reſtored again to its beauty; in the firſt, by tinging it afreſh with the ſame liquor, and in the laſt, by only expoſing it for ſeveral days to the ſun.

It is well known, that by means of fire alone the amethyſt, the ſapphire, and the other gems, may alſo be wholly diveſted of their beautiful colours. The method of doing this, is, to put the gems into a crucible, ſurrounding them with ſand, or with ſteel filings; then putting them into the fire, they loſe their colour as they become hot, and are taken out wholly colourleſs. If the white agate be calcined in this manner alone, it becomes of a cloudy or opake white; but if it has before been ſtained with the ſolution of ſilver, thoſe ſpots or ſtains become of a yellow colour, which aqua fortis afterwards has no power to take away. If the agate be calcined firſt, and afterwards rubbed over with the ſolution of ſilver, it receives ſome ſpots and lines of brown. The cornelian loſes a great part of its redneſs by calcination, and becomes of a duſky fleſh-coloured white; and the Mocoa *ſtone*, treated in the ſame manner, loſes all its colour, and the delineations of trees diſappear.

There are many *ſtones* on which the ſolution of ſilver has no effect; of this number are all the gems, rock cryſtal, and the like. The dendrites of Catalonia is alſo of this kind; and of this *ſtone* the artificers relate an odd phænomenon, which is, that if it be ſawn aſunder there are very few delineations obſerved in it, but if it be ſplit by a blow, it is uſually found full of them. The reaſon of this is only that theſe delineations are ſo many flaws and cracks, and the *ſtone* breaks eaſieſt in theſe places.

The effects of the ſolution of ſilver are different, as to degree of colour, on different *ſtones*. The Oriental agate receives from it a deeper and blacker tinge than the common chalcedony. Some agates, naturally diſtinguiſhed by their yellow ſpots, receive a purple colour from it. The jade *ſtone*, uſed by the Turks, takes only a faint tinge of brown. The common prime emerald, or root of the emerald, becomes blackiſh with it. The Oriental granite is tinged in many places with a violet colour by it; this is principally effected in the white parts. The ſolution does not act much on the black ones, only that it takes ſome of them away. The ſerpentine marble receives an olive colour from it; but it is remarkable that the amianthuſes, and the talcs, and other foliaceous *ſtones*, are wholly unaffected by it.

Marble being a ſubſtance greatly ſofter than agate, receives the colours with much greater eaſe, and the doing this in an accurate manner has been the ſubject of the attempts of many eminent men. Kircher has given ſome directions for the ſtaining marble, which have been tranſlated word for word into the Philoſophical Tranſactions; but they are ſo indeterminate and uncertain, that nothing can in reality be learned from them. Many others have written alſo on the ſame ſubject, but Mr. Du Fay is the only one whoſe experiments are plainly and clearly laid down, and may be followed by any body.

This gentleman choſe the common white marble without veins for making his experiments, for the ſame reaſon that he choſe the plain agates, becauſe in the veined ones there are ſeveral different ſorts of matter, all of which are not to be penetrated with equal eaſe. The ſolution of ſilver penetrates into marble to the depth of an inch, or more, and gives a tinge, reddiſh or purple, at firſt, and afterwards brown, from which colour it never varies afterwards. It always takes off the poliſh of the marble, eating away a part of its ſurface. The ſolution of gold does not penetrate ſo deep into marble as that of ſilver, but it gives a beautiful violet colour. Both theſe operations are much aſſiſted by expoſing the marble to the ſun. The liquors uſually diffuſe themſelves, and ſpread every way in the marble, ſo that it is not eaſy to make any figure with them that ſhall keep its outline tolerably regular.

The ſolution of copper gives marble a beautiful green tinge, but it does not penetrate deep, and on the application of boiling water becomes black; when the ſurface is poliſhed off afterwards, however, it becomes again of a beautiful green. Beſide the powerful acid menſtruums, there are many other liquors which have a power of penetrating deep into marble. Of this nature are all the oily fluids; but the expreſſed oils have this diſadvantage, that they leave a fattineſs in the marble which will not ſuffer it afterwards to take a good poliſh. All ſubſtances which can penetrate marble, can carry colours into it; but ſuch are moſt eligible, which having lodged the colours evaporate, and leave them there, without injuring the *ſtone*. Spirit of wine is of this number; it is excellently qualified for the extracting beautiful tinctures, and ſinks them very deep. Oil of turpentine alſo has its value, but it does not take tinges ſo well as the ſpirit. Some have recommended lixiviums of the fixt alkaline ſalts, but they very rarely produce any beautiful colour. In the uſing theſe fluids the marble is to be gently heated, and the ſpirit is by that means evaporated before it is cooled, leaving its colour always behind. White wax penetrates very deep into hot marble, and conveys colours into it in a very beautiful and determinate manner. There are however but a few bodies, which will impart their colours to wax, and therefore this valuable means is of a very limited uſe.

Several of the gums alone are alſo able to tinge marble very ſtrongly. Dragons blood, and gamboge, if rubbed on hot marble, penetrate it to the depth of about a twelfth of an inch: the gamboge requires the marble to be hotter than the other, and tinges it to a very beautiful yellow; the dragons blood tinges to a red in different degrees, according to the heat of the marble.

If theſe gums have been uſed to poliſhed marble, there is no farther caution neceſſary, than the cleaning them off from the ſurface with a little ſpirit of wine: but the way to make them ſink deeper into the *ſtone*, is to take off the poliſh by rubbing the ſurface with pumice, or the like, and then the gums ſink much farther, and the colours appear very beautiful when the marble is poliſhed again.

Though theſe gums act alone, yet they will ſucceed much better if diſſolved in ſpirit of wine, and applied with a pencil; for by this means they ſink deeper in, and the figures traced out will keep their determinate form and outlines, theſe ſolutions fixing immediately, without ſpreading any way. It is alſo remarkable, that the ſolution of dragons blood hardens the marble, and renders it leſs ſoluble in acids than before; ſo that if a piece, ſtained in part with this ſolution, be afterwards rubbed over with an acid diſſolvent, and its ſurface eaten away to ſome depth, the parts which are coloured will all ſtand out above the reſt.

A tincture of Braſil wood in ſpirit of wine tinges marble red, and if the heat given to the marble be greater, it becomes purple; but both theſe colours fade a little in keeping. A tincture of cochineal gives a purpliſh red, and the more the marble is heated, the farther the colour penetrates, and the deeper it is. In oil of turpentine the colour of cochineal penetrates much deeper into the marble, but it has a browniſh caſt. Alkanet root, by means of ſpirit of wine, gives alſo a red colour, which, if the heat be too great, changes to brown; and this, and moſt other of the like matters, tinge the marble, in tincture with ſpirit, to a ſlight depth; and in oil of turpentine they ſink much deeper, but then the oil leaves a greaſy look upon the marble.

If verdigreaſe be boiled a conſiderable time in white wax, it tinges marble, when rubbed hot upon it, to a beautiful green, little inferior to that of the coarſer emeralds, and the colour ſpreads itſelf very equally, and penetrates to a third of an inch deep; if the marble be made too hot, the colour becomes that of the jade *ſtone*. Alkanet boiled in white wax gives a fleſh colour, which penetrates very deep; and the roucou boiled in wax makes a permanent yellow, which alſo ſinks very deep. The beſt way of heating marble for this purpoſe, is to lay the piece, intended to be ſtained, upon a bed of ſand, a fifth of an inch deep, upon an iron plate; this is to be ſet over the fire, and when of a proper degree of heat, the colour is to be applied. The juſt degree can only be found by experience, and it varies indeed in almoſt every colour; but in general, the finer colours require the marble to be of ſuch a heat, that the hand can juſt bear to be laid upon it, and the others require a ſomething greater degree than this.

Black is, of all colours, the moſt difficult to give in this manner to marble; and perhaps indeed it is impoſſible to give that colour in any degree of perfection, and that for this plain reaſon, that all theſe colours only fill the interſtices between the granules of the marble, thoſe granules themſelves remaining unaltered: thus, in the other colours, the whiteneſs of the granules is only a heightning to the tinge, making it brighter, and a little paler; but the whiteneſs can never fail to appear diſtinguiſhably as ſuch in black, and by that means deſtroy that colour.

Next to black, blue ſeems the moſt difficult, of all the colours, to give to marble. Mr. Du Fay, however, having found by Mr. Geoffroy's experiments, that oil of thyme, by long ſtanding with ſpirit of ſal armoniac, acquired a blue colour, tried this mixture, and found it ſucceed very beautifully. But this is one of thoſe colours which require the marble to have but a very ſmall degree of heat, ſince a greater would evaporate them before the colour had time to penetrate. The colours of the gums may be laid on when the marble is cold, and on heating it afterwards they will ſink into it.

There is another very elegant ſort of workmanſhip to be employed on marble, that is, the tracing figures in relief in it; and this is done much more eaſily than might be imagined, there being nothing more required to it, than the ſaving the parts which are to be left in relief, by covering them with a varniſh, and eating away the reſt by means of an acid. For this purpoſe let the deſigned figures be traced in chalk upon the marble, and cover them with a bed of varniſh, made by diſſolving a piece of common red ſealing-wax in ſpirit of wine; then pour on the marble a mixture of equal parts of ſpirit of ſalt and diſtilled vinegar, and this will eat down all the ground, and leave the figures ſtanding, as if engraved with immenſe trouble. The adding the colours, before deſcribed, to theſe marbles afterward, in a regular manner, will give them a ſurpriſing beauty. Mem. Acad. Par. 1728.

Electrical attraction of STONES. Many *ſtones* have been obſerved by Dr. Liſter to have a ſort of *electrical attraction* to vegetable reſins.

This author obſerves, that having placed ſome foſſils in a cabinet made of Barbadoes cedar, and examining them at ſome diſtance of time, he found them all covered with a liquid reſin like Venice turpentine. Many of the *ſtones* were wrapt up in papers, yet theſe, as well as the reſt, were covered with this reſin; though, upon the moſt diligent ſearch, there could not be found any exſudation on any part of the cabinet. The iron ores were moſt of all covered with reſin, all the kinds of the hæmatites being thick coated with it; and among the aſtroitæ ſome were thinly covered, and others perfectly free from it.

It was not owing to the texture and denſity of the *ſtones*, that they either eſcaped this, or had it, but thoſe of the moſt open grain, and thoſe of the cloſeſt, were indifferently covered with it. It is certain from this ſingular obſervation, that the whole body of the turpentine of the cedar wood was carried up into the air, and floating in it was again condenſed, on the coming into contact with certain *ſtones*, tho' not with others.

There are ſeveral vegetable ſubſtances, which in this manner emit their whole body into the air: of the number of theſe is camphor; but the *ſtone*, that will again condenſate this into camphor, is not known. Philoſoph. Tranſact. N° 110.

Formation of STONES. See LITHOGENESIA.

Medical STONES, a term uſed by ſome to expreſs thoſe particular *ſtones*, which for their real or imaginary virtues have, at one time or other, been made ingredients in medicinal preparations.

The opinions of the antients, in regard to the virtues of gems and precious *ſtones*, were very whimſical; they ſuppoſed that they had certain ſympathetic properties, and that the wearing them on the finger, or carrying them in the pocket, would cure diſeaſes, render the Gods propitious to their prayers, or ſave them from thunder. Theſe have been deſervedly laughed out of the world in our more enlightened times; but it has remained a queſtion, and does ſo even to this time, whether or not ſome of the gems have real medical virtues, naturally reſulting from their parts, and conſtituent matter. It appears from the preſent ſtate of the gems, that they were once fluid bodies, or, at leaſt, made up in part of ſuch ſubſtances as were once fluid; and as in this ſtate they were capable of receiving metalline admixtures, it is poſſible they may derive certain virtues from thoſe admixtures; and ſome concurrent circumſtances in that mixture may have exalted the virtues of the bodies received, beyond what they could naturally and ſingly have excited.

The diaphaneiety, the external figure, and the internal ſtructure of gems, all argue ſtrongly for their having once been in a fluid ſtate; and their colours, which ſeem to be evidently adventitious, and imparted either by ſome coloured mineral juice, or ſome tinged exhalation, could have ſo deeply affected the denſe texture of theſe *ſtones*, as to paſs through all their parts in no other manner, than when that *ſtone* was in *ſolutis principiis*, or in a fluid ſtate.

There are ſometimes found extraneous matters lodged in the bodies of the gems themſelves, which could only have been enveloped in them in this manner while they were ſoft; and even in moſt of them, the art of the chemiſt is able to diſcover real particles of metals, which muſt have been mixed in their ſubſtance at ſuch a time, and to which they may very probably be indebted for real virtues.

Rubies, when too ſmall to be of value as gems, are in ſome places, where they make a ſort of ſand in the rivers, worked to ſome advantage as ores of gold. The amethyſt evidently contains iron, and the emerald copper; why ſhould it then be ſuppoſed impoſſible, that the virtues of theſe metals may be found in the gems which contain themſelves, and that in ſo pure and fine a ſtate, as no chemical proceſs can afford them in? The weight of many of the coloured gems is much greater than could be expected in *ſtones* of that hardneſs and conſiſtence, and is plainly owing to the admixtures of the metalline particles of the various ſorts they contain.

Mr. Boyle's opinion of the origin of the real virtues of the gems, is, that while the petreſcent matter was yet in a fluid ſtate, the mineral matter was received into, and intimately mixed with it, ſo as that the whole became but one *ſtone*; and that the virtues are always ſuch, as may be derived from the impregnating metal or mineral, and are various in degree, according to the various ſtates of the metal, and its quantity received into the compoſition.

If this ſyſtem holds good as to the gems, it will be much more naturally applicable to the ſemipellucid *ſtones*; many of which have gravities ſo great, as plainly to denote the metalline or mineral matter that makes a part of them. The metalline ſubſtances, that may be ſeparated out of theſe *ſtones*, give great proof of the truth of this ſyſtem: thus the hæmatites contain a very large quantity of iron, and the lapis lazuli, and turquoiſe *ſtone*, contain very large quantities of copper; and many of the jaſpers hold no inconſiderable portion of the ſame metal. *Boyle* of the Origin and Virtues of Gems.

STONE *for building*. Care muſt be taken to dig *ſtone* at the proper ſeaſon; for that *ſtone* which, taken out of the quarry at one time, would ſoon moulder away, will at another ſeaſon endure the weather for many years, if not ages. *Boyle*'s Works Abr. Vol. I. p. 111.

Bolonian STONE. See LAPIS *Bononienſis*.

Chalk STONES. See CHALK.

Chick STONE. See CICERUM *lapis*.

Copperas STONE. See LAPIS *atramentarius*.

Eft STONES. See EFT.

Figured STONES. See FIGURED *ſtones*.

Fleſh STONE. See SARCITES.

Free STONE. See FREE *ſtone*.

Gypſine STONE. See GYPSINE.

Horn STONE. See LAPIS *corneus*.

Moor STONE. See MOOR.

Oil of STONES. See OIL *of ſtones*.

Shoad STONES, among the miners of Cornwall. See the article SHOAD *ſtones*.

Staining of STONES. See STAINING.

STONE, in commerce. The *ſtone troy*, in Scotland, contains ſixteen pounds, the pound being two marks, or ſixteen ounces. Tr. Pract. Geom. p. 153. See POUND.

STONE-*braſh*, in agriculture, is a light lean ſoil, full of larger and ſmaller maſſes of rubble *ſtones*.

Theſe are to be tilled according to the condition in which they are found, for if they are graſſy they fallow them pretty late; but if they have no graſs upon them, they fold them in winter, when the ſheep's dung, with the help of ſome hay-ſeed, will furniſh them with graſs: or elſe, early in the ſpring they lay upon them old thatch or ſtraw, or the ſtrawy part of old dunghills, earth out of ditches, or the like, which will all, more or leſs, help forward a coat of graſs upon the land; for it is a rule in regard to theſe lands, that they muſt have a covering of graſs before they are fallowed, elſe they will yield but a poor crop. *Plot*'s Oxfordſhire, p. 247. See STONY *land*, infra.

STONE-*chatter*, in zoology, the name of a ſmall bird of the *œnanthe*, or fallow-finch kind, called by ſome authors *rubetra* and *muſcicapia*, and in ſome places the *ſtone-ſmich*, and the *moor-titling*.

It is about the ſize of the common linnet. Its beak is longiſh, ſtrait, and ſharp, and is black, as is alſo its mouth within. Its head is large, and in the male is black almoſt all over, as is alſo the upper part of the throat; but in the female theſe parts are variegated with black and brown. The neck is black, and marked on each ſide with a white ſpot, the two ſeen together looking ſomewhat like a white ring. The middle of its back is alſo black, but the extremities of the feathers are yellowiſh. It has a white ſpot juſt above the rump. Its breaſt is of a ſomewhat reddiſh yellow, and its belly white, with a faint caſt of red. In the female, the feathers of the back and neck are of a ſomewhat greeniſh tawny, with black middles; the upper part of the throat is grey, and the breaſt red. It is common on heaths, and makes a very loud, and often repeated noiſe. *Ray*'s Ornitholog. p. 169.

STONE-*curlew*, in zoology, the Engliſh name for the *œdicnemus*, a bird of the colour of the curlew. See the article ŒDICNEMUS.

STONE-*phoſphorus*. See LITHOPHOSPHORUS.

STONE-*plant*. See LITHOPHYTON.

STONE-*ſmich*, a common Engliſh name for that ſpecies of œnanthe, which we more frequently call the *ſtone-chatter*. See the article STONE-*chatter*.

STONE-*ſucker*, in zoology. See PETROMYZON.

STONY *land*. The farmers expreſs by this term two ſorts of land, the one full of large flints and pebbles, and the other full of fragments of free *ſtone*, or other coarſe *ſtones*.

Theſe lands in many places yield good crops, and the general rule is, that in ſtiff and cold lands the *ſtones* ſhould be as carefully picked out as may be, but in light and dry grounds they ſhould be left. In Oxfordſhire they have great quantities of a lean earth, and a ſmall rubble-*ſtone*, or a ſower ſort of land mixed with it; this is ſometimes very full of weeds, and ſometimes very clear of them: if they are weedy they fallow them late, but if they be ſeary, as they expreſs it, that is, if they have no ſwerd upon them, they either fold them in winter, and add ſome hay-ſeed to the ſheep's dung, to bring up graſs, or elſe they lay old thatch or ſtraw, and dung upon it; for they reckon, that if theſe lands have no ſwerd upon them before they are fallowed, they will by no means be brought to bear a good crop, but a great deal of May-weed, and other unprofitable herbs. In September, November, and December, they fallow as the ſwerd directs them: if this is done in either of the two laſt months, they call it a winter fallowing, and never ſtir it again till they plow it, and ſow it with barley; and theſe lands are reckoned to do better than if finely tilled. They will bear wheat and meſlin in a kindly year, and large crops of barley, if they are well managed, and kept in good heart.

They always fallow theſe lands every other year, unleſs they ſow peaſe upon them; ſometimes they ſow them with lentils; and when they are quite worn out, they lay them down for clover, or rey-graſs. *Mortimer*'s Huſbandry, p. 71.

STOOL (*Cycl.*)—STOOL, in mining, is uſed when the miners leave digging deeper, and work in the ends forward. The end before them is called the *ſtool*. *Houghton*'s Compl. Miner in the Explan. of the Terms.

Bloody STOOLS, in medicine. The ſpirit of vitriol, mixed with the patient's drink, has often been found beneficial in cures of *bloody ſtools*.

Retention of the firſt STOOLS, in infants. See INFANT.

STOP, in the manege, is a pauſe, or diſcontinuation of going. In order to *ſtop* a horſe, the rider ſhould, in the firſt place, bring to the calves of his legs, to animate the horſe, then bending his body backwards, raiſe the bridle-hand, without moving the elbow; then vigorouſly extend the hams, and reſt upon the ſtirrups, to make him form the times or motions of his *ſtop*, in falcading with his haunches three or four times. You ſhould not form the *ſtops* of your horſe ſhort and precipitate, leſt you ſpoil his hams and mouth. After *ſtopping*, a horſe ſhould be made to make two or three corvets.

The oppoſite term to *ſtop* is *parting*. In former times, the *ſtop* of a horſe was called *parade*. See the articles RAISE and NAILS.

Half a STOP, is a *ſtop* not finiſhed by a *peſate*; ſo that the horſe, after falcading three or four times upon the haunches, reſumes and continues his gallop, without making *peſates*, or *corvets*. See the articles PESATE, CORVET, &c.

STOP, at ſea, a word uſed by him that holds the half-minute glaſs, in heaving the log; for immediately when the glaſs is out, he calls *ſtop* to them that let run the line. See the article STOPPING.

STOPPAROLA, in zoology, the name of a bird of the lark kind, deſcribed by Aldrovandus, and ſuppoſed by Mr. Ray to be the ſame with the *ſpipoletta*, or the *tordino* of the Venetians. See the article SPIPOLETTA.

STOPPER, in a ſhip, a piece of rope having a wale-knot at one end, with a lannier ſpliced into it, and at the other end made faſt in the place where it is to be uſed. Its uſe is to ſtop the main-halliards, or the cable. The *ſtopper* for the halliards is faſtened at the main-knight, and it ſerves, when they are hoiſing the main-yard, to ſtop it, that it don't run out too faſt. They bind the wale-knot about the cable with the lanniers, and that ſtops it, ſo that it cannot ſlip away. This *ſtopper* is faſtened to the bottom of the bits by the deck. The word is, *lay on the ſtoppers*; and a ſhip is ſaid to ride by the *ſtoppers*, when the cable is faſtened, or tied only by them, and not bitted; but this is not ſafe riding in a ſtreſs of weather.

STOPPING (*Cycl.*)—STOPPPING *a leak*, at ſea. See LEAK.

STOPPING *a ſhip*, at ſea. When a ſhip comes to an anchor, and the cable is veered out by degrees till the ſhip is found to ride well, and then ſtopped, it is called *ſtopping the ſhip*.

STORAX (*Cycl.*)—The writers of the middle ages have greatly perplexed the hiſtory of this drug in general.

The true ſtate of the caſe is this; all authors, of all times, have deſcribed at leaſt two kinds of *ſtorax*, a dry and a liquid kind. The Arabians and Greeks have both joined to call the dry kind *calamita*; but neither the origin of that epithet, nor its true ſignification, have been conſidered as they ought.

The *ſtorax ſicca*, or *calamita* of the Arabians, was the worſt of all the kinds of *ſtorax*; it was only the refuſe, after making the artificial liquid kind.

They ſometimes boiled the fruit of this tree, and ſometimes its bark, and out of both extracted a liquid *ſtorax*; and the remainder of both was ſaved under the name of *dry*, or *calamite ſtorax*. It is no wonder, therefore, that the *calamite ſtorax* of the Arabians was the worſt of all the kinds; and as ſuch the term is always to be underſtood, when met with in the works of the Arabians.

On the other hand, when the Greeks would expreſs the very beſt and fineſt *ſtorax*, they always do it by the term *calamite ſtorax*. The two kinds of *ſtorax* they mention, are the reddiſh and the black. The latter was foul, and much leſs in eſteem. The former was the fine pure *ſtorax*, naturally exſudating from the tree. This they ſometimes called *calamite*, becauſe in the form of pieces of reed.

The common opinion, in regard to this word, is, that it was an epithet given to the fineſt *ſtorax*, from its being put into reeds to be brought over with ſafety: but this was not the caſe. The fineſt of all *ſtorax*, was that which voluntarily exſudated from the tender twigs, and young ſhoots of the tree: this ſometimes coated over the whole twigs for an inch or two in length, and reſembled a reed, or other hollow cylindric body, drawn on over the twig. This was the origin of the name *calamite*, or reed-like *ſtorax*, given to this which was of the red *ſtorax* kind, but finer than that of the trunk or larger branches, and approaching to a yellowiſh hue.

Pliny gives even a ſtricter account of the name than this: he ſays, and that from the authority of authors of repute, that the *ſtorax*-tree being very ſweet taſted, and very ſoft in the young wood, worms were very apt to get into the ſhoots; and that when they did ſo, they would eat away all the woody matter, and leave only the bark. The *ſtorax*, extravaſated by theſe punctures, uſed to coat over theſe tubes, and they then exactly reſembled pieces of reed artificially covered with ſome gum.

According to this account, the name *calamita* was extremely appoſite to that *ſtorax*, and it had as much title to the epithet, in all appearance, as the *adarce calamites*, which always gathered about reeds, and was therefore ſometimes ſimply called *calamites*. See ADARCE.

STOREA, among the Romans, a kind of baſket made of ropes or ruſhes, for gathering flowers or garden-fruits. *Pitiſc.* Lex. Ant. in voc.

STOREA was likewiſe a kind of defence, made of large cables faſhioned into a ſort of nettings; which was ſo ſtrong, that no weapon, though thrown out of an engine, could penetrate it. See *Pitiſc.* in voc. and *Cæſ.* Bell. Civ. II. 9.

STORM-*fink*, in zoology, the name of a ſmall bird deſcribed by Hoier, and ſaid to be ſeen principally at ſea, where it is looked on as a foreteller of bad weather.

It is a little larger than the common ſparrow, and is all over of a greyiſh colour. It is very remarkable for its ſkimming very ſwiftly along the ſurface of the water. When large flocks of theſe appear, the mariners know they are to expect a *ſtorm*, and prepare for it. *Ray*'s Ornithol. p. 306.

STORYNE, the name of an inſtrument uſed by the antients for drawing blood from the noſe; but we are not perfectly informed of its ſhape or ſtructure.

STOVE (*Cycl.*)—STOVES, in gardening, are buildings erected for the preſervation of tender exotic plants, which, without that aſſiſtance, will not bear the cold of our winter, becauſe they require an artificial warmth.

Stoves are of two kinds, diſtinguiſhed by the names of the *dry*, and the *bark ſtove*.

The dry *ſtove* has the flues, in which the ſmoak is carried, either laid under the pavement of the floor, or erected in the back part of the houſe over each other, and returned ſix or

eight times all along the *ſtove*. In theſe *ſtoves* the plants are placed on ſcaffolds, and benches of boards, raiſed above one another; and the plants, principally preſerved in theſe, are the aloes, cereuſes, euphorbiums, tithymals, and other ſucculent plants, which are impatient of moiſture in winter, and therefore are not to be kept among trees, or herbaceous plants, which perſpire freely.

The bark *ſtoves* are made with a large pit, nearly of the length of the houſe, which is three feet deep, and ſix or ſeven feet wide. This pit is to be filled with freſh tanner's bark to make a hot-bed, and in this the pots, containing the tender plants, are to be plunged.

This invention of tanner's bark for hot-beds has been of prodigious ſervice to the curious in gardening, as many plants are, by this means, annually preſerved and raiſed, which no other method could have made endure our climate.

The dimenſions of theſe *ſtoves* muſt be wholly directed by the number of plants intended to be preſerved; and for the dry *ſtove*, the floor muſt be raiſed above the ſurface of the earth, more or leſs, according to the dryneſs or wetneſs of the ſoil. In the front there is to be a walk about twenty inches wide, for the convenience of walking. The fire-place may be made either in the middle, or at one end, and the furnace muſt be contrived according to the nature of the fuel which is to be burnt there. The beſt firing, when it can be had, is turff, for it burns longer, and more moderately, than any other fuel, as alſo more uniformly, and therefore requires leſs attendance.

The entrance into the bark *ſtove* ſhould always be either out of a green-houſe, or the dry *ſtove*, or elſe through the ſhed where the fire is made; becauſe in cold weather the front glaſſes muſt not, by any means, be opened, and the top ſhould be covered either with tarpaulins, or ſliding ſhutters, in bad weather.

The tender ſhrubs and exotic plants muſt be plunged in their pots into the bark beds; ſuch are the caſhew, cabbage-tree, cocoa-tree, dumb-cane, fuſtick, logwood, mancinel, papaw-tree, ſour-ſop, and the like; and upon the top of the flues may be ſet the melon, thiſtle, the tender cereuſes, and the like.

The thermometer, by which the heat in the *ſtove* is regulated, muſt always be hung with its back to the ſun, and as far from the flues as may be. The proper ſtructure of theſe ſhelters, for the curious part of the vegetable creation, is to have a green-houſe in the middle, and two *ſtoves*, and a glaſs caſe, at each end. The particular rules for the ſtructure of all theſe, with plans of them, are accurately given by Mr. Miller in his Dictionary. *Miller*'s Gardner's Dictionary.

STOWS, in mining, are ſeven pieces of wood, ſet upon the ſurface of the earth, faſtened together with pins of wood.

STOWING *the hold*. See the article HOLD.

STRAIGHT, (*Cycl.*) in geography. See the article FRETUM.

STRAIGHT, in the manege. To part, or go *ſtraight*, or right out, is to go upon a tread traced in a *ſtraight* line. When you would puſh your horſe forwards, make him part *ſtraight*, without traverſing, or bearing ſidewiſe.

STRAIGHT *membered*, called in French *droit ſur les jambes*. See the article LEG.

STRAIKS, in the military art, are ſtrong plates of iron, ſix in number, fixed with large nails, called *ſtraik-nails*, on the circumference of a cannon wheel, over the joints of the fellows, both to ſtrengthen the wheel, and to ſave the fellows from wearing on hard ways or ſtreets.

STRAKE, in the ſea phraſe, a ſeam between two planks; as the *garboard-ſtrake* is the firſt ſeam next the keel. They ſay alſo a ſhip *heels a ſtrake*; that is, hangs or inclines to one ſide the quantity of a whole plank's breadth.

STRAMONIUM, *thorn-apple*, in botany, the name of a genus of plants, the characters of which are theſe. The flower is of the infundibuliform kind, and conſiſting of one leaf, and divided into ſeveral ſegments at the edge. The piſtil ariſes from the cup, and is fixed, in the manner of a nail, to the hinder part of the flower. This afterwards becomes a fruit of a roundiſh figure, echinated in moſt of the ſpecies, and divided into four cells, containing ſeveral large ſeeds, uſually of a kidney ſhape. The ſeptum, which divides the head or fruit, is of a cruciform ſhape, and has four placentæ, to which the ſeeds adhere.

The ſpecies of *ſtramonium*, enumerated by Mr. Tournefort, are theſe. 1. The round thorny-fruited *ſtramonium* with ſingle white flowers. 2. The round thorny-fruited *ſtramonium* with double white flowers. 3. The round thorny-fruited *ſtramonium* with ſingle violet-coloured flowers. 4. The round thorny-fruited *ſtramonium* with double violet-coloured flowers. 5. The Ægyptian *ſtramonium* with double flowers, white within, and of a violet colour on the outſide. 6. The white-flowered *ſtramonium* with an oblong prickly fruit. 7. The purple-flowered *ſtramonium* with oblong prickly fruit. 8. The violet-flowered *ſtramonium* with oblong prickly fruit. 9. The ſharp long-thorned *ſtramonium*, called by authors *ſtramonium ferox*. 10. The ſmaller American *ſtramonium* with leaves like thoſe of alkekengi. 11. The ſmooth-fruited *ſtramonium* of Malabar with ſingle violet-coloured flowers. 12. The ſmooth-fruited *ſtramonium* of Malabar with double flowers. *Tourn.* Inſt. p. 118.

STRANGALIDES, a word uſed by authors to expreſs hard tumors in women's breaſts, ariſing from coagulations of obſtructed milk after child-birth.

STRANGLES, in the manege, is a collection of foul humors formed in the body of a young colt; which are voided by the noſtrils, or by a ſuppuration of ſome glands or knots, that lie between the bones of the lower jaw, and are crowded with impurities.

The *falſe ſtrangles* happen in old horſes, that have not well caſt the *ſtrangles*.

STRANGULATIO, a word uſed to expreſs that kind of ſuffocation which is common to women in hyſteric diſorders; and for the ſtraitning the inteſtines in hernias.

STRANGULATORIA, in the materia medica, a name by which Avicenna, and ſome other authors, have called the *doronicum*, or leopard's bane. *Ger.* Emac. Ind. 2.

STRANGURY (*Cycl.*)—The vulgar generally underſtand by this word the three ſeveral complaints, called by phyſicians *ſtrangury*, *dyſury*, and *iſchury*; the differences of which are theſe.

The *ſtrangury* is properly and diſtinctly a difficult excretion of urine, which comes away by drops, with a ſenſation of a ſpaſmodic pain about the ſphincter and neck of the bladder.

The *dyſury* is a difficulty of making water, attended with a violent attempt and preſſure of the parts. This ſometimes has its origin from the kidneys, ſometimes from the bladder.

The *iſchury* is a total ſuppreſſion of urine for ſome days, without the leaſt drop being voided, or the patient's feeling the leaſt ſtimulus toward attempting to void it.

Theſe three diſtemperatures of the urinary organs, though very properly diſtinguiſhed by their ſeveral names, are, however, in reality all the ſame in their origin, and differ only in degree.

In the *ſtrangury*, the difficulty of voiding the urine is ſomewhat tolerable, and is not attended with any ſenſation of heat, but rather with a coldneſs; and though the urine is voided only by drops, yet, as this is continual, there is more in quantity voided in this, than in the ſame time in a *dyſury*.

The *ſtrangury* ſeems a ſort of middle complaint, combined of the two others, the *diſury* and *iſchury*; and it differs in point of duration, being ſometimes only a complaint of a few hours, and ſometimes fixing itſelf upon the patient for a long time. Sometimes alſo it is idiopathic, and is properly a diſeaſe in itſelf; but ſometimes it is ſymptomatic, attending nephritic complaints of ſeveral kinds.

Phyſicians alſo diſtinguiſh the *iſchury* into the proper, and improper: the firſt is the denomination they give to this diſeaſe, when the bladder is full of urine all the time, and is ſo diſtended, that it brings on ſpaſmodic affections, which prevent the natural efforts for the excretion of it. The improper *iſchury* is that in which there is no ſuch fullneſs of urine, but this fluid is, by ſome means, prevented from flowing as it ought into this receptacle. We muſt be careful not to confound with theſe diſtempers the natural imminution of urine, which happens after copious ſweats, or diarrhœas, in which a great quantity of wet ſtools have been voided: this is diſtinguiſhed from theſe morbid affections, by its being attended with no pain, and always going off of itſelf.

Symptoms of a STRANGURY. Theſe are of frequent irritations to make water, which are ſucceeded either by a few drops, or a ſomewhat larger quantity, according to the nature and violence of the caſe; there is always a ſenſation of coldneſs while the urine is coming away, and a heat afterwards; and the whole body is very frequently affected with ſhiverings and ſudden coldneſs.

In a *dyſury*, the difficulty of voiding the urine is great, and the pain violent; but in this caſe it does not go off as ſoon as the urine is voided, but continues afterwards.

In the *iſchury*, while there is for ſeveral days together no attempt to the voiding any urine, if the complaint is in the bladder, the patient feels a weight and preſſure upon the os pubis; but when the kidneys and ureters are in fault, the pain is felt in the loins; and ſometimes this is attended with heart-burnings, iſchiatic pains, and even with diſorders of the ſtomach, and actual vomiting; and if the cauſe is ſome inflammable tumor, which is not unfrequently the caſe, then the pains are very violent, and the body is all over preternaturally hot.

The *dyſury* more frequently attacks thoſe who are ſubject to the ſtone in the kidneys or bladder, or to other nephritic complaints, and ſuch as have taken cantharides internally, and by that means brought on an eroſion of the neck of the bladder; ſometimes, alſo, this becomes a ſymptom in hyſteric complaints.

The *iſchury* principally attacks young men, and moſtly thoſe of plethoric habits; and thoſe who have been too free with hot medicines, ſtrong liquors, and powerful diuretics.

Cauſes. The cauſe of a *ſtrangury* is a ſpaſmodic contraction of the ſphincter, and neck of the bladder, attempting to throw off ſomething that is troubleſome; and the fermentative ſtate of the urine, accuſed by many as the cauſe of this diſeaſe, has indeed no ſhare in the occaſioning it. The *dyſury* ſometimes has its cauſe and origin in the kidneys, ſometimes in the bladder, and when in the laſt place, a ſpaſmodic conſtriction of the ſphincter is often the caſe, and this is not unfrequently brought on by a high diet, the feeding on very ſalt foods, or uſing too much ſpices. The *iſchury* is often occaſioned by accidents; ſuch as a ſtone, gravel, a worm, a grume of blood, or a collection of purulent matter ſtopping up the paſſage in the neck of the bladder; ſometimes it is occaſioned by a venereal caruncle, or inflammatory tumor; ſometimes by the weight of the uterus in women with child, when near the time of their delivery; ſometimes by external violence; and ſometimes by the ſitting a long time drinking, without going to make water; but this laſt more rarely happens. *Junker*'s Conſp. Med. p. 533.

Prognoſtics in theſe caſes. A ſimple and idiopathic *ſtrangury* is rather a painful, than a dangerous diſeaſe; but if it often recurs upon the perſon, it beſpeaks a calculous nephritic complaint for its cauſe: and, in general, it is a worſe complaint in old people, than in the young or middle aged. The *dyſury* is of the ſame nature with the *ſtrangury* in its event, but the longer it continues, the greater danger there is of its bringing on ſpaſms and fevers. But though theſe two caſes are not attended with any very imminent danger, the *iſchury* is, eſpecially when it is of ſome days ſtanding; for if it is not cured before the ſeventh day, an inflammatory fever comes on, which is uſually followed by a ſpeedy mortification, and by the death of the patient with hiccups and violent convulſions. People ſubject to *iſchuries* are alſo in danger of dropſies; and dropſical people are more ſubject to this complaint than any others, eſpecially when the diſeaſe is increaſed to a conſiderable height.

Method of cure. The *ſtrangury* and *dyſury* are to be treated in the ſame manner. The acrimony of the fermentitious matter in the blood, which might be apt to occaſion new congeſtions, is to be obtunded, and the ſpaſtic motions taken off: both theſe purpoſes are excellently anſwered by nitre, whether given alone, or mixed with ſome abſterſive ſalt, or with an abſorbent, mixed with a ſmall quantity of an acid to ſaturate it, and with a little cinnabar. A compound powder may be prepared of theſe ingredients, and a ſcruple of it given four times a day, will uſually ſoon take off the complaint. The cooling emulſions, made with barley-water and almonds, and with the cold ſeeds, are alſo of great ſervice; and when there is farther occaſion for medicines, gum arabic, and pills of boiled turpentine, are found very good ones; and decoctions of liquorice-root in barley-water, with ſyrup of marſh mallows, may be drank in large draughts. Many people are alſo fond of external remedies, and recommend onions, roaſted and buttered, to be applied to the pubes, and goat's ſuet to be rubbed warm about the navel.

In caſes of the *iſchury* there is occaſion for greater medicines, and the method muſt neceſſarily be varied, according to the ſtate of the patient, and the cauſe of the diſeaſe. The firſt thing to be done, is the injecting an emollient clyſter to looſen the bowels, for when theſe are emptied, the other complaint will be much more eaſily removed: after the clyſter, powders compoſed of cinnabar, nitre, and diaphoretic antimony, are to be given, to prevent an inflammation in the abdomen, and to attemperate the offending matter. When theſe things are done, the peculiar cauſes of the diſeaſe are to be examined. If a plethora and violent emotion of the blood be in fault, making a congeſtion of it at the kidneys; in this caſe, if the beforementioned methods do not take effect, bleeding in the foot will be of ſervice, and an external uſe of camphorated ointments probably will compleat the cure. When the cauſe is a ſpaſtic conſtriction of the ureters and kidneys, then the relaxing medicines are to be given, and gentle purges of ſenna, manna, and the like, will be of great uſe. Externally warm baths, oily liniments and ointments, and emollient cataplaſms, are alſo great aſſiſtants to the internal medicines.

If a ſmall ſtone, or a grume of blood, or mucous matter, or a worm, have ſtopped up the paſſage, and prevented the urine from paſſing after the clyſter, and the powders are found not to have the deſired effect, the catheter is to be introduced; or if the ſtone be lodged in the urethra, the injecting a little oil may be of uſe to lubricate the paſſage, and eaſe its way out. When a genuine nephritis is in the cauſe, this is firſt of all to be regarded, and treated in the common way. See NEPHRITIS.

If a venereal caruncle be in the way, it muſt be taken down by the ſurgeon with the ſeptics uſually employed on thoſe occaſions; and if the caſe be violent, and of this kind, the cure muſt be perfected, by treating the patient in the uſual method in venereal caſes.

If an inflammatory tumor ſtops the neck of the bladder, this is to be diſcuſſed by reſolvents internally taken, and externally applied to the pubes; and if there is an eroſion, or ulceration, balſamics are to be given, and particularly the pills of boiled turpentine. *Iſchuries* in infants are cured by giving crabs eyes, and the like powders, with the uſual catarrhal medicines to the nurſe who gives them ſuck. Finally, in caſes of grown people, as ſoon as the urine comes away at all, the common diuretics are to be given, as the daucus ſeeds, and the like, with gentle purges at the intermediate times; but it is a very dangerous practice to give diuretics, before the cauſe of the obſtruction is removed, and ſince they always add greatly to the pain and miſery of the patient.

There is no medicine ſo uſeful in theſe caſes as nitre, and it is better given in ſubſtance than any other way; for its dulcified ſpirit, though well known as a diuretic, is leſs ſafe than the ſalt itſelf. Many people have a great opinion of ſpecifics in theſe caſes, and golden-rod, and mouſe-ear, and ground ivy, are accounted of that number, as alſo violet ſeeds, and powder of egg-ſhells; but it is a very dangerous thing, in caſes of ſo great importance, to rely upon uncertain remedies. A common *ſtrangury* often is carried off by mere diluters, ſuch as tea, barley-water, or any other watery liquor, drank in large quantities till a ſweat comes on; and in the gentler caſes, where theſe alone are not quite effectual, there is no better addition to them than a little nitre. Bleeding in time often prevents great miſchiefs from theſe diſorders; and in caſes of a *dyſury*, brought on by the taking cantharides, there is no remedy ſo powerful as warm milk alone, drank in large quantities. The great Mr. Boyle has alſo ſaid much in the favour of Venice ſoap on this occaſion. *Junker*'s Conſp. Med. p. 534, 535.

STRAP (*Cycl.*)—STRAP, in a ſhip, the rope which is ſpliced about any block, and made with an eye to faſten it any where on occaſion.

STRAPS, in the manege. The *ſtraps* of a ſaddle are ſmall leather *ſtraps*, nailed to the bows of the ſaddle, with which we make the girths faſt to the ſaddle.

STRAPAZINO, in zoology, the name of a bird of the wheat-ear kind with a white rump and tail, and of a browniſh yellow on the head and back. Its wings are variegated with black and yellow, and its beak is longer, and of a browniſh colour. Its throat, breaſt and belly, of a yellowiſh white. It is common in Italy, and is frequently brought to market among the ſmall birds. *Bellonius*, de Avibus.

STRASITES, STASITES, or STAXITES, a ſtone deſcribed by the writers of the middle ages, and famed for its imaginary virtue of promoting venery, aſſiſting digeſtion, and the like, and that whether taken inwardly, or outwardly applied. It is not eaſy, from the accounts they have left us, to gueſs what ſtone they mean.

STRATA, (*Cycl.*) the beds of different kinds of matter, of which the cruſt of the earth is compoſed.

The moſt frequent opportunities we have of obſerving theſe in England, is in the coal mines in coal countries. Here we find them lying in a regular manner, on what appears to us a plane, as we ſee any ſmall part of it; but when we conſider the ſame *ſtrata*, according to the globular figure of the earth, and ſuppoſe the maſs of the earth to conſiſt of the foregoing, and perhaps in different parts, and at different depths of *ſtrata*, of ten thouſand other kinds, all originally, while in a ſoft and fluid ſtate, tending toward the center, we ſhall find that it muſt mechanically, and almoſt neceſſarily follow, by the continual revolution of the crude maſs from weſt to eaſt, like the winding up of a jack, or the rolling up of the leaves of a paper-book, that every one of theſe *ſtrata*, though they each reach the center, muſt, in ſome place or other, appear to the day, or on the ſurface. In which caſe, there needs no ſpecific gravitation to cauſe the lighteſt to be uppermoſt; and were it practicable to ſink to the center of the earth, all the *ſtrata* that are would be found in every part, and, according to the poet, *ponderibus librata ſuis*. Add to this, that, according to an obſervation of Dr. Stukely, the precipices of all hills are to the weſtward, whereas the aſcent to the eaſt is more gradual. Philoſ. Tranſ. N° 391. p. 396.

STRATEGUS (*Cycl.*)—Towards the declenſion of the Roman greatneſs, the chief magiſtrate of Athens was called by the name of Στρατηγος, *dux*. Conſtantine the great, beſides many other privileges granted to that city, honoured him with the title of Μεγας Στρατηγος, *magnus dux*. *Potter*, Archæol. Græc. lib. 1. cap. 7.

STRATOR, among the Romans, an officer who took care of the horſes, furniſhed by the provincials for the public ſervice. *Pitiſc.* in voc.

STRATOR is alſo uſed for an officer in the army, whoſe buſineſs it was to take care there was nothing in the roads to hinder or incommode the army in its march. For which purpoſe he ordered banks and ſteep eminences to be levelled; laid bridges, cut down woods, and aſſiſted the quarter-maſter to find out places proper for tranſporting the army over rivers. *Pitiſc.* in voc.

STRATOR is alſo uſed for an equerry, who held the bridle of the prince's horſe, and aſſiſted him in mounting. This officer was by the Greeks called *anaboleus*. *Pitiſc.* in voc. See the article ANABOLEUS.

STRATOR likewiſe denotes a ſurveyor of the high-ways. *Pitiſc.* loc. cit.

STRAWBERRY, *fragaria*, in botany. See FRAGARIA.

The common *ſtrawberry* is frequent in the woods of England, and is thence tranſplanted into gardens. The beſt ſeaſon for this is in September, that the plants may be rooted before the froſts. They may alſo be tranſplanted in February; but then, if the ſpring ſhould prove dry, they will require a great deal of watering to keep them alive.

The proper ſoil for *ſtrawberries* is a light hazely loam, not over rich; the ground muſt be well dug, and very carefully cleared of all noxious weeds; and when it is levelled even, it ſhould be marked out into beds about three feet and a half wide, leaving a pathway between each bed of two feet broad. In each of theſe beds ſhould be planted four rows of plants, ſo that they may ſtand about a foot diſtant from each other in the rows, and they ſhould be planted at about eight inches plant from plant in each. This is the proper diſtance for the wood *ſtrawberry*, which is of the leaſt growth of any; but the ſcarlet *ſtrawberry* muſt be planted at a foot diſtance every way, and the heautboy ſixteen inches; and finally, the large Chili *ſtrawberry*, which is the largeſt grower of all, muſt be ſet at twenty two inches diſtance plant from plant.

In the ſpring, when the *ſtrawberries* begin to flower, if the ſeaſon is dry, they muſt be very plentifully watered, and they muſt be kept very carefully cleared from weeds. At Michaelmas the beds ſhould be dreſſed, the weeds all very carefully taken up, all the ſtrings or runners muſt be taken from the roots, and the weak plants, which ſtand too cloſe, muſt be pulled up; throwing a little fine earth, at the ſame time, over the plants, alſo greatly ſtrengthens their roots. Theſe beds, however well managed, will not continue good above three years; and the beds of the firſt year bearing but few fruit, it is neceſſary to new-plant ſome freſh ground every third year, and deſtroy the old beds; but the new ones muſt be firſt of one year's growth.

Different palates prefer different ſpecies of *ſtrawberry*, but the white-fruited one is, of all others, the beſt flavoured; though it is but a very bad bearer. The great Chili *ſtrawberry* is cultivated in the fields in that country; it is a much ſtronger and larger plant than any of our kinds, and its fruit is as large as a wallnut, but not ſo well taſted as our own *ſtrawberries*. Mr. Frezier brought them ſome years ago to Paris, and ſince that they have been ſpread over the ſeveral parts of Europe. They grow beſt in a loamy ſoil, under the ſhade of trees. *Miller*'s Gard. Dict.

STRAWBERRY-*tree*. See the article ARBUTUS.

STREAK-*fallowing*, in huſbandry, a particular ſort of tillage.

The way of doing it, is to plow one furrow, and leave one, ſo that but half the land is plowed, each furrow that is ſo lying on that which is not: when this is ſtirred, it is then clean plowed, and laid ſo ſmooth, that it will come, at ſowing time, to be as plain as before. This is done, when lean and poor lands are not ſwardy enough to bear clean tillage, nor light enough to lie to get ſward. The intent of this tillage is to keep the ſun from ſcorching them too much; but in many places they think this wears their land too faſt, and therefore are not fond of having recourſe to it. *Plot*'s Oxfordſh. p. 248.

STREAMERS, in a ſhip, the ſame with *pendants*. See the article PENDANT, *Cycl.*

STRENGTH *(Cycl.)*—STRENGTH *of ſpirits*, among diſtillers, that quality by which they become inflammable, and which they have in greater or leſſer proportion, as they are more or leſs debaſed by an addition of water.
