Minerals yearbook: Metals, minerals, and fuels 1973. Year 1973, Volume 1 1973

Minerals Yearbook 1973

Volume I

METALS, MINERALS, AND FUELS

Prepared by staff of the

BUREAU OF MINES

UNITED STATES DEPARTMENT OF THE INTERIOR • Stanley K. Hathaway, Secretary

BUREAU OF MINES • Thomas V. Falkie, Director

As the Nation's principal conservation agency, the Department of the Interior has basic responsibilities to protect and conserve our land and water, energy and minerals, fish and wildlife, and park and recreation areas, and for the wise use of all those resources. The Department also has a major responsibility for American Indian reservation communities and for the people who live in Island Territories under U.S. administration.

U.S. GOVERNMENT PRINTING OFFICE

WASHINGTON : 1975

For sale by the Superintendent of Documents, U.S. Government Printing Office
Washington, D.C. 20402 - Price $14.40

Foreword

The Federal Government, through the medium of the Minerals Yearbook or its predecessor volumes, has for 91 years reported annually on mineral industry activities. This edition of the Minerals Yearbook presents the record on worldwide mineral industry performance during 1973. In addition to statistics, the volumes provide background information to help in interpreting the year's developments. The content of the individual volumes is as follows:

Volume I, Metals, Minerals, and Fuels, contains chapters on virtually all metallic, nonmetallic, and mineral fuel commodities important to the domestic economy. In addition, it includes a general review chapter on the mineral industries, a statistical summary, and a chapter on mining and quarrying trends.

Volume II, Area Reports: Domestic, contains chapters on the mineral industry of each of the 50 States, the U.S. island possessions in the Pacific Ocean and the Caribbean Sea, the Commonwealth of Puerto Rico, and the Canal Zone. This volume also has a statistical summary, identical to that in Volume I.

Volume III, Area Reports: International, contains the latest available mineral data on more than 130 foreign countries and discusses the importance of minerals to the economies of these nations. A separate chapter reviews minerals in general and their relationships to the world economy.

The Bureau of Mines continually strives to improve the value of the Yearbook for its users. Therefore, the constructive comments and suggestions of readers will be welcomed.

THOMAS V. FALKIE, *Director.*

Acknowledgments

Volume I, Metals, Minerals, and Fuels, of the Minerals Yearbook summarizes the significant data pertaining to mineral commodities obtained as a result of the mineral intelligence gathering activities of the divisions and offices of the Associate Directorate—Mineral and Materials Supply Demand Analysis.

The collection, compilation, and analysis of data on the domestic minerals and mineral fuel industries were performed by the staffs of the Divisions of Ferrous Metals, Nonferrous Metals, Nonmetallic Minerals, Coal, and Petroleum and Natural Gas. Statistical data were compiled by the statistical staffs of these Divisions from information supplied by mineral producers, processors, and users in response to production and consumption canvasses, and their voluntary response is gratefully acknowledged. The information obtained from individual firms by means of confidential surveys has been grouped to provide statistical aggregates. Data on individual firms are presented only if available from published or other nonconfidential sources or when permission of the companies has been granted. Other material appearing in this volume was obtained from the trade and technical press, industry contacts, and numerous other sources.

Statistics on U.S. imports and exports, world production, and foreign country trade were compiled in the Office of Technical Data Services. The foreign trade data for the United States were obtained from reports of the Bureau of the Census, U.S. Department of Commerce. World production and trade data came from numerous sources, including reports from the Foreign Service, U.S. Department of State.

The Office of Technical Data Services also provided general guidance on the preparation and coordination of the chapters in this volume and reviewed the manuscripts to insure statistical consistency among the tables, figures, and text, between this volume and other volumes, and between this edition and those of former years.

Acknowledgment is also particularly made of the splendid cooperation of the business press, trade associations, scientific journals, international organizations, and other Federal agencies that supplied information.

The Bureau of Mines has been assisted in collecting mine production data and the supporting information appearing in the Minerals Yearbook by numerous cooperating State agencies. These organizations are listed in the acknowledgment to Volume II.

ALBERT E. SCHRECK, *Editor-In-Chief*

CONTENTS

Review of the Mineral Industries

By Daniel E. Sullivan[1] and Nicholas G. Theofilos[2]

Although monetary and fiscal policies were less expansive in 1973 than in 1972, inflation was the major problem confronting the U.S. economy in 1973. Output expanded in all four quarters of the year, although the expansion was strongest in the first quarter. Income and employment increased and unemployment declined. The inflation was worsened by heavy demand and limited production of some food and fuel commodities.

Total output of the U.S. economy in 1973 as measured by the gross national product (GNP) grew 11.5%. Real GNP measured in 1958 dollars increased 5.9%, and inflation as measured by the implicit price deflator increased 5.3%. Greater inflation during 1973 caused the growth in GNP, in current dollars, to be larger than the 1972 growth of 9.4%, while in real 1958 dollars the growth in GNP was larger for 1972—6.1% as opposed to 5.9%. The increase in the implicit price deflator for 1972 was 3.2%. Gross private domestic investment and State and local purchases increased at a greater rate than did total GNP for 1973 as Federal purchases declined in real terms. The Federal Reserve Board (FRB) index of industrial production increased 9% during 1973.

Employment continued to increase during 1973. The unemployment rate averaged 4.9%, declining from the 5.6% average for 1972. Unemployment was near 5.0% at the beginning of the year, declined to a low of 4.6% in October, and returned to 4.8% in December. The labor force increased as it had during 1972, but in contrast to 1972 it did not dampen the decline in unemployment.

Prices increased more rapidly during 1973 than during any period since the Korean War. The overall consumer price index at 133.1 was 6.2% more than it was in 1972. Inflation in food prices proved to be a major problem area in 1973; the average was 14.5% above that for 1972. All nonfood commodities increased 3.4%. The 1973 wholesale price index increased to 135.5, 13.8% greater than the 1972 index. Farm product prices increased 41% and industrial commodities prices increased 8.5%. The 1973 implicit price deflator was 5.4% more than the 1972 figure, which was 3.2% greater than in 1971.

Monetary policy was much less expansive during 1973 than during the previous year. The FRB pursued a policy of active restraint in order to combat the severe inflation that had developed. During the year the money supply M_1, defined as currency plus demand deposits, grew 6.1% as opposed to a growth of 7.7% during 1972. M_2, defined as M_1 plus time deposits, grew at a rate of 8.8% as opposed to a growth of 10.9% during 1972. Both short- and long-term interest rates rose during 1973.

Federal fiscal policy was also less expansive during 1973 than during 1972. The deficit in the unified budget for 1973 was $14 billion, $11 billion less than had been projected the previous year. The reason for this was that outlays were slightly lower and receipts were considerably higher than expected. An even less expansive fiscal policy would have had more impact on the strong excess demand.

The present international monetary and trading system, with managed floating exchange rates, makes the measurement of the overall balance of payments less important. When exchange rates were fixed, one of the major functions of overall measures of balance of payments was to signal when an adjustment in the exchange

rate was necessary. Early in 1973 the official price of gold rose from $38 to $42.22 per ounce. The price of gold on the private market was $112 at the end of 1973. Since the market price of gold has been much higher than the official price, governments have been reluctant to use it in international settlements. The U.S. basic balance during the first quarter of 1973 was in deficit by $0.9 billion, during the second quarter it was in deficit by $0.6 billion, and during the third it was in surplus by $2.5 billion.

Significant Federal actions of interest to the minerals sector included activities to slow inflation and meet the energy crisis in addition to the continuing mineral-related programs. During 1973 the anti-inflationary activities of the Economic Stabilization Act of 1971 were in effect. These activities included phase 2, phase 3, a 60-day freeze, and the implementation of phase 4. The energy crisis became more severe late in the year, leading to the introduction of a number of conservation and allocation programs. Mineral-related legislation approved by Congress and passed by the President during 1973 covered such areas as energy, the environment, water, public lands, the national stockpile, and import duties.

During 1973 research programs of the Bureau of Mines continued to emphasize the effective utilization of our national mineral and fuel resources so as to insure adequate mineral supplies without objectionable environmental, social, and occupational effects.

During 1973 energy use in the United States continued to rise. Domestic production of coal and crude petroleum declined while marketed production of natural gas increased slightly. Energy consumption increased in all major consuming sectors. This increased demand was met by increased imports and the drawdown of stocks. Fuel imports increased 33.1% over 1972 in spite of the Arab oil embargo in the fourth quarter.

The mining industry faced problems of minerals nationalism and environmental control during 1973. The industry was also affected by the strong inflation and increased demand that were prevalent in the economy as a whole. The industrial minerals continued their growth during 1973, but profits were lower. All mineral industries, and especially the high-energy-consuming industries, felt the effects of the energy shortage.

World trade increased strongly in 1973 despite monetary shifts and shortages in basic supplies. The international monetary system stood fast while allowing governments to make adjustments without disrupting international flows. Inflation was the major problem facing the world economy. Continued economic growth occurred in the developed countries.

SOURCES AND USES

ALL MINERALS

Production.—Domestic mineral production in 1973 was valued at $36.8 billion, a 14% increase from 1972. Production of all mineral groups increased at about the same rate except that of metals, which increased almost 20% during the year. In constant 1967 dollars the value of total mineral output increased only 5% from $25.7 billion in 1972 to $27.0 billion in 1973; metals and nonmetals increased about 8%, but mineral fuels increased less than 4%. Exports of primary minerals and mineral fuels increased 12% to $1.7 billion, and imports increased over 46% to $6.6 billion.

The Bureau of Mines total index of physical volume of mineral production (1967=100) increased a little more than 1% to 114.2 index points in 1973. The index for the average of all metals increased over 7% to 136.8. Within the metals group ferrous metals increased almost 18% and nonferrous metals increased less than 2%. In the nonferrous group, the base metals index increased over 2%, that for monetary metals declined almost 8%, and the other nonferrous index increased almost 2%. The index for the average of all nonmetals increased over 7%. The indexes for construction and for other nonmetals both increased at rates close to 9%; that for chemicals increased at a 3% rate. The overall index for fuels declined almost 2%, with the coal index declining less than 1%, and that for crude oil and natural gas declining less than 2%.

The FRB Index of Industrial Production (1967=100) increased almost 9% during 1973, from 115.2 to 125.2 index points. The

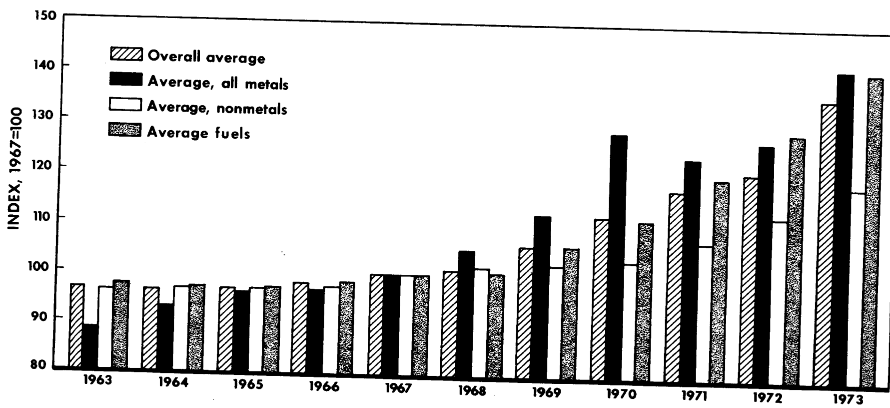

Figure 3.—Indexes of implicit unit value.

average for all mining increased 1.4 index points to 110.2, the metal and the stone and earth minerals indexes increased strongly, while the coal and the oil and gas indexes both decreased moderately. Strong increases in the primary metals, iron and steel, and nonferrous metals and products indexes ranged from 12% to 14%, and the clay, glass, and stone products index increased almost 10%.

The FRB monthly index of mining production (1967=100) was less than 109 index points for January and more than 110 points for February. It stayed between those two points for the next 4 months. In July it was 111 points, and it remained greater than 111 points until December when it was 110.7 points. The coal, oil, and gas index followed the same pattern although the individual coal index tended to be higher earlier in the year and lower late in the year, and the crude oil and natural gas index was highest both early and in the middle of the year. Metal, stone, and earth minerals remained between 116.0 and 117.0 index points for the first 5 months of the year, except in February when it reached 117.6 points. In June it hit a low of 111.8 index points and then rebounded, remaining above 120.0 index points for the final 5 months of the year.

Total net supply for most of the selected principal metals and nonmetals increased during 1972. The net supply of two-thirds of the selected ferrous metals increased. The largest increase was 50% in the net supply of tungsten, and the smallest was a 7% increase in the net supply of nickel. Iron ore, pig iron, and molybdenum all increased at rates in the teens while cobalt increased one-third. The net supply of steel ingot declined over 1%, chromite declined over 18%, and manganese declined over 13%. The patterns of change for the net supply of nonferrous metals reflected this same trend, with two commodities showing increases for each one showing a decline in net supply. The largest increase was over 27% for platinum-group metals and the smallest was less than 3% for cadmium. Copper, magnesium and zinc all had rates of increase in net supply at or above 4%. Rutile increased 9%, mercury over 21%, and uranium concentrate increased almost as much as platinum-group metals. The net supply of lead increased only a negligible amount. The net supplies of tin, aluminum, antimony, and ilmenite and slag decreased 11%, 7%, 6%, and 2% respectively. The net supply of all selected nonmetals except salt increased. The increases ranged from 19% for crude barite to 2% for finished fluorspar. Asbestos, bromine, clays, sand and gravel, and sulfur all increased about 8%; gypsum and phosphate rock increased at rates near 5%; all other increases were at rates in the teens. Common salt declined more than 2%.

Stocks and Government Stockpile.—During 1973 stocks of crude nonfuel minerals at primary producers, as reflected by the Bureau of Mines index (1967=100), declined substantially for all the selected metals and nonmetals. The overall index declined 22% to 110 index points and that for all metals declined 34%. The largest decline in the metals sector was a 51% drop in the index for other ferrous metal stocks. The iron ore index declined 26%, and the nonferrous index declined 14%. The nonmetals index declined almost 7%. Stocks of nonfuel minerals held by mineral manufacturers, consumers, and dealers as reflected by the Bureau index also declined, but not so strongly as those held by primary producers. The overall index declined almost 11%, with the index for all metals also declining by the same amount. The largest decline within the metals sector was in the other ferrous metals index which declined 27%, as was the case in the index of crude minerals held by primary producers. The stock index for iron declined 10%; those for base and other nonferrous metals both declined 9%. The index for nonmetals, excluding fuels, declined only 3%.

Producer stocks of bituminous coal and lignite decreased 14% in 1973, a sharp contrast to the large increase of the previous year. Coke stocks declined almost 60%. Stocks of carbon black and natural gasoline, plant condensates, and isopentane increased substantially. Total stocks of crude petroleum and petroleum products increased 5%, although those of most petroleum products except distillate fuel oil and the other products category declined. Distillate fuel oil stocks increased 27%, and the other products category increased 17%. Stocks of natural gas increased almost 11%.

From December 1972 to December 1973, the seasonally adjusted book value of product inventories increased for all selected industries except blast furnaces and steel mills. Petroleum and coal products increased 15.3% to $2,653 million as of December 1973. Stone, clay, and glass products increased 13.3% to $2,791 million. Total primary metals inventories decreased 3.6% to $9,314 because blast furnace and steel mills inventories decreased 11.8% to $4,645 million, while other primary metals inventories increased only 6.4% to $4,669 million. Total seasonally adjusted book value of inventories for selected mineral processing industries increased 2.3% to $14,421 million during 1973.

The national stockpile of strategic materials contained an important component of the Nation's mineral supply during 1973. Stockpile commodities of significant market value included aluminum, chromium, copper, lead, manganese, silver, tin, tungsten, and zinc.

Exports.—The total value of selected minerals and mineral products exported during 1973 increased 41% to $6,613 million. Exports in all sectors increased: Crude and scrap metals more than doubled; manufactured metals increased almost 60%; chemicals increased 44%; manufactured nonmetallic minerals increased 24%; and crude nonmetallic minerals increased 13%. The lowest rate of expansion occurred in exports of mineral energy resources and related products, which were up only 8% above those of 1972. Exports of only two mineral products declined; they were crude and partially refined petroleum, and uranium and thorium metals and alloys.

There were many changes in the geographical distribution pattern of selected mineral exports during 1973. Exports of sulfur and unroasted pyrites to other North American countries comprised 3% of the total exports of these commodities in 1972. in 1973 they increased to 42%. Exports to Asia of coke, coal, and briquets, including peat, declined from 34% to 2%. Exports of crude petroleum to North America increased to 29%, compared with none in 1972. Exports of iron and steel ingots and iron and steel rails shifted from North American to South American countries. Exports of silver, platinum, and platinum-group metals shifted in emphasis from Europe to Asia. Exports of zinc shifted from North America to South America and Asia. Exports of tin shifted from North America to South America; exports of uranium and thorium and their alloys to Europe remained steady while Asia received a larger share and North America a smaller share.

Imports.—The total value of selected mineral imports increased almost 38% to $16,047 million in 1973, with increases reported for all major categories. The most important and largest increase was in imports of mineral energy resources and related products, which increased 68% to $8,091 million. Within this group, coal, coke, and briquets (including peat) increased 2.6 times to $60 million, crude and partially refined petroleum increased 77% to $4,584 million, petroleum products except chemicals increased 72% to $2,954 million, and natural and manufactured gas imports increased 3.4% to $493 million. Imports of crude nonmetallic minerals increased 18.5% to $353 million. All imports within the nonmetallic group increased except those of sulfur and unroasted pyrites which decreased 11% to $15 million. Imports of crude and scrap metals increased 20% to $1,188 million. Within this group all minerals increased except nonferrous base metal ores and concentrates, which declined 1% to $466 million. Chemical imports increased 26% to $682 million. Within this group, only the mineral tar category declined. The manufactured nonmetallic minerals and the manufactured metals categories increased 35% and 14% respectively to $299 million and $5,435 million.

The percentage distribution of imports of principal minerals and mineral fuels and related products in 1973 by area of origin was generally stable with a few exceptions. One notable change was in imports of coal, coke, and briquets. In 1972, 92% of these imports came from North America and 1% from Europe. In 1973 the figures were 26% and 73% respectively. Other changes in import trade patterns were as follows: In 1972, 95% of phosphates came from North America, and none from Europe; in 1973 the figures were 78% and 11%; 14% of copper ores came from North America, 27% from South America, and 56% from Asia in 1972; in 1973 the figures were 48%, 35%, and 16% respectively; the distribution of imports of tantalum, molybdenum, and vanadium ores and concentrates shifted from South America to North America between 1972 and 1973; in 1972, 70% of the tin waste and scrap came from North America and none from South America; in 1973 the figures were 38% and 50% respectively; among platinum-group metals, ores, concentrates and wastes the import distribution pattern showed less from North America and more from Africa in 1973; North America supplied a smaller percent of the natural gas imported and South America a larger percent; some mercury import sources shifted from North America to Africa.

Consumption.—During 1973, consumption of most major mineral products increased substantially. Ferrous metals reflected this trend with the exception of manganese ore, consumption of which declined about 8%. Raw steel and iron ore consumption increased by 13% and 12%, respectively. Consumption of molybdenum increased by 25%. Consumption of all major nonferrous metals increased, with consumption of aluminum increasing less than 2% and that of copper increasing more than 7%. Consumption of antimony and silver increased by 28% and 30%, respectively while that of platinum-group metals increased 17%. Consumption of all other nonferrous metal commodities increased at rates between 2% and 5%.

Consumption of nonmetals increased for all major commodities except salt, which declined over 2%. Potash and crushed stone both increased more than 15%. Asbestos increased over 8% and phosphate rock increased less than 2%. All other major nonmetallic commodities increased at rates between 3% and 8%.

Total energy resource inputs in terms of British thermal units (Btu) increased almost 4% to 74,742 trillion Btu. Consumption of most mineral energy resources increased. That of anthracite coal remained constant and natural gas consumption declined less than 1%. Bituminous coal consumption increased almost 8%, and petroleum consumption increased over 5%.

Total net electricity generation increased 5% during 1973. Utilities increased almost 6% and industrial production declined almost 7%. Within the utilities, conventional fuel-burning plants increased 5%, hydropower declined less than 1%, and nuclear power consumption increased more than 54%.

ENERGY

Energy use in 1973 rose above the record high levels of 1972. As in other recent years, domestic energy raw material production did not match this increase; there were declines in the production of key fuels. This demand was met through a combination of increased imports of natural gas, crude oil, and petroleum products, increased production of natural gas, and a drawdown of stocks. This energy crisis was compounded late in the year when several Arab nations cut back crude oil production and curtailed shipments to the United States. However, petroleum imports had increased so strongly before the embargo that total imports of all fuels showed an increase for the year. The energy crises led to intensified efforts to encourage the discovery and development of new domestic sources of energy.

Production.—Total production of mineral energy resources and electricity from hydropower and nuclear power declined less than one-half of a percentage point in 1973 to 61,817 trillion Btu. All sources of energy production decreased except wet natural gas, which increased less than one-half of a percentage point, and nuclear power, which increased over 54% but remained less than 2% of total production. Anthracite declined almost 4%, bituminous coal and lignite and hydropower both declined less than 1%, and crude petroleum declined less than 3%.

Consumption.—U.S. energy consumption increased almost 4% in 1973 to 74,742 trillion Btu. Consumption of anthracite declined 4% in terms of Btu's. Consumption of bituminous coal and lignite increased 8% and that of petroleum 6%. Natural gas consumption declined less than 1% and natural gas liquids declined 1%. Consumption of electricity from hydropower declined less than 1%. Electric consumption from nuclear power increased 54%.

In 1973, the household and commercial sector received 40% of its energy input from natural gas; 38% from petroleum; 20% from electric utilities; and almost 2% from coal. The distribution of the inputs for industrial users was 46%, 25%, 11%, and 18% respectively. The transportation sector received 96% of its energy from petroleum. Energy inputs to electric utilities were from bituminous coal and lignite, 44%; natural gas, 19%; petroleum, 18%; hydropower, 15%; and nuclear power, 4%.

Coal.—The domestic supply of anthracite declined 4% in 1973 to 5.7 million tons; that for bituminous coal and lignite increased almost 8% to 556 million tons. Exports of anthracite declined almost 3%, and those of bituminous coal declined almost 6%. Imports of bituminous coal increased 170% to 127,000 short tons in 1973 after declining 64,000 short tons in 1972. Electric utilities used almost 70% of bituminous coal. The household and commercial sector was the largest user of anthracite.

Natural Gas.—The domestic supply of natural gas in 1973 was 22,245 billion cubic feet, almost 1% less than in 1972. Most supply components increased; the major factor in the decline in supply was the addition of 442 billion cubic feet to stocks. Domestic production increased less than 1%, exports decreased 1%, and imports increased 1%. Demand for natural gas declined in all consuming sectors except the largest, the industrial sector, which increased over 4% in 1973. The total demand for natural gas declined 1% in 1973.

Petroleum.—The domestic crude oil supply increased 6% to 4,537 million barrels in 1973. Domestic production declined almost 3%; exports more than tripled, but remained negligible; and imports increased almost 46% to 1,184 million barrels in spite of the Arab oil embargo. The domestic supply of refined petroleum products increased 5% to 6,298 million barrels. Demand for petroleum increased 5% to 5,578 million barrels. Transportation accounted for almost 53% of total domestic product demand.

Nuclear Energy.—In 1973 nuclear energy consumption was almost 54% greater than in 1972. In terms of Btu's it increased from just under 1% of total energy consumption in 1972 to 1.2% of the total in 1973. Research continued to be devoted to increasing the energy output from nuclear sources.

Hydropower.—Consumption of hydropower during 1973 was slightly less than in 1972. It provided less than 4% of the total energy consumption in the United States.

Other Energy.—The search for new sources of energy included the investigation of those sources which are only theoretical at this time, and others which will be significant only in the long term. Some of the types of energy being investigated were geothermal, oil shale, solar, wind, tidal, and biological (from organic wastes). Geothermal resources have received attention as a possible major source of energy. Geothermal resources are being developed rapidly, but the emphasis has been placed on developing known fields. Full development of geothermal energy will come only with the discovery of new fields and the technology they require.

EMPLOYMENT AND PRODUCTIVITY

Employment.—Employment in selected mineral industries increased during 1973, with total mining employment increasing over 4%. Employment in most sectors of the mining industries increased except that in other coal, and crude petroleum and natural gas fields each of which declined about 3%. Bituminous coal mining employment increased at a rate exceeding 10%, and oil and gas field services employment increased at a rate of almost 6%.

Minerals manufacturing employment increased 4% to 868,500 during 1972. All categories except total fuels and petroleum refining increased. Petroleum refining represents 78% of total fuels employment.

Hours and Earnings.—The hourly earnings in the mining sector continued to trend upward in 1973 with a 12.7% increase over 1972 earnings, a rate significantly higher than those of recent years. Weekly earnings increased 9.8% to $198.39 at an average of 44 hours per week. The highest hourly earnings in the mining sector were paid in the bituminous coal category, which increased by 40 cents to $5.74. The petroleum industry paid $4.69 per hour, slightly lower than the average for all mining. Hourly earnings for all metal mining increased almost 6.5% to $4.76, which is slightly more than the average for all mining, while average hours were slightly less than that for all mining. Hourly earnings for copper mining increased 5.6% to $4.88; for iron ore mining they increased 3.3% to $4.65. Average weekly hours for both copper and iron ore mining were close to the average for all metal mining. The nonmetallic mining and quarrying category paid the lowest hourly wages in the mining sector and also had the longest workweek with $4.18 and $47.1 hours, respectively.

Average weekly earnings in the manufacturing sector were $224.92, and average hourly earnings were $5.41, a 39-cent increase from the 1972 rate. The nonfuel manufacturing categories increased in weekly earnings by more than 9%, with the cement industry paying the most per week ($233.20), but the blast furnaces, and steel and rolling mills had the highest hourly earnings at $5.56. The fertilizer industry had the lowest weekly earnings ($156.66) and also the lowest hourly earnings. Average weekly earnings in the nonferrous smelting and refining industry increased 9.6%, and the hourly wage rate was $4.81.

Wages and Salaries.—In 1973 total wages and salaries for all industries increased substantially. The 10.3% increase was one percentage point above the 1972 increase. In the mining sector total wages and salaries also increased substantially but not as much as in 1972. The increase in manufacturing wages and salaries, which matched the increase in all industries in 1972, exceeded that for all industries in 1973. Average yearly earnings per full-time employee for all industries increased 5.8%, not as great as the 6.8% increase of 1972. In both mining and the manufacturing sectors, earnings increased more than those of all industries but were below the increases recorded in 1972.

Labor Turnover Rates.—The accession rate (hires and rehires) increased in 7 of the 10 selected mineral industries surveyed in 1973. The largest increase was in the copper ore category with seven employees being hired per thousand. The manufacturing, metal mining, and petroleum industries also increased their accession rate by four employees per thousand. The categories showing a decline in accession rates were the blast furnaces, steel and rolling mills, iron ores, and coal mining. The employee separation rate declined or remained the same in most of the selected mineral industries. Of the three categories showing increased separation rates, copper ores led with an increase of seven employees per thousand, followed by manufacturing, and petroleum refining and related industries. The layoff rate decreased in 1973 for all of the selected mineral industries except petroleum refining and related industries, which remained the same as in 1972.

Productivity.—Changes in labor productivity for selected mineral industries were mixed during 1972 (latest data available) according to the labor productivity indexes for selected minerals. Although the index for copper ore mined per employee and per production worker man-hour increased, the index per production worker declined slightly. The indexes of recoverable copper metal mined per employee, production worker, and production worker man-hour all declined during 1972. The indexes for crude iron ore mined and usable iron ore mined all increased significantly, as did those for refined petroleum. For bituminous coal and lignite the indexes showed small but mixed changes. The index of output per employee increased slightly and those for output per production worker and production worker man-hour showed small declines.

PRICES AND COSTS

Index of Average Unit Mine Value.—The index of average unit mine value and the index of implicit unit mine value, discussed below, give similar results but are developed by different methods. A detailed discussion of these indexes can be found in Bureau of Mines Information Circular 8275.[3] The total index of average unit mine value (1967=100) increased over 12% to 136.3 during 1973, following the rise in prices in the general economy. The index for ferrous metals increased at more than a third of the rate of increase of the total index, and the average for nonferrous metals increased more strongly than the rate of the total index. The base metals index grew at slightly less than the rate of increase for all nonferrous metals, but the index for monetary metals grew by more than 60%, and that for other nonferrous grew only slightly. Nonmetals increased at less than half the rate of increase in the total index. The construction index grew slightly more slowly than the index for all nonmetals, and the chemical, and other nonmetal indexes both grew at a faster rate. The fuels index grew more strongly than the total index. Coal increased at a slower rate and crude oil and natural gas grew at a faster rate than the total index.

Index of Implicit Unit Value.—The index of implicit unit value (1967=100) increased over 12% to 136.2 during 1973, reflecting the inflation of the economy as a whole. The index for ferrous metals increased at less than a third of the overall rate. The average for nonferrous increased at a greater rate than the overall index. Base metals reflected this growth, but the monetary metals index grew more than 50% and that for other nonferrous metals grew only slightly. Nonmetals increased at less than half the rate of increase for the overall index. The construction index grew slightly more slowly than the index for all nonmetals, and the chemical and other nonmetal indexes grew at a slightly faster rate. The fuels section increased almost as much as the overall index; within this group, coal grew less than the overall index, and crude oil and natural gas increased more strongly than the overall index.

Prices.—The wholesale price index for all commodities other than farm and food increased 7.7% during 1973. The index for all commodities, which include farm and food, increased at a rate of 13.8%, almost twice the rate of increase of the nonfarm index. The price indexes for various selected metals, minerals, and fuels either increased or remained unchanged. The index for metals and metal products increased 7.5%. Within this group the increases ranged from 2.3% for semifinished steel products to 54.4% for iron and steel scrap. Most other metal indexes increased moderately, with the exception of the nonferrous scrap index, which increased 44.2%; the primary metal refinery shapes, 20.3%; and

[3] Johnson, E. E. Index Numbers for the Mineral Industries. BuMines IC 8275, 1965, 85 pp.

nonferrous metals, 15.5%. Prices of nonmetallic mineral products increased 3.3%. Price changes in this group ranged from no change in phosphates and phosphate rock to a 6.5% increase in potassium sulfate. The price index for fuels and related products and power increased 22.7. Changes in this group ranged from a 6.4% increase in the electric power index to a 39.0% increase in the refined petroleum products price index. The coal price index increased 12.5%, and the crude petroleum index increased 10.7%.

Prices of most mineral energy resources increased substantially during 1973. The price of bituminous coal at merchant coke ovens increased almost 12%. Anthracite prices increased at a slower rate. The prices of petroleum and petroleum products all increased except for No. 6 residual fuel oil, maximum 1% sulfur, at Philadelphia, which declined almost 5%. The price of crude petroleum increased almost 15%. The average dealers' price for gasoline increased 10%. The average price for all gulf ports bunker C residual fuel oil increased 67%. The price of No. 2 distillate fuel oil at Philadelphia increased 14%, which is small when compared to the 104% increase in its price at all gulf ports. The average price of natural gas at the well increased 16%, but at the point of consumption it increased 7%.

The average cost of electrical energy in 1972 (latest data available) increased 0.1 cent to 1.8 cents per kilowatt-hour. Both residential market and commercial and industrial market costs increased 0.1 cent per kilowatt-hour, the former to 2.3 cents per kilowatt-hour and the latter to 1.5 cents per kilowatt-hour. Costs in all but two geographic areas increased. The exceptions were the East and West South-Central regions in which residential costs increased but the overall cost remained constant. Alaska and Hawaii remained the highest cost areas, and the East South-Central region remained the lowest cost area.

Principal Metal Mining Expenses.—The index of principal metal mining expenses (1967=100) showed the same pattern of increasing prices that was prevalent for the economy as a whole during 1973. The total index increased at a slightly higher rate than it did during 1972. The supply component increased at exactly the same rate as the total index, and the electrical energy and labor components increased at lower rates than the total index. The fuel components of the index increased almost 23%, which is more than three times the rate of increase of the total index.

Costs.—The 1973 index of relative labor costs and productivity generally reflected the inflationary aspects of the economy. For iron ore the index of labor cost per dollar of product was down significantly. This reflected the large increase in the index of value of product per man-period as the index of labor costs per unit of output declined slightly. For copper ore, while the index of labor costs per dollar of product declined slightly, both the index of value of product per man-period and the index of labor costs per unit of output increased significantly. In bituminous coal the index of labor costs per dollar of product increased slightly, and both the index of value of product per man-period and the index of labor costs per unit of output increased significantly. The indexes for petroleum for 1971 (latest data available) showed labor costs per dollar of product remaining unchanged, and the value of product per man-period and labor costs per unit of output both increasing.

The 1973 price indexes for mining construction and material handling machinery and equipment (1967=100) all showed increases over the equivalent 1972 index. The index for portable air compressors, which is the only index that declined in 1972, increased the least in 1973, 1.6%. The index for scrapers and graders increased the most, 9.4%.

INCOME AND INVESTMENT

National Income Generated.—In 1973 national income originating in all industries was $1,066 billion, a 12.6% increase over 1972. The mining industries income increased at a rate slightly above that for all industries to $9.4 billion. The rate of increase for metal mining income was almost double the rate for all industries. It reached the level of $1.2 billion. Income in coal mining increased to $2.4 billion, an 8% advance. The rate of increase in income for the crude petroleum and natural gas industries was just above the overall rate. It increased to $4.0 billion. Income originating in the mining and quarrying of nonmetallic minerals increased 15.8% to $1.8 billion. Income originating in the manufacturing sector increased 13.4% to $287.2 billion. The figure for the chemical and allied products industries increased 13.7% to $21.0 billion. The petroleum refining and related industries and the stone, clay, and glass products industries both had 14.3% increases in income, to $9.4 billion nad $9.9 billion respectively. Income originating in the primary metals industries increased 19.4% to $22.0 billion.

Profits and Dividends.—The average annual profit rate on shareholders' equity in all manufacturing industries increased during 1973 to 12.8%. Profit rates for all the selected mineral manufacturing industries increased significantly, and all but two industries (stone, clay, and glass products, and chemicals and allied products) increased at a greater rate than that for all manufacturing. One of these, chemicals and allied products, was the only mineral manufacturing industry with a greater average profit rate than that for all manufacturing. Profit rates in the primary metals industries, which were the lowest among the selected mineral manufacturing industries, increased more than 68%. Within this industry, the rates for primary iron and steel increased 58%, and those for primary nonferrous metals increased 83%. Profit rates in petroleum refining and related industries increased 33% to a rate of return of 11.6%.

Total dividends for primary metals increased in the same pattern as the profit rate, with primary nonferrous metals dividends increasing 46.8% to $543 million and dividends in the primary iron and steel industry increasing 21.3% to $559 million. Dividends for the stone, clay, and glass products, and for the chemicals and allied products industries increased at a slower rate than that for all manufacturing, which was 10.3%. Dividends in the petroleum refining and related industries were the largest among the selected mineral industries at almost $3.5 billion, a 3.8% increase over the previous year. Total dividends for all manufacturing in 1973 were almost $17.8 billion.

The total number of industrial and commercial failures in 1973 declined for the third consecutive year, although their current liabilities increased substantially. The total number of failures was 9,345, and the value of their liabilities reached almost $2.3 billion. There were 32 mining failures reported in 1973, 12 less than the figure for 1972, although current liabilities doubled from 1972 to the 1973 value of $23.9 million. In the manufacturing sector the number of failures declined in 1973, as did the current liabilities.

New Plant and Equipment.—New plant and equipment expenditures by mining and selected mineral manufacturing industries increased substantially in 1972. The figure for mining firms increased 14.0% to $2.76 billion; that for all manufacturing firms increased 21.2% to $38 billion. Expenditures increased for all of the selected mineral manufacturing firms. Primary nonferrous metals expenditures increased 42.4%, the largest increase; the smallest increase was a 3.0% increase in the expenditures of the petroleum and coal products industries.

Estimates of plant and equipment expenditures of foreign affiliates of U.S. companies in mining and smelting were revised back to 1966. Details may be found on page 19 of the December 1973 Survey of Current Business. Expenditures in mining and smelting increased 1% in 1973 to $1,261 million. Expenditures in Canada and Europe declined substantially, 26% for the former and 40% for the latter. Latin American expenditures increased over 7%, and those for all other areas increased almost 53% to $537 million. Expenditures in petroleum increased almost 16% to $6,180 million. All reporting areas except Latin America showed gains. The manufacturing sector showed gains in expenditures of almost 9% to a value of $7,743, with increases in all geographic areas.

Issues of Mining Securities.—Estimated gross proceeds of new securities offered by extractive industries totaled $1,073 million in 1973, compared with $2,010 million in 1972. Common stock accounted for 77.5% of the proceeds, preferred stock for 0.9%, and bonds for 21.6%.

Foreign Investment.—In 1972 direct private investment by U.S. companies abroad increased 9% to $94.0 billion (latest data available). The increase in the petroleum sector was also 9%; therefore, as a percent of the total, investments in the petroleum sector remained unchanged. The developed countries received $14.2 billion of the petroleum industry investment, while the developing countries received $9.9 billion. The book value of Canadian petroleum affiliates gained $162 million, compared with $327 million in 1972. The value of investments in European petroleum industries increased $800 million to $7.0 billion, the highest of all categories. Investment in Europe for all U.S. industries also increased. The Latin American countries' share of U.S. investment at the end of 1972 was $16.6 billion, compared with $15.8 billion in the beginning of the year. Investment for all industries was the lowest in the Middle East. Japan received the lowest investment in the petroleum sector, $796 million.

U.S. direct investments in foreign mining increased $411 million to $7.13 billion during 1972 (latest data available). Net capital outflows declined to $411 million. Reinvested earnings increased from $26 million in 1971 to $34 million in 1972. The developed countries again accounted for more than 60% of U.S. direct investments.

The value of foreign direct investments in the United States as a whole and in the U.S. petroleum sector continued to increase through 1972 (latest data available). Total foreign direct investments increased 5% to $14.4 billion, and in the petroleum sector the figure increased 4% to $3.2 billion.

TRANSPORTATION

The total quantity of selected minerals and mineral energy products transported by rail and water in the United States increased in 1972 (latest data available) but not at a rate as great as that for all commodities. Rail transportation of mineral products increased 2.2%, and water transportation increased 3.1%. More metals and minerals except fuels were transported by rail than water; however, for mineral energy resources and related products, the reverse was true. Total mineral products accounted for 56.2% of all commodities transported by rail and 83.4% of all commodities transported by water.

The quantity of metals and minerals except fuels transported by rail decreased by 1.1% to 396.5 million short tons. Iron ore and concentrates, iron and steel ingot, plates, rods, bars, tubing and other primary products, sand and gravel, crushed and broken stone, and phosphate rock were the largest users of rail transport in volume terms. Rail transport of most ferrous metals declined during 1972, and that of most nonferrous metals and nonmetals increased.

The quantity of metals and minerals except fuels transported by water increased 2.5% during 1972. Iron ore and concentrates and sand, gravel, and stone continued to be the two largest commodities transported by water in volume terms.

Mineral energy resources transported by rail increased 5.5% to 418 million short tons during 1972. Shipments of bituminous coal and lignite accounted for almost 89% of the total selected mineral energy resources and related products transported by rail.

The total volume of selected mineral energy resources and related products transported by water increased 3.4% to 577 million short tons during 1972. Coal, crude petroleum, and residual fuel oil accounted for almost 62% of this total.

A total of 951,200 miles of gas pipeline existed in 1972 (latest data available), a 1.9% increase above that of 1971. Total petroleum pipeline mileage in 1971 (latest data available) as reported previously was 219,000 miles. The total petroleum pipeline mileage reported was distributed among the following: Crude and gathering systems in field operations, 33%; large size crude trunklines, 34%; and petroleum product pipelines that extend from refineries to extraction terminals, 33%.

RESEARCH ACTIVITIES

Total expenditures for research and development activities for all industries were $19.5 billion during 1972 (latest data available). This was an increase of 6% over the $18.4 billion expended during 1971. Company expenditures increased almost 5% to

$11.2 billion, and expenditures by the Government increased almost 8% to $8.3 billion. Research and development in petroleum refining and extraction continued to decline, reaching $475 million during 1972. The great bulk of these expenditures was financed by private funds. Research and development expenditures in the chemical and allied products industries increased to $1.9 billion in 1972. Most of these expenditures also were privately financed.

Bureau of Mines.—Research activities of the Bureau were directed toward facilitating the efficient use of our natural mineral and fuel resources so as to insure adequate mineral supplies without objectionable environmental, social, and occupational effects. Bureau research concentrated on the following areas: Mining, metallurgy, resource recovery and pollution abatement, coal, petroleum, oil shale, economics, health and safety, explosives, and helium.

Bureau of Mines funding obligations for mining and mineral research and development were $77.50 million during fiscal year 1973, 9.3% more than for fiscal year 1972. Funds for applied research increased to $34.6 million, 44.6% of the total. Funds for basic research fell to $6.8 million, 8.9% of the total, and funds for development increased to $36.1 million, 46.5% of the total. Obligations for fiscal year 1974 were estimated to increase more than 16% to $90.1 million. Most of this increase was in funds for applied research. Bureau of Mines obligations for total research were $41.5 million for fiscal year 1973, a 2% increase above that of 1972. Funds for engineering sciences were $30.5 million; the figure for physical sciences declined almost $1.3 million to $9.3 million, the figure for mathematical sciences was almost $0.6 million, and the figure for environmental sciences increased to $1.1 million. Bureau of Mines funding obligations for total research for fiscal year 1974 were increased more than 25% to $52.0 million. Funds for engineering sciences were estimated to increase almost 25%, and those for physical sciences about 15%; those for mathematical and environmental sciences were estimated to almost double. Highlights of the accomplishments of Bureau research programs, including work in progress, are as follows:

Mining.—Bureau research investigations in the area of ground control have successfully tested, under actual mine conditions, both direct-wired and radio frequency models of a gage to monitor deflections of the mine roof. These gages provide early warning of roof sag and sound an alarm when critical deformation is reached. A titanium rock bolt load cell was developed and field tested at four mines in conjunction with other research projects. Several inquiries were received from mines wishing to obtain the cells for their own use. An instrument manufacturer has begun preliminary arrangements to obtain a license to produce the cells commercially.

A study to correlate strength of laboratory and in situ oil shale pillars was conducted as a first step in developing design criteria for underground room-and-pillar mining of oil shale. The conclusions drawn thus far were (1) high-angle joints can severely decrease in situ pillar strength and (2) the strength of jointed oil shale pillars can be determined accurately from laboratory strength tests on model pillars containing joints oriented as in its in situ counterpart.

One of the most promising techniques for mine stabilization is to consolidate the backfill. Laboratory tests using large-scale model stopes demonstrated the feasibility of consolidating mill run tailings by electrokinetics. The technique has an attraction to the operator in that the entire tailings output of the mill can be constructively used underground. Conventional backfill practice requires desliming and disposal of the slime fraction in surface ponds or dams. Increasingly stringent regulations for surface disposal make underground utilization of the tailings an attractive alternative.

A mine test of a flexible tunnel liner was completed. An 8-foot-diameter corrugated aluminum liner was installed with a 2-foot thickness of sand backpacking in extremely heavy ground at the Burgin mine (Utah). After 11 months, the drift is still open and usable. In contrast, a section of the same drift supported by yieldable steel arches was rehabilitated, but the steel arches have now failed a second time and that section of the drift has been abandoned.

An elastic-plastic, finite element analysis showing that a hydraulic backfill can effectively decrease stope closure and reduce pillar stress has been verified by field measurements in operating stopes. This better quality, higher modulus fill could permit removal of greater quantities of ore from the pillar area before a pillar rock-burst situation develops.

A preliminary experiment on the use of chemical explosives in vertical blast holes to fracture ground for in situ leaching of a shallow copper oxide ore body was successfully completed. The fractures were qualitatively judged adequate from the standpoint of creating permeability for leaching fluids. The encouraging results of this experiment have led to a cooperative agreement for further work at an operating mine in Arizona.

A study to determine the economics of using a large-diameter (12- to 24-inch) void hole in a burn cut and determine the influence of void hole diameter on fragmentation efficiency, depth of round pulled, and placement of the muckpile was begun. The first series of experiments were conducted in an underground copper mine and utilized a specially designed horizontal rotary drill to bore 12¼-inch-diameter holes. Several holes of this diameter were bored to a depth of 14 feet, and adjacent blastholes were fired to determine the correct burden and spacing. Using these results, a 50 foot-long, 12¼-inch hole was then bored and a 10- by 20-foot heading driven for this distance with excellent results in terms of blast efficiency and size distribution and placement of the muckpile. An advance of "pull" of 18 feet per blast round was achieved, which is approximately double the average advance previously attained in this mine using V-cuts.

High-pressure water jet cutting tests were made in conglomerate copper rock blocks over a broad range of pressures, standoff distances, and traverse speeds. Tests were conducted over a pressure range from 10,000 to 30,000 pounds per square inch. Under optimum conditions, depths of cut exceeding ¾ inch were obtained. Supplementary tests have shown that total energy requirements can be substantially reduced when mechanical action is used to augment the action of the water jets.

To eliminate problems of past mining activities, research efforts contained on subsidence control, controlling coal mine fires and burning coal refuse banks, utilizing coal mine refuse, and stabilizing and vegetating areas damaged by various types of past coal mining and processing activities. During the year four underground and/or outcrop coal mine fires on public and private lands were controlled, resulting in the conservation and protection of about 15 million tons of coal reserves.

Metallurgy.—The general objective of the metallurgy program was to provide, through research and development, the scientific and technical information necessary to encourage and stimulate the nonfuel minerals industry to make advancements in technology. During the year, industry frequently acknowledged its utilization of many of the Bureau's past research accomplishments in areas of metallic and nonmetallic minerals recovery as well as the production of improved metals, alloys, and ceramics.

The Bureau's program to demonstrate and evaluate processes for recovery of alumina from domestic nonbauxitic resources made excellent progress during the year. The first phase of the program, a miniplant for nitric acid leaching, was designed, installed, and successfully operated. Started in August 1973, the facility was capable of treating 60 pounds of calcined clay per hour. Representatives from industry attended the first full-scale demonstration of the miniplant in which the validity of the general flowsheet, and the chemistry of the process was shown. Invitations were also extended to the aluminum industry to participate in a 3-year program on a cost-sharing basis in order to accelerate the effort. To date, eight companies have indicated a willingness to enter the program starting in July 1974. Following the nitric acid evaluation, further evaluations are planned on hydrochloric acid, sulfurous acid, and lime-soda sinter processes. A significant new development in this program was the discovery that aluminum nitrate can be converted to the oxide using a fused-salt bath. The high heat transfer efficiency of the bath over proposed fluid bed schemes offers a significant energy and economic advantage as well as the means for effective recovery of reusable nitric acid.

Because of a pending worldwide shortage of rutile, considerable attention was given to developing methods for using domestic ilmenite to make feed material suitable for pigment-grade titania and titanium. The Bureau demonstrated a method to treat domestic ilmenite, including massive rock-type ores, using smelting and mineral synthesis techniques to yield high purity rutile. This method was applied successfully to both Idaho (33% TiO_2) and New York (45% TiO_2) ilmenites, to obtain 96% TiO_2 material, comparable to natural rutile in size, bulk density, purity, and response to chlorination. In another process, carbiding of calcium titanates and ilmenites after removal of iron was successfully achieved by adding lime and carbon to low-iron slags at elevated temperatures. The furnace product contained up to 70% Ti, 2.4% Fe, 24% C, and 0.7% SiO_2, which can be successfully converted to titanium tetrachloride with over 95% of the titanium in the feed converted to high purity titanium tetrachloride. Smelting with soda ash, in another process, demonstrated significant cost savings performance improvements, compared with using sodium borate as the flux.

The U.S. imports 90% of the ore needed to produce primary nickel. Research was started on developing the technology needed to utilize submarginal laterite deposits near the California-Oregon border and the nickel-copper deposits in Minnesota. The laterite process involved (1) carbon monoxide reduction, (2) multiple-stage oxidizing leach of reduced material, (3) extraction of nickel from solution, (4) extraction of cobalt from the raffinate, (5) magnesium removal by ion exchange, (6) recycling the solution back to the leach step, (7) stripping nickel from the solvent, and (8) electrolytic recovery of nickel. Recoveries from a laterite containing 1% nickel and 0.2% cobalt were 90% of the nickel and 83% of the cobalt, and no contaminating effluents were produced.

In fundamental flotation studies on galena, significant results were achieved in demonstrating the influence of surface oxidation products on electrochemical behavior. Results agreed with an earlier Bureau theory on the mechanism by which oxygen increases the flotability of sulfides using xanthate collectors, and the importance of semiconductor properties.

In continued research on gold and silver recovery, an improved cell for electrowinning gold from carbon strip solution was developed which promised notable improvements in convenience, cleanout time, and current continuity. Industry has expressed interest in using the Bureau cell, and adoption appears probable in the near future. In recent research, the carbon-in-pulp process was applied to silver ores, by moderately increasing the number of adsorption stages. Another promising low-cost carbon adsorption process was developed for recovering silver from mill tailings, in which 95% of the silver was selectively precipitated with sodium sulfide and removed by filtration. The effluent was passed through an activated-carbon column to collect the gold and residual silver, followed by newly developed alcohol-stripping techniques. An aqueous alkaline cyanide solution and methyl alcohol at ambient temperature, followed by elution with methyl alcohol distillate, stripped essentially all metals from the carbon. As a result of earlier research, pilot studies were initiated by a major gold producer for the recovery of gold from carbonaceous ore using the Bureau's electro-oxidation technique.

Because large reserves of native copper ores are too costly to mine and process by conventional methods, an in-place leaching method using ammonium carbonate was developed. In early leaching tests on 2% copper conglomerate ore with a 12-inch maximum rock size, about 57% of the copper was extracted in 60 days. In other Bureau research on copper heap leaching practices, major improvements in the recovery of copper and byproduct metals such as molybdenum, gold, and silver from some sulfide mine strip wastes were shown to be possible, by floating off the fines and using only the coarse rock. As much as 35% of the copper, 38% of the molybdenum, and 19% of the silver were recovered from the fines, while an additional 33% of the copper was recovered by leaching the coarse fraction. A total copper recovery of 68% was achieved, as compared to only 47% from leaching the ore, as received.

Considerable energy could be conserved and products improved if refractory-lined electric furnaces were used in place of water-wall cupolas for producing mineral wool from slags. A series of evaluation tests were conducted by the Bureau which demonstrated the superior performance of the high-alumina and basic refractories in resisting the molten slags. A demonstration test in a large electric arc furnace is being planned.

A new dicalcium silicate foundry mold

material suitable for both brass and steel castings was developed. This refractory material has the capability of self-decrepitation on cooling, permitting easy removal of the casting, and can also be reused. The mold material is produced by reacting $CaCO_3$ and SiO_2 at 1,400° C to form the gamma phase dicalcium silicate which changes in volume on cooling, causing the decrepitation. The beta phase portion of the material provides for its hydraulic setting capability in being made into a mold. More extensive foundry tests are planned.

Resource Recovery and Pollution Abatement.—The Bureau continued laboratory and pilot plant work to develop the citrate process for removing sulfur dioxide from waste gas. Construction was completed on phase 1 of the Bureau's citrate pilot plant at the Bunker Hill Co. lead smelter in Kellogg, Idaho. The citrate process is also being tested on stack gas from a coal-fired steam-generating station at the Pfizer, Inc., Vigo chemical plant, Terre Haute, Ind.

Extracting fertilizer from Florida phosphate minerals produces a slime, difficult to dewater, and requiring extensive holding ponds for storage. The Bureau's research, in cooperation with the Florida Phosphate Council, resulted in better characterization of the slime; data needed to develop an economical dewatering process. The amount of attapulgite in the slimes was highly variable and found to be a major factor in preventing easy dewatering. An anionic polyacrylamide was found to be an effective flocculating agent and is being investigated. Additions of tailing sand or use of sand as filter bed media also helped the dewatering. Another settling technique being developed moves screens slowly downward through vertical columns of slime, compacting the solids and collecting clear supernatant water above the screen.

Red muds from the Bayer alumina extraction process also pose a severe mineral waste disposal problem because of dewatering difficulties due to the extreme fineness of the suspended particles. In static settling tests, muds only changed from 14% to 20% solids in 48 hours; pH had no effect. In consolidation tests using vertical wick-drains, 34% solids resulted in 72 hours. The amount of liquid recovered was proportional to the number of drains, and the rate was dependent on the distance between drains. High-pressure filtration produced a 70% solids filter cake, compared to 50% for low-pressure filtration.

Several techniques for purifying waste waters from mineral- and metal-processing operations were developed. Methods for controlling troublesome calcic scale included an ion-exchange system for removing calcium sulfate and the use of trace quantities of chemical agents for preventing scale formation. Another ion-exchange technique used an inexpensive, naturally occurring zeolite for sorbing ammonia from waste water. Lignite was found to be an inexpensive scavenger for traces of mercury and cadmium remaining in waste water after conventional lime treatment. Selenium was precipitated from waste water using either metallic iron or zinc precipitants; testing on a larger scale is planned at a zinc refinery.

The Bureau's raw refuse pilot plant facility was significantly improved during the past year. High-quality glass was recovered from putrescibles by a multistep froth flotation process. High-quality aluminum was recovered from the glass by screening. Mixed heavy nonferrous metals were accumulated at the bottom of the jig bed. Reshredding and washing of the magnetic product, mostly tin cans, was simplified to prepare this material for detinning. In addition, combustible products obtained from the pilot plant were evaluated as potential fuel. On the average, refuse as received produced 5,000 Btu per pound and total combustibles, as recovered, produced 6,200 Btu per pound. A suitable method for recovery of aluminum from the secondary air classifier heavy product is being developed. Electrostatic separation showed considerable promise, producing concentrates of 80% to 85% aluminum with recoveries as high as 98%. High-frequency induction-repulsion also appeared promising with recoveries of up to 90%. Bureau-developed technology will be used extensively in constructing a new facility at Berlin, Conn., for the Connecticut Resource Recovery Authority.

The Bureau's incinerator residue recovery pilot plant was operated in support of the demonstration plant to be built at Lowell, Mass., by Raytheon Service Co.

Bureau junk automobile research has produced a new improved incinerator designed for smokeless burning. The prototype is capable of burning 10 flattened or 6.5 unflattened cars per hour. Currently, 26 similar junk auto incinerators are planned, under construction, or in operation. A much larger incinerator was built, based on Bureau design and capable of handling 1 railroad car or 20 scrap autos at a time. Equipment was also designed for separating the nonmagnetic reject of junk auto shredders into polyurethane foam, plastic, and metal concentrates. Further separation is possible to recover reusable materials.

The feasibility of preheating beds of ferrous scrap using exhaust gas from a basic oxygen furnace (BOF) was demonstrated. Using this technique, the 28% cold scrap maximum contained in the normal BOF metallic charge could be increased to 40% with heated scrap, a significant increase. This method recovers up to 50% of the energy contained in the offgases.

A new technique was developed for treating aluminum dross that eliminates the need for salt fluxes. Recoveries up to 100% of available metallic aluminum were obtained from samples held in an inert gas atmosphere at 740° C. This technique significantly reduces air contamination, eliminates slag formation, and yields aluminum recoveries equal to or greater than those obtained with salt fluxes. In addition, a hydrometallurgical process was developed for treating high-salt aluminum slags to recover fluxing salt, aluminum metal, and aluminum oxide. The process appears economically adapted to commercial application. A small demonstration plant will be operated for treating 50 to 100 pounds of slag per hour.

Other significant research was concerned with recovering metals and sands from foundry operations, silicon carbide from granite sawing, and metals from flue dust, mill scale, and industrial sludges.

Coal.—Coal research undertaken by the Bureau showed increased emphasis on the conversion of coal to low-ash, low-sulfur fuels through either gasification or liquefaction. At the same time continued effort was expended to improve the quality of the environment.

Work on the SYNTHANE pilot plant has progressed significantly. This Bureau-developed process gasifies any kind of coal with oxygen and steam to produce substitute natural gas. Following completion of pilot plant construction, operation should provide data essential to demonstrate the commercial feasibility of the process.

Favorable results were obtained in converting high-sulfur coal to low-sulfur oil by the SYNTHOIL process. In this process, coal slurried in recycle oil is propelled by rapid, turbulent flow of hydrogen through a fixed bed catalytic reactor at 840° F (450° C) at pressures up to 4,000 pounds per square inch. Using a cobalt molybdate catalyst, about 95% of the coal is transformed into an oil that is fluid at room temperature and is suitable for boiler plant fuel. Design of an 8-ton-per-day pilot plant is underway. In addition, a feasibility study of the process was completed by an outside engineering firm.

In coal-hydrogasification research, a preliminary test in the 10-pound-per-hour HYDRANE process developed unit (PDU) resulted in smooth operation of the first stage for 1½ hours. This was followed by a second 1½-hour run in the integrated first and second stages, during which test the moving-bed second stage operated at 1,290° F (700° C) and 1,035 pounds per square inch with a product gas containing 35% methane.

Research during the year on the Bureau's COSTEAM process showed that ash recovered from easily liquefied coals can effectively catalyze the liquefaction of more refractory (difficult to liquefy) coals.

During the year the final report on the design to be used in construction of the wood-to-oil pilot plant was completed. This pilot plant is to be erected at the Albany Metallurgy Research Center, and will be capable of converting 3 tons per day of wood chips to about 6 barrels of low-sulfur fuel oil.

In combustion research during the year, the combustion characteristics were determined for low-volatile (5%) chars prepared from Illinois and Utah coals. When the chars were fed to the 500 pound-per-hour pulverized-fuel-fired furnace at ambient temperature, supplemental fuel equivalent to 15% of the total thermal input was required to maintain stable flames. Preheating the primary air-char stream to 450°–500° F eliminated the supplemental fuel requirement.

In related coal combustion studies, construction was continued on the three-stage combustor, designed to produce low-ash, high-temperature gas suitable for use in open-cycle MHD power generation. This combustor could also be used as a source of low-Btu gas for firing boilers.

Testing of the stirred-fixed bed gas producer continued during the year, employing both caking and noncaking coals, again illustrating the versatility of this equipment. Preliminary results showed that when limestone chips were added to the coal feed, about one-half of the coal sulfur, which otherwise would appear as H_2S in the product gas, could be retained in the ash in the bed.

Treatment of dried lignite with oil was found to reduce reactivity of very-low-moisture lignite more effectively than similar treatment of lignite dried to a midmoisture content. The deactivation of dried low-rank coals to permit safe shipment and storage is a major objective in upgrading low-rank coals by drying. Such results may help establish commercial feasibility of the process.

Bureau research in coal preparation has resulted in the development of a two-stage pyrite flotation process, which in laboratory tests removed up to 90% of the pyrite contained in a Lower Freeport bed coal. Recently, the Bureau entered into a cooperative research program with a coal company to study the applicability of this process to a high-sulfur coal now being discarded as waste. Meanwhile, the two-stage pyrite flotation process is also being considered by a major steel company for commercial application to sulfur removal from Pittsburgh-bed coal.

Petroleum.—In what is planned to be a series of cooperative projects for increasing the production of domestic petroleum and natural gas, the Cities Service Oil Co. has signed a contract with the Bureau of Mines to perform a field demonstration of a micellar-polymer recovery method. Cities Service has chosen as the test site the El Dorado field, Butler County, in south-central Kansas. The field is typical of a depleted waterflood project that still contains oil that is unrecoverable by present technology. It is expected that nearly a year will be required to drill the pattern wells and prepare the field for the injection of the micellar fluids, and completion of the demonstration will take about 5 years.

A contract has been negotiated with the Sohio Petroleum Co. and others for use in in situ oil recovery field tests on 10 acres within a 320-acre tract they own in the Northwest Asphalt Ridge tar sand deposit.

Detailed characterization studies were initiated with the receipt of a sample of Utah Syncrude. This coal-derived oil, produced by the pyrolysis of Utah A-seam coal in the Coal-Oil-Energy Development (COED) process development unit at Princeton, N.J., has been hydrotreated to make a synthetic crude oil. This is the first in a series of samples to be analyzed in cooperation with the Office of Coal Research. The compositional data to be provided by the Bureau will be used to evaluate the oils in terms of ease of processing into quality fuels and to select the most appropriate plant operating conditions to produce such oils.

The Committee on Data for Science and Technology (CODATA) of the International Council of Scientific Unions (ICSU) recently issued a set of CODATA Recommended Key Values for Thermodynamics of 22 chemical species. The values are based on selections made at the U.S. National Bureau of Standards and the Institute for High Temperatures of the Academy of Sciences, U.S.S.R. Enthalpy-of-formation data provided by the Bureau of Mines were used in selecting the enthalpies of formation values for 6 of the 22 species.

In studies aimed toward developing an understanding of asphalt-aggregate adhesion, sulfoxides have been identified and quantitatively measured in the strongly adsorbed material found at the asphalt-aggregate interface. Sulfoxides are readily formed during the preparation of hot-plant road mixes from the sulfur compounds normally present in petroleum. They account for up to 25% of the strongly adsorbed materials and may be important to the water stability of the asphalt-aggregate bond. Moisture-induced damage in asphalt pavements is a major cause of road failure in many parts of the country.

Information recently has been released from both Government and industry sources showing that fuel economy of late-model autos has been reduced sharply in changing engines to control emissions. With fuel supply in deficit, the question is now asked—"Would economy be improved if emission controls were deactivated?" Although the Bureau has neither proposed nor endorsed such a course of action, its technical staff recognized a need for relevant data. To that end, fuel economy data were obtained on seven late-model cars, each tested both in standard configuration and with simple modifications that deactivated some emission controls. Results showed an average 9% gain in fuel economy. As expected, taken overall, emissions were increased—hydrocarbon up an average 30%; oxides-of-nitrogen, about 100%. Carbon monoxide emissions were relatively unchanged. It should be noted, however, that these percentage increases were from a low base and that at the higher values the emissions levels were, on the average, far below levels that were typical of precontrol autos. Detailed information on the test procedures and the results have been placed in an open file report.[4]

Particulate matter in the atmosphere can be a health hazard depending upon its composition, particle size, and other as yet poorly defined characteristics. In underground mines, diesel engines are a source of such airborne solids. Because of the possible health effects, the Bureau's experimental program on diesel exhausts included study of exhaust particulate. Results of experiments completed recently indicated that the mass loading of particulates in the exhaust from typical "clean" diesels may be as great as 100 times the allowable level in the working atmosphere. While ventilation air must be supplied to ensure adequate dilution of other toxic components in the exhaust, the amount required to purge the atmosphere of particulates may be even greater and thereby constitute an additional cost burden. In addition to the particulate matter, sulfuric acid droplets may be formed from the sulfur contained in the fuel. Results to date show that H_2SO_4 levels are very low except in the case where engines have been outfitted with oxidation catalysts. In this latter case, levels of sulfate have been found to be as great as 100 times the tolerable level. The sulfates are measured as an integral part of any particulate study.

The Higgins-Leighton waterflood prediction mathematical model and associated computer programs have been used extensively by industry since its publication by the Bureau several years ago. Using the model, an oil operator can select the operating conditions that will recover the highest possible percentage of the oil in the ground to meet the Nation's energy requirements. The model can also reveal inadequacies in the existing reservoir data.

Experimental work was recently completed on a study to determine how ambient temperature influences automotive emissions. Results showed that, in general, unburned hydrocarbon and carbon monoxide emissions were lowest when operating a vehicle within the 70°–80° F range. Amounts of those materials in the exhaust tended to increase with either lower or higher temperatures. The inference to be drawn is that measurements of emissions that are at the "normal" ambient test conditions may not provide a true measure of the emissions problem under real-world conditions. The data will provide a basis for judging (1) the need to adjust emissions estimates for existing ambient temperature, (2) the need for certification testing at more than one temperature, and (3) the need for some degree of control on the temperature-related degradation of emission under control system performance.

Oil Shale.—The oil shales of the Western United States represent one of the largest accumulations of hydrocarbon reserves in the world. Efforts have been undertaken to promote the development of these reserves. A new project was initiated on managing wastes and pollutants. The first problem to be undertaken—a study of the migration of fluids in connection with in situ oil shale processing—will utilize the in situ project already underway near Rock Springs, Wyo. An additional site in the northern Green River Basin was chosen at which underground water conditions will be established prior to any processing activity. Automatic data processing techniques are to be used to gather, store, process, and disseminate the mass of data required for a statistically sound project design.

Work continued at the Rock Springs site in preparation for an in situ combustion experiment at moderate depth. The zone to be retorted is being prepared by detonation of explosives injected into horizontal fractures created by hydraulic facturing, in contrast to a previous experiment at similar depth in which explosives were detonated in boreholes to establish the fracture system. A significant advance in fracturing research was obtained during the current site preparation by the creation of a system of three horizontal fractures separated by

[4] Eccleston, B. H. Emission Controls and Fuel Economy of Seven 1973 Vehicles. BuMines Open File Report, Feb. 15, 1974, 12 pages.

intervals of only about ten feet of shale at depths of 146 to 172 feet.

Experimentation in laboratory and pilot-size retorts simulating in situ conditions was continued to determine effects of operating variables, A series of six runs was completed in a 10-ton retort to study scale-up factors, using operating conditions duplicating previous runs in a 150-ton retort, and a new series was begun involving the addition of steam to the retort atmosphere. A small pressure retort was used to study effects of simulated overburden pressures in an inert atmosphere (nitrogen), and a report was prepared describing the effects on oil yield and quality. A similar series of experiments was begun using hydrogen as the retorting atmosphere. Preliminary results indicated that oil yields are higher than in the experiments with nitrogen.

Major contributions were made to the Department of the Interior Prototype Oil Shale Leasing Program, both through assistance in preparation of the Final Environmental Impact Statement and through rapid and timely assay of additional core samples from lease tracts and other sites in Colorado, Utah, and Wyoming. A report was published describing for the first time the oil shales in the Washakie Basin of Wyoming which includes two of the tracts offered for lease.[5] In addition to the Washakie Basin report, other reports on properties of oil shales relevant to their processing included one on shales at the Bureau's site near Green River, Wyo., one on the oil shales in Uintah County, Utah, one on the occurrence of aragonite in oil shale, one on a technique to estimate nahcolite and dawsonite from oil-yield data, and one on the thermal properties of two of the important oil shale minerals, dolomite and shortite.

Work directly concerned with oil shale processing resulted in a report on the kinetics of oil shale pyrolysis and three papers on shale oil processing. These papers covered the subjects of production of a shale oil Syncrude, characterization of this Syncrude, and catalytic denitrification of a shale gas oil.

Bench-scale research was conducted on gasification of shale oil or oil shale as an alternative or supplementary method of obtaining fuel values from oil shale by in situ processing. A series of single-stage hydrogasification experiments with in situ crude shale oil was completed, new equipment for two-stage hydrogasification was installed, and experiments were begun. Initial experiments obtained higher gas yields than with single-stage hydrogasification, and showed that over 97 weight-percent of the crude shale oil can be converted to gas with a high methane content.

Major progress was made under a lease agreement for an industry-sponsored project to develop and demonstrate a new aboveground retort design at the Bureau's Anvil Points facility in Colorado. The operating company, Development Engineering, Inc., took over the facility and completed construction of a pilot-size retort on which shakedown operations were begun with promising results. Installation of a semi-works-scale retort also neared completion.

Economic Analysis.—The Bureau's economic research program concentrated on analysis of the economic situation within the minerals sector as well as on how the mineral industries affect and are affected by conditions prevalent in the national and international economies. This research was designed to determine and interpret with accuracy the current situation so as to provide decisionmakers with adequate background material for their deliberations. The economic analysis program attempted to pinpoint pertinent data, and to develop the general methodology needed for such analysis. Major long-term research projects undertaken included the study and forecasting of demand, supply, and productivity; projections of economic data; financial analysis; mineral taxation; waste recycling; index numbers; input-output analysis; measures of economic activities stimulated by mineral industries; and the study and reporting of weekly price changes. Short-term projects, responding to the need to deal with rapidly changing economic conditions, were also a major part of the Bureau's economic research program. During 1973, short-term projects undertaken included oil shale leasing, alternatives for natural gas, a short-term energy forecasting model, an environmental impact statement on surface mining of coal, the impact of the Arab oil embargo on U.S. petroleum refineries, the impact of deficits of coal supplies on the U.S. economy, a solid waste

[5] Trudell, Lawrence G., Henry W. Roehler, and John Ward Smith. Geology of Eocene Rocks and Oil Yields of Green River Oil shales on Part of Kinney Rim, Washakie Basin, Wyoming. BuMines RI 7775, 1973, 151 pp.

management model for Spain, international mineral resources, minerals futures markets, projections of demand for stone and sand and gravel, energy's contribution to GNP, the value of primary minerals, and the impact of increased cost of gasoline on the demand for minerals.

Health and Safety.—Major efforts have been continued by the Bureau toward improving and securing the health and safety of miners. A portion of the research is summarized below.

The Bureau's pumpable roof bolt was field tested at the White Pine copper mine in Michigan. Because of the White Pine success, a contract was awarded for large-scale field demonstrations of the pumpable bolt. Under this contract a prototype pumpable roof-bolt machine was constructed, which would provide for remote-automatic installation of the bolts and incorporate the latest safety features developed under other program areas. Pumpable bolts will then be extensively tested in direct comparison to conventional bolting systems in at least two operating coal mines.

The Bureau's shortwall mining demonstration was initiated with the signing of a cooperative agreement with a coal operator and subsequent purchase of a shortwall roof support system. The props were delivered and installed, panels laid, and mining begun. The coal operator is to supply all of the remaining equipment. A rock mechanics study has been initiated to provide data from this demonstration which will aid other operators in determining the applicability of shortwall mining to their individual situations.

A comprehensive study of the behavior of the rock mass above an operating longwall was initiated. Fieldwork was conducted in cooperation with an operating coal company over a longwall mine in West Virginia. The data will be used to help operators and to further the understanding of subsidence.

Efforts to develop coatings to replace urethane foams for coal mines continued. A variety of sealants previously applied in the Ireland mine, Moundsville, W. Va., have been evaluated for their durability and effectiveness under severe conditions. Of the sealants tested, urethane foams (applied as a basis for comparison) and vermiculite cement sealants showed the least evidence of a sloughing or deterioration. More recently, about 15,000 square feet of roof and rib were coated with a magnesium oxsulfate sealant. Laboratory testing of this incombustible sealant indicated that it may be capable of replacing urethane foams in many instances. Field testing at the Ireland mine is designed to provide performance data for comparison with that of the sealants previously tested.

Techniques to strengthen rock in advance of mining by polymeric grouting were tested at a coal mine in West Virginia. Core sampling after mining had advanced showed that the polymeric material was completely cured, and that cracks as fine as 1 mil had been successfully bonded. The test showed that a friable coal mine roof can be successfully bonded into a more competent structure.

An evaluation determined that six brands of currently available wearable audiodosimeters met required response and overall accuracy requirements. A prototype time-resolved dosimeter, an instrument which records noise exposure as a function of time, was built and gave results that agreed well with data from a concurrent noise survey in a coal mine.

Tests of a trace gas technique that was developed for observing the course of ventilation air in metal and nonmetal mines showed it to be an excellent method for evaluating recirculation and the transit times of air and determining flow volumes and velocities, air exchange rates, and auxiliary fan effects in large airways with velocities too low for standard methods.

Four ignition suppression devices were being tested on continuous miners that are producing coal in gassy mines in West Virginia. The success of this effort will be evaluated after each of these machines has mined at least 20,000 tons of coal. Techniques have been developed for the construction of airtight and watertight seals from the surface through boreholes into the mine where out-of-control mine fires cannot be fought directly. The system was proved by the sealing of various passageways including a massive four-way intersection in a mine in West Virginia.

Work was completed on a contract to select the type of large mobile mining equipment most prone to fire, and to develop and demonstrate a fire sensing and control system for this equipment. The fire control system was successfully field-tested at two mines, each with adverse hot and cold temperatures, on a 100-ton-capacity ore truck. Fires set in the engine compartment and brake grid areas were automatically sensed and suppressed. Safety and management personnel at these mines were very interested in this piece of hardware, because it offered protection to the truck driver and protected a very expensive piece of equipment.

Meaningful progress toward acquisition of a multientry fire and explosion underground test facility was made during the year. The conventional mining system portion of the Inherently Safe Mining Systems (ISMS) demonstration phase was being conducted in a new single-section mine in Kentucky. Negotiations to acquire this site on a long-term basis, for fire and explosion research subsequent to the ISMS work, were in progress at yearend.

Preliminary results indicated that direct gas measurement on exploration cores can be used to estimate coalbed gas content and approximately predict methane emissions from a prospective mine. Monitoring of the vertical boreholes that have been drilled far in advance of mining has shown that dewatering of the coal is the key to successful degasification.

Respirable dust research was rapidly shifting to underground evaluation and demonstration. Dust suppression by water infusion was studied in three separate coal mines. In one of the sections significant respirable dust reduction was obtained, and the mining company has decided to modify a longwall section for routine application of the infusion procedure as part of the mining cycle. The remaining two companies have incorporated infusion into their dust control plans. An air curtain respiratory protective device that is part of the miner's hat was designed, developed, tested, and fabricated. Underground tests are to be conducted. A Stanford Research Institute optical particle counter developed under contract was evaluated in the laboratory. It has a linear response in the range of 1 to 40 milligrams per cubic meter and is easily reproducible and very reliable for relative measurements of dust concentrations. A new rapid infrared technique for the evaluation of alpha quartz in an individual field sample was developed. Comparison of this new technique with existing infrared and X-ray techniques showed positive correlation.

Two self-contained personal breathing apparatus have been developed to replace the currently used self-rescuers which are ineffective in atmospheres containing more than 1½% carbon monoxide and less than 16% oxygen. One apparatus has a 10-minute oxygen supply and the other a 1-hour supply. Both will protect the miner regardless of the toxic gases in the mine air. Both units have been tested and approved by the National Institute for Occupational Safety and Health.

Two improved communications methods for rescue teams have been developed to replace the heavy sound-powered telephone system which includes a handset and reel of wire. One method is a versatile, lightweight radio (walkie-talkie) that uses an unattached small-diameter wire between the radios for an antenna. The other method consists of a hand-free conduction microphone and ear speaker mounted on the rescuer's hardhat and a relatively lightweight attached wire between the fresh-air base and the rescue team.

Prototype electromagnetic hardware for locating trapped miners within 40 feet has been developed and tested successfully at four mines in West Virginia and Pennsylvania having overburdens as thick as 900 feet. The system consists of a miniature transmitter packaged inside the miner's cap lamp battery and operates from a small amount of excess energy in the battery. The signal is transmitted through the earth from a loop of wire connected to the transmitter and is detected by equipment carried on the ground surface or suspended from a helicopter.

Equipment and procedures were being developed to warn of unsafe conditions caused by high levels of CO, CO_2, and NO_x in diesel engine exhaust. Several types of monitors were investigated for each gas. Other efforts were directed specifically at reducing the levels of toxic emissions from diesel engines to the lowest levels practical without sacrificing engine performance.

Thirty-seven coating materials were tested in the laboratory for their ability to stop radon gas. Fifteen were successful in stopping 50% or more of the radon emanation from uranium ore specimens, and five of the best were selected for field testing. An instant working-level meter was developed by adapting and modifying an existing prototype instrument. This improved unit will sample, analyze, and indicate automatically the working level exposure resulting from the three different radon daughters and their ratios. The Bureau of Mines Dakota Experimental Uranium Mine near Grants, N. Mex., was used extensively for underground evaluation of laboratory-developed control technology and advanced instrumentation. A new experimental mine, located in Uravan, Colo., was leased following expiration of the Dakota mine contract. The new mine is being prepared for extensive use in 1974.

The toxic gases and vapors that may result from mine fires can present a major hazard to miners. A large number of brattice cloths, conveyor beltings, and hydraulic fluids have been approved in the past on the basis that they are fire retardant; however, their potential for toxic gas generation through decomposition has not been determined. Investigations were undertaken to determine and quantitatively analyze the toxic products produced upon thermal decomposition or combustion of these thermally unstable materials. Fourteen different items have been investigated using three different thermal test methods to determine the toxic compounds formed on a weight per weight basis, including gases and vapors.

A mine monitoring system has been developed, installed, and operated in a West Virginia coal mine. The system monitors a variety of environmental parameters at the intake and return of an air split. The data are telemetered to the surface, then sent via a leased telephone line to a remote computer where they are accumulated and analyzed. Results to date indicate that the monitoring system is suitable for use in underground mine environments and can be used to predict problems in the mine. Based upon experience from this and other mine monitoring systems that have been developed and are under evaluation, a new miniaturized mine monitoring and telemetry system has been developed by the Bureau. The system monitors four parameters (methane, ventilation, carbon monoxide, and temperature) and computes temperature rate of rise. The underground monitor station is housed in an enclosure approximately the size of a loud-speaker telephone and displays the results of the monitored parameters underground as well as telemetering this information to a small surface console.

A "Call Alert" system has been developed which consists of small pocket-sized receivers worn by roving miners that can be selectively activated from remote locations underground and on the surface. This system can be used to alert a specific individual that he is wanted on the loud-speaker telephone. The system is simple and inexpensive and requires only a small modification to the existing mine telephone circuit.

First generation mine lighting systems using circularly polarized, high-pressure sodium lamps were evaluated in high coal in an operating mine. The portable area system in both conventional and continuous miner sections and the machine-mounted system achieved the desired level of illumination in accordance with existing proposed standards, had very low maintenance, and in general were acceptable to mining personnel.

Efforts were continued to develop and test the feasibility of using protective canopies on low-coal electric face equipment. Adjustable canopies have been designed, fabricated, and installed on two shuttle cars, a cutter, a drill loader, and a roof bolter. Installation was made in two mines. The preliminary results appeared promising. Research continued to investigate the feasibility of using remote, semiautomatic or automatic controls on mining machines used in the face area and on shuttle cars. Various facets of these systems have been successfully demonstrated.

A contract was let in fiscal year 1972 to determine the adequacy of available circuit breakers for use on 300- to 600-volt direct current (v.d.c.) circuits. The existence of "molded case breakers" suitable for interrupting 300- and 600-v.d.c. service in underground coal mines has been demonstrated. Permissible quick-opening electrical enclosures with a built-in feature to lock and check the access cover have been developed. This new design will provide more expeditious access to components inside explosion-proof boxes for maintenance and inspection and still maintain the essential explosion-proof provisions of these boxes.

An automated prototype peristaltic conveyor was developed, and a number of coal slurry tests were made. The conveyor consists of air-actuated rubber valves connected in series. A slurry of ¼-inch by 0 coal with a concentration of 55% by weight was successfully conveyed; tests using larger coal sizes and greater concentrations have been unsuccessful to date. The peristaltic conveyor has potential for moving high-concentration slurries over short distances and for injecting solids into a pressurized continuous hydraulic transportation pipeline.

The primary technology transfer effort in 1973 was the active dissemination of research accomplishments through the mechanisms of Open Industry Briefings (OIB) and topic seminars. The Bureau held six Open Industry Briefings in conjunction with various mining associations across the United States. These briefings provided status reports to the mining industry on Bureau research programs such as methane control, respirable dust, fire explosion prevention, and others. Four seminars were also held by the Bureau during 1973. Seminars, unlike the OIB, dealt in much finer detail with the specifics of the Bureau's research accomplishments, including the engineering details of applying technologies of oil and gas well plugging, methane control, instrumentation for mine design, mine communications, and ground control aspects of coal mine design. These meetings, attended by representatives from the mining and associated industries, have in fact provided impetus for adoption of Bureau-developed research accomplishments. An additional effort of this type was the technology transfer exhibit at the 1973 coal show at which a large number of Bureau-developed devices were displayed. The first of a new publication series, *Technology News,* was also being prepared for distribution throughout the industry. The series will offer concise, definitive, application-oriented statements of accomplishments that have resulted from the research program and will provide timely information to potential technology users.

Explosives and Explosions.—The technical feasibility of the major objective of the explosive identification program was accomplished by successfully extracting a seven-element code from phosphor grains surviving detonations. However, raw phosphor grains were found to sensitize some explosives; suitable grain coatings are currently being explored to eliminate this effect.

Various sensitivity tests were conducted on a large number of different blasting agents used in metal and nonmetal mining. Ammonium nitrate-fuel oil (AN-FO) mixtures using four types of Canadian AN were found to exhibit unusually high sensitivities; the most sensitive mix had a 50% initiation velocity (V_{50}) of 640 meters per second and was cap sensitive.

The feasibility of formulating a water-based explosive without the use of flaked aluminum or explosive sensitizers was demonstrated.

Seven experimental detonators with different casing material were evaluated for incendivity in 8% natural gas-air. The least incendive material was nickel-clad steel, which was found to be slightly less incendive than copper and could serve as a substitute in times of copper scarcity.

In research on hazardous materials, the effort to improve the drop weight, static spark, and friction sensitivity tests was continued. It was found that primary explosives like lead azide could be initiated with the same spark stimulus in an N_2 atmosphere as in air, while substances like powdered tetryl which appear to deflagrate could not be initiated in an N_2 atmosphere at spark energies several orders of magnitude higher than that observed in air trials. Laser ignition of explosives was also demonstrated.

Quantitative luminosity measurements on the light generated by water-based permissible explosives established that they generate a larger amount of visible radiation than conventional permissible explosives; however, this is not reflected in an increase in their relative incendivities in natural gas-coal dust-air mixtures. An empirical ignition probability model which related explosive chemical composition and relative incendivity was developed during extensive computer studies of incendivity test results.

Helium.—The Bureau of Mines has over the years maintained at least a minimum research effort in the areas of helium production and analytical methods and techniques relating to helium in natural gas and the impurities in the purified helium. During 1973, laboratory work continued in this vein with the development of a highly sensitive analytical procedure which accurately detects the helium-3 content in helium-4 in the parts-per-billion range.

In conjunction with this development, the Bureau completed a laboratory project which lowers the helium-3 content of helium-4 from the normal level of about

250 parts per billion to below 20 parts per billion. This special helium-4 has application in the developing field of helium-cooled nuclear reactors. Helium-3 molecules circulating around a reactor core, along with the normal helium-4, are bombarded with neutrons. As a result, radioactive tritium is formed. When the helium-3 is removed from helium-4, the potentially troublesome radioactive source is removed. Helium-4 leaves no such radioactive product.

LEGISLATION AND GOVERNMENT PROGRAMS

Significant Federal activities in the minerals sector included special actions to fight inflation and to meet the energy crisis as well as continuing programs dealing with the environment, water, public land, national stockpile, and tariffs.

Actions taken under the Economic Stabilization Act of 1971 included shifting from phase 2 (which was in effect during all of 1972) to phase 3 in January 1973. Phase 3 was intended to be a step toward the eventual end of price controls. It involved the self-administration of a modified version of the general standards of phase 2. Prenotification for price increases was modified and eliminated for wage increases. Fewer firms were required to report, and rents were added to the phase 2 exemptions to the price standards. The rate of inflation during the first 5 months of 1973 remained disappointingly high, with few signs that it would slow later in the year. On June 13 the President announced a new 60-day freeze to be followed by phase 4. Phase 4 combined some aspects of both phase 2 and phase 3 although in some cases it was stricter than phase 2. Phase 4 remained in effect for the remainder of 1973. Inflation continued to be a major problem during 1973 in spite of the price controls.

During 1973 the United States was faced with an energy crisis. Shortages of petroleum late in the year following the decision by several Arab nations to cut back crude oil production and to curtail shipments to the United States impelled the Federal Government to attempt to conserve and allocate energy supplies to insure the availability of fuels for critical uses. A long-range outcome of the energy crisis was "Project Independence" which was designed to ensure an expansion of domestic energy production so that the economy would no longer face disruption or the threat of disruption from sudden curtailment of vital energy supplies.

Legislation affecting the mineral sector and approved during the first session of the 93d Congress covered such areas as energy, the environment, water, public lands, the national stockpile, and duties. Energy was the concern of a number of laws. P.L. 93–159 gave the President the authority to deal with the energy shortages. Two other laws dealt with energy conservation. P.L. 93–182 put the country on daylight saving time year-round. P.L. 93–239, which was passed during 1973 but not signed by the President until early 1974, established a maximum 55-mph national speed limit. P.L. 93–88 amended the Euratom Cooperation Act to increase the amount of contained uranium 235 which the U.S. Atomic Energy Commission is authorized to transfer to the European Atomic Energy Community. Several laws concerning the environment were passed. A number supplied funding to continuing environmental programs; others were concerned with international environmental agreements. P.L. 93–207 extended and expanded the Federal Water Pollution Control Act. Other measures of interest to the minerals sector included laws for disposing of the zinc, copper, silicon carbide, molybdenum, and aluminum in the national stockpiles, and laws which extended the suspension of duties on certain copper, certain kinds of metal scrap, and manganese ore. A listing of mineral related Federal legislation signed into law during 1973 follows:

Public Law (P.L.)	Description	Signed into law
Energy:		
P.L. 93–88.	—To increase enriched uranium ceiling under Euratom Cooperation Act.	Aug. 14
P.L. 93–159.	—Proposing more precise and definite authority for the President to deal with emergency shortages of petroleum products.	Nov. 27
P.L. 93–182.	—Providing for use of daylight saving time on a year-round basis until April 1975.	Dec. 15
Environmental quality:		
P.L. 93–14.	—Authorizing funds for the administration of the Solid Waste Disposal Act for fiscal year 1974.	Apr. 9

Public Law (P.L.) Description	Signed into law
Environmental quality—Continued	
P.L. 93-15.—Authorizing funds for the administration of the Clean Air Act for fiscal year 1974.	Apr. 9
P.L. 93-36.—Authorizing funds for the Office of Environment Quality for fiscal years 1974 and 1975.	May 18
P.L. 93-119.—Implementing the 1969 and 1971 amendments to the International Convention for the Prevention of the Pollution of the Sea by oil.	Oct. 4
P.L. 93-188.—Providing for U.S. participation in the United Nations environmental program.	Dec. 15
P.L. 93-201.—Proposing removal of certain restrictions on the transportation of dry bulk commodities by water carriers.	Dec. 27
Water resources:	
P.L. 93-51.—Authorizing funds for the saline water conversion program for fiscal year 1974.	July 1
P.L. 93-207.—Proposed Federal Water Pollution Control Act Amendments.	Dec. 28
Public lands:	
P.L. 93-153.—To establish a Federal policy granting rights-of-way across Federal lands.	Nov. 16
P.L. 93-184.—Providing for the conveyance of certain mineral rights in and under lands in Onslow County, N.C.	Dec. 15
National stockpile:	
P.L. 93-212.—Authorizing disposal of zinc from the national stockpile.	Dec. 28
P.L. 93-214.—Authorizing disposal of copper from the national stockpile and supplemental stockpile.	Dec. 28
P.L. 93-216.—Authorizing disposal of silicon carbide from the national stockpile.	Dec. 28
P.L. 93-219.—Authorizing disposal of molybdenum from the national stockpile.	Dec. 28
P.L. 93-220.—Authorizing disposal of aluminum from the national stockpile.	Dec. 28
Tariffs and duties:	
P.L. 93-77.—Extending to June 30, 1974, the suspension of duty on certain copper.	July 30
P.L. 93-78.—Extending to June 30, 1975, exiting suspension of duty on certain kinds of metal scrap.	July 30
P.L. 93-99.—Extending until July 1, 1976, the existing suspension of duty on manganese ore.	Aug. 16
Miscellaneous:	
P.L. 93-183.—Naming the Geological Survey National Center under construction in Reston, Va., as the "John Wesley Powell Federal Building."	Dec. 15

The acquisition cost of strategic materials in Government inventories totaled $5.2 billion with a market value of $7.4 billion as of December 31, 1973. Materials in these Government inventories with a market value of $6.5 billion, which is 88% of the total market value on hand, were considered in excess of stockpile needs. In calendar year 1973 the Government disposed of $953 million worth of mineral commodities, a more than threefold increase from the 1972 figure.

Sales of aluminum had a value greater than $400 million and comprised more than 40% of the total minerals sold. Major mineral stockpile items sold during the year with a sales value of at least $50 million each included lead, magnesium, metallurgical manganese, ferro-high-carbon manganese, tin, and zinc. Cobalt had a value greater than $20 million, and magnesium sales were greater than $40 million.

WORLD REVIEW

World Economy.—International trade and investment grew significantly during 1973 in spite of the adverse effects of inflation, wide fluctuations in exchange rates, large capital flows, capacity limitations, crop failures, and cutbacks in oil production by major producers. The international monetary system was maintained while allowing governments to deal with their economic problems without disrupting international trade and investment flows. The international economic system was strengthened by mutual efforts to arrive at solutions to common problems.

Inflation was the major problem facing the world economy during 1973. There were large increases in the prices of basic foods and processed materials. Some measures taken by governments in response to the inflation had the effect of shifting the inflation to other countries, but in general tensions created by such policies were eased.

Continuing economic growth was the typical pattern for the developed countries. Industrial production grew at a rate greater than 10% for the countries of the Organization for Economic Co-Operation and Development, although those located in Europe grew at a rate just over 8%.

World Production.—The United Nations (UN) indexes of world mineral industry production (1963=100) for the extractive industries increased 9 index points to 166 for 1973. The metal mining index increased 8 points to 158, the coal index increased 2 points to 104, and the crude petroleum and natural gas index increased 12 points to 202. The mineral processing industries indexes show a 17-point increase to 182 for base metals, a 15-point increase to 192 for the nonmetallic mineral products index, and a 26-point increase to 250 for the chemicals, petroleum and coal products index. Overall industrial production as measured by the UN index rose 17 points to 194 for 1973.

World Trade.—The value of world trade reached $412.4 billion in 1972, almost 19% greater than the value for 1971. The value of mineral commodities exports for 1972 was $83.4 billion, almost 14% greater than the previous year. The value of metals exports increased 11% in 1972 after declining 5% the previous year. Within this group, all ores, concentrate and scrap exports increased almost 7%, iron and steel exports increased almost 13%, and nonferrous metals exports increased almost 12%. Nonmetal exports were $2.9 billion, almost 14% greater than they were in 1971. World trade in mineral fuels reached $41.2 billion, 16% greater than it was in 1971.

World Prices.—Mineral commodity export price indexes (1963=100) increased in both the metal ores sector and the fuels sector. In 1973 metal ores increased by 27 index points and fuels by 45 points, reaching 161 and 188, respectively. Total minerals prices increased significantly in both developed and developing areas. Nonferrous base metal prices in developed areas increased by 38% while those of the developing areas increased by 57%.

1973 p	85	85	79	99	92	79	91

p Preliminary.
[1] Excludes fuels.

Table 10.—Physical stocks of mineral energy resources and related products at yearend

(Producers' stocks, unless otherwise indicated)

Fuels	1969	1970	1971	1972	1973 p
Coal and related products:					
Bituminous coal and lignite [1] short tons	80,482,000	92,275,000	89,985,000	115,372,000	99,022,000
Coke do	3,120,000	4,113,000	3,510,000	2,941,000	1,184,000
Petroleum and related products:					
Carbon black thousand pounds	208,020	296,087	296,028	237,695	320,325
Natural gasoline, plant condensates, and isopentane thousand barrels	5,704	7,046	6,176	6,075	7,835
Crude petroleum and petroleum products [2] do	974,419	1,010,815	1,037,771	952,904	1,000,472
Crude petroleum do	265,227	276,367	259,648	246,395	242,478
Gasoline do	217,392	214,348	223,771	217,149	209,395
Special naphthas do	6,292	6,193	5,384	5,232	4,514
Liquefied gases [3] do	59,602	67,043	94,713	85,717	83,086
Distillate fuel oil do	171,714	195,271	190,622	154,319	196,421
Residual fuel oil do	58,395	53,994	59,681	55,216	53,480
Petroleum asphalt do	16,753	15,779	21,202	21,636	15,024
Other products do	179,044	181,820	182,750	167,240	196,074
Natural gas [4] billion cubic feet	2,852	3,207	3,523	3,523	3,906

p Preliminary.
[1] Stocks at industrial, consumer, and retail yards and on upper lake docks.
[2] Includes natural gas liquids.
[3] Includes ethane.

Table 12.—Value of selected minerals and mineral products imported and exported by the United States in 1973, by commodity group and commodity [1]

(Thousand dollars)

SITC code [2]		Exports	Imports
	Minerals, nonmetallic (crude):		
271	Fertilizers, crude	114,340	7,301
273	Stone, sand, and gravel	23,194	29,733
274	Sulfur and unroasted iron pyrites	34,488	14,855
275	Natural abrasives (including industrial diamonds)	48,693	79,856
276	Other crude minerals	167,621	221,221
	Total [3]	388,335	352,966
	Metals (crude and scrap):		
281	Iron ore and concentrates	37,921	533,836
282	Iron and steel scrap	598,498	21,542
283	Ores and concentrates of nonferrous base metals	183,949	465,699
284	Nonferrous metal scrap	242,727	84,358
285	Platinum and platinum-group metal ores and concentrates	16,975	82,653
286	Uranium and thorium ores and concentrates	750	254
	Total	1,080,820	1,188,342
	Mineral energy resources and related products:		
321	Coal, coke, and briquets (including peat)	1,051,985	59,754
331	Petroleum, crude and partly refined	2,621	4,584,326
332	Petroleum products, except chemicals	515,403	2,954,298
341	Gas, natural and manufactured	100,497	492,832
	Total	1,670,506	8,091,210
	Chemicals:		
	Inorganic chemicals:		
513	Elements, oxides, and halogen salts	337,888	429,024
514	Other inorganic chemicals	205,990	95,745
515	Radioactive and associated materials except uranium and thorium	283,560	150,747
521	Mineral tar, crude chemicals from coal, petroleum, and natural gas	72,469	6,025
	Total	899,907	681,541
	Minerals, nonmetallic (manufactured):		
661	Lime, cement, and fabricated building material, except glass and clay	23,129	150,803
662	Clay and refractory construction materials	78,585	78,436
663	Mineral manufactures, not elsewhere specified	114,130	68,616
	Total	215,844	297,855
	Metals (manufactured):		
671	Pig iron, spiegeleisen, sponge iron, iron and steel powder and shot, and ferroalloys	42,545	240,199
672	Iron or steel ingots and other primary forms	74,168	30,886
673	Iron or steel bars, rods, angles, shapes, and sections	174,167	761,251
674	Iron or steel universals, plates, or sheets	381,880	1,326,935
675	Iron or steel hoops and strips	83,076	64,309
676	Iron or steel rails and railway track construction materials	24,895	7,603
677	Iron or steel wire (excluding wire rod)	20,615	164,845
678	Iron or steel tubes, pipes, and fittings	344,738	395,632
679	Iron or steel castings or forgings, unworked	154,713	16,896
681	Silver, platinum, and platinum-group metals	106,475	455,029
682	Copper and copper alloys	383,468	655,131
683	Nickel and nickel alloys	61,573	374,270
684	Aluminum and aluminum alloys	345,513	286,442
685	Lead and lead alloys	27,097	53,252
686	Zinc and zinc alloys	20,924	274,740
687	Tin and tin alloys	13,379	198,758
688	Uranium and thorium metals and alloys	270	3
689	Miscellaneous nonferrous base metals	98,355	128,901
	Total	2,357,851	5,435,082
	Grand total	6,613,263	16,046,996

[1] Data in this table are for the indicated SITC numbers only, and therefore may not correspond to the figures classified by commodity in the "Statistical Summary" chapter of this volume.

Table 15.—Consumption of major mineral products, mineral fuels, and electricity 1972, 1973, and projections

Commodity	1972	1973 p	2000
MINERAL PRODUCTS			
Ferrous metals:			
Iron ore (including agglomerates) --thousand long tons--	126,943	146,922	NA
Raw steel (production) ----thousand short tons--	133,241	150,799	NA
Chromite ores (gross weight):			
Metallurgical grade ----do----	727	920	NA
Refractory grade ----do----	224	261	NA
Chemical grade ----do----	189	206	NA
Manganese ore (35% or more Mn) ----do----	2,331	2,140	3,900
Molybdenum (Mo content) ----thousand pounds--	45,558	57,049	188,000
Tungsten (W content) ----do----	14,107	15,386	76,400
Nonferrous metals:			
Aluminum (apparent consumption) -thousand short tons--	5,588	5,685	28,400
Antimony, primary ----short tons--	16,124	20,613	48,000
Copper, refined ----thousand short tons--	2,239	2,402	7,100
Lead, primary and secondary ----do----	1,485	1,541	2,730
Zinc, all classes ----do----	1,844	1,932	3,090
Mercury, primary ----76-pound flasks--	52,907	54,283	102,000
Platinum-group metals ----thousand troy ounces--	1,562	1,831	3,157
Silver (industrial consumption) ----do----	151,063	195,941	420,000
Ilmenite and titanium slag (estimated TiO_2 content) short tons--	649,030	678,518	1,840,000
Uranium (U_3O_8, estimated purchases by private industry) do----	11,600	12,100	73,113
Nonmetals:			
Asbestos (apparent consumption) --thousand short tons--	809	876	2,430
Cement (apparent consumption) ----do----	85	90	NA
Clays (apparent consumption) ----do----	59,456	61,520	174,000
Lime (sold or used) ----do----	20,290	21,090	NA
Phosphate rock (P_2O_5 content, apparent consumption) do----	13,753	13,972	NA
Potash (K_2O content, apparent consumption) ----do----	4,815	5,570	14,455
Salt (apparent consumption) ----do----	47,616	46,488	158,900

1973 p	174	14,214	24,876	18,818	2,847	888	61,817

p Preliminary.
[1] Heat values employed for bituminous coal and lignite are 1969, 12,450 Btu per pound; 1970, 12,290 Btu; 1971, 12,120 Btu; 1972, 12,025 Btu; and 1973, 12,025 Btu.
[2] Heat values employed for crude petroleum are 1969, 5,601,070 Btu per barrel; 1970, 5,620,900 Btu; 1971, 5,594,100; 1972, 5,598,100; and 1973, 5,598,900 Btu.
[3] Hydropower and nuclear power include installations owned by manufacturing plants and mines as well as government and privately owned public utilities. The fuel equivalent of hydropower and nuclear power is calculated from the kilowatt-hours produced, converted to theoretical energy resources inputs calculated from national average heat rates for fossil-fueled steam electric plants provided by the Federal Power Commission using 10,398 Btu per net kilowatt-hour in 1968, 10,447 Btu in 1969, and 10,494 Btu in 1970. The heat rate used for hydropower in 1971 is 10,478 Btu per net kilowatt-hour generated and 10,379 Btu in 1972 and 1973. Energy inputs for nuclear power from 1971 through 1973 are converted at an average heat rate of 10,660 Btu per net kilowatt-hour based on information from the Atomic Energy Commission.

p Preliminary.
[1] Heat values employed are anthracite, 12,700 Btu per pound, and bituminous coal and lignite, weighted average British thermal units provided by the Division of Fossil Fuels, Branch of Coal, 12,330 Btu per pound in 1969; 12,110 Btu per pound in 1970; 11,980 Btu per pound in 1971; 11,875 Btu per pound in 1972 and 1973. Weighted average Btu for petroleum products obtained by using 5,248,000 Btu per barrel for gasoline and naphtha-type jet fuel, 5,670,000 for kerosine and kerosine-type jet fuel, 5,825,000 for distillate, 6,287,000 for residual, 6,064,800 for lubricants, 5,537,280 for wax, 6,636,000 for asphalt, and 5,796,000 for miscellaneous. Natural gas dry, 1,031 Btu per cubic foot in 1969–71; 1,027 Btu in 1972–73; natural gas liquids, weighted average British thermal units: natural gasoline and cycle products, 110,000 Btu per gallon; LP-gases, 95,500 Btu per gallon; and ethane, 73,390 Btu per gallon. Hydropower (adjusted for net imports or net exports) and nuclear power are derived from net electricity generated, converted to theoretical energy resources inputs calculated from national average heat rates for fossil-fueled steam-electric plants provided by the Federal Power Commission, using 10,447 Btu per net kilowatt-hour in 1969, and 10,494 Btu in 1970. The heat rate used for hydropower in 1971 is 10,478 Btu per net kilowatt-hour generated, and 10,379 Btu in 1972 and 1973. Energy inputs for nuclear power 1971–73 are converted at an average heat rate of 10,660 Btu per net kilowatt-hour based on information from the Atomic Energy Commission.

[p] Preliminary. NA Not available. XX Not applicable.

[1] Excludes natural gas liquids.

[2] Petroleum products including still gas, LRG, and natural gas liquids.

[3] Represents outputs of hydropower (adjusted for net imports or net exports) and nuclear power converted to theoretical energy inputs calculated from national average heat rates for fossil-fueled steam-electric plants provided by the Federal Power Commission using 10,447 Btu per net kilowatt-hour in 1969 and 10,494 Btu in 1970. Energy inputs for hydropower in 1971 are converted at an average heat rate of 10,478 Btu per net kilowatt-hour generated, and in 1972–73 at 10,379 Btu. Energy inputs for nuclear power in 1971–73 are converted at an average heat rate 10,660 Btu per net kilowatt-hour based on information from the Atomic Energy Commission. Excludes inputs for power generated by nonutility fuel-burning plants which are included within the other consuming sectors.

[4] Gross energy is that contained in all types of commercial energy at the time it is incorporated in the economy, whether energy is produced domestically or imported. Gross energy comprises inputs of primary fuels (or for derivatives) and outputs of hydropower and nuclear power energy converted to theoretical inputs. Gross energy includes energy used for production, processing, and transportation of energy proper.

[5] Utility electricity, generated and imported, distributed to the other consuming sectors as energy resource inputs. Distribution to sectors is based on sales reported in the annual issues of the Edison Electric Institute Yearbook. Conversion of electricity to energy equivalent by sectors was made at the value of contained energy corresponding to 100% efficiency using a theoretical rate of 3,412 Btu per kilowatt-hour.

[6] Energy resource inputs by sector, including direct fuels and electricity distributed.

[7] Includes bunkers and military transportation.

[8] Data may not add to totals shown because of independent rounding.

p Preliminary.

1 Marketed production includes wet gas sold or consumed by producers, losses in transmission, producers' additions to storage, and increases in gas pipeline fill: excludes repressuring and quantities vented and flared. British thermal unit value of production is for wet gas prior to extraction of natural gas liquids. Higher Btu values assigned to extraction loss are reflected in value of natural gas liquids production for each year.

2 Extraction loss from cycling plants represents offtake of natural gas for natural gas liquids as reported to the Bureau of Mines. Energy equivalent of extraction loss is based on annual outputs of natural gasoline and associated products at 110,000 Btu per gallon, annual outputs of LPG at 95,500 Btu per gallon, and annual outputs of ethane at 93.390 Btu per gallon. (Prior to 1967, ethane production was included with LPG in converting to Btu values.)

3 Includes transmission losses and unaccounted for of 328,002 million cubic feet in 1972 and 195,863 million cubic feet in 1973.

4 Includes some fuel and power used by raw material industries.

5 Estimated from partial data.

NOTE.—Conversion factor for dry gas is 1,027 Btu per cubic foot.

p Preliminary.

[1] Supply and demand for crude oil and petroleum products. Petroleum products include products refined and processed from crude oil, including still gas and LRG; also natural gas liquids transferred from natural gas.

[2] Btu value for crude oil for each year shown is based on average Btu value of total output of petroleum products (including refinery fuel and losses) adjusted to exclude natural gas liquids inputs and their implicitly derived values. Value for imports of crude is based on the average value of crude runs to stills.

[3] Includes some Athabasca hydrocarbons.

[4] Btu values for natural gas liquids for each year shown are implicitly derived from weighted averages of production of major natural gas liquids, derived by converting natural gasoline and cycle products at 110,000 Btu per gallon, LPG at 95,500 Btu per gallon, and ethane at 73,390 Btu per gallon.

[5] Includes natural gas liquids other than those channeled into refinery input as follows: Petrochemical feedstocks, direct uses for fuel and power, and other uses.

[6] Includes bunkers and military transportation.

[7] Includes some fuel and power used by raw materials industries.

p Preliminary.
[1] Includes liquefied refinery gas and natural gas liquids.
[2] Includes bunkers and military transportation.
[3] Includes some fuel and power used by raw materials industries.
[4] Lubricants are distributed on basis of data from Bureau of the Census survey.
[5] Includes portions of petroleum coke estimated to be consumed in nonfuel uses.
[6] Includes ethane.
[7] Includes LPG for synthetic rubber.

[1] Index of labor costs per unit of output: Iron ore and copper indexes are computed from data found in U.S. Department of Labor, Employment and Earnings and Wholesale Price Indexes. Bituminous coal index based upon net tons per man per day (see chapter on Bituminous Coal) and index of average earnings derived from Bureau of Labor Statistics data on hourly earnings; petroleum index based on barrels per year (see chapter on Petroleum) and Bureau of Employment Security data on total wages in petroleum production.

Index of value of product per man-period: Iron ore and copper indexes are computed from data found in U.S. Department of Labor, Employment and Earnings and Wholesale Price Indexes. Bituminous coal index based on net tons per man per day and mine value of production; petroleum index based on average employment and total value of production.

Index of labor costs per dollar of product: Iron ore and copper indexes are computed from data found in U.S. Department of Labor, Employment and Earnings and Wholesale Price Indexes. Bituminous coal index based on index of value per man per day and index of average earnings; petroleum index based on total value of production and total wages.

[2] Indexes are for recoverable metal.

Table 57.—Summary of Government inventories of strategic and critical materials, December 31, 1973

	Acquisition cost	Market value [1]
Total inventories in storage:		
National stockpile	$3,420,829,900	$5,612,408,700
Supplemental stockpile	1,288,714,100	1,502,197,400
Defense Production Act	510,142,400	285,499,200
Total on hand	5,219,686,400	7,400,105,300
Inventories within objective: Total on hand	525,818,000	868,632,000
Inventories excess to objective: Total on hand	4,693,868,400	6,531,473,300

[1] Market values are computed from prices at which similar materials are being traded, or in the absence of current trading, at an estimate of the price which would prevail in commercial markets. Prices used are unadjusted for normal premiums and discounts relating to contained qualities, or for inherent materials-handling allowances. Market values do not necessarily reflect the amount that would be realized at time of sale. The uncommitted excess excludes the unshipped sales; the inventories in storage include quantities that have been sold but not shipped.

r Revised.

[1] Data presented are for selected major commodity groups of the Standard International Trade Classification—Revised (SITC—R) and as such exclude some mineral commodities classified in that data array together with other (nonmineral) commodities. SITC—R categories included are as follows: Ores, concentrates and scrap—SITC Division 28; iron and steel—SITC Division 67; nonferrous metals—SITC Division 68; nonmetals (crude only)—SITC Division 27; mineral fuels—SITC Division 3. Major items not included are the metals, metalloids, and metal oxides of SITC Group 513; mineral tar and crude chemicals from coal, petroleum, and natural gas of SITC Division 52; manufactured fertilizers of SITC Division 56; and nonmetallic mineral manufactures of SITC Groups 661, 662, 663, and 667.

Mining and Quarrying Trends in the Metal and Nonmetal Industries[1]

By John L. Morning[2]

Growing concern for environmental considerations, health and safety standards, price controls, inflation, material shortages, and increased dependence on imports created problems for the mineral industries in 1973. Although productivity increased for most mineral commodities, the annual rate of increase has slowed in recent years, indicating a maturing technological situation.[3]

Despite these problems, the mineral industry buoyed by strong demand in 1973 continued to expand and established new record highs for crude ore production and total material handled. Crude ore production rose 11% while total quantity of material handled increased 12% compared with that of 1972. Increased production of metallic crude ores outpaced that of nonmetals as metals increased 14% and nonmetals 10%. Along with the increase in quantity of crude ore produced, value of metallic and nonmetallic mineral output increased nearly 15% compared with that of 1972. Over the past decade, total value of metal and nonmetal crude ore output increased from $6,638 million in 1964 to $11,607 million in 1973.

Materials Handled.—Producers of metal and nonmetallic minerals (excluding fuels) handled nearly 4.7 billion tons of crude ore and waste, 12% more than in 1972 and 56% more than in 1964. Material handled at metal mines accounted for nearly 42% of the total material handled compared with 40% in 1972 and 31% in 1964.

Total tonnage of crude ore produced increased 11% and tonnage of waste material removed rose 13% compared with 1972 figures. Continuing a trend that was observed a decade ago, the percentage of crude ore to total material handled fell to 63% in 1973 compared with 66% in 1969 and 75% in 1964. Most of the growth in crude ore production and material handled in the mineral industry since 1960 (table 1) has been from the development of new surface mining operations and expansion of existing surface operations.

Fourteen States each reported handling over 100 million tons of material, an increase of three States over those reported in 1972. In 1964, only six States handled over 100 million tons of material. Three States reported handling over 200 million tons of crude ore while six other States each moved over 100 million tons of waste. The leading States in crude ore output were Florida (primarily phosphate rock and titanium minerals); Minnesota (primarily iron ore); and Arizona (primarily copper ore). The same three States were also leaders in waste material handled. Arizona reported moving 429 million tons of waste and accounted for 25% of the Nation's total. Arizona and Florida continued to lead the Nation in total material handled as they have since 1965.

Magnitude of the Mining Industry.—Output of crude ore in 1973 was reported from 14,437 mines and quarries, a 5% increase over the number of mines reporting in 1972. However, owing to an incomplete uranium canvass, many small uranium operations were not counted, and reporting uranium mines dropped to 75 from 189 for the previous year. In addition to the above mines, there were 109 wells, ponds, or pumping operations which produced sulfur, salt, lithium, boron, and magnesium. Output of crude ore from individual mines ranged from 1 to nearly 44 million tons

[1] Formerly Technologic Trends in the Mineral Industries.

[2] Supervisory physical scientist, Division of Ferrous Metals—Mineral Supply.

[3] Staff, Bureau of Mines. Technologic and Related Trends in the Mineral Industries, 1973. BuMines I.C. 8643, 1974, 52 pp.

and total material handled ranged from 1 to 138 million tons.

Twenty-one mines each reported over 10 million tons of crude ore production, five more mines than in 1972. Copper and phosphate rock accounted for the increase, as copper mines rose from 8 to 11 and phosphate rock mines from 2 to 4 mines. In 1966, 14 mines each had output of over 10 million tons of crude ore.

The 25 leading metal mines produced nearly 448 million tons of crude ore, 17% more than in 1973, and accounted for 68% of the total output of crude ore from metal mines. In terms of total material handled, the 25 leading metal mines moved 1,366 million tons of material, 19% more than in 1972.

The Minntac mine of United States Steel Corp. replaced the Utah Copper mine of Kennecott Copper Corp. as the leader in crude metal ore production. The Utah Copper mine had ranked first since 1968. Utah Copper, however, retained its leadership in total material handled for metal mines for the sixth successive year.

Various phosphate rock mines have been leaders in output of crude nonmetal ore during the past 10 years, but in 1973 the limestone producing Calcite mine of United States Steel Corp. ranked first in output of crude ore. The Kingsford mine of International Minerals and Chemical Corp. retained its leadership in total material handled.

The 25 leading nonmetal mines, in terms of crude ore output, produced 187 million tons of crude ore, 11% more than in 1972, and accounted for 8% of the total crude ore output from nonmetal mines. The 25 leading nonmetal mines, in terms of total material handled, moved 399 million tons of material, a decrease of 2%.

Copper mines (15) and iron mines (7) dominated the list for crude ore output at metal mines while phosphate rock mines (13) dominated the list for nonmetal mines. The same commodities topped the listings for total material handled. Arizona with 10 mines and Florida with 15 mines, had the most large mines in the top 25 metal and nonmetal mines, for output of crude ore.

Value of Principal Mineral Products.—When possible, the value measurement used in table 4 is for mine output, the form in which the minerals are extracted from the ground. For some commodities, the value is of beneficiated products. Values for some metals are assigned according to the average selling price of refined metal.

Average value for all commodities increased 4% compared with that of 1972. Compared with a decade earlier, average value rose 20%. For most mineral commodities, values continued to increase. Among the metals, only titanium (ilmenite) failed to increase significantly; for the nonmetals, diatomite, fluorspar, scrap mica, and dimension stone indicated decreased value per ton of ore mined.

Byproducts contributed to the value of nearly two-thirds of the mineral commodities listed in table 4. The value of byproducts was a significant part of the total value for the metals such as bauxite, 9%; copper, 8%; lead, 34%; silver, 19%; and zinc, 20%; and for the nonmetals such as feldspar, 9%; fluorspar, 9%; and salt, 15%. In general, values of products produced at underground mines were substantially higher than at surface mines. Byproducts accounted for 8% of the value for metal ores and 1% for nonmetal ores. Excluding the large volume commodities of sand and gravel and stone, byproducts contributed nearly 7% to the combined value of metal and nonmetal ores, and nearly 3% to nonmetal ores. Percentages for metal and nonmetal ore values were unchanged from those of 1972.

Comparison of Production From Surface and Underground Mines.—Crude ore production from surface mines continued to increase while that from underground mines remained relatively stable. Owing to the dominance of the large volume nonmetallic minerals—sand and gravel, stone, and clay—all of which are primarily mined by surface methods, little annual change was noted in the percentages of crude ore production from surface and underground operations. However, over the past decade surface crude ore production of copper increased from 84% to 89%; iron ore from 90% to nearly 96%; molybdenum from 0% to 29%; and talc, soapstone, and pyrophyllite from 43% to 64%. For all metal commodities, surface crude ore production increased from 81% in 1964 to 88% in 1973.

Three metal commodities, antimony, lead, and zinc, and three nonmetal commodities, potassium salts, sodium carbonate, and wollastonite were mined entirely by underground methods. Over 99% of the crude ore of tungsten was produced from underground operations. Crude ore production of 8 metals and 18 nonmetals came entirely from surface mines.

Ratio of Ore Treated to Marketable Product.—The ratio of ore treated to marketable product, the amount of ore processed to produce one unit of marketable product, varies with the type of mineral commodity. The ratio ultimately depends on the grade of ore treated and type of valuable mineral content. For many of the nonmetal commodities, the ratio is essentially one to one. Ratios are significantly lower for underground mines than for surface mines for a specific commodity because of higher mining costs.

Ratios for many of the mineral commodities increased in 1973 compared with those of 1972, continuing the trend that has persisted for more than a decade. Notable exceptions were lead and barite, both of which showed lower ratios.

Exploration and Development.—The reported 20.8 million feet in exploration and development work in 1973 continued the annual trend of reduced activity that has persisted in the minerals industry since 1969. All of the decreased activity compared with that of 1972 was for metals; nonmetal footage was about the same as in the previous year. Among the metals, only silver and tungsten indicated increased footage while copper footage decreased significantly. Although the overall total for nonmetallic minerals remained unchanged, footage for asbestos and gypsum decreased significantly and increased for all other nonmetals.

Exploration drilling including trenching decreased 17% compared with that of 1972. With the exception of churn drilling and other drilling methods, both of which indicated increased footage, other types of exploration methods showed reduced activity. In particular, percussion drilling was down 43% compared with that of 1972.

Underground development work was 19% lower than in 1972. Most of the decrease was in drifting and crosscutting, primarily for metals.

Four States, two less than in 1972, reported over 1 million feet of exploration and development work. Wyoming led the nation with 25% of the total, followed by South Dakota, 20%; New Mexico, 18%; and Texas, 15%. Exploration and development activity in Wyoming was primarily for uranium; in South Dakota, for gold and uranium; in New Mexico, for copper and uranium; and in Texas, for iron-ore and uranium.

Data presented in table 16 on total material handled from development work is not directly comparable with that of previous years because of a change in statistical reporting. Stripping data includes only that related to development work in preparing a proved ore body for mining. Stripped material from producing operations is included in table 2.

Explosives.—Total consumption of explosives in the United States in 1973 continued to increase and set a new record high for the fifth consecutive year. The average growth rate for the past 5 years has been 4.4% annually. Of the total industrial consumption, the minerals industry accounted for 84%. Although explosive usage decreased in coal mining, this loss was more than offset by increased consumption in metal and nonmetal mining including quarrying. The increase in consumption was due to continued growth in the use of blasting agents.

Of the 2.3 billion pounds of explosives used in the minerals industry, coal mining accounted for 51%, metal mining 21%, and quarrying and nonmetal mining 28%. Kentucky, Pennsylvania, and Alabama were the leading States in explosive consumption for coal mining, accounting for 52% of the total. Arizona, Minnesota, and New Mexico were leading States in explosive consumption for metal mining, accounting for 65% of the total. For nonmetal mining and quarrying, Kentucky, Ohio, and Pennsylvania were leading States accounting for 20% of total explosives used in this category.

Blasting agents and unprocessed ammonium nitrate were the leading explosives used, accounting for 70% of the total explosives used in the minerals industry.

Beginning in 1972, the Institute of Makers of Explosives (IME) adopted new product classifications for industrial explosives and blasting agents. As a result, detailed data are not directly comparable with previous years.

More detailed explosives information is published in the Annual Explosive issue, Mineral Industry Surveys, prepared by the Division of Nonmetallic Minerals, Bureau of Mines.

Statistical Summary

By Staff, Office of Technical Data Services—Mineral Supply

This chapter summarizes mineral production data for the United States, its island possessions, and the Commonwealth of Puerto Rico. Tables are also included that show the principal mineral commodities exported from and imported into the United States, and that compare world and U.S. mineral production. The detailed data from which these tables were derived are contained in the commodity chapters of volume I and in the State chapters of volume II of this edition of the Minerals Yearbook.

Mineral production may be measured at any of several stages of extraction and processing. The stage of measurement used in this chapter is what is normally termed "mine output." It usually refers to minerals or ores in the form in which they are first extracted from the ground, but customarily includes the product of auxiliary processing at or near the mines.

Because of inadequacies in the statistics available, some series deviate from the foregoing definition. In the case of gold, silver, copper, lead, zinc, and tin, the quantities are recorded on a mine basis (as the recoverable content of ore sold or treated). However, the values assigned to these quantities are based on the average selling price of refined metal, not the mine value. Mercury is measured as recovered metal and valued at the average New York price for the metal.

The weight of volume units shown are those customarily used in the particular industries producing the commodities. Values shown are in current dollars, with no adjustment made to compensate for changes in the purchasing power of the dollar.

Table 1.—Value of mineral production[1] in the United States, by mineral group

(Millions)

Year	Mineral fuels	Nonmetals (except fuels)	Metals	Total[2]
1969	$17,965	$5,624	$3,333	$26,921
1970	20,152	5,712	3,928	29,792
1971	21,247	6,058	3,403	30,708
1972 r	22,061	6,482	3,642	32,185
1973	25,012	7,413	4,362	36,788

r Revised.

1 Production as measured by mine shipments, sales, or marketable production (including consumption by producers).

2 Data may not add to totals shown because of independent rounding.

e Estimate. r Revised. NA Not available. W Withheld to avoid disclosing individual company confidential data; included with "Value of items that cannot be disclosed." XX Not applicable.

1 Production as measured by mine shipments, sales, or marketable production (including consumption by producers).

2 Includes a small quantity of anthracite mined in States other than Pennsylvania. In 1971, value excluded that of Arizona, which is withheld to avoid disclosing individual company confidential data; value included with "Nonmetal items that cannot be disclosed."

3 Grindstones, pulpstones, grinding pebbles, sharpening stones, and tube mill liners.

4 Excludes abrasive stone, bituminous limestone, bituminous sandstone, and soapstone, all included elsewhere in table.

Table 3.—Minerals produced in the United States and principal producing States in 1973

Mineral	Principal producing States, in order of quantity	Other producing States
Antimony ore and concentrate	Idaho, Mont., Nev.	
Aplite	Va.	
Asbestos	Calif., Vt., Ariz., N.C.	
Asphalt (native)	Tex., Utah, Ala., Mo.	
Barite	Nev., Mo., Ark., Alaska	Calif., Ga., Tenn.
Bauxite	Ark., Ala., Ga.	
Beryllium concentrate	Utah.	
Boron minerals	Calif.	
Bromine	Ark., Mich., Calif.	
Calcium-magnesium chloride	Mich., Calif.	
Carbon dioxide (natural)	N. Mex., Calif., Colo., Utah.	
Cement	Calif., Pa., Tex., Mich	Ala., Ariz., Ark., Colo., Fla., Ga., Hawaii, Idaho, Ill., Ind., Iowa, Kans., Ky., La., Maine, Md., Minn., Miss., Mo., Mont., Nebr., Nev., N. Mex., N.Y., N.C., Ohio, Okla., Oreg., S.C., S. Dak., Tenn., Utah, Va., Wash., W. Va., Wis., Wyo.
Clays	Ga., Tex., Ohio, N.C	All other States except Alaska, R.I., Vt.
Coal	Ky., W. Va., Pa., Ill	Ala., Alaska, Ariz., Ark., Colo., Ind., Iowa, Kans., Md., Mo., Mont., N. Mex., N. Dak., Ohio, Okla., Tenn., Tex., Utah, Va., Wash., Wyo.
Copper (mine)	Ariz., Utah, N. Mex., Mont	Calif., Colo., Idaho, Maine, Mich., Mo., Nev., Okla., Oreg., Pa., Tenn., Wash.
Diatomite	Calif., Nev., Wash	Oreg.
Emery	N.Y	Oreg.
Feldspar	N.C., Calif., Conn., Ga	Ariz., Colo., S. Dak., Wyo.
Fluorspar	Ill., Colo., Mont., Nev	Ariz., Ky., Tex., Utah.
Garnet, abrasive	N.Y., Idaho.	
Gold (mine)	S. Dak., Utah, Nev., Ariz	Alaska, Calif., Colo., Idaho, Mont., N. Mex., Oreg., Tenn., Wash.
Graphite	Tex.	
Gypsum	Mich., Calif., Tex., Iowa	Ariz., Ark., Colo., Idaho, Ind., Kans., La., Mont., Nev., N. Mex., N.Y., Ohio, Okla., S. Dak., Utah, Va., Wash., Wyo.
Helium	Kans., Tex., Okla., Ariz.	
Iodine	Mich.	
Iron ore	Minn., Mich., Calif., Mo	Ala., Ariz., Ark., Colo., Ga., Idaho, Mont., Nev., N. Mex., N.Y., N.C., Pa., Tex., Utah, Wis., Wyo.
Kyanite	Va., Ga., Fla.	
Lead (mine)	Mo., Idaho, Colo., Utah	Alaska, Ariz., Calif., Ill., Maine, Mont., N. Mex., N.Y., Va., Wash., Wis.
Lime	Ohio, Pa., Tex., Mo	Ala., Ariz., Ark., Calif., Colo., Conn., Fla., Hawaii, Idaho, Ill., Ind., Iowa, Kans., Ky., La., Md., Mass., Mich., Minn., Miss., Mont., Nebr., Nev., N.J., N. Mex., N.Y., N. Dak., Okla., Oreg., S. Dak., Tenn., Utah, Va., Wash., W. Va., Wis., Wyo.
Lithium minerals	N.C., Nev., Calif.	
Magnesite	Nev.	
Magnesium chloride	Tex.	
Magnesium compounds	Mich., Calif., N.J., Fla	Del., Miss., Tex., Utah.
Manganese ore	Mont.	
Manganiferous ore	Minn., N. Mex.	
Manganiferous residuum	N.J.	
Marl, greensand	N.J.	
Mercury	Calif., Nev., Alaska, Tex	Oreg.
Mica, scrap	N.C., Ala., Ga., S.C	Ariz., Conn., N. Mex.
Molybdenum	Colo., Ariz., Utah, N. Mex	Calif., Nev.
Natural gas	Tex., La., Okla., N. Mex	Ala., Alaska, Ariz., Ark., Calif., Colo., Fla., Ill., Ind., Kans., Ky., Md., Mich., Miss., Mo., Mont., Nebr., N.Y., N. Dak., Ohio, Pa., Tenn., Utah, Va., W. Va., Wyo.

Table 3.—Minerals produced in the United States and principal producing States in 1973—Continued

Mineral	Principal producing States, in order of quantity	Other producing States
Natural gas liquids	Tex., La., Okla., N. Mex.	Ala., Alaska, Ark., Calif., Colo., Fla., Ill., Kans., Ky., Mich., Miss., Mont., Nebr., N. Dak., Pa., Utah, W. Va., Wyo.
Nickel	Oreg.	
Olivine	Wash., N.C.	
Peat	Mich., Ill., Ind., N.J.	Calif., Colo., Fla., Ga., Iowa, Maine, Md., Mass., Minn., Mont., N. Mex., N.Y., Ohio, Pa., S.C., Vt., Wash., Wis.
Perlite	N. Mex., Ariz., Calif., Nev.	Colo., Idaho, Tex.
Petroleum, crude	Tex., La., Calif., Okla.	Ala., Alaska, Ariz., Ark., Colo., Fla., Ill., Ind., Kans., Ky., Mich., Miss., Mo., Mont., Nebr., Nev., N. Mex., N.Y., N. Dak., Ohio, Pa., S. Dak., Tenn., Utah, W. Va., Wyo.
Phosphate rock	Fla., Idaho, Tenn., N.C.	Mo., Mont., Utah, Wyo.
Platinum-group metals	Alaska.	
Potassium salts	N. Mex., Utah, Calif.	
Pumice	Oreg., Ariz., Calif., Hawaii	Colo., Idaho, Kans., Nev., N. Mex., Okla., Utah, Wash., Wyo.
Pyrites ore and concentrate	Tenn., Colo., Ariz.	
Rare-earth metal concentrate	Calif., Ga., Fla.	
Salt	La., Tex., N.Y., Mich.	Ala., Calif., Colo., Hawaii, Kans., Nev., N. Mex., N. Dak., Ohio, Okla., Utah, Va., W. Va.
Sand and gravel	Calif., Mich., Ohio, Ill.	All other States.
Silver (mine)	Idaho, Ariz., Mont., Colo.	Alaska, Calif., Ill., Maine, Mich., Mo., Nev., N. Mex., N.Y., Okla., Oreg., S. Dak., Tenn., Utah, Wash.
Sodium carbonate (natural)	Wyo., Calif.	
Sodium sulfate (natural)	Calif., Tex., Utah.	
Staurolite	Fla.	
Stone	Pa., Ill., Fla., Tex.	All other States except Del.
Sulfur (Frasch)	Tex., La.	
Talc, soapstone, pyrophyllite	Vt., N.Y., Tex., Mont.	Ala., Ark., Calif., Ga., Md., Nev., N.C., Oreg., Va., Wash.
Tin	Colo., N. Mex.	Alaska.
Titanium concentrate	N.Y., Fla., N.J., Ga.	
Tripoli	Ill., Okla., Ark., Pa.	
Tungsten concentrate	Calif, Colo., Nev.	Ariz., Idaho, Mont., Utah, Wash.
Uranium	Wyo., N. Mex., Tex., Utah	Alaska, Colo., Wash.
Vanadium	Ark., Idaho, Colo., Utah	N. Mex.
Vermiculite	Mont., S.C.	
Wollastonite	N.Y.	
Zinc (mine)	Mo., N.Y., Tenn., Colo.	Ariz., Calif., Idaho, Ill., Ky., Maine, Mont., N.J., N. Mex., Pa., Utah, Va., Wash., Wis.
Zircon concentrate	Fla., Ga.	

Table 4.—Value of mineral production in the United States and principal minerals produced in 1973

State	Value (thousands)	Rank	Percent of U.S. total	Principal minerals, in order of value
Alabama	$413,056	21	1.12	Coal, cement, petroleum, stone.
Alaska	328,789	25	.89	Petroleum, sand and gravel, natural gas, stone.
Arizona	1,304,988	8	3.55	Copper, molybdenum, sand and gravel, cement.
Arkansas	273,705	29	.75	Petroleum, bromine, natural gas, cement.
California	2,041,686	3	5.55	Petroleum, cement, sand and gravel, natural gas.
Colorado	532,776	19	1.45	Petroleum, molybdenum, coal, sand and gravel.
Connecticut	36,804	44	.10	Stone, sand and gravel, feldspar, lime.
Delaware	3,889	50	.01	Sand and gravel, magnesium compounds, clays.
Florida	601,100	17	1.63	Phosphate rock, petroleum, stone, cement.
Georgia	305,479	26	.83	Clays, stone, cement, sand and gravel.
Hawaii	35,147	45	.10	Stone, cement, sand and gravel, pumice.
Idaho	136,081	33	.37	Silver, phosphate rock, lead, zinc.
Illinois	825,608	12	2.24	Coal, petroleum, stone, sand and gravel.
Indiana	351,405	24	.96	Coal, cement, stone, sand and gravel.
Iowa	158,800	31	.43	Cement, stone, sand and gravel, gypsum.
Kansas	646,299	16	1.76	Petroleum, natural gas, natural gas liquids, cement.
Kentucky	1,164,762	9	3.17	Coal, stone, petroleum, natural gas.
Louisiana	5,819,610	2	15.82	Petroleum, natural gas, natural gas liquids, sulfur.
Maine	33,493	46	.09	Sand and gravel, cement, zinc, stone.
Maryland	131,907	34	.36	Stone, cement, sand and gravel, coal.
Massachusetts	59,682	43	.16	Stone, sand and gravel, lime, clays.
Michigan	789,022	14	2.14	Iron ore, cement, copper, sand and gravel.
Minnesota	852,785	11	2.32	Iron ore, sand and gravel, stone, cement.
Mississippi	281,738	27	.77	Petroleum, natural gas, sand and gravel, cement.
Missouri	512,634	20	1.39	Lead, cement, stone, iron ore.
Montana	385,285	22	1.05	Copper, petroleum, coal, sand and gravel.
Nebraska	80,821	42	.22	Petroleum, cement, sand and gravel, stone.
Nevada	201,813	30	.55	Copper, gold, sand and gravel, diatomite.
New Hampshire	14,119	48	.04	Sand and gravel, stone, clays, gem stones.
New Jersey	114,016	37	.31	Stone, sand and gravel, zinc, titanium concentrate.
New Mexico	1,305,644	7	3.55	Petroleum, natural gas, copper, natural gas liquids.
New York	375,866	23	1.02	Cement, stone, salt, sand and gravel.
North Carolina	146,930	32	.40	Stone, sand and gravel, cement, feldspar.
North Dakota	111,853	38	.30	Petroleum, coal, sand and gravel, natural gas.
Ohio	806,979	13	2.19	Coal, stone, cement, lime.
Oklahoma	1,323,626	6	3.60	Petroleum, natural gas, natural gas liquids, stone.
Oregon	81,466	40	.22	Sand and gravel, stone, cement, nickel.
Pennsylvania	1,401,900	5	3.81	Coal, cement, stone, sand and gravel.
Rhode Island	4,340	49	.01	Sand and gravel, stone, gem stones.
South Carolina	88,361	39	.24	Cement, stone, clays, sand and gravel.
South Dakota	81,139	41	.22	Gold, sand and gravel, cement, stone.
Tennessee	275,690	28	.75	Stone, coal, cement, zinc.
Texas	8,442,494	1	22.95	Petroleum, natural gas, natural gas liquids, cement.
Utah	674,210	15	1.83	Copper, petroleum, coal, gold.
Vermont	29,366	47	.08	Stone, asbestos, sand and gravel, talc.
Virginia	540,595	18	1.47	Coal, stone, sand and gravel, cement.
Washington	114,329	36	.31	Sand and gravel, cement, coal, stone.
West Virginia	1,503,045	4	4.09	Coal, natural gas, stone, cement.
Wisconsin	114,339	35	.31	Sand and gravel, stone, iron ore, cement.
Wyoming	928,105	10	2.52	Petroleum, sodium compounds, uranium, natural gas.
Total	36,788,000	--	100.00	

Table 5.—Value of mineral production per capita and per square mile in 1973, by State

State	Area (square miles)	1970 population (thousands)	Value of mineral production: Total (thousands)	Per square mile: Dollars	Per square mile: Rank	Per capita: Dollars	Per capita: Rank
Alabama	51,609	3,444	$413,056	$8,004	20	$120	21
Alaska	586,412	300	328,789	561	50	1,096	4
Arizona	113,909	1,771	1,304,988	11,456	14	737	7
Arkansas	53,104	1,923	273,705	5,154	31	142	18

Oxide (gross weight) ---do---	1,134	2,330	1,150	2,714
Salts and compounds (gross weight) --do---	82	44	r 62	r 51
Columbium ore ---do---	3,227	1,927	2,826	2,201
Copper: (copper content)				
Ore and concentrates ---short tons--	80,740	81,055	19,582	16,029
Regulus, black, coarse ---do---	1,453	1,134	139	106
Unrefined, black, blister ---do---	77,162	72,514	128,166	159,922
Refined in ingots, etc ---do---	175,703	172,772	206,297	262,706
Old and scrap ---do---	10,787	9,766	18,266	21,967
Ferroalloys: Ferrosilicon (silicon content) ---do---	23,154	8,815	63,388	21,087
Gold:				
Ore and base bullion ---troy ounces--	265,453	14,023	234,692	19,388
Bullion ---do---	5,860,749	343,666	3,610,073	336,762
Iron ore ---thousand long tons--	35,761	415,934	43,296	533,488
Iron and steel:				
Pig iron ---short tons--	636,932	33,518	445,626	28,925
Iron and steel products (major):				
Iron products ---do---	41,428	18,158	38,043	19,113
Steel products ---do---	18,117,041	r 2,974,072	15,571,833	3,026,099
Scrap ---do---	295,000	14,304	336,693	18,716
Tinplate ---do---	17,040	437	11,940	384
Lead:				
Ore, flue dust, matte (lead content) --do---	51,642	10,554	94,355	17,409
Base bullion (lead content) ---do---	895	238	4	1
Pigs and bars (lead content) ---do---	245,598	64,096	178,095	52,927
Reclaimed scrap, etc. (lead content) --do---	1,753	450	2,745	522
Sheet, pipe, shot ---do---	r 179	r 69	38	18
Magnesium:				
Metallic and scrap ---do---	4,298	1,990	2,874	1,404
Alloys (magnesium content) ---do---	168	464	389	1,104
Sheets, tubing, ribbons, wire and other forms (magnesium content) --do---	13	103	20	129
Manganese:				
Ore (35% or more manganese) (manganese content) ---do---	792,695	34,315	722,635	37,403
Ferromanganese (manganese content)-do---	274,717	49,846	303,867	53,308
Mercury:				
Compounds ---pounds--	9,028	45	3,543	30
Metal ---76-pound flasks--	28,834	r 5,881	46,026	12,151
Minor metals: Selenium and salts ---pounds--	448,964	4,362	590,173	6,023
Nickel:				
Pigs, ingots, shot, cathodes ---short tons--	125,364	r 330,825	120,083	343,494
Scrap ---do---	2,306	3,517	2,642	3,906
Oxide ---do---	5,988	12,038	6,301	13,466
Platinum group:				
Unwrought:				
Grains and nuggets (platinum) troy ounces--	58,284	7,254	19,146	2,396

See footnotes at end of table.

p Preliminary. r Revised. NA Not available. W Withheld to avoid disclosing individual company confidential data.

[1] May not represent total world production because confidential U.S. data are excluded for some commodities. World totals include reported figures and reasonable estimates; however, for some commodities where data were not available, no reasonable estimates could be made and none have been included.

[2] Includes small quantities of lignite for People's Republic of China, and Pakistan, and anthracite for Colombia.

[3] Includes low- and medium-temperature and gashouse coke.

[4] Less than ½ unit.

[5] Includes Puerto Rico.

[6] Kaolin sold or used by producers.

[7] Year ended June 30 of year stated (United Nations).

[8] World total exclusive of the U.S.S.R.

[9] Dry bauxite equivalent of crude ore.

[10] Recoverable.

[11] Includes byproduct ore.

[12] Includes secondary.

[13] Smelter output from domestic and foreign ores, exclusive of scrap.

[14] Lead refined from domestic and foreign ores; excludes lead refined from imported base bullion.

[15] Data from American Iron and Steel Institute. Excludes production of castings by companies that do not produce steel ingot.

[16] Includes tin content of alloys made directly from ore.

Abrasive Materials

By Robert G. Clarke [1]

The output of natural abrasives increased 16% in both quantity and value compared with that of 1972, excluding the value of emery. Production of tripoli-type crudes increased 16% in quantity and 17% in value. The output of silica stone products increased 7% in quantity and 1% in value. The production of garnet increased 20% in quantity and 22% in value. The production of emery was essentially unchanged in quantity.

Overall, the production of artificial abrasives increased 10% in quantity and 17% in value. A new abrasive, fused aluminum zirconium oxide, was added to the canvass by the Bureau of Mines for 1973.

FOREIGN TRADE

Imports of abrasive materials were 28% more in value than in 1972, and exports plus reexports increased 24%. Net imports, the excess of imports over exports and reexports, were $24.2 million, a 55% increase over 1972 net imports. The volume as well as the unit value of nearly all abrasive materials imported increased.

The trade in industrial diamond continued to have a major influence on the total value. Industrial diamond imports totaled 19.2 million carats valued at $65.6 million, an increase of 27% in quantity, and 25% in value above those of 1972. The exports of industrial diamond amounted to 10.5 million carats, an increase of 19%, and the value was $29.4 million, an increase of 22%. Reexports of industrial diamond amounted to 4.5 million carats, a decrease of 1%, and the value was $29.2 million, an increase of 10%. Dust and powder accounted for 95% of the carats and 85% of the value of exports, whereas other diamond, or stones, accounted for 80% of the carats and 88% of the value of reexports of industrial diamond.

[1] Physical scientist, Division of Nonmetallic Minerals—Mineral Supply.

TRIPOLI

Fine-grained, porous, silica materials are discussed as a group because they have similar properties and end uses. Commercially the term "tripoli" is applied to material from Arkansas, Missouri, and Oklahoma; and the term "amorphous" or "soft" silica is applied to the material from the Southern Illinois area. Rottenstone mined in Pennsylvania is more earthy but its properties render it suitable for end uses similar to those of tripoli and amorphous silica. Production of crude tripoli (table 1) increased 16% in quantity and 17% in value. Processed tripoli (table 5) for abrasive use was 62% of the total, and material for filler use was 36%, compared with 63% and 35%, respectively, in 1972.

Tripoli producers in 1973 were Malvern Minerals Co., Garland County, Ark., which produced crude and finished material, and The Carborundum Co., which produced crude in Ottawa County, Okla., and finished material in Newton County, Mo. Amorphous silica producers were Illinois Minerals Co. and Tammsco, Inc., both in Alexander County, Ill. Keystone Filler and Manufacturing Co., in Lycoming County, Pa., mined and processed rottenstone. The largest amounts of amorphous silica and rottenstone were used for abrasive purposes; there was minor use as a filler.

Prices quoted in Engineering and Mining Journal, December 1973 for tripoli and amorphous silica were as follows:

Tripoli, paper bags, carload lots, f.o.b., cents per pound:

White, Elco, Ill.:	
Air floated through 200-mesh	1.35
Rose and cream, Seneca, Mo. and Rogers, Ark.:	
Once ground	2.90
Double ground	2.90
Air float	3.15

Amorphous silica, bags, f.o.b., dollars per ton:

Elco, Ill.:	
Through 200 mesh, 90 to 95%	27
Through 200 mesh, 96 to 99%	28
Through 325 mesh, 90 to 95%	29
Through 325 mesh, 96 to 98%	31.50
Through 325 mesh, 98 to 99.4%	32.50
Through 325 mesh, 99.5%	46.50
Through 400 mesh, 99.9%	68
Below 15 microns, 99%	75
Below 10 microns, 99%	95
Dierks, Ark.:	
200 mesh	30
325 mesh	40

Table 5.—Processed tripoli[1] sold or used by producers in the United States, by use[2]

[1] Includes amorphous silica and Pennsylvania rottenstone.
[2] Partly estimated.
[3] Data may not add to totals shown because of independent rounding.

SPECIAL SILICA STONE PRODUCTS

Special silica stone products include the following: Oilstones from Arkansas, whetstones from Arkansas and Indiana, grindstones from Ohio, grinding pebbles and deburring media from Minnesota and Wisconsin, and tube-mill liners from Minnesota. Production increased overall in both quantity and value.

Novaculite for oilstones, all from operations in Garland County, Ark., was produced by John O. Glassford, Cleve Milroy, M. V. Smith, and Norton Pike Division of Norton Co. Whetstones were produced by Arkansas Abrasives, Inc., and Hiram A. Smith Whetstone Co., both in Garland County, Ark., and by Hindostan Whetstone Co. in Orange County, Ind. Cleveland Quarries Co. produced grindstones at its Amherst quarry, Amherst County, Ohio. Jasper Stone Co. produced grinding pebbles and tube-mill liners from its quarry in Jasper County, Minn. Baraboo Quartzite Co., Inc., produced deburring media at its quarry in Sauk County, Wis.

Table 6.—Special silica-stone products sold or used in the United States[1]

Year	Quantity (Short tons)	Value (Thousands)
1969	3,311	$600
1970	3,134	665
1971	2,349	563
1972	3,241	670
1973	3,466	677

[1] Includes grinding pebbles, grindstones, oilstones, tube-mill liners, and whetstones.

NATURAL SILICATE ABRASIVES

Garnet.—Sales of domestic garnet increased 20% in quantity and 22% in value. Normal processing included crushing, grinding, and screening to produce specified particle sizes and grits. However, further processing was performed on some material to meet specifications for special end uses. There were four active producers—two in New York and two in Idaho. Barton Mines Corp., Warren County, N.Y., the largest producer, processed the garnet for use in coated abrasives, glass grinding and polishing, and metal lapping. Also in New York, Interpace Corp., Essex County, recovered garnet as a byproduct of wollastonite ore. Idaho Garnet Abrasive Co. and Emerald

Creek Garnet Milling Co. produced garnet from placer deposits in Benewah County, Idaho. The latter three producers reported the use of garnet for a variety of purposes, such as sandblasting, water filtration, nonskid paints, and miscellaneous abrasive applications.

Prices for New York garnet, f.o.b. North Creek, N.Y., 2,000-pound release, in 330 to 370 pound containers; in cents per pound were as follows:

Untreated for manufacturing of coated abrasives:

Grades 16 through 36	18
Grades 40 through 220	20
Grades 240 through 280	28
Grades 320 through 600	25

Untreated for technical grinding and lapping:

Mesh sizes 20 to 240	15
Mesh sizes 280 to 360	20
Micron sizes 27 to 23	22
Micron sizes 20 to 8	25
Micron sizes 6 to 5	19
Micron sizes 4 to 2	34

Prices for Idaho garnet, f.o.b. Seattle, ranged from 5.5 to 9 cents per pound.

Table 7.—Abrasive garnet sold or used by producers in the United States

Year	Quantity (Short tons)	Value (Thousands)
1969	20,458	$1,874
1970	18,837	1,936
1971	18,984	1,934
1972	18,916	1,957
1973	22,772	2,380

NATURAL ALUMINA ABRASIVES

Corundum.—Domestic production of abrasive-grade corundum on a commercial scale was last reported in 1918. In recent years nearly all of the corundum used by domestic industry was imported from Southern Rhodesia, but this trade was halted by the sanctions imposed in 1968 by the United Nations. The Office of Emergency Preparedness in 1969 dropped corundum from the list of strategic and critical materials for stockpiling. In 1971, Bendix Abrasives Division, Westfield Facility, of Westfield, Mass., acquired 1,964 short tons of corundum from Government stockpiles after Congressional approval was granted. Domestic industry completed the consumption of accumulated stocks in 1973.

Emery.—Domestic production of emery in 1973 was by two producers, De Luca Emery Mine, Inc., near Peekskill in Westchester County, N. Y., and Oregon Emery Co. near Sweethome in Linn County, Oreg. Data on value of production were withheld to avoid disclosing individual company confidential data. The quantity of production, 2,884 tons, was slightly more than that of 1972. Emery use was mostly in aggregate for heavy-duty nonslip floors, pavements, and stair treads. In lesser amounts it was used in coated abrasives and tumbling abrasives.

World production data, in short tons, are mainly for two countries. In 1971, production of emery in Turkey was 87,353 tons; and in 1972, production was 87,998 tons. Production of emery in Greece was estimated to be 7,716 tons for each year, 1971 and 1972.

[e] Estimate. [p] Preliminary. [r] Revised. NA Not available.

[1] In addition to the countries listed, Southern Rhodesia may have continued to produce natural corundum at a significant level (several thousand tons annually), but available information is inadequate to make reliable estimates of output levels.

[2] Revised to zero.

[3] Less than ½ unit.

INDUSTRIAL DIAMOND

Domestic production of synthetic industrial diamond in 1973 was estimated to be 17 million carats, up 2 million carats from that of 1972. Secondary production comprising salvage from used diamond tools and from wet and dry diamond-containing wastes was estimated to be 2 million carats.

The Government stockpile inventory as of December 31, 1973, was 38.8 million carats of crushing bort and 22.6 million carats of stones. The objectives for both categories were reduced to zero and the inventories were considered excess. Prior enabling legislation for disposal was for bort, 15.1 million carats, and for stones, 2.6 million carats. Legislation was requested for disposal of the remaining 23.7 million carats of bort; and, 20.0 million carats of stones. The inventory of small diamond dies was 25,473 of which the objective was 7,900, and 17,573 were excess.

Exports and reexports of industrial diamond dust and powder, which included synthetics, were 10.4 million carats valued at $26.3 million. Crushing bort, except dust and powder, exported amounted to 0.5 million carats valued at $2.5 million. Exports and reexports of stones were 4.1 million carats valued at $29.8 million. The total of exports and reexports of dust and powder, bort, and stones was 15 million carats valued at $58.6 million.

Imports of industrial diamond in 1973 increased 27% in number of carats and 25% in value over 1972 figures. Receipts from Ireland were 9.4 million carats valued at $21.1 million, increases of 26% in quantity and 18% in value, respectively, in 1973 over the 1972 figures. The share of imports from Ireland was 49% of quantity and 32% of value. Of the industrial diamond listed as powder or dust, synthetic diamond was 5.2 million carats valued at $10.6 million, and natural diamond was 7.3 million carats valued at $15.8 million.

Table 9.—U.S. imports for consumption of industrial diamond (excluding diamond dies)

(Thousand carats and thousand dollars)

Year	Quantity	Value
1971	12,910	46,023
1972	15,134	52,619
1973	19,154	65,594

WORLD REVIEW

Angola.—Exports of the Companhia de Diamantes de Angola (DIAMANG), Angola's only diamond producer in 1972, dropped by 6% to 2,199,860 carats during 1972.[2] All diamond exports are destined for metropolitan Portugal. However, export income rose by 4% to $63.4 million in 1972, as the percentage of gem stones increased. The percentage of gems was expected to increase to about 70% in 1973. Diamonds accounted for 11% of Angola's export income in 1972. Several promising deposits of kimberlite were found in 1972 and 1973 by the Consorcio de Diamantes de Angola (CONDIAMA), the consortium of DIAMANG and De Beers Consolidated Mines Ltd.'s interests which inherited all but 50,000 square kilometers of DIAMANG's former concession area. None of the three small firms prospecting for diamond in the coastal area had announced any significant finds during the past year.

Botswana.—The Government and DeBeers Botswana Mining Co. (Pty) Ltd. discussed development of the Dk 1 kimberlite pipe 25 miles southeast of the existing Orapa mine, which currently produces 2.4 million carats worth about $30 million a year.[3] Dk 1 is an extensive primary diamondiferous deposit which can probably be worked initially as an open pit and could be operating by 1975.

Central African Republic.—Cominco, Ltd., of Canada, held majority interest in a new company, Société Centrafricaine d'Exploitation Diamantifère (SCED), formed with Diamond Distributors Inc. of New York to conduct diamond mining and exploration in the Central African Republic.[4] The new project resulted from meetings with Government officials in Bangui, the capital. Cominco will manage the company and provide technical direction for field work. Diamond Distributors will market the production.

r Revised.
1 Less than ½ unit.

China, People's Republic of.—The New China News Agency reported the production of synthetic industrial diamond by subjecting carbon substances to "dynamic high pressure," an explosive process. It was accomplished by the Institute of Physics of the Chinese Academy of Sciences in cooperation with the Peking Grinding-Wheel Works.[5] China became independent of other countries for industrial diamonds in fine sizes by this accomplishment.

Lesotho.—The Lesotho National Development Corp. (LNDC) continued efforts to interest commercial developers in diamond mining areas.[6] Rio Tinto Zinc Corp. (RTZ) abandoned the Letseng-la-Terai diamond pipe in the Mokhotlong District in 1972. The LNDC granted De Beers permission in July to conduct a 6-month evaluation of the Letseng pipe. Newmont Mining Corp. cancelled further exploration and development of the Kao pipe in Butha Buthe District early in 1973 after investing $5.6 million. Nord Resources Corp. of the United States and the Anglo American Corp. of South Africa Ltd. indicated an interest in the areas abandoned by RTZ and Newmont.

Sierra Leone.—Although diamond production in 1972 decreased from that of 1971, higher world diamond prices in 1972 resulted in greater revenue to Sierra Leone. The first 6 months of 1973 were well ahead of the comparable period of 1972 in both the number of carats produced and in value. Diamond exports continued to be the backbone of the Sierra Leone economy.

South Africa, Republic of.—The Central Selling Organization of the De Beers group announced record diamond sales of R920.7 million in 1973, an increase of 40.5% over sales in 1972.[7] Following the U.S. dollar devaluation, rand price increases were announced in succession thus: February, 11%; March, 7%; May, a selective 10% for certain categories of larger gem stones; and August, 10.2%. No breakdown was given for industrial or for gem stones but the price increases were applied to industrial stones as well as to gem stones.

U.S.S.R.—Natural diamond production in Siberia was estimated to exceed that of the Republic of South Africa. However, the proportion of gem stones actually mined in Siberia was less than that of South Africa making the value of South African production greater.

Zaire.—Although Zaire remains the number one producer of diamond, the proportion of industrial diamond (98% in Zaire) reduces the value of production there to a low rank.

TECHNOLOGY

Theories to explain the occurrences or formations of diamond pipes continued to interest scientists. Chemical analyses of minerals in the rock of the pipes, called kimberlite, and of diamond, have yielded new evidence about the eruptions.[8] Garnet peridotite, which is composed of garnet, enstatite, diopside, and olivine, is typically found in kimberlite. The amount of mixing of the materials or minerals indicates the depth, or pressure, and the temperature of formation. Analyses of South African kimberlite samples indicated formation at depths from 145,000 yards to 200,000 yards and temperatures from 950° C to 1370° C. From the depths, water and liquefied gases in the earth's mantle forced a passage upwards. The fluid mixture of water and liquefied gases moved slowly at first, but as the fluid neared the surface, it was vaporized by reduced pressure. The resulting expansion drove the eruption with increased velocity, creating a shape much like the crater left by a meteor. Erosion destroyed the crater, leaving behind a column of cooled and hardened material as a pipe in the earth's crust. Kimberlite pipes have pierced coal seams without buring the coal. The rapid decompression, according to the expanding gas theory, would have had a tremendous chilling effect.

British diamond lapping specialists marketed microscopic-sized gelatin capsules containing wetted diamond particles.[9] Microencapsulation is designed to provide individual abrasive particles at the workface free from agglomeration and surrounded and wetted by lubricant in a pressure-rupturable wall. Potentially toxic or carcinogenic materials needed to assist the abrasive action are controlled and present no health hazards.

Alternative abrasive materials such as natural or synthetic ruby, sapphire, fused

e Estimate. p Preliminary. r Revised.

[1] Total (gem plus industrial) diamond output for each country is actually reported except where indicated to be an estimate by footnote. In contrast, the detailed separate reporting of gem diamond and industrial diamond represents Bureau of Mines estimates in the case of all countries except Lesotho (1971 and 1972), Liberia (1971 and 1972), and Venezuela (1971 and 1972), where sources give both total output and detail. The estimated distribution of total output between gem and industrial diamond is conjectural in the case of a number of countries, based on unofficial information of varying reliability.

[2] Exports of diamond originating in Lesotho; excludes stones imported for cutting and subsequently reexported.

[3] Exports for year ending August 31 of that stated.

[4] Exports.

[5] All company output from the Republic of South Africa except for that from the Premier mine; also excludes company output from the Territory of South West Africa and from Botswana.

aluminum oxide, silicon carbide, cubic boron nitride, and others can be used in conjunction with lubricants and chemical agents. As an alternate to gelatin, polyethylene oxide, styrene maleic anhydride, cellulose acetate phthalate and numerous others may be used as wall materials.

Polished 0.2-carat natural diamonds were shaped in the form of precision gaging points to monitor coin thickness at the Bavarian main mint in Munich, West Germany.[10] The increasing use of vending machines required tighter tolerances on the dimensions, weights, and composition of coins to counteract the growing use of low value substitutes for official coins. The diamond measuring tips improved the consistency in dimensional accuracy.

About 230 tons of diamond have been mined in history and to get this quantity, miners have had to handle 5 billion tons of rock, sand, and gravel for which the diamond content was only one part in 20 million. Of this total of 230 tons, 100 tons of diamond has been produced between 1960 and 1972. The new techniques, which have been added to already highly developed mining, quarrying, earth moving, and sophisticated recovery processes, were described in a well-illustrated publication.[11]

Abstracts relative to properties of diamond, hard materials, machines, and patents were published monthly in the periodical Industrial Diamond Review.

Each monthly issue, January to December 1973, contained from 14 to 18 pages of abstracts and patent information.

ARTIFICIAL ABRASIVES

Crude fused aluminum oxide was produced in 1973 by five firms in the United States and in Canada. The Carborundum Co., Norton Co., and General Abrasive Co., Inc., each operated plants in both countries. The Exolon Co. and Simonds Canada Abrasive Co., Ltd., operated plants in Canada. Output of white, high-purity material was 28,146 tons and of regular grade was 168,159 tons. Twelve percent of the combined output of white and regular was used for nonabrasive applications, principally in the manufacture of refractories. Output was 69% of the rated capacity of the furnaces assigned to fused aluminum oxide.

Crude fused alumina zirconia abrasive was produced in 1973 by four firms in the United States and in Canada. The Carborundum Co., Exolon Co., General Abrasive Co., Inc., and Norton Co. reported production from their plants for the first time. All production was reportedly used for abrasive applications. Output was 82% of the rated capacity of the furnaces marked for production of fused alumina zirconia.

Silicon carbide was produced in 1973 by six firms in the United States and Canada. The Carborundum Co. operated plants in both countries and Electro-Refractories & Abrasives Ltd., the Exolon Co., Norton Co., and General Abrasive Co., Inc. operated in Canada; all produced crude for abrasive, refractory, and miscellaneous uses. Satellite Alloy Corp. operated in the United States and produced crude for nonabrasive applications. Production by the six firms was 86% of capacity and 48% was reportedly used for abrasive applications. Nonabrasive use was 52% of the output and was mostly for refractory and metallurgical applications.

In the Stockpile Report to the Congress by the General Services Administration crude fused aluminum oxide in calendar year 1973 was reduced in inventory by 61,038 tons to 312,431 tons as of December 31; aluminum oxide abrasive grain was unchanged at 50,905 tons, and silicon carbide crude was unchanged at 196,453.

The manufacture of metallic abrasives in 1973 increased 6% in quantity and 21% in value. Of the total quantity sold or used, steel shot and grit comprised 78%; chilled iron shot and grit, 17%; annealed iron shot and grit, 4%. Other metallic abrasives sold or used included aluminum, copper, stainless steel, and zinc. Production from Ohio was 32% of the total quantity, the highest of the producing States. Michigan, Indiana, and Pennsylvania followed in rank of quantity and their combined output was 61% of the total. The remaining 7% was produced at plants in Alabama, New York, and Connecticut. Three companies reworked ma-

TECHNOLOGY

Vibratory or tumbling barrels may be used for finish grinding or polishing of objects. Media are the abrasive materials used to deburr, descale, grind, and burnish. Compounds enhance these actions, as well as provide other operational benefits. The fundamentals of media selection and compounds, what they are, what they do, and how to use them were described.[12]

As in previous years, the number of patents describing the use of abrasive materials in abrasive and refractory products was large, but most of the patents described improvements in the materials, products, and machines. Trade journals and magazines furnished many articles describing new processes, new products, and new applications.

A need exists for education in the technology of metalworking processes and products. Many abrasive materials producers sponsor training in the use of abrasives for personnel of consuming industries to supplement the courses offered by technical schools. An example was described.[13]

Wheelabrator-Frye ,Inc	Hamilton, Ohio
	Mishawaka, Ind.

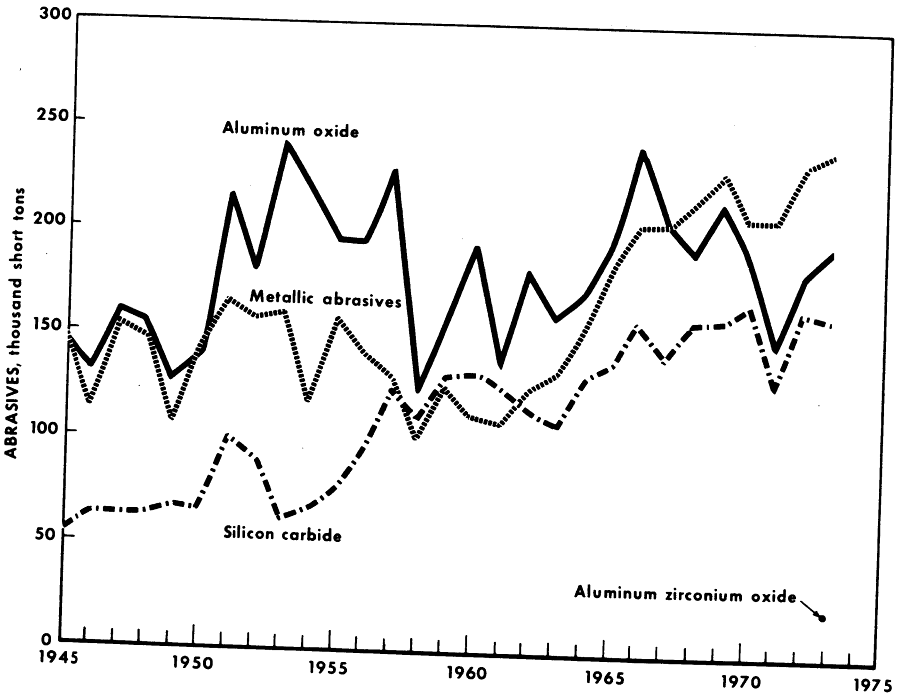

Figure 1.—Artificial abrasives production.

Aluminum

By John W. Stamper [1]

Estimated world demand for primary aluminum surged ahead by about 12% over that of the previous year. Shortages of electric energy held output growth significantly below potential in the United States and Japan and caused a decline in production in India. As a result, world production of primary aluminum was up only 10%, and although sales from government-held stocks in the United States helped avert a drastic shortage in that country, supply was tight in all major consuming areas during most of the year. Some 10% to 15% of the electric energy used to produce primary aluminum in many countries was believed to be provided by oil-fired thermal generating plants and the sharp increase in world oil prices during the latter part of 1973 compounded energy supply problems and accelerated industry interest in locating aluminum plants close to sources of low-cost thermal or hydroelectric power, most of which are outside the major consuming areas.

Legislation and Government Programs.—During 1973, 698,800 short tons of primary aluminum was shipped from government inventories. The total quantity shipped by the government from December 1965, when the disposal program was initially implemented, to the end of 1973, was 1,322,298 tons. Late in December 1972, the stockpile objective for aluminum was reduced from 450,000 tons to none and Public Law 93-220, which authorized the disposal of the 450,000 tons of primary aluminum held in the national stockpile against the objective, was signed by the President.

The U.S. Tariff Commission determined that imports of aluminum ingot from Canada, which had been the object of an investigation under the Antidumping Act of 1921 during part of 1972 and 1973, was neither injuring or nor likely to injure a domestic industry. As a result, aluminum ingot imported from Canada during that period was not subject to special dumping duties.

r Revised.

DOMESTIC PRODUCTION

Primary.—Production of primary aluminum increased 10% over that of 1972, despite a serious shortage of electric energy in the Pacific Northwest, which normally accounts for about one-third of total output. The power shortage was caused by low water conditions, and resulted in the closure of one or more potlines at some plants in the area for several months during the year. However, industry was able to obtain some alternate supplies of electric power albeit at higher costs. Water conditions improved at the end of the year and total production in the area was slightly higher in 1973 than that in the previous year.

Because of the stringent supply of petroleum products, which developed in the latter part of 1973 as a result of the oil producers embargo, domestic steel companies were considering burning coke oven tars, as a source of energy. Coke oven tar from the steel industry is the principal source of coal tar pitch used as a binder for carbon anodes used in the electrolytic reduction of alumina to aluminum metal. About 40 gallons of coal tar pitch is required per ton of primary aluminum produced and there was no known substitute for pitch binder for making aluminum anodes. Witco Chemical Co. announced plans to produce a suitable pitch binder from petroleum at a semicommercial plant at Perth Amboy, N. J. Silicon, a principal alloying element in aluminum also was in short supply during the year.

The Anaconda Aluminum Co. started production of primary aluminum from its new 120,000-ton-per-year plant at Sebree, Ky., and the Aluminum Company of America (Alcoa) increased its total primary aluminum capacity to 1,570,000 tons per year. Alcoa also began construction of a large new potline to expand its primary aluminum capacity at Massena, N.Y., to 190,000 tons per year by 1976, and began site preparation for construction of a 15,000-ton-per-year primary aluminum plant at Palestine, Tex. This new plant will use an experimental process involving electrolysis of aluminum chloride. The plant was expected to begin operations in 1975 and could eventually be expanded to 300,000 tons if the new technique, which requires 30% less electric energy than the present process, proves out.

American Metal Climax, Inc. (AMAX) and Howmet Corp. (Howmet), announced plans to expand annual production capacity of Howmet's Eastalco alumina reduction plant at Frederick, Md., by 86,700 short tons. A new company was expected to be formed to operate the Frederick facility, which would be owned 50% each by Howmet and AMAX. Mitsui & Co., Ltd., a primary aluminum producer in Japan also announced an agreement in principle to purchase half interest in AMAX's aluminum operations for $125 million.

Consolidated Aluminum Corp. (Conalco), 60% of which is owned by Swiss Aluminium Ltd. (Alusuisse) of Zurich, Switzerland, and the remainder by Phelps Dodge Corp., purchased the aluminum operations of Olin Corp. for $126 million. The Olin operations which were put up for sale in November 1972 included half interest in the primary aluminum plant at Hannibal, Ohio, plus a sheet and plate mill, two electrical conductor plants, and six other fabricating facilities.

Kaiser Industries Corp. and principal affiliates including Kaiser Aluminum & Chemical Corp., were discussing a broad technology exchange agreement with representatives of the U.S.S.R., which could result in the construction of primary aluminum plants utilizing the large hydroelectric power potential in Siberia.

Secondary.—Recovery of secondary aluminum, calculated from reports to the Bureau of Mines, was 1,038,480 short tons, 10.0% above the 1972 level. Calculated recovery of all metallic constituents from aluminum-base scrap increased 9.63% to 1,106,041 tons.

The Bureau estimated that full coverage of the industry would indicate a total scrap consumption of 1,472,000 short tons in 1973. Using this estimate, aluminum recovery totaled 1,147,000 short tons and metallic recovery was estimated at 1,235,000 tons.

Vulcan Materials Corp., a producer of secondary aluminum alloys, announced

plans to spend $6.5 million during the year to expand capacity. About $4.5 million of the total was expected to be used for pollution control equipment.

The Ohio Valley Aluminum Co. was expected to expand its secondary aluminum extrusion billet capacity at Shelbyville, Ohio, from 2,000 tons per month to 2,500 tons per month by the end of 1973. The Hall Aluminum Co. also was increasing capacity for producing secondary foundry-grade aluminum alloys and fluxes at its Chicago Heights, Ill., facility.

Apex Smelting Co., Inc., a subsidiary of AMAX, and a member of the AMAX Aluminum Group, announced plans to construct a new secondary aluminum and alloyed zinc production facility in Checotah, Okla. The $2.6 million facility, scheduled to go onstream in late 1974, will employ about 100 people and have an annual production capacity of up to 20,000 tons of secondary aluminum and 12,000 tons of alloyed zinc. The new facility will give Apex a total capacity of 92,000 tons of secondary aluminum when added to capacities of existing plants

in Chicago, Ill., Cleveland, Ohio, and Long Beach, Calif.

Alcoa undertook a multimillion dollar expansion at its Warrick operations near Evansville, Ind., to enable it to recycle an additional 30,000 tons per year of aluminum beer and soft drink cans. The company's Warrick plant reportedly had a capacity to recycle about 110,000 tons of aluminum scrap per year, including container scrap.

American Can Co., formed a new company to market a recycling system for recovering aluminum, steel, and other materials from household wastes. The new firm, Americology, Inc., announced that the basic model of its system, costing about $2 to $3 million each, will process 500 tons of garbage per day (equivalent to the output of a typical city of 150,000 people). The firm also planned to provide continuing marketing and technical management counselling to purchasers of its system, and offered a guaranteed market for the ferrous scrap.

[1] Gross weight, including copper, silicon, and other alloying elements. Secondary smelters used 16,300 and 34,797 tons of primary aluminum in 1972 and 1973, respectively, in producing secondary aluminum-based alloys.
[2] No allowance was made for consumption or receipts by producing plants.

CONSUMPTION

Aluminum demand continued strong in 1973, and consumption, as measured by shipments of aluminum ingot and mill products to domestic users, surged upward by 18.6%. Total shipments including exports increased by 20.8%.

The transportation market, representing the second largest market for aluminum products, gained about 26% over that of the previous year, and had the largest quantity increase of any of the major markets. The estimated average use of aluminum in 1974 model cars was about 80 pounds per unit compared with about 78 pounds in 1973 models. The increase was attributed to greater use of aluminum in the General Motors Corp. Vega engine, in bumpers, air conditioning, and some body sheet, especially for hoods.

1973	4,587,348	+59,484	196,514	841,966	5,685,312

[1] Crude and semicrude. Includes ingot equivalent of scrap imports and exports (weight multiplied by 0.9).
[2] Aluminum content.

An Alcoa study, described in a report,[2] showed that about 52 pounds of aluminum (about 75% of which was in engine parts such as pistons, carburetors, fuel pumps, etc.) was used in light trucks weighing about 6,000 to 10,000 pounds per unit. Remaining uses of aluminum in light trucks included body, hardware and trim applications (about 18% of the total), and air conditioners (5%). Alcoa estimated that the average large truck tractor with a gross weight (including the trailer) of over 33,000 pounds used 785 pounds of aluminum mainly in the cab, frame, radiator, fuel tanks, wheels, battery boxes, bumpers, and air conditioners. The average use of aluminum in all trucks increased 3½ pounds per unit to an estimated 99 pounds per unit in 1974 models.

Shipments for machinery and equipment applications, which include special industrial machinery, chemical processing and material handling equipment, irrigation pipe, and service equipment and supplies, had the largest percentage gain, reaching 475,000 tons, 26.7% above that of the previous year.

Shipments to the electrical industry also increased sharply to 1,029,000 tons, 21%

[2] Rakowski, Leo R. Trucks Go Light With Aluminum. Mod. Metals, v. 29, No. 5, June 1973, pp. 49–62.

higher than in 1972. Part of this increase was attributed to the expansion of the use of copper-clad aluminum conductors, which can be satisfactorily joined with a good electrical connection. Shipments of copper-clad aluminum conductors for wiring houses reportedly exceeded shipments of solid aluminum conductors for that purpose and continued to gain on solid copper conductors for houses.[3]

Consumption of aluminum for air conditioners, cooking utensils, refrigerators, and other consumer durables increased about 19% to 669,000 tons. The increases in aluminum shipments for building and construction and the container and packaging markets of 13% and 14%, respectively, were below the overall average increase for consuming industries.

The use of aluminum coatings to improve the corrosion resistance of steel roofing and structural components was expected to triple by 1976.[4] About 0.8 ounce of aluminum per square foot of steel surface was said to reflect up to 80% of the radiant heat that strikes it and does not need any initial or maintenance painting. The aluminized steel could be fabricated into a variety of shapes, only one coating of porcelain enamel was required on the outside of aluminized steel compared with a double coating of porcelain required on the outside of untreated steel, and was available in strengths up to 50,000 pounds per square inch. A porcelain coating was not required on interior surfaces protected with aluminum.

Table 10.—Net shipments of aluminum wrought [1] and cast products by producers

(Short tons)

	1972	1973 p
Wrought products:		
Sheet, plate, and foil	2,993,850	3,257,856
Rolled and continuous cast rod and bar, wire	690,144	675,221
Extruded rod, bar, pipe, tube, shapes; drawn and welded tubing and rolled structural shapes	1,188,081	1,317,781
Powder, flake, and paste	113,185	128,698
Forgings (including impacts)	61,383	71,186
Total	5,046,643	5,450,742
Castings:		
Sand	114,820	129,825
Permanent mold	209,888	220,100
Die	596,086	652,184
Others	7,042	10,918
Total	927,836	[2] 1,013,027
Grand total	5,974,479	6,463,769

p Preliminary.
[1] Net shipments derived by subtracting the sum of producers' domestic receipts of each mill shape from the domestic industry's gross shipment of that shape.
[2] Subject to possible upward revision of approximately 10% to 15%.

Table 11.—Distribution of wrought products

(Percent)

	1972	1973 p
Sheet, plate, and foil:		
Non-heat-treatable	50.1	49.7
Heat-treatable	2.6	2.9
Foil	6.7	7.1
Rolled and continuous cast rod and bar; wire:		
Rod, bar, etc	4.3	2.7
Bare, wire conductor and nonconductor	1.1	1.1
Bare cable (including steel-reinforced)	4.6	4.5
Wire and cable, insulated or covered	3.7	4.1
Extruded products:		
Rod and bar	.8	.6
Pipe and tubing	1.9	2.1
Shapes [1]	18.7	19.4
Tubing:		
Drawn	.9	1.0
Welded, non-heat-treatable [2]	1.2	1.1
Powder, flake, and paste:		
Atomized	1.8	1.9
Flaked	(3)	(3)
Paste	.2	.3
Powder, n.e.c	.2	.2
Forgings (including impacts)	1.2	1.3
Total	100.0	100.0

p Preliminary.
[1] Includes a small amount of rolled structural shapes.
[2] Includes a small amount of heat-treatable welded tube.
[3] Less than 0.1%.

STOCKS

Reflecting the strong upturn in demand, industry stocks of primary aluminum ingot at reduction plants declined from 120,465 tons (revised) at the beginning of the year to 62,234 tons at yearend. Although all producers do not report stocks of aluminum at reduction plants to the Bureau of Mines, the Bureau of Domestic Commerce (BDC) reported that the total metal inventory held by the aluminum industry, which includes stocks of all metal forms at reduction and other processing plants, also declined. Total industry stocks of aluminum metal, including scrap, dropped from 2,430,584 tons (revised) at the beginning of the year to 2,183,031 tons at yearend.

PRICES

The major domestic producers price for primary aluminum, quoted in the American Metal Market at the beginning of 1973, was 25 cents per pound, and was raised to 29 cents per pound at yearend. By the end of estimated the market price for primary aluminum at about 20 cents per pound in January, 23 to 23.5 cents per pound in March, 25 cents per pound in May, and 33 cents per pound at yearend. By the end of the year the estimated world market price for primary aluminum was 36 to 38 cents per pound, compared to an estimated 28 to 30 cents per pound at the beginning of the year.

In the middle of the year requests by two leading domestic aluminum companies to increase the aluminum base or ceiling price for primary aluminum to 29 cents per pound, which prevailed in May 1970 when market prices were believed to be about 26 to 27 cents per pound, was rejected by the Cost of Living Council (CLC). Anaconda and Alcan were permitted under price regulations to raise their price for primary aluminum to 27.5 cents per pound in October. On December 6, the CLC restored the May 1970 base price for aluminum of 29 cents per pound and, after subsequent clarifications by the CLC, all major domestic producers raised their quoted prices to that level by the end of the year.

Prices (in cents per pound) quoted by the American Metal Market for aluminum-base scrap and secondary alloy ingot, also increased markedly during the year, as follows:

	Jan. 2, 1973	Dec. 31, 1973
Aluminum clippings (new scrap)	11.5 –15.5	19.00–24.00
Old cast scrap	11.5 –12.25	17.00–18.00
Smelter's alloys (secondary alloy ingot, excluding deoxidizing ingot)	26.75–32.00	34.00–40.00

Increased costs for silicon, a major alloying ingredient in secondary aluminum alloy ingot was credited with causing part of the increase in the price of secondary aluminum alloys, as well as the increase in aluminum-base scrap prices.

FOREIGN TRADE

Despite strong domestic demand, exports of crude and semicrude aluminum metal, including scrap, were 70% higher than those in 1972. Most of the increase was in the form of aluminum ingot, slabs and crude, the total quantity of which was more than double that in 1972. Aluminum scrap exports also were more than double those of 1972. Canada was the principal destination of U.S. aluminum exports, receiving 24% of the crude and semicrude aluminum shipped, chiefly in the form of ingot and scrap. Of the ingot, slabs, and other crude forms exported, Japan, Canada, Argentina, West Germany and Mexico, in that order, were the principal recipients.

U.S. imports for consumption of crude and semicrude aluminum decreased to 613,606 short tons, 29% less than 1972 imports. Aluminum in the form of metal and alloys, ingots, and other crude forms, as in past years dominated imports, accounting for 83% of the total. Scrap imports declined 12% during the year to 46,808 tons. As in past years, Canada was the principal source of U.S. aluminum imports, accounting for 85% of the ingot and other crude forms and for 85% of the scrap imports. Other principal sources of imported ingot and other crude forms were Ghana, Norway, Surinam, and the United Kingdom.

WORLD REVIEW

Estimated world demand for primary aluminum surged ahead by about 12% over that of the previous year. Shortages of electric energy supplies held output growth significantly below the potential in the United States and Japan and caused a decline in production in India. As a result, world production of primary aluminum was up only 10%. Although sales from government-held stocks in the United States helped avert a drastic shortage in that country, supply was tight in all major consuming areas during most of the year. Some 10% to 15% of the electric energy used to produce primary aluminum in many countries is believed to be based on oil-fired thermal generating plants. The sharp increase in world oil prices during the latter part of 1973 compounded energy supply problems and accelerated industry interest in locating aluminum plants near sources of low-cost thermal or hydroelectric power, most of which are found outside major consuming areas.

Large expansions of primary aluminum capacity, however, were completed in 1973 in major consuming countries, including Italy, Japan, Spain, the United Kingdom, and the United States. Countries which were being considered for aluminum plants because of energy availability included Abu Dhabi, Brazil, Indonesia, Kuwait, Qatar Shiekdom, Saudi Arabia, and Venezuela.

Argentina.—Aluminio Argentino S.A. (ALUAR), apparently continued construction of the 140,000-ton-per-year primary aluminum plant at Puerto Madryn in Chubut Province, but it appeared unlikely that the plant would begin significant production before 1975 because of delays in completing the hydroelectric power facilities on the Futaleufu River. Beginning in late 1974 or early 1975, 100,000 tons of alumina from Australia was scheduled to be delivered annually to the plant under a contract with Alcoa.

Australia.—The Tasmanian State Government reportedly was considering construction of a 170,000-ton-per-year primary aluminum plant in cooperation with Nippon Light Metals Co. Ltd. (NLM) and other Japanese interests. By 1977, Comalco Industries Pty. Ltd. reportedly planned to construct an 88,000-ton-per-year primary aluminum plant near Gladstone, Queensland.

Brazil.—Companhia Mineira de Alumínio, S.A., 50% owned by Alcoa, was expected to increase capacity at its alumina reduction facilities at Poços de Caldas to about 70,000 tons per year by 1976. The capacity of the Companhia Brasileira de Alumínio S.A. (CBA) primary plant at Sorocaba was to be raised to 77,000 tons per year by 1976. Capacity at the Alumínio Minas Gerais, S.A. plant at Arutü, owned by Alcan, was raised to 15,000 tons per year. Capacity at Alcan's Saramenha facility was

scheduled to be increased to 36,000 tons per year by 1974. The planned expansion would bring total capacity in Brazil at existing plants to about 200,000 tons per year by 1976.

A proposed new plant to produce primary aluminum near Recife and at other locations was being planned by Brazilian, Canadian, and Japanese interests in connection with the development of the Trombetas bauxite deposits. Total domestic production capacity for primary aluminum was expected to reach 300,000 to 400,000 tons per year by the 1980's.

Canada.—Alcoa announced plans to construct a 60,000-ton-per-year primary aluminum plant near Valleyfield, Quebec, by 1976. Alcan reportedly had flexible plans to add 300,000 tons of new or expanded capacity in Canada over the next 10 years. The company was considering construction of a 90,000-ton-per-year primary aluminum plant in the Saguenay-Lac St. Jean area of Quebec for possible completion in 1977, was scheduled to boost annual productive capacity at its Arvida plant by 38,000 tons in 1976, and reportedly was discussing, with NLM, a 50% owned company based in Japan, the possibility of expanding existing Canadian capacity or of constructing new primary aluminum facilities in Canada.

China, People's Republic of.—Based on a published report, primary capacity at the Fushun plant was about 60,000 tons per year. The plant was said to be operated efficiently and possibly to be using alumina from the aluminous shales near Kiaoning.[5] Strong demand for primary aluminum apparently continued since imports were established to have been in the 100,000-ton-per-year range, the same as last year. Reportedly, more metal would have been purchased if prices had been lower.

Czechoslovakia.—Primary aluminum capacity was expected to be increased to 132,000 tons per year by the 1980's.

France.—The primary aluminum plant at Nogueres was shut down from June 27 to August 16 because of a dispute between management and workers. The electrolyte and molten metal left in the cells froze, and production was not resumed until September. By yearend about 90% of the plant was believed to be operating. Some 40,000 tons of production was said to have been lost, and possible damage to anodes caused by the freezing of the cells had not been fully assessed.

Germany, Federal Republic of.—The 88,000-ton-per-year alumina reduction plant at Stade, operated by Vereinigte Aluminium-Werke A.G. (VAW) was commissioned. Commercial production also was being started at the new 110,000-ton-per-year primary aluminum facility at Hamburg, operated by Reynolds.

Greece. — The Government and Alcoa reached agreement in principle to construct a $350 million alumina-aluminum complex at Pachi, near Megara. The facility will include a 286,000-ton-per-year primary aluminum production plant which is to become

[5] Mamen, C. China Report—Part 2. Mines and Plants Visited. Canadian Mining J., v. 94, No. 3, March 1973, p. 33.

operational in two stages. The first stage was expected to be operating by 1976, and the second by 1978 or 1979. Share capital investment was to be $105 million, 60% by Alcoa and 40% by the Government through the Hellenic Industrial Development Bank, which also was to arrange for loans to raise the remaining $245 million.

Hungary. — Government spokesmen reportedly announced plans to expand primary aluminum capacity from about 69,000 tons per year in 1973 to 96,000 tons per year by 1985. Fabricating capacity during the same period was expected to be increased to between 270,000 and 300,000 tons per year, compared with about 100,000 tons per year in 1973. Primary aluminum requirements were received from the U.S.S.R. under barter arrangements in exchange for alumina produced in Hungary.

India.—The capacity data shown in table 17 include some expansions believed to have been completed in 1972 or 1973 but not operated during 1973 because of an electric power shortage. The Madras Aluminium Co. Ltd. (Malco), Hindustan Aluminium Corp. Ltd. (Hindalco), and Indian Aluminium Co. Ltd. (Indal), were especially affected by the power shortage. Because of the energy problems, total output of primary aluminum was curtailed during the year. The Tamil Nadu government announced plans to nationalize Malco.

Indonesia.—The government and five Japanese aluminum companies apparently agreed in principle to build hydroelectric power and primary aluminum production facilities costing $500 million at Kuala Tanjung on the east coast of Northern Sumatra. Alcoa and Kaiser participated at various times in the preliminary discussions of the project and reportedly were still considering plans to join the Japanese firms, which included Mitsui Aluminum Industry Co., Ltd., Mitsubishi Chemical Industries, Ltd., NLM, Showa Denko K.K., and Sumitomo Chemical Co., Ltd. The primary aluminum plant was scheduled to have an initial capacity of 250,000 tons per year beginning in the early 1980's and eventually be expanded to 450,000 tons per year. The power facilities would have a 480,000-kilowatt capacity.

Although many details were yet to be agreed upon, the plan reportedly called for nationalization of the power facility 30 years after it was commissioned. The initial agreement also called for a fixed tax of $16.55 per short ton of aluminum produced plus a corporation tax on profits of 37.5% for the first 10 years and 45% thereafter.

Italy.—MCS S.p.A., owned by the State corporation Ente Participazione Finanziamento Industria Manifattura (EFIM), acquired 94% of the aluminum operations of Montecatini Edison S.p.A. MCS also started production of primary aluminum at a new plant at Porto Vesme in Sardinia.

Japan.—Primary aluminum capacities at Niigata, Chiba, and Toyama were expanded. Electric power supply problems and increased costs of imported oil threatened to cause production cutbacks at about half of the primary aluminum plants toward the end of the year. The increased fuel costs were expected to encourage the location of primary aluminum capacity outside Japan.

Korea, Republic of.—A new firm, the Daehan Aluminum Co., was formed by the Korean Development Bank and Péchiney Ugine Kuhlmann (PUK) to operate the primary aluminum plant at Ulsan. The plant was to be expanded to about 100,000 tons per year by 1978, at a cost of $88 million, about 20% of which was to be raised locally.

Netherlands.—Capacity of the Vlissingen primary aluminum plant operated by the PUK Group was expected to be doubled early in 1974. Pending availability of electric energy, a third potline, increasing capacity to 278,000 tons per year, was expected to be constructed by 1977.

Norway.—Subject to availability of electric power, market conditions, and financial arrangements. A/S Ardal og Sunndal Verk (ASV) planned to increase primary aluminum capacity at its Ardal plant to 215,000 tons per year by 1980. The 33,000-ton-per-year plant at Hoyanger would be dismantled after a new 110,000-ton-per-year facility is started up in 1981. The Sunndal plant was to be expanded to 200,000 tons per year by 1980. Det Norske Nitridaktieselskap (DNN) planned to phase out its primary aluminum plant at Eydehavn in 1974, and was considering expansion of capacity at its Tysseldal plant to 50,000 tons per year. Lista Aluminiumverk A/S (Elkem) also was considering expansion of its primary aluminum plant to 88,000 tons per year by 1975.

New Zealand.—New Zealand Aluminium Smelters Ltd., planned to expand capacity of its Bluff primary aluminum plant to 166,000 tons per year by 1976. Government restrictions, placed on the level of Lake Manapouri, the source of electric power for the plant, appeared to limit the ultimate capacity of the facility, which had previously been scheduled to reach 250,000 tons per year.

Philippines.—Tentative plans for construction of two primary aluminum plants were reported. Reynolds International Inc., a subsidiary of Reynolds Metals Co. of the United States, and the Government signed a letter of intent to construct, near Ormos, Leyte, a 100,000-ton-per-year aluminum plant in which each will hold a 50% interest. Reynolds was to manage construction and provide technical assistance for the project. Implementation of the plans apparently was contingent on whether sufficient sources of geothermal power could be found.

Alusuisse reportedly was selected to supply the technical knowhow for a proposed new 22,000-ton-per-year primary aluminum facility in Mindanao, planned by the Aluminum Corp. of the Philippines.

South Africa, Republic of.—Capacity of the primary aluminum plant at Richards Bay was expected to be expanded to 84,000 tons per year in 1974.

Spain.—An agreement in principle was reached between Alcan, PUK, the Government entity, and the Instituto Nacional de Industria (INI), for the formation of a new corporation to produce alumina and primary aluminum metal at Villagarcía de Arosa in Galicia. Empresa Nacional del Alumínio S.A. (ENDASA), 50.5% of which was owned by INI, a government corporation, would own 50.5% of the new organization, Alcan would hold 25%, and the remainder would be held by Aluminio de Galicia, S.A. (Alugasa), which in turn is owned 66% by PUK, and 34% by Spanish interests.

Projected capacity of the primary aluminum plant, scheduled to be in operation in 1977, was 193,000 tons per year. Alumina was to be supplied from a domestic plant using Brazilian bauxite. Electric power would be based on lignite and would be supplied by the Puentes de Garcia Rodriquez generating plant.

Turkey.—Production was started at the primary aluminum plant at Seydisehir early in the year. Initial capacity was estimated at about 22,000 tons per year and was to be increased eventually to 66,000 tons per year.

U.S.S.R.—PUK reportedly was discussing plans to provide technical assistance for building a $500 million primary aluminum plant near the Syano-Shushenska hydroelectric facilities under construction in the Yenissey-Ankara River Basin in Siberia. Production at the planned 500,000-ton-per-year aluminum plant was expected to begin after initial operation of the hydroelectric facilities in 1977.

Venezuela.—Plans for major expansion of domestic primary aluminum capacity were announced. The capacity of the existing primary aluminum plant at Matanzas was being doubled to 50,000 tons per year. Mitsubishi Chemical Industries, Ltd., and other Japanese firms, and Reynolds, half owner of the Matanzas plant, were discussing plans for a new plant or an additional expansion to 200,000 tons per year. In addition, three Japanese firms, Showa Denko, K.K., Kobe Steel Co., and Marubeni, K.K., and the Corporación Venezolana de Guyana (CVG) a government agency, formed a new company, Industria Venezolana de Aluminio C.A., to construct a 75,000-ton-per-year primary aluminum plant by 1977, which was scheduled to be doubled by 1979. Showa Denko and Kobe Steel would each own 35% of the new company. Marubeni would own 10%, and the CVG would own the remaining 20%.

Yugoslavia.—Production reportedly was started at the new 83,000-ton-per-year primary aluminum plant at Sibenik. Electric power for the plant apparently was limited, restricting output. Capacity reportedly was scheduled to be increased to 110,000 tons per year by 1976. Despite the apparent problems with electric power supply, expansion of the capacity of the Titograd primary aluminum plant also was planned.

TECHNOLOGY

The trend toward automation of primary aluminum production facilities through computerization continued. Showa Denko K.K. of Japan found that computer-controlled, high-ampere (150,000 ampere), large-sized, prebaked aluminum potlines were generally more efficient than other types, although cathode wear was somewhat higher owing to the high amperage.[6] The new line was especially designed to reduce labor and power requirements.

Computerized, automated feeding of alumina to reduction cells at the ASV primary aluminum plant at Sunndal, Norway was tested.[7] Two groups of reduction cells each with 11 cells, were used in the test. Alumina was added to the cells in one of the groups in sufficient quantities to establish stability in the cells, following each "anode effect" or period of time during which the voltage across the cell increases sharply, indicating a depletion of alumina in the bath. The other group was supplied a specific constant quantity of alumina after each anode effect and feeding cycle. The group with interim alumina additions based on an assumed interval of 24 hours between anode effects, consumed less power and fluoride, and the anode effects were easier to control. Under these conditions about one anode occurred in each cell per day. By extending the assumed anode effect to 48-hour intervals, the actual anode effects were reduced to 0.6 per day.

Commercial operating experiences with the National Southwire Aluminum Co. computer-controlled alumina reduction plant at Hawesville, Ky.,[8] and at Intalco's Ferndale, Wash.,[9] plant were described. The experimental computer-controlled operation of 20 reduction cells at the Granges Aluminum Co. reduction plant at Sundsvall, Sweden was described in detail.[10] Granges planned to install a $1 million computer control system at its plant during 1973 and 1974.

The Bureau of Mines published two reports on its investigations of methods to recover aluminum and other metals from wastes and scrap.[11]

The Bureau operated a 5-ton-per-hour pilot plant for continuous mechanical separation of values contained in raw urban refuse. The entire system was assembled using commercially available equipment. The process relies on multistage processing including shredding, air classification, screening, gravity concentration, and electrostatic separation. Compactor trucks delivered raw refuse collected along typical routes in metropolitan Washington, D.C., to the pilot plant. The loads were separated into concentrates of (1) light-gage iron, (2) massive metals, (3) glass, (4) putrescibles and waste combustibles, (5) paper, and (6) plastics. Although some refinements remain to be made in the processing system flowsheet, the data obtained to date were highly encouraging, indicating favorable economics for commercial-size plants.

Three cryogenic methods were investigated in conjunction with crushing and classifying techniques to separate and reclaim the metallic components contained in insulated wires, shredded automobile nonferrous metal concentrates, small motors, generators, and rubber tires. Excellent separation of zinc die-casting alloys from copper and aluminum contained in shredded automobile nonferrous metal concentrates was attained by chilling at −72° C for 1 minute, crushing in a grateless hammer mill, and screening. From the screened products, 97.2% and 100% of the copper and aluminum, respectively, were recovered in the plus 1-inch fraction, and 100% of the zinc was recovered in the minus 1-inch fraction of over 97% zinc die-cast purity. Laboratory experimental results comparing direct and indirect chilling indicated that a sufficiently

low temperature could be attained by indirect chilling to permit use of a liquid CO_2-dry ice system on insulated wires and mixed nonferrous metallic concentrates.

Other industry developments in processing scrap materials included development of an air classifier system, which reportedly enabled the production of high-quality fuel from the lightweight part of shredded trash and enhanced recovery and recycling of metals and other heavy material.[12] In the system, garbage is shredded into small pieces and introduced into the air classifier. Air is drawn upward through the material causing separation of the solid waste into light and heavy fractions. A series of magnetic belts are used to separate the ferrous products from the other heavy components. Using the system, American Can Co. proposed a full system for treating a municipality's solid waste—erecting a treatment facility, operating and managing it, marketing recoverable materials, and disposing of unsalable residues. The system was proposed in several major metropolitan areas.

Cryogenics Inc., reportedly was expanding a large-scale pilot plant operation utilizing a nitrogen freezing method to generate 50 tons per day of clean aluminum, steel, copper, and precious metals from conglomerate scrap.[13] After nitrogen freezing, aluminum, copper, and steel-bearing motors were processed in hammer mills, shaker screens, and air and magnetic separation equipment.

Increasingly stringent restrictions on the emission of pollutants and the continuing cost-price squeeze in production of primary aluminum has resulted in intensified efforts to reduce fluorine consumption. The quantities of fluorine used, the reasons for the losses, and the trends in consumption of fluorine including a forecast of use to 1980, were dicussed.[14]

Methods for controlling fumes released when magnesium is removed from molten aluminum were described in proposed rules for effluent guidelines for the secondary aluminum industry.[15] Wet scrubbing techniques in effect transfer an air pollution problem to a water pollution problem whether chlorine or aluminum fluoride are used to remove the magnesium. Water from fume scrubbing techniques is neutralized to precipitate aluminum and magnesium compounds and the supernatant water is recycled.

Dry processes must contend with corrosive gasses in both methods for removing magnesium. In the Derham process, which has been licensed for use at about five plants in the United States, magnesium chloride is entrapped in a liquid flux covering the molten aluminum in a special compartment.[16] The resulting flux is reused in melting operations. The Alcoa process is a fumeless process for removing magnesium from molten aluminum and recovers magnesium chloride as a product. This process uses no flux and achieves high chloride efficiency through extending the time of contact between chlorine and magnesium in the melt. In the coated baghouse or Teller technique, the fumes resulting from magnesium removal are passed through filter bags coated with a solid material to absorb effluent gasses as well as to retain particulates.

Antimony

By Charlie Wyche [1]

Responding to a generally tight supply and increasing demand, the domestic antimony industry increased both mine and primary smelter production during 1973. Increases were also recorded in both consumption and secondary smelter production. The 28% increase in consumption of primary antimony was balanced by withdrawals from the U.S. stockpile as imports of ore, metal, and oxide decreased from those of 1972. Byproduct antimonial lead at primary lead refineries increased 56%. Secondary smelters operated at a high rate throughout the year, and production of antimony from scrap increased 3% over that of 1972. The domestic primary metal price rose from $0.59 per pound in January to $0.94 in mid-December. Consumer stocks of primary antimony increased about 1,500 tons during the year.

Legislation and Government Programs.—The General Services Administration (GSA) as authorized under Public Law 92–105, enacted August 11, 1971, continued disposal of some 6,000 tons of surplus Government stocks of antimony metal. The metal was in the form of granules, pigs, slabs, cakes, and ingots, and was of stockpile grades "C" and "D" quality. Initially, the rate of disposal was set at 800 tons per calendar quarter; however, this was increased in May to more than 2,000 tons per quarter. In late November, GSA had exhausted that portion of its stocks that Congress authorized it to sell. Since the stockpile metal was less pure than the two commercial grades, GSA prices were lower than commercial prices. The quoted price range of GSA for grade "C" metal rose to $0.68 per pound, from $0.62 at the beginning of the year. Purchasers had to agree that the antimony was for domestic consumption. Firms that purchased antimony for resale had to agree to sell the metal at no more than the price charged by GSA. Total sales from Government stocks in 1973 amounted to 5,975 tons; Government inventory at yearend was 40,702 tons.

Exploration assistance for antimony continued under the Office of Minerals Exploration, and Government participation remained at 75%.

DOMESTIC PRODUCTION

MINE PRODUCTION

Domestic mine production of 545 tons of antimony in 1973 was 11% above that of 1972, reversing the downward trend, which began in 1971. Production of antimony from antimony ores increased in relation to that from other sources, but antimony recovered as a byproduct of lead-silver ores by the Sunshine Mining Co. remained the predominant source of mine production. The lead-silver ores of the Coeur d'Alene district of Idaho contributed 322 tons (59%) of the total supply. Production would have been even higher if a 4-month strike had not occurred at the company's Kellogg, Idaho, plant.

U.S. Antimony Corp., the only U.S. mine that operated primarily for antimony, increased its metal production substantially during the year. Although the smelter began operating on a regular basis in the spring of 1973, there were still some metallurgical problems to be solved at yearend. The operation is a batch process and has a capacity of approximately 600 tons of metallic antimony annually. A planned 50% increase in mill output is expected to increase metal production to about 800 tons per year. The company is also studying the feasibility of producing antimony trioxide.

The only other source of domestic mine production was a mine in Nevada. In addition, 731 tons of antimony was recovered in antimonial lead from domestic lead ores at primary lead smelters.

Table 2.—Mine production and shipments of antimony in the United States

(Short tons)

Year	Antimony concentrate (quantity)	Antimony Produced	Antimony Shipped
1969	5,707	938	943
1970	6,681	1,130	1,029
1971	4,721	1,025	1,073
1972	2,072	489	547
1973	2,468	545	494

SMELTER PRODUCTION

Primary.—Primary smelter production of antimony was 17,206 tons, an increase of 29% over that produced in 1972. The increase resulted essentially from higher output of oxide, byproduct antimonial lead, and residues. However, production of metal and sulfide decreased 25% and 60%, respectively. The antimony content of byproduct antimonial lead recovered at primary lead refineries from domestic and foreign ores increased to 1,143 tons, 56% above that of the previous year. Ores and concentrates used by primary smelters to produce metal was derived from the following: 92% from foreign antimony ores and base metal ores, and 8% from domestic mine production of antimony concentrate and as a byproduct at domestic lead smelters. Most of the byproduct antimony recovered was consumed at the smelter in the manufacture of antimonial lead; the remainder was processed to oxide or recycled in residues.

The quantities and types of material produced at the smelters were as follows: Metal, 16%; oxide, 65%; antimonial lead, 7%; ground residue, 11%; and sulfide, 1%. Antimony metal was produced by NL Industries, Inc., Sunshine Mining Co., and U.S. Antimony Corp. Oxide was produced by American Smelting & Refining Co., Harshaw Chemical Co., McGean Chemical Co., M & T Chemicals Inc., NL Industries, Inc., and U.S. Antimony Corp. Byproduct antimonial lead was produced at lead refineries operated by American Smelting & Refining Co., The Bunker Hill Co., and St. Joe Minerals Corp.

Secondary.—Recovery of antimony from antimonial lead scrap totaled 24,062 tons, a 7% increase from 1972. The overall rise was attributed to the increased availability of old antimonial lead scrap. Secondary smelters recovered 20,459 tons, primary smelters recovered 24 tons, and manufacturers and founderies recovered the remaining 3,579 tons. Old scrap represented 85% of the total secondary antimony produced and consisted of the following: Batteries, 66%; type metal, 14%; babbitt, 12%; and all other material, 8%. Drosses and residues were the only sources of secondary antimony recovered from new scrap, which contributed 15% of the total. The antimony content of antimonial lead recovered from secondary sources was normally insufficient to meet commercial specifications of antimonial lead alloys. To prepare the desired alloys, about 2,275 tons of primary antimony was required to supplement the secondary antimony during 1973, compared with 2,570 tons in 1972.

1973	15,455	731	412	24	1,167	7.6

1 Includes primary residues and a small quantity of antimony ore.
2 Includes foreign base bullion and small quantities of foreign antimony ore.

CONSUMPTION AND USES

Total domestic consumption of primary and secondary antimony in 1973 was 44,675 tons, 13% greater than that of 1972. Primary antimony contributed 46% of the total (20,613 tons), and secondary metal supplied 54% (24,062 tons). Virtually all of the secondary antimony was consumed in the manufacture of antimonial lead grids for use in batteries and other hard-lead alloys.

Industrial usage of primary antimony by class of material consumed increased in all areas except ore and concentrate. In the category of consumption by products, the use of metal decreased in all products except antimonial lead, ammunition, castings, and solder. Antimony metal and antimony oxide represented 45% and 55%, respectively, of the raw material consumed. Total consumption of primary metal products increased 26%, resulting principally from increased usage for antimonial lead.

Table 6.—Industrial consumption of primary antimony in the United States

(Short tons, antimony content)

Year	Class of material consumed						
	Ore and concentrate	Metal	Oxide	Sulfide	Residues	Byproduct antimonial lead	Total
1969	507	6,275	8,756	72	330	1,903	17,843
1970	380	4,989	7,157	46	384	981	13,937
1971	387	5,080	6,944	28	136	1,132	13,707
1972	1,226	5,473	8,389	104	201	731	16,124
1973	582	5,824	10,970	255	1,839	1,143	20,613

In nonmetal products, a substantial growth rate of antimony oxide usage was experienced in the area of flame retardants. Oxide consumption was given an even greater impetus by Government legislation requiring that the interior trims of 1973 model cars be treated with flame retardants. Since this requirement applied also to imported cars, the upsurge in demand for antimony oxide was noticeable throughout the world. Domestic consumption in ceramics and glass also continued the upward trend. A total of 2,219 tons of antimony was consumed in "other" nonmetal products. Of this quantity, approximately 73% was used as sodium antimonate as an opacifier in enamel frit. An additional 14% of this total was consumed as antimony trichloride, petroleum additives, antimony sulfide, and chemicals in a variety of applications.

STOCKS

Industry stocks were down in the second quarter, but increased steadily in the final quarters to 10,078 tons at yearend, the largest quantity on record. The increase was due primarily to the sale and delivery of about 5,000 tons of Government stocks to purchasers during the year. Increases in metal and ore stocks more than offset the decline of about 1,100 tons in oxide stocks. Stocks of residues and antimonial lead were substantially above the 1972 level. Antimony sulfide was the only other stock that was below the 1972 figure.

Government stocks of antimony on December 31, 1973, totaled 42,591 tons. Of the total inventory, the strategic stockpile contained 20,560 tons, and the supplemental stockpile contained 22,031 tons.

Table 8.—Industry stocks of primary antimony in the United States, December 31

[1] Inventories from primary sources at primary lead refineries only.

PRICES

The domestic price for antimony metal increased four times during the year. The increases, which occurred in February, April, November, and December, raised RMM antimony metal from $0.57 to $0.92 per pound f.o.b. Laredo. The Lone Star grade increased from $0.68 to $1.09 per pound during the same period. The price increases took place in spite of the fact that GSA sold 5,947 tons of antimony metal in 1973. The price increases were attributed to the rapidly growing demand for antimony metal and compounds, particularly in flame retardants, and the reluctance of the People's Republic of China to sell any significant tonnages at its spring and fall Canton Fairs. Also, early in December, price decontrol for minor metals allowed U.S. antimony prices to aline with the generally higher prices in world markets. Prices for antimony trioxide also increased from $0.69 at the beginning of 1973, to $1.05 per pound by the close of 1973.

Strong demand for antimony metal and oxide during the year boosted the price of ore. The quoted price of European lump ore, 60% antimony, rose to $17.65–$18.65 per short ton unit, up from $7.60–$8.60 at the beginning of the year.

Table 9.—Antimony price ranges in 1973

Type of antimony	Price per pound
Domestic metal [1]	$0.57–0.92
Foreign metal [2]	.55–1.35
Antimony trioxide [3]	.69–1.055

[1] RMM grade, f.o.b., Laredo, Tex.
[2] Duty-paid delivery, New York.
[3] Quoted in Metals Week.

FOREIGN TRADE

Exports of antimony metal, alloys, and waste and scrap were 515 tons, appreciably above the 121 tons exported in 1972, and the value, $468,976, was more than five times that of the preceding year. Antimony scrap comprised the bulk of material exported, and consignments were made to 24 countries. Canada and Belgium were the leading importers with 79 tons each, followed by the United Kingdom. The oxide exported was 388 tons, 25% more than the 1972 total, with a value of $425,981 in 1973. West Germany, Canada, Brazil, and Belgium, in descending order of receipts, received over 73% of the total exports.

General imports of various antimony materials totaled 21,265 tons, a decline of 10% in comparison with 23,743 tons received in 1972. The decrease extended over all three categories of materials imported, but the largest decline was in receipts of metal. The Republic of South Africa, Bolivia, Mexico, Chile, and Turkey supplied over 90% of the ore and concentrate. Ten other countries supplied small percentages of the remainder. The People's Republic of China, the United Kingdom, and Mexico supplied over 65% of the metal. Yugoslavia, Belgium-Luxembourg, Brazil, Spain, and Turkey were the only other countries to supply any appreciable quantities of metal. Oxide deliveries came chiefly from the United Kingdom and France (77%).

Other imports included 100 tons of alloy containing 83% or more antimony, 57 tons of which came from the United Kingdom; 21 tons was received from Mexico; 20 tons was supplied by Belgium-Luxembourg, and 2 tons came from Canada. This material had a total value of $102,803.

WORLD REVIEW

World primary antimony production, responding to favorable economic conditions, and escalating prices, increased 4% above that in 1972. Higher production rates, compared with 1972 were reported for most of the foreign countries, but only Bolivia, the Republic of South Africa, and Turkey had significant tonnage increases. Demand, however, exceeded supply in all major consuming countries. The Canton Fairs were of little help because the quantity of antimony supplied to the Japanese industry was small. Also, metal made available to the European market was at very high prices. Because of the unbalanced supply-demand relationship, antimony producers

[1] Antimony content of smelter products; excludes output from New Brunswick, which is believed to be small.
[2] Includes antimony content of antimonial lead.
[3] Exports.
[4] Antimony content of antimony concentrates, lead concentrates, and lead-zinc concentrates.

worldwide continued to develop new mines and expand existing ones.

Australia.—Australia's Antimony Corp. N.L. reported that its antimony mine at Dorrigo, New South Wales, was brought into production in May. The company entered into an agreement with Broken Hill Antimony, Pty. Ltd. to process the ore. Broken Hill Antimony installed additional flotation facilities at the site to increase production to 4,000 tons of concentrate per year. Demand from buyers was heavy, and several offers of long-term contracts were considered. Proven ore reserves at Dorrigo exceeded 500,000 tons, and development work was being conducted in adjacent areas. The Antimony Corp. also has antimony prospects in the Taylor's Arm district near Macksville, New South Wales.

Munga Creek Minerals N.L. increased antimony ore production, despite rising production costs and the adverse affects of currency revaluations. The increased ore production (at the lease areas in the Kempsey district of New South Wales) and improved milling plant techniques will provide a continuous supply of antimony at lower prices to markets in North America, Europe, and Japan.

Atherton Antimony N.L. commenced opencut mining at the Antimony Reward mine in North Queensland. More than 9,000 tons of ore has been stockpiled, and exploration was continued to determine the extent of ore reserves. In Victoria, Mid-East Minerals N.L. continued underground development of the Brunswick Reef at Costerfield. Values of 20% to 30% antimony and up to 2.25 troy ounces of gold per ton have been reported in a vein 10 to 20 inches wide at a depth of 150 feet.

Bolivia.—Construction of an antimony smelter in Bolivia continued on schedule. This 5,000-ton-per-year smelter was expected to be completed during 1973. The Czechoslovakian firm, Skoda Export, carried out the feasibility study and helped to construct the $5 million smelter.

Burma.—In Burma, an antimony refining plant was constructed by the Mineral Development Corp. and was in operation near Moulmein.

Canada.—Consolidated Durham Mines & Resources Ltd. remained Canada's only antimony mine. The company mined vein-type ore deposits containing stibnite at its Lake George property near Fredericton, New Brunswick. The mill operated throughout 1973 after implementing a water pollution control system and undertaking additional shaft sinking and underground development in late 1972. The mill produced concentrates containing over 64% antimony, which was shipped to Japan, Europe, and the United States. Several other Canadian deposits of stibnite were explored and partly developed, but results were generally discouraging. The better known deposits were in the Atlantic Provinces, Quebec, British Columbia, and the Yukon Territory.

Japan.—Japan's Hibino Metal Co. made plans to import 40 to 50 tons of antimony metal on a long-term basis. Although the company presently produces a combined total of 300 tons of oxide and metal, it was reported that pollution controls, would prohibit expanded production from ore.

South Africa, Republic of.—In the Republic of South Africa, Chemetron Corp. (U.S. company) signed an agreement to form a joint venture company (Antimony Products (Pty.) Ltd.) to produce crude antimony oxide. The other participants were Consolidated Murchison Ltd. and Johannesburg Consolidated Investment Co. Ltd. Antimony Products Ltd. will build a plant near the antimony mines operated by Consolidated Murchison in the Northern Transvaal at Gravelotte, Republic of South Africa. The plant was scheduled for operation by the end of the year; annual capacity was to be around 3,500 tons.

Thailand.—A $1.2 million antimony mining and smelting project was in progress at Lampang Province (Northern Thailand) by Amco Metal Industries Corp. The annual capacity of the smelter will be 15,400 short tons of 99.8% metal. The new project will substantially enlarge the capacity of the country's antimony industry, which totaled 11,100 tons of ore and only 200 tons of metal in 1972. The additional tonnage will also alter somewhat the world production pattern and place Thailand among the top 10 antimony metal producers.

TECHNOLOGY

Two U.S. patents concerning the extraction of antimony metal and compounds were issued during the year. One patent, issued to the Federal Bureau of Mines, covers a method of producing hydrated antimony pentoxide electrolytically from either stibnite, tetrahedrite or livingstonite.[2] The ground ore concentrate was slurried in an aqueous brine of sodium chloride, potassium chloride, or potassium bromide, and the mixture electrolyzed at a temperature of not over 50° C and current density of from 0.1 to 1.0 ampere per square inch for a period of up to 24 hours, whereby the insoluble hydrated pentoxide was formed. The insoluble product was filtered off and converted to the metal by conventional procedures. The other patent described a method of processing antimony sulfide ore concentrate to obtain antimony oxide.[3] Flotation concentrate or other finely divided ore was fluidized with air or oxygen. The fluidized ore was heated to a temperature of 1,200–1300° C for a period of about 4 seconds under turbulent conditions, and the resulting antimony oxide was recovered from the kiln offgases.

An article[4] described how sintering of iron-antimony mixtures inhibit γ-grain growth as a result of the solid-phase diffusion of antimony in iron. When heated, the pellets of higher antimony contents exhibited a swelling that developed in one of two stages corresponding to the formation of intermetallic compounds.

A Canadian patent was issued pertaining to a process for removing antimony impurity from copper matte or copper sulfide.[5] The molten material was treated with scrap iron, and the treated melt partially oxidized with air or oxygen-enriched air to oxidize the scrap iron and cause the major portion of the antimony content to pass from the copper into the coverter slag.

Asbestos

By Robert A. Clifton [1]

Shipments of asbestos in the United States increased 14% and established another record high in 1973. The construction boom was the main reason for the increased demand. Imports were 8% above 1972 levels.

Canada, the world's leading producer of asbestos increased shipments 7% to its largest market, the United States. Canada's total shipments increased 10% over those of 1972.

Legislation and Government Programs.—The Environmental Protection Agency (EPA) published asbestos emission standards in April. In October, EPA published the first portion of its effluent guidelines for asbestos manufacturing point sources. On April 16, 1973, in a Presidential message to the Congress proposing stockpile disposal legislation, the national stockpile objective for amosite was reduced to zero, and that of chrysotile to 1,100 short tons. In1973 the General Services Administration (GSA) reduced Government inventories by disposing of 419 short tons of amosite, 6,076 tons of crocidolite, and 266 tons of chrysotile. Rhodesian asbestos continued to arrive in the country under the "strategic material" exception in the U.S. observance of the United Nations sanctions.

Environmental Impact.—Threatened effects of environmental regulations on the asbestos market remained just threats in 1973. The new regulations of the Office of Safety and Health Administration (OSHA) of the Department of Labor did not slow asbestos use in manufacturing. EPA promulgated its regulations on asbestos dust on April 6.

The controversial Reserve Mining Co. case was still before the U.S. District Court in Duluth, Minn., at year-end. Appellate action was deemed likely whichever side won.

Energy.—The Bureau of Mines conducted a comprehensive study of energy use in the asbestos mining industry in 1973. The survey covered all producers in Arizona, California, North Carolina, and Vermont.

Sources of energy included 2.2 million gallons of heavy fuel oil (43% of total usage), 168 million cubic feet of natural gas (22%), 47.6 million kilowatt-hours of purchased electricity (21%), 545,000 gallons of diesel oil (10%), 182,000 gallons of liquefied petroleum gas (LPG) (3%) and 64,000 gallons of gasoline (1%). to equivalent kilowatt-hours, total energy used was 226 million kilowatt hours, of which 59 million (26%) was used in mining and 167 million (74%) in milling. On a tonnage basis, energy used per ton of usable asbestos was 1,500 kilowatt-hours. Estimated cost was $1.7 million or $11.32 per ton.

DOMESTIC PRODUCTION

U.S. mines shipped 14% more asbestos in 1973 than in 1972. The value increased 21%. Four States produced asbestos; California, with 70% was the leader, followed in order by Vermont, Arizona, and North Carolina. Total output was 150,036 tons valued at $16,288,000.

The California segment of the asbestos industry continued to grow, with a 16% increase in production to 105,663 tons, and was led by Pacific Asbestos Corp.'s mine in Calaveras County. The next leading producing county was Fresno, with Coalinga Asbestos Co. Inc. and Atlas Asbestos Corp. mines. Union Carbide Corp. had significant production in San Benito County. The State's increased production realized a $2,213,000 increase in value.

GAF Corp.'s mine in Orleans County, Vt., remained the asbestos mine in the

United States with the highest production, but was surpassed by Pacific Asbestos in product value. With only Jaquays Mining Corp.'s mine in Gila County operating in 1973, Arizona production decreased 27%. The production in North Carolina of Powhatan Mining Co. declined another 64% in 1973. U.S. asbestos producers and mine sites are as follows:

State and company	County	Name of mine	Type of asbestos
Arizona: Jaquays Mining Corp	Gila	Chrysotile	Chrysotile.
California:			
Atlas Asbestos Corp	Fresno	Santa Cruz	Do.
Coalinga Asbestos Co., Inc	do	Christie	Do.
Pacific Asbestos Corp	Calaveras	Pacific Asbestos	Do.
Union Carbide Corp	San Benito	Santa Rita	Do.
North Carolina: Powhatan Mining Co	Yancey	Hippy	Anthophyllite.
Vermont: GAF Corp	Orleans	Lowell	Chrysotile.

CONSUMPTION AND USES

Overall consumption in 1973 increased 8% over that of 1972 with no usage trends apparent.

The data shown in table 6 although collected on the same form as the 1972 data, are not really comparable with 1972 data because expansion of the mailing list resulted in a 17% increase in the share of apparent consumption reported by respondents. It appears however, for example, that the large increase in consumption shown by floor tile manufacturers was the result of better coverage rather than any great change in the market. The cooperation of the industry continued to result in more complete data. The chrysotile data in table 6 have been adjusted to reflect 96% of the apparent consumption. Data for other types of asbestos are presented as reported.

While continuity between 1972 data and those of 1973 is disclaimed in the preceding paragraph, the increase in consumption for minor or "Other" uses (to 22% of the total) is logical and can be explained as reflecting data from new respondents who have minor end uses. Of total consumption, the eight major uses were: Construction 30%, floor tile 20%, paper 10%, friction products 8%, asphalt felts 5%, packing and gaskets 2%, insulation 2%, and textiles 1%.

Analysis of the newly available data on U.S. asbestos consumption was facilitated by selectively grouping commercial chrysotile grades as shown in table 5. These selected groupings disregarded chemical and physical properties, etc., and are based loosely on the Quebec Asbestos Mining Association standards.

Crudes, and Groups 1, 2, and others, while not milled, have the same ultimate textile uses as Group 3, and will be grouped as "BM I," (spinning). Groups 4 and 5 will be "BM II," shingle and paper. Groups 6 and 7 will be "BM III," shorts.

Note that the spinning grades (BM I) are consumed only in four of the major

Table 5.—Bureau of Mines groupings of commercial chrysotile grades

end uses, and comprised 2% of the reported tonnage consumed. Shingle and paper grades (BM II) comprised 20% of the weight of the fibers reported and were consumed in all the major use categories but floor tile and textiles. The remainder, 78% of the reported fibers were shorts (BM III) and were consumed in every major use except textiles.

The construction field accounted for 17% of the anthophyllite reported consumed with minor uses the remainder.

Eighty-four percent of the reported amosite consumption was used for insulation, 6% for construction, and 7% for asphalt felts.

Construction accounted for 50% of the crocidolite consumed and paper 1%.

A market survey made by a major inorganic fiber manufacturer, covering 1972 sales, distinguished between product categories and major consuming industry usage. This distinction between products and end uses was adhered to in this chapter.

Analysis of table 7 shows that although 100% of the obvious products were used in the construction industry, there were enough portions of other products used to show the construction industry accounting for 77% of the total asbestos consumption. This is probably high and caused in part by assigning all asbestos consumption to only three major industries. Another possible source of error can come from assigning no insulation (thermal or electrical) consumption to the transportation industry, because shipboard, train, and truck uses for insulation products are many.

The major industry breakdown of gaskets and packing, friction materials, coatings and compounds, and plastics are of interest.

An EPA report shows that nine of the major asbestos products manufacturing firms have captive fiber sources through United States and Canadian mines either wholly or partially owned. The total present production capacity of these mines exceeds 2 million short tons per year.

Table 6.—U.S. asbestos consumption in 1973

(Short tons)

End uses	Chrysotile (adjusted)				Anthophyllite (reported)	Amosite (reported)	Crocidolite (reported)

PRICES

Quoted prices for Quebec asbestos in 1973 rose 8%, effective May 1, 1973. British Columbia and Vermont asbestos prices remained unchanged. The price of all asbestos was expected to rise in the future.

Prices for some grades of Arizona chrysotile asbestos were raised on September 1, 1973. Quotations, f.o.b. Globe, were as follows:

Grade	Description	Per short ton
Group No. 1	Crude	$1,650
Group No. 2	do	950
AAA		853
Group No. 3	Nonferrous filtering and spinning	550– 700
Group No. 4	Nonferrous plastic and filtering	550– 600
Group No. 5	Plastic and filtering	385– 425
Group No. 6	Refuse or shorts	350
Group No. 7	do	65– 100

As of February 15, 1973, Vermont chrysotile asbestos, f.o.b. Morrisville, was priced as follows:

Grade	Description	Per short ton
Group No. 4	Shingle fiber	$218.00–371.00
Group No. 5	Paper fiber	157.50–185.00
Group No. 6	Waste, stucco, or plaster fiber	114.00
Group No. 7	Shorts and floats	43.50– 95.00

Quotations for Canadian (Quebec) chrysotile, f.o.b. mine, were as follows, as of May 1, 1973:

Grade	Description	Per short ton
Group No. 1	Crude	Can $1,745
Group No. 2	do	945
Group No. 3	Spinning fiber	445–730
Group No. 4	Shingle fiber	240–414
Group No. 5	Paper fiber	177–209
Group No. 6	Waste, stucco, or plaster	129
Group No. 7	Refuse or shorts	54–105

Prices for British Columbia, Canada, chrysotile asbestos were effective January 1, 1973. Quotations, f.o.b. Vancouver, were as follows:

Grade	Description	Per short ton
AAA	Nonferrous-spinning fiber	Can $895
AA	do	711
A	do	541
AC	Asbestos cement fiber	388
AK	Shingle fiber	276
CP	do	261
AS	do	240
CT	do	235
AX	do	219
CY	do	155
AY	do	155

Private negotiated sales are the African asbestos producers' modus operandi. Because this rules out market quotations, the following are average values, regardless of grade, imported from Republic of South Africa calculated from U.S. Department of Commerce data:

Type	Per short ton				
	1969	1970	1971	1972	1973[1]
Amosite	$153	$160	$164	$187	$187
Crocidolite	189	196	212	211	210
Chrysotile	192	198	120	202	260

[1] First 8-month data on imports, U.S. Bureau of the Census.

The increased demand for asbestos in all categories resulted in price increases almost across the board. Further price rises are expected early in 1974.[2]

[2] Asbestos. V. 55, No. 7, January 1974, p. 40.

FOREIGN TRADE

The value of exports of asbestos products manufactured in the United States increased 27% over the value of those exported in 1972. Six of the nearly 100 countries buying these products accounted for more than 60% of the foreign sales. They were Canada (40%), West Germany (8%), the United Kingdom (7%), Mexico (3%), Australia (3%), and Venezuela (1%).

The major products exported were packing and gaskets with 26% of the value, brake linings with 19%, and textiles and yarns 16%.

In 1973 the United States imported 90% of its crude asbestos needs. This was 1% below the 1972 percentage. Canada provided 96% of the imports, the Republic of South Africa provided 3%, and 13 other countries provided the remainder. Chrysotile, with 97%, dominated the imported types. There was a 13% increase in the dollar value of imported fibers.

WORLD REVIEW

All available information leads to the conclusion that 1973 was a record setting year for asbestos throughout the world. Demand, at least in the Non-Communist countries outstripped supply, as evidenced by the world's largest mine having its entire year's production sold by August. Market growth was limited by supply, but no real hardships surfaced, with the exception of spinning-grade fibers, which were in very short supply the latter part of the year.

The market situation, and worldwide inflation would indicate substantial price increases in 1974.

Australia.—The Woodsreef mine ran into trouble on two fronts. The revaluation of the Australian dollar decreased revenue at a time when equipment inadequacies would not permit increased production. New equipment eased the situation somewhat, but maybe not enough to reach the break-even point by the end of the year.

Bolivia.—A further influx ($658,000) of money was earmarked by the United Nations Industrial Development Organization (UNIDO) to the budding asbestos industry at Cochabamba. Corporacion Boliviana de Fomento was to contribute an additional $328,000 toward achieving a 5,000-ton-per-year operation there.

Canada.—For the second straight year Canadian production reached a record high, with a 17% increase over the previous year, and remains firmly in the lead as the worlds primary producer. A controversial proposal was put forward in Quebec to have the province's asbestos (80% of Canadian total) marketed through a provincial government "Development Council." The mining community reacted unfavorably. Major activity centered around the following:

1. Canadian Johns-Manville Co., Ltd. officially dedicated the new concentrator plant at its Jeffrey mine in Asbestos, Quebec. This marks the end of its $75 million expansion program. The mine, probably the world's largest, now produces 600,000 tons per year of fiber, which represents 37% of Canada's output and 13% of world chrysotile production.

2. United Asbestos, Inc., the name of the company resulting from the merger of United Asbestos Corp., Ltd., and Allied Mining Corp., reported that its property in Midlothian Township, Ontario, contains 31 million tons of 9% fiber ore in grades 5, 6, and 7. Production of 100,000 tons per year of fiber is planned to start in 1974 after a very successful test marketing effort.

3. Abitibi Asbestos Mining Co., Ltd., reported proven ore reserves of 100 million tons of ore averaging 4% fiber at its property 50 miles north of Amos, Quebec. Bulk tests have been run through its pilot plant, and fibers are being amassed for test marketing.

4. Rio Tinto Canadian Exploration, Ltd., was evaluating the McAdam Mining Corp., Ltd., property under its option. The property, 20 miles east of Chibougamau, Quebue, has a "C" zone containing 105 million tons of ore grading 3.92% fiber and three other zones containing 86.4 million tons of 3.55% ore.

5. Lake Asbestos of Quebec, Ltd., a subsidiary of American Smelting and Refining Co., has purchased the assets of National Gypsum Co.'s Canadian subsidiary National Asbestos Mines, Ltd., at Thetford Mines. The combined production will put Lake Asbestos at nearly 200,000 tons per year of fiber.

Colombia.—Asbestos Colombianas, S.A. and Nicolet Industries, Inc. is raising its sights from 25,000 tons per year to 60,000 tons per year of fiber from its find in the Department of Antioquia. Reserves are estimated at 18.2 million tons of 4.3% fiber content.

Greece.—The emergence of a healthy and growing asbestos cement products industry has stabilized the "on again, off again" picture of the Kozani deposit. The Asbestos Mines of Northern Greece Mining, S.A. (MABEM), which is 90% owned by Cerro Corp., has finished exploration and pilot plant studies. A plant with 50,000 tons per year (expandable to 1,000,000) will be started in 1974 to process the 50 million tons of ore containing 3% chrysotile of grades 4, 5, and 6.

New Zealand.—Cassiar Asbestos Corp., Ltd., was selected by Kennecott Copper Corp. and Lime and Marble Corp. as a partner to explore and, if warranted, develop the Pyke asbestos find. Exploration and bulk sampling were underway.

Philippines.—La Suerta Resources and Industries, Inc., was actively developing an asbestos prospect in Zambales and negotiating for a Japanese market.

Spain.—Active prospecting for asbestos was underway in the Sierra Nevada where short fibers were once produced.

Swaziland.—The Havelock mine, now owned by Havelock Asbestos Mines, Ltd., in which the Swaziland Government owns a 40% share, with Turner & Newall owning the rest, was having difficulties with weak rock underground. Yield and profits have been suffering.

U.S.S.R.—Comecon members are to construct an asbestos mining and concentration plant at Kiembay in Kazakhstan, according to "Novosti." The 500,000 tons per year of asbestos will be proportioned to members based on their contribution to construction costs. Ore reserves are a reported 24 million tons.

[4] Exports only.

Barite

By Frank B. Fulkerson [1]

Barite producers in the United States sold or used over 1.1 million tons of primary barite in 1973, the highest since 1957. Compared with 1972 figures, quantity and value advanced 22% and 12%, respectively. The tonnage produced in Nevada increased 73%. Imports of crude ore were the highest since 1962. Sales of ground and crushed barite produced from domestic and imported material rose 8% in quantity and 19% in value. Barite mining and processing companies were increasing capacity, to meet growing demand for drilling-mud minerals.

DOMESTIC PRODUCTION

Domestic producers reported that 1,104,000 short tons of primary barite was sold or used in 1973. The term "primary barite," as used in this chapter, applies to the first marketable product and includes crude barite, flotation concentrate, and other beneficiated material such as washer, jig, or magnetic separation concentrates.

[1] Industry economist, Division of Nonmetallic Minerals—Mineral Supply.

Barite was produced at 38 mines in 7 States in 1973 (30 mines in 1972). Nevada supplied 50% of the tonnage but only 28% of the value. Barite produced in Nevada had relatively low value, owing to transportation costs and distance to markets. Missouri ranked second in barite production.

Principal producers were Baroid Div., NL Industries, Inc., with mines in Arkansas, Missouri, Nevada, and Tennessee; Dresser Minerals Div., Dresser Industries, Inc., with mines in Arkansas, Missouri, and Nevada; Milchem, Inc., with mines in Missouri and Nevada; IMCO Services, Halliburton Co., with a mine in Nevada; and Alaska Barite Co., Inlet Oil Corp., with a mine in Alaska.

Ground and crushed barite was produced mainly in Louisiana and Texas from imported material, and in Arkansas, Missouri, and Nevada from domestic barite. Processing mills were also located in California, Georgia, Illinois, Tennessee, and Utah.

Among the developments in 1973, Milchem, Inc., began construction near Battle Mountain, Nev., of its second beneficiation plant and its first Nevada grinding mill. Dresser Minerals completed a new beneficiation plant at its Greystone, Nev., mine and announced it would double its production capacity in Missouri by constructing two washing plants.

The remote East Northumberland District in the Toquima Range, Nye County, Nev., recorded its first significant barite production when IMCO Services began a mining operation in the district. Mine run ore was hauled by truck 150 miles to Mina in Mineral County for stockpiling and shipment to the company grinding plant at Houston, Tex. Other new producers in Nevada included Eisenman Chemical Co. and Rocky Mountain Refractories, both in Elko County, and the Milwhite Co. in Elko and Lander Counties.

Molybdenum Corp. of America included a circuit to recover up to 60 tons per day of byproduct barite in its new mill at the Mountain Pass rare earth mine, San Bernardino County, Calif. The large rare earth carbonate ore body contains about 20% barite.[2]

The Minerva Co. commenced production of flotation barite concentrate from the zinc-fluorspar flotation tailing circuit at its Mine No. 1 mill near Cave in Rock, Ill.

Dresser Minerals ceased production at its Magnet Cove, Ark., mine and at the Malvern mill, 12 miles away. Officials said to continue producing would have required a capital expenditure of more than $2 million, because it would be necessary to go to a lower level in the mining operation and construct a new mill nearer the mine. The mine was opened in 1940 by Magnet Cove Barium Corp., which was acquired by Dresser Industries, Inc., in 1949.

CONSUMPTION AND USES

More than 83% of the ground and crushed barite sold in 1973 was used as a weighting agent in oil- and gas-well drilling muds. This use increased 143,100 tons (12%), owing to greater drilling activity. Barite usage as a filler in paint and for barium-chemical manufacturing advanced 6,100 tons (13%) and 3,100 tons (3%), respectively. All other uses declined 37,500 tons (26%). These other uses included filler in rubber, plastics, and paper; flux, oxidizer, and decolorizer in glass manufacturing; and miscellaneous, including ballast for ships, heavy aggregate for concrete, applications in foundries, and unspecified.

Principal consumers of barite to produce barium chemicals were Chemical Products Corp., Cartersville, Ga.; the Great Western Sugar Co., Johnstown, Colo.; Inorganic Chemicals Div., FMC Corp., Modesto, Calif.; Mallinckrodt Chemical Works, St. Louis, Mo.; and Sherwin Williams Chemicals, Coffeyville, Kans. The Great Western Sugar Co. produced barium hydroxide, which it used in sugar beet refining. The other companies sold their production of barium chemicals. Demand exceeded supply, as the result of barium-chemical plant closures in 1971 and 1972.

1 Only data reported by barium-chemical plants that consume barite are included.
2 A plant producing more than one product is counted only once in arriving at total.

PRICES

Price quotations reported in Engineering & Mining Journal were higher in December 1973 than in December 1972. These quotations serve as a general guide and do not necessarily reflect actual transactions. Barite prices are negotiated between buyer and seller.

The average value per ton excluding container cost of crushed and ground barite f.o.b. plant increased from $31.20 in 1972 to $34.67 in 1973. These values were calculated from producers' statements.

Table 5.—Barite price quotations

Item	Price per short ton December 1972	Price per short ton December 1973
Chemical, filler, and glass grades, f.o.b. shipping point, carload lots:		
Hand picked, 95% $BaSO_4$, not over 1% iron	$22.50–$24.50	$29.50–$31.80
Magnetic or flotation, 96% $BaSO_4$, not over 0.5% iron	26.50– 28.50	34.50
Water ground, 99.5% $BaSO_4$, 325 mesh, 50-lb bags	55.00– 78.00	60.00– 80.00
Drilling-mud grade:		
Ground, 83%–93% $BaSO_4$, 3%–12% iron, specific gravity 4.20–4.30, f.o.b. shipping point, carload lots	37.00– 44.00	40.00– 47.00
Crude, imported, specific gravity 4.20–4.30, c.i.f. gulf ports	14.00– 18.00	17.00– 21.00

FOREIGN TRADE

Imports of crude barite totaled 716,000 tons, an increase of 15% over those of 1972 and the highest since 1962. Average values per ton of crude barite at foreign ports were as follows for the indicated countries: Ireland, $11.12; Mexico, $11.11; and Peru, $7.43. Barite, nearly all of drilling-mud grade, entered the United States through the following customs districts: New Orleans, La., 48%; Laredo, Tex., 23%; Port Arthur, Tex., 21%; and El Paso, Houston, and Galveston, Tex., 8%. Foreign trade statistics also showed imports of crushed or ground witherite (natural barium carbonate), mostly from the United Kingdom, totaling 4,500 tons.

Barium chemical imports, mainly from West Germany and the United Kingdom, increased as the result of a drop in U.S. production of these chemicals.

U.S. barite exports increased 29%. Most of the exports went to Canada and Singapore and were handled through the following customs districts: New Orleans, 50%; Seattle, 22%; Detroit, 19%; other, 9%. The United States exported mostly ground barite and imported mostly crude barite.

WORLD REVIEW

A two-part article in Industrial Minerals discussed the effect on the world barite industry of increased oil- and gas-well drilling due to the energy shortage. The first part dealt with the North European shelf, and the second part analyzed conditions in Australia, the Far East, and other areas.[3]

Australia.—Dresser Australia Pty., Ltd., planned to place a new barite mine in operation by mid 1975 near Port Hedland in Western Australia.

Canada.—In view of growing demand in foreign markets for drilling-mud grade barite, American Smelting & Refining Co. studied the feasibility of recovering barite from old tailings at its Buchans, Newfoundland, lead-zinc-copper mine. The ore mined at Buchans contains barite as a gangue mineral.[4] Scientists of the National Research Council of Canada recovered grades as high as 97% barite from the old

tailings in laboratory tests using a two stage agglomeration process.[5]

Dresser Minerals planned to open a new mine in northern British Columbia to serve the drilling mud market in western and northern Canada.

France.—A research group formed in 1968 by the Bureau de Recherches Géologiques et Minières, and Mines de Garrot S.A. completed a study of methods to treat ore from the large Chaillac deposit, situated 30 miles southwest of Châteauroux, in the Indre area. Exploitation of the deposit has been prohibited by the nature of the ore, which is a very fine barite-iron oxides composite. Flotation was the beneficiation process finally chosen. It was estimated that the recovery of barite would be about 85%. The content of concentrates would be about 97% $BaSO_4$.

India.—High-grade lump barite was being exported from a new mine 120 miles from Madras. Shipments included a 15,000-ton cargo to Poland and smaller lots to Norway and elsewhere. Production at the mine was running at 500 tons per day and was entirely by hand labor using a labor force of over 400.[6]

Ireland.—Milchem, Ltd., began production in September at its 60,000-ton-per-year barite flotation plant in County Galway. The plant treats the Irish Base Metals, Ltd., tailings pond. Both Milchem and IMCO Services conducted barite exploration programs in Ireland in 1973.

Thailand.—Most of the barite produced in Thailand was shipped to grinding mills in Singapore. Several barite prospects were investigated during the year. Jalupathan Cement Co. installed grinding equipment for production of drilling mud grade barite.

United Kingdom.—Aberdeen Barytes Co., Ltd., installed a grinding mill at Aberdeen, Scotland. Anchor Drilling Fluids Division, Maritime Drilling Services, Ltd., planned to construct a new grinding mill at Dundee, Scotland.

TECHNOLOGY

The Calico mining district about 10 miles east of Barstow, Calif., contains extensive deposits of low-grade silver-barite ore. Laboratory beneficiation work was done by Bureau of Mines scientists on four ore samples from the district to develop methods to recover the values. The samples assayed at 2 to 3 ounces of silver per ton and 7% to 12% barite. Cyanidation recovered from 47% to 60% of the silver. From 75% to 90% of the barite was recovered in a plus 92% barite product from cyanidation residues. Salt roasting the ore samples before cyanidation increased silver recoveries, but a high-grade barite product could not be floated from the residues.[7]

Sachtleben Chemie Gmbh of Cologne, West Germany, developed a new weighting agent for oil and gas well-drilling muds. The material, known as Fer-O-Bar, was prepared from iron oxide cinders resulting from the calcination of pyrite ores. Laboratory tests showed that the Fer-O-Bar might be a satisfactory substitute for barite.[8]

Bauxite

By Horace F. Kurtz [1]

World bauxite production totaled about 70 million long tons in 1973, compared with 30 million tons 10 years earlier. The strong growth in world bauxite production, 9% in 1973, largely reflected a continued rising demand for aluminum, the principal end use of bauxite. World alumina production, the intermediate step between bauxite and aluminum production, increased 11% to nearly 29 million short tons.

U.S. production and imports of bauxite in 1973 remained near the 1972 levels. A reduction in bauxite inventories enabled domestic alumina production to be increased. This increase, together with sharply higher imports of alumina, was sufficient to meet the demand for making aluminum.

Legislation and Government Programs.—Jamaica-type metallurgical-grade bauxite in government stockpiles was authorized for sale during 1973, but none was sold. Surinam-type bauxite sold previously was shipped from government stockpiles.

The Environmental Protection Agency issued proposed plant effluent limitations which included restrictions on the discharge of waste water from alumina plants into navigable waters.[2]

r Revised.

1 Import figures for Jamaica, Haiti, and the Dominican Republic were adjusted by the Bureau of Mines to dry equivalent. Other bauxite imports, which are virtually all dried, are on an as-shipped basis. Excludes calcined bauxite and bauxite imported into the Virgin Islands.

DOMESTIC PRODUCTION

Bauxite production in the United States increased 4% to 1.88 million long tons (dry equivalent) in 1973. About 90% of the bauxite was produced in Arkansas. The remainder was mined in Alabama and Georgia. Except for the Mars Hill underground mine of Reynolds Mining Corp. in Saline County, Ark., all of the bauxite mines were open pit operations.

In Arkansas, Aluminum Co. of America (Alcoa), American Cyanamid Co., and Reynolds produced in Saline County, and Stauffer Chemical Co. mined in Pulaski County. Bauxite-processing plants were operated by American Cyanamid, Porocel Corp., and Stauffer.

Bauxite was mined in Alabama in Barbour County by Eufaula Bauxite Mining Co., A. P. Green Refractories Co., and Wilson-Snead Mining Co., and in Henry County by Abbeville Lime Co., Harbison-Walker Refractories Co., and Wilson-Snead. Drying or calcining facilities were operated by A. P. Green, Harbison-Walker, and Wilson-Snead.

of 7.57 million short tons of alumina and aluminum oxide products in 1973, an increase of 8%. The total production included 6.83 million tons of calcined alumina, 635,000 tons of commercial alumina trihydrate, and 99,000 tons of tabular, activated, and other alumina. Consolidated Aluminum Corp. (Conalco), 60% of which is owned by Swiss Aluminium Ltd. and 40% by Phelps Dodge Corp., acquired half interest in the Burnside, La., alumina plant of Ormet Corp. when it purchased the aluminum operations of Olin Corp. near the end of the year. Revere Copper and Brass, Inc., owned the other half of Ormet.

Domestic alumina shipments totaled 7.56 million tons and were valued at $532 million, compared with $479 million (revised) in 1972. Approximately 6.57 million tons was shipped to primary aluminum plants. The chemical industry, including producers of aluminum fluoride fluxes for aluminum plants, received the second largest tonnage, and most of the remaining alumina was shipped to producers of abrasives, ceramics, and refractories.

Table 5.—Production and shipments of alumina in the United States

(Thousand short tons)

Year	Calcined alumina	Other alumina [1]	Total: As produced or shipped [2]	Total: Calcined equivalent

e Estimate by the Bureau of Mines.
[1] Capacity may vary depending upon the bauxite used.

CONSUMPTION AND USES

Bauxite consumption in the United States (including the Virgin Islands) increased 8% to 16.6 million long tons (dry basis). Most of the increase was consumed in the production of calcined alumina for the aluminum industry, although all major consuming industries increased the use of bauxite. Foreign sources provided about 88% of the total bauxite consumed in 1973.

The production of alumina and related products required 93% of the total bauxite consumed. An average of 2.11 long dry tons of bauxite was used to produce 1 short ton (calcined basis) of alumina. The two alumina plants in Arkansas used mainly bauxite mined in Arkansas, and the other seven alumina plants used only imported ore.

The refractories industry used nearly one-half million tons (dry weight basis) of bauxite, establishing another record high level. Nearly all of this bauxite was used in the calcined form, which weighs about 65% of the dry equivalent weight. Imports, mainly from Guyana, comprised 83% of the bauxite used in refractories.

Five companies consumed bauxite in manufacturing artificial abrasives, and all of the bauxite used was calcined. The bulk of the ore came from Surinam, while most of the remainder came from the People's Republic of China. Data on consumption by the abrasives industry included bauxite fused and crushed in Canada because much of this material is made into abrasive wheels and coated products in the United States. About 10% to 15% of this material is used for nonabrasive applications, principally refractories.

Bauxite consumption by the chemicals

[1] Data may not add to totals shown because of independent rounding.

industry increased 10%. The United States, Guyana, and Surinam were the principal sources of bauxite for this industry. Other consumers of bauxite, in descending order of magnitude, included the cement, oil and gas, and steel and ferroalloys industries, and municipal waterworks.

Thirty-one primary aluminum plants in the United States consumed 8.73 million short tons of calcined alumina, compared with 7.94 million tons in 1972. Alumina consumption data for other uses were not available. A significant quantity was used to make aluminum fluoride and synthetic cryolite, which is also used in the production of primary aluminum.

STOCKS

Total stocks of bauxite in the United States were drawn down by 6%, or about 1.2 million long dry tons, during 1973. A reduction in bauxite inventories at alumina plants accounted for about half of the decline. Government stockpiles were reduced 3%. About 314,000 tons of Surinam-type bauxite was shipped from Government defense inventories, and an additional 110,000 tons was withdrawn from a government stockpile accumulated during World War II.

The Government stockpile objectives for Surinam-type bauxite and refractory-grade bauxite were eliminated in 1973, and the stockpile objective for Jamaica-type bauxite was lowered to 4,638,000 tons. At yearend, the Government stockpiles contained an additional 9,789,000 long tons, dry basis, classified as uncommitted excess (unsold) bauxite. The remaining 1,602,000 tons were committed for sale.

Inventories of alumina and related products at plants producing alumina and primary aluminum totaled 1,239,000 short tons on December 31, 1973, an increase of 14% from the 1,083,000 tons (revised) at the end of 1972. The Government held no stocks of alumina except in the form of abrasive grain and crude fused aluminum oxide. These inventories totaled 390,000 short tons.

Table 10.—Stocks of bauxite in the United States [1]

(Thousand long tons, dry equivalent)

Sector	Dec. 31, 1972	Dec. 31, 1973
Producers and processors	r 791	684
Consumers	r 2,797	2,165
Government [2]	16,453	16,029
Total	r 20,041	18,878

r Revised.
[1] Domestic and foreign bauxite: crude, dried, calcined, activated; all grades.
[2] Includes bauxite stockpiled during World War II (781,000 tons Dec. 31, 1972, 671,000 tons Dec. 31, 1973) plus bauxite in defense material inventories (national stockpile, supplemental stockpile, Defense Production Act).

PRICES

Prices on most of the bauxite and alumina produced throughout the world are not quoted because the large tonnages used by the aluminum industry are usually obtained from affiliated companies or purchased under long-term negotiated contracts.

Bureau of Mines estimates of the value of domestic production were based on data supplied by producers. The Bureau's estimated average value of crude domestic bauxite shipments in 1973, f.o.b. mine or plant, was $11.58 per long ton, compared with $10.60 in 1972. The average value of shipments of domestic calcined bauxite was estimated at $41.78 per ton, compared with $31.38 in 1972. Bauxite values among producers varied widely because of differences in grade.

The average value of imported dried or partially dried bauxite consumed at alumina plants in the United States and the Virgin Islands in 1973 was estimated at $14.84 per long dry ton. Engineering and Mining Journal published the following prices on supercalcined refractory-grade bauxite imported from Guyana, car lots, per long ton:

	January–June	July–December
F.o.b. Baltimore, Md	$60.50	$62.50
F.o.b. Mobile, Ala	60.50	62.53

The average value of domestic calcined alumina shipments, as determined from producers' reports, was $66.85 per short ton. Shipments of alumina trihydrate averaged $77.71 per ton. The average value of imported alumina (including small quantities of hydrate) was $62.02 per ton at port of shipment. Exports of alumina from the United States and the Virgin Islands averaged $83.48 per ton.

Table 11.—Market quotations on alumina and aluminum compounds

(In bags, carlots, freight equalized)

Compounds	Jan. 1, 1973	Dec. 31, 1973

Table 12.—Average value of U.S. exports and imports of bauxite [1]

(Per long ton)

Type and country	Average value, port of shipment		
	1971	1972	1973
Exports: Bauxite and bauxite concentrate	$45.02	$44.59	$59.35
Imports:			
Crude and dried:			
Australia	10.68	11.24	11.37
Dominican Republic [2]	16.58	17.92	15.48
Greece	8.41	14.33	11.04
Guinea	4.93	5.37	8.53
Guyana	11.20	10.09	9.89
Haiti [2]	9.86	10.79	10.80
Jamaica [2]	12.76	13.48	13.28
Surinam	11.12	11.96	11.61
Average	12.46	13.21	12.72
Calcined:			
Guyana	39.85	50.49	53.93
Surinam	34.87	47.20	51.27
Average	39.33	50.04	53.60

[1] Excludes bauxite into the Virgin Islands from foreign countries: 1971—Australia $5.54, Papau New Guinea $4.31, Guinea $4.94; 1972—Australia $4.74, Guinea $4.82, Guyana $7.01; 1973—Australia $13.66, Guyana $6.98.

[2] Dry equivalent tons adjusted by Bureau of Mines used in computation.

Note: Bauxite is not subject to an ad valorem rate of duty, and the average values may be arbitrary for accountancy between allied firms, etc. Consequently, the data do not necessarily reflect market values in the country of origin.

FOREIGN TRADE

Exports from the United States classified as "bauxite and concentrates of aluminum excluding alumina" totaled only 12,000 long tons in 1973 and were valued at $811,000. Canada received 88% of the total.

Alumina exports, including 26,000 tons of aluminum hydroxide, decreased 13% to 765,000 short tons, the lowest level since 1967. Canada received 43% of the total, Ghana received 17%, and Mexico received 13%. Reduced shipments to the U.S.S.R. accounted for most of the decline in exports from the United States mainland, although the U.S.S.R. and Norway shared an additional 283,000 tons exported from the U.S. Virgin Islands to foreign countries.

Exports of aluminum sulfate increased to 21,000 tons, valued at $642,000. The largest of the 27 recipient countries were Venezuela, which received 15,000 tons, and Canada, which received 2,500 tons. Artificial corundum exports increased to 30,000 tons, valued at $11.5 million, of which 10,000 tons was shipped to Canada, 8,000 tons to the United Kingdom, and 2,000 tons to Sweden. Exports classified as "other aluminum compounds" totaled 42,000 tons and were valued at $14.1 million. Much of this tonnage was believed to be aluminum fluoride and synthetic cryolite shipped to other countries for use as a flux in making primary aluminum.

No duties were imposed on imports of bauxite, alumina, or aluminum hydroxide in 1973. All duties on these commodities were suspended effective July 15, 1971.

Imports of crude, partially dried, and dried bauxite declined 2% to 11.24 million long tons in 1973, the third consecutive year of reduced imports. Decreased imports of bauxite from Jamaica and Haiti more than offset increases from all other countries that regularly supply the United States; however, Jamaica continued to supply over half the total imports. Bauxite imports into the Virgin Islands totaled an additional 625,000 tons, virtually unchanged from the previous year. Imports from Guinea to the United States began on a regular basis in the second half of 1973 and were expected to become an important new source of bauxite.

Calcined bauxite imports, which were used largely in the manufacture of refractories, increased to 294,000 tons. Guyana provided 84% of the total and Surinam most of the remainder. Additional calcined bauxite was imported into Canada for manufacture into crude fused aluminum oxide, much of which was subsequently

[1] Includes small quantities of aluminum hydroxide.
[2] Less than ½ unit.

Note: Shipments from the Virgin Islands to the United States: 1971—120,000 short tons ($9,316,-000); 1972—67,051 short tons ($4,827,674); 1973—23,424 short tons ($1,686,505).

used in abrasive and refractory products in the United States. An estimated 80% of these Canadian imports came from Surinam, and most of the remainder came from the People's Republic of China.

Imports of alumina, including small quantities of aluminum hydroxide, increased 18% to a record high level of 3.4 million short tons. Receipts from Australia increased by 771,000 tons. Of the total alumina imports, Australia provided 57%, Jamaica 27%, and Surinam 11%.

WORLD REVIEW

World bauxite production was estimated at nearly 70 million long dry tons in 1973, an increase of 9%. The greatest production increases occurred in Australia, Jamaica, and Guinea, while India showed the largest decline. Australia and Jamaica together produced 44% of the world's supply.

World production of alumina increased 11%. The United States, with 26% of the total, remained the largest producer, but Australian output showed the greatest growth, increasing by over 1 million short tons.

Australia.—Australia was the world's largest producer of bauxite and the second largest producer of alumina. In Western Australia, Alcoa of Australia (W.A.) Ltd. operated alumina plants at Kwinana and Pinjarra using bauxite mined in the Darling Range. Alumina from both plants was shipped from Kwinana, but port facilities at Bunbury were being prepared to handle future shipments from Pinjarra. The Pinjarra plant was reported to be undergoing an expansion to a capacity of about 1 million tons per year, which should be completed in 1975. Additional expansion was being considered.

Comalco Ltd. conducted the world's largest bauxite mining operation at Wiepa, Queensland, on the Cape York Peninsula. The deposits and the operations were described.[3] Shipments of beneficiated bauxite from Wiepa increased by 2 million tons in 1973 to 9.1 million tons. Of the total, 4.3 million tons went to the Gladstone and Bell Bay alumina plants in Australia, 1.7 million tons to Japan, and 3.1 million tons to Europe and other areas. Sales of calcined abrasive-grade bauxite also increased. A second calcining kiln, with a capacity of 150,000 tons and costing $4.5 million, was expected to be completed by the end of 1974.

Queensland Alumina Ltd. completed the third expansion of its Gladstone alumina plant. Annual rated capacity was raised to 2.2 million short tons, and production in 1973 was about 2 million tons. Comalco shut down its 20-year-old alumina plant at Bell Bay, Tasmania, for economic reasons after operating it through most of 1973. After 4 years of study, a group of companies led by Comalco decided that it would be uneconomic to construct a large alumina plant in the Wiepa area in the near future.

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, Southern Rhodesia may have continued to produce bauxite during the period covered by this table. However, no information on bauxite-mining activities, if any, has been available since 1965.

[2] Dry bauxite equivalent of crude ore.

[3] Shipments.

[4] Dry bauxite equivalent of ore processed by drying plant.

[5] Bauxite processed for conversion to alumina in Jamaica plus exports of kiln-dried ore.

[6] Excludes materials other than bauxite used for the production of alumina, estimated as follows in thousand long tons: Nepheline concentrates (25% to 30% alumina), 1971—[r] 1,102, 1972—[r] 1,673, 1973—2,116, alunite ore (16% to 18% alumina), 1971—[r] 394, 1972—[r] 492, 1973—590.

[7] Diasporic bauxite for production of aluminum only; excludes 98,000 to 195,000 tons of production for refractory applications.

[8] Less than ½ unit.

Nabalco Pty., Ltd., produced bauxite and alumina at Gove, Northern Territory. The second stage of the Gove alumina plant was put into operation in the middle of the year increasing annual capacity to 1.1 million tons.

The Alwest bauxite and alumina project in southern Western Australia was reported to have been delayed because of financing difficulties. Federal rules requiring Australian majority equity and no-interest bank deposits of one-third of all foreign investments were cited as major deterrents to foreign participation.

Brazil.—Bauxite mining has historically been centered in Minas Gerais, and none has been mined commercially in northern Brazil. However, deposits discovered in the Amazon Area since 1967 may eventually prove large enough to give Brazil the greatest bauxite production potential in the Western Hemisphere. Government regulations and procedures relating to the development of mineral deposits were described.[4]

During 1973 Alcan Aluminum Ltd. and Companhia Vale do Rio Doce (CVRD) conducted a joint study of the possibility of developing the bauxite deposits Alcan discovered near the confluence of the Amazon and Trombetas Rivers. In December the companies announced the signing of a memorandum of understanding with eight other companies to underwrite further development of the project. Tentative plans called for construction to begin in mid-

e Estimate.

1974, first shipments of bauxite by 1977, and eventual export of over 3 million tons per year. Brazilians will own 51% of the venture and foreign companies 49%.

Plans to enlarge two alumina plants by 1976 have been reported. Companhia Mineira de Alumínio was expected to increase annual capacity at its Poços de Caldas plant to 154,000 short tons. Companhia Brasileira de Aluminio, S.A. planned to increase capacity of its Sorocaba plant to 173,000 tons.

Fiji.—Bauxite Fiji Ltd., owned by three Japanese aluminum producers, terminated plans to develop bauxite deposits on the island of Vanua Levu. Construction of production facilities was near completion but was abandoned because of rising costs.

Germany, West.—Aluminium Oxid Stade GmbH., owned jointly by Reynolds International, Inc., and Vereinigte Aluminium-Werke A.G. (VAW), completed construction of a new alumina plant at Stade. The plant has a capacity of 661,000 tons per year and may be expanded.

Ghana.—As a result of a new government policy that Ghana hold a majority interest in mining investments, British Aluminium Co. Ltd. and the Government agreed to form Ghana Bauxite Co. in which the Government would hold 55% of the equity shares and British Aluminium, 45%. British Aluminium has been the only bauxite producer in Ghana and has exported all of its production.

Greece.—Eight companies reportedly mined bauxite, all of which was produced in the Province of Central Greece. Bauxite was again the largest mineral export of Greece. Export quotas for 1973 were established as follows: European Economic Communities, 458,000 long tons; U.S.S.R., 443,000 tons; United Kingdom, 74,000 tons; United States, 74,000 tons; Sweden, 69,000 tons; Spain, 49,000 tons; five other countries, 79,000 tons.

Aluminium de Grèce S.A., a subsidiary of Péchiney Ugine Kuhlmann (PUK), was the only producer of alumina in Greece. Plans for several other alumina plants continued to be negotiated, but no final construction agreements had been concluded at yearend. The Government announced that it had agreed in principle on a joint venture wtih Alcoa to build alumina and aluminum plants near Megara. The venture, in which Alcoa would have a 60% interest and the Government 40%, would include an alumina plant with an annual capacity of 287,000 short tons which could eventually be doubled. Reynolds Metals Co. reportedly received Government approval for a 500,000-ton-per-year alumina plant to be located on the northern shore of the Gulf of Corinth. Reynolds would be associated with Bauxite Parnasse Mining Co. in this project.

Guinea.—The first shipload of high-grade bauxite from the large Boké project left the new port at Kamsar in early August. Production was scheduled at 4 to 5 million tons in 1974 and 9 million tons by 1979. The bauxite is mined at Sangaredi and shipped about 80 miles by rail to Kamsar where it is crushed and dried before exportation. Boké is operated by Guinea Bauxite Co. (CBG), which is owned by the Government of Guinea (49%) and Halco (Mining), Inc. (51%), a consortium consisting of Alcoa (27%), Alcan (27%), Martin Marietta Aluminum, Inc. (20%), PUK (10%), VAW (10%), and Montecatini-Edison S.p.A. (6%). The Government receives 65% of the profits of CBG.

Compagnie International pour la Production de l'Alumine (FRIA) was the only other producer of bauxite in Guinea in 1973 and the only producer of alumina in Africa. The name of the company was changed to Friguia during the year when the Government acquired a 49% ownership of the enterprise. The remaining 51% was owned by the Frialco Co. consortium, consisting of Olin Corp. (38.5%), PUK (36.5%), British Aluminium (10%), Alusuisse (10%), and VAW (5%).

Bauxite deposits at Debele in the Kindia Region were being developed by the Government with assistance from the U.S.S.R. Ore was to be shipped about 70 miles by rail to Conakry for export to the U.S.S.R. Production was expected to be at the level of 2.5 to 3.0 million tons per year. Initial shipments were delayed until 1974.

Hungary.—A new bauxite mine, Rakhegy II, near Lake Balaton in Transdanubia was opened and was expected to produce 350,000 tons per year.

India.—The alumina plant at Korba, Madhya Pradesh, of the government-owned Bharat Aluminium Co. was reported to have come onstream in April. The plant, with an annual capacity of 220,000 short tons per year, will use bauxite from Amarkantak and Phutkapahar. The State Government of Gujarat announced plans for an export-oriented plant of similar size to be located at Bhuj in the Kutch area. The bauxite is to be mined by Gujarat Mineral Development Corp.

Indonesia.—P.N. Aneka Tambang, a government-owned mining company, announced that it had increased its bauxite production and shipping capacity on Bintan Island. Exports to Japan, its principal customer, were to be increased from 1.0 million tons per year to 1.2 million tons. Reserves on Bintan have been estimated at 78 million tons. Following extensive exploration, Alcoa announced its intention to develop bauxite deposits on Kalimantan

(Indonesian Borneo) and to build a large alumina plant.

Jamaica.—Jamaica, the world's second largest producer of bauxite, was also the fourth largest alumina producer. Alcoa's new alumina plant was reported to have reached capacity production, but operating difficulties were encountered at the new plants operated by Alumina Partners of Jamaica, (Alpart) and Revere Jamaica Alumina, Ltd.

In addition to the bauxite produced in Jamaica to supply the five alumina plants on the island, Jamaican bauxite is exported by Kaiser Bauxite Co., Reynolds Jamaica Mines Ltd., and Alcoa. Production by Kaiser was interrupted for half of September because of a dispute over a labor contract. Reynolds was reportedly expanding bauxite capacity from 2.5 to 3.25 million tons per year.

Japan.—Japan's imports of bauxite increased 4% in 1973 and came from five sources, as follows:

Supplier	Quantity (thousand long tons)	
	1972	1973
Australia:		
Comalco Ltd	2,177	2,012
Nabalco Pty. Ltd. (Gove)	534	926
Indonesia: P.N. Aneka Tambang	1,089	997
Malaysia:		
Ramunia Bauxite Co	220	242
Southeast Asia Bauxites Ltd	475	507
Total	4,495	4,684

Sumitomo Chemical Co., Ltd., announced that the annual capacity of its alumina plant at Kikumoto would be increased to 955,000 tons by 1975.

Romania.—Production began at a new alumina plant at Tulcea. Production was not expected to reach full capacity of 276,000 tons until 1975.

Spain.—Plans were disclosed for the construction of an alumina plant in the area of Villagarcia de Arosa, Galicia, on the northwest coast. The plant would eventually have a capacity of 880,000 tons per year, and initial production was expected by 1977. The plant would be operated by a firm formed by two Spanish aluminum-producing companies, Empresa Nacional del Aluminio S.A. (Endasa), 55%, and Aluminio de Galicia S.A. (Alugasa), 45%. Endasa is owned by an agency of the Spanish Government, Institute Nacional de Industria (75%), and Alcan (25%). Alugasa is owned by Péchiney Ugine Kuhlmann and Spanish interests.

Surinam.—Bauxite was mined by Surinam Aluminum Co. (Suralco), an Alcoa subsidiary, and Billiton Maatschappij Suriname N.V. Suralco also produced alumina and aluminum and converted bauxite to alumina for Billiton. Reynolds Metals Co., under a 1971 joint agreement with the Government, continued bauxite exploration activities in the Bakhuys Mountains in western Surinam.

An agreement was signed in August under which Billiton is to bring its assets into the formation of a new corporation, Billiton Suriname, N.V., in which the Government will participate up to 25%. Billiton also is to take part up to 25% in the capital of the Government company of N.V. Grasshopper Aluminium Co. (Grassalco). The new Billiton company and Grassalco will form a joint venture to develop bauxite and other mineral deposits.

Alcan Aluminium Ltd. and Billiton International Metals B.V. began a feasibility study for a joint project to produce refractory-grade calcined bauxite, based on Billiton's reserves. Depending on the outcome, possible annual production was foreseen at 150,000 tons, beginning in 1976.

Turkey.—Production began at the new Seydisehir alumina plant in March 1973. Over half of the output of the 220,000-ton-per-year plant will be used at a nearby aluminum plant when it is put into operation. Most of the remaining alumina is to be exported to the U.S.S.R., which assisted in financing the complex. Bauxite exports to the U.S.S.R. during the year were reported at 150,000 tons.

United Kingdom.—British Aluminium was phasing out alumina production at its Newport plant and expected to close the plant early in 1974. Its Burntisland plant was being converted entirely to the production of nonmetallurgical grades of alumina.[5] Bauxite for the plant has been imported mainly from the company's mines in Ghana.

Yugoslavia.—Construction was reported to have begun on an alumina plant near Obrovac in northern Dalmatia. The plant will have a designed capacity of 330,000 tons per year. Hungary and East Germany will provide part of the equipment and financing for the plant.

[5] Metal Bulletin Monthly. New Lease of Life for Burntisland. No. 36, December 1973, pp. 41, 43.

TECHNOLOGY

Aluminum resources in the United States were assessed by the U.S. Geological Survey.[6]

In December a joint venture of Earth Sciences. Inc., National Steel Corp., and Southwire Co. began test production of alumina from alunite in a new pilot plant at Golden, Colo. The group was reported to have extensive alunite reserves near Cedar City, Utah.

The Bureau of Mines evaluated a sulfurous acid-sulfuric acid process for recovering alumina from clay. The process appeared to be less attractive economically than some alternate techniques of producing alumina from clay.[7] The Bureau initiated a project at Boulder City, Nev., to test and evaluate the most promising processes for recovering alumina from domestic nonbauxitic raw materials. A small-scale continuous pilot plant was under construction, and industry was being invited to support the program. The first process to be investigated will be a nitric acid leach of kaolinitic clay.

Methods for determining nahcolite and dawsonite content in oil shales were investigated and evaluated.[8]

Beryllium

By E. Chin[1]

Domestic production of beryl ore increased in 1973, and one mining company, which mined bertrandite, recovered and stockpiled sufficient ore to maintain a 2-year supply for its operation. The demand for beryllium metal, which is used principally in military and aerospace applications, weakened in 1973. However, a strong demand for beryllium-copper alloys and beryllium oxide ceramics was reflected by increased sales and shipments of those products. The Government's Poseidon missile program, which has been a large user of beryllium components, passed its peak, and the industry did not receive orders for the 1974 requirements for beryllium components.

Table 1.—Salient beryllium mineral statistics

	1969	1970	1971	1972	1973[p]

Bertrandite ore: Utah, low-grade, shipped from mines ------short tons--	W	W	W	W	W
World production of beryl ------do------	8,869	6,857	[r]5,791	4,634	4,291

[p] Preliminary. [r] Revised. W Withheld to avoid disclosing individual company confidential data.
[1] Includes some bertrandite ore which was calculated as equivalent to beryl containing 11% BeO.

Legislation and Government Programs.— In 1973, the Office of Preparedness removed beryl and beryllium-copper master alloy from the list of strategic and critical materials, and the stockpile objectives for these items were abolished. The stockpile objective for beryllium metal was reduced from 150 short tons to 88 short tons. Government inventories of beryl decreased 487 short tons during 1973 as a result of stockpile disposals.

As the result of public hearings held by the Environmental Protection Agency in 1972, emission standards for beryllium were published in the Federal Register on April 6, 1973. The beryllium emission standards cover extraction plants, foundries, ceramic manufacturing plants, machine shops (processing beryllium or beryllium alloys containing more than 5% beryllium), and disposal of beryllium-containing waste. The standards for sources of beryllium dust, fume, or mist emission into the atmosphere were established to insure that ambient concentrations of beryllium would not exceed daily 0.01 microgram per cubic meter, based on a 30-day average.

DOMESTIC PRODUCTION

The largest domestic source of beryllium ore was the Spor Mountain bertrandite mine near Delta, Utah. The bulk of the activity in beryl mining was confined to prospecting and assessment work, primarily in Colorado and South Dakota.

During 1973, Brush Wellman, Inc. (Brush), mined sufficient bertrandite to maintain a desired 2-year supply for its operations. Brush's facilities include extraction plants at Delta, Utah, and Elmore, Ohio, to convert bertrandite and beryl, respectively, to beryllium hydroxide. The Elmore plant also has manufacturing and fabrication facilities for beryllium metal, beryllium-copper master alloy and beryllium oxide ceramics shipped in 1973.

Brush expanded its facility at Elmore to provide additional furnace and casting capacity. Brush also is constructing a building at Elmore to house a new rolling mill for beryllium-copper and phosphor-bronze alloys. At Shoemakersville, Pa., Brush installed a new continuous strip annealing line which included furnace, quench, and brushing capability. An 18-inch slitter was added to the beryllium-copper strip line. In early 1974, Brush expected to complete a new facility in Clinton, N.J., to accommodate the expanded demand for beryllium oxide ceramic parts. In midyear, Brush announced the closing of its beryllium metal machining facility at Hayward, Calif.

Kawecki Berylco Industries, Inc. (KBI), used beryl for its primary ore, most of which was imported. The beryl was processed at its Hazelton, Pa., plant. Further processing and fabricating was done at both the Hazelton and Reading, Pa., plants. In 1973, KBI closed its beryllium machining and compacting facility at Yonkers, N.Y. The work done at that plant was to be absorbed by the company's other finishing plants.

KBI installed new mills for the production of precision beryllium-copper strip, and new furnaces for heat treating beryllium-copper at its facilities in Pennsylvania. Additionally, mechanical cleaning equipment was being installed to improve the quality of strip products.

CONSUMPTION AND USES

The beryllium industry consumed beryllium ore equivalent to 8,695 short tons of beryl containing 11% BeO. Because demand for beryllium metal in aerospace and defense programs declined during the year, less metal was shipped in 1973 than in 1972. However, there was an increase in the amount of beryllium-copper master alloy and beryllium oxide ceramics shipped in 1973.

Beryllium metal is used where a high stiffness-to-weight ratio is needed, as in the aerospace industry. It is used for space optical devices, X-ray windows, and airplane brakes, and in missile parts and nuclear structures.

Beryllium-copper alloy products consumed the largest quantity of beryllium. These alloys combine the properties of good electrical and thermal conductivity, strength, hardness, and resistance to fatigue, corrosion, and wear. They are used in an ever-increasing variety of markets such as in the business machine, appliance, transportation, and communication industries. Beryllium-copper alloys are used in electrical and electronic systems for connectors, sockets, switches, and temperature- and pressure-sensing devices to facilitate miniaturization and to provide reliability and long service life.

Beryllium oxide ceramics are used in parts for lasers and microwave tubes, and in semiconductors. Typical applications include power amplifiers for microwave and radio communications, electronic ignition systems, and power regulators such as light-dimming switches.

STOCKS

Consumer stocks of hand-sorted beryl at the end of 1973 totaled 5,894 short tons compared with 6,913 short tons at yearend 1972. Dealers' stocks of beryl are not reported. Stocks of bertrandite are company confidential data.

PRICES AND SPECIFICATIONS

Domestic beryl prices were negotiated between producers and buyers and were not quoted in the trade press. While the price of imported beryl was probably negotiated, the quoted price in 1973 was $30 to $35 per short ton unit. This price range was quoted by Metals Week throughout the year.

Prices for beryllium metal products also remained steady throughout 1973. Beryllium billet was quoted at $70 per pound and 98% powder ranged from $44 to $54 per pound. The yearend price for 5-inch-diameter beryllium rod was $102.82 per pound.

Beryllium-copper master alloy was quoted at $53 per pound. Casting ingot containing 2% to 2.25% beryllium in copper started at $2.06 per pound and dropped in March to $2.035 per pound for the remainder of the year. The quoted base price for Alloy 25 strip was $3.05 per pound at yearend.

FOREIGN TRADE

Exports of beryllium alloys, waste, and scrap in 1973 totaled 109,199 short tons, valued at $1,220,000. For the second consecutive year, the average unit value for beryllium exports was low in comparison with prior years due to increased shipments of beryllium waste and scrap generated from machining operations. The principal destination for this material was Japan.

Imports of beryl decreased for the fourth consecutive year and the quantity received was down 53% from that in 1972. The average unit value for imported beryl was $303 per short ton. About 89% of the beryl imported was from Brazil, the Republic of South Africa, Argentina, and Australia, with Brazil furnishing over one-half of the imports. In addition to the imports of beryl, there were 89 pounds of beryllium metal, wrought, unwrought, and waste and scrap imported, with a value of $889,000.

Table 3.—U.S. exports of beryllium alloys, wrought or unwrought, and waste and scrap[1]

WORLD REVIEW

Australia.—Seleka Mining and Investments, Ltd. (Seleka), completed an initial drilling program in early 1972 to determine the extent of beryl mineralization at its mine near Perenjori about 200 miles northeast of Perth. By the end of 1972, more than 300 tons of beryl was recovered using small-scale opencut methods. In early 1973, Seleka signed a 5-year contract to supply the entire output of its beryl mine to an unnamed U.S. corporation. The contract was estimated to be around $120,000 per year. The unspecified company reportedly made a substantial interest-free loan to Seleka for the period of the contract.

France.—Tréfimétaux-Berylco S.A., jointly owned by Kawecki Berylco Industries, Inc., and Tréfimétaux, G.P., continued the expansion program at its plant in Coueron. Additional equipment is being added to the beryllium-copper production facilities.

Japan.—As reported by the Japan Society of Newer Metals, N G K Insulators, Ltd., produced beryllium metal, beryllium-copper alloys, and beryllium oxide. Yokosawa Chemical Co., Ltd., produced beryllium-copper alloys and beryllium oxide, while Santoku Metal Industry Co., Ltd., produced beryllium-aluminum alloys. Production data for 1973 were not available. Japan imported beryl principally from Africa, Brazil, and Australia, and beryllium metal scrap from the United States.

[1] In addition to the countries listed, the Territory of South West Africa may also have produced beryl, but mineral production from this area has not been officially reported since 1966, and no reliable information is available as a basis for estimating output since that time.

Nepal.—The Nepalese Industrial Development Corp. introduced incentives aimed at attracting foreign investment to exploit the country's mineral wealth. Deposits of interest in the country include beryl near Kathmandu, limestone, magnesite, muscovite, pyrite, and talc.

TECHNOLOGY

Because of the commercial application of beryllium-copper alloys as spring materials, information regarding the stress relaxation behavior of these alloys has significant practical value.[2] Stress relaxation experiments were used as a basis for determining the deformation parameters of a precipitation hardened alloy of copper with 1.87 weight-percent beryllium. The precipitate was found to strengthen the material mainly by increasing the long-range internal stress.

Considerable work was done by the industry in improving beryllium materials through the use of impact grinding of powders and a better understanding of the effect of purity on mechanical properties. These new materials (called S-65 at Brush Wellman and CIP/HIP-1 at KBI) have excellent room temperature and elevated temperature ductility. The minimum room temperature elongation of 3% obtained in these materials is twice that which is obtained in the more conventional grades of beryllium. The stress-strain curve indicates that these materials should be very useful under impact service conditions. The material can be consolidated by either hot pressing or by the CIP/HIP process which consists of cold isostatic pressing, followed by hot isostatic pressing.

Due to the sparse data on sputter-deposited beryllium, an investigation was conducted to obtain information on thick, sputter-deposited beryllium foils.[3] Specimens of sputter-deposited beryllium foils displayed strong textures for a deposition temperature range between 9.5° C and 470° C. The hardness of the deposits ranged from 275 to 800 diamond point hardness. The data indicated that it should be possible to sputter-deposit foils with specific properties.

A simple technique using mesityl oxide was developed for the solvent extraction of beryllium.[4] Mesityl oxide quantitatively extracts beryllium from 0.5 molar hydrochloric acid containing 5 molar potassium thiocyanate. The method is simple, sensitive, selective, and applicable for microgram concentrations of beryllium.

Two patents on the extraction of beryllium values from solutions produced by leaching beryllium ore with acid were issued.[5]

The large beryllium deposits in western Utah are a significant part of the world's beryllium resources.[6] A study conducted by the U.S. Geological Survey determined the mineralogy and chemical composition of the host tuff of the beryllium deposit at Spor Mountain and defined the principal alteration processes responsible for the deposition of the beryllium in the tuff.

Bismuth

By John A. Rathjen [1]

Consumption of bismuth in the United States during 1973 rose for the second consecutive year reaching a level of 2.9 million pounds. The largest increase was in metallurgical additives, although fusible alloys and chemical applications also registered strong gains.

The price of bismuth through the year was firm, with several increases reflecting currency fluctuations and strong market conditions. Domestic production was reduced slightly due to the final phaseout of one primary lead smelter, however, this was more than offset by increased imports which were 1.1 million pounds over the 1972 total. World mine production was down nominally reflecting curtailed production in Canada, which was partially offset by gains in Peru.

Legislation and Government Programs.—The General Services Administration (GSA) reported a stockpile inventory at yearend of 2,100,061 pounds of bismuth. The new objective is 95,900 pounds. This indicates a surplus of some 2,004,161 pounds which will require Congressional action for release to the public sector.

Bismuth remained on the list of commodities eligible for aid from the Office of Minerals Exploration (OME), covering 75% of the exploration costs; however, no contracts were in effect during 1973 and no applications were pending.

DOMESTIC PRODUCTION

Primary production of bismuth in the United States continued to be from the American Smelting and Refining Company (Asarco) Omaha, Nebr., refinery. The raw material input appeared to be split on approximately a 50% basis between those ores and bullions which were of domestic origin and those which were imported for smelting and refining. Roughly 8% of the bismuth production was recovered as a secondary product by United Refining and Smelting Co. at Franklin Park, Ill., and UV Industries, Inc., formerly U.S. Smelting Refining & Mining Co., at East Chicago, Ind.

Individual data relating to U.S. refinery production are withheld to avoid a breach of confidentiality; however, overall production figures were down some 10% in 1973 as compared with 1972 production.

Additional domestic production of bismuth can be expected when The Anaconda Company brings the Victoria mine in Elko

[1] Mineral specialist, Division of Nonferrous Metals—Mineral Supply.

County, Nev., into full operation. This is a copper mine which has remained idle through the years because of the high bismuth content in the ore which is deleterious to current methods of copper smelting. The perfection of the new hydrometallurgical Arbiter process will now make it possible to separate the copper and the bismuth economically and plans are to bring the complex onstream by 1975. It has been announced that the bismuth in the copper concentrate will run about 0.7%, which indicates that possibly an additional 400,000 pounds of bismuth could be added to the market annually.

CONSUMPTION AND USES

Domestic consumption of bismuth in 1973, at 2.9 million pounds, was the highest recorded figure since 1966 when 3.2 million pounds were consumed. There were increases in virtually all categories with metallurgical additives up 51%, fusible alloys up 24%, and pharmaceutical-chemical applications up 14%.

In spite of the fact that the use of bismuth oxychloride as a cosmetic aid and the use of bismuth-based indigestion remedies were on the decline, overall use of bismuth in the pharmaceutical-chemical area increased, indicating new industrial-commercial applications. The new uses were essentially in catalytic applications for plastics manufacture since exhausted and undesirable uranium-based catalysts were being replaced by newer, more adaptable molybdenum-bismuth compounds.

Increased use of bismuth in the metallurgical field during 1973 was attributed to the extremely high rate of activity in the ferrous and aluminum metals industries where bismuth is used as an aid to the casting of white cast iron and also to improve machinability of certain steels and aluminum.

Increased construction of industrial plants and high-rise complexes, as well as rehabilitation of older buildings where bismuth is used as a low melting point alloy for fire control devices probably accounts for the increased consumption of fusible alloys.

Table 2.—Bismuth metal consumed in the United States, by use
(Pounds)

Use	1972	1973

[1] Includes bismuth contained in bismuth-lead bullion used directly in the production of an end product.
[2] Includes industrial and laboratory chemicals and cosmetics.

STOCKS

Consumer stocks dropped for the second consecutive year to a level of 541,000 pounds as compared with 717,000 pounds in 1972, a reduction of 25% on an annual basis. A quarterly review of the stock position is indicative of the supply-demand picture as it developed through the year. Starting at a level of 717,000 pounds, the figure rose to 907,000 pounds at the March closing. Inventories dropped to 767,000 pounds at the end of June and then climbed to 909,000 pounds at the end of September. A very sharp drop occurred in the fourth quarter to 541,000 pounds or a decrease of 60% in 3 months.

PRICES

Currency fluctuations in addition to strong market requirements were important factors in the increase in domestic prices throughout the year. The January price of $4 per pound was increased to $4.50 in March where it remained until June when a split price of $4.75–$5 was established. In September, the sellers of foreign bismuth raised quotations to $5.50 per pound; this price remained firm until November when the price was further increased to $6.50 per pound resulting in a spread of $5–$6.50 per pound of bismuth metal. In December the Cost of Living Council authorized the domestic producer to increase its price to meet the high level of competition and established a uniform domestic price at $6.50 per pound. At yearend, dealer and foreign prices were highly volatile and the outlook for a price increase in 1974 was probable.

FOREIGN TRADE

Exports of bismuth in all forms during 1973 dropped sharply to a level of 151,000 pounds as compared with 264,000 pounds in 1972, a reduction of some 43%. Shipments were recorded to 18 countries, with six of those representing 94% of the total. In order of declining volume the countries were Canada, 42,000 pounds, (28%); Argentina, 42,000 pounds, (28%); the Netherlands, 21,000 pounds, (14%); Mexico, 14,000 pounds, (9%); the United Kingdom, 13,000 pounds, (8%); and Belgium, 11,000 pounds, (7%).

General imports of metallic bismuth in 1973 reached a record high of 2.7 million pounds. This can be attributed to increased demand, lower domestic production, and cessation of stockpile sales. The principal contributors to imports in quantitative order were Japan, 754,000 pounds, (28%); Peru, 489,000 pounds, (18%); the United Kingdom, 488,000 pounds, (18%); Mexico, 358,000 pounds, (13%); and West Germany, 344,000 pounds, (13%).

r Revised.

WORLD REVIEW

The world market for bismuth continued to improve through 1973 resulting in a strong price structure and a changing pattern of international trade. Total production remained steady at 8.8 million pounds in 1973. Bismuth continued to be produced basically as a byproduct of smelting lead, copper, molybdenum, and zinc ores although it was reported that substantial quantities were being returned to the market from secondary treatment of spent catalysts. Bolivia remained the world's largest producer of metal from primary ore.

The First Ordinary General Assembly of the Bismuth Institute convened on April 2 and ended on April 4, 1973. The officers forming the board of directors were elected and the statutes of the Institute were approved.

The principal objectives of the Institute are to develop new applications for the use of bismuth, to increase the use of bismuth in its present applications, and to study patents and publications of relevant technical significance which may lead to a wider use of bismuth. In the first two bulletins, issued in October and December 1973, 48 patent references were cataloged along with a survey of publications, a history of bismuth, and a detailed paper on the use of bismuth in medicine. Charter members included Cerro de Pasco Corp., Peru; Corporación Minera de Bolivia (COMIBOL); Mining & Chemical Products Ltd., United Kingdom; Salsigne S.A., France; Sidech S.A., Belgium; and Peko-Wallsend Ltd., Australia.

The Institute was incorporated in La Paz, Bolivia, and maintains an information center in Brussels, Belgium.

Australia.—Mine production during 1973 was estimated to be some 815,000 pounds. The anticipated surge in production from the Peko-Wallsend Ltd. properties did not occur due to severe flooding which affected both mining operations and smelter construction. The initial program is still in effect and when the program is completed in 1974, an additional 2 million pounds of bismuth might be available to the market. Current production of bismuth from all sources is being exported for smelting and refining with the bulk going to Japan and the balance to Europe.

Bolivia.—Production from all sources in 1973 was estimated to be 1.4 million pounds. Of this, a substantial portion was treated at the Telamayu smelter operated by COMIBOL. A rich bullion produced at the smelter was exported to Europe for refining and ultimate sale in the world market by COMIBOL. The balance of production in the form of ores and concentrates was sold directly to merchants and exported for treatment.

Canada.—Production of bismuth in Canada was reduced sharply in 1973 to 90,000 pounds as compared with 275,000 pounds during 1972. Most of the loss was attributed to curtailed molybdenum production in Quebec where bismuth is recovered as a byproduct. Interruptions at the lead smelter of Cominco Ltd. at Trail, British Columbia, could also account for some of the reduction. The other Canadian bismuth producer, Brunswick Mining and Smelting Corp. Ltd. at Belledune, New Brunswick, was still in the process of converting its furnace facilities.

Mexico.—Bismuth production in Mexico remained stable during 1973 with an estimated 1.4 million pounds, basically the same output as in 1972. The two principal producers were Asarco Mexicana, S.A., and Industrias Peñoles, S.A. at the Met-Mex Peñoles, S.A., plant. Both refineries are located at Monterrey in the State of Nuevo León.

Peru.—Mine production of bismuth in Peru during 1973 increased to a level of 1.7 million pounds as compared with 1.5 million pounds in 1972. During the course of the year Cerro Corp., one of the major world suppliers of bismuth from its refinery at La Oyora, was expropriated by the Peruvian Government and Minèro Peru became the operating and marketing agency for all production at this facility. On December 29, 1973, an official decree was released announcing total Federal Government control and assigning Centromin (a new governmental agency) the operating and marketing responsibilities for the complex. Minèro Peru was to operate and develop the mining facilities.

1 In addition to the countries listed, Brazil, Bulgaria, East Germany, and South West Africa are believed to produce bismuth, but information is inadequate to make reliable estimates of output levels.

2 Less than ½ unit.

3 Production by COMIBOL and exports by medium and small mines.

4 Bismuth content of refined metal, bullion and alloys recovered indigenously, plus recoverable content of concentrates exported for processing.

Boron

By K. P. Wang [1]

Production and domestic consumption of boron minerals continued the rising trend that began in 1961 and reached new highs in 1973. Recorded exports in terms of B_2O_3 content also showed a sharp increase over those of 1972, but lower than the high levels of 1969–70. All U.S. output had been in the form of sodium borates and boric acid. Recently, production of calcium borate (colemanite) was resumed on a small scale in California, the same State that provides the entire domestic production of boron minerals.

DOMESTIC PRODUCTION

Domestic production and sales of boron increased about 9.4% in 1973. As in past years, most of the output came from Kern County, Calif., and to a lesser extent from San Bernardino County, Calif.

At Boron in Kern County, the large open pit mine of U.S. Borax & Chemical Corp., a subsidiary of the British-owned Rio-Tinto Zinc Corp. Ltd., remained the world's foremost source of boron. U.S. Borax produced upgraded crude sodium borates (better than 96% purity), refined borates (including anhydrous borax), and boric acid (including anhydrous boric acid) at the mine site. High-purity and specialty products were produced mainly at Wilmington, Calif., and secondarily at Burlington, Iowa. Wilmington was also the company's port of export. These plants, led by the one at Boron had a combined annual capacity of more than 600,000 short tons of equivalent B_2O_3 in 1973. U.S. Borax maintains a storage center at Botlek in the Netherlands from which borax and borates are shipped to other parts of Europe. All told, the company increased production by nearly 12% during 1973. Crude sodium borates, known by the commercial name of Rasorite, represented about one-half of U.S. Borax's overall output in terms of value and 60% in terms of tonnage.

Kerr-McGee Corp.'s subsidiary, American Potash & Chemical Co., and Stauffer Chemical Co. produced boron compounds as coproducts from brines of Searles Lake in San Bernardino County, Calif., at their adjacent plants in Trona. American Potash's 1973 output was somewhat less than its annual capacity of 100,000 short tons of B_2O_3, and Stauffer Chemical was also producing below its capacity of 25,000 to 30,000 tons of B_2O_3. Both companies increased output by about 10% during the year. In 1973, Kerr-McGee moved ahead on its program to build a $100 million soda ash plant along with possibly additional borate refining facilities.

[1] Supervisory physical scientist, Division of Nonmetallic Minerals—Mineral Supply.

During 1973, Tenneco Oil Co. increased output slightly, although it continued to produce less colemanite than was originally planned, from its deposit in the Furnace Creek district of Inyo County, Calif., and nearby processing plant in Nevada. Tenneco had designed the facilities to produce about 70,000 short tons of calcined colemanite per year, but actually turned out only a fraction of this owing to difficulties in calcining. However, the 48% B_2O_3 grade calcined colemanite found a ready market at the Owens-Corning Fiberglass Corp. plants in Anderson, S.C., and Burkette, Tenn.

CONSUMPTION AND USES

Because of the wide range of products, and the lack of statistics on the large tonnages of crude borates exported, U.S. consumption of boron materials is difficult to estimate. Official U.S. trade statistics do not list crude borate exports separately, and the major domestic producers do not publish details on shipments to foreign countries. It appears however, that shipments of unfinished products to foreign countries were much larger than those of fully refined products, and that a major proportion of U.S. Borax's output of crude borates was shipped to Europe. In general, less than half of the domestic output of boron minerals and compounds was consumed at home, and the remainder was exported.

About 40% or more of the boron compounds consumed domestically, were used in the manufacture of various kinds of glasses. Boron materials account for 5% to 10% of many special glasses by weight and 50% to 75% by value. About 15% of all boron consumed went into insulating fiberglass, 10% into textile fiberglass, and 15% to 20% into all other glasses. Manufacture of enamels, frits, and glazes for protective and decorative coatings on sinks, stoves, refrigerators, and many other household and industrial appliances accounted for another 10% of the boron consumption.

Approximately 15% of the boron compounds consumed in the United States went into soaps and cleaners during 1973, with possibly one-third in the form of sodium perborate detergents. In Europe, on the other hand, sodium perborate detergents used primarily in high-temperature washing account for more than a quarter of all the boron consumed. Borax and boric acid uses in the cleansing field include toothpaste, mouthwash, and eyewash, because of its bactericidal characteristics, easy solubility in water, and excellent water-softening properties.

Borax added to fertilizers to supply boron, an essential plant nutrient, accounted for about 5% of the U.S. boron demand. Another 2% to 3% went into making herbicides. Substituting colemanite for fluorite in steelmaking did not progress much beyond the pilot plant stage.

About one-fourth of the boron consumed in the United States went into many miscellaneous uses. Minor amounts of boron compounds were used as fluxing materials in welding, soldering, and metal refining. Some elemental boron was used as a deoxidizer in nonferrous metallurgy, as a grain refiner in aluminum, as a thermal neutron absorber in atomic reactors, in delayed action fuses, as an ignitor in radio tubes, and as a coating material in solar batteries. Use of boron compounds in abrasives gained ground, particularly cubic boron nitride produced by synthetic diamond producers. Use of boric acid as a catalyst in the air oxidation of hydrocarbons accounted for more than 3% of the boron consumption. Boron materials went into many other areas, including direct consumption in chemicals, conditioning agents or precursors to chemicals, plasticizers, adhesive additives for latex paints, fire retardants, antifreeze, textile and paper products, biocides in jet fuels, photography, and composite materials.

PRICES

Prices of most borate products at yearend 1973 were about 6% more than the prices posted for yearend 1972. Prices of various kinds of borates are shown in table 2.

Table 2.—Borate prices at yearend, 1973

	Price per short ton [1]
Borax, technical:	
Anhydrous, 99%:	
Bags	$119.75
Bulk	109.50

[3] Anhydrous and granular $10 to $12 per short ton lower in bulk.
Source: Chemical Marketing Reporter and industry sources.

FOREIGN TRADE

U.S. exports of boric acid totaled 41,407 short tons valued at $6.9 million in 1973, as compared with 27,655 tons in 1972. Exports of refined sodium borate increased to 168,826 tons valued at $19.4 million in 1973, from 162,123 tons in 1972. Combined exports of all refined boron compounds was therefore higher than tonnages in 1971 and 1972, although still lower than the previous record levels during 1969–70. As noted, these figures do not tell the whole story because exports of crude borates, not separately recorded, were actually much higher than exports of refined borates.

A detailed breakdown of recorded exports in 1973 is shown in table 3. Within this table, data for all countries outside of Western Europe are accurate.

While the overall total exported to Western Europe is accurate, the quantities shown for individual countries of Western Europe do not reflect the true picture. In table 3, the Netherlands appears as the major recipient of U.S. exports. However, the Netherlands is actually a major transshipment point, and a significant portion of the material shown destined for that country is ultimately shipped to other nearby countries. A more meaningful array of recipient nations, including an estimate for crude borates, would show that West Germany, France, the United Kingdom, Japan, Belgium, Spain, and Italy were the ranking final destinations, in that order; the Netherlands was actually eighth in 1973.

In 1973, the United States imported 18,216 short tons of calcium borate (colemanite) valued at $568,000, all from Turkey. This compares with 20,227 short tons valued at $626,000 during 1972.

WORLD REVIEW

China, People's Republic of.—Large resources of borates reportedly occur in the Iksaydam dried lake area of Tsinghai Province where there is a plant producing mixed salts. National output of borates and boric acid combined may be several tens of thousands of tons annually. The textile fiberglass industry which has been expanded sharply in recent years, consumes a considerable quantity of borates annually. China ships a few thousand tons of surplus borates annually to Japan.

Turkey.—Turkey's 1973 production of boron minerals increased to possibly 250,000 short tons of B_2O_3 content. Actual production is hard to estimate since Turkey has both colemanite (calcium borate) and "tincal" (sodium borate) reserves and was in the process of expanding processing capacity. Because of the extensive reserves and great demand for boron products in world markets, Turkey's relative production position regarding the United States continued to improve. The Government-owned Etibank gained further importance as the principal producer of borates at the expense of Türks Boraks Madençilik A.S. (a subsidiary of Rio-Tinto inc Corp.) and others. The issue of nationalization was not settled at yearend, but it appeared imminent that the "boron" industry would be totally nationalized.

Etibank owns the largest reserves of borates in Turkey and operated some of the most important mines and plants. Under its jurisdiction are both colemanite and tincal deposits. Although details on 1973 data are not available, Etibank's production in 1972 comprised about 190,000 short tons of upgraded colemanite (about 40% B_2O_3 grade) 90,000 short tons of upgraded tincal (perhaps 35% B_2O_3 grade), 30,000 tons of borax, and 12,000 short tons of boric acid. The tincal was used to manufacture borax and boric acid at the Bandirma plant, which was designed and built by Polish engineers around 1968.

The nature of Etibank's operations has undergone steady change. Two colemanite mines were in existence at yearend 1973—an open pit mine, Emet, and an underground mine, Espey, both in Kutahya Province and roughly 215 miles from the port city of Bandirma. Combined known reserves exceed 10 million short tons of 27%–30% ore, but potential reserves are many times larger. A washing plant with a capacity to upgrade 660,000 short tons of ore into 330,000 short tons of product (40%–45% grade) was in full-scale operation at Hisarcik in 1973.

Etibank's tincal deposits were discovered at Kirka only a few years ago. Known reserves are several tens of million tons of ore (26% plus grade), and potential reserves may be more than 10 times greater. A washing plant with an annual capacity of 440,000 short tons of product (35% B_2O_3 grade) was under construction and expected to be completed by the summer of 1974. Tincal from Kirka has replaced colemanite from Kutahya as the principal feed at the Bandirma plant. Plans are underway to eventually build facilities to transform the tincal product to crude borax pentahydrate, crude anhydrous borax, and refined anhydrous borax. These developments will further strengthen Turkey's position in the world as a supplier of boron minerals and products.

U.S.S.R.—As an order of magnitude, the U.S.S.R. may be producing at a rate corresponding to 20% to 30% the U.S. level from reserves that may be half as much. The borate industry of the U.S.S.R. was born in 1934, when several dozen deposits of relatively standard ores were discovered along a fracture zone of a large Permian salt dome in the Inder District, 150 miles north of the Caspian Sea. Other deposits were subsequently discovered in Kazakhstan, the Caucasus, and Siberia. Recently, a complex boron mineralization in the form of azoproit (contains titanium and magnesium also) was found on the western shores of Lake Baikal. The U.S.S.R. has had a surplus of boron compounds, judging from imports made by Japan from the Soviet All-Union Export-Import Agency, Dalintorg. Japan imported 3,725 short tons of boric acid and 52,665 tons of borax (probably penta variety) from the U.S.S.R. during 1973, a little more than average tonnages in 1971–72.

TECHNOLOGY

The use of colemanite as a substitute for fluorspar in the basic oxygen furnace (BOF) steel process made some progress. Widespread application showed little promise because of the adequate world supply of fluorspar and increasing demand for boron minerals in the manufacture of insulating fiberglass. However, despite high costs and some deleterious side effects, colemanite already was used in limited quantities in flux mixes to eliminate sulfur and phosphorus from specialty high-carbon steels.

Oxidation, erosion, wear, and corrosion resistance, as well as hardness, of steel bonded carbides and various grades of steel reportedly can be improved by using a new diffusion process that imparts a layer of boron on the surface of these metals. It was also claimed that various wear and tooling applications are foreseen.[2]

Alkali borate and B_2O_3 glasses containing large concentrations of gaseous noncondensed compounds (including Ar and H_2) were synthesized at high temperatures and pressures, and the solubilities of the gases were determined.[3]

The U.S. Air Force continued its investigation of using boron as part of a fluidized-solids propellant mixture, but have not yet reported its findings.

It was claimed that many reagents derived from boron, such as borane and diborane, exhibited enormous versatility in types of organic synthesis reactions and therefore should be used much more industrially.[4]

Bromine

By Charles L. Klingman [1]

The bromine industry had another record year in 1973, registering an 8.1% increase in the quantity of elemental bromine used or sold, compared with a 7% historic growth rate. Even ethylene dibromide, a gasoline additive, showed a 5.5% increase in spite of a national effort to reduce atmospheric pollution through the use of less tetraethyl lead and ethylene dibromide in gasoline. Greater increases were evidenced in the production of flame retardants and agricultural chemicals. Estimates of bromine and bromine compounds exports were obtained for the first time through a Bureau of Mines survey, and it indicated that about 10% of the U.S. bromine production was exported.

The average unit value of bromine produced, as indicated by reports of bromine producers, dropped about 2.5% in 1973, continuing a trend in price reduction which has persisted for several years. Average production costs were probably reduced by the increased production from Arkansas brines, which are richer than Michigan brines in bromine content.

In 1973, the future of the bromine industry was difficult to predict because of the uncertain position of additives in gasoline. If the additives were reduced by 1979 to 23% of the 1973 usage, as required by Environmental Protection Agency (EPA) regulations, there could be an excess supply of bromine on the market. Certain bromine plants which primarily produce ethylene dibromide might be forced to close or to diversify into the manufacture of other bromine compounds. On the other hand, if EPA regulations were modified, there could be much more demand for bromine than could be supplied by existing facilities.

Legislation and Government Programs.—Regulations issued by EPA during 1973 to reduce the lead content of gasoline for public health protection had a potentially critical effect on the bromine industry. Ethylene dibromide is added to gasoline in direct proportion to the amount of tetraethyl lead contained, and serves as a scavenger to remove lead from automobile engines after combustion. The average lead content of gasoline in 1973 was 2.2 grams per gallon, but EPA rules called for a reduction to an average of only 77% of the 1973 level by the end of 1974. The final goal was to reduce the lead content to an average of 0.5 gram per gallon, 23% of the 1973 level, by January 1, 1979.

In terms of ethylene dibromide production, the proposed 1974 reduction would amount to a loss of 73 million pounds, and the final EPA goal would reduce ethylene dibromide output by 243 million pounds per year. The Ethyl Corp. and others entered a lawsuit against EPA to nullify the 1973 regulations, contending that EPA had not proved that the use of lead in gasoline was detrimental to public health.

Bromine was not considered to be of strategic importance to the United States, and there was no Government-sponsored stockpile for bromine or its compounds. There was a small tariff, however, on imports of bromine and a few bromine compounds.

[1] Physical scientist, Division of Nonmetallic Minerals—Mineral Supply.

DOMESTIC PRODUCTION

Bromine production in 1973, from the leading State of Arkansas increased 13% over that of 1972, continuing the State's historic rise in bromine production. By contrast, Michigan showed about 3.8% decrease in bromine production. Approximately 9.4% of the bromine produced was sold in the elemental form to nonmanufacturers of bromine compounds.

In 1973, there were 10 bromine-producing plants in 3 States operated by 7 companies. Two of these plants confined their operations to the extraction of elemental bromine and did not manufacture compounds.

Table 1.—Elemental bromine sold as such or used in the preparation of bromine compounds by primary producers in the United States

(Thousand pounds and thousand dollars)

	Morton Chemical Co	Manistee	Manistee	Do.

CONSUMPTION AND USES

The Bureau of Mines does not survey the consumption of bromine and bromine compounds. From production records, however, it was known that 68% of the 1973 elemental bromine production went to the manufacture of ethylene dibromide. Most of this production was used as a gasoline additive, but the compound was also used as a solvent and in agriculture. In spite of pessimism in the industry over the future of ethylene dibromide as a gasoline additive, its consumption increased by 5.5% in 1973.

New developments in the consumption of bromine were centered around flame retardants and agricultural applications. Flame retardants for plastics provided a growing and potentially profitable outlet for bromine. Agricultural chemicals were led by methyl bromide, a soil sterilant and an insect fumigant. Many bromine-bearing agricultural chemicals were considered to be proprietary in nature.

Elemental bromine was utilized as a disinfectant, as an algaecide, and as an oxidizer in the manufacture of other chemicals.

PRICES

Prices for bromine and certain bromine compounds at yearend were quoted in the Chemical Marketing Reporter as follows:

	Cents per pound
Bromine, purified:	
Cases, carlots,	49
Cases, carlots, truckloads, delivered east of Rocky Mountains	49
Zone I:[1]	
Returnable drums, carlots, truckloads, delivered east of Rocky Mountains	20
Bulk tank car, tanktrucks (45,000-pound minimum), delivered	18
Ammonium bromide, national formulary (N.F.) granular, drums, carlots, truckload, freight equalized	48.0–48.5
Bromochloromethane, drums, carlots, freight equalized	54.5
Tanks, same basis	53
Ethyl bromide, technical, 98%, drums, carlots, freight allowed, East	68
Ethylene dibromide, drums, carlots, freight equalized	25
Tanks, freight equalized	20
Methyl bromide, distilled, tanks, 140,000-pound minimum, freight allowed	34
Potassium bromate, granular, powdered, 200-pound drums, carlots, freight allowed	64–77
Potassium bromide, N.F., granular, drums, carlots	43.5
Sodium bromide, N.F. granular, 400-pound drums, freight equalized	40

[1] Delivered prices for drums and bulk shipped west of Rockies, 1 cent per pound higher. Bulk truck prices 1 cent per pound higher for 30,000-pound minimum and 2 cents per pound higher for 15,000-pound minimum. Price f.o.b. Midland and Ludington, Mich., freight equalized, 1 cent per pound lower.

The average unit price of bulk elemental bromine as evaluated by producers in 1973 was 2.5% less than the 1972 average price, continuing a historic trend toward lower prices.

FOREIGN TRADE

The Bureau of Mines annual survey of bromine producers obtained information, for the first time, on exports of bromine and bromine compounds. The total reported for the United States is known not to include all shipments but is given below for reference:

1973 exports	*Quantity (pounds)*
Bromine in compounds	40,683,000
Elemental bromine	535,000
Total	41,218,000

A review article covering bromine activities in 1973[2] quoted H. W. Andre of the Great Lakes Chemical Corp. as saying that one-third of the U.S. production of ethylene dibromide (100 million pounds) was shipped overseas in 1973.

Imports of bromine compounds remained quite small in 1973, totaling only 57,000 pounds of contained bromine. Imports consisted mostly of potassium bromide and sodium bromide from Israel, France, Canada, and West Germany. Japan also shipped a small amount of ethylene dibromide to the United States in 1973.

WORLD REVIEW

The United States produced and consumed about 70% of the world bromine supply in 1973. The estimated production for other major bromine-producing countries is given in table 4. Bromine reserves in all producing countries are believed to be large, but quantities are unknown. Sea water, of course, provides an unlimited source of bromine at relatively low levels of bromine concentration.

In France, bromine is produced as a coproduct at the potash mines in Mulhouse in the Alsace area. Production from these mines is limited by law to prevent excessive damage to the ecology.

Israel has virtually unlimited resources of bromine in the waters of the Dead Sea, but the unstable political situation in that area has prevented extensive increases in present bromine production.

The United Kingdom is supplied with bromine in the waters of the Dead Sea, but tion on British bromine production is concealed to avoid disclosure of company confidential data. Very few mineral production facts are available from any of the Soviet bloc countries. Bromine production in the U.S.S.R. is indirectly estimated from related data at about 28 million pounds per year.

[2] Chemical & Engineering News. Bromine Outlook Tied to Clean Air Rules. V. 52, No. 8, Feb. 25, 1974, pp. 11–12.

Table 4.—Bromine: World production, by country[1]

(Thousand pounds)

Country[2]	1971	1972	1973[p]

United States	355,946	386,864	[e] 421,000

[e] Estimate. [p] Preliminary.

[1] Owing to incomplete reporting, this table has not been totaled.

[2] In addition to the countries listed, several other nations may also produce bromine (including, most notably, the U.S.S.R.), but output data are not reported and no basis is available for estimating output levels.

[3] Elemental bromine from thermal and marine waters only; additional bromine may be produced in the form of compounds and/or as elemental bromine from other sources.

[4] Spanish bromine production was officially reported to be 32 metric tons in 1971, but according to other Spanish sources, this figure is low, excluding quantities of elemental bromine that were consumed by the manufacturing firms in the process of producing bromine compounds. The Advisory and Technical Studies Commission of the Spanish Chemical Industry (Comisión Asesora y de Estudios Téchnicos de la Industria Quimica Española) indicates that 1971 output was of the order of 400 metric tons, and that productive capacity totaled 1,500 metric tons (source: La Industria Quimica en España 1971, Madrid, 1972, pp. 38–39). No later published figures are available.

TECHNOLOGY

Two scientists of The Dow Chemical Co. discovered[3] that bromine chloride was a more active brominating agent and was much less corrosive than bromine. Both chemicals required the presence of moisture to develop their corrosive nature, but moist bromine was found to be much more corrosive than bromine chloride.

An advance in pacemaker batteries was announced by General Electric Co.[4] The cell had a bromine cathode, a sodium-amalgam anode, and a beta-alumina ceramic electrolyte. Its expected life was about 10 years.

One increasing use for bromine was as a reagent to produce brominated vegetable oil, BVO.[5] This soybean-oil-based product was used mainly by soft drink producers to adjust the density and cloudiness of citrus flavorings. The safety aspects of BVO were under investigation by the U.S. Food and Drug Administration in 1973. Less than 1 million pounds of BVO per year were manufactured.

Cadmium

By J. M. Hague [1]

Declining domestic production of cadmium continued to reduce the percentage of United States self-sufficiency in a period of expanding domestic and world demand. Of 6,228 tons of cadmium apparently consumed in the United States in 1973, only about 32% came from domestic mines. U.S. zinc smelters produced 60% of the cadmium supply from a mixture of domestic and imported materials; net metal imports accounted for 29%, the Government stockpile 6%, and drawdown of industry stocks 5% of supply. Six companies produced primary cadmium at eight domestic plants. Canada was the major source of imported metal and concentrates. Price increases for cadmium during 1973, from $3 per pound to $3.75 per pound, were moderate when compared with other nonferrous metals. The unit of measure for statistical data contained in this chapter has been changed to short tons from the thousand pound measure used in previous editions.

Legislation and Government Programs.—Sales from the national stockpile administered by the General Services Administration (GSA) were 385 tons (770,405 pounds) in 1973. At the end of the year, the total stockpile inventory was 4,242 tons, including 21 tons already committed, the objective for retention was 2,223 tons, and the quantity available for disposal was 1,221 tons. Prices for GSA sales were at current producer prices for balls, and 5 cents below the producer price for sticks, f.o.b. storage locations in lots of 2,000 pounds or more.

In April 1973, the Office of Preparedness revised the stockpile objective for cadmium from 3,000 tons to 2,223 tons. A bill, H.R. 9596, was introduced in the Congress in July to authorize the release of this difference, 777 tons, from the national stockpile. No hearings had been held on this bill by the end of 1973. The previous authorization under Public Law 91–314 provided for the releases made throughout the year.

Phase 4 price controls were applied to cadmium by the Cost of Living Council on June 13, 1973, and were removed on December 6, 1973; the quoted price remained at $3.75 per pound throughout this period, and continued at that figure after the control was lifted.

Exploration cost assistance for cadmium is available from the Office of Minerals Exploration with 50% of allowable costs furnished by Government participation. No contracts were sought or active in 1973.

[1] Mining engineer, Division of Nonferrous Metals—Mineral Supply.

[3] Average quoted price for cadmium sticks and balls in lots of 1 to 5 tons.

DOMESTIC PRODUCTION

Domestic production of cadmium continued at a rate slightly below the 1972 pace, diminishing in each quarter until the fourth, which showed a recovery to a quarterly rate close to 950 tons. The long-term decline in cadmium production was an expected result of declining zinc production, but the two do not show a direct correlation owing to stockpiling of intermediate products and variations in cadmium content of zinc concentrates received by zinc-cadmium producers. Total production for 1973 was 3,714 tons, a decrease of 10% from the 1972 level. Shipments exceeded production as stocks were drawn down, and the value of shipments increased 26% to $24 million, mostly because of price increases early in the year.

Imports of flue dust from Mexico decreased 78% from the 1972 rate, further decreasing the supply of raw material for domestic producers. Imports of zinc concentrate decreased 22%, which also reduced the cadmium content available for domestic recovery.

The cadmium content of sulfide compounds produced (including cadmium sulfoselenide and cadmium lithopone) increased 4% over the level of the previous year, reaching a 38% share of total domestic production.

Cadmium oxide was produced at two plants and cadmium metal was produced at eight plants, all owned by six companies; secondary cadmium was remelted or refined at one secondary metal plant.

Table 2.—Cadmium sulfide[1] produced in the United States

(Short tons)

Year	Sulfide[2] (cadmium content)
1969	1,220

1971	1,118
1972	1,357
1973	1,412

[1] Cadmium oxide withheld to avoid disclosing individual company confidential data.

[2] Includes cadmium lithopone and cadmium sulfoselenide.

CONSUMPTION AND USES

The apparent consumption of cadmium, a total of 6,228 tons, was little changed from the 1972 consumption. (See figure 1.) Government sales continued to contribute substantially to the total supply.

Metal used for electroplating parts for appliances, motor vehicles, machinery, and hardware probably accounted for slightly less than half of U.S. consumption. Compounds used as colorants (red, orange, yellow) in paints and frits, and compounds used as stabilizers in plastics accounted for about one-third of the total usage. Nickel-cadmium and silver-cadmium batteries, alloys, cadmium phosphors, and other uses accounted for the one-sixth remainder.

STOCKS

Stocks held by industry declined 20% in 1973, continuing the decline of 1972. Stocks of cadmium metal and cadmium content of compounds at the end of 1973 totaled 1,326 tons, half of the inventory of 2 years ago. Cadmium remaining in the GSA stockpile, not included in the table, was 4,242 tons, of which 1,221 tons was presently available for disposal.

r Revised. W Withheld to avoid disclosing individual company confidential data; included with "Compound manufacturers."

PRICES

Producer prices for cadmium at the beginning of the year were $3.00 per pound for 1-ton lots. On January 25, the price was raised to $3.25 per pound by American Smelting & Refining Co. (Asarco); other producers followed this lead the next day. On March 1, Bunker Hill Co. raised its price to $3.50 per pound and Asarco, Cominco, Ltd., and American Metal Climax Inc. (AMAX) then quoted $3.75, but St. Joe Minerals Corp. and The New Jersey Zinc Co. remained at $3.25 throughout March. Early in April all producers moved to the $3.75 per pound quotation, and this quoted price remained unchanged to the end of the year. Dealer prices were 15 to 20 cents below the producer price in much of the second quarter and part of the third quarter, more in line with lower European prices. By the end of the year, U.S. dealer quotations were only 5 to 10 cents under the $3.75 producer price, and the European price was $3.60 to $3.65 per pound.

April 2 to Dec. 31	3.75

FOREIGN TRADE

Exports of cadmium metal and scrap decreased from 509 tons in 1972 to 153 tons in 1973. Principal destinations were as follows: France 43%, Belgium 20%, Japan 13%, and West Germany 11%. Much of the cadmium going to Belgium was probably scrap or secondary material sent for refining in European plants.

Imports of cadmium metal increased by 61% to compensate in part for the marked decrease in imports of flue dust from Mexico. Canada was again the main source of imported metal, accounting for 41% of the total. Other sources of foreign cadmium were Australia 18%, Belgium-Luxembourg 17%, Peru 5%, and others 19%.

No duties are imposed on metal or flue dust imported from most-favored nations, but a statutory duty of 15 cents per pound is levied on cadmium metal imported from communist-bloc countries, except Yugoslavia.

Table 6.—U.S. exports of cadmium metal and cadmium in alloys, dross, flue dust, residues, and scrap

WORLD REVIEW

World smelter production of cadmium increased 2.0% to a preliminary total of 18,747 short tons, not equaling the record 19,374 tons produced in 1969. The United States was the largest metal producer with 20% of the total, followed by Japan 18%, U.S.S.R. 15%, Belgium 8%, West Germany 7%, Canada 5%, and other countries 27%.

Apparent consumption in the United States was about 33% of world production. Table 8 presents data on world cadmium smelter production.

During 1973, the U.S. Geological Survey published a review of world cadmium ores and resources.[2] The average ratio of zinc to cadmium in "average world zinc concentrate" is given as 230:1, but selected assays show a wide regional variation. U.S. smelters recovered cadmium as a byproduct of zinc production in the ratio of 1:229, indicating that materials fed to U.S. smelters contain slightly more cadmium than the world average and also suggesting that U.S. smelter recovery is reasonably good.

During 1973, an increase in cadmium plant capacity was announced by Texasgulf Inc., at its Timmins, Ontario, Canada, plant, and a new cadmium producing plant was started by Amax Zinc Company, Inc., at Sauget, Ill. Amax plans to gradually phase out cadmium production at the Blackwell, Okla., zinc smelter. Two large Japanese producers announced cutbacks in cadmium production because of the energy shortage.

e Estimate. p Preliminary. r Revised.

[1] Table gives unwrought metal production from ores, concentrates, flue dusts, and other materials of both domestic and imported origin. Sources generally do not indicate if secondary metal (recovery from scrap) is included; where known, this has been indicated by footnote. Data derived in part from World Metal Statistics (published by World Bureau of Metal Statistics, London) and from Metal Statistics (published by Metallgesellschaft Aktiengesellschaft, Frankfurt am Main). Cadmium is produced in ores, concentrates, and flue dusts in a number of other countries, but these materials are exported for treatment elsewhere to recover cadmium metal, therefore such output is not recorded in this table to avoid double counting.

[2] Includes secondary.

[3] Output of Tsumeb Corp. Ltd. for year ending June 30, 1971.

[4] Output of Tsumeb Corp. Ltd. for calendar year 1972.

TECHNOLOGY

During 1973, the National Environmental Research Center was reviewing the current knowledge of cadmium in the environment seeking to set standards for control consistent with the provisions of the Clean Air Act. In July, the Environmental Protection Agency (EPA) issued a list of toxic pollutants, including cadmium and cadmium compounds, in accordance with provisions of the Water Pollution Control Act. Interested parties were invited to submit comments concerning establishment of standards for effluents to meet the requirements of the Act.[3] Late in December, EPA proposed effluent standards for nine toxic pollutants, including cadmium, restricting discharges into navigable waters.[4] The daily average cadmium concentration permitted depends on the flow of the stream into which discharge is made, but shall not exceed 40 micrograms per liter in fresh water and is further restricted by a daily weight limit.

Continued interest in cadmium in the environment was shown by numerous papers

[3] Federal Register. Proposed List of Toxic Pollutants. V. 38, No. 129, July 6, 1973, pp. 18044–18045.

[4] Federal Register. Proposed Toxic Pollutant Effluent Standards. V. 38, No. 247, Dec. 27, 1973, pp. 35388–35395.

in a wide variety of scientific and engineering publications.[5]

The cadmium content of Illinois coals was investigated by the Illinois State Geological Survey; the range reported was 0.3 to 28 parts per million, with cadmium occurring as a solid solution component of sphalerite (ZnS) particles which were separated by heavy-liquid concentration from the low-temperature ash.[6]

An electrochemical process for removing cadmium, mercury, chromium, lead, and other heavy metals from waste water effluents was developed by a division of Rockwell International at Canoga Park, Calif., under the sponsorship of the State of California. Metallic impurities are plated out on a bed of fluidized conductive particles. Projected operating costs are claimed to be competitive with chemical precipitation or ion-exchange processes.[7]

Interest grew during 1973 in the development of solar energy systems using cadmium sulfide photovoltaic cells. Solar energy research programs are being conducted at the University of Delaware and several other U.S. universities as well as research centers in Japan, U.S.S.R., Israel, Australia, and other countries.[8]

A rapid method of measuring minute concentrations of cadmium was announced using an absorption spectrophotometer developed by Varian Associates, Palo Alto, Calif.[9]

A patent was granted and assigned to Bunker Hill Co. for the precipitation of cadmium from zinc sulfate solutions used in the electrolytic recovery of zinc.[10]

Conditions in a single pore of a cadmium battery plate were studied using microscopy to reveal the morphology causing loss in capacity on repeated charge and discharge.[11]

Diffusion in the silver-cadmium alloy system at 600° C was investigated to determine intrinsic diffusion coefficients and vacancy wind effects found to be appreciable in this system.[12]

Developments in cadmium technology are frequently abstracted in Zinc Abstracts, a bimonthly publication available free of charge from the Zinc Institute, Inc., 292 Madison Avenue, New York, N.Y. 10017. Numerous publications on cadmium were reviewed during 1973 describing diffusion, densities and other properties of alloys, treatment of urban and industrial effluents, the solid state physics of cadmium compounds used for semiconductors and photoconductive films, vacuum metallizing, occupational health hazards, classification for pigments, brush plating, distillation of cadmium and lead from Waelz oxides, nickel-cadmium battery components, distribution of cadmium in deep sea sediments, addition agents in cadmium plating, determination of cadmium in blood, permissible limits of metal release from glazed ceramic ware (British), corrosion resistance studies of plating and alloys, surveys of and determination of trace amounts of cadmium in

Calcium and Calcium Compounds

By Avery H. Reed [1]

One company in Connecticut manufactured calcium metal. Calcium-magnesium chloride was produced by two firms in California and three in Michigan. Synthetic calcium-magnesium chloride was manufactured by four companies, in New York, Ohio, and Washington.

DOMESTIC PRODUCTION

Pfizer Inc. produced calcium metal at its Canaan, Conn., plant by the Pidgeon process, in which quicklime and aluminum powder are heated in vacuum retorts. At 1,170° C, calcium vaporizes and is collected at one end of the retort.

Leslie Salt Co. and National Chloride Co. of America produced calcium-magnesium chloride from dry lake beds in San Bernardino County, Calif. Output declined 8%. The Dow Chemical Co., Michigan Chemical Corp., and Wilkinson Chemical Corp. recovered calcium-magnesium chloride from wells in Gratiot, Lapeer, Mason, and Midland Counties, Mich. Output increased 3%.

Total production of natural calcium-magnesium chloride was 609,000 tons, 3% more than that in 1972 but 7% below the 1969 record.

Allied Chemical Corp., Syracuse, N.Y.; PPG Industries, Inc., Barberton, Ohio; and Reichold Chemicals, Inc., and Hooker Chemical Corp., Tacoma, Wash., manufactured synthetic calcium-magnesium chloride as a byproduct of soda ash. Total output decreased 23% to 249,000 tons and was 40% below the 1968 record. During the year, PPG Industries and Hooker Chemical Corp. closed their plants.

CONSUMPTION AND USES

Calcium metal was used as a reducing agent to separate such metals as columbium, tantalum, thorium, titanium, uranium, vanadium, and zirconium from their oxides; to form alloys with aluminum, lead, lithium, magnesium, and silicon; as a scavenger in the steel industry; and in the manufacture of calcium hydride.

The principal use for calcium-magnesium chloride was to melt snow and ice from roads, streets, bridges, and pavements. It was also used as a dust suppresant on roads and driveways, and as an accelerator for concrete.

[1] Physical scientist, Division of Nonmetallic Minerals—Mineral Supply.

PRICES AND SPECIFICATIONS

Calcium metal prices in 1972 ranged from $1 to $5 per pound. Calcium chloride is usually sold either as solid flake or pellet averaging about 75% $CaCl_2$, or as a concentrated liquid averaging about 40% $CaCl_2$. In 1973, on a 75% basis, average value for natural calcium chloride was $28.90; the average value for synthetic calcium chloride was $36.30.

Table 1.—Price quotations for calcium chloride

(Per short ton)

Grade	Dec. 24, 1972	Dec. 31, 1973
Flake or pellet, 94%–97% [1]	$56.50	$57.75
Flake, 77%–80% [1]	44.50	45.00
Powdered, 77% minimum [1]	52.50	53.00

FOREIGN TRADE

Exports of calcium chloride in 1973, mainly to Canada, Mexico, Austria, and Brazil, totaled 889 tons valued at $117,779. Dicalcium phosphate exports, mainly to Mexico, Canada, Italy, and Brazil, were 2,447 tons valued at $369,707. Exports of precipitated calcium carbonate totaled 385 tons valued at $35,236 and were mainly to Canada, Mexico, El Salvador, and Japan.

Total imports of calcium and calcium compounds were 231,000 tons valued at $10,181,000. Imports of calcium metal from Ontario, Canada, were 55 tons valued at $77,864. Calcium chloride imports, mainly from Canada, were 7,357 tons valued at $317,007, an increase of 20% from those of 1972. Imports of other calcium compounds, mainly from Norway, the Netherlands, France, and Turkey, were 224,000 tons valued at $9,774,000.

The other calcium compounds imported included 156,113 tons of calcium nitrate from Norway, the Netherlands, Sweden, and Canada; 26,653 tons of whiting from France, the United Kingdom, Switzerland, West Germany, and Belgium; 18,216 tons of calcium borate from Turkey; 7,143 tons of calcium carbide from Canada and France; 3,893 tons of calcium cyanide from Canada, Japan, and Mexico; 3,794 tons of calcium cyanamide from Canada, Norway, West Germany, and Japan: 3,332 tons of precipitated calcium carbonate from the United Kingdom, Japan, and West Germany; 2,755 tons of dicalcium phosphate from Belgium and Canada; 530 tons of calcium hypochlorite from Japan; 140 tons of chlorinated lime from the United Kingdom and West Germany; and 1,013 tons of miscellaneous calcium compounds, mainly from Canada, Japan, and Switzerland.

Table 2.—U.S. imports for consumption of calcium and calcium chloride

Year	Calcium		Calcium chloride	
	Quantity (pounds)	Value	Quantity (short tons)	Value
1969	662,200	$619,000	9,226	$349,998
1970	164,769	141,125	8,280	359,096
1971	48,391	29,751	13,019	543,656
1972	248,080	181,437	6,128	225,463
1973	110,407	77,864	7,357	317,007

Table 3—U.S. imports for consumption of calcium chloride, by country, in 1973

Country	Quantity (short tons)	Value
Belgium-Luxembourg	212	$13,893
Canada	6,918	251,702
Germany, West	50	40,806
Japan	165	9,900
United Kingdom	12	706
Total	7,357	317,007

WORLD REVIEW

Canada.—Chromasco Corp. Ltd. produced calcium metal at its Haley smelter near Renfrew, Ontario. Canada continued to lead all other countries in the production of calcium metal; output in 1972 was 477,000 pounds valued at $342,000. Canada was the leading source of U.S. imports of calcium chloride.

France.—Planet-Wattohm S.A., a subsidiary of Compagnie de Mokta, produced calcium metal by the Pidgeon process.

TECHNOLOGY

Calcium deoxidation has given rise to a new family of more machinable steels for carburized worms and pinions. Fine-grain steels, developed by Republic Steel Corp. and sold under the trade name "Cal-DeOx" carbon and alloy gear steels, can improve cutter life 30% to 100%. Longitudinal mechanical properties and heat-treat response in annealing, and carburizing and hardening for the new steels are similar to aluminum-silicon deoxidized steel. However, Cal-DeOx steels are expected to have better transverse properties and fatigue resistance. One gear and axle plant already has increased productivity 25% by switching to the new steels.[2]

---

[2] Materials Engineering. Calcium Deoxidized Steels Improve Gear Cutting. V. 77, No. 7, May 1973, pp. 48–50.

Carbon Black

By John L. Albright [1]

Carbon black production and shipments increased during 1973, continuing the trend of the last 3 years. Domestic sales reached 3,314 million pounds, more than double the sales of 20 years earlier. Producers' stocks declined below the 1972 level. Texas produced more carbon black than any other State, and Louisiana maintained its position as the country's second largest producer. Total production was 3,500 million pounds. Increased furnace black production more than offset declines in channel black, and total production recorded a 9.3% increase over the 1972 output. Overall demand continued to increase, although channel black, Intermediate-Abrasion Furnace (ISAF) and Superabrasion Furnace (SAF) production and shipments decreased during 1973.

Shipments totaled 3,507 million pounds, including 192.7 million pounds exported. Domestic shipments increased for the third consecutive year and totaled 3,315 million pounds, surpassing the previous year's shipments by 5.3%. Exports, ending a 4-year downward trend, increased 81 million pounds over the 1972 low and totaled 193 million pounds in 1973. Imported carbon black and bone black totaled 8.7 million pounds and was supplied mainly by Canada, Indonesia, and West Germany.

Numerous industries utilized carbon black, but the largest volumes were consumed by ink, paint, plastic, and rubber products manufacturers. The rubber industry continued to be the largest consumer, and most carbon black went into the manufacture of highway vehicle tires and tubes. According to the Rubber Manufacturers Association, Inc., 189.2 million motorcycle and passenger tires were produced in 1973, a decrease of 3.3% from the previous year; bus and truck tire production reached a record 34.3 million units, up 0.8% from that of 1972. Combined tire shipments during the year totaled 238.9 million units, including exports.

Carbon black producing plants operated at 82.9% capacity in 1973, the highest rate reported since 1968, and plant capacity increased 1.4% during 1973. Daily plant capacity has grown 4.5 million pounds during the last 10 years. More than three-fourths of the carbon black plant capacity is in Louisiana and Texas.

Average value of carbon black produced was 8.12 cents per pound in 1973, an increase of 0.36 cent per pound over the 1972 average. Recent annual average values had not exceeded 8 cents per pound. Carbon black production from liquid hydrocarbons and natural gas, with nearly 93% of the production from liquid hydrocarbons feedstocks, was up 1.4% from 1972 and 3.6% from 1971. Natural gas feedstock continued its downward trend; the volume of natural gas used declined 4,257 million cubic feet. Yield from natural gas declined 24.6 million pounds, from 5.02 pounds per thousand cubic feet in 1972 to 4.96 pounds per thousand cubic feet in 1973. More than 32 million additional gallons of liquid hydrocarbon feedstocks were utilized, and average yield of carbon black from this feedstock increased from 4.96 to 5.22 pounds per gallon.

---

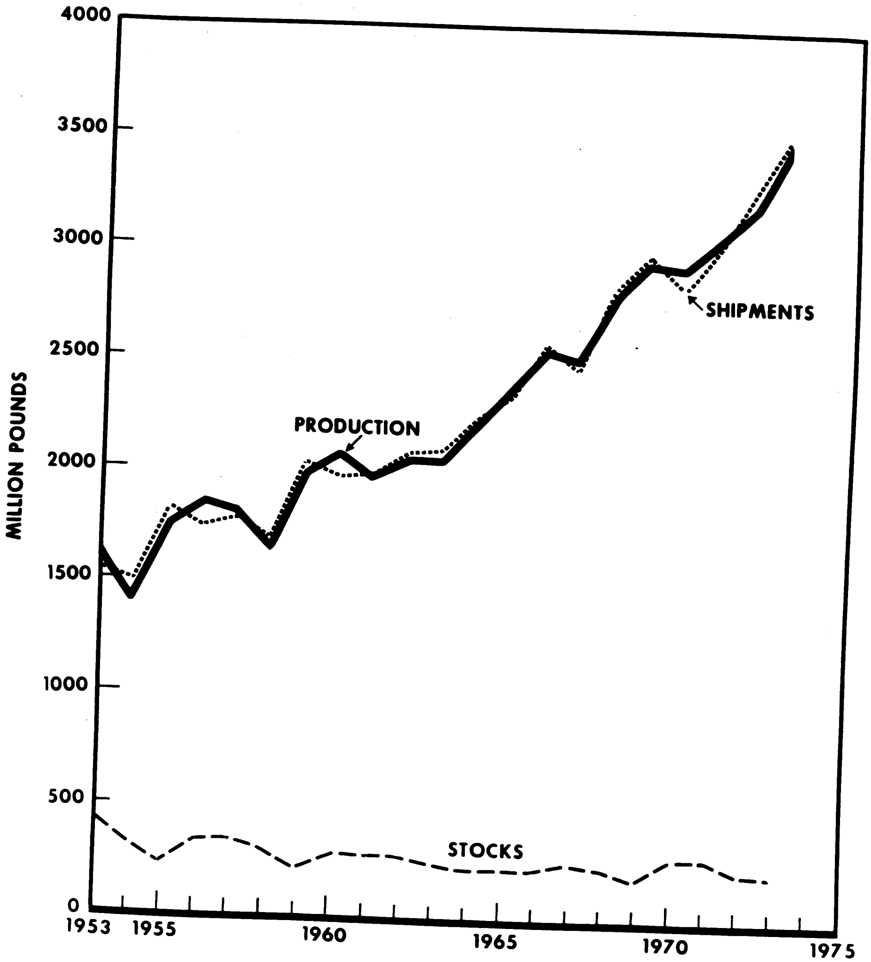

Figure 1.—Production, stocks, and shipments of carbon black.

PRODUCTION AND CAPACITY

Production by State.—In 1973, carbon black production totaled 3,500 million pounds, an increase of 299 million pounds over the previous year's total. Louisiana and Texas plants produced an aggregate of 2,719 million pounds, 77.7% of the national total. The remaining carbon black production came from plants in Alabama, Arkansas, California, Kansas, Ohio, Oklahoma, and West Virginia.

Production by Grade and Type.—Seven major grades of carbon black, produced by the furnace combustion and thermal cracking methods, comprised 99.6% of the 1973 production. The remainder was produced by the channel black process, which continued its long-term diminishing pattern. Channel black production was 14 million pounds in 1973, down 36.5% from the previous year. The combined production of General-Purpose Furnace (GPF) and High-Abrasion Furnace (HAF) grades accounted for 60.5% of the furnace blacks produced. Semireinforcing Furnace (SRF) was the major grade of carbon black produced by the gas furnace process.

Number and Capacity of Plants.—Thirty-four carbon black plants continued to operate in the United States, unchanged from the previous year, and more than three-fourths of the installed plant capacity was in Louisiana and Texas. Although no new plants were constructed, capacities of existing plants were increased during the year. Cabot Corp. introduced new technology furnace blacks in 1973 to replace many of the darkest color channel blacks for specialty applications. The corporation announced plans to shut down its last channel black plant during 1974. Cabot's new product, Large-Particle Furnace (LPF), was developed as a replacement for regular thermal black. Significant capital expenditures were made by Cabot during 1973 for modernization of the Ville Platte, La., plant and for expansions at the Franklin, La., installation. During 1973 Cabot added approximately 120 million pounds per year of furnace black plant capacity and reduced the capacity of thermal black by approximately 30 million pounds per year.

J. M. Huber Corp. continued expanding its Texas carbon black plants. A second thermal black unit was completed during 1973, at Borger, increasing the company's annual thermal capacity to 42 million pounds. Other improvements underway at the Baytown and Borger, Tex., facilities were scheduled for completion in mid-1974. At that time, the company's annual capacity of oil furnace blacks will be 333 million pounds, and the gas furnace black annual capacity will be 36 million pounds.

Phillips Petroleum Co. added 20 million pounds per year capacity to its Borger, Tex., carbon black plant. A further 47 million pounds of yearly capacity was authorized to be added to Phillip's Texas facilities, 27 million pounds at Borger and the remainder at Orange.

Materials Used and Yields.—In 1973, a total of 623.2 million gallons of liquid hydrocarbons was consumed in the manufacture of 3,254 million pounds of carbon black. There was 32 million gallons more of liquid hydrocarbons consumed in 1973 than in 1972. Yields averaged 5.22 pounds per gallon from liquid hydrocarbons, compared with 4.96 pounds per gallon in 1972. Natural gas feedstock decreased 4,257 million cubic feet to 49,682 million cubic feet, and the volume of carbon black produced from natural gas was 246 million pounds, a decline of 24.6 million pounds from the 1972 production. Yields from natural gas in 1973 averaged 4.96 pounds of carbon black per thousand cubic feet, a decrease of 1.2% from that of the previous year.

CONSUMPTION AND USES

Over 90% of the carbon black consumption was in rubber applications, and the rubber tire industry was the principal consumer. Carbon black is an essential ingredient in the manufacture of tires. Passenger car tires use 6 to 7 pounds of carbon black each, and average truck tires contain approximately 20 pounds of blacks. Domestic sales of carbon black increased in 1973 by 166.9 million pounds, or 5.3%. Aggregate sales enjoyed the third consecutive year of growth, as records were established in all major consuming sectors, except the paper industry. Sales for use in the manufacture of ink increased 1.8 million pounds and those to the rubber industry increased to 3,115 million pounds in 1973.

STOCKS

Yearend 1973 carbon black stocks were 230.3 million pounds, down 7.4 million pounds from the yearend 1972 inventory. Channel black stocks declined significantly from 7.7 million pounds to 2.4 million pounds, and furnace black inventories were 2.0 million pounds below the yearend 1972 level. Yearend 1973 stocks of GPF, HAF, and SRF grades of furnace blacks were slightly higher than stocks available at the end of 1972, but this increase was offset by reduced stocks of thermal, Fast-Extrusion Furnace (FEF), ISAF, and SAF grades of carbon blacks.

FOREIGN TRADE

Carbon black exports totaled 192.7 million pounds, an increase of 81.4 million pounds over the 1972 total, and was the largest volume exported since 1969. Channel black accounted for less than 8% of the quantity exported but 31% of the $24.1 million total value of exported carbon blacks. Average value of channel black exported in 1973 was 49.9 cents per pound, (46.3 cents per pound in 1972) and that of furnace black was 9.3 cents per pound (9.4 cents per pound in 1972).

The Netherlands, Canada, and Brazil purchased the largest consignments of U.S. produced carbon black, followed by France, Taiwan, and Japan. These six countries accounted for more than 63% of U.S. exports. Carbon black imported during 1973 amounted to 8.7 million pounds plus 230 thousand pounds of bone black. This represented an impressive increase from the 1972 carbon black imports, but imported blacks accounted for only 0.2% of total supplies. More than 96% of the imported material originated in Canada, Indonesia, and West Germany. In 1973, imported carbon black was valued at an average 11.4 cents per pound compared with the average value of 12.5 cents per pound for exported carbon blacks; the 1972 values were 15.3 and 13.4 cents per pound respectively.

WORLD REVIEW

More than three-fourths of the known worldwide carbon black production was from Western European and North American plants. North America accounted for nearly half of the 1973 world production of carbon black. The Republic of South Africa was the only producer in Africa. Production information was sparse for Communist countries. The United States, Japan, and West Germany were the three largest producers, as shown in table 11.

In 1973, world demand was strong for carbon black, and plants operated at near capacity. Increased shipments were recorded by carbon black producers in most countries, as 1973 sales surpassed previous levels, and production and bulk storage installations were expanded to meet increasing demand. In Canada, Cancarb Ltd. completed the construction of the Medicine Hat, Alberta, thermal carbon black plant, with an initial capacity of 40 million pounds annually of pelletized medium thermal black.

New carbon black plants were inaugurated in Asia and the Middle East. Plans were finalized for a 25-million-pound-per-year plant to be built by Australian Carbon Black Pty., Ltd. (ACB) near Port Dickson, Malaysia. Malaysian Government and private groups will hold 50% ownership in the new plant, and ACB will hold the remaining stock and will operate the facility. Iran Carbon Co.'s carbon black plant, the first in the Middle East, was under construction during 1973 at Akwaz, Iran. It is scheduled to begin production in 1974. Initially, the plant will have an annual capacity of 33 million pounds and will market most of its products domestically. After 4 years of operation, the Iranian plant's capacity is to be doubled, and exports will commence to consumers along the Indian Ocean, the Persian Gulf, and the Red Sea.

Cities Service Co. and Phillips Petroleum Co. acquired 50% interest each in the Sevalco Ltd. (formerly Philblack Ltd.), Bristol, England, carbon black plant. The Bristol facility had an annual capacity of 251 million pounds. During 1973 Continental Carbon Co. sold a license to a Taiwan firm to use its patent rights and technical knowledge in the manufacture of carbon black in that country.

TECHNOLOGY

Carbon black, a petrochemical, is an extremely fine soot, primarily carbon (90% to 99%), that contains some hydrogen and oxygen. Oil furnace black may also contain small amounts of sulfur. Properties of carbon black are determined largely by the process by which it is manufactured. Furnace black, which accounts for 99% of all carbon black produced, is made by three different processes—gas furnace, oil furnace, and thermal. Brief descriptions follow of these processes, the channel process, and the manufacture of lampblack and acetylene black.

Gas Furnace.—The gas furnace process is based on partial combustion of natural gas in refractory-lined furnaces. Carbon black is removed by flocculation and high-voltage electric precipitators. Yields of the gas furnace blacks range from 10% to 30% and are lowest for the smaller particle-size grades. Properties of gas furnace blacks can be modified to a degree by changing the ratio of air to gas. High-Modulus Furnace (HMF) and SRF grades are generally produced from gas.

Oil Furnace.—Liquid hydrocarbons are used in the oil furnace process. Natural gas is generally burned to furnish the heat of combustion, and atomized oil is introduced into the combustion zone to be burned to various grades of carbon black. Yields range from 35% to 65%, depending on the grade of black produced. Oil furnace grades are FEF, GPF, HAF, ISAF, and SAF.

The most desirable feedstock oil for furnace black plants has 0° to 4° API gravity, is low in sulfur, and is high in aromatics and olefins. It comes from near the "bottom of the refinery barrel" and is similar in many respects to residual fuel oil. Rising costs of natural gas have been a factor in the shift to greater use of liquid feedstocks and a decline in the use of natural gas as a source of carbon. Oil furnace processing has become highly flexible, supplementing channel blacks in most high-performance applications, notably passenger car tires. Over the past 2 decades, carbon black technology has centered on the oil furnace black process.

Thermal.—Unlike channel and furnace blacks, thermal blacks are produced by cracking hydrocarbons; that is, by separating carbon from the hydrogen and not by the combustion of hydrocarbons. Thermal furnaces are built in a checkerboard brickwork pattern. Two refractory-lined furnaces, or generators, are used. One generator is heated using hydrogen as a fuel, while the other generator is charged with natural gas, which decomposes to produce thermal black and hydrogen. Hydrogen collected is used as fuel for the generator being heated. Yields of carbon black are primarily in the large particle sizes and range from 40% to 50%.

Channel Black.—Made by the oldest process, channel black is a product of incomplete combustion of natural gas. Small flames are impinged on cool surfaces, or channels, where carbon black is deposited and then scraped off as the channel moves back and forth over a scraper. Properties of channel black are varied by changes in burner tip design, distances from tip to channel, and the amount of air made available for combustion. The process is extraordinarily inefficient chemically. For rubber-reinforcing grades, the yield is only 5%; for high-color blacks of finer particle sizes, the yield shrinks to 1%. Low yields and rising gas prices have spurred the industry to develop other methods to make blacks.

Lampblacks.—Lampblacks are manufactured by slowly burning selected oils and tars in a restricted supply of air. These blacks are of large particle size, possess little reinforcing ability in rubber, and are low in jetness and coloring power. They are of value as tinting pigments in certain paints and lacquers. In most applications lampblacks have been replaced by carbon blacks.

Acetylene Black.—Acetylene blacks, produced by the thermal decomposition of acetylene, possess a high structural, or chaining, tendency. Their particle size is about 40 millimicrons. They provide high elastic modulus and high conductivity in rubber stocks.

Coal-derived carbon blacks have yet to be produced commercially, but several small companies are marketing carbon black extenders and fillers which are produced from anthracite and bituminous coals. These carbon black substitutes are used in rubber compounding and in the production of carbon paper, ink, paint, and plastic. Extenders-fillers from coal are being utilized in conjunction with furnace carbon blacks, replacing thermal carbon blacks.

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, the People's Republic of China, Norway, Poland, Turkey and the U.S.S.R. produce carbon black, but available information is inadequate to make reliable estimates of production levels.

[2] Less than ½ unit.

Cement

By Robert E. Ela [1]

Portland cement shipments from plants in the United States and Puerto Rico continued at record levels for the third consecutive year to attain a new high of 86,399,000 tons in 1973, surpassing the 1972 record by 6%. Mill value rose to $1.89 billion, an increase of 15%, reflecting a unit increase of $1.57 per ton.

The supply and demand relationship changed dramatically in many parts of the country. Contributing factors were curtailed production due to previous closings of older and uneconomical plants, minor fuel shortages, shifting markets, labor disputes, severe weather conditions, and spring floods. The construction industry which represents virtually the entire market for the cement industry reached an historical milestone in 1973 when over $100 billion in contracts were awarded.

During the year increased volume in industrial, commercial, and government construction projects, such as mass transit, more than offset a decline in residential and highway construction. Housing starts declined because of increased lumber prices, labor costs, and high interest rates.

The cement industry, which only recently became highly dependent on oil and natural gas for its fuel requirements, was now returning to coal as a means of assuring uninterrupted production. Many companies were initiating plans to secure adequate supplies of fuel for existing systems.

Two companies changed corporate names. American Cement Corp. was changed to Amcord, Inc., and Penn Dixie Cement Corp. was changed to Penn Dixie Industries. Columbia Cement Company Division of PPG Industries, Inc., was sold to Filtrol Corp. in mid-1973. The sale involved the plants at Bellingham, Wash., and Zanesville, Ohio, and all distribution facilities. The cement plant at Barberton, Ohio, was not included in the sale and continued to operate as a unit of the Chemical Division of PPG Industries, Inc.

Statistical data in some of the tabulations are arranged by cement districts. A cement district represents either a State, a segment

[1] Statistical specialist, Division of Nonmetallic Minerals—Mineral Supply.

r Revised.
[1] Excludes Puerto Rico.
[2] Includes portland, masonry, and slag cement (1969). Excludes slag cement (1970–73).
[3] Includes imported cement shipped by domestic producers only.
[4] Value received, f.o.b. mill, excluding cost of containers.
[5] Includes portland, masonry (1970–73), slag cement (1969).
[6] Quantity shipped plus imports minus exports.
[7] Adjusted to eliminate duplication of import (clinker and cement) shipped by domestic cement manufacturers.

of a State, or a group of States not necessarily contiguous. The States of California, New York, and Pennsylvania are further divided to provide additional marketing information. The divisions for these States are as follows:

California, Northern.—Points north and west of the northern borders of San Luis Obispo and Kern Counties and the western borders of Inyo and Mono Counties.

California, Southern.—All other counties in California.

New York, Western.—All counties west of a dividing line following the eastern boundaries of St. Lawrence, Lewis, Oneida, Madison, Chenango, and Broome Counties.

New York, Eastern.—All counties east of the above dividing line.

New York, Metropolitan.—The five counties of New York City, (Bronx, Kings, New York, Queens, and Richmond) plus Westchester, Rockland, Suffolk, and Nassau Counties.

Pennsylvania, Eastern.—All counties east of the eastern boundaries of Potter, Clinton, Centre, Huntingdon, and Franklin Counties.

Pennsylvania, Western.—All other counties in Pennsylvania.

Legislation and Government Programs.—On November 27 the Cost of Living Council (CLC) exempted from price and wage controls (under the Economic Stabilization Program) manufacturers' sales of cement and wages paid to workers in the cement industry. The exemption from price controls applied to cements listed in Part 9 of the 1973 Annual Book of ASTM Standards as follows: C–150 (portland cement); C–10 (natural cement); C–91 (masonry cement); C–595 (blended hydraulic cements); and expansive, calcium aluminate, oil well, plastic, and regulated-set cements. The CLC received commitments that production capacity would be increased expeditiously to alleviate developing supply problems.

The United Cement, Lime, and Gypsum Workers International Union and the Cement Employers Association agreed to establish a series of joint meetings to consider and discuss labor relation problems in the cement industry.

Public Law 93–87, an act to authorize appropriations for the construction of certain highways in accordance with title 23 of the United States Code and for other purposes, was passed on August 13, 1973.

In a suit brought by the Portland Cement Association the United States Court of Appeals for the District of Columbia Circuit ruled that Environmental Protection Agency (EPA) procedures left the question of achievability in doubt and precluded cement manufacturers from demonstrating that the standards were not achievable. The EPA, recognizing that emission of dust in excess of standards will occur for short periods during startup, shutdown, and equipment malfunctions, amended its air pollution standards for new and substantially modified cement plants.

On September 7, 1973, EPA published in the Federal Register, volume 38, No. 173, a notice of proposed rulemaking for the cement manufacturing category relating to effluent limitations guidelines for existing sources and standards of performance and pretreatment standards for new sources. The EPA also published a document entitled "Economic Analysis of Proposed Effluent Guidelines: Cement Industry." The document was available in limited quantities through EPA.

The Federal Trade Commission (FTC) approved an agreement by OKC Corp. to sell the ready-mix concrete and building materials operation of Jahncke Service, Inc. The remaining assets of Jahncke will be sold in compliance with the FTC divestiture order. Under the terms of an FTC consent order issued in June 1972, Lehigh Portland Cement Co. sold its wholly-owned subsidiary, Virginia Concrete Co., and had until June 1974 to select the divestiture of either its Miami, Fla., cement operation or certain Florida ready-mixed concrete operations. The divestiture of Botsford Ready-Mix Co. was also completed in accordance with the consent agreement entered into by the Missouri Portland Cement Co. and the FTC.

Environmental Activities.—Millions of dollars continued to be spent on advanced pollution control equipment to bring existing plants into full compliance with the National Environmental Policy Act (PL 91–109) signed into law January 1970.

Alpha Portland Industries, Inc., was installing additional pollution control equipment at its St. Louis, Mo., plant and installed an electrostatic precipitator at its Jamesville, N.Y., plant. Lone Star Industries, Inc., completed a new $3.5 million air quality control installation at its New Orleans, La., plant. Louisville Cement Co. placed a new electrostatic precipitator into service at Bessemer, Pa., to bring that plant's kilns into compliance with new emissions standards. Additional dust collection equipment was being installed by Medusa Cement Co. Div., Medusa Corp., at its York, Pa., and Charlevoix, Mich., plants. Improvement projects were begun by Martin Marietta Corp. at the Davenport, Iowa, and Calera, Ala., plants. Ideal Cement Co. Div., Ideal Basic Industries, Inc., installed new electrostatic precipitators at the Trident, Mont., and Devil's Slide, Utah, plants and at the existing Portland, Colo., plant. Projects were underway to upgrade precipitator performance at the Ada, Okla., and Mobile, Ala., plants.

Many companies were financing pollution control facilities through tax-exempt bonds and securities issued by municipalities and local government agencies. Companies will repay the loans under a lease arrangement with the local governments. These bond issues represented an effective means to raise capital at relatively low cost for essential but nonproductive equipment.

The city of Metropolis, Ill., authorized the issuance of pollution control and industrial development bonds to finance a portion of the expansion program by Missouri Portland Cement Co. at Joppa, Ill. Dundee Cement Co. negotiated the sale of $7 million of tax-exempt bonds to finance two major pollution control projects at the Dundee, Mich., plant. Cost of installation of pollution control equipment by Universal Atlas Cement Div., United States Steel Corp. at its new Leeds, Ala., plant will be financed by a $4.5 million environmental improvement revenue bond issued by the Industrial Development Board of the city of Leeds.

Amcord, Inc., was the defendant in litigation and in environmental control proceedings involving emissions from some of the company's cement plants.

Ideal Cement Co. Div., Ideal Basic Industries, Inc., phased out operations at its 60-year-old San Juan Bautista, Calif., plant and abandoned plans to construct a new plant at San Juan due to environmental problems. The company cited the attitudes toward construction, reflected by California court decisions, and voter response to environmental matters as having an influence that would restrict construction activity for the short range and have an adverse effect on the long range as well. Inflation and environmental design changes for the proposed new plant boosted the original estimated cost of $37 million to $48 million. The quarry and plant site will be rehabilitated following demolition of the old plant.

DOMESTIC PRODUCTION

PORTLAND CEMENT

The cement industry, in spite of operating clinker-producing plants at near capacity levels to meet the escalating demand for cement, had to import recordbreaking quantities of cement and clinker to meet domestic requirements.

Manufacturers in the United States and Puerto Rico produced 78.2 million tons of clinker, imported 2.7 million tons of clinker, and used stockpiled clinker to grind an alltime record 83.5 million tons of portland cement and 4 million tons of masonry cement.

Eight companies accounted for 41% of the total clinker and portland cement produced in the United States and Puerto Rico. They were: Amcord, Inc.; General Portland, Inc.; Ideal Cement Co. Div., Ideal Basic Industries, Inc.; Kaiser Cement & Gypsum Corp.; Lone Star Industries, Inc.; Marquette Cement Mfg. Co.; Martin Marietta Cement, Martin Marietta Corp.; and Universal Atlas Cement Div., United States Steel Corp.

Production Capacity.—The cement industry in the United States and Puerto Rico was capable of grinding 100.4 million tons of cement annually, based on the fineness necessary to grind Type I and II cement, and making allowances for downtime required for maintenance.

By yearend 471 kilns were operating at 166 plants, including eight white cement plants, in 41 States and Puerto Rico with an estimated 24-hour daily clinker production capacity of 274,000 tons. An average of 60 days downtime was reported for kiln maintenance and replacing refractory brick. Based on 305 days of operation, the apparent annual clinker production capacity of the industry was 84 million tons. The industry operated at 93.5% of its apparent capacity.

In addition to 166 clinker-producing plants, seven plants had only grinding mills operating on imported, purchased, or interplant transfers of clinker.

Capacity Changes.—An explosion and fire in recently installed electrostatic precipitators forced Marquette Cement Mfg. Co. to shut down its new kiln and cut back production at the Oglesby, Ill., plant from May through August. In December, two old 11-foot-diameter by 200-foot-long wet process kilns were shut down. The company also had reduced production at the Cape Girardeau, Mo., plant earlier in the year because of flooding of the Mississippi River.

Glens Falls Cement Co. Div. of The Flintkote Co. completed installation of a new 15-foot-diameter by 235-foot-long dry process kiln equipped with a 220-foot-high, four-stage counter flow suspension preheater at its Glens Falls, N.Y., plant. The new kiln replaced three old wet process kilns with a combined capacity of 320,000 tons annually.

Early in the year a new kiln with a capacity of 360,000 tons went on line at the Louisville Cement Co., Speed, Ind., plant. Operation of three old kilns, two dating back to 1910, were discontinued. This change resulted in a net increase in capacity of 188,000 tons.

Ideal Cement Co. Div. of Ideal Basic Industries, Inc., completed a $12 million modernization program at Trident, Mont. The successful startup of a new 12-foot-diameter by 450-foot-long kiln, which replaced four old kilns, raised the plant's capacity 16% to 333,000 tons per year.

At Miami, Fla., General Portland, Inc., completed modification of two kilns in a modernization program.

Monarch Cement Co. completed installation of a new dry process kiln with a preheater at Humboldt, Kans. The new 12-foot-diameter by 165-foot-long kiln was put onstream in October. A second identical kiln was scheduled for operation in 1975. Two old kilns will be phased out in 1974.

In October Coplay Cement Mfg. Co. reactivated six kilns at its recently purchased Egypt, Pa., plant, formerly the property of the Giant Portland Cement Co. and now an integral part of the Coplay plant. The addition of the six kilns increased the annual capacity of the new plant complex to 1,350,000 tons.

Arizona Portland Cement Co. Div. of California Portland Cement Co. completed the major portion of a modernization and expansion program at its Rillito, Ariz., plant. Included in this phase of the program was the startup of the new raw crusher, 4-mile belt conveyor from quarry to plant site, raw mill, and preheater kiln. Additional expansion currently underway at the Rillito plant includes a new finish grinding mill, additional bulk loading facilities, and dust collecting equipment to be installed on the original facilities. Completion of the entire program in early 1974 will more than double the plant's present capacity of 500,000 to 1,150,000 tons annually.

The new kiln under construction for Giant Portland Cement Co. at Harleyville, S.C., did not become operational in 1973 as expected. The new kiln is scheduled to be completed early in 1974 and will replace the smallest of four old kilns currently in production.

Planned Expansion and New Plants.—Major construction projects undertaken by Ideal Cement Co. Div. of Ideal Basic Industries, Inc., were proceeding satisfactorily. A new cement-producing facility adjacent to the present plant at Portland, Colo., was nearing completion with operations scheduled to begin June 1974. The new addition will increase the plant's capacity from 415,000 to 885,000 tons of cement per year. The new plant at Trident, Mont., was designed for coal-firing in anticipation of possible natural gas and oil shortages. The company was proceeding with a feasibility study on the construction of a new cement plant in the Mobile, Ala., area.

Expansion programs by OKC Corp. at its Pryor, Okla., and New Orleans, La., plants were nearing completion. A new finish grinding mill and kiln modifications at Pryor will increase the capacity of the Oklahoma Cement Co. plant to 425,000 tons of cement annually. The completion of a second kiln, raw grinding mill, and finish grinding mill at New Orleans will more than double the output of the Louisiana Cement Co. plant.

Medusa's new kiln at Clinchfield, Ga., was nearing completion and was due onstream early in 1974. The 15-foot-diameter by 220-foot-long kiln with suspension preheater will replace three short wet kilns now in operation. The new facilities are expected to reduce by more than 50% the Btu's presently required to produce a ton of cement.

Six other plant expansions and modernization programs were in various stages of construction and scheduled for completion in 1974: Santee Portland Cement Co., Holly Hill, S.C.; Diamond-Kosmos Cement Div. of The Flintkote Co., Kosmosdale, Ky.; Gifford-Hill Portland Cement Co., Harleyville, S.C.; Texas Industries, Inc., Columbus, Miss.; Centex Cement Corp., LaSalle, Ill.; Southwestern Portland Cement Co., subsidiary of Southdown, Inc., Fairborn, Ohio.

An $11.5 million expansion was underway at the Kaiser Cement & Gypsum Corp., Longhorn Div., cement plant at San Antonio, Tex. It will include an efficient dry-process kiln that will consume less fuel per ton than the plant's three existing wet process kilns. The clinker capacity of the plant will nearly double to 785,000 tons per year when completed early in 1975. Additional air pollution control equipment will be included in the expansion to keep the plant in compliance with environmental regulations.

Lehigh Portland Cement Co. announced plans to expand the Mitchell, Ind., cement plant by 50% to an annual capacity of 750,000 tons. The project is scheduled for completion in 1976 at an estimated cost of approximately $10 million.

Martin Marietta was adding a new finishing mill and storage silos in an effort to expand the production capacity of its Calera, Ala., plant.

United States Steel's Universal Atlas Cement Div. started a modernization project which will almost double the production capability of the Leeds, Ala., plant. The new manufacturing facility will consist of a dry-process preheater kiln, a new raw mill capable of drying raw materials in the mill circuit replacing the present wet grinding mills, and a new clinker grinding mill. When the new facilities are completed, they will have a cement processing capacity of more than 600,000 tons per year.

Lone Star Industries, Inc., and Canada Cement Lafarge Ltd., which is 50.1% owned by Ciments Lafarge, Paris, France, signed a joint-venture agreement to form Citadel Cement Corp. to produce hydraulic cement. The new company with headquarters in Atlanta, Ga., will begin operations January 1, 1974. Initial assets include Lone Star plants in Roanoke, Va., and Birmingham, Ala. Citadel Cement Corp. continued the $35 million expansion program that will double annual capacity at the Roanoke plant to 1.2 million tons when completed by mid-1975. The company plans to start a $50 million construction project on a new plant with an annual capacity of 750,000 tons at an undisclosed location to serve the eastern Gulf Coast.

Missouri Portland Cement Co. began a $30 million expansion program that will more than double the production capacity of its Joppa, Ill., plant. New equipment will include a dry process kiln equipped with a single-stage preheater having an annual capacity of 750,000 tons and pollution control facilities. Although the expansion program will span 10 years, the major portions were scheduled for completion by mid-1975. A 7,500-horsepower finish grinding mill, one of the largest mills in the United States, will also be installed in the new facility.

Florida Mining & Materials Corp. announced plans to begin construction immediately of a new cement plant 7 miles north of Brooksville, Fla. The plant, scheduled for completion late in 1975, will have a dry-process kiln equipped with a suspension preheater and an annual capacity of 546,000 tons.

Portland Cement Co. of Utah announced a $5.5 million modernization program without a guarantee of increased production for its plant at Salt Lake City.

Alpha Portland Industries, Inc., planned to increase the capacity of its St. Louis, Mo., plant to 340,000 tons per year.

Amcord, Inc., announced an expansion project which will increase the volume of the Stockerton, Pa., plant by 16%.

Additional expansion programs currently underway are listed below. Scheduled completion dates are shown in parentheses: Whitehall Cement Mfg. Co., Cementon, Pa. (1975); Coplay Cement Mfg. Co., Coplay, Pa. (1975); Monolith Portland Cement Co., Monolith, Calif. (1974–76); Southeastern Materials, Inc., Miami, Fla. (1975); and Pennsuco Cement & Aggregates, Inc., subsidiary of Maule Industries, Inc. (1974–75).

Puerto Rican Cement Co., Toa Alta, Puerto Rico, San Juan Cement Co., Dorado, Puerto Rico, and Hawaiian Cement Corp. at Barbers Point, Hawaii, are also expanding plant facilities.

Cement Grinding Facilities.—The old Jefferson Avenue plant of American Cement Corp. in Detroit, Mich., purchased by Edward C. Levy Co. in June 1972, began to operate under the name of Jefferson Marine Terminal in 1973, grinding clinker imported from Sweden and Canada.

In March, Pennsuco Cement & Aggregates, Inc., placed an order for an additional 6,300-horsepower grinding mill to be installed early in 1975 that will increase the grinding capacity by nearly 1 million tons.

Gulf Coast Portland Cement Co. Div. of McDonough Co. completed installation of an 11- by 34-foot finish mill at its plant in Houston, Tex.

River Cement Co. installed a 13- by 34-foot, 3,500-horsepower finish-grinding mill with an annual capacity of 178,000 tons. The plant's annual grinding capacity will be increased to 1,128,000 tons.

Ash Grove Cement Co. completed installation of new crushing facilities and two 13- by 47-foot, 4,400-horsepower finishing mills at its plant in Louisville, Nebr. Work on the new dry process kiln continued.

National Portland Cement Co. of Florida was expected to be in operation early in 1974. The new plant, with an annual capacity of 282,000 tons, will operate on clinker imported from Europe.

In addition to these grinding plants, the following companies operate grinding facilities on imported, purchased, or interplant transfer of clinker: Wyandotte Cement, Inc., at Wyandotte, Mich., and Universal Atlas Cement Div. of United States Steel Corp. at Milwaukee, Wis.; Huron Cement Div. of National Gypsum Co. at Superior, Wis.; Allentown Portland Cement Co. Div. of National Gypsum Co. at West Conshohocken, Pa.; and G. & W. H. Corson, Inc., at Plymouth Meeting, Pa.

Raw Materials.—Several companies were involved in exploration and development work for basic raw materials. Ideal Basic Industries, Inc. completed a $4.5 million program which will triple the capacity of limestone operations at Texada Island, North Vancouver, Canada. The plant supplies high-quality limestone to the company's Seattle cement plant and to other cement and chemical companies in the Pacific Northwest.

Lehigh Portland Cement Co. signed an agreement with Brinco Ltd. of Montreal, Canada, for the joint examination of a limestone deposit in the Port-au-Port Peninsula of western Newfoundland.

Martin Marietta Cement announced that new limestone and clay deposits for future development, calculated to last 30 years or more, were added to reserves for the Georgia plant and an additional limestone source was added to reserves of the Colorado plant.

MASONRY CEMENT

Demand for masonry cement continued at a recordbreaking pace. Total shipments were 4,130,000 tons, exceeding the previous alltime high established in 1972 by 7%. The unit value increased $2.91 per ton to $29.43, and the total value advanced 19% to $121.5 million.

During the year 42 companies manufactured masonry cement at 115 plants. The combined output of six companies accounted for 52% of the total masonry cement produced in the United States. The companies in descending order were Louisville Cement Co.; Martin Marietta Corp.; Marquette Cement Mfg. Co.; General Portland, Inc.; Ideal Cement Co., Div. of Ideal Basic Industries, Inc.; and Medusa Cement Co., Div. of Medusa Corp. Masonry cement

Table 5.—Raw materials used in producing portland cement in the United States[1]

(Thousand short tons)

Raw materials	1972	1973
Calcareous:		
Limestone (includes aragonite)	84,922	86,699
Cement rock (includes marl)	25,879	26,067

was produced exclusively at only three plants: Riverton Lime & Stone Co., Inc., Riverton, Va.; M. J. Grove Lime Co. Div. of The Flintkote Co., Frederick, Md.; and Martin Marietta Cement, a subsidiary of Martin Marietta Corp., Birmingham, Ala. Quantities produced on the job by masons who prefer to purchase portland cement and add clay or lime for plasticity are not included in table 6.

ALUMINOUS CEMENT

A totally new patented process for the production of calcium aluminate cements was developed and put on stream by Universal Atlas Cement Div. of United States Steel Corp. at its Buffington complex in Gary, Ind. Stoichiometric mixes of finely powdered limestone and bauxite are pelletized and passed through a drier/preheater before being sintered in a specially designed high-temperature rotary kiln. The sintered pellets are then ground into calcium aluminate cements.

The Aluminum Co. of America operated a calcium aluminate plant at Bauxite, Ark.

The completion in June of a $3 million grinding and packing facility at Norfolk, Va., will enable Lone Star Lafarge Co., the joint venture formed in 1970, to distribute to customers in the United States calcium aluminate cement produced from imported clinker.

ENERGY

Energy economics has become an absolute operating necessity to an industry that requires 490 trillion Btu's of fossil fuels energy and 10.9 billion kilowatt-hours of electrical energy. Based on national totals, the average cement plant used 5.6 million Btu's of fuel and 124 kilowatt-hours of electricity to produce 1 ton of cement.

The cost of fuel and electrical energy, representing 40% of the production cost, was expected to rise 25% in some areas and nearly double in Hawaii where only oil is burned.

In an industry which recently became largely dependent on oil and natural gas because of convenience, availability, relatively low prices, and strict environmental regulations, many plants are now returning to coal as a means of assuring uninterrupted production. Modifications of existing fuel systems will hopefully be completed before shortages of natural gas and oil reach a point where production might be curtailed. Capital cost of these changes are expected to be substantial.

Plans to assure adequate supplies of fuel were underway by many companies. Ideal Basic Industries, Inc., picked up an option to explore a coal property in Oklahoma, negotiated long-term contracts to purchase low-sulfur coal for two of its cement plants, and signed a letter of intent with Rocky Mountain Energy Co., a subsidiary of Union Pacific Corp., to form a joint venture to

reopen and expand the presently inactive Stansbury underground coal mine owned by Rocky Mountain Energy Co. Initial production exceeding 1 million tons of coal per year was planned to begin in 1975 at the mine near Rock Springs, Wyo.

As the result of an active program during the last 2 years, Kaiser Cement & Gypsum Corp. obtained rights to natural gas production and purchased natural gas reserves in Texas. Its gas supplies will provide the San Antonio cement plant with a portion of its fuel requirements during periods of interruption from normal sources. Natural gas exploration programs initiated by Lone Star Industries, Inc. in 1972 were showing excellent progress. During the year, a natural gas drilling program launched in New Mexico, Oklahoma, and Texas by the Diversified Industries Group resulted in 25 successful well completions out of 28 starts. Continuation of the gas development program is planned for the next several years.

A venture by Medusa to explore for gas and oil has proved successful and should supply part of its fuel requirements next year. Exploration is expected to increase in 1974.

TRANSPORTATION

Spring floods on the Mississippi, Missouri, and Ohio Rivers affected transportation. High water at shipping and receiving docks upset normal patterns of barge traffic to terminals, causing shortages of cement in areas dependent on river transportation.

Cement was transported from manufacturing plants in bulk or in containers, by truck, rail, or waterway. Of the 84,424,000 tons of portland cement shipped from plants, 79% was sent directly to customers from producing plants and 21% was transferred to distribution facilities strategically located in principal market areas for customer delivery by short-haul truck loads. Eleven percent of the cement shipped from plants to terminal and to customer moved via low-cost water transportation. One producer, interestingly, calculated that river transportation required 80% less fuel than truck transportation to move 1 ton of cement 1 mile. Although trucks were used to haul 84% of the total cement to customers, they accounted for only 5% of the total cement transferred from plants to terminals. Manufacturers continued to use railroad and waterways almost equally as the principal means of supplying distribution centers.

[1] Includes Puerto Rico.
[2] Includes cement used at plant.
[3] Bulk shipments were 91.4% (74,397 tons); container (bag) shipments were 8.6% (7,035 tons) for 1972. Bulk shipments were 92.0% (79,462 tons); container (bag) shipments were 8.0% (6,938 tons) for 1973.
[4] Data does not add to total shown because of independent rounding.

A novel aircraft method was developed for transferring cement to Alaska for its oil exploration program. Stored cement was blown into tanks fitted inside the compartments of a cargo carrier. The cement was discharged at the destination by reversing the procedure. Each loading and unloading operation required approximately 15 minutes to dispose of 39,000 pounds of cement.

CONSUMPTION AND USES

Shipments of cement by State of destination are considered to be consumption. Consumption of portland cement continued at record levels for the third consecutive year, surpassing the 1972 record by 7%.

Domestic producers shipped 86.4 million tons of portland cement, which included 1.7 million tons of imported cement. In addition to the imported cement shipped by domestic manufacturers, 1.9 million tons of portland cement was imported and shipped or used by others not producing cement in the United States and Puerto Rico.

Consumption was greater than in the previous year in all but seven States. The largest increase was in Florida, with 849,000 tons; Illinois, 543,000; Ohio, 497,000; New York, 433,000; and in Nebraska, Wisconsin, and Pennsylvania, the increase was in excess of 200,000 tons. The seven States showing decreased activity included Georgia, with a decline of 85,000 tons, followed by Michigan, Louisiana, Virginia, Rhode Island, Vermont, and Alaska.

Demand in excess of available supplies placed shipments of cement under allocation in some areas of the country during part of the year.

Ready-mix concrete producers were the primary consumers of portland cement, accounting for 66% of the total cement shipped by domestic producers. Concrete product manufacturers used 14% of the cement shipments to make concrete block and pipe, precast, prestressed concrete, and other concrete products. Building material dealers received 8% of the total cement consumed; direct shipments to highway contractors were 7%; other contractors received 3%; and Federal, State, or other governmental bodies and other miscellaneous users accounted for the remaining 2%.

[1] Less than 0.1%.
[2] Cement imported and distributed by domestic producers only. Source of imports withheld to avoid disclosing individual company confidential data.
[3] Data may not add to totals shown because of independent rounding.

PRICES

The average mill value[2] of portland cement (all types) was $21.88 per ton in 1973, an increase of $1.57 per ton. The mill value ranged from a low of $18.12 in western Pennsylvania to a high of $29.17 in Hawaii. The average mill value of gray cement advanced $1.56 per ton to $21.73 and white cement increased $0.75 per ton to $46.06.

Published mill prices in the Engineering News-Record showed that December prices for bulk shipments ranged from a low of $21.60 per ton in Independence, Kans., to a high of $32.00 per ton in Waianae, Hawaii. Bagged cement prices for these areas were $25.40 and $34.40, respectively. Most prices were subject to cash discounts. Base prices for portland cement f.o.b. city were reported monthly in the Engineering News-Record for 20 cities across the United States. The December 1973 average for bulk cement was $26.76 per ton compared with $25.25 per ton in December 1972. In the 20-city survey, bulk prices ranged from a low of $23.00 per ton in Pittsburgh, Pa., to a high of $33.40 per ton in Denver, Colo. Masonry cement in bags averaged $32.37 per ton in December 1973 and ranged from $25.40 per ton in Detroit, Mich., to $37.00 per ton in Kansas City, Mo.

Rising costs of labor and fuel at cement plants continued to outpace selling prices in effect under the Economic Stabilization Act. When Phase II ended in January, the CLC granted modest price increases which were cost justified and fully documented by the applicant. The relatively modest price adjustments permitted within phase III guidelines resulted in some restoration of optimism in the industry. A significant event occurred November 27, when the CLC exempted the cement industry from wage and price controls. The decontrol action was

[2] Mill value is the actual value of sales to customers, f.o.b. plant; less all discounts and allowances; less all freight charges to customer; less all freight charges from producing plant to distribution terminal, if any; less total cost of operating terminal, if any; less cost of paper bags and pallets.

Table 13.—Portland cement shipped by plants in the United States, by type[1]

(Thousand short tons and thousand dollars)

1973	21.88	W	29.43	22.22

W Withheld to avoid disclosing individual company confidential data.
[1] Includes Puerto Rico.
[2] Includes masonry cements made at portland, natural, and slag cement plants.
[3] Includes slag cement.

designed to make cement price adjustments possible to the extent allowed by competitive forces, to offset increased operating costs, and to provide an adequate return on investments to make plant improvements and new capacity economically feasible.

FOREIGN TRADE

Exports of cement from the United States totaled 325,000 tons to attain the highest level since 1956 and reversed the decline which began in 1971. More than 90% of the total exports was marketed in only five countries—Canada, Mexico, Netherlands Antilles, Leeward and Windward Islands, and the Dominican Republic.

The cement industry imported cement and clinker at a recordbreaking level to supplement production and to relieve the strain on available capacity. Imports continued escalating for the sixth consecutive year, rising 36%, from 4,911,000 tons in 1972 to 6,683,000 tons in 1973, setting another alltime high. Imports, economically logical only in areas bordering points of entry, were most significant in Florida. More than 2,363,000 tons, or 35% of the total imports, entered through two customs districts, Tampa and Miami, in Florida.

Canada continued to be the principal foreign source of cement, supplying 42% of the imported cement and clinker, followed by United Kingdom with 17%, Bahamas with 14%, Norway with 10%, Spain with 5%, France with 5%, and Mexico with 4%. The combined imports from nine other countries accounted for the remaining 3%.

Total imports exceeded the cement manufactured in each individual State except for California, Pennsylvania, and Texas and were 676,000 tons more than was produced in Michigan, the 4th State in rank. Clinker comprised 41% of the total imports in 1973 compared with 34% in 1972. Nineteen plants were operating on imported clinker—six in Texas, three in Michigan, two each in Florida and South Carolina, and one each in Maine, New York, Pennsylvania, Virginia, Washington, and Wisconsin. Four of the plants used imported clinker exclusively to produce cement.

Imports appeared to be at their peak and could trend downward when present contracts expire. One foreign cement producer already was unable to supply substantial quantities of cement for Gulf Coast markets. Other indications were: Foreign countries continued to absorb more of their production and placed stricter controls on exports; several foreign companies indicated that they did not intend to expand plant facilities to meet growing demands in the United States; and carriers may find it difficult to obtain adequate ship fuel to transport cement and clinker.

WORLD REVIEW

Increased costs of energy, wages, and transportation, plus the deterioration in profitability needed to maintain full utilization of production capacities were cause for concern by those manufacturers already confronted by the increased strain on available capacity.

In 1973, the European countries belonging to the European Cement Association (CEMBUREAU) put into operation at existing plants a total of 15 new kilns with a combined annual capacity of 8.5 million tons and started production at seven new plants with a total annual capacity of 4.1 million tons. Twenty-seven plant expansions and five new plants under construction will increase annual clinker production capacity by 20.3 million tons when completed in 1974.

Austria.—Gmunder Portlandzementfabrik Hans Hatschek A.G. and Schretter & Cie. each placed a new kiln into operation. The addition of these two kilns with a combined annual capacity of 680,000 tons, and the phasing out of five kilns with a combined capacity of 470,000 tons resulted in a net increase of 210,000 tons for the cement industry.

Belgium.—The expansion and modernization of the Obourg plant by Ciments d'Obourg S.A. (CBR), which includes a new 3,000-ton-per-day kiln and a 250-ton-per-hour grinding plant, is scheduled for completion late in 1975. A new 550,000-ton slag cement plant under construction by CBR at Gand is expected to be operational in 1974.

Brazil.—The new cement plant being constructed at Pedro Leopoldo in Minas Gerais by Cimento Nacional de Mines S.A. is expected to be operational late in 1974. The new plant will be equipped with a dry kiln with a 4-stage heat exchanger and will have an annual capacity in excess of 1 million tons.

Canada.—Lake Ontario Cement Ltd. completed the first phase of an expansion program at its Pitcon, Ontario, cement plant with the installation of two roller mills. The company is proceeding with phase two of the program and will install an 850,000-ton-per-year kiln system which will double clinker capacity of the existing plant. The latest technical developments available are to be built into the new kiln system to insure maximum production at minimum cost.

Genstar Ltd. acquired Miron Co. Ltd. of Montreal late in 1973. The acquisition of Miron Co. Ltd., with its more than 1 million tons of cement production capacity, makes Genstar Ltd. the second largest cement producer in Canada. A computerized central control system was installed at the company's Edmonton plant; modifications were made at the Bamberton plant to improve fuel efficiency; and work was underway to winterize the Winnipeg plant to allow operations to continue over a longer period of time each year.

The largest grinding mill of its type in the world, 18 feet in diameter by 72 feet in length, with a rating of 6,500 kilowatts was put into service by St. Lawrence Cement Co. at its Mississauga plant at Clarkson, Ontario.

Colombia.—Cementos Boyacá S.A. was constructing a new 100-ton-per-hour grinding mill at its plant near Bogotá. The modernization program also includes greater storage capacity and improvements in quarry and distribution facilities. The program is expected to be completed at the end of 1974.

Costa Rica.—Industria Nacional de Cemento S.A. completed the first phase of its expansion program at the Cartago plant and was rapidly proceeding with the second phase of the program. Under phase two, the company will reactivate and convert the wet process kiln to the dry process, install a new electrostatic precipitator, and construct a new raw grinding mill with a capacity of 100 tons per hour. Completion of the expansion program in 1974 will raise the plant's daily capacity of 1,300 tons.

Finland.—Paraisten Kalkkivuori Oy plans to install a new 550,000-ton-per-year coal-fired kiln at its Pargas plant.

France.—Output rose 2% in spite of the longest strike in the history of the French cement industry. Cement production was curtailed from November 16 to December 18. France remained the leading cement exporter of the CEMBUREAU, exporting 2.3 million tons.

The overall production capacity of the newly created Ciments d'Origny S.A. group (formerly Ciments d'Origny-Desvroise with three plants and S.A. des Chaux et Ciments Portland du Haut-Rhin with one plant) and its affiliated companies totals 4.4 million tons per year. Of this, 2.4 million tons was from the four Ciments d'Origny S.A. plants; 880,000 tons from the two Ciments de Champagnole plants; 770,000 tons from the Biache Saint Vaast plant of Ciments de Biache; and 330,000 tons from the Le Boucau plant of Ciments de l'Adour. A new 1,500-ton-per-day kiln being constructed by Ciments d'Origny at its Lumbres plant is expected to increase the annual capacity of the Origny group from 4.4 to 4.9 million tons.

Ciments Français began operating a new dry process kiln with an annual capacity of 360,000 tons at its Beffes plant and expects a 1-million-ton kiln now under construction at its Couvrot plant to begin operation in 1974.

Germany, West.—A new 3,300-ton-per-day kiln was put in service by Alsen-Breitenburg Zement-und Kalkwerke, G.m.b.H., at its Lägerdorf plant. Nordcement A.G. was unable to achieve continuous operation of a new kiln at its Alemannia plant at Höver due to unexpected technical difficulties. When the new facilities are fully operational, they will be capable of producing 1 million tons of cement annually.

Each of the following cement manufacturers completed installation of a new kiln: Georg Behringer Portlandzement und Kalkwerke; Portland-Zementwerke Heidelberg A.G.; E. Schwenk, Zement und Steinwerke; and Portlandzementwerk Wittekind Hugo Miebach Söhne.

Greece.—The acquisition of Hellenic Cement Co. in December 1972 and the completion of its new 700,000-ton plant at Drepanon, Patras, in June 1973 raised the Titan Cement Co.'s total annual capacity to 3.4 million tons. Halyps S.A. delayed completion of the new kiln at its Skaramanga plant until the end of 1974. Chalkis Cement Co. continued construction on its third 1-million-ton unit at Mikro Vathy, Avlidos. Basil B. Katsiapis received government approval to erect a 500,000-ton-per-year plant on the Island of Crete. Failure to obtain a license resulted in the cancellation of a joint venture by General Cement Co., Titan Cement Co., and Chalkis Cement Co. to build a 600,000-ton-per-year plant on Crete.

Indonesia.—Construction was started on the $35 million P.T. Semen Cibinong cement plant. The plant was to have a dry-process kiln with a suspension preheater and when completed in 1975, it would have an annual capacity of 550,000 tons. The company plans to more than double this capacity at some later date.

Iran.—Asia Cement Co., Teheran, authorized "Holderbank" Management and Consulting Ltd. to undertake the engineering work on a new 3-million-ton-per-year cement plant.

Israel.—Acceleration in consumption and difficulties in handling a greater volume of cement imports created serious problems for the cement industry. Israel Portland Cement Works "Nesher" Ltd., the only cement manufacturer in Israel, with plants at Haifa, Ramla and Bet Shemesh, was able to supply only 60% of the domestic requirements for cement. The rehabilitated Bet Shemesh plant purchased in 1972 was producing cement from imported clinker. The plant's maximum output of 600,000 tons is expected to be attained early in 1974. A new bulk cement unloading facility capable of handling 60 tons of cement per hour or 15,000 tons per month was erected at the port of Ashdod. A second unloading facility was expected to be installed at Ashdod and an order has been placed for one to be installed at Haifa. Solel Bonek, in joint ownership with Israel Corp. Investment Co., was given the option to construct a new cement plant at Mizpe Ramon, Negev.

Japan.—Ryukyu Cement Co. Ltd. completed a $2.3 million expansion program in Okinawa and increased productive capacity 18%, to 530,000 tons per year.

Lebanon.—Improved harbor facilities and installation of new loading equipment was completed by Société des Ciments Libanais at its Chekka plant. These improvements will enable the company to export cement considered to be in excess of domestic needs.

Mexico.—Cementos Apasco S.A. started construction of a new preheater kiln with a daily capacity of 2,000 tons at its Apaxco plant. The kiln was scheduled for operation late in 1974. Cementos Veracruz S.A. continued erection of a new 1,200-ton-per-day kiln at its Orizaba plant. The startup of the new kiln was scheduled for late 1974. Plant expansion was underway at Cementos Apasco, Cementos Veracruz, and Cementos Mexicanos.

Netherlands.—N.V. Eerste Nederlandse Cement Industrie (ENCI), in a joint venture with the Belgian CBR group, is constructing a new kiln at Lixhe with an annual capacity of 1 million tons. ENCI completed installation of a new 6,000-horsepower cement mill at its Rozenburg plant, increasing the annual capacity of the plant to 1 million tons of slag cement.

New Zealand.—New Zealand Cement Holdings Ltd. announced that it will add a third kiln with an annual capacity of 150,000 tons to its Westport plant. Both of the company's cement plants, at Westport and Barnside, operated at near capacity.

Nicaragua.—Production of portland cement went from 130,000 tons in 1972 to 194,000 tons in 1973, an increase of 49% to meet the demands created by the reconstruction of Managua after the December 23, 1972, earthquake. A new kiln being installed at the country's sole cement manufacturing plant at San Rafael del Sur is expected to raise the production capacity to 307,000 tons per year.

Norway.—Norcem, the sole manufacturer of cement in Norway, was established November 14, 1968, by merger of A/S Christiania Portland Cementfabrik, A/S Dalen Portland-Cementfabrik, and Nordland Portland Cementfabrik A/S. The combined output of the three plants, Slemmestad near Oslo (1.1 million tons), Dalen near Brevik (1.2 million tons), and Kjøprilk in Nordland (340,000 tons), provided Norcem with 2.7 million tons of cement annually. Norcem, with its fleet of 28 specially equipped bulk carriers, exported 676,000 tons of cement in 1973 to the United States.

Portugal.—Cia. Industrial do Cimento do Sul completed construction of its new 330,000-ton plant at Loulé. The new 550,000-ton plant under construction for Cia. de Cimentos do Norte at Souselas in northern Portugal is scheduled to begin production in 1974.

Spain.—Cementos Alba S.A. and Portland Valderrivas S.A. completed construction of their new cement plants. When full operation is attained, combined capacity of the two plants will be 1.5 million tons.

Switzerland.—The new 770,000-ton-per-year cement plant presently under construction by Cementfabrik Holderbank at Rekingen-Mellikon, Aargau, was scheduled to be operational early in 1975. Société des Chaux et Ciments de la Suisse Romande completed one phase of its modernization project at the Eclépens plant with the startup of a new raw mill and raw material installation early in the year. The next phase, which includes a new 1,500-ton-per-day dry-process kiln, was expected to be completed early in 1974. Bündner Cementwerke A.G. expects to have a new 1,600-ton-per-day dry-process kiln in operation at its Untervaz plant about mid-1974. A new kiln under construction for Wuerenlinger-Siggenthal is scheduled to be completed in 1974.

Thailand.—The 1973 cement production capacity was 4.3 million tons. Future expansion programs at the three cement companies in existence and the establishment of a fourth, approved by the Ministry of Industry, will raise the capacity to 6.8 million tons. Siam City Cement Co., Ltd., will increase capacity from 2,000 to 5,000 tons per day (approximately 1.5 million tons per year); however, no completion date has been announced. Jalaprathan Cement Co., Ltd., will boost capacity from the current rate of 1,500 to 3,000 tons daily at its plant at Amphu Cha-am, Petchaburi Province. Capacity at the firm's plant at Amphu Takli in Nakhon Sawan Province will be raised to 1,250 tons per day from the present 1,000 tons. Total annual capacity of the two plants will be about 1.3 million tons. While no completion date has been set for the Cha-am project, the Takli expansion is expected to be completed by the end of 1974. Siam Cement Co., Ltd., has ordered a new kiln and related equipment for its plant at Kaeng Khoi, Saraburi Province, to increase annual output 800,000 tons per year. The company's four plants after mid-1975 will have an aggregate plant capacity of 3.6 million tons per year. Thai Sathapana Co., Ltd., received permission from the Ministry of Industry in September 1973 to erect a 1,000-ton-per-day plant at Amphu Pak Tho in Ratchaburi Province. The plant, under construction, is due to go into production early in 1975.

Turkey.—Goltas Cimentos A.S. started production at its new plant at Isparta. The new plant under construction by Bolu Cimento Sanayii A.S. at Bolu will come into production in 1974. Five other plants under construction and scheduled for completion in 1975 are Unye at Ordu (620,000 tons); Mardin Cimento at Mardin (580,000 tons); Iskenderun at Hatay (550,000 tons); Kars Cimento at Kars (275,000 tons); and Akcimento at Mersin (in excess of 1 million tons).

Yemen Arab Republic.—The Soviet-built facility at Bajil was producing at 50% of its planned capacity of 50,000 tons of cement per year. There are plans to expand the Bajil plant and to build another cement plant to meet growing domestic needs.

TECHNOLOGY

Fuel requirements for kiln heat transfer systems vary widely among different clinker production systems as the following tabulation illustrates:

System	*10^6 Btu per ton of clinker*
Long dry kiln	5.00 to 7.80
Long wet kiln with chains	4.70 to 9.45
Long dry kiln with chains	3.90 to 6.10
Long dry kiln with waste heat boiler	4.95 to 6.10
Long dry kiln with internal crosses	3.90 to 5.85
Suspension preheater	2.85 to 4.45
Lepol grate preheater	3.55 to 3.85

Source: Kaiser Engineers.

Within each category, heat usage varies depending on a number of factors, the most important of which are the design of the systems, the degree of maintenance, the skill of the operator, and the composition of the raw materials. However, on the whole, the air suspension preheater consistently keeps the fuel expenditure much lower than any other type of system.

A method for disposing of oil slicks on coastal waters, rivers, and the like, using portland cement or other hydraulic cement was patented.[3] The method uses a finely ground cement, 1,000 to 12,000 square centimeters per gram, previously coated with hydropholic, natural, or synthetic oil. The coated cement is usually sprayed on the oil slick, forming oil-cement globules, which sink rapidly. The oil-cement globules are relatively stable, disintegrating only over a lengthy period of time, releasing small, noninjurious oil globules.

In accordance with the 1972–73 U.S.-Soviet Agreement on Exchanges and Cooperation in Scientific, Technical, Educational, Cultural, and Other Fields, signed April 11, 1972, four Soviet experts in the field of special cements and polymer concrete arrived in the United States in May 1973.

e Estimate. p Preliminary. r Revised.

[1] Includes production from the Azores and Madeira Islands as follows in thousand short tons: 1971—None; 1972: Azores—17; Madeira—33; 1973: Azores—24 (estimated); Madeira—37 (estimated). The balance of output in each year was from continental Portugal.

[2] Year beginning March 21 of that stated.

[3] Included with Japan.

Chromium

By John L. Morning [1]

In 1973 worldwide demand for chromium brought increased production of chromite and chromium products worldwide. A record year for domestic stainless steel producers created a strong demand for chromium alloys. As a result, the domestic chromium alloy industry returned to the production levels of 1969 and 1970, imports of ferrochromium reached a new high, and domestic consumption of chromium alloys exceeded 500,000 tons for the first time.

Legislation and Government Programs.—The Office of Emergency Preparedness (OEP) on April 12 revised stockpile objectives for chromium materials as follows: Chemical-grade chromite, 8,400 tons; metallurgical-grade chromite, 444,710 tons; refractory-grade chromite, 54,000 tons; and high-carbon ferrochromium, 11,476 tons. A zero objective was established for low-carbon ferrochromium, ferrochromium-silicon, and chromium metal. At midyear, OEP was abolished and the Office of Preparedness under the General Services Administration (GSA) was established.

Government chromium stockpile material inventories are shown in table 2. Included in the inventories is material sold but unshipped. This includes chemical-grade chromite, 185,268 tons; metallurgical-grade chromite, 85,342 tons; and refractory-grade chromite, 135,339 tons. In addition, 191 tons of chromium metal was inventoried as undelivered sales.

GSA under various disposal programs offered for sale all three grades of chromite and chromium metal. Sales were as follows: Metallurgical-grade chromite, 39,931 tons; refractory-grade chromite, 191,000 tons; and chromium metal, 1,055 tons.

Deliveries of chromite from Government stockpiles from current or prior year sales contracts were as follows: Chemical-grade, 155,412 tons; metallurgical-grade, 56,586 tons; and refractory-grade, 62,433. In addition, delivery of 864 tons of chromium metal added to the domestic supply.

The Ferroalloys Association in early May sought relief against a high level of imports of chromium and manganese alloys by petitioning the Tariff Commission under Section 301 of the Trade Expansion Act of 1962. By late June, the worldwide steel boom had been initiated, order books were filled, and profits improved. The domestic ferroalloy producers then requested a suspension of the complaint.

The Environmental Protection Agency (EPA) proposed effluent limitation guidelines for existing sources, and standards of performance and pretreatment standards for new sources for the electroplating point source category.[2]

EPA also proposed rules for the ferroalloy manufacturing point source category and effluent limitation guidelines for existing sources; and standards of performance and pretreatment standards for new sources.[3]

The National Institute for Occupational Safety and Health (NIOSH) submitted criteria for recommended standards governing exposure to toluene diisocyanate or chromic acid and toluene. Chromic acid was defined as meaning chromium trioxide and solutions of chromium trioxide. The criteria document recommended that no worker be exposed to chromic acid in concentrations greater than 0.05 milligram per cubic meter of air determined as a time-weighted average, or a ceiling concentration greater than 0.1 milligram per cubic meter determined by sampling time of 15 minutes.

---

DOMESTIC PRODUCTION

Domestic mine production of chromite ceased in 1961 when the last Government Defense Production Act contract was phased out. However, the United States continued to be one of the world's leading chromite consumers in producing chromium alloys, refractories, and chemicals. The principal producers of these products were as follows:

Company	Plant
Metallurgical industry:	
Airco Alloys and Carbide Div., Air Reduction Co. Inc	Calvert City, Ky. Niagara Falls, N.Y. Charleston, S.C.
Chromium Mining & Smelting Corp	Woodstock, Tenn.
Foote Mineral Co	Vancoram, Ohio Graham, W.Va.
Interlake Inc	Beverly, Ohio
Ohio Ferro-Alloys Corp	Brilliant, Ohio
Shieldalloy Corp	Newfield, N.J.
Union Carbide Corp	Niagara Falls, N.Y. Marietta, Ohio Alloy, W.Va.
Refractory industry:	
Basic, Inc	Maple Grove, Ohio
Corhart Refractories Co., Inc	Louisville, Ky.
General Refractories Co	Baltimore, Md. Lehi, Utah
Harbison-Walker Refractories Co. (Div. of Dresser Industries, Inc.)	Hammond, Ind. Baltimore, Md.
Kaiser Aluminum & Chemical Corp	Moss Landing, Calif. Columbiana, Ohio
E.J. Lavino & Co. (Div. of IMC)	Plymouth Meeting, Pa.
North American Refractories Co	Womelsdorf, Pa.
Ohio Fire Brick Co	Jackson, Ohio
Chemical industry:	
Allied Chemical Corp	Baltimore, Md.
Diamond Shamrock Corp	Castle Haynes, N.C. Kearny, N.J.
PPG Industries, Inc	Corpus Christi, Tex.

CONSUMPTION AND USES

Domestic consumption of 1,387,000 tons of chromite ore and concentrate containing about 429,000 tons of chromium was 18% higher than in 1972. Of the total chromite consumed, the metallurgical industry used 66.3%, the refractory industry 18.8%, and the chemical industry 14.9%. The metallurgical industry consumed 920,000 tons of chromite containing 303,000 tons of chromium in producing 417,745 tons of chromium alloys and metal. About 67.6% of the metallurgical-grade ore had a chromium-to-iron ratio of 3:1 and over, 16.8% had a ratio between 2:1 and 3:1, and 15.6% had a ratio of less than 2:1.

Producers of chromite-bearing refractories consumed 261,000 tons of ore containing about 63,000 tons of chromium. The chemical industry consumed 206,000 tons of chromite containing about 64,000 tons of chromium in producing 159,000 tons of chemicals (sodium bichromate equivalent).

Chromium has a wide range of applications in three consuming industries. In the metallurgical industry its principal use is in stainless steel. Owing to a record year in stainless steel production, demand for chromium alloys was strong, especially during the last 9 months of the year. Stainless steel accounted for 73% of total chromium alloys consumed, an increase of over 100,000 tons compared with that of 1972. Consumption of alloys in most other end use categories increased significantly with the exception of carbon steel.

In the refractory industry, chromium was used in the form of chromite primarily for the manufacture of refractory bricks to line metallurgical furnaces. Consumption of chromite for refractory purposes increased 17% compared with that of 1972.

The chemical industry consumes chromite for manufacturing sodium or potassium dichromate, the base material for a wide range of chromium chemicals. Chromite consumption in this industry increased 9% compared with that of 1972.

[1] Includes magnetic and nonferrous alloys.
[2] Includes 5,181 tons of chromium metal.
[3] Includes 698 tons of chromium metal.

STOCKS

Chromite stocks decreased significantly for the second successive year; however, the metallurgical industry accounted for virtually all of the decrease. Stocks in the metallurgical industry decreased nearly 44%, while stocks in the chemical and refractory industries were about the same as in 1972.

Owing to strong demand for chromium alloys, producer stocks decreased 55% as consumer stocks rose 77% compared with those of 1972.

Table 6.—Consumer stocks of chromite, Dec. 31

(Thousand short tons)

Industry	1969	1970	1971	1972	1973
Metallurgical	296	387	667	601	339
Refractory	301	235	233	160	154
Chemical	143	111	119	96	104
Total	740	733	1,019	857	597

Stocks of chromium chemicals (sodium bichromate equivalent) at producer plants decreased from 13,936 tons in 1972 to 6,858 tons in 1973.

PRICES

Despite vastly improved demand for chromite ore and chromium products, ore prices were generally down somewhat from their 1972 levels. Some ferrochrome prices, on the other hand, showed conspicuous advances. Imported ferrochrome also increased in price owing to dollar revaluations and increased demand.

Soviet metallurgical-grade ore continued to decline in price for the second straight year after a continuous 4-year rise that peaked in 1971. Midyear prices for Soviet ore with a 4:1 chromium-to-iron ratio decreased to \$37 to \$39 per metric ton, 48% Cr_2O_3 pricing basis, f.o.b. Soviet ports. Turkish 3:1 chromite was down to \$37 per long ton, 48% basis, f.o.b. Atlantic coast ports. In contrast to declining prices for Soviet and Turkish ores, South African chromite rose to $33 to $34 per long ton, f.o.b. Atlantic coast ports.

Domestic ferrochromium prices, which were eroded in 1972 owing to lack of demand and an influx of ferrochromium imports, increased in the second quarter of 1973. Further increases in price during the year were not permitted under the Goverment's economic stabilization program.

Selected chromium alloy prices published by Metals Week for December 28, 1973, follow:

Material	Cents per pound of chromium
High-carbon ferrochromium [1]	23.7
Charge chromium	22.0–23.0
Imported charge chromium	21.0–22.5
Low-carbon ferrochromium (0.25% carbon)	36.5
Low-carbon ferrochromium (0.05% carbon)	35.0
Imported low-carbon ferrochromium	34.0
	Cents per pound of product
Aluminothermic chromium metal	138
Electrolytic chromium metal	153

[1] 1972 price; 1 producer's price was 26.2 cents for 1973.

FOREIGN TRADE

Exports of chromite were about the same as in 1972, but reexports decreased 40% compared with those of 1972. Major exports were to Canada, 41%; Ireland, 31%; and Mexico, 18%; the balance went to seven other countries. Reexports were shipped to Mexico, 64%; Ireland, 19%; and Canada, 17%.

Ferrochromium exports increased 18% to 15,164 tons valued at $5.1 million. West Germany received 34%; Canada, 30%; the United Kingdom, 14% and 16 countries received the balance.

Chromium and chromium alloys (wrought and unwought) and waste and scrap exports increased to 388 tons valued at $556,000 from 200 tons in 1972.

Exports of pigment-grade chromium chemicals increased 50% compared with those of 1972, rising to 249 tons valued at $461,000. Canada received 38% of the shipments; Japan, 20%; and the United Kingdom, 16%; the balance went to 21 other countries. Non-pigment-grade chromium chemicals exported totaled 2,568 tons valued at $2,687,000, increasing 103% in quantity and 76% in value compared with those of 1972.

Exports of sodium chromate and dichromate more than tripled, rising to 12,341 tons valued at $3,374,000. Canada was the leading recipient of shipments with 35% of the total, followed by the Republic of Korea, 13%; Taiwan, 11%; and Japan, 10%. Thirty-two other countries also received shipments.

Despite a big year in the domestic consuming industries, imports of chromite decreased 12% compared with those of 1972. Imports from the U.S.S.R. and Southern Rhodesia decreased 44% and 53%, respectively, while imports from the Philippines, the Republic of South Africa, and Turkey increased 45%, 22%, and 36%, respectively.

Imports of ferrochromium set a record yearly high for the third year in a row as 155,541 tons valued at $35,175,000 was received. The Republic of South Africa (30%), Japan (25%), Sweden (14%), and Southern Rhodesia (11%) accounted for 80% of the low-carbon ferrochromium imports, whereas Southern Rhodesia (41%), the Republic of South Africa (37%), Finland (8%), and Brazil (6%) accounted for 92% of the high-carbon ferrochromium imports.

Ferrochromium-silicon imports were 55% higher than in 1972. Three countries supplied 13,037 tons valued at $3,127,000. Southern Rhodesia supplied 68%; the Republic of South Africa, 31%; and Sweden, 1%.

Chromium carbide imports of 308 tons valued at $882,000 were nearly double those of 1972. West Germany supplied 80% and the United Kingdom the balance.

Imports of chromium metal, unwrought and waste and scrap, increased to 2,690 tons valued at $6,080,000 from 1,894 tons valued at $3,791,000 in 1972. Of the nine countries supplying imports, the United Kingdom accounted for 59% and Japan for 33%.

ments were as follows: Chrome green, 161 tons; chrome yellow, 4,492 tons; chromium oxide green, 915 tons; hydrated chromium oxide green, 10 tons; molybdenum orange, 5,031 tons; and zinc yellow, 1,347 tons. Total value was $5.6 million, 11% lower than in 1972. Chromium yellow accounted for 53% of the total value of these products. The leading suppliers were Japan, 42% of total value, and Canada, 22%.

Sodium chromate and dichromate imports totaled 1,031 tons valued at $209,000, a substantial decrease from the 5,748 tons imported in 1972. Japan supplied 84% of the imports and the Republic of South Africa the balance. In addition, 6 tons of potassium chromate and dichromate was received from West Germany.

WORLD REVIEW

Albania.—According to the head of the State Planning Commission, chromite production will be a future growth area. For the 5-year plan of 1971–75, chromite output was targeted at 992,000 tons in 1975. Chromite concentrate was first exported in 1972, and export sales were expected to double in 1973. The state agency, Exportal, controls sales to foreign markets.

Greece.—Chromite production in Greece primarily comes from two mines. Metallurgical ore (concentrate) was produced by the General Mineral Exploration and Mining Development Corp. (GEMEE) at the Skoumtsa mine in the Kozani area of Macedonia, while refractory ore was produced by the Scalistiri Group at Tsangli near Fársala in Thessaly. A full assessment of Greece's chromite resources has not been made, but exploration activity during the past few years increased estimated reserves to 6.5 million tons proven and 2 million tons possible. Chromite consumption in Greece, primarily refractory-grade ore, was used at a brick plant operated by the Scalistiri Group.

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, Bulgaria, North Korea and North Vietnam also produce chromite, but available information is inadequate to permit estimation of output levels.

[2] Less than ½ unit.

[3] Exports.

India.—India's chromite production in 1972 increased nearly 13% compared with that of 1971. Exports, all to Japan for the fourth consecutive year, dropped by 33,547 tons to 62,218 tons. Ferrochromium output fell from 13,756 tons in 1971 to 1,422 tons. The country's principal ferrochromium producer, Ferroalloy Corp. Ltd., did not operate owing to poor marketing conditions; Industrial Corp. of Orissa, Ltd. ceased operating in June; three other producers operated intermittently to meet limited requirements.

Japan.—Japan's production of chromium alloys in 1971–72 reached 450,000 tons. Over one-half was charge chromium; 120,000 tons of low-carbon ferrochromium and 80,000 tons of ferrochromium-silicon were also produced. Demand for chromium alloys for stainless steel production in 1974 was projected at 760,000 tons.

Mozambique.—Interest was shown by Companhia Moçambicana de Minas S.A. (CONOCMIN) in the ultrabasic formation of Mount Achiza. Chromium and nickel minerals have been identified in the area.

Philippines.—Output of chromite increased 66% compared with that of 1972; 84% was classified as refractory-grade and 16% as metallurgical-grade. Exports of refractory-grade chromite totaled 492,143 tons. The United States received 55%; Japan 15%, and the United Kingdom 11%. The balance was shipped to nine other countries. Japan received all of the 105,466 tons of metallurgical-grade chromite exported.

Rhodesia, Southern.—United Nations economic sanctions, which were applied in 1966, brought retaliation by the Rhodesian Government in the form of an embargo on mining news, primarily production data. Firm production data has been unavailable since 1965. Estimated annual chromite production of 400,000 tons has been carried by the Bureau of Mines for several years, and numerous sources have indicated that the figure is too low. Rhodesian ferrochromium production capacity could utilize more than the estimated figure. Accordingly, the Bureau of Mines estimate has been increased to 600,000 tons annually for 1971–73.

South Africa, Republic of.—Chromite production in the Republic of South Africa totaled over 1.8 million tons, an 11% increase compared with 1972 output. Of the total, 729,000 tons was classified as less than 44% Cr_2O_3, 1,056,000 tons from 44% to 48% Cr_2O_3, and 33,000 tons as over 48% Cr_2O_3. Local sales of chromite accounted for 497,000 tons and exports for 1,205,000 tons.

Transvaal Consolidated Land Exploration Co., Ltd., reported record sales of chromite owing to South African and worldwide demand for chromite. The firm maintained its position as the largest single producer of chromium ore in the Republic, and further expansion programs at new and existing mines were being undertaken.

Development of a chromite mine of Lavino (S.A.) (Pty.) Ltd., Steelpoort, Eastern Transvaal, was initiated in 1955, and shipments began in 1957. One seam of chromite about 50 inches thick currently is being worked and ranges in depth below surface from 16 feet to about 300 feet. A crushing and screening plant produces six sizes of ore ranging from 4-inch lump to minus 30-mesh foundry sand. Mine capacity is about 260,000 tons annually. Shipments are made to Lourenço Marques for export or to the African Metals Corp. Ltd. Ferrometals plant at Witbank.

Turkey.—Etibank (a State Agency) planned to initiate construction of a facility at Elâziğ to produce 25,000 tons of ferrochromium annually. The plant will produce ferrochromium and ferrochromium-silicon. Japanese financing is involved in return for ferrochromium shipments.

TECHNOLOGY

The basic principles of chromite flotation were discussed, and a review of previous work was presented.[5]

In addition, the results of experimental studies on Albanian, Cuban, and Russian chromite were described. The authors concluded; (1) of the various ions that can be present in the pulp, aluminum ions have the greatest influence on the flotation behavior of chromite; (2) in anionic flotation of chromite, aluminum species cause depression in the pH range of 4.5 to 8 and activation between pH 10 and 12; (3) complex effects of the gangue minerals and soluble species in solution cause similar flotation behavior of chromium ore with anionic and cationic collectors; and (4) because of high acid consumption and unfavorable conditions in acid environments, flotation of chromium ores should be undertaken under alkaline conditions.

Showa Denko KK (Japan) announced plans to produce a reduced chromite pellet for use in stainless steel manufacture. The pellets, made from chromite concentrate, would be 80% reduced in a rotary kiln. Full-scale testing was scheduled for mid-1974.

The growth of argon-oxygen decarburization (AOD) process for the manufacture of stainless steel in 1973 continued worldwide, as at least eight new installations initiated operations. The combination of the AOD process with that of continuous casting (CC), together with a listing of AOD and CC worldwide installations, was published.[6] It can be expected that other stainless steel producers in the United States and worldwide will team up AOD and CC.

Nippon Steel Corp. produced stainless steel by employing a combination of the basic oxygen steelmaking process and the RH-OB process developed by Nippon. The RH-OB process utilizes oxygen for final decarburization in a vacuum degassing unit.

Researchers showed considerable interest in thermodynamic properties of chromium alloys.[7]

Constitution diagrams for chromium-iridium and for chromium-rhodium were published.[8]

Analytical determination of chromium and manganese in steel is tedious and time consuming. A rapid spectrophotometric procedure that proved satisfactory over a 3-year period was published.[9]

The reactions occurring during the anodic polarization of tinplate passivated cathodically in a dichromate solution (CDC tinplate) were ascertained. It was found that a large portion of the CDC passivation film consists of chromium in the metallic state.[10]

M & T Chemicals Inc. announced the development of a commercial process for single-layer microcracked chromium plating that provides brighter deposits and a reproducible fine crack pattern in a plating time of 4 to 6 minutes. The firm claims the process leads to less corrosion and cost-cutting for electroplaters. In many applications it can enable the plater to have the same protection of the base metal with less nickel, thereby allowing platers to increase productivity and cut plating costs.

Patent activity during the year concerned burden preparation and prereduction of ore for production of ferroalloy;[11] direct reduction of oxide ores;[12] silicon control in production of high-carbon ferrochromium;[13] methods for purifying low-carbon ferrochromium and production of chromium metal;[14] methods for production of chromium chemicals;[15] and methods for chromium electroplating.[16]

Clays

By Sarkis G. Ampian [1]

Clays in one or more of the classification categories (kaolin, ball clay, fire clay, bentonite, fuller's earth, or common clay and shale) were produced in 47 States and Puerto Rico. Clay production was not reported in Alaska, the District of Columbia, Rhode Island, or Vermont. The States leading in output were Georgia, 7.7 million tons; Texas, 5.7 million tons; and Ohio, 4.7 million tons; followed in order by North Carolina, Pennsylvania, and Alabama. Georgia also led in total value of clay output with $160.4 million; Wyoming was second with $24.0 million. Compared with 1972 figures, clay production increased in 30 States and value increased in 34 States. Total quantity of clays sold or used by domestic producers in 1973 was approximately 8% higher than in 1972, and total value was approximately 17% higher. Both the total tonnage and value of clays produced were alltime highs. Modest increases in value per ton were reported for all clays in 1973 owing to increased labor, fuel, and material costs. The increasing shortage and costs of fuels were causing considerable concern among clay producers and clay product manufacturers. Industrywide efforts were made to both economize and obtain standby fuels for their requirements. The costs of environmental protection equipment and environmental restrictions, combined with the energy crisis, were beginning to adversely affect production during the last quarter of 1973.

Kaolin in 1973 accounted for only 9% of the total clay production but for 46% of the domestic clay and shale value.

Table 1.—Salient clay and clay products statistics in the United States [1]

(Thousand short tons and thousand dollars)

	1969	1970	1971	1972	1973
Domestic clays sold or used by producers	58,694	54,853	56,666	59,456	64,351
Value	$264,415	$267,912	$274,431	$303,022	$354,058
Exports	1,574	2,076	1,973	1,847	2,097
Value	$45,767	$66,116	$65,329	$66,216	$79,774
Imports for consumption	82	87	64	67	53
Value	$1,750	$1,802	$1,501	$1,309	$1,879
Clay refractories, shipments (value)	$257,507	$256,384	$236,563	$274,679	$323,479

[1] Excludes Puerto Rico.

DOMESTIC PRODUCTION, PRICES, AND FOREIGN TRADE, BY TYPE OF CLAY

KAOLIN

Domestic production of kaolin in 1973 increased 13%, and the value increased 19%. The average unit value for all grades of kaolin in 1973 was $27.26 per ton, $1.51 higher than in 1972. Kaolin was produced at mines in 16 States. Two States, Georgia (75%) and South Carolina (13%), accounted for 88% of the total U.S. production in 1973, Arkansas ranked third, Alabama fourth, and Texas fifth. Output in 1973 de-

[1] Physical scientist, Division of Nonmetallic Minerals—Mineral Supply.

clined in California and increased in Alabama, Arkansas, Florida, Georgia, Idaho, Minnesota, Missouri, Nevada, North Carolina, Pennsylvania, South Carolina, Texas, and Utah. Indiana became a new producing State in 1973.

Kaolin is defined as a white, claylike material approximating the mineral kaolinite. It has a specific gravity of 2.6 and a fusion point of 1,785° C. The other kaolin-group minerals, such as halloysite and dickite, are encompassed.

During 1973 J. M. Huber Corp. began construction of one of the world's largest spray dryers at its Wren, Ga., facility. Spray dryers were also added by Engelhard Minerals & Chemicals Corp. at its McIntyre, Ga., operation, and by Anglo-American Clay Corp. at its Sandersville, Ga., plant. Anglo-American's spray dryer was part of a completed expansion program started in early 1972 to meet the increasing demand for its high-brightness paper-coating grades. Anglo-American and Union Camp Corp. were jointly exploring the latter's lands in Georgia for commercially valuable kaolin deposits. Allied Chemical Corp. purchased a large kaolin property in Wilkinson County, Ga. Horton International announced its intentions to produce air-floated kaolin from its deposits near Sandersville and also to custom grind for other kaolin producers.

The Georgia Senate, seeking to capitalize on the aluminum potential of the State's kaolin, resolved to offer $250,000 to the first person or firm to commercially produce alumina or aluminum chloride from Georgia's deposits. The resolution, which stipulates that at least 300,000 tons must be produced the first year, must be passed by the Georgia House of Representatives and approved by the public as a constitutional amendment.[2] Georgia's kaolin deposits are considered to be the world's largest.

Exports of kaolin, as reported by the U.S. Department of Commerce, increased from 668,000 short tons valued at $26.3 million in 1972 to 732,000 tons valued at $30.5 million in 1973. The tonnage and value of the kaolin exported in 1973 increased 10% and 16%, respectively, over that shipped in 1972. The unit value per ton increased $2.29. This increase in the unit value of the kaolin exported was attributed to the greater percentage of the higher quality paper-coating grades shipped.

Kaolin was exported to 56 countries. The recipients were Japan, 31%; Canada, 22%; West Germany, 20%; Italy, 11%; and the remaining countries, 16%. Generally, exports to all countries increased, except for those to the Netherlands, France, Brazil, and Italy, which decreased 95%, 54%, 33%, and 4%, respectively. The kaolin producers reported the end use for their exports as follows: Paper coating, 55%; paper filling, 4%; rubber, 8%; and others, including refractories, fiberglass, paint, and plastics, 33%.

Kaolin imports in 1973 reversed the downward trend reported for a number of years by increasing from 25,481 short tons valued at $736,000 in 1972 to 34,203 tons valued at $881,000. The United Kingdom supplied nearly 98%; Canada, nearly 2%; and two other countries, less than 0.5%.

Kaolin prices quoted in the trade journals in 1973 were unchanged from 1972. Chemical Marketing Reporter, December 31, 1973, quoted prices as follows:

Waterwashed, fully calcined, bulk carload lots, f.o.b. Georgia, per ton	$76.00
Partially calcined, same basis, per ton	69.00
Paper-grade, uncalcined, same basis, per ton:	
No. 1 coating	$40.00–41.00
No. 2 coating	32.00–33.00
No. 3 coating	31.00–32.00
Filler, general purpose, same basis, per ton	14.00
Delaminated, waterwashed, uncalcined, paint-grade, 1-micrometer average, same basis, per ton	67.00
Dry-ground, air-floated, soft, same basis, per ton	14.00
National Formulary, powder, 50-pound bags, 5,000-pound lots, works, per pound	0.0675
National Formulary, colloidal, 150-pound drums, works, per pound	0.1650

The average unit value reported by domestic kaolin producers was $27.26 per ton, an increase of $1.51 above the 1972 value.

BALL CLAY

Production and value reported for domestically mined ball clay in 1973 increased 14% and 20%, respectively. Tennessee mines provided 64% of the Nation's output, followed in order of output by Kentucky, Mississippi, Texas, Maryland, New York, and California. Production in Kentucky, Maryland, Mississippi, and Tennessee increased over that reported in 1972, while California production decreased.

Ball clay is defined as a plastic, white-firing clay used principally for bonding in ceramic ware. The clays are of sedimentary

[2] Chemical Engineering. Chementator. V. 81, No. 3, February 1974, p. 19.

origin and consist mainly of the clay mineral kaolinite and sericite micas.

In 1973 Old Hickory Clay Co. installed a fluidized-bed dryer at its Gleason, Tenn., plant. This fluidized-bed dryer, an industry first, was reportedly capable of operating at lower temperatures than the present rotary dryers, thereby eliminating the danger of calcining or overfiring which reduces the natural plasticity of ball clays. H. C. Spinks Clay Co. began constructing a drying and grinding facility scheduled for completion in 1974, at Gleason. This facility will both expand production of air-floated and mechanically dried clays and eliminate costly hauling from its Gleason area mines to other plants.

The average unit value for ball clay reported by domestic producers rose in 1973 to $16.88 per ton, an increase of $0.89 per

Table 2.—Clays sold or used by producers in the United States in 1973, by State[1]

Grand total	681,086	754,969

[1] Fertilizers and rubber.

[2] Includes animal feed; electrical porcelain (1973); fiberglass; fine china/dinnerware; ceramic floor and wall tile (1972); glazes, glass, and enamels (1973); gypsum products; paint; paper filling; plastics (1973); pottery; sanitary ware; and other uses.

ton. Chemical Marketing Reporter, December 31, 1973, listed ball clay prices unchanged from 1972 as follows:

Domestic, air-floated, bags, carload lots, Tennessee, per ton	$18.00–$22.00
Domestic, crushed, moisture-repellent, bulk, carload lots, Tennessee, per ton	8.00– 11.25
Imported, air-floated, bags, carload lots Atlantic ports, per ton	70.00
Imported, lump, bulk, Great Lakes, per ton	40.50

Ball clay exports in 1973 amounted to 114,000 short tons valued at $2.2 million, compared with 87,000 tons worth $1.7 million in 1972. Exports increased 31% over that shipped in 1972, while the value was nearly 30% higher. The unit value of ball clay exported in 1973 declined $0.14 per ton, from $19.41 in 1972 to $19.27. These shipments were made to 21 countries. The major recipients were Canada, 47%, and Mexico, 45%; 19 countries accounted for the remaining 8%.

FIRE CLAY

Fire clay sold or used by domestic producers in 1973 was reported at 4,067,983 short tons valued at $36.2 million. Fire clay is defined as detrital material, either plastic or rocklike, containing low percentages of iron oxide, lime, magnesia, and alkalies to enable the material to withstand temperatures of 1,500° C or higher. Fire clay is basically kaolinite but usually contains other materials such as diaspore, ball clay, bauxite clay, and shale. Fire clays commonly occur as underclay below coal seams and are generally used for refractories. Some fire clay was previously reported in other end uses.

Fire clay production was reported in 1973 from mines in 20 States. The first four States in rank, Ohio, Pennsylvania, Missouri, and Alabama, accounted for 78% of the total domestic output.

In 1973, A. P. Green Refractories Co. purchased the plants and properties of H. K. Porter Co., Inc., near Fulton, Mo., and Bessemer, Ala.

Exports of fire clay increased from 124,000 short tons worth $2.9 million in 1972 to 196,000 tons valued at $3.82 million in 1973. Fire clay exports rose 58% in tonnage and 32% in value. The price of exported fire clay declined by $3.94 to $19.49 per ton.

Fire clay was exported to 48 countries, with Canada and Mexico receiving 56% and 26%, respectively. No imports of fire clay were reported during 1973.

There are no price quotations in domestic journals for fire clay, but the per-ton value reported by producers ranged from $2 to about $9. The reported average unit value for fire clay produced in the United States increased 9%, from $8.15 per ton in 1972 to $8.89 in 1973.

BENTONITE

Bentonite production in 1973 increased 11% in tonnage and 19% in value over that of 1972. A general increase in domestic consumption, particularly in iron ore pelletizing, drilling mud, animal feed, and oil filtering uses, was noted along with an overall increase in exports.

Bentonite was produced in 15 States. Increased bentonite production was reported for all States except Montana, Nevada, Texas, Mississippi, Oklahoma, Oregon, and South Dakota.

Generally, the high-swelling or sodium bentonites are produced chiefly in Wyoming, Montana, and South Dakota. The calcium or low-swelling bentonites are produced in the other States.

A new production facility scheduled for completion in 1974 was begun in Worland, Wyo., by Black Hills Bentonite Co. The facility will substantially increase Black Hills' overall production capacity. Industry-wide improvements were made in environmental controls systems and in automating, bagging, and handling procedures.

On April 23, 1973, Chemical Marketing Reporter quoted bentonite price increases as follows: Domestic, 200-mesh, bags, carload lots, f.o.b. mines, from $14.00–$14.40 to $15.50–$16.00 per ton; and imported Italian, white, high-gel, bags, 5-ton lots, ex-warehouse, from $116.60 to $337.60 ($0.1688 per pound) per ton. The average unit value reported by domestic producers for bentonite sold or used in 1973 was $11.34, an increase of $0.74 from the $10.60 average of the previous year. Per-ton values reported in the various producing States ranged from $4 to $30, but as in 1972, the average value reported by the larger producers was near the Wyoming average figure of $11.17.

Bentonite imports in 1973, including chemically activated and special-purpose Italian material, totaled 2,670 short tons valued at $243,000, compared with 2,853 tons valued at $229,000 in 1972. The 2,571 tons of chemically activated bentonite was imported from six countries, with Canada supplying 44%; Mexico, 35%; West Germany, 8%; Japan, 12%; and the Netherlands and the United Kingdom the remaining 1%. Imports of Italian bentonite in 1973 decreased from 127 short tons in 1972 to 99 tons.

Bentonite exports in 1973 increased from 521,000 short tons in 1972 valued at $15.1 million to 551,000 tons valued at $18.4 million. Although the tonnage exported increased only 6% from that shipped in 1972, the value increased 22%. The greater increase in value was the result of the unit value of exported bentonite increasing $4.33 per ton, from $29.01 per ton in 1972 to $33.34 per ton. This increase in per-ton value was attributed to a large increase in the amount of higher cost drilling mud and foundry-grade bentonites shipped. Exports in previous years consisted of a larger percentage of the lower cost pelletizing grades. Domestic bentonite producers were facing increased competition in foreign markets. Bentonite from the Greek island of Milos was being blended with the U.S. clay for pelletizing Canadian taconite ores on a large scale.

Bentonite was exported to 77 countries, an increase of 6 from the previous year. The major recipients were Canada, 43%; the United Kingdom and West Germany, 9% each; Australia, 8%; Saudi Arabia, 5%; Japan and the Netherlands, 4% each; and others, 18%. Domestic bentonite producers reported the end use of their exports were foundry sand, 41%; iron ore pelletizing, 29%; drilling mud, 25%; and others, including animal feed, ceramics, ore treatment, and waterproofing and sealing, 5%.

Total	423,094	438,216

[1] Includes animal feed, ceramics, oil treatment, oil refining catalysts, waterproofing and sealing, and other uses.

FULLER'S EARTH

Production of fuller's earth in 1973 increased 15% in quantity and 20% in total value. The unit value assigned by domestic producers increased $0.99 in 1973 to $24.07 per ton. This increase in value was due to modest increases in unit value by both the Florida and Georgia producers.

Fuller's earth production was reported from operations in nine States, an increase of one over 1972. The two top producing States, Georgia (39%) and Florida (37%), accounted for 76% of the domestic production. The other seven States accounted for the remaining 24%. Georgia, Mississippi, Tennessee, California, Florida, Texas, and Utah showed gains in production, while Illinois declined slightly. The new producing State in 1973 was South Carolina.

Fuller's earth is defined as a nonplastic clay or claylike material, usually high in magnesia, which has adequate decolorizing and purifying properties.

In 1973 Southern Clay, Inc., installed new bagging lines and a dryer at its Paris, Tenn., facility. Production from the region that includes Attapulgus (Decatur County), Ga., and Quincy (Gadsden County), Fla., is composed predominantly of the distinct lath-shaped amphibole clay mineral attapulgite. Most of the fuller's earth produced in the other areas of the United States contains varieties of montmorillonite.

Prices for fuller's earth were not publicly quoted in 1973, but the per-ton values re-

ported by producers ranged from $25 to under $40; montmorillonite prices ranged from $10 to under $25.

Exports of fuller's earth to 40 countries increased from 39,000 short tons in 1972 to 58,000 tons valued at $2.7 million in 1973. Export tonnage increased 49%, and its value increased nearly 59%. The unit value of exported fuller's earth rose $2.91 per ton. The major recipients were Canada, 29%; the United Kingdom, 22%; France, 12%; and other countries, the remaining 37%.

Imports of fuller's earth in 1973 were 52 short tons valued at $17,000, all from Japan and West Germany. Imports increased nearly 21%.

COMMON CLAY

Domestic production of common clay and shale in 1973 totaled 49.3 million short tons valued at $79.4 million. Common clay and shale represented 77% of the quantity and 22% of the value of the total clay and shale produced domestically in 1973. In addition, Puerto Rican production of common clay and shale was reported at 463,621 tons valued at $473,195. Domestic output in 1973 increased 7% over that reported for 1972.

Common clays and shales are for the most part used by the producer in fabricating or manufacturing a product. Less than 10% of the total clay and shale output was sold. The average unit value for all common clay and shale produced in the United States in 1973 was $1.61 per short ton, $0.01 more than in 1972. The range in unit value reported for the bulk of the output was from $1 to $2 per ton.

Common clay is defined as a clay or clay-like material which is sufficiently plastic to permit ready mold and vitrification below 1,100° C. Shale is a consolidated sedimentary rock composed chiefly of clay minerals that has been both laminated and indurated while buried under other sediments. These materials are used in the manufacture of structural clay products, such as brick and drain tile, portland cement clinker, and bloated lightweight aggregate.

In 1973 a new brick plant was put on-stream in Endicott, Nebr., by the Endicott Clay Products Co., and another tunnel kiln was added by Continental Clay Products Co. at its Martinsburg, W. Va., facility. Other brick plants were opened by the Henry Brick Co. in Selma, Ala., and in Mississippi. New plants and/or kilns were also put on-stream in Mississippi by Delta Macon Brick and Tile Co., Inc., in Macon and Tri-State Brick and Tile Co., Inc., in Jackson. Oklahoma Brick Corp. announced that its fully automatic 60-million-brick-per-year Oklahoma City plant was fully operational and that it intended to build a $4 million expanded shale aggregate plant at El Reno, Okla. The Onondaga Lightweight Aggregate Corp., Warners, N.Y., completed an expansion project which tripled its capacity. The project included a second sintering hearth and ancillary equipment acquired from the Consolidated Edison Power Co. in New York City. Increased production at Western Brick and Aggregates plant in Nebraska City, Nebr., was accomplished by installing lifters in its rotary kiln.

The output of the energy-intensive common clay and shale industry was curtailed by shortages of fuel, labor, and descumming barium chemicals in 1973. Industrywide attention was focusing on coal firing as a possible escape from the high cost and shortages of oil and gas.

Exports of common clay and shale are not tallied by the U.S. Department of Commerce. Most countries have local deposits of either clays or shales which are adequate for manufacturing structural clay products, cement clinker, and lightweight aggregates, and thus have no need to import such materials.

Table 14.—Common clay and shale sold or used by producers in the United States, by State[1]

CONSUMPTION AND USES

The manufacture of heavy clay products (building brick, sewer pipe, drain tile), portland cement and clinker, and lightweight aggregate accounted for 39%, 20%, and 18%, respectively, of the total 1973 domestic consumption of clays. In summary, 77% of all clay produced in 1973 was consumed in the manufacture of these clay- and shale-based construction materials. The foregoing clay tonnage relationships were similar to those reported for 1972. The utilization of clays in 1973 for heavy clay products and portland cement increased 10% and 2%, respectively, over that reported in 1972.

Heavy Clay Products.—The values reported for shipments of heavy clay products in 1973 rose by 8% to $783 million from the 1972 value of $722 million. The trends in corresponding quantities were less consistent. Thousand-unit counts for building or common face brick increased 6% in 1973 over that shipped in 1972, while shipments of glazed and unglazed ceramic tile and glazed brick, and of clay floor and wall tile decreased 6% and 2%, respectively. The tonnage of unglazed structural tile, and vitrified clay sewer pipe and fittings shipped during the year declined 6% and 5%, respectively. The value of these shipments, except for clay sewer pipe which decreased 5%, rose 14% for building brick, 15% for structural tile, 12% for ceramic tile, and 6% for clay floor and wall tile.

Lightweight Aggregate.—Consumption of clay and shale in the making of lightweight aggregate increased in 1973 to an alltime high of 11,657,978 short tons. This was an 8% increase over the 10.8 million short tons used in 1972.

The tonnage of raw material mentioned in tables 15 and 18 for lightweight aggregate production refers only to clay and shale and does not include the quantity of slate and blast furnace slag similarly used. In 1973, a total 1,092,021 short tons of slate was expanded for lightweight aggregate, 14% below the 1972 figure of 1,269,646 tons. The National Slag Association reported the amount of slag used for lightweight concrete aggregate and in block manufacture increased 23% in 1973, from 1,264,000 tons in 1972 to 1,560,000 tons.

Refractories.—All types of clay were used in manufacturing refractories. Fire clay, bentonite, and kaolin accounted for 72%, 16%, and 10%, respectively, of the total clays used for this purpose. Bentonite was used primarily as a bonding agent in proprietary foundry formulations. Minor tonnages of ball clay (1%), fuller's earth, and common clay and shale (the remaining 1%) were also used, primarily as bonding agents.

The tonnage used for refractories in 1973 increased from 7% in 1972 to 8% of the total clays produced. This slight increase in the use of clay-based refractories continued for a second year, a reversal in the downward pattern set for a number of years. The increase was due primarily to both the continued expansion in refractory aggregate production and an upsurge in the manufacturing of more conventional brick-type refractories. Refractory aggregates are used mostly in plastic, gunning, ramming, and castable mixes.

Filler.—All clays are used to some extent as fillers in one or more areas of use. Kaolin and fuller's earth are the principal filler clays. Kaolin was used in the manufacture of a large number of products, such as paper, rubber, plastics, paint, and fertilizers. The other important filler clay, fuller's earth, was used primarily in pesticides and fertilizers. Clays in pesticides and fertilizers are used either as carriers, diluents, or prilling agents.

Six percent of the clay produced in 1973 was used in filler applications. Kaolin accounted for 90%, and fuller's earth accounted for 6% of all the clay used for these purposes. The other clays accounted for the remaining 4%. The consumption of kaolin decreased, except for paper filling and coating, and pesticide grades which increased 11% and 1%, respectively. Kaolin used in rubber decreased 2%, in fertilizer 5%, in paint 7%, and in plastics 13%. Total quantity of fuller's earth used in insecticides and fungicides increased 21%.

Absorbent Uses.—Absorbent uses for clays, approximately 725,587 short tons, consumed slightly more than 1% of the total 1973 clay production. Demand for absorbents in 1973 increased 22% from that reported for 1972. Fuller's earth was the principal clay used in absorbent applications; 63% of the entire output was consumed for this purpose. Bentonite was used to a lesser degree. Demand for clays in animal litter, representing 47% of the 1973 absorbent demand, decreased 41% from that reported for 1972. Demand for use in floor absorbents, chiefly to absorb hazardous oily substances, represented the remaining 53% of absorbent demand and increased 11% from the 1972 figure.

Drilling Mud.—Demand for clays in rotary-drilling muds increased 7% in 1973, from 596,180 short tons in 1972 to 639,339 tons. This increase in demand, mostly in exploratory gas well drilling and a lesser degree in oil well drilling, was spurred by the deregulation of "new" gas introduced into the interstate market after April 6, 1972. Drilling muds consumed slightly less than 1% of the entire 1973 clay production. Swelling-type bentonite is the principal clay used in drilling mud mixes, although fuller's earth or nonswelling bentonite is also used to a limited extent. Bentonite and fuller's earth accounted for nearly 100% of the total amount of clay used for this purpose. Small amounts of ball clay and common clay and shale were used in specialized formulations.

Floor and Wall Tile.—Common clay and shale, ball clay, fire clay, and kaolin, in order of demand, were used in manufacturing floor, wall, and quarry tile. This tile end-use category accounted for less than 1% of the total clay production in 1973. Demand in 1973, 484,275 short tons, increased 7% from that shown in 1972.

Pelletizing Iron Ore.—Bentonite is used as a binder in forming iron ore pellets. Demand, resuming the general trend which declined last year, increased 10% in 1973 to 776,490 short tons. This rise in the use of bentonite for iron ore pelletizing, reflecting an upturn in steel production, was accomplished in spite of inroads made by cheaper foreign bentonites into a traditional U.S. clay market. Of the total bentonite produced in 1973, about 25% of the swelling variety (a decrease from the 26% in 1972) was consumed for this purpose. U.S. deposits continued to be the major source for swelling bentonites.

Pottery.—The total demand for clays in the manufacture of pottery, sanitary ware, china/dinner ware, and related products, excluding clay flower pots, accounted for 1% of the total 1973 clay output. The total clay demand, principally ball and kaolin clays rose about 7% from 646,515 short tons in 1972 to 691,530 short tons in 1973.

Tabe 15.—Clays sold or used by producers in the United States in 1973, by kind and use, including Puerto Rico

Total	11,657,978	15,755,883

Table 19.—Shipments of refractories in the United States, by kind

Product	Unit of quantity	Shipments 1972 Quantity	Shipments 1972 Value (thousands)	Shipments 1973 Quantity	Shipments 1973 Value (thousands)
CLAY REFRACTORIES					
Fire clay (including semisilica) brick and shapes, except superduty; glasshouse pots, tank blocks, feeder parts, and upper structure shapes used only for glass tanks.[1]	1,000 9-inch equivalent	214,475	r $49,475	234,781	$55,551
Superduty fire clay brick and shapes	----do------	67,826	24,930	68,147	26,715
High-alumina brick and shapes (50% Al_2O_3 and over) made substantially of calcined diaspore or bauxite.[1 2]	----do------	r 74,735	51,524	86,491	64,254
Insulating firebrick and shapes	----do------	44,684	14,824	54,373	18,332
Ladle brick	----do------	r 194,341	r 30,499	214,784	35,511
Sleeves, nozzles, runner brick, tuyeres	----do------	47,265	15,979	50,647	18,289
Hot-top refractories	Short tons	r 25,504	r 1,985	21,677	1,731
Clay-kiln furniture, radiant-heater elements, potters' supplies, other miscellaneous shaped refractory items.	------------	NA	11,883	NA	13,599
Refractory bonding mortars, air-setting (wet and dry types).[3]	Short tons	67,019	11,263	101,318	16,378
Refractory bonding mortars, except air-setting types.[3]	----do------	8,632	1,262	11,024	1,691
Plastic refractories and ramming mixes[4]	----do------	174,403	18,162	207,497	22,091
Castable refractories (hydraulic-setting)	----do------	192,624	24,528	212,682	28,286
Insulating castable refractories (hydraulic-setting)	----do------	44,642	7,647	45,725	8,012
Other clay refractory materials sold in lump or ground form.[5 6]	----do------	368,660	10,046	454,560	13,039
Total clay refractories		XX	r 274,007	XX	323,479
NONCLAY REFRACTORIES					
Silica brick and shapes	1,000 9-inch equivalent	32,437	12,877	36,668	15,309
Magnesite and magnesite-chrome brick and shapes, magnesite predominating (excluding molten-cast and fused magnesia).	----do------	r 87,763	r 107,620	110,487	146,311
Chrome and chrome-magnesite brick and shapes, chrome predominating (excluding molten-cast).	----do------	18,713	20,044	19,964	24,420
Graphites crucibles, retorts, stopper heads, and other shaped refractories containing natural graphite.	Short tons	15,756	15,759	18,567	18,313
Mullite brick and shapes made predominantly of kyanite, sillimanite, andalusite, or synthetic mullite, excluding molten-cast.	1,000 9-inch equivalent	4,517	8,917	4,918	9,961
Extra-high-alumina brick and shapes made predominantly of fused bauxite or fused or dense-sintered alumina, excluding molten-cast.[7]	----do------	r 2,475	8,629	2,998	11,379
Silicon carbide brick and shapes made predominantly of silicon carbide, including kiln furniture.	----do------	3,355	13,347	4,635	19,759

See footnotes at end of table.

Table 19.—Shipments of refractories in the United States, by kind—Continued

Product	Unit of quantity	Shipments 1972 Quantity	1972 Value (thousands)	1973 Quantity	1973 Value (thousands)
NONCLAY REFRACTORIES—Continued					
Zircon and zirconia brick and shapes made predominantly of either of these materials.	1,000 9-inch equivalent	1,785	$6,571	2,387	$8,785
Forsterite, pyrophyllite, dolomite, dolomite-magnesite, molten-cast and other nonclay brick and shapes including carbon refractories, except those containing natural graphite.[8]	----do------	r 33,882	r 64,019	37,187	73,258
Mortars:					
Basic bonding mortars, magnesite or chrome ore predominating.	Short tons--	11,465	1,355	16,198	1,639
Other nonclay refractory mortars	----do------	r 29,855	5,995	32,217	7,057
Nonclay refractory castables, hydraulic-setting	----do------	r 49,282	r 12,813	62,300	15,752
Plastic refractories and ramming mixes, wet and dry types:					
Basic—magnesite, dolomite, or chrome ore predominating.	----do------	r 129,225	18,371	141,339	22,062
Other nonclay plastic refractories and ramming mixes.	----do------	80,884	19,394	99,431	24,174
Dead-burned magnesia or magnesite	----do------	115,164	10,075	123,373	11,237
Nonclay gunning mixes	----do------	303,108	35,817	352,887	41,880
Other nonclay refractory materials sold in lump or ground form.[5]	----do------	342,587	11,620	393,280	13,745
Total nonclay refractories		XX	r 373,223	XX	465,041
Grand total refractories		XX	r 647,230	XX	788,520

r Revised. NA Not available. XX Not applicable.

1 Excludes data for mullite and extra-high-alumina refractories; these products are included in the nonclay refractories section.

2 Calcined as applied to diaspore and bauxite implies heat treatment short of fusion for volume stability prior to use in a refractory product. In the process volatile materials are driven off and chemical changes take place.

3 Includes bonding mortars which contain up to 60% Al_2O_3 dry basis; bonding mortars which contain more than 60% Al_2O_3 are included in the nonclay refractories section.

4 Includes products referred to as plastic fire brick and the less plastic materials intended for ramming into place after the addition of water, when shipped in dry form; excludes mixes made of mullite or alumina, which are included in the nonclay refractories section.

5 Includes shipments for direct use as finished refractory products by establishments classified in "manufacturing" industries and excludes shipments to refractory producers for reprocessing in the manufacture of brick and other refractories.

6 Includes data for calcined clay, ground brick and siliceous and other gunning mixes.

7 Fused as applied to bauxite and alumina means complete melting, as in an electric furnace; after cooling, the product is crushed and graded for use in the refractory. Dense-sintered alumina refers to heat treatment (short of melting) to render it relatively volume-stable for use in a refractory.

8 Molten-cast refractories are made by fusing refractory oxides, as in an electric furnace, and pouring the molten material into molds to form finished shapes.

WORLD REVIEW

Australia.—English China Clay Ltd. (ECC) and Abaleen Minerals NL disclosed additional information regarding their kaolin plans. ECC's new plant near Melbourne went on-stream, producing kaolin intended primarily for the Asian market. The new plant was to enable ECC to compete more effectively in Asia. Abaleen announced it was now able to acquire kaolin lease titles near Port Lincoln in South Australia. Previously Abaleen was working in agreement with three other companies. Abaleen's reserves were put at over 22 million tons with production scheduled for 1974. Production was targeted mostly for Europe and Asia. Preliminary tests on bulk samples from Abaleen's prospects showed the minus 2-micron kaolin fraction was highly suitable for papermaking. Presently, there is no Australian production of high-quality coating clays.[3]

The Yenyenning kaolin deposits in Western Australia were reported to contain two unspecified grades of economically important kaolins. Provisional estimates were around 7 million tons of high-grade material.[4]

Austria.—Kernfest-Ashland-Süd-Chemie Gieserei Chemikalien GmbH, formed by Ashland Chemical Co. and Süd-Chemie, acquired a 50% interest in Georg Hantos and Co. of Vienna. Hantos is an established supplier to the Austrian foundry market. The newly formed, jointly owned company was believed to be handling Wyoming bentonite. Ashland, through its association with Federal Bentonite Co. (USA), sells Federal's foundry line.[5]

Belgium.—A new rotary kiln 246 feet long and 15 feet in diameter was put onstream by Argex S.A. in Antwerp to supplement the output of its older kilns. Argex produces over 10% of the world's Leca expanded clay aggregates at its plant on the mouth of the Scheldt River. A significant

e Estimate. p Preliminary. r Revised. NA Not available.

[1] In addition to the countries listed, Brazil, People's Republic of China, East Germany, Lebanon, Southern Rhodesia, and Yugoslavia also produced kaolin, but information is inadequate to make reliable estimates of output levels. Morocco produced less than 500 tons in each of the years covered by this table.

[2] Kaolin sold or used by producers.

[3] Less than ½ unit.

[4] Includes kaolinitic clay.

[5] Excludes unwashed kaolin as follows in short tons: 1971—118,256; 1972—115,743; 1973—116,000 (estimated). This material has a value of less than 1/10th of the washed kaolin reported in table.

[6] Year beginning March 21 of that stated.

[7] Data given are for ceramic and pottery and paper filler clays.

[8] Includes ball clay.

portion of the plant's output, now rated at 1 million cubic yards per year, was exported, largely to Britain but also to other European countries.[6]

Brazil.—Ashland Chemical Co., in another overseas marketing expansion, set up a new company, Ashland Resinas Synteticas S.A. in São Paulo, with Bentonit União to sell both Ashland's present foundry chemicals and unannounced newer products.[7] A large kaolin deposit of good quality was located on the Jari River, a tributary of the Amazon, by National Bulk Carriers, Inc. Feasibility tests were underway to determine if processing facilities were warranted.[8]

Canada.—Indusmin Ltd. abandoned a kaolin prospect in northern Ontario and a bentonite project in Saskatchewan.[9] Production of iron-pelletizing-grade bentonite was started by Inland Cement Industries, Ltd., at its Regina, Saskatchewan, plant. Acceptance of this bentonite as a substitute for Wyoming material by the eastern Canadian iron ore operations was expected to result in construction of a separate Saskatchewan facility. Inland Cement's deposits are about 50 miles south of Regina near Truax.[10]

Czechoslovakia.—Additional capacity was added by the major kaolin-processing companies to meet increasing demand for their paper-filling grades. In spite of intensive research, these companies have been unsuccessful in producing acceptable paper-coating clays.[11]

France.—The diversified Saint-Gobain-Pont-A-Mousson group gained control of a major French refractory manufacturer, Société Genérale des Produits Réfractaires S.A. (SGPR), by purchasing Pechiney Ugine Kuhlmann's 33% interest.[12] The St. Gobain

[e] Estimate. [p] Preliminary. [r] Revised.
[1] In addition to the countries listed, France, Iran, Japan, and Turkey have reportedly produced fuller's earth in the past and may continue to do so, but output is not reported and available information is inadequate to make reliable estimates of output levels. Similarly, no information is available on output in the Communist nations of Europe and Asia, but at least some of them also are presumably producing fuller's earth.
[2] Data are for year ending June 30 of that stated.

group also concentrated its refractory activities under a new company, Société Europiene des Produits Réfractaires S.A. (SEPR). SGPR, a vertically integrated company, produces a range of clay and non-clay refractories as well as insulating firebricks and fused-cast refractories.[13]

Modifications of the Engelhard Minerals & Chemicals Corp. and Solvay's jointly owned Brittany kaolin facility were completed, and limited quantities of filler and coating-grade clays were shipped to European markets.[14]

Greece.—Total reserves of irregular kaolin deposits on the islands of Milos and Lesbos, and smaller occurrences on Santorni and Paliaigos, were put at 2.5 million tons proven and 3.5 million tons probable material. The kaolin occurs in grades suitable for paper coating and filler, and for manufacturing cement, refractories, and ceramics. The total bentonite reserves on Milos were 11 million tons proven and 17 million tons probable and possible. The two largest Milos bentonite producers, Silver and Baryte Ores Mining Co. and Mykobar S.A., were undergoing plant enlargements.[15]

Guyana.—The Government has intensified efforts to delineate kaolin reserves in light of Japanese, East German, and American interests. Proven reserves at Topirah (site of a large bauxite mine), in the upper Demerara region, have been estimated at 2.2 million tons where the bauxite has already been mined. Additional reserves totaling 6 to 7 million tons were reported to be adjacent to existing mining areas. Georgia-quality kaolins are believed to accompany the bauxite. Plans were also formulated to set up a kaolin-processing plant at Topirah with Japanese participation. The East Germans were concerned with manufacturing porcelain. The interested U.S. company, Philipp Bros., is the marketing agent for the state-owned Guyana Bauxite Co. and is also a member of the Englehard group which mines and processes Georgia kaolin.[16]

India.—Plans were announced by Minechem Processors and Grinders (associated with Dhandhania and Co.) to produce 25,000 tpy of china clay, quartz, feldspar, limestone, and soapstone through its grinding and calcining facilities in Bihar beginning in 1974.[17]

Indonesia.—An unnamed U.S. company was participating with the P. N. Timah Co. in exploring a large kaolin deposit.[18]

Italy.—S. A. Mineraria Isole Pontine (SAMIP), already mining an extensive high-grade bentonite deposit on the island of Ponza, announced discovery of a 3-million-ton deposit in Sardinia. The deposit is located near Isili and Nurallao. Preliminary reports imply the deposit may contain as much as 10 million tons of bentonite. Süd-Chemie, the Bavarian bentonite producer,

[17] Work cited in footnote 9.
[18] Work cited in footnote 8.

reported it was constructing a plant at Giba in southwest Sardinia. SAMIP and Süd-Chemie now join two other companies, Baroid S.p.A., a subsidiary of NL Industries, Inc., and Industria, Chemia Carlo Laviosa, already working the Sardinian bentonites.[19]

Japan.—International Trading Co., Inc., exporting agent for Georgia Kaolin Co., and Sumitomo Metal Mining Co. Ltd. constructed a new bulk terminal near Osaka.[20] This bulk terminal should lower delivery costs to Japanese markets. Bulk shipments to Europe started in the mid-1960's.

Netherlands.—A 50% interest in the second largest Dutch refractory producer. Chamotte-Unie NV of Geldermalsen, was reportedly taken by Gibbons Dudley Ltd. of the United Kingdom.[21] Rotterdam is currently being used by Euroclay Handelmaatschapij NV, a joint undertaking of Georgia Kaolin Co. (GK) and Amberger Kaolinwerke AG (West Germany), for a storage and distribution center for supplying GK's filling and coating clays to the European paper industry. Euroclay can store up to 30,000 tons to insure delivery.[22]

New Zealand.—New Zealand processed bentonites, available in 5,000- to 5,500-ton lots either bulk or bagged, were offered for sale in Australia by Bulk Minerals Pty. Ltd.[23]

Spain.—Laporte Industries of the United Kingdom bought a 40% interest in the Spanish bentonite producer, Minas de Gador. This privately owned company accounts for 80% of the Spanish bentonite production. Laporte, the largest bentonite producer in the United Kingdom, has facilities at Redhill in Surrey and Combe Hay in Bath, Somerset. Laporte is expected to develop the company's deposits and furnish technology for constructing acid-activating and sodium-base exchanging facilities near Almeria.[24] Argilexpand of Vallés, in Barcelona Province, planned to erect a sodium bentonite processing plant on an undisclosed site.[25]

Turkey.—A new vertically integrated company, Sogut Seramik Sanayii AS, was formed to establish a ceramics industry in the Sögüt area of Bilecik in Western Anatolia.[26]

United Kingdom.—Applied Aluminum Research Corp. of the U.S.A. in conjunction with the London merchant bankers, Bremar Holdings, revealed details of the world's first semicommercial plant to produce aluminum metal by the Toth process. This semicommercial plant, probably located within the United Kingdom, reportedly will cost about $25 million to build and have a metal capacity of 35,000 tons per year.[27] ECC continued modernizing its old installation in Cornwall. The planning permission for extending ECC's operation into Lee Moor was received following assurances about various environmental safeguards.[28]

Production of Laponite, a synthetic hectorite-type clay, was to be expanded at Laporte Industries' Stallingborough plant near Grimsby. Hectorite is mined in the United States. Laponite and hectorites have the unique ability to produce clear suspensions and gels at extremely low concentrations, and are finding increasing application as thickeners in highly specialized fields and for their heat-resistant, anti-static, nontoxic, and clarifying properties.[29]

The Refractories Division of the Gibbons Dudley Ltd. group, consisting of Gibbons Refractories Ltd., United Fireclay Products Ltd., and Thomas Wragg and Sons (Sheffield) Ltd., has formed a new company, Gibbons International Refractories Ltd., to coordinate exports for the entire division.[30]

TECHNOLOGY

The Bureau of Mines at its Boulder City (Nev.) Metallurgy Laboratory initiated plans to set up and operate miniplants utilizing the more promising processes for extracting alumina from nonbauxitic materials, starting with the nitric acid processing of Georgia kaolin. The nitric and hydrochloric acid processes, the next to be studied, for treating alumina-bearing clays were judged the most promising for economically producing alumina from nonbauxitic ores. Other aluminiferous materials scheduled for future miniplant studies include other clays, anorthosite, dawsonite, and alumina-bearing wastes, such as shales and slates, from coal mining and processing. A cooperative project between the Bureau of Mines and the aluminum industry was being explored.

Work at Applied Aluminum Research Corp. (AARC)[31] and Reynolds Metal Co.[32] on direct aluminum metal processes was described. AARC's process, called the Toth process, applicable to clays and bauxites, begins by chlorinating a calcined clay in the presence of a reductant, such as coke, followed by fractional condensation to separate the aluminum, iron, silicon, and titanium chlorides. The separated aluminum chloride is subsequently reduced to aluminum metal and manganese chloride. The manganese chloride is further processed to both recover and recycle the manganese metal and chlorine. The other fractionally condensed metal chlorides are either converted to oxides, thereby recovering the chlorine, or sold as is.

The Reynolds process involves reducing titaniferous clays in a fused-salt bath to an aluminum-titanium alloy. The alloy is kept molten below 1,000° C causing it to separate into a low-titanium and aluminum supernatant and a heavier high-titanium and aluminum intermetallic compound. The intermetallic compound is periodically tapped, leaving a recoverable supernatant phase.

Other patents issued during the year cover a prereduction process for producing alumina and aluminum alloys from clays[33] and a method for recovering alpha-alumina, also from clays.[34] In the first patent, the initial step involves prereducing an ore-coal or coke mixture at temperatures from 1,500° C to 1,800° C. The second step transfers the prereduced product to an electric furnace, where it is fluxed and heated to between 2,000° C and 2,300° C, converting the silicon carbide to silicon and the alumina to aluminum metal. The second patent details treating a calcined clay with hot nitric acid, resulting in a leach liquor containing less than 0.05% by weight of silica contaminant. The silica and other impurities are removed from the leach liquors by combined flocculation and solvent extraction steps. A purified hydrated aluminum nitrate is subsequently crystallized and heated in a fluidized bed forming recyclable nitric acid vapors and a dried aluminum nitrate, which is calcined to an alpha-alumina.

High-gradient magnetic separation (HGMS), a new and promising technology presently applied only in cleaning kaolin clays, was the topic of a thorough article.[35] HGMS devices were being used by several Georgia kaolin companies in removing micron-size discoloring particles, mainly weakly magnetic, yellow iron oxide stained rutile grains, from kaolin slurries destined for glossy white paper coating. HGMS devices, available for licensing to the clay industry by J. M. Huber Corp., were reportedly making available kaolin reserves which previously could not be beneficiated economically. The commercial-scale continuous attrition grinding of coarse paper filler kaolins to the finer paper-coating grades was reported by the Bureau of Mines.[36] A 20-inch-diameter grinding system was described along with optimized operating parameters. The role of kaolin in water-based latex paints, with emphasis on TiO_2 substitution, was reviewed.[37] The market

growth for clay and nonclay extender and filler pigments in the North Atlantic countries was forecast.[38]

A comprehensive article on the structures and compositions of clay materials, clay-water-exchange cation relations, and the thermal behavior of clay minerals and clay materials was published.[39] The reaction rates of aqueous phosphate solutions with kaolinite and alumina were detailed in another work.[40] The kinetics obeyed a first-order rate law probably involving nucleation and growth of a hexagonal $AlPO_4$ phase. The research gives an insight into the high phosphorous-binding capacity of sediments, eventually leading to the more efficient removal of phosphate pollutants from streams. Phosphorus has long been recognized as one of the main nutrients which accelerates eutrophication. The orientation of the hydroxyl ion in kaolinite, dickite, and nacrite was determined.[41] This work should contribute to the more efficient calcining of kaolins which are widely used in refractories, in ceramics, and as fillers and extenders. The dehydroxylization of kaolins is also the primary step in "opening-up" many clays for recovery of their alumina. The Gibbs free energies of formation of kaolinites, flint clays, illites, calcium, and sodium montmorillonites (nonswelling and swelling bentonites) were also determined from experimental work.[42] These data will permit more meaningful thermodynamic calculations for existing and predicted pyrogenic processes involving clays. An X-ray diffraction study of montmorillonites revealed that heat-treated clays give a more reliable estimate of silicate layers per particle than the conventional organic-treatment methods.[43] Penetration of the montmorillonite layers by the organic glycol molecules, normally an indication of swelling and/or exchange capacity, was found to be subject to uncontrolled variables which could lead to misleading results. Heat treatment combined with X-ray diffractometry was shown to give a more accurate measure of the silicate layers. The study of transmission[44] electron images coupled with selected area electron diffractometry revealed the presence of fine-grained micas in Camp Berteaux Moroccan bentonites. The study also showed the Wyoming bentonites were better crystallized, of larger crystalline size, and relatively free of the mica contaminants found in the Moroccan bentonites. The Moroccan bentonites also were reported to contain minor amounts of chlorite and kaolinite.

A detailed article on fuller's earth in England and the European bentonite industry was published.[45] The fuller's earth discussion dealt with Laporte Industries Ltd. sodium and calcium bentonites and activated earth operations at Redhill, Cockley, and Copyhold. The article also stressed new marketing areas, largely in civil engineering, and in animal feeds, absorbents, and insecticides. The Redhill mining operation supplies the Cockley works which produces the firm's acid-activated earths. The Copyhold facilities prepare the natural and exchanged clays. A concise account of the two acid activating processes—sulfuric and hydrochloric—used at Cockley and the sodium-exchange works at Copyhold, including their "Laponite" production—a synthetic hectorite—was also detailed. The bentonite portions covered the geology, mining and processing techniques, technological advances, environmental problems, markets, products, and future of the industry in Bavaria, West Germany; Ponza, Italy; and elsewhere in Europe and the Mediterranean. A similar article on bentonites in the United States was published.[46]

The role of bentonite in pelletizing iron ores was investigated thoroughly. This investigation was primarily to either reduce the quantity or find suitable alternatives to

Wyoming bentonites.[47] The influences of wet and dry strengths, drying rates, pellet porosity and moisture level were obtained from carefully prepared sized particles and interpreted in terms of the physical and chemical characteristics of United States, Western Australian, and New Zealand bentonites. The iron ore in this research was a hematitic ore from Koolen Island, Western Australia. Wyoming bentonites produced the highest green and dry strengths, enabling more efficient operations and high drying temperatures. Suppression and control of spontaneous combustion in English coal mines was controlled with bentonite slurry injections.[48]

A detailed discussion of the Western European refractory industry, both clay and nonclay raw materials, finished refractory goods, fired bricks and shapes, and monolithics, by country, was highlighted.[49] The discussion dealt with many individual companies. A similar in-depth study of the refractory industry in Japan was detailed in another article.[50] Selection of refractory rotary kiln linings consistent with a continuous increase in portland cement clinker output and a decrease in heat consumption was treated exhaustively.[51] Another comprehensive work on the performance of fire clay and high-alumina refractories in the sliding gate method of metal pouring was published.[52] Substantial savings on refractory costs were realized with fire clay and other lower alumina content nozzles.

A concise article on moving and renovating a fly ash sintering plant into an expanded shale operation was published.[53] The article included a flowsheet for the renovated plant. Another paper on preparing expanded shale aggregates for agricultural uses was published.[54] Comparative tests showed that expanded shales outperformed all other materials, such as perlite, vermiculite, peat, sand, sawdust, and styrofoam, as a rooting medium. The expanded shales were particularly effective in well-drained areas. Mineralogy and geochemistry of Pennsylvanian shales and underclays were correlated with their suitability for lightweight aggregate and refractory ladle brick at the Fall meeting of the AIME.[55]

Coal—Bituminous and Lignite

By L. Westerstrom [1]

DOMESTIC PRODUCTION

Bituminous coal and lignite production declined from 595.4 million tons in 1972 to 591.7 million tons in 1973. In 1973, coal demand exceeded supply throughout the year. The coal industry at times was unable to provide coal for new customers, while regular customers drew heavily from inventories. The loss in production, despite a strong demand for coal, was caused by insufficient mine capacity, unauthorized work stoppages, lower productivity in underground mines, and unfavorable weather.

Underground production declined 4.8 million tons in 1973 while production from surface mines, strip and auger, increased 1.1 million tons. Production increased in Western States and in the major coal-producing States of Kentucky and Pennsylvania, but declined in Alabama, Illinois, Indiana, Ohio, Virginia, and West Virginia.

This survey includes all bituminous coal produced in the United States except that from mines that produced less than 1,000 tons per year. All quantity figures represent marketable coal and exclude washery and other refuse. Statistics are based upon detailed annual reports furnished by producers. For production not directly reported (chiefly that of small mines), data were obtained from the records of State mine departments, which have statutory authority to require such reports. Thus, complete coverage of all mines producing 1,000 tons per year or more is reported.

The weekly and monthly estimates of production, summarized in tables 6 and 7, are based upon railroad car-loadings of coal reported weekly by railroads, river shipments reported by the U.S. Army Corps of Engineers, reports from mining companies, and monthly production statements complied by local operator associations and State mine departments.

Employment declined from 149,300 men in 1972 to 148,100 men in 1973. Productivity was also lower in 1973, but the rate of decline was less than in the 4 previous years. The average output per man-day at all mines fell from 17.74 tons in 1972 to 17.58 tons in 1973. At underground mines, output declined from 11.91 tons to 11.66 tons; output at strip mines increased from 35.95 tons to 36.30 tons per man-day.

RESERVES AND RESOURCES

The United States has vast coal resources. The U.S. Geological Survey has identified, at depths of less than 3,000 feet, deposits containing nearly 1,600 billion tons of coal. An additional hypothetical coal resource of comparable size is surmised to exist on the basis of broad geologic knowledge and theory. The Bureau of Mines has evaluated the information on identified deposits in order to determine the quantity of coal available in relatively thick beds and near enough to the surface to mine at this time by conventional surface or underground methods.[2]

Tables 2, 3, and 4 summarize the quantity of in-place coals calculated under specified depth and thickness criteria, which has been termed the "reserve base" by the Bureau of Mines. Thickness criteria were 28 inches or more for bituminous coal and anthracite, and 60 inches or more for subbituminous coal and lignite. The maximum depth for all ranks except lignite was 1,000

[1] Industry economist, Division of Fossil Fuels—Mineral Supply.

[2] U.S. Bureau of Mines. Demonstrated Coal Reserve Base of the United States on January 1, 1974. Mineral Industry Survey, June 1974, 6 pp.

feet. Only lignite beds that can be mined by surface methods were included—generally those beds that occur at depths no greater than 120 feet. Some coalbeds that did not meet the depth and thickness criteria were included because they are presently being mined or it was judged that they could be mined commercially at this time. "Demonstrated" is a collective term for the sum of materials in both the measured and indicated reserve categories, as defined by the Bureau of Mines and Geological Survey. These categories are based upon a high degree of geologic identification and engineering evaluation. The quantity of coal that can be recovered economically and legally from the reserves base is termed "the coal reserve."

CONSUMPTION AND DISTRIBUTION

Consumption of bituminous coal and lignite in the United States increased 7.6%, primarily at electric utility and oven coke plants and at steel-rolling mills. The remaining principal consumers used less coal than in the previous year. Consumers drew heavily from stockpiles during the year, and at the end of December, inventories had been depleted by over 14 million tons.

Tables 40, 41, and 42 summarize the shipments of coal and lignite in 1973. Table 43 shows the quantitative changes, by geographic division, and States of destination from 1969 through 1973. The distribution data, by consumer use, does not necessarily conform to the consumption data because the latter represents actual use at consumers' facilities, whereas the distribution data represents shipments from mines, some of which were in transit or in consumers' storage. These distribution data are based on reports submitted quarterly to the Bureau of Mines by producers, sales agents, distributors, and wholesalers, who normally produce or sell 100,000 tons or more annually. Their reported tonnage accounted for 93% of the coal produced or shipped in 1973. To account for total industry shipments, estimates for the remaining shipments are included, based on data from the Federal Power Commission and other reliable coal statistical reporting agencies.

Additional details of bituminous coal and lignite distribution for 1973 are presented in a Bureau of Mines report.[3]

PRICES

The average f.o.b. mine value for all coal increased from $7.66 per ton in 1972 to $8.53 per ton in 1973. At underground mines, the average price of coal increased from $9.70 per ton in 1972 to $10.84 per ton in 1973. The average price of coal at strip mines increased from $5.48 to $6.11 per ton. Average rail freight charges on coal increased from $3.67 per ton in 1972 to only $3.71 per ton in 1973 despite substantial increases in railroad freight rates. The slight increase in rail costs for transporting coal reflected the increase in unit-train traffic of nearly 19 million tons at reduced freight rates.

FOREIGN TRADE

Less coal was shipped from eastern and midwestern coal-producing districts in 1973. Shipments from the Appalachian Region were 18 million tons less than in 1972; shipments from western Kentucky, Illinois, and Indiana were approximately 2 million tons below those of 1972. Total shipments from Western States increased nearly 14 million tons in 1973.

In 1973, the United States exported 52.9 million tons, 3.1 million tons less than in 1972. Japan maintained its position as the principal U.S. foreign market with a 36.3% share of total U.S. coal exports. Shipments of coal to Canada, Europe, and South America accounted for 30.7%, 26.9%, and 5.0%, respectively.

TECHNOLOGY

Coal research by the Bureau of Mines during 1973 showed increased emphasis on the conversion of coal to low-ash, low-sulfur fuels through either gasification or liquefaction. At the same time, continued effort was expended to improve the quality of the environment.

Work on the SYNTHANE pilot plant has progressed to approximately 70% completion. This process, developed by the Bureau, gasifies any kind of coal with oxygen and steam to produce substitute natural gas. Following completion of the pilot-plant, which was scheduled for December 1974, operation was expected to provide data essential for demonstrating the commercial feasibility of the process.

Favorable results were obtained in converting high-sulfur coal to low-sulfur by the SYNTHOIL process. In this process, coal slurried in recycle oil is propelled by a rapid, turbulent flow of hydrogen through a fixed-bed catalytic reactor at 840° F at pressures up to 4,000 pounds per square inch. Using cobalt molybdate catalyst, about 95% of the coal is transformed into an oil that is fluid at room temperature and is suitable for boiler plant fuel. Design of an 8-ton-per-day pilot plant is underway; construction was scheduled to start in 1975. In addition, a feasibility study of the process was completed by an outside engineering firm.

In related coal combustion studies, construction continued on the three-stage combustor, designed to produce low-ash, high-temperature gas suitable for use in open-cycle magneto hydrodynamic (MHD) power generation. This combustor could also be used as a source of low-Btu gas for firing boilers.

Treatment of dried lignite with oil was found to reduce the reactivity of very low-moisture lignite more effectively than similar treatment of lignite dried to a mid-moisture content. The deactivation of dried low-rank coals to permit safe shipment and storage is a major objective in upgrading low-rank coals by drying. Such results may help establish the commercial feasibility of the process.

Bureau research on coal preparation has resulted in the development of a two-stage pyrite flotation process, which in laboratory tests removed up to 90% of the pyrite contained in coal from the Lower Freeport seam. Recently, the Bureau entered a cooperative research program with a coal company to study the applicability of this process to a high-sulfur coal now being discarded as waste. The two-stage pyrite flotation process is also being considered by a major steel company for commercial application to remove sulfur from coal from the Pittsburgh coalbed.

Research during the year on the Bureau's COSTEAM process showed that ash recovered from easily liquefied coals can effectively catalyze the liquefaction of more refractory (difficult to liquefy) coals.

During the year the final report on the design to be used in constructing the wood-to-oil pilot plant was completed. This pilot plant is to be erected at the Albany Metallurgy Research Center, Albany, Oreg., and will be capable of converting 3 tons per day of wood chips to about 6 barrels of low-sulfur fuel oil.

In combustion research during the year, the combustion characteristics were determined for low-volatile (5%) chars prepared from Illinois and Utah coals. When the chars were fed to the 500-pound-per-hour pulverized-fuel-fired furnace at ambient temperature, supplemental fuel equivalent to 15% of the total thermal input was required to maintain stable flames. Preheating the primary air-char stream to 450°–500° F eliminated the supplemental fuel requirement.

Table 1.—Salient statistics of the bituminous coal and lignite industry in the United States

Item	1969	1970	1971	1972	1973
Production thousand short tons	560,505	602,932	552,192	595,386	591,738

[1] Prior to 1973, the average heat content of the annual output of bituminous coal and lignite was measured at 13,100 Btu per pound. This value was based on an estimate made in 1949 (U.S. Bureau of Mines Information Circular 7538). In recent years, this heat value has not been representative of the average unit heat value of the total annual coal supply because of the large annual increases in utilization of coal of lower heat values by the electric utility industry. The annual production values shown in this table are weighted averages of known and estimated Btu values of coal shipments to each major consuming sector. They include, for example, the Btu value of coal consumed at electric utility generating plants as reported to the Federal Power Commission and compiled by the National Coal Association. Currently, electric utility plants account for 70% of total domestic coal consumption. The averages for U.S. consumption exclude shipments overseas and to Canada, the preponderance of which is of high Btu value metallurgical coal, thus accounting for the difference in values between total production and domestic consumption.

Table 6.—Production of bituminous coal and lignite in the United States, with estimates, by week

(Thousand short tons)

W Withheld to avoid disclosing individual company confidential data.
[1] Includes coal loaded at mines directly into railroad cars or river barges, hauled by trucks to railroad siding, and hauled by trucks to waterways.
[2] Includes coal used at mine for power and heat, made into beehive coke at mine, used by mine employees, used for other purposes at mine, and shipped by slurry pipeline from Arizona.
[3] Data may not add to totals shown because of independent rounding.
[4] Value received or charged for coal, f.o.b. mine. Includes a value, estimated by producer, for coal not sold.
[5] Less than 500 tons.

W Withheld to avoid disclosing individual company data.

[1] Includes coal loaded at mine directly into railroad cars or river barges, hauled by trucks to railroad sidings, and hauled by trucks by slurry pipeline in Arizona.

[2] Includes coal used at mine for power and heat, made into beehive coke at mine, used by mine employees, used for all other purposes at mine and shipped by slurry pipeline from Arizona.

[3] Data may not add to totals shown because of independent rounding.

[4] Value received or charged for coal f.o.b. mine. Includes a value for coal not sold but used by producers, such as mine fuel and coal coked as estimated by producers at average prices that might have been received if such coal had been sold commercially.

[5] Less than 500 tons.

Table 19.—Number of mines, men working daily, days active, and output per man per day at bituminous coal and lignite mines in the United States, in 1973, by State and county

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, Ecuador produces coal, but output was less than 500 tons annually in the years covered by this table.

[2] Excludes production from the State of Texas.

[3] May include a small amount of anthracite.

[4] Includes materials reported in natural sources as brown coal.

[5] Available sources report only lignite production; a small amount of bituminous coal may also be produced.

[6] Official sources report the aggregate of bituminous coal and anthracite; distribution to these separate grades is estimated from reported total.

[7] Output from Norwegian controlled portion only. Output of that portion of Svalbard controlled by the U.S.S.R. is presumably included in the total output recorded for that country.

[8] Run-of-mine output.

[9] Sales, for year ending August 31 of that stated.

[10] Year beginning March 21 of that stated.

[11] Year ending June 30 of that stated.

[12] Bituminous coal plus lignite for the People's Republic of China and Pakistan.

Coal—Pennsylvania Anthracite

By Dorothy R. Federoff [1]

Data in this chapter refer only to anthracite or hard coal, produced in 12 counties in northeastern Pennsylvania. The anthracite region is divided geologically into four fields: Northern, Eastern Middle, Western Middle, and Southern. The area is also grouped into three trade regions: Wyoming, Lehigh, and Schuylkill.

The production of anthracite continued to decline in 1973, but at a decelerated rate. Increased world demand for steel, shortages of metallurgical bituminous coal, and the curtailed availability of oil supplies in the last quarter of 1973 all combined to open additional markets for anthracite, creating a demand greater than the supply.

Total production of anthracite in 1973 was 6.8 million short tons, a decrease of approximately 3.9% from that of 1972. Of the total output, 48% was produced at strip pits, 35% at culm and silt banks, 11% at underground mines, and 6% at dredging operations. When compared with tonnages produced in 1972, underground production declined 23%; strip production, 6%; and dredge coal, 8%; however, culm and silt production increased 8%.

Total value of the 1973 output was $90.3 million, a 5.9% increase over that of 1972. The average value f.o.b. preparation plants for all sizes of anthracite, including dredge coal, was $13.22 per ton, compared with $12.00 per ton in 1972. The average value of pea and larger sizes increased $1.58 to $18.76 per ton, and the average value of buckwheat No. 1 and smaller sizes increased $1.16 to $11.30 per ton. Although production was less in 1973, value was greater due to the increase in prices.

Apparent consumption of Pennsylvania anthracite in the United States in 1973, calculated as production minus exports, excluding that exported to West Germany for use by the U.S. Armed Forces, totaled approximately 5.7 million tons compared with 5.9 million tons in 1972—a decrease of 4.1%. Although use data are incomplete for anthracite, slight declines occurred in all categories.

Exports of Pennsylvania anthracite, according to the U.S. Bureau of the Census, totaled 716,546 tons shipped to Canada, Europe, and other foreign countries. A more accurate measurement of exports can be obtained by adding the quantity shipped for use by the U.S. Armed Forces in West Germany to the tonnage reported by the Bureau of the Census. This computation indicates that approximately 1,159,000 tons was actually exported, or 2.7% less than in 1972.

The Pennsylvania anthracite mining industry worked an average of 234 days in 1973, compared with 216 days in the preceding year. The work force averaged 4,083 men, a drop of 14.6% below the 1972 level. Of that total, 40% were employed at strip pits, 21% at underground mines, 8% at culm and silt recovery, 1% on dredges, and 30% at breakers. Although there was a slight decline in total production and the number of men working daily, the productivity rate in average tons per man-day increased from 6.88 tons in 1972 to 7.15 tons in 1973. The rise was due primarily to an increase in surface mining. One fatality occurred in 1973 (2 in 1972), and 370 nonfatal injuries, compared with 272 in 1972.

The Bureau of Mines publishes a series of weekly reports containing estimates of weekly and monthly production based on carloadings reported by railroads, and monthly production statements of truck shipments provided by the Commonwealth of Pennsylvania.

[1] When slate content in sizes from broken to chestnut, inclusive, is less than the above standards, bone content may be increased by 1½ times the decrease in slate content under the allowable limits, but slate content specified above shall not be exceeded in any event.
A tolerance of 1% is allowed on maximum percentage of undersize and maximum percentage of ash content.
Maximum percentage of undersize is applicable only to anthracite as it is produced at preparation plants.
Slate is defined as any material that has less than 40% fixed carbon.
Bone is defined as any material that has 40% or more, but less than 75%, fixed carbon.
[2] Ash determinations are on a dry basis.

Legislation and Government Programs.— Federal and State government programs in the environmental area continued through 1973, and included control and extinguishment of fires at abandoned underground and surface mines, prevention of surface subsidence above abandoned mines, reclamation of old strip pits and culm banks, and mine-water control projects designed to secure the safety and livelihood of mine personnel and to protect anthracite reserves from the hazards of adjoining abandoned mine pools and possible inundation by surface floodwaters.

Hydrologic studies to evaluate mine-water problems were continued. They involved determination of the varying heights of underground mine pools, their hydrostatic pressures and possible effect upon barrier pillars and mine dams protecting active mining operations, acid mine-water drainage into surface streams, and the unconsolidated valley fill. A comprehensive series of mine pool monitoring stations has been installed in the Western Middle and Southern Fields. The time available for project work particularly in map work related to subsidence, mine-water, and levee studies, was severely limited because of additional assignments resulting from the flood in 1972.

Schuylkill County:			
Shenandoah Borough	Appalachia mine fire control at site of former Kehley Run colliery, Phase I exploratory drilling only; control work taken over by Commonwealth of Pennsylvania in 1970.	----do----------	Completed in 1973.
SURFACE MINE RECLAMATION PROJECTS			
Lackawanna County:			
Taylor Borough ----	Keyser Valley strip mine area reclamation demonstration project.	Commonwealth of Pennsylvania and U.S. Bureau of Mines.	Part I started 1972, completed 1973. Part II started and completed, 1973.
Luzerne County:			
Preston -----------	Conservation and Development—Refuse bank reclamation demonstration project.	----do----------	Started 1973, still in progress.

The development of new technology to backfill underground mine voids to prevent subsidence was demonstrated successfully. The work consisted of drilling exploratory boreholes, sonar caliper surveying of mine beds, receiving crushed culm or breaker material from a mixer-blender plant, and flushing the material as a water slurry through the boreholes into the inundated and dry mine voids of the demonstration mines. When the project is completed, the boreholes are then pulled and sealed with concrete.

An overall program aimed at controlling fires in anthracite and other coal refuse banks included investigations into the cause and environmental effects of these fires, attempts at their early detection and inventorying, and the development of economic techniques for quenching and removing burning coal refuse banks. Two demonstration projects have been completed—one evaluating the most effective use of relatively conventional means of extinguishment, and the other involving a technique of simultaneously quenching burning material by surface sprinklers and a subsurface water injection system. Work was judged successful in terms of the amount of water utilized in extinguishment and material removed. Under the two phases of the project, a total of 390,000 cubic yards of bank material was quenched, excavated, and leveled.

The value of the longstanding map folio program to the public was demonstrated by the numerous requests received by the Bureau of Mines from various local authorities to evaluate subsurface conditions in relation to subsidence potential for proposed civic improvements and investigations of possible structural failure in bridges and highways. The data accumulated by the program have also proved an invaluable aid in evaluations made by the U.S. Army Corps of Engineers for the maintenance, and possible expansion, of flood control projects under its jurisdiction in the Northern anthracite field.

In a continuation of the project to record the maps of underground workings at anthracite mines, maps of a total of 301 major and 20 independent mines located in the 4 anthracite fields have been photographed. Work continued on compiling surface and bed maps in stratigraphic sequence for selected areas in the Northern field.

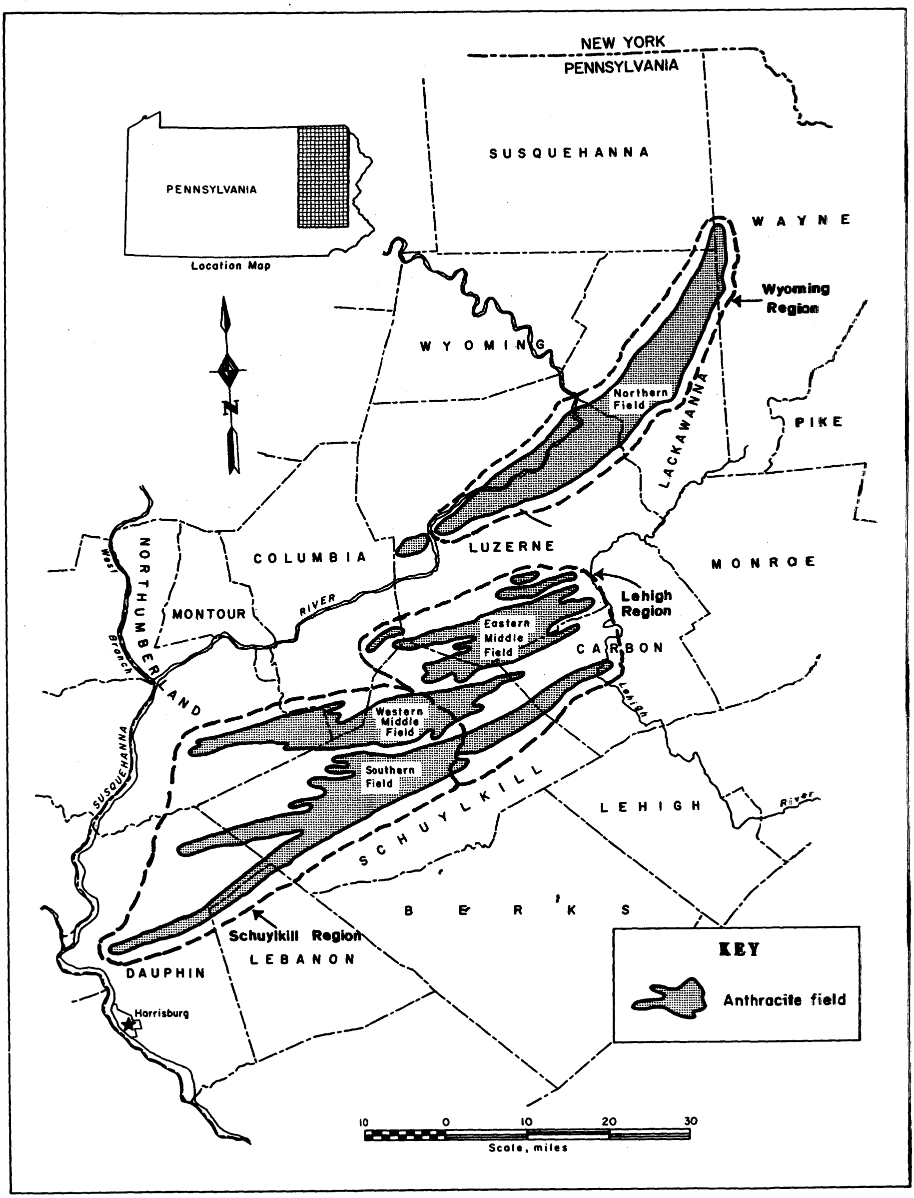

Figure 1.—Coalfields, regions, and counties of the Pennsylvania anthracite area.

DOMESTIC PRODUCTION

Production of Pennsylvania anthracite totaled 6.8 million short tons in 1973, a decrease of approximately 3.9% from that of 1972. Underground production accounted for 11% of the total output, compared with 13% in 1972. The decline in underground mining was due to health and safety consideration, manpower shortages, and the high cost of pumping water from flooded mines. Strip production totaled 48% (49% in 1972); culm and silt recovery, 35% (31% in 1972); and river coal, 6% (7% in 1972).

Two of the producing regions showed losses in 1973. In the Schuylkill region, total production was 0.8% less than that in 1972, and the total production in the Wyoming region showed a decrease of 24%. However, production in the Lehigh region indicated a slight gain of 5% over that in 1972. The Schuylkill region contributed 59% of the total production; the Lehigh region, 26%; and the Wyoming region, 15%.

The two leading counties in the production of anthracite were Schuylkill County with a total of 3 million tons, and Luzerne County with approximately 2 million tons. Other counties producing anthracite were Berks, Carbon, Columbia, Dauphin, Lackawanna, Lancaster, Northumberland, Snyder, Sullivan, and Susquehanna.

In operation at strip pits and in culm recovery were 138 front-end loaders, 50 power shovels, and 112 draglines.

Underground production in 1973 totaled 725,789 tons, a decrease of 23% from that in 1972. The Schuylkill region accounted for 77% of the output, and the Wyoming region for the remainder. Output in the Schuylkill region decreased by approximately 13%; the Wyoming region output dropped 44%.

Of the total underground anthracite produced, 58% was loaded mechanically, compared with approximately 63% in 1972. The mechanical loading of anthracite declined 29% from the level of 1972, with a concurrent decrease of approximately 14% in the number of loading units. The total mechanical equipment consisted of 72 scraper loaders, 4 mobile loaders, and 47 conveyor and pit-car loaders.

Production from strip mines totaled approximately 3.3 million tons, a decrease of 5.9% from that of 1972, and accounted for 48% of the total production in 1973. Output in the Schuylkill region totaled 1.4 million tons, a decrease of 7.4%; and in the Wyoming region, approximately 683,000 net tons, a decrease of 20.6%. However, the Lehigh region, with approximately 1.2 million tons, indicated an increase of 8.1% over that in 1972.

Culm and silt recovery totaled 2.4 million tons, an increase of approximately 182,000 tons, or 8% above the 1972 output. The Schuylkill region indicated a slight increase, 68% of the total recovered in 1973, compared with 64% in 1972. However, the percent of recovery decreased in the Lehigh region, to 26% compared with 28% in 1972; and in the Wyoming region, to 7% compared with 8% in 1972.

Dredging operations produced approximately 441,000 tons in 1973, a decrease of 8% from that in 1972, and a significant drop from the 1.5 million tons recovered in 1941. In the preceding decades, many dredges worked the rich coal deposits on the river beds; a significant portion was consumed in the generating of electricity. After 50 years of river dredging, the Pennsylvania Power and Light Co. will discontinue their river mining because of insufficient coal remaining on the riverbed to make the salvage operation economically feasible.

DISTRIBUTION

Shipments of Pennsylvania anthracite reported for the calendar year January 1, 1973, to December 31, 1973, totaled 6,341,928 net tons, a decrease of approximately 5.8% from the 1972 calendar year. Of this amount, 81.7% was shipped to markets within the United States (a decrease of 6.5%), 7.5% was exported to Canada (a decrease of 1.4%), and 10.8% was exported to countries other than Canada (a decrease of 1.4% from 1972).

In the U.S. market, shipments of pea and larger sizes decreased by 4.2%, and buckwheat No. 1 and smaller decreased by 7.5%. In the Canadian market, the pea and larger sizes dropped 36.3%, while the total buckwheat No. 1 and smaller sizes increased by 5.5%. Exports to countries other than Canada indicated an increase of 3.3% in the pea and larger sizes, but a decline of 8.6% in the buckwheat No. 1 and smaller sizes.

All market areas in the United States indicated losses, except the South Atlantic and the Lake States, which showed increases of 91.7% and 17.5%, respectively. In 1973, shipments to West Virginia were included in the South Atlantic States instead of the "Other States" category as they were in 1972, which accounts for the greater percentage increase in that area. Shipments to the New England States and the Middle Atlantic States decreased by 2.5% and 9.3%, respectively.

CONSUMPTION AND USES

Apparent consumption of Pennsylvania anthracite in the United States in 1973, calculated as production minus exports, including shipments to the U.S. Armed Forces in West Germany, totaled 5.6 million tons, compared with 5.9 million tons in 1972. Of the total anthracite consumed, 51% was used for space heating, 25% by the electric utilities, and 13% by the iron and steel industry; the remaining 11% was distributed among cement plants, colliery fuel, and other uses.

Although use data are incomplete, all categories indicated slight declines in the consumption of anthracite. The declining market for anthracite in space heating and electric utilities is attributable to the conversion from anthracite to the more convenient and less costly fuels. However, due to the curtailed availability, and the rising cost of oil and gas in the near future, the decline in the space-heating market for anthracite may decelerate.

The Federal Government continued to supplement the fuel needs of the U.S. Armed Forces in West Germany with purchases of anthracite. Shipments in 1973 were approximately 443,000 net tons, compared with 448,000 tons in 1972, a 1% decrease.

STOCKS

The electric utilities reported an increase in their inventory of 171,000 short tons of anthracite to 1,066,000 tons at yearend 1973, compared with 895,000 tons at yearend 1972, an increase of 19.1%

Stocks at coke plants totaled 97,000 tons at yearend 1973, compared with 84,000 tons at yearend 1972, an increase of 15.5%.

Monthly data on stocks held in retail yards indicated an inventory of 106,000 tons at yearend 1973, a decrease of 13.9% from yearend 1972.

Stocks at Upper Lake docks (Lake Superior and Lake Michigan) comprised less than 500 tons at yearend 1973, relatively comparable to yearend 1972.

PRICES AND SPECIFICATIONS

Based on total production, including colliery fuel and dredge coal, the average value of Pennsylvania anthracite for 1973 was $13.22 per ton, compared with $12.00 per ton in 1972. Total value of production was approximately $90.3 million, an increase of 6% over that in 1972. Although production had declined, the value was greater than in 1972 because of increases in the price of coal. Anthracite producers increased prices on all sizes during the year to compensate for additional taxes to cover black lung benefits, increased workmen's compensation taxes, and higher costs of mining.

The average value per ton of the larger sized groups was $18.76 f.o.b. preparation plants, an increase of $1.58. The price increase per ton for the larger sizes was egg, $1.44, stove, $1.78, chestnut, $1.64, and pea, $1.26. The average value per ton of the smaller sizes increased by $1.16, to $11.30 per ton. The individual prices of the smaller sizes were as follows: Buckwheat No. 1, $16.60 (an increase of $1.22); buckwheat No. 2 (rice), $16.77 (an increase of $1.65); buckwheat No. 3 (barley), $14.11 (an increase of $1.14); buckwheat No. 4, $10.78 (an increase of $1.67); buckwheat No. 5, $8.39 (an increase of $2.36); and other, $5.78 (an increase of $0.63). All of these prices exclude dredge coal.

Average wholesale prices as quoted in the Black Diamond magazine f.o.b. preparation plants were as follows: Egg and stove, $19.75 to $23.50; chestnut, $19.50 to $22.50; pea, $17.50 to $19.60; buckwheat No. 1, $17.50 to $19.60; buckwheat No. 2 (rice), $17.50 to $19.60; and buckwheat No. 3 (barley), $16.50 to $18.50.

FOREIGN TRADE

According to the data released by the Bureau of the Census, U.S. Department of Commerce, 716,546 tons of Pennsylvania anthracite were exported in 1973, a decrease of approximately 4% from that exported in 1972. Of the total, 67% was shipped to Canada (5% less than in 1972), 26% to Europe, 5% to South America, and the remainder to other countries. However, this does not fully reflect the total shipments to Europe because the Bureau of the Census does not include in its figures coal shipped abroad for use by the U.S. Armed Forces in West Germany. A more accurate measure of the export trade can be obtained by adding the military tonnage (442,699 net tons) to the Bureau of the Census data. Consequently, 1,159,000 net tons of anthracite were exported in 1973.

WORLD REVIEW

World production in 1973 totaled 191.9 million short tons, compared with 192.6 million tons in 1972. The combined production of the U.S.S.R., the People's Republic of China (PRC), and North Korea totaled approximately 138.3 million tons, or 72% of the total.

Anthracite imports by Japan totaled 1,057,675 short tons in an 11-month period (January–November) of 1973, and represented an increase of 41.6% over imports in the same period in 1972. The PRC supplied 319,471 tons, or 30.2% of the total. The Republic of Korea increased its exports to Japan by 231,767 tons for the same period, and shipments of 154,611 tons of anthracite from the Republic of South Africa was an 84.8% increase over the same period in 1972. Imports from Canada decreased slightly for the January–November period; 112,749 short tons were shipped in 1973, compared with 118,233 tons in 1972.

Exports from North Vietnam to Japan increased significantly after the shipping blockade was lifted in August. Since shipments resumed, Japan has purchased approximately 190,000 tons of Honggai anthracite, compared with 74,000 tons in 1972. A group of Japanese companies has negotiated a contract with North Vietnam for the purchase of 500,000 to 700,000 tons of anthracite for 1975.

Anthracite continued to be the Republic of Korea's most valuable mineral, representing 70% of the total value of minerals produced. Despite the heavy storm that flooded several major coal mines in August 1972, production totaled 13.7 million tons, and increased to approximately 15.0 million tons in 1973.

The Republic of South Africa showed an increase in the production of anthracite to 1.6 million short tons in 1973, compared with 1.5 million tons in 1972. Exports increased by 135,982 tons, totaling 998,114 tons. Prices registered increases of 14.6% for domestic sales and 9.3% for exports.

The U.S.S.R. production of anthracite in 1973 was approximately 83.2 million tons, a slight increase over that in 1972. Exports totaled approximately 4.8 million tons. The major markets for Soviet coal are Japan, Italy, France, and Austria. Most coal exports are shipped under relatively long-term trade agreements and usually vary slightly from the agreed tonnages reported.

France produced approximately 7.7 million tons of anthracite in 1973, a decline of 17.7% from that in 1972. Of the total anthracite imported (2.8 million tons), the Soviet Union supplied 33%; the Federal Republic of Germany, 23%; the Republic of South Africa, 14%; and the Netherlands, 12%. The United States and the United Kingdom completed the list of the more significant suppliers.

During the first 6 months of 1973, Yugoslavia's imports of solid fuels increased slightly from the corresponding period of 1972. Anthracite imports increased from 83,057 tons in 1972 to 96,717 tons in 1973, and accounted for 16.5% of the solid fuels imported.

Anthracite production for the United Kingdom and West Germany, decreased by 19% and 20%, respectively in 1973.

As Italy has insignificant coal resources of its own, it is almost entirely dependent on imports for its coal requirements. The Soviet Union, the United States, and France supplied Italy with anthracite in 1973.

TECHNOLOGY

The use of anthracite as a molecular sieve was investigated. Several coal gasification processes now under development require a supply of oxygen. If air is used for gasification, not only is the product gas of lower calorific value because of dilution with nitrogen, but also the volume of gas to be cleaned of sulfur is much larger, and therefore, the cleaning is more expensive. Studies at Pennsylvania State University indicated that anthracite has the possibility of making a cheaper separation of oxygen and nitrogen, as well as other important industrial gases.[2] Anthracites, as they occur naturally, have a large volume within their pore structures, but the pore entrances are so small that few gases can enter, and those only slowly. However, if a small part of the anthracite is gasified, the pore entrances can be enlarged in a controlled manner. In several anthracite samples, 6.9%, 8.0%, and 9.1% of carbon was gasified by heating each sample in air to 425° C, and then in nitrogen to 950° C.

This small difference in amount gasified was enough to make a large difference in the rate at which methane could enter the porous structure. For carbon dioxide the amount that could enter and be absorbed within the 9.1% sample was only 1.6 times the amount within the 6.9% sample. For the hydrocarbon neopentane, which has a larger molecule than carbon dioxide, the amount that could be adsorbed under the same conditions increased by a factor of 100.

The results demonstrate that the production of effective molecular sieves from anthracites is feasible. They also show that the fine control over pore entrance sizes that is provided by slight gasification gives a means of tailormaking molecular sieves to perform a variety of important separations.

Consumption of anthracite for molecular sieve production would obviously be less than consumption of coal for direct fuel uses, but it would be enough to make a significant contribution to the total utilization of anthracite resources.

r Revised.
1 Furnished by initial carriers.
2 Pennsylvania Department of Mines and Mineral Industries.
3 Association of American Railroads.
4 Ore and Coal Exchange, Cleveland, Ohio.
5 Data furnished by Lake dock operators.
6 Less than ½ unit.
7 U.S. Department of Commerce. Does not include shipments to the U.S. military forces.
8 Federal Power Commission.
9 Estimated from reports submitted by a selected list of retail dealers located outside the producing region.
10 Furnished by the Bureau of Labor Statistics from data obtained from authorized trade publications.

NOTE:—According to the Association of American Railroads, 659,516 short tons of anthracite were exported to Europe during 1973 compared with 697,092 short tons for 1972. Of this total 436,507 short tons were consigned to West Germany and the Netherlands, including exports to the U.S. military forces. This compares with 464,680 short tons for 1972.

NOTE:—According to the Association of American Railroads, 659,516 short tons of anthracite were exported to Europe during 1973, compared with 697,092 short tons for 1972. Of this total 436,507 short tons were consigned to West Germany and the Netherlands, including exports to the U.S. military forces. This compares with 464,688 short tons for 1972.

Vietnam, North[e]	3,300	2,200	3,300
Total	[r] 198,713	192,612	191,919

[e] Estimate. [p] Preliminary. [r] Revised.

[1] An unspecified amount of semianthracite is included in figures for some countries.

[2] In addition to the countries listed, Canada, Colombia, New Zealand, and South Vietnam produce anthracite, but the level of production is not recorded and available information is inadequate to make reliable estimates; in Colombia output may total 100,000 tons annually, while in New Zealand and South Vietnam output is insignificant.

Cobalt

By John D. Corrick [1]

Demand for cobalt in 1973 continued the upward trend that began in 1972 and reflected a general increase in the industrial activities of the Nation. High-purity metal including cobalt powder, and salts and driers were in greatest demand during 1973. Consumer stocks in 1973 began to rebound from their low levels of 1971 and 1972. Government releases of cobalt from the strategic stockpile were again a significant source of supply during 1973 with over 8.5 million pounds released.

Legislation and Government Programs.—General Services Administration (GSA) continued to offer specification-grade cobalt metal in various forms for sale during 1973. Sales were on an unrestricted-bid basis except that total sales of specification-grade material were limited to approximately 1 million pounds per month and 500,000 pounds per bidder per month. Government sales of cobalt for the year totaled 7,500,589 pounds compared with 8,629,692 pounds sold in 1972. The stockpile objective for cobalt was lowered from 38,200,000 to 11,945,000 pounds in 1973. The action was taken under Section 2(a) of Public Law 520 (79th Congress), Reorganization Plan No. 1 of 1958, as amended, and Executive Order 11051.

As of December 31, 1973, total U.S. Government stockpile inventory was 62,930,793 pounds of cobalt. Of this quantity, 62,380,307 pounds was stockpile grade.

DOMESTIC PRODUCTION

There was no domestic mine production of cobalt in 1973. Nevertheless, Amax Nickel, a division of American Metal Climax Inc., continued to renovate its Port Nickel, La., refinery. When the refinery becomes operational early in 1974 it will have a capacity to produce over 80 million pounds of nickel per year plus substantial quantities of cobalt, copper, and associated byproduct metals depending on feed material.

[1] Physical scientist, Division of Ferrous Metals—Mineral Supply.

CONSUMPTION AND USES

Consumption of cobalt in the United States in 1973 was 18.7 million pounds, 33% above that of 1972 and exceeded the 1969 record consumption by 20%. Increased consumption was a direct result of a rise in industrial activity that began in the latter half of 1972 and continued strong through 1973. The pattern of cobalt consumption was little changed from that of 1972 with major consumption occurring in magnetic alloys, salts and driers, superalloys, and cutting and wear-resistant materials. Data reported by consumers showed that of the cobalt consumed in the United States in 1973, 75% was as metal, 19% was as salts and driers, 4% was as oxide, and 2% was as purchased scrap.

Huntington Alloys Products Division, of International Nickel Co. of Canada Ltd. (Inco), marketed a new nickel iron-cobalt alloy, Incoloy 903. Principal uses for the low thermal expansion alloy will be in rocket engines, gas turbines, and special instruments in which high stresses are a problem. According to company officials, Incoloy 903, hardened with additions of aluminum, columbium, and titanium, has greater thermal conductivity than many other high-stress alloys and performs over a temperature range of minus 43° to plus 1,200° F.[2] General Electric Co. introduced a new superalloy in 1973 designated Rene 95. Company officials believed the alloy would find wide use in turbine blades and compressor discs. Forgings of the alloy offered extremely high strengths up to temperatures of 1,200° F.

A National Aeronautics and Space Administration (NASA) fluoride-metal composite impregnated into porous nickel, cobalt, or iron alloys was to be marketed for the first time in 1973 by Astro Met Associates of Cincinnati, Ohio. The self-lubricating alloy may find applications in rotary engines like the Wankel.[3]

Hitachi Magnetics Corp. of Japan announced their first commercial production of samarium-cobalt material for use in making powerful magnets having strengths of 16 to 23 million gauss-oersteds. Hitachi Metals, America, acquired the magnetic materials facilities of General Electric at Edmore, Mich., in March 1973. The magnets will be marketed worldwide under the name Hicorex.[4]

E. I. du Pont de Nemours & Co. introduced a new intermetallic compound and designated it Tribaloy. The new material was reportedly resistant to wear, friction, and corrosion. Tribaloy was expected to compete with stainless steel types 304 and 316, nickel base alloys, tungsten carbide, and some superalloys. The cobalt-based alloy was expected to be used in plasma flame spraying of heavy duty brakes, journal or sleeve bearings, ball and roller bearings, cams, pump and valve parts, and seals.[5]

PRICES

The producer price of $2.45 per pound for cobalt metal granules (shot) or broken cathodes in 551-pound (250-kilogram) drums was increased to $3 in February and to $3.30 on August 13. Eighteen days later the price was adjusted downward to $3.20 per pound where it remained until November 28, when the price was adjusted to $3.10 per pound, f.o.b. New York or Chicago. A weighted average price for the year was calculated to be $3 per pound of cobalt.

Sales of cobalt metal by the Government on a "sealed-bid" basis ranged in price from $2.3851 to $2.988 per pound for specification-grade material. All prices were f.o.b. carrier's conveyance at Government storage locations.

FOREIGN TRADE

Exports of unwrought cobalt metal and alloys and of waste and scrap totaled 2,492,730 pounds, gross weight, having a value of $4,193,595 and went to 18 countries. Japan and the United Kingdom received the greater part, 1,498,246 pounds ($2,484,652) and 374,385 pounds ($399,825), respectively. Exports of wrought cobalt metal and alloys, 1,396,938 pounds, gross weight, having a value of $4,738,396, went to 26 countries. The imports of cobalt salts and compounds given in table 7 came principally from the United Kingdom and France.

[e] Estimate.

WORLD REVIEW

Aided by United States Government stockpile releases, cobalt production in the Non-Communist countries was sufficient to meet demand in 1973. Zaire again led all countries in mine production of cobalt and accounted for 59% of the total world output. Cobalt production in 1973 increased in all major producing countries except Zambia and Morocco when compared with that of 1972.

Australia.—Development of the Greenvale nickeliferous laterite deposit by Freeport Queensland Nickel Inc., a wholly-owned subsidiary of Freeport Minerals Co. of the United States, and Metals Exploration N. L. of Australia continued on schedule during 1973. Early in 1973 a contract was let for the construction of the town of Greenvale in Queensland. At the same time the treatment plant foundation was poured at Yabulu, near the coast, 140 miles from the mine site. Stripping of the mine overburden began early in 1973 as did construction of a 140-mile-long railway connecting the mine at Greenvale with the Yabulu treatment plant. The plant was designed to treat a million dry tons of ore annually and produce over 50 million pounds of nickel and 2.75 million pounds of cobalt in the form of nickel-cobalt sulfide. The hydrometallurgical process to be used was based on ammoniacal leaching of the pyrometallurgically reduced ore. At yearend production was still scheduled for 1974. Ore reserves were officially stated as 44 million tons containing 1.57% nickel and 0.12% cobalt.

Belgium.—A 3-week strike at the Olen refinery in Hoboken, Belgium, operated by Société Générale de Belgique created a temporary shortage of cobalt metal powder in 1973. Settlement of the labor dispute was expected to increase wages by approximately 17%. The cobalt refinery at Olen had an annual capacity of approximately 11 million pounds.

Canada.—Mine production of cobalt increased in 1973 by 18% compared with that of 1972. Inco's deliveries of cobalt were 1,870,000 pounds in 1973 compared with the 2,210,000 pounds in 1972 and 1,980,000 pounds in 1971. In October Inco opened its new Copper Cliff nickel refinery in Sudbury, Ontario. The refinery and ancillary facilities cost approximately $140 million. Annual capacity was placed at 100 million pounds of nickel pellets and nickel-iron powder. Electrolytic copper, cobalt, and precious metals will be recovered from the refinery residue as a byproduct. Falconbridge Nickel Mines, Ltd., was able to increase deliveries of cobalt in 1973 to 1,614,000 pounds compared with 1,150,000 pounds in 1972 as a result of commissioning of a new cobalt refinery at Kristiansand, Norway. The Kristiansand cobalt refinery was destroyed by a fire in May 1972. According to company officials, the stockpile of cobalt residue that accumulated during the shutdown should be exhausted by the end of 1974. Reportedly Sherritt Gordon Mines Ltd. produced 616,000 pounds of cobalt in 1973 compared with 809,000 pounds in 1972. Cobalt sales for the 2 years were 569,000 and 713,000, respectively.

Cuba.—Cuba rearranged the sales price of cobalt to the U.S.S.R. to $2.27 per pound of contained cobalt as part of the recent Cuban-U.S.S.R. plan to renovate and modernize both the Moa Bay and Nicaro nickel-cobalt facilities and develop the new Punta Gorda nickel deposits. Estimates are that the renovation and construction of a new plant will double Cuba's output of nickel and cobalt over the next 3 years.

Finland.—The completion in 1973 of a major long-term investment program by the Finnish company Outokumpu Oy should permit Finland to increase mine output of cobalt in the near future. Upon completion of the program, the concentrator and mine at Vuonos had a capacity to produce 72,000 tons per year of cobalt-rich iron-pyrites. The Kokkola refinery treated the nickel, copper, and zinc-bearing cobalt-rich pyrites (cobalt content of about 0.7%) using the Outokumpu process. The plant had an annual capacity of about 2.6 million pounds of cobalt or about 5% of the world's production. Cobalt was produced as a metal and sold in the form of powder or briquets.

India.—Reportedly work began in 1973 on the development of India's largest known nickel deposit at Sukinda, in the eastern state of Orissa. The project will cost approximately $43 million and was expected to produce 5,300 tons per year of nickel, 200 tons per year of cobalt, and 19,000 tons per year of byproduct ammonium sulfate. The State-owned Hindustan Copper Ltd.

was to manage the project until a separate corporation could be formed.

Indonesia.—To date, the largest planned Indonesian nickel-cobalt operation was that of P. T. Pacific Nickel Indonesia in which Sherritt Gordon held a 10% interest. Activities in 1973 were limited to engineering studies pending development of a financing plan acceptable to shareholder companies. During the year Internatio-Muller N.V. withdrew from the project and sold its 10% interest to the other four participants. The project involved the development of a laterite deposit on Gag Island, Irian Barat.

P. T. International Nickel Indonesia, a wholly owned subsidiary of Inco, announced in April 1973 a decision to proceed with the first phase of a lateritic mining and processing project on the island of Sulawesi. At yearend construction had begun and contracts were awarded to the Dravo Corp. for engineering and construction of the processing plant and project infrastructure and to the Montreal Engineering Co., Ltd., for engineering of the town site. The plant, to become operational in 1976, was to have a production capacity of over 15,000 tons of nickel plus cobalt per year in the form of 75% nickel matte.

Morocco.—Cobalt production in 1973 was 1,567 tons in the form of 14% cobalt concentrate compared with 1,766 tons in 1972. Production came from one mine in southern Morocco, 65% owned by the French firm Omnium Nord-African and 35% by Bureau de Recherches et de Participations Minières (BRPM). Ore reserves were estimated as being sufficient to last 8 to 10 years at the current rate of production. Exports in 1972 were up 125% over those of 1971. Of the cobalt exported 7,800 tons went to France and 3,205 to the People's Republic of China. Under a prior agreement, Soviet geologists have combined a search for cobalt deposits in Morocco with a study of the Rif mountains .

Philippines.—Construction of the Nonoc nickel refinery by Marinduque Mining and Industrial Corp. made significant progress in 1973. Procurement of engineering equipment was completed in 1973. During the year, pier facilities for ocean-going tankers and a tank farm were completed, a three-quarter mile long airstrip became operational, all-weather roads were completed, and housing for junior and senior staff members neared completion. Also, nearing completion at yearend was a dam on the Sabang River in northern Dinagat Island designed to provide water and standby power for the Nonoc operation. The first mining block was developed in 1973. Production was expected to begin in August 1974. With a designed capacity of 3.8 million dry tons of ore annually, the refinery will not only make the Philippines the largest producer of pure nickel in Southeast Asia but will produce 3.3 million pounds of cobalt per year in the form of mixed sulfides.

Pacific Metals Co., subsidiary of Nippon Steel, of Japan agreed to purchase Universal Oil Products Co.'s 40% interest in Rio Tuba Nickel Mining Corp. Rio Tuba expected to develop a mine on Palawan Island in the Philippines at an estimated cost of $50 million. This included a 1-million-ton-per-year ore operation, an ore treatment plant, and a ship-loading facility. Plans called for mining of 2 million tons of ore per year. The lower grade ore would require treatment such as smelting and would be considered at a later date. The higher-grade ore would be shipped to Japan for processing. A. Soriano Corp. continued their evaluation of an ore deposit on Palawan Island during 1973. A feasibility study completed in 1973 detailed a plant to produce 35 million pounds of nickel per year and 1.3 million pounds of cobalt per year at a cost of $125 million, including infrastructure. The company was studying during 1973 a $175 million leach plant with an annual capacity of 60 million pounds of nickel plus cobalt. Plant products would be in the form of a nickel sinter oxide 90 and a mixed nickel-cobalt sulfide.

Uganda.—The Ugandan Government offered new terms to Kilembe Copper Cobalt Ltd. for renewal or extension of the company's 21-year lease on the Kilembe mines which expired at the end of 1973. The Government owned 10% of Kilembe mines, and Falconbridge Nickel owned 72.8% of Kilembe Copper Cobalt which in turn owned 70% of Kilembe mines. Indications were that production increased in 1973 compared with 1972, following settlement of labor problems that arose from the expulsion of technicians by the Government in 1972.

Zaire.—Zaire, through the state holding company, La Générale des Carrières et Mines du Zaire (GECAMINES) and its operating company La Générale Congolaise des Minérais (GECOMIN) produced over 33 million pounds of cobalt in 1973 and accounted for over 59% of the total world mine output. Early in 1973 GECAMINES increased the feed rate capacity of its concentrator at Kambove from 1.08 million tons of ore per year to 1.44 million tons per year. Ore for the concentrator was supplied principally from the Kambove underground mine, which had a capacity of 960,000 tons per year in 1973. The mine was being expanded in 1973 to a capacity of 1.44 million tons per year in order to supply the concentrator. The deficit between the concentrator capacity and mine capacity in 1973 was made up from open pit mines in the area. Officials of GECAMINES announced during 1973 that the company had discovered a new deposit estimated at 121.5 million tons of ore containing 3.8% copper and 0.4% cobalt near Dikuluwe-Mashamba, southwest of Kolwezi. At yearend the acting director general of GECAMINES announced details of its 1974–77 expansion plan. Under the plan two new open pit mines would be commissioned in the area of the newly discovered deposits. The major purchasing effort would be in the metallurgical processing field and would be aimed at increasing domestic refining capacity. The plan when completed was expected to increase cobalt production to 18,000 tons per year. The cost of the new 5-year expansion plan was estimated at $160 million and included improvements to industrial and social infrastructure.

Société Minière de Tenke-Fungurume (SMTF) was formed in 1970 to explore and develop copper-cobalt deposits in the Tenke-Fungurume district of Zaire. The shareholders in the company and their respective interests were: Zairian Government, 20%; Charter Consolidated, Ltd. (UK), 28%; Amoco Minerals Co., a subsidiary of Standard Oil Co. of Indiana (U.S.), 28%; Mitsui & Co. (Japan), 14%; Bureau de Recherches Géologiques et Minières (BRGM) (France), 3.5%; Omnium de Mines S.A. (France), 3.5%; and Leon Templesman & Sons, Inc. (U.S.), 3%. At the end of 1972 SMTF had completed 350 test boreholes with a combined length of 153,845 feet. Ore reserves were estimated at 45.7 million tons of oxide mixed with sulfide and contained 5.5% copper and 0.44% cobalt. The oxide portion was estimated at 20.4 million tons of ore containing 5.6% acid soluble copper and 0.39% acid soluble cobalt. Parsons-Jurden Corp., a division of the Ralph M. Parsons Co. of Los Angeles, Calif., and Holmes & Narver, Inc. were awarded a contract as consultants to SMTF in 1973. The consultants began an independent review and validation of earlier technical and economic feasibility studies and were in an advanced state at yearend 1973. SMTF reportedly was concerned over the supply of adequate electrical power to the area and was attempting to coordinate its financing and construction plans with those of the Inga-Shaba high-voltage transmission project being planned by the Zairian Government. The company planned to begin production shortly after the completion of the power project, sometime in 1977. Capital expenditures for SMTF's copper-cobalt project were estimated at $300 million. The company employed approximately 1,000 people in 1973.

Zambia.—On January 9, 1973, Rhodesia closed its common border with Zambia causing the latter country to seek alternate routes for shipping its copper and cobalt to world markets. The company instituted emergency plans which included expanding the road services to Dar es Salaam and Mombasa, and extending the use of the rail route to Lobito. While the task of rerouting the flow of materials presented some problems, the sale and movement of cobalt was not unduly affected. Cobalt sales for the period ending March 31, 1973, were reported at slightly over 6 million pounds of cobalt compared with sales of 5.4 million pounds in 1972.

The Zambian Government in 1973 appeared to be moving ahead with its plans to gain full control of the country's copper and cobalt mining operations. During the year President Kenneth Kaunda announced major policy changes that affected Zambia's mining sector. The immediate impact of President Kaunda's action toward the minority shareholders in Nchanga Consolidated Copper Mines Ltd. (NCCM) and Roan Consolidated Mines Ltd. (RCM) was not known at yearend. Although the president did remark that steps were to be taken to insure that RCM and NCCM provide for themselves all management and technical services which are now provided by the minority shareholders. One major step taken toward industrial nationalization in 1973 was the merging of the research and development units of NCCM and RCM. Plans were discussed during 1973 for the development of a new process to produce cobalt from converter slag. The process would improve the efficiency of smelter furnaces.

e Estimate. p Preliminary. r Revised. NA Not available. W Withheld to avoid disclosing individual company confidential data.

[1] In addition to the countries listed, Bulgaria, Cyprus, East Germany, New Caledonia, Poland, Spain and Sweden are known to produce ores (copper, nickel and/or pyrite) that contain recoverable quantities of cobalt, but available information is inadequate to make reliable estimates of output levels. Other nations may also produce cobalt as a byproduct component of ores and concentrates of other metals.

[2] In addition to the countries listed, the United Kingdom recovers cobalt metal from intermediate metallurgical products produced in Canada, but data on output is inseparable from the total reported by Canadian producers, and Czechoslovakia presumably recovers cobalt from materials imported from Cuba, but data are inadequate to estimate output. Belgium and Japan, both of which import substantial quantities of crude materials containing cobalt, have not recorded output in recent years, but may be producing metal and/or cobalt compounds. Poland also apparently processes cobalt-bearing copper ores but no data on cobalt recovery are available.

[3] Actual output not reported.. Data presented for mine output are total cobalt content of all products, including nickel oxide sinter shipped to the United Kingdom for further processing and nickel-copper matte shipped to Norway for further processing. Data presented for metal output are total cobalt content of all products less cobalt output recorded for Norway. Thus, the metal data include cobalt content of oxides and other compounds that are not produced as metal and total cobalt metal output in the United Kingdom as well as actual metal output in Canada itself.

[4] Domestic mine output, if any, is negligible.

[5] Produced entirely from nickel-cobalt matte imported from Canada; domestic mine output is recovered abroad.

[6] Insufficient data are available to permit separate estimates for mine and metal production

[7] Metal output, used in lieu of unreported mine production.

[8] Figures include reported metal production plus an estimate for cobalt content of cobalt hydroxide produced.

TECHNOLOGY

Bureau of Mines scientists filed an invention report in 1973 in which they described an efficient extraction and treatment process for low-grade lateritic ores. The oxide ore was selectively reduced and leached in an ammonia-ammonium sulfate system to recover 90% of the nickel and more than 80% of the cobalt. The nickel was selectively separated by liquid extraction and subsequently recovered by electrolysis; cobalt was precipitated from the leach solution as a cobalt sulfide. Bureau researchers continued investigations into the development of economic methods for beneficating low-grade domestic ores containing cobalt in 1973. Bureau metallurgists reported on the preparation of samarium-cobalt permanent magnets. The method used to fabricate the magnets consisted of arc-melting, crushing and grinding the alloy, alining and pressing the powder, and sintering the green compacts. Optimum composition was reported to be 36.7 ± 0.3 weight-percent samarium and 63.3 ± 0.3 weight-percent cobalt.[6]

A new process for the recovery of nickel and cobalt from limonites by aqueous chlorination in seawater was described in a

[6] Walkiewicz, J. W., J. S. Winston, and M. M. Wong. Preparation of Samarium-Cobalt Permanent Magnets. BuMines RI 7784, 1973, 18 pp.

joint paper by scientists of Dartmouth College at Hanover, N. H., and of Delft University of Technology at Delft, the Netherlands.[7] The process was based on selective reduction of the ore pyrometallurgically and on aqueous chlorination in seawater. Reportedly, advantages gained from the process were high recovery of nickel and cobalt, rapid dissolution rates, and the use of saline in place of fresh water.

The second International Symposium on Superalloys was held in 1973. The subjects covered at the symposium were melting and casting of superalloys, primary working of superalloys, control of superalloy properties through thermal and deformation techniques, fabrication of superalloys, and new processes and alloy developments in superalloys. The latter session dealt with the ramifications of powder metallurgy as they applied to superalloys.

As in the past years, a large number of patents were issued in the United States and abroad, ranging from extractive metallurgy through smelting technology to the formation of new cobalt alloys. A large number of the patents issued during 1973 dealt with the extraction and recovery of cobalt from lateritic ores. Of the patents issued for extraction of cobalt from ores, a large portion dealt with the liquid extraction of cobalt values using an ammonia-ammonium process. A patent was assigned to Deepsea Ventures, Inc. for the extraction of manganese, copper, cobalt, and nickel from ocean-floor manganese nodules. The process described in the patent specified the pelletization of a mixture of nodules, coal, and sodium chloride. The pellets were contacted with chlorine gas under conditions that vaporize the metal chlorides along with water and oxides of carbon. The metal chlorides were condensed and leached with water to convert the iron chloride impurity to iron oxide, the remaining metal chlorides were separated by liquid ion exchange. The metal values were recovered by electrolyzing the metal chloride fractions. Technical papers were presented during 1973 on heat-resisting alloys, magnetic materials, tool and wear-resistant steels and alloys, other alloys, metallic films and coatings, nonmetallic uses, unalloyed cobalt and cobalt compounds, cobalt alloy systems and phases, and analytic procedures.[8]

Coke and Coal Chemicals

By Eugene T. Sheridan [1]

Production of coal coke in the United States in 1973 was 6% greater than output in 1972. Most of the increase resulted from a greater demand for coke for use in iron blast furnaces. Also contributing to the increase was a larger demand for foundry coke. However, shipments of coke to other industrial plants declined significantly in 1973.

Production remained relatively stable throughout the year and averaged 5.4 million tons per month. The average daily output for all plants ranged from a low of 173,000 tons in July to a high of 179,000 tons in June. Average daily output for the year averaged 176,000 tons.

Except for August, monthly demand for coke exceeded production and producers month-end stocks of oven coke were 60% lower at the end of the year than when the year began. Stocks on hand at oven-coke plants at the end of 1973 were equivalent to a 7-day production at the December rate of output.

Blast furnaces continued to use the bulk of the Nation's coke production, receiving 92% of the 66.4 million tons of coke distributed by producers. However, consumption of coke per ton of hot metal produced at blast furnaces decreased because of a significant increase in the quantities of fuel oil, tar, and pitch used as supplemental fuels in blast furnaces.

Breeze production increased 15%, mainly because more coal was carbonized. Breeze is unsuitable for most metallurgical applications because of its small size and high ash content, the larger part of the breeze production is used by producers for sintering iron ores and for other industrial purposes. However, 44% of the 1973 output was sold, mainly for use as a reductant in the electric furnace processing of phosphate rock to elemental phosphorus. Sales of breeze in 1973 remained at about the 1972 level.

The average delivered value of coals carbonized increased 16% in 1973 and averaged $18.24 per ton. This increase was reflected directly in average coke prices which increased 6% to $42.92 per ton. The largest price increases were made in coke sold to foundries. Foundry coke prices, which averaged $54.73 per ton, f.o.b. plant, were 7% higher than in 1972.

Production of light oil and coke-oven gas increased, principally, because more coal was carbonized. However, output of both tar and ammonia declined.

Foreign trade was relatively small with coke exports of 1.4 million tons comprising only 2% of the production. The bulk of the exported coke was shipped to Canada and West Germany. Coke imports increased significantly in 1973, but exports exceeded imports by 317,000 tons.

The total value of all coals carbonized was $1,716 million, and the total value of all products of carbonization was $2,931 million. The combined value of coke and breeze, the principal products, accounted for 88% of the total value of all products.

COKE AND BREEZE

DOMESTIC PRODUCTION

A substantial increase in pig iron and ferroalloys output in 1973 was accompanied by increased demand for blast-furnace coke and domestic coke production rose 6%. Output was stable throughout the year with monthly production varying between 5.0 million and 5.5 million tons, with the largest amount produced in May. Daily production for the year averaged 176,000 tons, up 7% from the average daily output of 1972.

Ninety-two percent of the oven coke in 1973 was produced at furnace plants. These plants, owned by or financially affiliated with iron and steel companies, are operated mainly to produce coke for use in blast furnaces. The remaining oven coke was produced by merchant plants. This is the segment of the coke industry that produces various grades of coke for sale on the open market. There were 48 furnace plants and 14 merchant plants in operation throughout the year.

Coke was produced in 19 States in 1973. The relative amounts of coke produced in the various States have changed little in the past decade, except that Connecticut and Massachusetts have ceased to be producing States and production was discontinued in New Jersey in 1971. Because coke is used principally for blast furnace fuel, the coke industry is concentrated in the major steel-producing areas of the Eastern and North Central States. The bulk of the 1973 coke output was produced in 12 States east of the Mississippi River. Six States west of the Mississippi River produced coke.

Pennsylvania, the largest producer, accounted for 26% of the output and was followed by Ohio, Indiana, and Alabama in the order named. The combined output of these four States was 63% of the national total.

An average of 1,367 pounds of coke was produced for each ton of coal carbonized in the United States in 1973. The 1973 yield of coke from coal, which averaged 68.35%, has remained fairly constant during the past decade.

Breeze is the term applied to the small sizes of coke that result from screening. Although there is no designated size, breeze refers generally to coke that passes through a ½-inch screen. Coke producers consumed 58% of the breeze produced in 1973, principally as a fuel in agglomerating plants. The remainder was sold, mainly for use as a fuel for smelting phosphate rock to produce elemental phosphorus. The amount of breeze sold has increased significantly in recent years and, in 1973, nearly one-half of the quantity produced was sold.

The breeze yield varies according to operating practices and the quality of the coals carbonized. The lowest yield, 3.7% was recorded for Pennsylvania, while the yield for Illinois averaged 7.2%. The national average yield of 5.3% in 1973 has not varied significantly during the past decade.

An average of 105.6 pounds of breeze was produced for each ton of coal carbonized at oven-coke plants in 1973. Breeze yields at beehive-coke plants were substantially higher than those at oven plants, but beehive breeze production was negligible because only a few plants had recovery facilities.

CONSUMPTION AND SALES

Apparent consumption of coke in the United States in 1973 totaled 65.8 million tons. This quantity (domestic production plus imports, minus exports and changes in stocks) was nearly 6 million tons more than that consumed in 1972 and the increase was attributed principally to greater demand for blast-furnace coke, caused by a 12-million-ton increase in blast-furnace pig iron and ferroalloys production.

Blast-furnace coke rates continued to decline and the amount of coke required to produce 1 ton of blast-furnace output decreased from 1,222 pounds in 1972 to 1,200 pounds in 1973. The net effect of this reduction is that the blast-furnace coke requirement of 60.7 million tons in 1973 would have been 1.1 million tons larger if the coke rate had remained at the 1972 level.

Although a variety of operating practices affect blast-furnace coke rates, the pronounced reduction in the 1973 coke rate resulted mainly from a substantial increase in the quantities of supplemental fuels and oxygen consumed over those used in 1972. The principal fuels used in blast furnaces to reduce coke consumption in 1973 were fuel oil; tar and pitch; and natural, coke oven, and blast furnace gas. Although the units of measurement differ, and the quantity of each fuel used varied greatly, the total calorific value of all supplemental fuels consumed in blast furnaces in 1973 was equivalent to approximately 11 million tons of coke. Oxygen consumption in blast furnaces, which increased 35% in 1973, further reduced blast-furnace coke requirements by making available more sensible heat for the reduction of iron ore to pig iron.

A total of 66.4 million tons of oven and beehive coke was sold and used for all purposes, of which 90% was oven coke supplied by furnace plants. The bulk of this coke was retained by producers for use in their own blast furnaces. Furnace plants sold about 2 million tons of coke—30% of the total coke sold commercially. Fifty-seven percent of the furnace-plant sales was shipped to other blast-furnace plants.

Merchant plants distributed 5.6 million tons of coke in 1973, 96% of which was sold on the open market. Principal markets were blast-furnace operations without coke facilities, independent gray-iron foundries, nonferrous smelters, and chemical plants. A few merchant plants operated coke ovens to supply their own requirements; about 4% of the merchant coke distributed was used by producers. This coke was used principally in chemical plants and affiliated foundries.

One percent of the coke distributed was supplied by beehive plants. The bulk of the beehive coke also was sold to blast-furnace plants.

All States except Alaska, Hawaii, and Nevada received shipments of coke in 1973. Alabama, Illinois, Indiana, Maryland, Michigan, New York, Ohio, Pennsylvania, and West Virginia, which are the major iron- and steel-producing States, received 89% of the total distributed.

The bulk of the coke distributed was blast-furnace coke that was consumed within the producing State, as most blast furnaces are integrated with coke ovens. A few companies shipped coke to affiliated blast furnaces in other States.

About 5% of the coke distributed was shipped to foundries. The chief recipients of foundry coke were the automotive, farm-machinery, machine-tool, heavy-machinery, railroad, and electrical-equipment industries. Most of these industries are concentrated in the East and Midwest. In 1973, the combined consumption of Alabama, Illinois, Iowa, Indiana, Michigan, New Jersey, New York, Ohio, Pennsylvania, Virginia and Wisconsin accounted for more than four-fifths of the foundry-coke shipments. Foundry coke also was consumed in 35 other States.

Coke used for miscellaneous applications was widely distributed, with 41 States receiving shipments of other industrial coke. The principal consumers were nonferrous smelters, alkali plants, and plants that manufacture calcium carbide and elemental phosphorus. Alabama, Idaho, Indiana, Michigan, Ohio, and Pennsylvania received the largest quantities of other industrial coke.

Minor quantities of coke were used for residential heating. This market, which in past years received as much as 10 million tons of coke annually, is virtually nonexistent at this time.

STOCKS

Yearend stocks of coke decreased 60% as the quantity of coke distributed exceeded production by about 2 million tons. Oven-coke plants ended the year with an average 7-day supply at the December rate of production. Normally, beehive plants do not stock coke.

The bulk of the stock was at furnace plants, which had roughly a 7-day supply compared with a 4.3-day supply at merchant plants. There were no producers' stocks of beehive coke at the end of 1973.

Stocks of coke breeze at producers' plants decreased 12% during 1973. Roughly, three-fourths of the breeze on hand was at furnace plants.

VALUE AND PRICE

Coke prices increased again during 1973; the average value of receipts for all grades of oven coke reached $42.92 per ton, and beehive coke averaged $27.31 per ton. The 1973 values represented increases of 5% for oven coke and 24% for beehive coke.

All grades of coke increased in price. An increase of 7% raised the average price of foundry coke to $54.73 per ton, while blast-furnace coke prices were increased an average of 6% to $32.41 per ton. Coke used for other industrial purposes increased, on the average, only slightly in price.

The large variance in the price of blast-furnace and foundry oven coke was attributed principally to lower recovery yields for foundry coke and to its superior properties, which make it a more valuable product. The differences in the average values of oven and beehive coke were due largely to additional transportation costs of coal delivered to oven-coke plants.

FOREIGN TRADE

There was a continuing demand for U.S. coke in foreign markets and exports increased 13% to 1.4 million tons. The bulk of the increase resulted from substantially larger shipments to Canada and West Germany.

Canada remained the principal foreign market, receiving nearly three-quarters of a million tons, 54% of the foreign shipments. Other countries receiving substantial amounts of U.S. coke were West Germany, Mexico, and the Netherlands. Although coke was shipped to more than 21 countries in 1973, the above countries, with Canada, received seven-eighths of the total exports.

The bulk of the coke exported was shipped from the Baltimore, Buffalo, Detroit, Laredo, Norfolk, and Philadelphia customs districts. However, coke was exported through at least 15 other ports.

Because of shortages of domestic coke in certain areas, imports increased nearly six times and totaled 1.1 million tons. This was the largest quantity of coke imported in a single year to date. About two-thirds of the imported coke came from West Germany, and most of the remainder, from Canada.

COKING COALS

QUANTITY AND VALUE OF COAL CARBONIZED

A total of 93.6 million tons of bituminous coal was carbonized at high temperatures for the production of coke in 1973. This quantity was 16% of the 1973 bituminous coal output of the United States, and coke production was the second largest coal market. In addition to bituminous coal 467,000 tons of anthracite was used in coking-coal blends. Anthracite was used principally in the production of foundry coke to achieve greater size and density, properties that are desirable in coke used for the smelting of iron in foundry cupolas.

The delivered average value of all coal carbonized by oven-coke plants in 1973 was $18.32 per ton, and the value of that carbonized by beehive-coke plants averaged $12.42 per ton. The difference in value was attributed mainly to transportation charges for coal shipped to oven-coke plants, as all beehive plants are located at or near the source of the coal they consume. In some instances, transportation costs exceed the value of the coal at the mine; this partially accounts for the high value of the coal consumed in some States.

The average value per ton of coal consumed for coke production at both oven- and beehive-coke plants was 17% greater than in 1972. Coals delivered to some States, however, had increases in average value per ton ranging up to 22%. The highest coal prices were recorded for Maryland and New York where the delivered value of coals used for coke production by all plants averaged $22.59 per ton.

An overall average of 1.46 tons of coal, valued at $26.75, was required for each ton of oven coke produced in 1973. Beehive ovens required an average of 1.58 tons of coal per ton of coke output, but coal costs averaged only $19.62 per ton because of the lower unit value of the coals charged.

BLENDING

Blending of coals is standard practice at oven-coke plants because individual coals do not possess all of the properties required for the production of high-quality coke. In general, blending is used to improve the chemical and physical properties of coke, to control the pressure developed during carbonization, to regulate the yield of products, and to broaden the use of lower-quality coals which could not be used alone for metallurgical-grade coke production. Standard oven-coke operating practice is based upon the use of relatively small proportions of low-volatile coals and high percentages of high-volatile coals. High-volatile coals are not used alone because they produce low yields and weak coke. Low-volatile coals, when added to high-volatile coals improve the yield and the physical properties of the coke. However, the proportions of low-volatile coals used must be restricted because they are highly expanding and, if used alone or in large proportions, would damage oven walls when coke was discharged. Some plants add medium-volatile coals or other materials such as anthracite or coal-tar pitch to their high- and low-volatile coals. Additions of medium-volatile coals can regulate the volatile matter in a mix to the desired content, while anthracite and pitch impart strength, size, and density to the coke.

Blending also permits the use of some high-sulfur coals which are otherwise unsuitable for coke production. Such coals can be blended with low-sulfur coals to the extent that the coal mix contains no more total sulfur than that contained in the coals normally used for producing high-quality coke.

The overall proportions of high-, medium-, and low-volatile coals used in coke mixes has varied little in the past decade, but there are wide variations in the proportions of the different types used by individual plants. West Virginia plants and those in the Western States used the largest percentages of high-volatile coals in their blends, while plants in Minnesota and Wisconsin used relatively high percentages of low-volatile coal. Compared with furnace plants, merchant plants used larger percentages of low-volatile coal because this type produces strong foundry coke, which is produced mainly by merchant plants.

SOURCES

Of the 23 States that produced bituminous coal in 1973, only 13 produced coal that was shipped to coke plants. Of this number, only 10 can be considered suppliers of coking coals as the combined shipments of 3 States were less than one-fourth million tons.

Of the coals received by oven-coke plants, 35% was produced in West Virginia and 27% in Pennsylvania. West Virginia shipments were principally low-volatile coals from McDowell, Wyoming, and Raleigh Counties; medium-volatile coals from McDowell and Nicholas Counties; and high-volatile coals from Boone, Fayette, Kanawha, Logan, Mingo and Nicholas Counties. Pennsylvania supplied mainly high-volatile coals from Allegheny, Green, and Washington Counties and low-volatile coals from Cambria and Somerset Counties. Pennsylvania and West Virginia coals were widely distributed and used in most of the coke producing States.

Kentucky, which supplied 15% of the shipments to coke plants, was another major supplier. All Kentucky coal shipped to coke plants was high-volatile coal produced mainly in Floyd, Harlan, Letcher, and Pike Counties.

Illinois produced high-volatile coking coals, mainly in Franklin and Jefferson Counties; other States with substantial production were Alabama, Colorado, Utah and Virginia. Most of the coal produced in these States was used within the State. Colorado and Utah, however, supplied most of the coals that were carbonized in California.

CAPTIVE COAL

More than one-half of the coal received by oven-coke plants was produced by company-owned or affiliated mines. This captive coal, ordinarily, does not move in commercial channels. Iron and steel producing companies own the bulk of the captive mines and, in 1973, 57% of the coal received by furnace plants was captive. Some merchant plants also own coal mines, but only 24% of the coal they received in 1973 was their own production.

STOCKS

Stocks of bituminous coal at oven-coke plants, remained fairly constant throughout the year, ranging from an average supply of 24 to 35 days at each plant. Bituminous stocks reached their highest yearly level during May when month-end quantities totaled 8.8 million tons. The lowest level, 6.1 million tons, was reported at the end of July.

Because of market competition for low-sulfur coals during the latter part of 1973, bituminous coal stocks at the end of 1973 were 24% lower than when the year began. The 7 million tons on hand at all plants on December 31, 1973, was equivalent to an average supply on hand at each plant of 27 days at the December 1973 rate of consumption.

Only small quantities of anthracite are stocked. Stocks at the end of 1973 totaled only 97,000 tons.

COAL CHEMICALS

The term "coal chemicals" refers to the materials recovered from the volatile matter released from coal during carbonization. Normally, three basic materials—ammonia, tar, and light oil—are recovered at oven-coke plants through a series of complex condensation and absorption processes. The remaining material, which is rich in hydrogen and methane, is called coke-oven gas. Except for ammonia, which is recovered as an aqueous solution or converted to a salt and sold as produced, the basic materials are, in most instances, further processed to yield a number of primary organic chemicals or chemical mixtures of which the most important are benzene, toluene, xylene, solvent naphtha, crude chemical oil, and pitch. Although most oven-coke plants in the United States are equipped to process tar and light oil, the extent to which individual plants produce the various products depends upon economic conditions and the general size of the plant, as yields of the various chemicals are relatively low.

Yields of chemicals vary with the kind of coals carbonized, carbonizing temperatures, and operating techniques and equipment, but approximately 315 pounds of coke-oven gas, 90 pounds of tar, 20 pounds of light oil, and 5 pounds of ammonia are recovered for each ton of coal carbonized. In standard units of measure these quantities amount to about 10,500 cubic feet of coke-oven gas, 10 gallons of tar, and 3 gallons of light oil. Ammonia is recovered as ammonium sulfate at most operations, and the yield per ton of coal presently averages about 16½ pounds.

In terms of calorific value, the products, excluding coke, recovered by oven-coke plants in 1973 totaled 567 trillion Btu's. This quantity was equivalent, roughly, to about one-fourth of the heating value of the coals carbonized.

COKE-OVEN GAS

Coke-oven gas has a relatively high calorific value and producers use most of it as fuel for heating coke ovens and other steel- and allied-plant furnaces. Small quantities are also sold for distribution through city mains and for other industrial use.

Gas yields vary but the quantity of gas produced for each ton of coal carbonized in all slot ovens in 1973 was 10,720 cubic feet. This was slightly more than the yield of 10,570 cubic feet recorded for 1972. However, total gas production increased 9% because about 6 million more tons of coal was carbonized in 1973.

Thirty-nine percent of the coke-oven gas produced in 1973 was used for heating coke ovens. Gas used otherwise, called surplus gas, was used by producers to fire boilers, transferred to steel or allied plants to heat open-hearth and other metallurgical furnaces, sold for industrial use, or distributed through city mains. A small part of the production was wasted because storage facilities at most plants are limited, and the gas was burned in the atmosphere when production exceeded demand.

Coke-oven gas was the principal fuel used for heating coking ovens in 1973 but some operators used blast-furnace gas, a mixture of coke-oven and blast-furnace gas, or natural gas for underfiring. A total of 428 billion cubic feet of coke-oven gas equivalent was so consumed, of which approximately 90% was coke-oven gas.

Surplus coke-oven gas used and sold in 1973 was valued at $190 million, a 32% increase above the 1972 value. No value was reported by producers for coke-oven gas used to heat coke ovens, but applying the average value of $0.319 per thousand cubic feet reported for surplus gas to the gas used for underfiring, the total value of all coke-oven gas used and sold in 1973 would be $312 million. This amount is equivalent to nearly one-fifth of the total value of the coal carbonized at oven-coke plants.

COKE-OVEN AMMONIA

Coal carbonized at high temperatures releases nitrogen which forms ammonia. Ammonia must be removed from the gas prior to processing and coke plant operators normally recover ammonia as an aqueous solution, or as ammonium sulfate or phosphate. However, 13 plants did not recover ammonia as a salable product in 1973.

Production of ammonia decreased 3%, mainly because of a lower yield but, also, because the number of recovery plants decreased by two. The average value per ton of both ammonium sulfate and ammonia liquor increased, however, as did the total value of sales. Ammonia products sold in 1973 represented 5% of the total value of all coal-chemicals sales.

COAL TAR AND DERIVATIVES

All oven-coke plants produced tar but yields varied and ranged generally between 6 and 9 gallons per ton of coal carbonized. High-volatile coals normally evolve a larger percentage of tar and California, Colorado, and Utah—States that used large percentages of high-volatile coals—had the highest tar yields.

Despite the substantial increase in the quantity of coal carbonized at oven-coke plants, tar production decreased slightly because of the lower yield in 1973. Both merchant and furnace plants had lower yields and also lower production.

Coke-plant operators consumed 53% of the tar produced. Of this quantity, 58% was processed (refined or "topped") while 42% underwent no processing and was burned for fuel. The remaining tar was sold, principally to tar-distilling plants which refine tar to produce a variety of derivatives.

Most of the coke plants that processed tar in 1973 partially refined the tar in a process called "topping." In this method, the low-boiling distillate fraction, consisting mainly of tar acids, bases, and naphthalenes, was separated from the crude tar. The residue, called soft pitch, was, in most instances, burned for fuel. Furnace plants in particular benefit from this method of operation since they can sell the distillate and retain the pitch for use as fuel. This reduces the amount of other fuels that they must normally purchase. However, the relative quantities of tar topped and burned, as well as the quantities sold, depend upon a number of economic factors, such as the availability and current market prices of tar, tar distillates, and other substitute fuels. Most of the merchant plant tar production was sold because these plants have no use for the pitch, which makes up the bulk of the products they recover through topping.

The majority of the plants that processed tar recovered only crude chemical oil and a residual tar, or soft pitch. However, some of the larger plants recovered a number of tar derivatives, including creosote oil, cresylic acid, cresols, naphthalene, phenol, pyridine, and medium and hard pitch. Statistics on some of these products could not be shown in this report, but the data were transmitted to the U.S. Tariff Commission, which publishes them along with similar data from tar distillers and petroleum refiners in monthly and annual reports on synthetic organic chemicals.

CRUDE LIGHT OIL AND DERIVATIVES

Light oil is a liquid that contains a number of aromatic hydrocarbons that are extracted from the gas after tar, ammonia, and in some instances, naphthalene have been removed. Crude tar also contains a small amount of light oil, but this usually is not recovered at coke plants. Virtually all light oil produced at coke plants is recovered by an absorption process in which the gas is sprayed with a higher boiling petroleum oil as the gas stream is channeled through absorption towers. After light oil is recovered, it is separated from the absorption oil by direct steam distillation. Approximately 3 gallons of light oil, equal to about 1% of the weight of the coal, is recovered for each ton of coal carbonized. Yields vary with the kind of coals carbonized and with operating conditions but an average of 2.63 gallons of light oil was recovered at plants that extracted light oil in 1973. Most plants recovered light oil, but some found it uneconomical to remove the light oil and left it in the gas to be burned as fuel. Yields per ton of coal decreased at both merchant and furnace plants in 1973.

Producers sold 45% of their crude light oil output. The large increase in light oil sales in recent years is attributed principally to the inability of some plants to produce derivatives that meet the more rigid specifications established for these products. Such plants sell light oil to petroleum-refining companies which process it along with petroleum fractions into benzene, toluene, and a number of other chemical intermediates.

As with other coal-chemical materials, yields of products derived from light oil vary, but approximately seven-eighths of the light oil processed is recovered as salable products. Of the light-oil processed by coke plants in 1973, 61% was recovered as benzene; 11% as toluene; 3% as xylene; and the remainder, as other products.

Ninety-six percent of the benzene production was specification grades. In past years, large amounts of motor-grade benzene was produced for use in gasoline to increase anti-knock properties but present petroleum refining techniques have all but eliminated this use for benzene.

The unit value of all light oil derivatives sold in 1973 ranged from $0.17 per gallon for other industrial-grade benzene to $0.267 per gallon for specification-grade benzene. The average value of all light oil products sold increased 26% to $0.255 per gallon.

WORLD REVIEW

World production of metallurgical coke in 1973 was estimated at 402 million short tons. This quantity was 5% higher than the 1972 output and the increase was attributed largely to production gains in Japan, the United States, and the U.S.S.R.

Europe, with 55% of the total, led in world production. European output was 2% greater than in 1972, mainly because of larger output in the U.S.S.R. Asia, with eight producing countries, ranked second in output while North America, with only three producing countries, ranked third.

The Soviet Union, with nearly one-fourth of the world output, was the largest producer of coke. Soviet production increased 2% over that of 1972 and the estimated 90 million tons of coke and breeze produced in 1973 was a record output for the country. Metallurgical coke production, however, probably totaled about 85 million tons as an estimated 5 million tons of e production was breeze.

The United States, with 16% of the world total, ranked second in production, and Japan, with 13%, ranked third. The United States had a 6% production increase, but Japan's output was 21% above the level recorded in 1972.

Other leading coke-producing countries in order of output were West Germany, the People's Republic of China, the United Kingdom, and Poland. The production of these countries combined with that of the U.S.S.R., the United States, and Japan accounted for more than three-quarters of the world production.

In addition to the metallurgical-grade coke, which is produced at high-temperatures in conventional slot- and beehive-coke ovens, there was 11 million tons of other coke that was produced at high, medium, and low temperatures in vertical and horizontal retorts and other types of carbonizing equipment. Commonly referred to as "gashouse" or "soft" coke, this material is not suitable for most metallurgical applications but is used principally for domestic heating, chemical processing, and gas production. Production of "gashouse" coke has been declining in recent years and the 1973 world output was only about one-fourth as large as a decade ago.

TECHNOLOGY

Developmental work at coke plants continued to be focused upon systems for the reduction of atmospheric pollution. In some instances, success has been realized; however, no device or combination of devices has proved totally effective.[2]

Current energy shortages and dislocations, as well as more stringent requirements for improved air quality at coke plants, has prompted new interest in the dry quenching of coke. This technique, developed after World War I in Switzerland, features a completely enclosed system that employs an inert gas which serves as a cooling and heat transfer medium. Quenching by this method also imparts a number of desirable physical properties to coke. Test results have revealed that dry quenched coke has a higher heating value, a higher strength and greater stability. Moreover, the unit furnishes a return on the initial investment. This system, which features pollution control along with energy recovery, has been employed in the U.S.S.R. since the early 1960's.[3]

The effects of oven door leakage have also become the focal point of much concern. A technique has been refined that employs a system of vertical and horizontal chimneys within the lining of the oven door which has helped to alleviate oven-gas pressure and leakage around sealing rings. Although the idea is not new, the technology and methods have been tuned to a point that renders these modifications feasible. Prior to success, the strength of the oven door was compromised because of the innovations. Also, the diameter of the chimneys was such that difficulty was encountered in keeping them clear of coal and char. However, with the above measures initiated, oven-gas pressure taken near the floor of the oven was reduced from 140 millimeters of water to levels in the range of 30 millimeters.

Many attempts have been made to control pollution which occurs during the charging of coke ovens and one method that has been successful is staged sequential charging. This operating practice limits the exposure of the free openings and simultaneously maintains a positive draft on the openings, thus, curtailing smoke emissions. Unlike other approaches to the charging problem, this "system" does not employ any exotic equipment. In essence, the problem of smoke emissions is managed by the charging of one or two portals and closing them before the charging occurs from the other coal hoppers.[4 5]

The Calgon Corp. has developed a new method for the treatment of coke plant effluents. This is a sequential process that consists of chemical clarification of waste water for the removal of solids; adsorption with granular activated carbon for the removal of dissolved organics; and catalyic oxidation for the removal of cyanide. In the clarification step, suspended materials are removed and the pH of the water is adjusted so that an optimum adsorption rate can be achieved in the next step. Then, by means of activated carbon, dissolved organic chemicals are removed from the water after which free cyanide is removed by catalyic oxidation of the cyanide on granular carbon.[6]

In an effort to neutralize predicted future shortages of natural gas, heavy oil, and more important, metallurgical grade coal, the Japanese have developed a technology for producing a cheap reducing gas by reforming some of the hydrocarbons contained in blast-furnace top gas with carbon dioxide and water from the reforming raw material. The top gas of a blast furnace is thus reformed to a reducing gas which can be injected into the furnace stack and used in conjunction with other supplemental fuels. Introduced on a pilot scale, the Japanese were able to reduce the coke rate in an experimental furnace to less than 700 pounds per net ton of hot metal.[7]

r Revised.
[1] Comprises 371,000 tons valued at $19,326,000 used in foundries; 239,000 tons valued at $8,391,000 for other purposes.
[2] Included with "Undistributed" to avoid disclosing individual company data.
[3] Less than ½ unit.
[4] Includes coke used "For residential heating."
[5] Data may not add to totals shown because of independent rounding.

e Estimate. p Preliminary. r Revised.

1 In addition to the countries listed, Algeria, Malaysia, People's Republic of China, Mexico, Norway, Romania, and the U.S.S.R. have produced gashouse coke in previous years and may have continued production during the time period covered by this table. However, no official statistics are available and information is inadequate to make reliable estimates of production levels. Except where otherwise noted, coke breeze has been excluded from this table.

2 Coke produced at high temperature in conventional carbonizing equipment (including slot and beehive coke ovens).

3 Includes breeze.

4 Includes relatively small amounts of gas coke.

5 Includes relatively small amounts of low-temperature coke.

6 Data are total of so-called hard coke production from collieries and coke plants (including those at steelworks).

7 Data are for years beginning March 21 of that stated.

8 Includes coke produced at high temperatures in carbonizing equipment designed primarily for gas manufacture (horizontal and vertical coal-gas retorts). In addition to the countries listed, Canada and Finland produce gas coke. However, this figure is not reported separately and has been included with metallurgical coke.

9 Excludes small quantities of gashouse coke which are included with metallurgical coke.

10 Less than ½ unit.

11 Data are for years beginning March 31 of that stated.

12 Includes coke produced at low and medium temperatures, as well as that produced in unconventional equipment (chain-grate cokers).

13 Includes coke produced from lignite at high temperatures.

Table 22.—Quantity and value at ovens of coal carbonized in the United States in 1973, by State

State	Coal carbonized			Coal per ton of coke	
	Thousand short tons	Value		Short tons	Value
		Total (thousands)	Average

XX Not applicable.
[1] Includes products of tar distillation conducted by oven-coke operators under the same corporate names.
[2] Soft-water-softening point—less than 110° F; medium—110° to 160° F; hard-oven—160° F. Figures on hard pitch includes small amount of medium-pitch.
[3] Creosote oil, cresols, cresylic acid, naphthalene, phenol, pyridine, refined tar, tar paint.
[4] Included with sulfate to avoid disclosing individual company data.
[5] Includes gas used for heating oven and gas wasted.
[6] Data may not add to totals shown because of independent rounding.
[7] 130,009,000 gallons refined by coke-oven operators to make derived products shown.

Table 34.—Coal equivalent of the thermal materials, except coke, produced at oven-coke plants in the United States

Year	Materials produced				Estimated equivalent in heating value [1] (billion Btu)					Coal equivalent (thousand short tons)
	Coke breeze (thousand short tons)	Surplus gas (billion cubic feet)	Tar (thousand gallons)	Light oil (thousand gallons)	Coke breeze	Surplus gas	Tar	Light oil	Total	
1969	4,401	595	768,766	258,910	88,020	327,250	115,315	33,658	564,243	21,536
1970	4,665	585	760,926	244,107	93,300	321,750	114,139	31,734	560,923	21,409

Columbium and Tantalum

By Joseph A. Sutton [1]

Demand for columbium in steelmaking increased 9% to a new record high as consumption in the ferrocolumbium form totaled 3.2 million pounds. High strength-low alloy steel continued to be in high demand and was the dominating end-use category for columbium. Higher prices for columbium and tantalum raw materials were the result of increased demand and inflationary trends that prevailed during 1973. Imports of columbium- and tantalum-mineral concentrates were about 12% and 11% below those of the previous year, respectively. Government stockpile objectives were revised downward during the year for columbium carbide powder, ferrocolumbium, columbium metal, tantalum minerals, tantalum carbide powder, and tantalum metal. Columbium and tantalum materials continued to be released from the stockpile. Superconductors made of columbium alloyed to other metals continued to be one of the most interesting and important areas for the future growth of columbium. Tantalum continued to be primarily used in capacitors and other electronic devices.

Legislation and Government Programs.—The General Services Administration (GSA) continued its columbium and tantalum disposal program and sold to industry 1,855,103 pounds of columbium and 217,203 pounds of tantalum in the forms of ores, concentrates, and minerals, 457,515 pounds of columbium in the form of ferrocolumbium, and 75,537 pounds of columbium in the form of columbium oxide powder. Total value of all sales of columbium-bearing materials was $4,591,453 in 1973, and for tantalum-bearing materials, it was $2,121,845. The quantities of columbium and tantalum materials reported in Government inventories as of December 31, 1973, are given in table 3.

Pursuant to Section 2(a) of Public Law 520 (79th Congress), Reorganization Plan No. 1 of 1958, as amended, and Executive Order 11051, GSA stockpile objectives for columbium and tantalum materials were revised in accordance with Office of Emergency Preparedness (OEP) Stockpile Objective Action 368 issued April 12, 1973. Objectives were revised downward as follows: Columbium carbide powder from 20,000 pounds of contained columbium (Cb) to 16,000 pounds; ferrocolumbium, from 930,000 pounds of contained Cb to 748,000 pounds; columbium metal, from 45,000 pounds of contained Cb to 36,000 pounds; tantalum minerals, from 2,947,045 pounds of contained tantalum (Ta) to 312,000 pounds; tantalum carbide powder, from 26,750 pounds of contained Ta to 2,900 pounds; and tantalum metal, from 360,000 pounds of contained Ta to 45,000 pounds.

The Office of Minerals Exploration (OME), U.S. Geological Survey, continued to offer financial assistance of 50% and 75% of costs for exploration of approved columbium and tantalum resources, respectively.

DOMESTIC PRODUCTION

Domestic mining activity was insignificant during the year. One company produced a few pounds of columbium and tantalum while doing exploration and development work in Larimer County, Colo., but none of the material was marketed.

Production of columbium metal powder increased 16% in 1973, but data continued to be withheld to avoid disclosing individual company confidential information. Production of columbium metal ingot increased 23%, but again specific information was withheld. Production of tantalum metal powder (including capacitor-grade powder) increased 20% to 810 tons in 1973; production of tantalum metal ingot increased 38% to 356 tons.

Ferrocolumbium was produced by the thermite process by the Reading Alloys Co., Inc., and Shieldalloy Corp. Kawecki Berylco Industries, Inc., and Union Carbide Corp. produced the material in electric furnaces. The Foote Mineral Co., a former producer of ferrocolumbium, did not produce ferrocolumbium in 1973. In December, an official of Foote Mineral Co. announced that production and sales operations for all grades of ferrocolumbium were to be discontinued as of January 1, 1974. During the last 4 years production of ferrotantalum-columbium has not been reported by the industry.

CONSUMPTION AND USES

The quantity of columbium consumed in the form of high-purity metal was 17% above that reported in 1972 and totaled 253,882 pounds. High-purity columbium metal in powder and ingot forms continued to be used to make high-temperature ferrous and nonferrous superalloys required by the aerospace industry.

Tantalum metal (including capacitor-grade powder) consumed during the year increased from the 921,851 pounds reported in 1972 to 1,095,694 pounds. Tantalum metal continued to be used primarily in powder or ingot form in the manufacture of capacitors, other electronic equipment, and corrosion-resistant chemical equipment.

Columbium and tantalum used in ferroalloys for adding to steels to control grain size accounted for 80% of the ferrocolumbium (FeCb), ferrotantalum-columbium (FeTa-Cb), and other columbium and tantalum materials consumed. Consumption of FeCb, FeTa-Cb, and other columbium and tantalum materials increased in all end-use categories except electric steel, tool steel and miscellaneous and unspecified. The largest increase in the consumption of columbium plus tantalum occurred in the carbon steel category, but the largest quantity required was in the high strength-low alloy steels category.

Domestic consumption of columbium and tantalum in ferroalloy forms of FeCb, FeTa-Cb, and of other columbium and tantalum materials, by major end-use categories, was as follows: High strength-low alloy steel (29%); carbon steel (25%); stainless and heat resisting steel (18%); superalloys (17%); full alloy steel (9%); alloys other than alloy steels and superalloys (1%); and miscellaneous and unspecified (1%).

The total quantity of columbium consumed in steelmaking (excluding electric and tool steels) in the FeCb form was approximately 3.1 million pounds, an increase of 13% over the total for 1972. Consumption of columbium and tantalum in the ferroalloy form of FeTa-Cb continued to be small and amounted to less than 1% of the columbium and tantalum consumed in the forms of FeCb, FeTa-Cb, and other columbium and tantalum materials. The major end-use category for columbium and tantalum consumed in the form of FeTa-Cb was superalloys.

Kawecki Berylco Industries, Inc., reported that the use of tantalum powder and wire was on the increase in electronic capacitors.[2] For example, a new Interstate Highway Emergency Call Box System was reported to rely on 30 tantalum capacitors in the main electronic system of each call box. Superconducting materials of columbium-titanium coated with tin and columbium-titanium filaments embedded in a high-purity copper matrix were, also, reported as being considered for use in levitated trains and for electrical generator and motor applications.

The 10,000-square-foot facility in North Chicago, used by Fansteel, Inc., for production of mill forms such as wire, sheet and foil, rod, tubing, as well as powder, was modernized to conform to present needs.[3] Major metal rolling and handling equipment from Fansteel's Baltimore plant, closed in July 1972, was relocated in the plant. The refurbished plant has the capability for producing refractory materials in sheet gages to precision tolerances in thicknesses down to 0.003 inch.

Teledyne Wah Chang was reported to be another source of supply to the electronics industry for capacitor-grade tantalum wire.[4]

Scrap	232,039	258,568
Oxide	90,386	37,101
Potassium tantalum fluoride (K_2TaF_7)	163,606	130,763
Other compounds	r 35,255	31,051

r Revised.

Stocks of columbium and tantalum raw materials, as reported by consumers and dealers at yearend 1973 (in short tons-1972 figures in parentheses) were as follows: Columbite, 1,310 (1,104); tantalite, 745 (1,120); pyrochlore, 229 (501); tin slag, 34,691 (33,775); and other, none (61).

Consumers inventories of ferrocolumbium and ferrotantalum-columbium as of December 31, 1973, were as follows (with 1972 yearend stocks in parentheses): Ferrocolumbium 1,456,283 pounds contained columbium (814,607); ferrotantalum—columbium, 22,867 pounds contained columbium plus tantalum (18,592); and other columbium and tantalum materials, 47,182 pounds contained columbium plus tantalum (40,061). Producer stocks of ferrocolumbium at yearend 1973 were 680,320 pounds contained columbium (638,000).

PRICES

Prices for pyrochlore and columbite were higher at the end of 1973 than at the end of 1972. Contract rates for Canadian pyrochlore, f.o.b. mine and mill, went from $1.39 per pound of CB_2O_5 content to $1.44. Those for Brazilian pyrochlore similarly went from $1.37 to $1.42. Columbite ore, c.i.f U.S. ports, increased from $1.10 to $1.15 per pound of contained pentoxides for material having a Cb_2O_5—to Ta_2O_5 ratio of 10 to 1 at the beginning of the year to $1.35 to $1.45 per pound at yearend.

Tanco tantalite, Bernic Lake concentrate produced by Tantalum Mining Corp. of Canada, at the beginning of the year was quoted at $7.00 per pound of Ta_2O_5, and at yearend, $10.00. Spot prices for other tantalite ores or concentrates at the beginning of the year were quoted at $5.25 to $6.00 per pound of Ta_2O_5, 60% basis, c.i.f. U.S. ports, and at yearend, $7.50 to $8.50.

Thailand tin slag, Union Carbide-Billiton tin smelter 12% Ta_2O_5 content, at the beginning of the year was quoted at $4.00 per pound of Ta_2O_5 content, and at yearend $4.50.

Price quotations for various grades of ferrocolumbium per pound of columbium content, ton lots, f.o.b. shipping point, at the beginning of the year were as follows: Low alloy, standard grades, $2.80 per pound of columbium content; high-purity grades, $4.12 to $6.81. Quotations at yearend increased to $3.10 for low-alloy grades and narrowed to $5.00 to $5.26 for high-purity grades.

The price of columbium metal remained unchanged during the year. Columbium powder was quoted at $11 to $22 per pound for metallurgical-grade material, and $12 and $23 per pound for reactor-grade material. Columbium ingot was quoted at $16 to $27 per pound for metallurgical-grade material and $17.50 to $28.00 per pound for reactor-grade material.

Prices for tantalum metal in the forms of powder and rod were lower at the end of 1973 than at the end of 1972. Tantalum metal at yearend was quoted at $30 to $37 per pound for powder, $30 to $40 per pound for rod, and $36 to $60 per pound for sheet.

FOREIGN TRADE

West Germany, Japan, and the United Kingdom received the majority of the columbium and tantalum exported during the year. Unwrought tantalum alloys in crude form and scrap, the largest export item by volume, were shipped to West Germany (36%), Belgium-Luxembourg (21%), Japan (14%), and Italy (6%). The remainder of this material (1% of the total) was exported to France, Austria, Mexico, Brazil, and Sweden. Tantalum and tantalum alloy powder, the largest export item by value, was shipped to Japan (27%), West Germany (21%), the United Kingdom (20%), France (9%), Italy (9%), and Canada (8%). The remainder of the tantalum and tantalum alloy powder (6% of the total) was destined for Switzerland, the Netherlands, Yugoslavia, India, and Sweden. Wrought tantalum and tantalum alloys, the second largest export item by value, were exported to Japan (27%), the

United Kingdom (23%), West Germany (13%), Canada (12%), France (12%), the Netherlands (6%), Switzerland (3%), and Italy (2%). The remainder of the tantalum material (2% of the total) was exported to Mexico, Nicaragua, Brazil, Argentina, Sweden, Belgium-Luxembourg, Austria, Yugoslavia, Israel, India, Australia, and the Republic of South Africa. Tantalum ores and concentrates, believed not to be of domestic origin, were shipped to Japan. Wrought columbium and columbium alloys were mostly exported to the Netherlands (39%), Japan (32%), the United Kingdom (12%), West Germany (8%), France (4%), and Canada (3%). The rest of this material was exported to Mexico, Austria, Switzerland, Italy, India, and the Republic of South Africa. Unwrought columbium alloys in crude form and scrap were shipped mostly to West Germany (61%), the United Kingdom (27%), and Japan (9%); the remainder (3% of the total) went to the Netherlands, Switzerland, and Trinidad and Tobago.

Imports for consumption of unwrought columbium metal, waste, and scrap, all from West Germany, increased from 400 pounds valued at $3,714 in 1972 to 3,974 pounds valued at $11,794 in 1973. Imports for consumption of wrought columbium metal decreased from 265 pounds valued at $14,876 in 1972 to 25 pounds valued at $1,988 in 1973. This import item was supplied by the U.S.S.R. (96%) and the United Kingdom (4%). Unwrought columbium alloys were not imported in 1973.

Imports for consumption of unwrought tantalum metal, including waste and scrap, were 100,808 pounds valued at $727,665 in 1973. The material was imported from West Germany (55%), Mexico (23%), France (9%), the United Kingdom (8%), Canada (3%), and the Netherlands and Belgium-Luxembourg (2%). Imports of wrought tantalum from Austria (56%), Switzerland (33%), and the United Kingdom (11%) decreased from 90 pounds valued at $3,664 in 1972 to 18 pounds valued at $2,098 in 1973. Imports of unwrought tantalum alloys, all from Japan, totaled 93 pounds valued at $3,800 and represented a sharp decrease from the 2,000 pounds valued at $13,183 that were imported in 1972.

In 1973, imports for consumption of columbium-mineral concentrates and tantalum-mineral concentrates were 12% and 11%, respectively, below those of 1972.

Receipts in tin slags came primarily from Thailand.

WORLD REVIEW

Australia.—On January 31, the government of Australia imposed export controls on all Australian minerals to be exported in raw or semiprocessed form. The objective for such an action was to insure that Australia's export prices are at reasonable levels in relation to export prices in other countries and to encourage more domestic processing of Australia's mineral resources before being exported.

Brazil.—During 1973 Brazil maintained its standing as the major world producer of columbium minerals. Companhia Brasileira de Metalúrgia e Mineração (CBMM), the country's leading producer, continued to recover columbium concentrate from rich pyrochlore ores at its Axará mine and mill operations and to produce ferrocolumbium (FeCb) at its pyrometallurgical plant by the thermite process.

Columbium and tantalum associated with columbite-tantalite and microlite continued to be produced in limited quantities from relatively small pegmatite operations located principally in Minas Gerais.

Canada.—St. Lawrence Columbium and Metals Corp. produced concentrates from its underground mining operations and milling facilities near Oka, Quebec, and continued to be Canada's sole columbium producer. In spite of labor problems that resulted in work slowdowns and a 1-month strike, the firm milled 612,487 tons of ore, which represented a 4% increase over that milled in fiscal year 1972 (ended September 30, 1972).

Two new pyrochlore ore zones were reported to be within easy reach of the present mine workings at the St. Lawrence Columbium and Metals Corp.[5] A development drift and two crosscuts were advanced on the 500-foot level of the Main Oka ore body that passes through the two new zones. Ore mined from these areas was used in a 1,750-ton mill test conducted by the company. Results of the test showed the new ore to be amenable to the company's concentration process and to be superior to ore presently being mined from the Main Oka ore body in regards to calcite content.

Ore reserves available to St. Lawrence Columbium and Metals Corp. at the end of the fiscal year (September 30, 1973) were reported to be 10,700,000 tons of proven ore, 6,500,000 tons of probable ore, and 8,200,000 tons of possible ore, giving a total of 25,400,000 tons of ore reserves at 0.443% Cb_2O_5.[6]

Chemalloy Minerals Ltd., which holds 75% of Tantalum Mining Corp. of Canada, confirmed that it offered to buy back from the Manitoba Development Corp. the 25% interest that it sold to the government agency in 1971.[7] Government action on the offer was still pending at yearend.

Copperfields Mining Corp. Ltd. and Quebec Mining Exploration Co. (SOQUEM) completed its exploration, definition drilling, and underground bulk sampling, and 11-month pilot plant program on its St. Honore carbonatite deposit, near Chicoutimi, Quebec.[8] Negotiations were initiated to finance into production the St. Honore columbium venture. Senior financing terms were arranged in principle and include $6,650,000 from a consortium of Canadian chartered banks and $3,000,000 from a customer with the balance to be provided by the sponsors. Long-term sales contracts for the pyrochlore concentrate to be produced at the mill were negotiated with companies in Europe, Japan, and the United States, and these markets were supposed to require about 95% of the anticipated mill production. The ore reserve of 40 million tons of 0.76% columbium pentoxide, based on a 0.5% cutoff, was to be mined underground.[9] Present plans call for a 1,500-ton-per-day mining and milling operation by mid-1975.

Japan.—According to the Ministry of International Trade and Industry (MITI), Japanese production of tantalum metal was 143% above that of 1972 for the period January through September and was equal to 63,933 pounds.

Mozambique.—In 1972 Mozambique's production of tantalite and microlite was reported to be 92,593 and 134,480 pounds,

respectively. The main pegmatite deposits, which have been the source of Mozambique's tantalum ores (columbo-tantalite), occur in the Alto Ligonha region.

Nigeria.—Two Japanese companies, Sumitomo Metal Mining Co. and Mitsubishi Corp., acquired a 76% interest in Tin and Associated Minerals, Ltd., the company that manages the 600-ton-per-year columbite mine at Odegi, Nigeria. The acquired interest was obtained from Quebec Iron and Titanium Corp., a Canadian subsidiary of the U.S. Kennecott Copper Corp., of Sorel, Quebec, and Anthony Coshinos, an American. The Odegi columbium mine at Jos in the northern part of Nigeria accounts for about one-third of the country's total output of columbite concentrate.

Zaire.—As a byproduct of tin mining, Zaire-Etain produced 143,299 pounds of columbium-tantalum concentrate in 1972. The mining operations from which the columbium-tantalum concentrate were produced are located in north central Shaba where cassiterite is mined from an ore bed approximately 3 miles long and from 328 to 1,312 feet wide.

Philips Brothers Sobaki (PHIBRAKI), continued to produce mixed cassiterite/columbium-tantalum ore from deposits at

[e] Estimate. [p] Preliminary. [r] Revised.

[1] Excludes columbium and tantalum-bearing tin concentrates and slags.

[2] In addition to the countries listed, Burundi, Spain, South-West Africa and the U.S.S.R. also produce or are believed to produce columbium and tantalum mineral concentrates, but available information is inadequate to make reliable estimates of output levels.

[3] Data on gross weight generally has been presented as reported in sources, divided into concentrates of columbite, tantalite, pyrochlore and microlite where information is available to do so, and reported in groups such as columbite-tantalite where it is not.

[4] Unless otherwise specified, content is estimated on the basis of the content reported for U.S. imports from the country in question. Entries specifically marked as estimates are based on estimated gross weights.

[5] Content calculated on basis of data in source publication recording gross weight.

[6] Exports.

[7] Metal content calculated from data reported in source publication (in terms of contained pentoxide).

[8] Less than ½ unit.

Kabili and in 1972 produced 194,181 pounds of the ore, which was 11,729 pounds less than that produced in 1971.

Cobelmin-Zaire (COBELMIN), a subsidiary of Compagnie Belge d'Enterprises Minières, continued to operate concessions owned by Compagnie Minière Des Grands Lacs (MGL) and Minerga. In 1972, production of columbium-tantalum-bearing materials was down 41%.

TECHNOLOGY

One phase of Bureau of Mines research was directed toward improving the methods of preparing metals and alloys from ores and compounds. A kinetics study of the reduction of Cb_2O_5 with NH_3 was conducted at 600° to 1,300°C, using vertical fixed-bed, flow-through reactors, with the goal of using the nitride as an intermediate in the preparation of columbium metal by way of a thermal decomposition step.[10] The effects of such reactor materials as stainless steel, nickel, molybdenum, graphite, alumina, and Vycor upon ammonia reactivity toward Cb_2O_5 were investigated. Columbium pentoxide was shown to form three types of reactor products, o-oxynitride at temperatures below 800°C, CbO_2 between 800° and 850°C, and hexagonal CbN at higher temperatures. The most rapid and complete reaction occurred with molybdenum or alumina reactors at 1,200°C.

A new high-strength corrosion-resistant alloy was added to the Latrobe Steel Co.'s specialty alloys production line.[11] The new alloy, known as MultiPhase MP 159 (U.S. Patent 3,767,385), was reported to be particularly suitable for such applications as jet engine components and high-stress parts and components in marine and petrochemical machinery and equipment. Its nominal composition includes 35.7% cobalt, 25.5% nickel, 19.0% chromium, 9.0% iron, 7.0% molybdenum, 3.0% titanium, 0.6% columbium, and 0.2% aluminum. Tests have shown the alloy to be extremely resistant to crevice corrosion and stress-corrosion cracking in hostile environments.

Columbium pentoxide and tungstic oxide have been used for a number of years as additives to titania enamels for the purpose of adjusting the color of these materials to a bluer shade of white. Prior to a study conducted by R. A. Eppler of Pemco Products, Glidden-Durkee Division of SCM Corp., Baltimore, Md., the exact role these additives played in adjusting the shade of titanic enamel was not known.[12] X-ray diffraction data reported, indicates that columbium pentoxide and tungsten oxide have pronounced effects on the solubility of titania in a titania opacified porcelain enamel. Columbium pentoxide depresses the solubility of titania at firing temperatures, and tungsten oxide lowers the temperature at which the minimum titania solubility occurs so that high concentrates of small anatase crystals can be obtained.

A new ion exchanger, tantalum antimonate, was synthesized and reported to be reproducible and chemically stable.[13] The ion exchanger was synthesized by mixing O.1M tantalum and antimony pentachloride solution in the ratio of 1:2 at room temperature and by adjusting the pH of the solution to 1 with ammonia and by refluxing the precipitate obtained with the mother liquor for 16 hours. Quantitative separations of such mixtures as VO^{2+}-Al^{3+}-Ti^{4+}, VO^{2+}-Fe^{3+}-Ti^{4+}, and UO_2^{2+}-Ti^{4+} were reported to be made with the tantalum antimonate ion exchanger.

The superconductivity field continued to be one of the most interesting and important areas for the future growth of columbium. Superconductors made of columbium alloyed to other metals are being considered for use in such commercial applications as electromagnets, electrical machinery, power transmission lines, and high-speed magnetic suspended trains.[14]

14 Popular Science. Cryogenic Power Lines: Cool Aid for Our Energy Crisis. October 1972, pp. 69-71 and 130.

An important step toward wider application in this field was made by a Westinghouse research worker. By means of a new sputtering process, John R. Gavaler produced a columbium-germanium compound Cb_3Ge, which becomes superconducting at 22.3K, thus allowing the use of a cooling system employing liquid hydrogen instead of lower boiling liquid helium.[15]

The first new piezoelectric material to be developed in many years was lithium tantalate. Single crystals of ferroelectric lithium tantalate for use in piezoelectric resonator and filter devices are being grown at Western Electric's Merrimack Valley Works by the Czochralski crystal-pulling technique.[16]

The continuing interest in methods of extraction and beneficiation of columbium and tantalum values was reflected by some of the patents issued during the year.[17]

Copper

By Harold J. Schroeder [1]

World mine production of copper increased 7% to 7.86 million tons, a record high for the sixth consecutive year. All major producing countries except Peru and Zambia contributed to the increase. Production from new mines or expansions to operating properties that were completed during 1972 and 1973 more than offset losses to production from strikes, political events, and transport difficulties.

In the United States consumption of refined copper increased substantially to a new record-high quantity. There was a modest increase in mine production and smelter production from primary materials with the latter category a new record high. Refinery output from primary materials declined but the output from scrap increased significantly with the total showing a slight decrease. Foreign trade in unmanufactured copper was characterized by a small reduction in net imports as exports rose significantly and imports were only slightly higher. Industrial stocks of refined copper were drawn down during the year to compensate for a level of consumption in excess of supplies from production and net imports. Changing market conditions were reflected in price increases of approximately 9½ cents per pound in three steps during the first quarter of the year and 8 cents in December for yearend quotations for electrolytic wirebar copper in a range of 68.15 to 69.25 cents per pound.

Legislation and Government Programs.—Copper in the national stockpile on January 1, 1973, was 60,112 tons of oxygen-free, high-conductivity (OFHC) copper, 7,067 tons of copper in beryllium-copper master alloys, and 191,480 tons of copper in "other" classifications, for a total of 258,659 tons, 33% of the objective of 775,000 tons. In March the copper stockpile objective was reduced to zero and on December 28, the President signed into law Public Law 93–214, authorizing the sale of 251,600 tons of stockpile copper. The General Services Administration decided to transfer 85,000 tons of the excess metal to the U.S. Bureau of the Mint and to sell the balance for domestic consumption on a sealed bid basis.

The Office of Minerals Exploration continued to offer up to 50% government participation in the authorized cost of exploration for copper deposits. There were no contracts executed in 1973 that involved copper.

Defense set-asides for copper controlled materials were unchanged during 1973. The controlled items and their percent set-asides were: Unalloyed brass mill products—sheet (2); rod (9), and tube (2); alloyed brass mill products—sheet (4) and rod (10); copper wire mill products (2); and copper foundry products (3).

The suspension of duties on unwrought copper and copper-base scrap, which had expired on June 30, 1972, after being in effect since February 9, 1966, was reinstated by Public Law 93–77, effective from July 1, 1973, to June 30, 1974. In addition to reinstating the duty suspension, the law also revised the peril point for automatically revoking the suspension from 36 to 51 cents per pound.

r Revised.

DOMESTIC PRODUCTION

PRIMARY COPPER

Mine Production.—Domestic mine production of recoverable copper was 1.72 million tons, an increase of 3% and only slightly below the record high of 1970. Principal copper-producing States were Arizona, with 54% of the total, Utah (15%), New Mexico (12%), Montana (8%), Nevada (5%), and Michigan (4%). These six States accounted for 98% of the total production.

Open pit mines accounted for 83% of mine output and underground mines for 17%. The production of copper from dump and in-place leaching, mainly recovered by precipitation with iron, was 159,022 tons or 9% of mine output. Total copper recovered by leaching methods was 241,917 tons, of which 211,859 tons was precipitated with iron and 35,058 tons was electrowon.

Duval Corp., a subsidiary of Pennzoil Co., operated the Duval Sierrita mine near Tucson, Ariz., at a steadily increasing rate during the year and in December a new high average daily operating rate of 89,000 tons of ore was achieved. Duval's Esperanza property adjacent to Sierrita resumed operations early in 1973 following a 1-year shutdown owing to a shortage of smelting capacity to treat stockpiled concentrate. Plant modifications initiated during the shutdown made possible a 25% increase in throughput.

The Anaconda Company produced 127,800 tons of copper from underground and open pit operations at Butte, Mont., compared with 125,800 tons in 1972. Production included 1,650 tons from the Continental East pit which reached operational status late in the year and is designed to

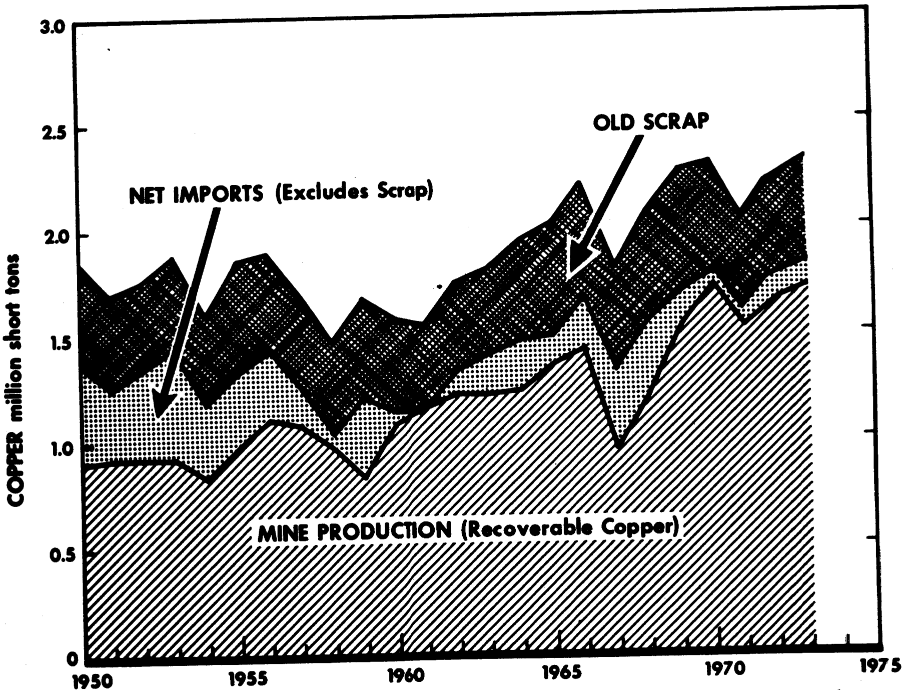

Figure 1.—Sources of copper supply for United States copper consumption.

produce at an annual rate of 24,000 tons. A modification of the copper concentrator at Butte was completed, increasing capacity from 40,000 to 50,000 tons of ore per day. The concentrator at Anaconda was reactivated to treat 14,000 tons of ore per day from the new Continental East pit. Production at the Yerington, Nev., property declined from 41,200 to 35,800 tons of copper. Development of the Victoria open pit mine and concentrator in eastern Nevada was initiated with production at an annual rate of 9,000 tons of copper in concentrates scheduled to start early in 1975. Exploration and feasibility planning continued toward development of a large underground mine at Carr Fork in the Bingham District of Utah.

Anamax Mining Company, formed January 1 as a joint venture of The Anaconda Company and American Metal Climax, Inc., operated the Twin Buttes, Ariz., open pit mine and produced 73,648 tons of copper in concentrates compared with 66,486 tons in 1972. A $200 million expansion program at Twin Buttes, including open pit expansion, an enlargement of the concentrator, and a leach-electrowinning plant for oxide ore, will increase capacity from 75,000 to 130,000 tons of copper with completion expected in 1975.

Kennecott Copper Corp. operated mines in Arizona, Nevada, New Mexico, and Utah; these mines produced a combined total of 471,700 tons of copper, compared with 460,600 tons in 1972. The Utah Copper Div. accounted for 255,000 tons of the total followed by the Ray Mines Div. (Arizona) with 98,900 tons, the Chino Mines Div. (New Mexico) with 67,800 tons, and the Nevada Mines Div. with 50,000 tons. Smelter capacity continued to be the limiting factor on Kennecott's mine production in 1973. At the Nevada Mines Div. replacement of flotation equipment to increase production was underway and will be completed by mid-1974. At the other operating divisions engineering studies to expand production capacities were in progress.

The American Smelting and Refining Company (Asarco) operated three copper mines in the vicinity of Tucson, Ariz. The Mission unit produced 46,600 tons of copper in concentrates compared with a 1972 output of 45,400 tons. Output at the Silver Bell unit increased slightly to 23,800 tons of copper in concentrates and precipitates. Production at the San Xavier mine as copper-bearing flux ore for use at Asarco's Hayden smelter and as precipitates from a new leach plant completed in May totaled 2,700 tons of copper. The new leach plant cost $12 million and has a design capacity to treat 4,000 tons per day of oxide ore that will yield approximately 12,000 tons of copper in precipitates per year. Construction work continued at the Sacaton mine at Casa Grande with an open pit mine and mill expected to be in operation early in 1974 and underground mining of deeper ore anticipated in 1979. The rated annual capacity of the Sacaton project is 21,000 tons of copper contained in concentrates.

Mines of the Phelps Dodge Corp. produced 319,600 tons of copper, a new record high that exceeded the previous 1970 record by 6,000 tons. The greater output reflected an increase at its Tyrone, N. Mex., operation from 78,800 to 104,000 tons which resulted from completion of an expansion program in July 1972. Production from the Arizona mines of Phelps Dodge declined from 226,200 to 215,300 tons. Of the total, 119,500 tons was produced at Morenci, 53,800 tons at Ajo, and 42,000 tons at Bisbee. The Bisbee open pit operations are expected to cease about mid-1974 owing to exhaustion of ore reserves and the underground operations are expected to continue at least through 1974 if copper prices are favorable. Removal of overburden and mill construction work continued at the Metcalf property near Morenci. This project has a rated capacity of 60,000 tons of copper per year with initial production planned for early 1975. Underground development work continued at Safford, Ariz., to determine the feasibility of mining a deep ore body containing an estimated 400 million tons of ore with an average grade of 0.72% copper. Reserves at producing mines and at the two properties under development were estimated at 1.9 billion tons of ore containing about 12 million tons of recoverable copper.

Cities Service Co., through its North American Chemicals and Metals Group, operated mines in Arizona and Tennessee that produced 39,600 tons of copper compared with 44,900 tons in 1972. Output from the Tennessee mines was reduced as a result of roasting and pelletizing problems encountered in early 1973 during startup operations of new facilities built for expansion of production. The 350 million ton, low-grade Pinto Valley copper deposit near Miami, Ariz., was under development with startup scheduled for mid-1974. A production rate of 40,000 tons of mill feed per day is expected by early 1975. Construction continued for underground mining from the high-grade Miami East ore body with production to start in 1975 and to reach a level of 2,000 tons of ore per day by 1978.

The White Pine, Mich., operations of White Pine Copper Co. milled a record 8,884,000 tons of copper ore averaging 1.0% copper with an 86.22% copper recovery in concentrate. Research on improved mining practices continued to be emphasized in an effort to reduce unit mining costs. One promising experiment was the use of a mobile crushing machine to reduce vehicle haulage and conveyor belt maintenance. With an average haul distance from the mine face to the mill of 3.3 miles in 1973 compared with 2.9 miles in 1972 it is apparent that haulage factors are becoming a more important cost consideration each year.

Magma Copper Co. operated the San Manuel and Superior mines in Arizona with a combined output of 158,300 tons of copper compared with 149,500 tons in 1972. At San Manuel the average daily production was a record high 61,553 tons of ore but somewhat below rated capacity owing to limitations in labor availability. At Superior the mine was shut down during July to enable transfer of haulage and hoisting operations to the new tunnel and shaft. By yearend mine production was near 3,000 tons of ore per day, about double the previous rate and the planned level of 3,300 tons is expected in 1974.

The Inspiration Consolidated Copper Co. operated open pit copper mines in the vicinity of Inspiration, Ariz.; 16.5 million tons of waste and 8.5 million tons of ore were mined for a combined record high 25 million tons of material handled. Approximately 6.7 million tons of the ore was treated in the concentrator with about 46% of the concentrator feed first processed in leaching tanks to recover acid soluble copper. The combined production was 43,134 tons of copper. Heap leaching of ore too low in copper content for in-plant treatment yielded an additional 8,198 tons of copper. In January, mining of the upper Ox Hide pit was almost completed and mining of the lower Ox Hide pit began. Copper production from the Ox Hide pits was 4,356 tons, a slight reduction from the previous year but the rate of production was increasing at yearend. At the Christmas open pit mine, southeast of Miami, Ariz., output was 9,508 tons, a 10% decline caused mostly by the lower copper content of ores treated. The ratio of waste removed per ton of ore mined rose from 4.94 to 5.77. Total mine production from all operating mines was 65,196 tons of copper.

Cyprus Mines Corp., through the Cyprus Pima Mining Co. (formerly Pima Mining Co.) operated the Pima mine near Tucson which produced 88,140 tons of copper in concentrates from milling 20.3 million tons of ore averaging 0.51% copper. The expanded plant facilities, including semi-autogenous grinding mills, completed early in 1973, resulted in increased capacity and reduced cost per ton. At yearend ore reserves were estimated at 221 million tons grading 0.49% copper. Exploration was in progress to test a mineralized area to the east and southeast of the present pit. The Cyprus Bruce Copper and Zinc Co. (formerly Bruce Mine Div.) operated its underground copper-zinc mine near Bagdad, Ariz., and produced about 3,000 tons of copper in concentrates from 93,000 tons of ore averaging 3.68% copper and 12.7% zinc. Reserves were estimated at 467,000 tons, sufficient for about 5 years of operation. The Cyprus Johnson Copper Company (formerly Johnson Camp Div.) is developing an oxide-copper ore deposit near Johnson, Ariz., with production scheduled for early 1975 at a rate of 4,000 tons of ore per day. Reserves were estimated at 14.7 million tons averaging 0.80% copper.

Cyprus Bagdad Copper Company, formed in 1973 by a merger of Cyprus Mines Corp. and Bagdad Mining Company, operated its Arizona mine and produced 12,000 tons of copper in concentrate and 7,133 tons as cathode copper, the latter obtained from oxide ore by a leach-electrowinning process. Sulfide ore mined in 1973 averaged 0.70% copper. A study was in progress to determine the feasibility of a major mine-mill expansion program and the possible construction of a smelter-refinery. Ore reserves for the expanded operation were estimated at 300 million tons averaging 0.49% copper with prospective additional reserves from exploration in progress.

Ranchers Exploration and Development Co. produced a record 7,382 tons of copper cathodes by a leaching-solvent extraction-electrowinning process at its Bluebird mine near Miami, Ariz. A fourfold enlargement of production capacity which would include a change from heap to vat or agitation leaching is under consideration. The in situ leaching operation at the Old Reliable deposit near San Manuel, Ariz., had an initial flow of copper-bearing solutions late in 1972 and by February 1973 output stabilized at about 250 tons of copper recovered in precipitates per month. Heap-leaching operations from mixed oxide-sulfide ore stockpiled during mining of high grade copper ore in 1970 at Ranchers' Big Mike mine near Winnemucca, Nev., yielded about 1,000 tons of cement copper. During the latter half of 1973 approximately 550,000 tons of copper ore and rock was blasted into the bottom of the old pit and the surface of the broken material was prepared for a leaching operation to recover copper from the copper-bearing solutions.

Hecla Mining Co. essentially completed the 7,500-foot twin 15-degree declines at its Arizona Lakeshore copper mine south of Casa Grande. Over 45,000 feet of underground openings have been driven and other facilities were under construction for a scheduled 1975 production with a designed capacity of 69,000 tons per year of copper. Poor ground conditions in the oxide ore body necessitated a change in plans to provide separate crushing facilities and hoisting of the ore through a vertical shaft instead of transfer by ore passes to the sulfide crushing-conveyor belt haulage system. Design engineering for the roast-leach-electrowinning plant, the oxide vat-leach plant, the sponge iron plant, and the byproduct sulfuric acid plant was in progress.

UV Industries Inc. operated its Continental mine near Bayard, N. Mex., and milled approximately 1,668,000 tons of copper ore compared with 875,000 tons in 1972. The increased quantity reflects completion of a mill expansion project. At yearend the company estimated ore reserves at 19.5 million tons of 2.0% copper amenable to underground mining plus 13.9 million tons of 0.8% copper amenable to open pit mining. An exploration program is planned to expand underground reserves both laterally and at greater depth.

Smelter Production.—Output of copper at primary smelters in the United States was 1.82 million tons, a 4% increase and a record high quantity for the second successive year. The record high was achieved despite some disruptions to production at several smelters caused by construction programs to modify existing facilities to meet air quality standards.

Asarco installed an anode casting plant at its Hayden, Ariz., smelter to eliminate casting blister copper cakes, previously remelted and cast into anodes at a refinery. A 1,000-foot smelter stack, the tallest in the country, was completed and when it becomes operational in 1974 the ambient-air quality will be improved by better dispersion of the weak sulfur dioxide gases that cannot be handled by the acid plant. At the El Paso, Tex., smelter a new sulfuric acid plant was dedicated in May and at the Tacoma, Wash., smelter a 200-ton-per-day liquid sulfur dioxide plant was under construction with startup scheduled for the spring of 1974.

Anaconda's smelter renovation program at Anaconda, Mont., to reduce emissions to the atmosphere and increase capacity from 30 million to 35 million pounds of copper per month was completed during the year. Construction of other facilities for dust control was underway. Kennecott had work in progress at its Hurley, N. Mex., smelter towards a mid-1974 completion of converter hoods, duct work, an electrostatic precipitator, and an acid plant; investigation of a low-fuel, direct smelting process was conducted on a pilot plant scale. At the McGill, Nev., smelter a 750-foot stack to improve dispersion of effluents was under construction; at the Hayden, Ariz., smelter an improved air quality control system, including an expanded acid plant and a computer monitored variable emissions control, was completed for full operation in 1974. A similar air quality monitoring network was placed in operation at the Garfield, Utah, smelter and construction was started on a new 1,200-foot smelter stack.

Phelps Dodge was constructing a new smelter in Hidalgo County, N. Mex., with a scheduled startup early in 1975. The facility will be required for treatment of concentrates from the Tyrone mine since the Morenci smelter presently handling the Tyrone output will be used to smelt concentrates from the new Metcalf mine. Cost of the new smelter project is estimated at $200 million, including $55 million for emission control facilities. It will be the first smelter in the United States to utilize the flash smelting process. At the Ajo, Ariz., smelter new emission control facilities, including a 600-ton-per-day sulfuric acid plant, were essentially completed. The company was about halfway through a $92 million program at the Morenci smelter which included a new reverberatory furnace, a ninth converter, waste heat boilers, electrostatic precipitators, and a 2,500-ton-per-day acid plant.

Magma Copper Co. experienced some output restrictions at its San Manuel, Ariz., smelter owing to anode casting problems and the necessity of installing water-cooled converter hoods as part of the air quality control program. An electrostatic precipitator and an acid plant were under construction and scheduled for operation in mid-1974. To provide a basis for comparison of conditions before and after installation of emission control facilities, an air monitoring network has been in operation for over a year.

Inspiration Consolidated Copper Co. essentially completed a $54 million construction program to replace much of its existing smelter at Miami, Ariz., and the facilities should become operational in 1974. The program replaced the reverberatory furnace with an electric furnace and the horizontal rotary converters with siphon-type converters, and it provides new sulfuric acid production facilities.

White Pine Copper Co. operated its slag recovery plant for the second year from April until the winter shutdown in December. The plant processed 881,000 tons of slag and recovered about 4.2 million pounds of copper for return to the smelter. Total 1973 smelter output was 157 million pounds of copper. It is estimated that 3 months of operation in 1974 will process all of the remaining slag.

Refined Production.—Production of refined copper from primary materials was 1.87 million tons, a slight decline from the record high of 1972. Refined copper produced from scrap was 465,100 tons compared with 423,243 tons in 1972. Total production of refined copper in the United States was 2.33 million tons, derived 80% from primary and 20% from scrap sources.

Asarco was constructing a new refinery of 420,000 tons of annual copper capacity at Amarillo, Tex., with completion scheduled for late 1975. This facility will replace the Baltimore refinery which will be phased out after 1975. Together with the necessary infrastructure and related facilities the new project will cost on the order of $100 million and will employ 700 people. At the Tacoma, Wash., refinery Asarco started construction of facilities for purifying the refining solution which will permit recovery of nickel salts.

Anaconda was enlarging its Great Falls, Mont., copper refinery to a capacity of 41 million pounds of cathode copper per month from the present 30 million pounds capacity.

Copper Sulfate.—Copper sulfate was produced from primary and/or secondary metal by companies with plants located as follows:

Company	Plant location
The Anaconda Company	Great Falls, Mont.
Chevron Chemical Co	Richmond, Calif.
Cities Service Co	Copperhill, Tenn.
Phelps Dodge Refining Corp.	Laurel Hill, N.Y.
	El Paso, Tex.
Van Waters & Rogers Inc	Wallace, Idaho.
	Midvale, Utah.
	Metaline Falls, Wash.

Copper sulfate production advanced 14% to 43,360 tons, the second successive increase following the slump in output during 1971. Shipments exceeded production and ending stocks were 4,580 tons. Of the total 44,090 tons shipped, producers' reports indicated that 19,840 tons was for agricultural uses, 23,220 tons was for industrial uses, and 1,030 tons was for other uses.

Phelps Dodge placed a new plant for producing copper sulfate from tankhouse electrolyte solutions at its El Paso copper refinery into operation.

Byproduct Sulfuric Acid.—Sulfuric acid was produced at eight copper smelters from the sulfur contained in offgases, and output increased for the 6th consecutive year from 1,010,600 to a record 1,088,300 tons, on a 100% acid basis. A 600-ton-per-day sulfuric acid plant was placed in operation during the year at the Anaconda, Mont., smelter of Anaconda. New sulfuric acid plants or expansions of existing plants were under construction at copper smelters at Ajo, Ariz., Hurley, N. Mex., Miami, Ariz., Morenci, Ariz., and San Manuel, Ariz.

SECONDARY COPPER AND BRASS

Domestic recovery of copper in all forms from all classes of purchased scrap totaled 1.36 million tons in 1973, a 5% increase from the 1972 total and the largest quantity since 1969. Recovery from copper-base scrap increased from 1.28 to 1.34 million tons. Brass mills accounted for 47% of the recovered copper, primary producers for 25%, and secondary smelters for 22%. The remaining 6% was reclaimed at chemical plants, foundries, and manufacturers.

Consumption of purchased copper-base scrap in 1973 was 1.86 million tons consisting of 63% new scrap and 37% old scrap. The major categories of brass mill products, refined copper, and brass and bronze ingots obtained from scrap all registered significant increases.

CONSUMPTION

Consumption of refined copper rose 7% to a record 2.40 million tons, reflecting the greater activity of the general economy. Wire mills accounted for 68% of refined copper consumption, brass mills for 30%, and all other consumer categories for the remaining 2%.

Apparent withdrawals of primary refined copper on domestic account was 1.70 million tons compared with 1.90 million tons in 1972.

STOCKS

Stocks of refined copper at primary producers decreased from 57,000 tons at the start of the year to 29,000 tons by the end of June, increased to 39,000 tons during July, trended down to 28,000 tons by the end of November, then rose to 37,000 tons by yearend. The trend of fabricators' stocks of copper in all forms was similar to that of the primary producers with stocks of 460,000 tons at the start of the year, drawn down to 419,000 tons by yearend.

PRICES

Domestic copper price quotations for electrolytic wirebar copper increased by 9½ cents per pound in three steps during the first quarter of 1973 to a quoted price of 60 to 60.25 cents per pound. Price controls prohibited any price increase between early

June and December 6 after which quotes were increased by approximately 8 cents to a range of 68.15 to 69.25 cents per pound. Prices on the London Metal Exchange increased from an average 50.7 cents per pound equivalent for January to 102.9 cents for November and then declined to 100.9 cents for December.

FOREIGN TRADE

U.S. exports of unmanufactured copper increased 18% to 277,600 tons. The largest category, refined copper, was 189,400 tons compared with 182,700 tons the preceding year. Exports of ore, concentrates, matte, and blister increased from 26,200 tons in 1972 to 30,900 tons and exports of copper scrap rose from 17,400 to 42,300 tons. Scrap exports were particularly large during June, July, and August following the domestic price ceilings imposed in early June and the escalation of foreign copper prices. Copper-base scrap was exempted from price controls, effective August 6, and there was a significant reduction in exports following this action.

U.S. imports of unmanufactured copper were 417,400 tons, a slight increase and the largest quantity since 1968. The largest category, refined copper, increased from 192,400 to 201,500 tons and the second largest category, blister copper, declined from 157,400 to 154,100 tons. Of the total imports Canada supplied 37%, Peru 24%, and Chile 14%.

WORLD REVIEW

World mine production of copper attained 7.86 million tons, an increase of 7% and a record high for the 6th consecutive year. All of the major producing countries except Peru and Zambia contributed to the increased output. Production from new mines or expansions to operating properties that were completed during 1972 and 1973 more than offset losses to production from strikes, political events, and transport difficulties.

The United States continued to lead the world in mine production with 22% of the total, followed by Canada with 11%, and Chile, Zambia, and the U.S.S.R. with 10% each.

Australia.—Mount Isa Mines, Ltd., operated its copper-lead-zinc-silver mine at Mount Isa and a copper smelter at Townsville to produce 129,300 tons of blister copper for the fiscal year ending June 30, 1973. An expansion program was completed by mid-1973 which gave a rated mine-mill-smelter productive capacity of 170,000 tons of copper per year. In the first 28 weeks of fiscal 1974, output of blister copper was 28% above the 1973 rate.

Mount Lyell Mining and Railway Co., Ltd., for the year ended June 30, 1973, produced a record 25,400 tons of copper in concentrate from 2.4 million tons of ore grading 1.19% copper mined and milled at its Tasmania operation. The transition of production from open pit to underground operations continued with 66% of production for the year from underground mining; compared with 41% in 1972. Reserves in all ore zones were estimated at 35 million tons of proven ore grading 1.48% copper and 10.6 million tons of probable ore grading 1.39% copper.

A joint Phelps Dodge Corp.-St. Joe Minerals Corp. exploration project on the Woodlawn deposit near Tarago, New South Wales, indicated 10 million tons of reserves averaging 1.5% copper, 3.0% lead, 7.5% zinc, and 1.5 ounces of silver per ton that may be minable by open pit methods. Pilot plant testing of bulk samples of the ore showed that processing will present considerable difficulties. Further drilling to test an indicated mineralized zone outside the proposed open pit limits is planned for 1974.

Botswana.—Bamangwato Concessions, Ltd. (BCL), brought its Selebi-Pikwe nickel-copper mining and smelting project into production in December, approximately 33 months after construction began. Initially, 2 million tons per year of ore from the Pikwe open pit and underground mines will yield about 17,000 tons of refined copper and 19,000 tons of refined nickel. In addition to the direct costs of the mining-smelting project, an estimated $82 million was expended by the Botswana Government to provide the needed infrastructure consisting of a dam on the Shashe River, a 50-mile-long water pipeline to the mine, a 50-megawatt coal-fired power station, a spur railroad track to the mine site, and a town for 12,000 people. Also there was an associated $4.5 million venture to provide a colliery and spur track to serve the smelter and power station.

The smelter product will be copper-nickel matte that will be refined at the American Metal Climax, Inc. (AMAX), rehabilitated nickel refinery at Braithwaite, La. A West German firm, Metallgesellschaft A.G., will purchase most of the copper production and more than half of the nickel output. Approximately 140,000 tons of byproduct sulfur will be marketed in southern Africa.

Ownership of BCL is 15% by the Government of Botswana and 85% by Botswana Roan Selection Trust, Ltd. (BRST), which in turn is owned 40% by the public and about 30% each by AMAX and the Anglo American Corp./Charter Consolidated Group.

A joint exploration project by Newmont Mining Corp., Tsumeb Corp., and United States Steel Corp. discovered moderate-grade copper intersections in a very large geologic structure.

Canada.—Production from mines that came onstream during 1972 and 1973 more than offset losses due to mine strikes and disruptions to rail transportation so that output rose 13% to 899,500 tons, a record high for the 4th successive year. British Columbia became the leading copper producing Province with 39% of the total followed by Ontario with 31%, Quebec 17%, Manitoba 8%, and the remaining Provinces, 5%.

Falconbridge Nickel Mines Ltd. operated nickel-copper mines and treatment plants in the Sudbury, Ontario, area during 1973 and metal deliveries of copper were 26,900 tons compared with 28,200 tons in 1972. Ore reserves at yearend were 93 million tons averaging 1.37% nickel and 0.68% copper. Falconbridge's Opemiska Div. mined and milled 1.1 million tons of 2.14% copper ore, which yielded 21,576 tons of copper in concentrate, compared with 1,074,000 tons of 2.3% copper ore in 1972. Ore reserves at yearend were 6.5 million tons with an average grade of 2.42% copper. The Lake Dufault Div. milled 555,000 tons of 3.65% copper to produce 18,890 tons of copper in concentrate. Reserves at yearend were estimated at 2.8 million tons grading 2.8% copper and 3.5% zinc.

Ecstall Mining Ltd., a subsidiary of Texasgulf Inc., mined 3.6 million tons of copper-lead-zinc-silver ore from the Kidd Creek mine near Timmins, Ontario, which yielded 205,600 tons of 25% copper concentrate and 1,300 tons of a copper-silver concentrate. Underground mining commenced in 1973 and by midyear supplied about 2,000 tons of ore per day, replacing an equivalent production from the open pit mine which will be phased out over the next few years. From start of operations in 1966 the mine has produced 25 million tons of ore averaging 1.53% copper. Remaining ore reserves above the 2,800-foot level are estimated at 95 million tons with a copper content somewhat above that previously mined. Deep drilling indicates a substantial tonnage of ore from the 2,800-foot level to well below the 4,000-foot level. A study is being made on the feasibility of constructing a copper smelter and electrolytic refinery with a capacity to produce 100,000 tons of copper per year from Kidd Creek concentrates.

The International Nickel Co. of Canada Ltd. (INCO) mined 19.7 million tons of nickel-copper ore from 16 mines in Ontario and Manitoba compared with 19 million tons from 14 mines in 1972. Improved grade control in mining operations increased the average grade from 1.33% nickel and 0.91% copper to 1.41% nickel and 0.98% copper. Copper deliveries from the Copper Cliff refinery were 163,560 tons with 154,090 tons in 1972. At yearend INCO estimated that proven ore reserves were 399 million tons containing 4.1 million tons of copper.

Noranda Mines Ltd. operated the Horne mine in Quebec and produced 550,000 tons of ore averaging 2.42% copper and 0.145 ounce of gold per ton. The mill treated 480,000 tons of sulfide ore and 130,000 tons of smelter slag which yielded 79,000 and 25,500 tons of copper concentrates, respectively. Sulfide ore reserves at yearend were 500,000 tons grading 2.40% copper, sufficient to maintain production into 1975. The company's Geco mine produced 1.5 million tons of copper-zinc-silver ore averaging 1.70% copper which yielded 22,900 tons of copper in concentrates. Output was curtailed by a 65-day strike which ended June 10 and by a shortage of skilled labor following the strike. Ore reserves at yearend were 29 million tons averaging 1.9% copper, 4.0% zinc, and 1.66 ounces of silver per ton. Noranda's smelter achieved a record high production of 260,000 tons of anode copper from smelting its own and custom concentrates. The Noranda Continuous Smelting Process prototype smelter, designed to treat 800 tons of copper concentrate per day, came onstream in midyear and contributed to the increased production.

Gaspé Copper Mines Ltd. operated the Needle Mountain and Copper Mountain mines and associated mills and smelter near Murdochville, Quebec. The Needle Mountain mine produced 11,400 tons of copper in concentrate from milling 1.2 million tons of ore averaging 1.12% copper. The Copper Mountain mine produced 22,730 tons of copper from milling 5.6 million tons of 0.56% copper ore. A new 22,500-ton-per-day sulfide concentrator started up in July and attained rated capacity in December. Feed to the smelter consisted of 107,400 tons from the Gaspé operation and 99,800 tons from custom sources for production of 49,300 tons of copper in anodes compared with 63,800 tons in 1972. The smelter was shutdown in May and June to install new equipment designed to increase annual capacity by 27,000 tons of blister copper. Startup difficulties hampered production and about 40,000 tons of concentrate were diverted for smelting elsewhere. The new acid plant was completed in December and the oxide ore leach plant is expected to be completed in the second quarter of 1974.

Madeleine Mines, Ltd., operated its copper mine and mill in Quebec, milling 714,000 tons of 1.31% copper ore to produce 8,797 tons of copper in concentrate. The shaft sinking project below the 2,720-foot level was completed and ore hoisting from the 2,400-foot level began in October. Reserves at yearend were 4.2 million tons with an average 1.1% copper content.

Hudson Bay Mining & Smelting Co., Ltd., operated nine mines along the Manitoba-Saskatchewan boundary and milled 1.8 million tons of ore to produce approximately 41,000 tons of copper in concentrates. The Centennial mine, whose discovery was announced in 1970, was under development in 1973. Exploration discovered a new ore body named the Western mine which is scheduled for development in 1974. Total ore reserves at yearend were 18 million tons with an average grade of 3.11% copper, 2.9% zinc, and 0.52 ounce of silver per ton.

Sheritt-Gordon Mines Ltd. operated the Fox, Lynn Lake, and Ruttan Lake mines in Manitoba with a combined output of 35,800 tons of copper in concentrates compared with 20,700 tons in 1972. The increase reflected the new Ruttan Lake copper-zinc open pit operation which commenced production in April. Shortage of skilled personnel and severe winter weather prevented achievement of the 10,000-ton-per-day rated capacity at the mine and mill on a sustained basis. The Lynn Lake nickel-copper mine had high production costs and continued operation is problematical.

The Granduc mine of Granduc Operating Co. north of Stewart, British Columbia, produced 33,500 tons of copper in concentrate from 2.8 million tons of ore grading 1.25% copper. An average 7,540 tons of ore was milled daily, the first year since operations started in 1970 that the design capacity of 7,000 tons was achieved. The sublevel caving system, the principal mining method, and an experimental cut-and-fill method are under analysis to improve efficiency and reduce dilution. Ore reserves, before dilution, are estimated at 33 million tons averaging 1.64% copper.

Similkameen Mining Co. Ltd., a subsidiary of Newmont Mining Corp., operated its mine near Princeton, British Columbia, at rates approaching the design capacity of 15,000 tons of ore per day. Output for the year was 20,600 tons of copper in concentrate from milling 5.4 million tons of 0.45% copper ore. Milling capacity is to be increased to 22,000 tons per day by early 1975 to enable treatment of material grading about 0.25% copper which is now mined and stockpiled. Ore reserves were estimated at 66 million tons averaging 0.53% copper.

Utah International Inc. shipped approximately 48,500 tons of copper in concentrate during the first full year of operation of its Island Copper mine on the northern end of Vancouver Island. The mill design capacity of 33,000 tons per day was exceeded by yearend after initial startup difficulties which required new equipment and modifications. Ore reserves were estimated at 280 million tons containing 0.52% copper and 0.025% molybdenum.

Brenda Mines Ltd. milled 8.9 million tons of ore averaging 0.20% copper and 0.06% molybdenum. This was 6% below that of 1972 and reflected the loss of production during a 40-day strike. Metal recoveries in concentrates were 89% for copper and 82% for molybdenum. An additional 2.8 million tons of low-grade ore was stockpiled for future treatment and 4.5 million tons of waste was stripped from the deposit.

Bethlehem Copper Corp. Ltd. mined a record 6.3 million tons of copper ore from open pit mines at Highland Valley, British Columbia, and produced concentrates containing 33,500 tons of copper. Proven ore reserves available to the present mill, including an extension south of the closed Jersey mine, total 61 million tons of 0.47% copper. Estimated reserves for other ore zones were 286 million tons of copper-molybdenum ore with an average grade of 0.43% copper and 0.017% molybdenum for the J-A ore body, 190 million tons of 0.48% copper for the Lake zone project, and at least 200 million tons of 0.40% copper equivalent for the Maggie ore zone.

Lornex Mining Corporation Ltd. began commercial production in October 1972 at its large, low-grade copper-molybdenum property in the Highland Valley of British Columbia and reached its mill design capacity of 38,000 tons of ore per day in March 1973. Approximately 14 million tons of ore were milled to produce 51,000 tons of copper and 1,740 tons of molybdenum in concentrates. The project was based on ore reserves estimated to be 293 million tons with an average grade of 0.427% copper and 0.014% molybdenum.

Gibralter Mines Ltd. during the first full year of operation at its copper-molybdenum deposit in the Cariboo District of British Columbia milled 15.1 million tons of ore at an average grade of 0.48% copper which yielded a total of 60,900 tons of copper in concentrate. The average daily throughput at the mill was 41,300 tons with a 83.4% copper recovery compared with 39,500 tons and 80.4%, respectively, during 1972.

Craigmont Mines Ltd. in the fiscal year ended October 31, 1973, produced 22,135 tons of copper in concentrate from 1.7 million tons of ore containing 1.38% copper from its mine near Merritt, British Columbia. Production was adversely affected by a strike at the mine, effective September 16 and output for the year was 6% below that of 1972.

Bell Copper Co. completed the first full year of production at its Babine Lake, British Columbia, property. Open pit mining consisted of 2.4 million tons of stripping, 1.0 million tons of low-grade ore stockpiled for future treatment, and 4.1 million tons of ore averaging 0.59% copper for delivery to the concentrator. The concentrator, with a rated capacity of 10,000 tons per day, averaged 11,270 tons and produced 77,800 tons of concentrate containing 20,300 tons of copper with an average 84.1% copper recovery.

Coast Copper Co., Ltd., suspended operations at its Benson Lake mine on northern Vancouver Island in November because of rising costs and unsatisfactory market conditions. During the 10 years of operations, 2.8 million tons of ore were mined to produce 157,000 tons of copper concentrate.

Chile.—Political turmoil associated with the military overthrow of the Allende Government in early September had a major impact on the copper industry in Chile. Problems of management, labor, and supply contributed to curtailment of production at levels far below the capacity that was available as a result of past substantial expansion programs. However, despite the disruptions, production for the year increased 2% to 818,800 tons of copper and by yearend the military junta, which had assumed operation of the Government, succeeded in increasing the annual rate of output to about 1,000,000 tons. If the problems of obtaining necessary foreign credits, replenishment of depleted supplies and equipment, and improvement in the general economy can be surmounted, the goal of achieving an output of approximately 1,000,000 tons may be attained in 1974. The Government indicated that the large copper mines, completely nationalized in 1971, will remain in that status but that the matter of compensation for the expropriated properties was subject to review.

Production from the large mines was as follows: Chuquicamata, 292,500 tons compared with 258,300 tons in 1972; El Teniente, 196,400 tons compared with 209,800 tons; El Salvador, 92,600 tons compared with 91,400 tons; Exótica, 35,100 tons, compared with 34,400 tons; and Andina, 61,900 tons compared with 59,400 tons.

Output at Chuquicamata was limited by a shortage of converter capacity at the smelter, and the developing instability of the pit walls may result in future mining problems. At El Teniente the shortage of water was being corrected and the associated Caletones smelter started up a third furnace in December to increase capacity to about 240,000 tons of copper per year. At Andina there were some initial rock mechanics difficulties in the block-caving mining system but by yearend the production goal of 65,000 tons per year was achieved.

British credit, contingent on insurance coverage, has been approved for construction of a new 220,000-ton-per-year smelter-refinery complex for El Salvador. A feasibility study was in progress for development of the large El Abra porphyry copper deposit about 45 miles northeast of Chuquicamata. Indicated reserves from preliminary drilling were 25 million tons of copper oxide ore underlain by 400 million tons of sulfide ore grading between 0.8% to 1.0% copper. Tentative plans would require a $450 million investment for a 330,000-ton-per-year copper facility to be placed in operation about 1980.

Cyprus.—The Cyprus Island Div. of Cyprus Mines Corp. operated open pit mines at Lefka and Skouriotissa and a pressure-leach plant for reprocessing of mill tailings. Output of copper contained in concentrates and precipitates totaled about 10,300 tons. Milled ore averaged 1.16% copper but reserves of this grade were exhausted during 1973. However, a deposit of lower grade in an adjoining area with reserves estimated to extend the life of the mining operations about 5 years was brought into production.

Indonesia.—Freeport Indonesia Inc., a subsidiary of Freeport Minerals Co., completed development of the 11,500-foot-high Ertsberg copper deposit in West Irian late in 1972 and the mine was considered operational on February 1, 1973. However, there were serious startup problems which required substantial modifications before the design capacity of 250,000 tons of copper concentrate per year was approached by yearend. Output for the year was 125,600 tons of concentrates containing 41,800 tons of copper plus quantities of gold and silver. The ore mined from the enriched upper part of the deposit averaged nearly 3.5% copper compared with the estimated ore reserve of 33 million tons averaging 2.5% copper; also 0.025 ounce gold and 0.265 ounce silver per ton.

Malaysia.—The Mamut Mines Development Co., a consortium of Japanese firms in a joint venture with the Sabah Government and other Malaysian interests, continued development of a copper deposit near Mamut, Sabah. Production is scheduled for early 1975 at a rate of 30,000 tons per year of copper in concentrate.

Mauritania.—Société Minière de Mauritanie (SOMIMA) operated their open pit copper oxide mine at Akjoujt and produced 23,450 tons of copper in concentrates, a 46% increase from 1972 but below the design capacity of about 30,000 tons of copper per year. The oxide ore is concentrated by use of the Torco segregation process.

Mexico.—Asarco Mexicana, S.A., increased the output of blister copper 3%, to 37,100 tons. Cía Mexicana de Cobre, 49% owned by Asarco Mexicana, continued plans toward construction of a 130,000- to 160,000-ton-per-year mine-mill-smelter-refinery complex to exploit a porphyry copper deposit at the La Caridad property near Nacozari in the State of Sonora. The deposit has an estimated ore reserve of 770 million tons grading 0.7% copper and 0.016% molybdenum.

Compañía Minera de Cananea, S.A., operated the Cananea mine and smelter to produce 45,412 tons of blister and refined copper compared with 44,574 tons in 1972. Production was hampered by mechanical problems in the metallurgical facilities. An expansion program in progress is designed to achieve an output of 70,000 tons of copper in 1976.

Panama.—Canadian Javelin Ltd. announced that exploration had disclosed reserves in excess of 2 billion tons of 0.8% copper ore in the Cerro Colorado project in western Panama. Feasibility studies to develop the ore body were in progress with a goal of 400,000 tons of copper production per year, half to be exported as concentrate and the remainder to be split between blister and refined copper. Copper exploration at the Petaquilla concession, about 90 miles east of the Cerro Colorado deposit, will be undertaken by Cobre Panama, a consortium of Japanese companies.

Papua New Guinea.—Bougainville Copper Pty., Ltd., in the first full year of operation of its open pit copper mine on Bougainville Island in the Territory of Papua New Guinea produced approximately 202,000 tons of copper in concentrate. Initial mining was in an enriched, mixed oxide-sulfide portion of the deposit. This large copper development, consisting of an open pit mine, a 90,000-ton-per-day concentrator, two towns, port facilities, a power station, and other ancillary facilities, has an annual rated productive capacity of 162,500 tons of copper in concentrate. The project is based on a porphyry copper deposit calculated to contain approximately

1 billion tons of ore grading 0.48% copper and 0.02 ounce of gold per ton.

Peru.—Production of Southern Peru Copper Corp., in terms of blister copper produced and export of copper in concentrates, was 133,500 tons compared with 148,300 tons in 1972. The reduced output was caused by strikes at both the Toquepala mine and the Ilo smelter. At the smelter 62 production days were lost compared with 43 days in 1972. Cerro Corp. mining-milling-smelting facilities were operated without interruptions and production of copper at its La Oroya smelter increased 10% to a record high 63,127 tons, with 46% of the output from purchased ores.

Progress on Southern Peru's Cuajone project in 1973 included stripping of 37 million tons of mine overburden, driving 24,800 feet of railroad tunnels, and start of construction on the concentrator, town sites, and other facilities. In November, Southern Peru concluded an agreement with a consortium of 29 United States, Canadian, European, and Japanese banks for a $200 million loan to help finance the project. Total cost of the project is estimated to be $550 million, and it is designed to have an annual output of 180,000 tons of blister copper, with production commencing late in 1976.

Compañía Minera del Madrigal, a subsidiary of Homestake Mining Co., processed 153,000 tons of ore at its Madrigal copper-lead-zinc mine in southern Peru during the first full year of operation. Ore grade averaged 1.8% copper, 3.2% lead, and 5.8% zinc. Approximately 26,000 tons of concentrates containing 7,600 tons of copper were produced and shipped to Japan.

Philippines.—Atlas Consolidated Mining & Development Corp., the largest copper producer in the Philippines, operated mines and mills on Cebu Island with a rated capacity of about 66,000 tons of ore per day. An expansion program was in progress to expand capacity to 100,000 tons of ore per day by early 1976. Atlas also planned to construct a 130,000-ton-yer-year smelter-refinery facility costing an estimated $148 million.

Marinduque Mining and Industrial Corp. planned an expansion program at its Sipalay copper mine on Negros Island from 13,500 to 18,000 tons per day of ore with completion scheduled for 1975. Benquet Consolidated began construction of the Tayson mine-mill, 20,000 tons of ore per day, project on Luzon Island with completion expected by the end of 1975. Philex Mining Corp. had an expansion program in progress to increase milling capacity at its operation near Tuba, Benquet Province, from 21,000 to 24,000 tons per day of ore. Western Minolco Corp. had under construction a 15,000-ton-per-day mining-milling project at its Boneng copper project near Baguio, Benquet Province, with initial output anticipated early in 1974.

Rhodesia, Southern.—M.T.D. Mangula Ltd. during the year ending September 30, 1973, produced 19,000 tons of copper in concentrates and precipitates from the Mangula mine about 80 miles northwest of Salisbury. Concentrates containing 16,000 tons of copper were produced from milling 1.3 million tons of sulfide ore and precipitates containing 3,000 tons of copper were produced from treating 440,000 tons of an oxidized ore in the leach plant. Proved sulfide ore reserves were 16.5 million tons averaging 1.27% copper and oxidized ore reserves amounted to 0.6 million tons of 0.72% oxide copper. The Norah and Silverside mines in the first full year of operation produced 2,600 and 2,200 tons of copper in concentrates, respectively. Proven sulfide ore reserves were 1.9 million tons of 1.35% copper at the Norah mine and 440,000 tons of 1.77% copper at the Silverside mine.

Lomagundi Smelting and Mining Ltd. produced 2,700 tons of copper in concentrate from mining and milling 300,000 tons of ore from the Alaska mine. The Shackleton mine yielded 9,700 tons of copper in concentrate from 610,000 tons of 1.68% copper ore. Proved reserves at yearend were 410,000 tons of 1.72% copper at the Alaska mine and 260,000 tons of 1.94% copper at the Shackleton mine. The Shackleton mine had an additional 2.9 million tons of probable ore averaging 1.99% copper.

Gwai River Mines Ltd. produced 1,700 tons of copper in concentrate from mining and milling 190,000 tons of 1.11% copper ore. Proved ore reserves were 260,000 tons of 1.12% copper.

South Africa, Republic of.—O'okiep Copper Co. Ltd. mined and milled 3.3 million tons of ore with an average grade of 1.34% copper which yielded 37,800 tons of blister copper compared with 40,700 tons in 1972. Ore reserves at O'okiep mines at the end of 1973 were estimated at 26.9 million tons averaging 1.58% copper. Exploration in progress indicated additional significant tonnages at deeper levels. An important development was the completion in October of an 80-mile pipeline from the Orange River to correct a water problem which has hampered operations in the past. O'okiep and the Tsumeb Corp. (South-West Africa) commissioned a feasibility study for a joint project to construct a 150,000-ton-per-year copper refinery at some suitable site in southern Africa to treat all of the blister copper production from their respective smelters.

Palabora Mining Co. Ltd. had a smelter production of 105,700 tons of copper, a 4% decline from 1972. Ore milled was 21.1 million tons of 0.57% copper compared with 21.3 million tons of 0.56% copper in 1972. Under the present plant the Palabora pit will have a life of about 16 to 18 years. Alternative plans are being studied to extend the pit life before conversion to underground mining occurs.

Messina (Transvaal) Development Co. mined and milled 1.27 million tons of 1.12% copper ore from its Messina mine which yielded 11,900 tons of copper in concentrate. The tonnage of proved ore reserves at yearend was estimated at 5.9 million tons averaging 1.45% copper.

Africa Triangle Mining Prospecting and Development Co. operated its copper-zinc mine near Prieska in northwestern Cape Province for the first full year following initial output in October 1972. Startup problems are expected to delay reaching the rated capacity of 250,000 tons of ore per month until about mid-1974. The development is based on an ore deposit with proven reserves estimated at 25 million tons grading between 1.5% to 2.0% copper and 3% zinc.

Phelps Dodge Corp. continued drilling and development work at two copper-lead-zinc-silver discoveries (Aggeneys project) about 3.5 miles apart in Cape Province. One deposit has an estimated 33 million tons of ore averaging 0.6% copper, 2.3% lead, 0.5% zinc, and 0.8 ounce of silver per ton that may be minable by open pit methods. In addition, possible reserves minable by underground methods were estimated at 53 million tons averaging 0.8% copper, 2.9% lead, 0.6% zinc, and 1.8 ounces of silver per ton. The other deposit has open pit reserves estimated at 41 million tons of 0.4% copper, 4.5% lead, 2.3% zinc, and 1.7 ounces of silver per ton and possible underground reserves of 28 million tons averaging 0.36% copper, 3.0% lead, 2.2% zinc, and 1.0 ounce of silver per ton.

South-West Africa, Territory of.—The Tsumeb Corp. Ltd. mined 494,000 tons of ore from the Tsumeb mine averaging 4.10% copper, 11.51% lead, and 2.65% zinc. At the Kombat mine 401,000 tons of ore grading 1.67% copper and 1.88% lead was mined. The Matchless mine, near Windhoek, was reopened in February and for 1973 produced 112,000 tons of ore averaging 2.23% copper. Smelter production at Tsumeb was 40,000 tons of blister compared with 28,800 tons in 1972 when feed to the smelter was reduced by a first quarter strike at the Tsumeb mine and a lower copper content in the ore from the Kombat mine. Tsumeb has contracted to custom-smelt additional copper concentrates from South-West Africa and is considering expanding its copper smelter to an annual productive capacity of 79,000 tons. Ore reserves as of the end of 1973 were estimated at 5.5 million tons assaying 4.68% copper, 8.52% lead, and 2.15% zinc for the Tsumeb mine; 1.3 million tons of 1.93% copper and 3.07% lead for the Kombat mine; and 1.0 million tons of 2.37% copper at the Matchless mine.

Oamites Mining Co. Ltd. operated the Oamites mine at capacity and produced 7,713 tons of copper in concentrate from milling 556,000 tons of 1.35% copper ore. A second decline from the surface and other development work accelerated output by 15% during the last quarter of 1973.

Uganda.—Kilembe Mines, Ltd., 70% owned by Falconbridge Nickel Mines Ltd. (Canada), processed 821,000 tons of ore to produce 10,000 tons of blister copper compared with 14,000 tons in 1972. Production was severely restricted in the latter half of the year due to numerous breakdowns in the electric furnace. There was also a scarcity of trained personnel and a supply problem. Ore reserves at yearend in the proven and probable category were estimated to be 5.8 million tons of 1.95% copper.

Zaire.—La Générale des Carrières et des Mines du Zaire (Gécamines), the Government-owned mining company, increased copper output 8% to 508,000 tons. A $250 million expansion program designed to increase production of copper to about 625,000 tons by 1978 was started. Included in the program were the opening of two open pit mines, a new concentrator, a flash smelting plant, and a refinery. An additional expansion is planned to increase capacity to about 660,000 tons copper output by 1980.

A joint Japanese corsortium, Zairian Government concern, Société de Développement Industriel et Minièr du Zaire (SODIMIZA), completed the first full year of operating the Mushoshi mine in Shaba Province. Technical difficulties continued to hamper production which was approximately 30,000 tons of copper contained in concentrates, about 70% of rated capacity. A second mine site at Kinsenda is in preliminary stages of development but a firm schedule for production has not been determined. Exploration was conducted at two other locations—Mokambo and Kilela-Balanda.

Société Minière de Tenke-Fungurume (SMTF), a consortium of companies which includes Amoco Minerals Co., Charter Consolidated Ltd., and Leon Tempelsman & Son Inc., continued feasibility studies on mining copper deposits in their concession area of Shaba Province. The mining-milling-refining complex with the related infrastructure for a production capacity of about 150,000 tons of copper per year is estimated to cost $500 million to $600 million. Production is planned for 1977 to coincide with completion of the Inga-Shaba power transmission line.

Zambia.—In January, Rhodesia closed the Zambia/Rhodesia border to Zambian imports, and the Government of Zambia decided to discontinue the use of routes through Rhodesia for all of its trade. A shift to alternate routes, chiefly an expansion of the road service to Dar es Salaam, Tanzania and Mombasa, Kenya and the rail route to Lobito, Angola caused little disruption in the export of copper. However, the reorganized routes for imports resulted in additional transport costs, delay in arrival of some supplies, and occasional spot shortages.

In August, the President of Zambia announced measures that will have a major impact on the copper mining industry. The provisions included redeeming outstanding external bonds issued in payment for the 51% ownership of the copper mines acquired by Zambia in 1970; making the dividends for minority owners subject to exchange control regulations; making the Minister of Zambia responsible for mines chairman of the two copper mining companies and having the Government appoint their managing directors; and establishing a new marketing company wholly owned by the Government.

Roan Consolidated Mines, Ltd. (RCM), operated the Mufulira, Chibuluma, Chambishi, Kalengwa, and Luanshya mines that produced 307,000 tons of refined copper in the year ended June 30, 1973, compared with 268,000 tons in the previous year. Rehabilitation of the Mufulira mine continued and by yearend was at 80% of the capacity prior to the 1970 cave-in and flooding.

Luanshya production continued to be hampered by poor ground conditions which both slowed the mining rate and increased dilution of the ore. The Baluba extension was brought into production in January but oxide ore from the upper levels caused handling and concentrating difficulties during the year. The Chibuluma mine also experienced mining problems and a lower ore grade. Exploration at Chibuluma West increased ore reserves by over 4 million tons and a new shaft to exploit this area is planned. At the Chambishi mine, a conveyor system from the open pit and additions to the crushing-concentrating plant were completed; also development for underground mining continued.

Nchanga Consolidated Copper Mines Ltd. (NCCM), through the Rokana, Chingola, and Konkola Divs., operated copper mines, a smelter, and a refinery. For the year ending March 31, 1973, output of refined copper increased 10% to 486,000 tons. Production in 1974 is projected to decline to about 455,000 tons as a consequence of production disruptions during implementation of an expansion program designed to achieve an annual rate of 550,000 tons by mid-1975. At the Rokana Div. construction of the oxide concentrator and development of the Mindola North open pit to provide feed to the concentrator were proceeding toward the scheduled yearend 1973 completion. The introduction of periodic current reversal in the refinery tankhouse to increase capacity was delayed due to technical problems but was expected to be operational late in 1973. At the Chingola Div. the Nchanga pit was extended to the east, the Chingola "C" pit was brought into production, and the "C" shaft deepening was completed. The leach precipitation plant operation was curtailed early in 1973 owing to a shortage of acid.

Initial output of the solvent extraction-ion exchange process plant began in August 1973 and was expected to be fully operational by mid-1974. The level of production, shaft sinking, and other underground developments continued at a satisfactory rate at Konkola despite difficult ground and water problems.

TECHNOLOGY

Articles published on copper resources included results of research on geologic comparisons for most producing porphyry copper deposits of South America;[2] a statistical analysis of physical dimensions and economic characteristics of 58 commercial porphyry deposits to provide assistance in exploration planning, engineering studies, and financial analysis;[3] and an evaluation, in terms of geologic parameters, of the apparent variation in copper, molybdenum, and gold in porphyry copper deposits.[4] Research was conducted on the phase relationships of the copper-antimony sulfide mineral, tetrahedrite.[5]

A study was made to evaluate the potential supply of copper from identified domestic resources that could be produced at various copper prices and the rates of return on the required capital investment.[6] Other mineral extraction studies included an estimate of production costs to mine a group of vein copper deposits in Alaska,[7] the influence of rock fracture patterns on the cavability of a copper ore,[8] a simulated in situ leaching technology for a deeply buried sulfide deposit,[9] and a description of the recovery of byproducts related to copper production.[10] Chemical and physical property analysis of tailings and mine waste at a copper mine were determined in a planned program to improve stabilization and revegetation of tailing dikes.[11]

Research related to copper pyrometallurgy included a study of oxidizing conditions during copper smelting to predict the optimum quantity of converter slag to be recycled to the reverberatory furnaces[12] and use of pure oxygen in an experimental furnace to produce blister copper and a concentrated SO_2 gas from copper sulfide concentrate.[13] The Smelter Control Research Association (SCRA) concluded from information obtained in its pilot plant studies and a review of commercial prototype systems in other industries that, at its present state of development, wet-limestone scrubbing is not a reliable process for removal of sulfur dioxide from copper reverberatory furnace gas. Accordingly, SCRA has decided to devote its future efforts to other processes that offer promise of greater reliability and better sulfur recoveries.

Research was conducted on recovering copper from scrap by preferential melting in molten salt baths,[14] by leaching in a cupric ammonium carbonate solution,[15] and by the use of cryogenic techniques.[16]

Tests, on an industrial scale, demonstrated the feasibility of using high-current densities of at least 480 amperes per square

meter in electrowinning of copper.[17] An article reviewed the factors involved in the choices of using various reducing agents such as wood, ammonia, natural gas, and propane for production of fire-refined copper.[18]

Research on the use of hydrometallurgy to recover copper was reported in papers describing the mechanism of copper cementation on iron in an aqueous solution;[19] flash roasting of cement copper as part of a postulated process for refining cement copper by oxidation roasting, acid leaching, and electrowinning;[20] dissolution of copper sulfide minerals in an aqueous chlorine solution;[21] sulfation roasting of chalcopyrite concentrates, followed by a water or dilute acid leach;[22] dissociation of chalcopyrite into simple sulfides by heating with elemental sulfur to enhance selective leaching of the copper;[23] and use of a substituted quinoline reagent to extract copper from leach solutions of copper-nickel concentrates.[24]

Table 2.—Copper produced from domestic ores, by source

(Thousand short tons)

Year	Mine	Smelter	Refinery
1969	1,545	1,547	1,469
1970	1,720	1,605	1,521
1971	1,522	1,471	1,411
1972	1,665	1,649	1,680
1973	1,718	1,705	1,698

Table 3.—Copper ore and recoverable copper produced, by mining method

(Percent)

Year	Open pit		Underground	
	Ore	Copper [1]	Ore	Copper [2]
1969	88	84	12	16
1970	89	84	11	16
1971	88	82	12	18
1972	85	80	15	20
1973	89	78	11	22

[1] Includes copper from dump leaching.
[2] Includes copper from in-place leaching.

Table 4.—Mine production of recoverable copper in the United States, by month

(Short tons)

Month	1972	1973
January	131,306	136,641
February	140,106	135,050
March	147,458	151,336
April	140,714	149,893
May	144,623	151,598
June	137,566	146,998
July	123,176	129,706
August	141,714	141,785
September	139,410	139,878
October	140,640	153,299
November	136,597	140,844
December	141,530	140,912
Total	1,664,840	1,717,940

Table 5.—Mine production of recoverable copper in the United States, by State

(Short tons)

State	1969	1970	1971	1972	1973
Arizona	801,363	917,918	820,171	908,612	927,271
California	1,129	2,308	515	598	369
Colorado	3,598	3,749	3,938	3,944	3,123
Idaho	3,332	3,612	3,776	2,942	3,625
Maine	1,320	2,703	2,510	1,220	1,107
Michigan	75,226	67,543	56,005	67,260	72,221
Missouri	12,664	12,134	8,445	11,509	10,273
Montana	103,314	120,412	88,581	123,110	132,466
Nevada	104,924	106,688	96,928	101,119	93,702
New Mexico	119,956	166,278	157,419	168,034	204,742
Pennsylvania	3,382	2,539	3,349	2,611	1,845
Tennessee	15,353	15,535	13,916	11,310	8,500
Utah	296,699	295,738	263,451	259,507	256,589
Other States [1]	2,319	2,500	3,179	3,064	2,107
Total	1,544,579	1,719,657	1,522,183	1,664,840	1,717,940

[1] Includes Oklahoma, Oregon, and Washington.

Table 6.—Twenty-five leading copper-producing mines in the United States in 1973, in order of output

Rank	Mine	County and State	Operator	Source of copper
1	Utah Copper	Salt Lake, Utah	Kennecott Copper Corp	Copper ore, copper precipitates, gold-silver ore.
2	San Manuel	Pinal, Ariz	Magma Copper Co	Copper ore.
3	Morenci	Greenlee, Ariz	Phelps Dodge Corp	Copper ore and copper precipitates.
4	Berkeley Pit	Silver Bow, Mont	The Anaconda Company	Do.
5	Tyrone	Grant, N. Mex	Phelps Dodge Corp	Do.
6	Ray Pit	Pinal, Ariz	Kennecott Copper Corp	Do.
7	Pima	Pima, Ariz	Pima Mining Co	Copper ore.
8	White Pine	Ontonagon, Mich	White Pine Copper Co	Do.
9	Sierrita	Pima, Ariz	Duval Sierrita Corp	Do.
10	Chino	Grant, N. Mex	Kennecott Copper Corp	Copper ore and copper precipitates.
11	Twin Buttes	Pima, Ariz	The Anaconda Company	Copper ore.
12	New Cornelia	do	Phelps Dodge Corp	Copper, gold-silver ores.
13	Inspiration	Gila, Ariz	Inspiration Consolidated Copper Co.	Copper ore and copper precipitates.
14	Mission	Pima, Ariz	American Smelting and Refining Co.	Copper ore.
15	Ruth Pit	White Pine, Nev	Kennecott Copper Corp	Do.
16	Yerington	Lyon, Nev	The Anaconda Company	Copper ore and copper precipitates.
17	Silver Bell	Pima, Ariz	American Smelting and Refining Co.	Do.
18	Butte Hill	Silver Bow, Mont	The Anaconda Company	Do.
19	Copper Cities	Gila, Ariz	Cities Service Co	Do.
20	Mineral Park	Mohave, Ariz	Duval Corp	Do.
21	Magma	Pinal, Ariz	Magma Copper Co	Copper ore.
22	Copper Queen	Cochise, Ariz	Phelps Dodge Corp	Do.
23	Continental	Grant, N. Mex	UV Industries, Inc	Do.
24	Bagdad	Yavapai, Ariz	Bagdad Copper Corp	Do.
25	Esperanza	Pima, Ariz	Duval Corp	Copper ore and copper precipitates.

Table 7.—Mine production of recoverable copper in 1973, by method of treatment

Method of treatment	Ore treated (thousand short tons)	Recoverable copper: Thousand pounds	Recoverable copper: Percent yield	Remarks
Copper ore:				
By concentration	272,688	2,893,091	0.53	See table 9.
By smelting	337	9,433	1.40	See table 10.
By leaching	16,973	[1] 165,788	.49	See table 11.
Total	289,998	3,068,312	.53	
Dump and in-place leaching	--	318,045	--	See table 11.
Miscellaneous from cleanup, tailings, and noncopper ores	--	49,523	--	--
Total	XX	3,435,880	XX	--

XX Not applicable.
[1] Includes 70,115,475 pounds of electrowon copper.

Table 8.—Copper ore shipped directly to smelters or concentrated in the United States, by State in 1973, with copper, gold, and silver content in terms of recoverable metal

State	Ore shipped or concentrated (thousand short tons)	Copper: Thousand pounds	Copper: Percent	Gold (troy ounces)	Silver (troy ounces)	Value of gold and silver per ton of ore
Arizona	164,194	1,601,927	0.49	101,923	7,130,066	$0.17
Colorado	1	53	4.53	26	15,568	42.37
Idaho	93	2,208	1.18	105	39,086	1.19
Michigan	8,884	144,442	.81	--	850,273	.24
Montana	18,977	220,314	.58	21,031	3,723,828	.61
Nevada	14,485	136,673	.47	39,354	463,634	.35
New Mexico	26,414	359,294	.68	13,245	974,838	.14
Tennessee [1]	1,323	17,000	.64	68	73,104	.15
Utah	38,504	416,414	.54	303,614	2,619,504	.95
Other States	150	4,199	1.41	--	20,561	.35
Total	273,025	2,902,524	.53	479,366	15,910,462	.32

[1] Copper-zinc ore.

Table 9.—Copper ore concentrated[1] in the United States, by State in 1973, with content in terms of recoverable copper

State	Ore concentrated (thousand short tons)	Recoverable copper content: Thousand pounds	Recoverable copper content: Percent
Arizona	163,915	1,593,082	0.49
Idaho	93	2,178	1.17
Michigan	8,884	144,442	.81
Montana	18,974	219,862	.58
Nevada	14,485	136,673	.47
New Mexico	26,359	359,252	.68
Tennessee [2]	1,323	17,000	.64
Utah	38,504	416,405	.54
Other States	151	4,197	1.39
Total	272,688	2,893,091	.53

[1] Includes following methods of concentration: "Dual process" (leaching followed by concentration); "LPF" (leach-precipitation-flotation); and froth flotation.
[2] Copper-zinc ore.

Table 10.—Copper ore shipped directly to smelters in the United States, by State in 1973, with content in terms of recoverable copper

State	Ore shipped to smelters: Short tons	Recoverable copper content: Pounds	Recoverable copper content: Percent
Arizona	278,955	8,844,059	1.59
Colorado	588	53,331	4.54
Idaho	524	30,381	2.90
Montana	2,843	452,335	7.96
New Mexico	54,500	41,975	[1] .04
Utah	31	9,348	15.08
Other States	46	1,219	1.32
Total	337,487	9,432,648	1.40

[1] Primarily smelter fluxing material.

Table 11.—Copper precipitates (from dump or in-place leaching) shipped directly to smelters and copper ore leached (heap, vat, or tank) in the United States, by State in 1973, with content in terms of recoverable copper

State	Precipitates shipped (short tons)	Recoverable copper content (pounds)	Ore leached (short tons)	Recoverable copper content (pounds)	Percent
Arizona	80,511	119,057,841	9,411,507	[1] 126,650,951	0.67
Montana	28,977	44,338,703	--	--	--
Nevada	12,601	17,757,186	7,243,449	31,791,952	.22
New Mexico	31,311	48,952,027	--	--	--
Utah	54,479	87,865,914	318,481	7,345,116	1.15
Other States	58	73,315	--	--	--
Total	207,937	318,044,986	16,973,437	165,788,019	.49

[1] Includes 70,115,475 pounds of electrowon copper.

Table 12.—Copper ore smelted and copper ore concentrated in the United States, and average yield in copper, gold, and silver

Year	Smelting ore		Concentrating ore		Total				
	Thousand short tons	Yield in copper, percent	Thousand short tons [1] [2]	Yield in copper, percent	Thousand short tons [1]	Yield in copper, percent	Yield per ton in gold, ounce	Yield per ton in silver, ounce	Value per ton in gold and silver
1969	485	2.17	204,704	0.62	223,752	0.60	0.0028	0.065	0.23
1970	542	3.51	235,586	.60	257,729	.61	.0023	.067	.20
1971	453	1.76	222,121	.56	242,656	.55	.0022	.059	.18
1972	484	1.68	248,663	.55	266,831	.55	.0019	.059	.21
1973	337	1.40	272,688	.53	289,998	.53	.0018	.058	.32

[1] Includes some ore classed as copper-zinc and minor amount of tailings (1971 excludes tailings).
[2] Excludes tank or vat and heap leaching. (See tables 7 and 11).

Table 13.—Copper produced by primary smelters in the United States

(Short tons)

Year	Domestic	Foreign	Secondary	Total
1969	1,547,496	37,995	77,329	1,662,820
1970	1,605,265	36,073	78,897	1,720,235
1971	1,470,815	29,181	66,333	1,566,329
1972	1,649,130	41,263	69,017	1,759,410
1973	1,705,065	38,898	77,815	1,821,778

Table 14.—Primary and secondary copper produced by primary refineries in the United States

(Short tons)

	1969	1970	1971	1972	1973
PRIMARY					
From domestic ores, etc.:[1]					
Electrolytic	1,296,749	1,359,751	1,274,084	1,520,943	1,536,819
Lake	76,417	66,091	57,218	70,025	78,179
Casting	95,723	95,341	79,221	89,444	83,339
Total	1,468,889	1,521,183	1,410,523	1,680,412	1,698,337
From foreign ores, etc.:[1]					
Electrolytic	225,714	215,088	167,213	160,781	159,786
Casting and best select	48,212	28,823	14,046	32,040	10,365
Total refinery production of primary copper	1,742,815	1,765,094	1,591,782	1,873,233	1,868,488
SECONDARY					
Electrolytic[2]	410,749	433,394	323,913	341,581	377,523
Casting	2,094	17,623	18,599	16,667	14,290
Total secondary	412,843	451,017	342,512	358,248	391,813
Grand total	2,155,658	2,216,111	1,934,294	2,231,481	2,260,301

[1] The separation of refined copper into metal of domestic and foreign origin is only approximate, as accurate separation is not possible at this stage of processing.
[2] Includes copper reported from foreign scrap.

Table 15.—Copper cast in forms at primary refineries in the United States

	1972		1973	
	Thousand short tons	Percent	Thousand short tons	Percent
Billets	118	5	133	6
Cakes	124	6	147	6
Cathodes	552	24	584	26
Ingots and ingot bars	218	10	196	9

Other forms	38	2	21	1
Total	2,231	100	2,260	100

Table 16.—Production, shipments, and stocks of copper sulfate

(Short tons)

Year	Production		Shipments	Stocks Dec. 31[1]
	Quantity	Copper content		
1969	50,568	12,642	49,556	4,248
1970	45,352	11,338	40,324	8,812
1971	34,648	8,662	36,852	5,936
1972	38,052	9,513	37,964	5,828
1973	43,360	10,840	44,092	4,580

[1] Some small quantities are purchased and used by producing companies, so that the figures given do not balance exactly.

Table 17.—Byproduct sulfuric acid[1] (100% basis) produced in the United States

(Short tons)

Year	Copper plants[2]	Lead and zinc plants[3]	Total
1969	685,775	1,086,938	1,772,713
1970	747,784	1,090,817	1,838,601
1971	803,284	971,946	1,775,230
1972	1,010,614	859,103	1,869,717
1973	1,088,322	[4] 966,128	2,054,450

[1] Includes acid from foreign materials.
[2] Excludes acid made from pyrites concentrates in Arizona, Montana, Tennessee, and Utah.
[3] Excludes acid made from native sulfur.
[4] Includes 146,591 tons produced at lead plants.

Table 18.—Secondary copper produced in the United States

(Short tons)

	1969	1970	1971	1972	1973
Copper recovered as unalloyed copper	514,593	521,137	429,095	447,409	484,623
Copper recovered in alloys [1]	860,900	726,465	771,025	853,564	827,682
Total secondary copper	1,375,493	1,247,602	1,200,120	1,300,973	1,312,305
Source:

Nickel silver and cupronickel	6,231	32,876	28,790	4,105	32,895	4,340
Low brass	7,242	29,090	28,181	1,238	29,419	4,809
Aluminum bronze	319	1,946	1,441	522	1,963	188
Low-grade scrap and residues [3]	37,983	332,703	144,851	194,199	339,050	31,636
Total	121,036	1,861,967	1,174,175	688,954	1,863,129	128,772

[1] Brass-mill stocks include home scrap; purchased scrap consumption assumed equal to receipts, so lines in brass-mill and grand total sections do not balance.
[2] Of the totals shown, chemical plants reported the following: Unalloyed copper scrap, 681 tons new and 2,857 tons old.
[3] Includes refinery brass.

Table 24.—Consumption of copper and brass materials in the United States by principal consuming group

(Short tons)

Year and item	Primary producers	Brass mills	Wire mills	Foundries, chemical plants, and miscellaneous users	Secondary smelters	Total
1972:						
Copper scrap	533,729	746,764	--	71,699	429,082	1,781,274
Refined copper [1]	--	667,218	1,526,296	35,400	9,953	2,238,867
Brass ingot	--	16,691	--	[2]284,581	--	301,272
Slab zinc	--	179,781	--	2,613	9,435	191,829
Miscellaneous	--	--	--	200	10,016	10,216
1973:						
Copper scrap	603,830	776,714	--	80,462	402,123	1,863,129
Refined copper [1]	--	714,438	1,672,255	39,760	10,595	2,437,048
Brass ingot	--	14,473	--	[2]285,531	--	300,004

e Estimate. p Preliminary. r Revised.

1 Data presented represent copper content (recoverable where indicated) of ore mined wherever possible. If such data are not available, the nonduplicative total copper content of ores, concentrates, matte, metal and/or other copper-bearing products measured at the least stage of processing for which data are available has been used.

2 Recoverable.

3 Copper content of concentrate produced.

4 Revised to zero.

5 Corporación Minera de Bolivia (COMIBOL) production plus exports by medium and small mines.

6 Partly estimated, partly calculated on the basis of data furnished by Companhia Brasileira de Cobre.

7 Smelter production.

8 Includes copper content of cupriferous pyrites.

9 Excludes an unreported quantity of copper in iron pyrites which may or may not be recovered.

10 Year ending September 30 of that stated.

11 Data are compiled from operating company reports of Tsumeb Corp. Ltd. and General Mining and Finance Corp. Ltd. for Klein Aub Loper Maatskappy Ltd.'s mine near Rehoboth. Data for 1971 are for fiscal year ending June 30, 1971; data for 1972 are a summation of company figures for calendar year 1972 for Tsumeb Corp. Ltd. and for fiscal year ending June 30, 1972, for General Mining and Finance Corp.; data for 1973 are a summation of company figures for calendar year 1973 for Tsumeb Corp. Ltd. and for fiscal year ending June 30, 1973, for General Mining and Finance Corp. Output of Tsumeb Corp. Ltd. for the period July 1, 1971, through December 31, 1971, was 12,813 short tons.

12 Copper content of matte produced.

13 Year beginning March 21 of that stated.

14 Copper content of concentrate. Copper content of run of mine production was as follows in short tons: 1971—133,411; 1972—125,248; 1973—103,871.

e Estimate. p Preliminary. r Revised.

[1] Unless otherwise noted, data presented for each country represent primary copper metal output, whether produced by thermal or electrowinning. To the extent possible, refined copper produced from imported blister or electrolytic anode copper has been excluded.

[2] Copper content of impure bars and electrolytic copper.

[3] Smelter output of domestic and foreign ores, exclusive of that produced from scrap. Production from domestic ores only was as follows: 1971—1,470,815; 1972—1,649,130; and 1973—1,705,065.

[4] Includes secondary copper (production from scrap). Partly estimated, partly calculated on the basis of data furnished by Companhia Brasileira de Cobre.

[5] Data are the nonduplicative sum of: (1) the copper content of blister copper production for sale as such; (2) the copper content of blister produced for refining in Chile at the Ventanas refinery; and (3) the copper content of fire refined and electrolytic copper (including copper obtained by electrowinning) excluding electrolytic output of the Ventanas refinery.

[6] Series revised from refined to smelter basis.

[7] Belgium reports a large output of refined copper, but this is produced largely from imported blister; domestic smelter production is reported output of blister copper from ores.

[8] Reported Norwegian copper output is derived in part from copper-nickel matte imported from Canada, and reported Canadian smelter production may also include this material. Norwegian smelter output from domestic ores was as follows (approximately) in tons: 1971—6,700; 1972—7,500; and 1973—7,500.

[9] Refined output.

[10] Year ending September 30 of that stated.

[11] Year ending June 30 of that stated.

[12] Includes secondary.

[13] Year beginning March 21 of that stated.

Diatomite

By Benjamin Petkof [1]

Domestic diatomite production remained strong in 1973, increasing 6% in quantity compared with 1972 data; value declined 4%. The United States retained its position as a major world producer of processed diatomite. U.S. exports of processed diatomite to nations throughout the world increased in both quantity and value over those of 1972.

[1] Physical scientist, Division of Nonmetallic Minerals—Mineral Supply.

DOMESTIC PRODUCTION

All U.S. production was derived from open pit operations in the western States of California, Nevada, Washington, and Oregon. California remained the largest producing State. Arizona reported no production for the year.

During 1973, 8 companies, with a total of 10 operations, actively mined and prepared diatomite to supply the demand of various industrial end users. The following companies supplied the bulk of the processed diatomite production: Johns-Manville Products Corp., with a quarry and processing plant near Lompoc, Calif.; Grefco, Inc., with operations near Lompoc, Calif., and Mina, Nev.; Eagle-Picher Industries, Inc., with facilities near Sparks and Lovelock, Nev.; and Kenite Corp., Division of Whitco Chemical Corp., with an operation near Quincy, Wash. The remaining producers were Basalt Rock Co. Inc., near Napa, Calif.; Airox, Inc., near Santa Maria, Calif.; Fernley Division, Cyprus Mines Corp., near Fernley, Nev.; and A. M. Matlock, near Christmas Valley, Oreg.

Average value per ton	$60.96	$54.63	$64.25	$65.19	$59.26

CONSUMPTION AND USES

All major end uses reported significant gains in consumption. However, the quantities consumed for abrasives and industrial fillers declined. Filtration remained the major end use of diatomite and required slightly in excess of three-fifths of domestic demand. Abrasives, industrial fillers and lightweight aggregates accounted for almost one-fourth of demand. The remainder was consumed for miscellaneous end uses such as a pozzolan, soil conditioner, inert carrier, and coating agent.

Table 2.—Domestic consumption of diatomite, by principal use

(Percent of total consumption)

Use	1969	1970	1971	1972	1973
Filtration	58	58	59	58	61
Fillers	20	19	W	W	W
Insulation	4	4	3	4	4
Miscellaneous	18	19	38	38	35

W Withheld to avoid disclosing individual company confidential data; included with "Miscellaneous."

PRICES

The weighted average value per ton of diatomite, for all end uses in 1973, declined 9% from that of 1972. This decline was caused by price decreases for major end uses such as filtration, industrial fillers, and miscellaneous uses. Uses such as insulation and lightweight aggregate showed price increases. The price of abrasive material varied only slightly.

Table 3.—Average annual value per ton of diatomite, by use

Use	1972	1973
Filtration	$73.08	$65.18
Insulation	47.02	50.39
Abrasives	125.27	125.46
Fillers	69.37	62.01
Lightweight aggregate	43.07	45.02
Miscellaneous	39.01	36.99
Weighted average	65.19	59.26

FOREIGN TRADE

Exports of prepared diatomite increased 20% in quantity and 15% in value over those of 1972. Exports represented 29% of domestic production. Major countries of destination were Canada 27%, Japan 10%, Federal Republic of Germany 8%, the United Kingdom 8%, Australia 5%, Brazil 4%, Republic of South Africa 4%, Italy 3%, and Spain 3%. The remainder was shipped to many other developed and less-developed countries of the world for various end uses. The average value of exported material was $81.64 per ton. Imports of diatomite totaled 164 tons, valued at $23,635. The bulk of the imports were received from Mexico; the remainder, from the United Kingdom.

Table 4.—U.S. exports of diatomite

(Thousand short tons and thousand dollars)

1972	148	12,603
1973	178	14,532

WORLD REVIEW

Overall world diatomite production, which varied only slightly from that of 1972, continued to meet the strong demand of the consuming nations.

Kenya.—Diatomite is a small but significant fraction of the mineral output of the country. Large diatomite deposits are found in the area of the Rift Valley. African Diatomite Industries, Ltd., a subsidiary of the Government of Kenya's Industrial and Commercial Development Corp., mines diatomite from the Kariandusi deposit near Gilgil. This operation provides all of the country's diatomite output, which is marketed by the Johns-Manville Products Corp. for use as filter aid, insulation, and industrial filler.

TECHNOLOGY

A recent Government publication reviewed the resource position of diatomite and concluded that domestic and other world diatomite resources are adequate for the foreseeable future. It was also indicated that the requirement for diatomite near markets and for particular uses encouraged the development of new sources. The paper also proposed that studies relating the geologic setting and history of diatomite to the occurrence and properties of the host rock would assist in the location of undiscovered deposits.[2]

Feldspar, Nepheline Syenite, and Aplite

By J. Robert Wells [1]

Domestic production of crude feldspar, after several years of indecisive ups and downs, rose sharply in 1973 and exceeded the corresponding figure for the preceding year by 8% and that for 1969, the record year heretofore, by 5%. Coinciding imports of more Canadian nepheline syenite than ever before, supplemented by near-record production of domestic aplite, attested that 1973 domestic consumption of feldspathic materials was at the highest level in history.

The feldspar industry was faced in 1973 with a number of unaccustomed problems, some already full-grown and some only recently emerging. It was evident in 1972 that new legislative programs relating to air, water, and noise pollution, land-use restrictions, and mined-land rehabilitation were becoming major incremental factors in determining feldspar production costs. Price increases passed on to purchasers early in 1973 were a predictable consequence, and in a related development, land-use and/or environmental impediments were reported to have been decisive in the September 1973 termination of Del Monte Properties' long-established feldspar operations in California. Many major producers depend heavily upon heat from natural gas for the drying of flotation cake feldspar and also use substantial quantities of fuel oil both for that purpose and as a necessary reagent in the flotation process. Potential deficits in the supply of those hydrocarbons looming toward yearend 1973 gave rise to deep concern and uncertainty that carried over into 1974. Indirect consequences from such shortages—possible curtailment of the production of energy-intensive (and feldspar consuming) glass and ceramics—could be foreseen as further unsettling influences in the industry's future.

Legislation and Government Programs.—According to provisions of the Tax Re-

form Act of 1969, which continued in force throughout 1973, the depletion rate allowed on feldspar production (both domestic and foreign operations) was 14%.

FELDSPAR

DOMESTIC PRODUCTION

Crude Feldspar.—In 1973, crude feldspar was mined in eight States (one fewer than in 1972), with North Carolina the leader in tonnage, followed in descending order by California, Connecticut, Georgia, South Dakota, Arizona, Wyoming, and Colorado. The combined outputs of the first four States named amounted to almost 94% of the U.S. total. South Carolina, after 14 years of inclusion in the list of feldspar-producing States, dropped out when Spartan Minerals Co. discontinued extraction of that mineral from fines generated in the crushing of Spartanburg County granite, switching instead to treatment of ore shipped from Bessemer City, N.C.

[1] Feldspar content.
[2] Data may not add to totals shown because of independent rounding.

Ground Feldspar.—Most of the feldspar used in glassmaking is ground no finer than 20 mesh, but feldspar to be used in ceramics and filler applications is usually pulverized to minus 200 mesh or finer. Nine companies, operating 14 plants in 8 States, ground feldspar for market in 1973, supplying ground material (total tonnage 1% more than in 1972) for shipment to destinations in at least 24 States, Puerto Rico, Canada, and Mexico. Listed in descending order of output tonnages, North Carolina had six grinding mills, while Connecticut, Georgia, and South Carolina had one each. These were the leaders in ground feldspar production and jointly accounted for 90% of the 1973 total. South Dakota with two mills, followed by California, Arizona, and Wyoming with one each, were the four States making up the remaining 10%. Colorado was the only crude feldspar-producing State in 1973 in which no grinding mill was operated.

CONSUMPTION AND USES

Crude Feldspar.—In 1973 there was no significant consumption of feldspar in the raw, unprocessed state in which it is taken from the mine; the majority of users acquired their supplies already ground and sized either by the primary producers or by merchant grinders. Some manufacturers of pottery, soaps, and enamels, however, continued their customary practice of purchasing crude feldspar for grinding to their preferred specifications in their own mills. The Bureau of Mines canvass of producers and merchant grinders does not provide information concerning the end-use distribution of the material handled in this way.

Ground Feldspar.—The 1973 pattern of ground feldspar consumption in the United States was not strikingly different from that of the preceding year, but the confidential status of some of the data precludes a detailed comparison. The 1973 end-use distribution showed that 53% of the total was consumed for glassmaking and 47% went for pottery, enamel, and miscellaneous uses compared with 1972 data showing 50% for glass, 44% for pottery, and 6% for enamel and other uses.

STOCKS

From a comparison of 1973 data on domestic production and sales of feldspar, it was estimated that U.S. producers had 283,000 short tons of feldspar (crude, ground, or in process) on hand on December 31, 1973.

PRICES

Engineering and Mining Journal, June through December 1973, quoted the following prices for feldspar, per short ton, f.o.b. mine or mill, carload lots, bulk, depending on grade (generally $1 per ton higher than the respective quotations of the previous year):

North Carolina:	
20 mesh, flotation	$13.00
40 mesh, flotation	14.00- 21.00
200 mesh, flotation	22.50- 23.50
325 mesh, flotation	27.00
Georgia:	
40 mesh, granular	21.00
200 mesh	25.50
325 mesh	26.50
Connecticut:	
20 mesh, granular	16.50
200 mesh	23.50
325 mesh	24.50

Feldspar prices were quoted by Industrial Minerals (London), December 1973, as follows (converted from pounds sterling per long ton to dollars per short ton):

Ceramic grade, powder, 200 mesh, bagged, ex-store	$41–$49
Lump, imported, c.i.f. main European port	21– 27

FOREIGN TRADE

In 1973, U.S. exports classified as feldspar, leucite, nepheline, and nepheline syenite (but presumably all or mostly feldspar) amounted to 9,554 short tons valued at $466,118, almost double the tonnage reported in 1972 and just over two and one-half times the value. Chief recipients of the exported material were Canada, 67%, and Mexico, 23%; the remaining 10% was shared among nine other countries. In marked contrast to rising exports of feldspar, U.S. imports of the mineral fell off notably in 1972 and dropped even more sharply in 1973, bringing this statistic to the lowest point since it was first separately recorded 50 years ago. In addition to feldspar and nepheline syenite (table

6), U.S. imports in 1973 included 850 tons of material, probably feldspathic in nature, that was classified as "Natural mineral fluxes, crushed, ground, or pulverized" and valued at $81,535.

The tariff schedule in force throughout 1973 provided for a 3½% ad valorem duty on ground feldspar; imports of crude feldspar were admitted duty free.

Table 4.—U.S. imports for consumption of feldspar

Country	1972		1973

WORLD REVIEW

An agency of the British Government issued a report tabulating world production and international trade statistics for many metals and industrial minerals for the years 1967 through 1971.[2] Based on that compilation, a rough ranking of countries according to apparent consumption of feldspar (exports subtracted from production plus imports) shows that in 1971 the United States was in first place, followed in descending order by West Germany, U.S.S.R., France, Italy, and the United Kingdom. Taking into account imported nepheline syenite and domestically produced aplite, U.S. apparent consumption of feldspathic materials in 1971 was more than 1 million tons and approximately three times the corresponding figure for second-place West Germany.

Canada.—Commercial production of feldspar in Canada was terminated, or at least suspended, in 1972, not because of any lack of exploitable mineral but as the result of a combination of unfavorable economic factors. Feldspar demand in Canada is not great—probably not over 8,000 tons per year—and the requirement most likely can be met with little difficulty by substitution of domestically produced nepheline syenite supplemented by limited quantities of imported mineral. In an article published in an industrial magazine, the Director of the Quebec Geological Exploration Service presented reasons, however, for concluding that a modestly profitable revival of the Canadian feldspar industry might be achieved with a limited expenditure of capital.[3]

Finland.—As is true in the United States, flotation concentrate now comprises the predominant part of Finland's feldspar production; hand-cobbed material, at one time the only form in which the mineral was recovered, amounted to less than 7% of Finland's 1972 total.

France.—French exports of feldspar outweighed imports in 1971, but only by a small margin; apparent consumption of the mineral thus came to slightly less than the figure of 212,000 tons reported for domestic production in that year.

Germany, West.—Feldspar consumption in West Germany in 1971 amounted to 477,000 tons, of which about four-fifths was supplied by domestic production and one-fifth was imported.

Italy.—Italy was a net exporter of feldspar in 1971 even though domestic consumption of the mineral accounted for almost 94% of the domestic production.

Kenya.—Although potentially workable deposits of feldspar are plentifully distributed throughout Kenya, the nonexistence of an export market, combined with the meagerness of internal demand (mostly for the manufacture of glass, ceramics, and scouring powder), acts to limit production to the efforts of a few small-scale operators. Government policy is now being aimed toward encouraging expanded development of this and other mineral resources by both national and foreign investors.

Rhodesia, Southern.—A consignment of material, shipped to the United States in July 1973 and listed as feldspar originating in the Republic of South Africa, was found to be petalite ore that had been mined in Southern Rhodesia. The importing firm, a large U.S. producer of alumi-

[e] Estimate. [p] Preliminary. [r] Revised. NA Not available.

[1] In addition to the countries listed, Brazil, People's Republic of China, Czechoslovakia, Romania and Territory of South-West Africa produce feldspar, but available information is inadequate to make reliable estimates of output.

[2] Described in source as lump feldspar; does not include nepheline syenite as follows, in short tons: 1971—176,470; 1972—[e] 176,000; 1973—[e] 220,000.

[3] Includes pegmatite.

[4] Revised to zero.

[5] Data are for years ending June 30 of that stated.

[6] In addition the following quantities of aplite and saba were produced: Aplite: 1971—448,162; 1972—501,648; 1973—547,665; saba: 1971—6,005; 1972—1,336; 1973—NA.

num, was indicted on a charge of violating import sanctions against Southern Rhodesia.[4]

United Kingdom.—In 1972 the United Kingdom produced 58,000 tons of "china stone" and also imported 131,000 tons of feldspar (from Norway, Finland, Sweden, and Portugal) as well as 57,000 tons of nepheline syenite (Norway and Canada), compared with the figures of 69,000 tons, 131,000 tons, and 70,000 tons, respectively, in the preceding year. Exports of feldspathic materials in 1971 amounted to less than 2% of the total quantity involved, indicating that the United Kingdom's net annual consumption approaches a quarter of a million tons or about one-fourth of the corresponding figure for the United States.

TECHNOLOGY

The manufacturing of glass, especially container glass, has been for many years the largest outlet for feldspar in the United States. The modern technology of glassmaking was summarized in an article, part of which was devoted to the functions of the various raw materials involved and

[4] Industrial Minerals (London). "Feldspar" for Aluminum Production. No. 74, November 1973, p. 31.

dealt specifically with feldspar and nepheline syenite.[5]

Two other articles provided brief reviews of the advancing technology of container glass manufacturing as well as some forecast of the effects upon that industry that can be expected from the rapidly changing energy and environmental situations.[6] A paper presented at the 1973 annual meeting of the Society of Mining Engineers (Chicago, February 25–March 1, 1973) discussed factors to be considered in compensating for changes in glass furnace feed materials including feldspar, nepheline syenite, aplite, and feldspathic sands.[7]

A number of notes in industrial journals dealt with investigations and developments that, by leading to the evolution of stronger and lighter glass containers, may at least indirectly affect the feldspar industry.[8]

Bureau of Mines participation in the recycling of waste glass during 1973 included research on the production of concrete blocks, roof slabs, and curtain walls based on a novel type of lightweight aggregate in which the principal ingredient was waste glass. Bureau scientists were invited to present a paper on an allied subject before the Society of Mining Engineers at the annual meeting in February 1974 at Dallas, Tex.[9] Financial considerations involved in reutilization schemes for salvaged waste glass were explored in a Bureau publication.[10]

The Glass Container Manufacturers Institute announced the start of construction at Franklin, Ohio, of the world's first waste glass reclamation plant. The facility, designed to subject an entering stream of municipal solid waste to the most modern techniques of treatment by high-intensity magnetism, air currents, screening, and optical sorting, will separate 4 tons of glass per day in a form suitable for remelting to make new containers.[11] In Denver, Colo., a picnic pavillion for a city park was constructed with so-called ecological panels formed by mixing rubble from demolished buildings with a large proportion of salvaged container glass. This novel building material, in a variety of textures and color combinations, was described as being attractive in appearance and highly resistant to weathering while providing an advantageous outlet for what otherwise would have been a burdensome accumulation of rubbish.[12]

Research carried out in England demonstrated the suitability of cement reinforced with coarsely crushed waste glass for such components as drain pipes, sewer linings, bridge decking, and marine hulls.[13] In a related application, recycled glass was crushed and then blended with a liquid plastic monomer into a mixture that was cured in molds to form lengths of sewer pipe. This sewer pipe was stronger than the conventional product and potentially competitive with it on a technical and economic basis. It was not found necessary to color sort the waste glass nor to free it from accompanying labels and metal cap rings.[14] The Midwest Research Institute, continuing an examination of various potentially profitable utilizations of waste glass in the building industry, undertook a study of ceramic foams and tile produced by firing mixtures of salvaged glass with dried residues from animal feedlots.[15]

Glasphalt is the name given to a street paving mixture composed of asphalt and crushed glass first introduced several years ago. Additional research on this material at the University of Missouri at Rolla

showed that it was permissible as well as economical to use for this purpose waste glass that had not been subjected to a complete and costly separation from foreign solids. It was found that an acceptable and serviceable pavement could be prepared by mixing asphalt with the glass-rich fraction of the original residue even when that fraction still contained as much as 17% of a miscellany of metals, plastics, stones, bones, and ceramics.[16]

The fluxing action of feldspar or other feldspathic materials was the basis for the enamels, frits, and glazes developed by the ceramists of ancient Egypt and continues to be of fundamental importance in most of those products in use today. The intricate technology of glazes and of their utilization were among the principles considered in a newly published book.[17] A radically new technique is being developed in the field of porcelain enamels, and an article was published discussing problems involved in applications of that innovation.[18]

The first white-burning body for ceramic wall tile on record as produced in the United States was of the classic clay-flint-feldspar type and most likely was compounded entirely from imported materials. Cornwall stone from England, the feldspathic material first used here in tile bodies, eventually yielded its place to Vermont feldspar, which was superseded in turn by feldspar from the large deposits of North Carolina. In more recent formulations, the tendency has been to replace at least part of the feldspar in this application by talc, pyrophyllite, or wollastonite. The changing technology of ceramic tile body mixtures was reviewed in a journal article.[19]

One of the less publicized applications for feldspar is in the production of porcelain for artificial dentures. Porcelain acceptable for this specialized service must combine to an extraordinary degree the properties of pleasing appearance and physical strength with the ability to resist chipping and abrasion. Porcelain used in dentures must also remain chemically stable for many years under conditions of frequent or prolonged contact with a wide variety of solid substances and liquids, some of which are quite vigorous solvents. A journal article described the sophisticated techniques by which one manufacturer turns out natural-appearing porcelain teeth from carefully chosen raw materials including a select grade of potash feldspar from Wyoming.[20]

A number of research papers were published relating to various types of feldspar and summarizing investigations that may provide bases for advances in the practical utilization of those minerals.[21]

NEPHELINE SYENITE

Nepheline syenite, a rock of igneous origin with a texture similar to that of granite, consists essentially of a mixture of nephelite with varying proportions of the alkali feldspars. Nepheline syenite found thus far in the United States has been of a quality suitable only for use as crushed stone, but an immense deposit in Canada (Blue Mountain, Ontario) has provided the United States with an abundance of imported material of higher grade. The Canadian material serves advantageously in glassmaking as an alumina-bearing ingredient in furnace feeds, in the whiteware industry either as a body component or as a fluxing agent in glazes, and increasingly in recent years as a filler for plastics, latex, paints, and paper. U.S. imports of Canadian nepheline syenite, which were first reported in the mid-1930's, have increased in all but a few of the years since, and now appear to be rising on a steepening curve. Starting at 10,000 tons per year (tpy) or less in 1936, the figure climbed to 100,000 tpy by 1955, to 200,000 tpy by 1964, to 300,000 tpy by 1968, and to 400,000 tpy by 1971. Further substantial increases in 1972 and 1973 have brought the half-million-ton-per-year mark well within sight. Under the present U.S. tariff schedule, imports of nepheline syenite, crude or ground, are admitted duty free.

The price range quoted for nepheline syenite in Ceramic Industry Magazine, January 1974, was from $10.25 to $23.40 per ton. Price ranges for this commodity listed in Industrial Minerals (London), December 1973, were equivalent (with a minor degree of uncertainty because of the floating sterling/dollar exchange rate) to the following:

Canadian, bagged ex-store:	
Glass grade, 30-mesh, 10-ton lots	$41–$47
Ceramic grade, 200 or 325-mesh, small lots	57– 65
Norwegian, ex-store:	
Glass grade, 32-mesh (Tyler), bulk	30– 33
Ceramic grade, 325-mesh (Tyler), bagged	43– 49

A British publication tabulated available data on world production, exports, and imports of nepheline syenite, 1967 through 1971.[22]

Table 6.—U.S. imports for consumption of nepheline syenite

Year	Crude		Ground	
	Quantity (short tons)	Value (thousands)	Quantity (short tons)	Value (thousands)
1971	636	$12	413,862	$4,912
1972	3,027	43	456,406	5,681
1973	258	4	473,838	6,022

APLITE

Aplite is a granitic rock with a high proportion of albite (soda feldspar) or plagioclase (lime-soda feldspar), either of which makes it potentially useful as a raw material for the manufacture of container glass. To become acceptable for that purpose, however, the mined material usually must be processed to eliminate most of the iron-bearing substances it commonly contains. Aplite of glassmaking quality was produced in the United States in 1973 from two open pit mines in central Virginia. The Feldspar Corp. mined aplite ore near Montpelier, Hanover County, and removed iron from it by an electrostatic process. Sobin Chemicals, Inc., an affiliate of International Minerals & Chemical Corp., operated a mine near Piney River, Nelson County, and subjected the crude aplite to a high-intensity magnetic separation to eliminate iron minerals. Tonnage and total value of the 1973 output, respectively 5% and 61% above the corresponding figures for 1972, were the highest on record.

Specific annual data on aplite production, sales, and value have not been released for publication since 1962. The output for 1962 amounted to 140,000 short tons, valued at $0.9 million. The price range for aplite quoted in Ceramic Industry Magazine, January 1974, was from $12.70 to $13.00 per ton, compared with $6.30 to $12.40 per ton quoted in January 1973.

[22] Page 400 of workcited in footnote 2.

Ferroalloys

By Norman A. Matthews [1]

The overall structure of the domestic ferroalloy industry did not change basically during 1973. The abnormally high demand for ferroalloys resulted in capacity production throughout most of the year; nevertheless shortages persisted for ferrosilicon and some manganese alloys. Two older plants, scheduled to close because of emission control equipment costs, were purchased by new owners and granted another year to install emission controls. Most producers had made provisions for emission control facilities and expenditures for such capital improvements continued at a high level.

Ferroalloy exports nearly doubled as world demand exceeded capacity. Imports continued to increase substantially, but the rate of imports decreased somewhat late in the year as imports from Western Europe and Japan declined.

Prices increased generally in the first quarter and then remained essentially static during the balance of the year under phase IV price controls. Dual level (two-tier) pricing developed in some silicon alloys as the smaller producers were permitted price increases justified by cost increases.

Detailed information concerning utilization of individual elements in various alloy products can be found in the chromium, manganese, silicon, molybdenum, nickel, tungsten, and vanadium chapters.

DOMESTIC PRODUCTION

The number of ferroalloy producers increased by 1 to 26 during the year as the Steubenville, Ohio, plant of Foote Mineral Co. was sold to Satra Corp. at yearend. Subsequently Satra Corp. announced that a large furnace would be added to produce charge chromium and that an overall plant modernization would be carried out to incorporate emission control facilities. At yearend Hanna Mining Co. purchased the Wenatchee, Wash., plant of Foote Mineral Co. which Foote had scheduled for closing. Of the 26 producing companies, 6 produced ferrophosphorus in 9 plants as a byproduct of phosphorus production. Reynolds Metals Co. announced the expansion of its captive silicon metal facility at Sheffield, Ala.; a second furnace will raise capacity from 7,000 to 17,000 tons per year with startup scheduled in 1975.

Steel, cast iron, and aluminum production were at record levels in 1973 and demand for ferroalloys increased proportionately. The ferroalloy industry operated at capacity, but because of extraordinary demand and a decline in imports of some categories of alloys, shortages of manganese and silicon alloys persisted throughout the last 6 to 8 months of the year. Substantial shipments of ferromanganese from the Government stockpile (65,000 tons) minimized the seriousness of the manganese shortage. Price controls under phase IV exaggerated the shortage of some alloys as producers concentrated on higher value alloys. An example was the continued shortage of 50% ferrosilicon grade traditionally utilized by foundries. Overall shipments of manganese, silicon, and chromium alloys increased by 12%, 16%, and 34%, respectively, compared with 1972 figures and producers inventories were reduced to low levels at yearend. Since no new ferroalloy capacity is scheduled until late 1974, the shortage of manganese and silicon alloys will probably persist as long as steel and foundry industries continue operating at capacity.

Several new ferroalloy facilities were planned or under construction. Northwest Alloys, Inc., a subsidiary of the Aluminum Company of America, completed plans for a magnesium and silicon alloy facility at Addy, Wash. but initial construction was delayed by environmental considerations. The Magnétherm process, developed in France, will be utilized. It involves the reduction of calcined dolomite by ferrosilicon in the presence of alumina under reduced pressure. The volatilized magnesium collects in an auxiliary chamber. The silicon alloy will be produced conventionally in a submerged arc furnace. Startup will be delayed until 1976.

Foote Mineral Co. announced the installation of a new 20-megawatt electric furnace, auxiliary air pollution control equipment, and modernization throughout its Graham, W. Va., plant. The new furnace, principally for silicon alloys, and modernization were estimated to cost $6.9 million with completion scheduled in mid-year 1975. Ohio Ferro-Alloys Corp. scheduled, for 1975, the installation of a modern 46-megavolt-ampere (MVA) furnace for silicon alloy production at its Philo, Ohio, plant. The furnace and a modularly constructed baghouse, designed by Ohio Ferro-Alloys, are estimated to cost $4.0 million. Union Carbide Corp. planned a new furnace for silicon alloys at its Alloy, W. Va., plant. Startup was anticipated for late 1974.

Tenn-Tex Alloy Corp. of Houston, Tex., announced plans for the installation of a second ferromanganese furnace of 35 MVA transformer capacity that will increase plant capacity 50,000 to 60,000 tons per year. Operation of the new furnace is scheduled for 1975. The National Metallurgical Division of Kawecki Berylco Industries announced a capital expansion program to cost $5.5 million which will double the productive capacity of its silicon plant at Springfield, Oreg. Construction was to begin early in 1974 and was to be completed in the first half of 1975.

Table 3.—Producers of ferroalloys in the United States in 1973

[2] Includes zirconium alloys, ferrosilicon magnesium, calcium silicon, and miscellaneous ferroalloys.

CONSUMPTION AND USES

Record raw steel production of 150.8 million tons and cast iron production of 18.1 million tons consumed record quantities of ferromanganese and silicon alloys. Aluminum castings production at a level of 1.0 million tons in 1973 also required a record quantity of silicon metal for alloying. Reported consumption of manganese alloys was 1,173,458 tons, an increase of 15% compared with 1972 totals whereas the steel and cast iron production increase in volume was 13% compared with 1972 production. Reported total silicon alloy consumption was 1,164,723 tons, an increase of 24% compared with that of 1972, a higher increase than would be expected from the 12% increase in cast iron and 7% increase in aluminum castings production. The additional requirements may well reflect a higher percentage of silicon killed steel production in the wrought steel total associated with the continuous casting process. Consumption of ferrotitanium and other forms of titanium for alloying and deoxidizing of steel almost doubled as formable high-strength steels became more widely accepted for automotive applications.

Chromium, molybdenum, and nickel consumption for stainless and alloy steels and other special alloys increased proportionately to the record production of these alloys in 1973. Chromium consumption increased 32% compared with that of 1972, molybdenum as ferromolybdenum increased 17%, and nickel as ferronickel increased 59%.

Consumption data for the alloying elements listed in table 5 understate total consumption of several elements since these data cover only the ferroalloy forms. The alloying elements nickel, molybdenum, tungsten, and vanadium may be added to metallic melts in any one of several forms. The practice varies as relative economics change and technological progress permits greater latitude in the choice of form of the alloying addition.

[1] Includes unspecified uses.
[2] Includes other chromium ferroalloys and chromium metal.
[3] Includes calcium molybdate but not molybdenum oxide.
[4] Includes melting base self-reducing tungsten.
[5] Includes other vanadium-carbon-iron ferroalloys.

The following tabulation gives the proportion of the alloying elements added in the ferroalloy state in relation to other product forms. It refers only to metallic products, omitting chemicals and other end uses.

Element	Added as ferroalloy [1] (Percent)	Added in other forms (Percent)
Molybdenum	28	72
Nickel	20	80
Tungsten	28	72
Vanadium	90	10

[1] Modified as in notes to table 5.

STOCKS

Producers stocks decreased substantially at yearend compared with stocks at the end of 1972 as might be expected in a period of great demand and scarcity in some alloys. Yearend silicon, manganese, and chromium alloy stocks decreased 68%, 50%, and 56% respectively, compared with stocks at the end of 1972. Consumer stocks of chromium and silicon alloys showed a modest increase whereas manganese alloys showed a slight decline. Consumer stocks of the alloying elements molybdenum, nickel, and vanadium showed the greatest percentage increase amounting to 39%, 95%, and 82% respectively.

[6] Includes calcium molybdate.
[7] Includes melting base self-reducing tungsten.

PRICES

Prices of manganese alloys were raised in April from $190 to $200 per gross ton for 78% high carbon ferromanganese; from 19.5 to 20 cents per pound for medium carbon ferromanganese; from 30.5 to 32.5 cents per pound for low-carbon ferromanganese. Prices of ferromanganese-silicon and other more specialized types were increased similarly.

Prices on several important chromium alloys were increased 1 to 2 cents per pound contained in March although prices were not published generally. Phase IV price controls then applied throughout the balance of the year and little additional price movement resulted. At yearend charge chromium (64% to 67%) was quoted at 20 cents and low-carbon ferrochromium (0.05 maximum carbon) at 33 cents per pound contained Cr.

Ferrosilicon price movement began in March and was reflected in an increase in published prices in April, for example, 50% ferrosilicon advanced from 15 to 16.5 cents per pound and 75% ferrosilicon advanced from 18.5 to 20 cents per pound. Two-tier pricing under Phase IV controls persisted during much of the second half of the year with the range of quoted prices embracing the earlier and later price ranges. Prices of magnesium ferrosilicon, ferrocolumbium, ferrotungsten, ferrovanadium, and ferromolybdenum remained unchanged during the year.

Costs of production increased substantially during the year due to: (1) power cost increases; (2) increased prices for scrap iron and other supplies; and (3) increased labor costs. However, Phase IV price controls prevented general price increases.

FOREIGN TRADE

Quantity of U.S. exports of ferroalloys increased substantially in 1973 compared with 1972 as demand by the steel industries of the world increased. Canada was the largest overall customer for U.S. ferroalloy exports, involving principally ferromanganese, ferrochromium, and ferrovanadium. Japan was second with respect to value of U.S. ferroalloys purchased, principally for ferromolybdenum. The overall tonnage exported increased from 44,641 tons in 1972 to 83,669 tons in 1973 and was valued at $33.8 million.

In general, imports continued to increase during 1973, although the rate of imports declined later in the year as Japan and some Western European countries reduced exports to the U.S. Overall tonnage of imports increased 26% compared with that of 1972 and value increased 39% compared with that of 1972. The largest increases were in the tonnage grades: (1) High-carbon ferromanganese; (2) high-carbon ferrochromium; (3) 75% ferrosilicon; and (4) ferrosilicon-manganese. Imports of nickel in ferronickel doubled, and the value of ferronickel imported was the largest of any single alloy at $70.5 million.

The Republic of South Africa was the dominant ferroalloy exporter to the U.S. market.

In chromium alloys, shipments to the United States ranked by value were from: (1) Republic of South Africa; (2) Southern Rhodesia; (3) Japan; and (4) Sweden. In ferromanganese, receipts were from: (1) Republic of South Africa; (2) France; (3) India; and (4) Japan. The value of silicon alloys imported more than doubled and was dominated by receipts from: (1) Norway; (2) France; (3) Canada; and (4) Yugoslavia. Spain, Yugoslavia and Greece became significant factors for the first time in ferroalloy exports to the United States; exports of ferromanganese from Spain will probably decline as new steelmaking capacity goes into operation there in 1975–76. The miscellaneous category of imports (n.e.c.) was dominated by ferrocolumbium imports from Brazil.

On May 4, 1973, the domestic ferroalloy industry petitioned the U.S. Tariff Commission for relief from imported alloy competition. The Ferroalloys Association, a 12-member group representing U.S. producers, submitted its request for higher duties, import quotas, or both, under Section 301(A) of the Trade Expansion Act of 1962. However, a few weeks later the association requested its bid be withdrawn with the unexpected steel and alloy demand that developed quickly. The commission agreed, cancelling scheduled hearings without prejudice to potential future actions.

Free world prices of ferroalloys increased substantially during 1973 whereas, except for silicon alloys, prices in the United States were under government control. By yearend considerable free market volume was diverted to countries other than the United States where higher prices and lower transportation costs prevailed.

WORLD REVIEW

Table 9 lists ferroalloy production in the world by country and furnace type for the years 1971 through 1973 from the most reliable sources. Production increased substantially overall as the steel industries of the world operated at capacity levels. The International Iron and Steel Institute reported steel production increased 10% in 1973 compared with 1972 production for the 24 countries reporting. The tabulated ferroalloy production figures show a more modest increase of 6.5% but, as in the United States, producers' inventories were reduced substantially at yearend so that shipment figures, if available, would correlate more closely with the increase in steel production.

New ferroalloy projects announced during 1973 are listed in the paragraphs that follow:

Australia.—Garrick Agnew Pty., Ltd., announced plans for a vanadium oxide facility at Wundowie near Perth involving roasting, leaching, and pelletizing to produce 3,500 tons per year of vanadium pentoxide. British Oxygen Ltd. and Mitsui Co. Ltd. each have a 20% interest in the project. Operation is projected late in 1975 or early in 1976.

Canada.—Copperfields Mining Corp., Ltd., and Quebec Mining Exploration Co. announced financing had been arranged for mining and concentrating facilities at Chicoutimi, Quebec, to process 1,500 tons per day of ore containing 0.76% Cb_2O_5. Ore reserves are estimated at 40,000,000 tons and startup is planned in 1975. The columbium oxide product is to be marketed in Europe, Japan, and the United States.

Greece.—The Japanese companies Tekkosha Co., Ltd., and Mitsubishi Chemical Industries, Ltd., signed an agreement with the Government of Greece to construct a $17 million, 12,000-ton-per-year plant to produce manganese dioxide electrolytically for dry cell batteries. The plant, scheduled for operation in mid-1975, will use manganese ore from the Chalkidiki area and can be expanded to a total capacity of 36,000 tons per year at a later date.

Iceland.—Union Carbide Corp. announced an agreement with the Government of Iceland for the construction of a $28 million ferrosilicon plant at Hvalfjördhar on the west coast. The plant, to be financed 65% by the Government of Iceland and 35% by Union Carbide, will have a capacity of 50,000 tons per year of 75% ferrosilicon and is expected to be operational by early 1976. Power will be provided from a new hydroelectric powerplant being constructed at Sigalda.

India.—The Industrial Development Corporation of Orissa, Orissa Province, announced a new ferrovanadium project. The facility, estimated to cost $15.6 million, involves mining, concentrating, and reduction facilities to provide 480 tons per year of ferrovanadium. Startup date has not been announced but the project is included in a 5-year plan beginning in 1974.

Mexico.—Cia. Minera Autlan S.A. de C.V. of Mexico has placed a contract for $15.5 million with Japan Metals and Chemicals Co., Ltd. for the first phase of a ferromanganese plant at Tamos near the Gulf port of Tampico. The first furnace with a 42 MVA transformer and a capacity of 50,000 tons per year is to be in operation late in 1975. Installation of additional furnaces is planned in stages to bring total capacity to 100,000 tons per year by 1977 and 200,000 tons per year by 1985.

South Africa, Republic of.—Johannesburg Consolidated Investment Co. Ltd. (JCI), African Metals Corp. Ltd. and Middleburg Steel and Alloys, Ltd., announced plans to raise ferrochromium capacity in the Republic to 500,000 tons per year. One specific project, utilizing the prereduced pellet process pioneered by Showa Denko K.K. of Japan was announced by JCI involving a 120,000-ton-per-year charge chromium plant in the Transvaal. The specific plant location had not been selected.

Union Carbide Corporation and General Mining and Finance Co. Ltd., announced a $38 million high-carbon ferrochromium project, located in eastern Transvaal, with a capacity of 120,000 tons per year and to be operational late in 1976. General Mining and Finance will provide ore supply, Union Carbide will design and operate the plant and the two companies will share marketing of the product.

e Estimate. p Preliminary. r Revised.

[1] In addition to the countries listed, the People's Republic of China and North Korea are known to produce ferroalloys but output of these materials are included in estimates for pig iron in the iron and steel chapter, therefore, they have been omitted here to avoid duplication. East Germany also is known to produce ferroalloys but it is not clear from source publications whether output has been included together with that of pig iron in the iron and steel chapter. Also, Colombia, Greece, Peru, Venezuela, and Southern Rhodesia may produce ferroalloys and output, if any, is also included with pig iron in the iron and steel chapter.

[2] Blast furnace ferroalloy production by Australia, Canada, and the United States included under electric furnace output; that of Czechoslovakia is included under pig iron.

[3] Blast furnace ferromanganese, ferrosilicon and spiegeleisen only; other blast furnace ferroalloys are included with pig iron production in the iron and steel chapter.

[4] Includes electric furnace ferroalloys if any are produced.

[5] In addition to the countries listed, the United Kingdom and the U.S.S.R. are known to have produced electric furnace ferroalloys and Romania may have produced some electric furnace ferroalloys, but output is not reported and no basis for estimation is available.

[6] May include small quantities of blast furnace ferroalloys, if any are produced.

[7] Year ended November 30 of year stated.

TECHNOLOGY

The stainless steel industry continued to adapt post-furnace refining techniques to finishing of stainless steel heats thereby reducing costs and increasing productivity. The argon-oxygen-decarburization (A.O.D.) and vacuum-oxygen-decarburization (V.O.D.) processes have furthered the trend towards greater utilization of high-carbon ferrochromium, minimizing the need for the low-carbon varieties. The ratio of high-carbon to low-carbon tonnage produced in 1973 approached 4 to 1, in contrast to the 3 to 1 ratio in 1972.

A modification of the A.O.D. process has been developed by Creusot-Loire and Uddeholm and applied by Uddeholm in the production of more than 5,000 tons of Extra Low Carbon 18% Cr-8% Ni stainless steel at the Degersfors plant of Uddeholm. Steam is basically substituted for argon during much of the treatment cycle. The sequence involves: (1) oxygen blowing to remove carbon until a critical temperature is reached; (2) oxygen and steam injection in varying ratios; and (3) argon and nitrogen injection to remove the hydrogen absorbed by the molten metal. Steam dissociates into oxygen and hydrogen and the hydrogen acts to reduce the partial pressure of carbon monoxide, continuing the carbon reduction with minimum oxidation of chromium. Dissociation of steam involving an endothermic reaction provides control of maximum temperatures and an overall recovery of over 98% of the chromium.

Inclusion shape control is essential to improve transverse ductility and raise toughness shelf energy values in high-strength low alloy steels for pipelines and automotive applications requiring high formability. Small additions of rare-earth metals, in conjunction with minimum sulfur levels and effective degassing prior to final deoxidation, are becoming increasingly necessary to meet the more stringent specifications. Rare-earth additions are made, generally during mold teeming, in the silicide form or as mischmetal.

The Japanese ferroalloy producer, Nippon Denko Co., Ltd., has been issued British Patent 1,317,523 covering a method of sintering chromite ore fines. A damp mixture of ore, coke, and forsterite or serpentine is sintered on a grate-type machine, cooled, and optionally broken. The low-melting magnesium silicate minerals provide a vitrified agglomerate with good strength. With power and capital investment costs increasing substantially, it is anticipated that prior treatment of ores, including partial reduction, will become more widespread as a means of increasing smelting furnace productivity and reducing unit power consumption.

Fluorspar

By H. B. Wood [1]

World supplies of fluorspar were ample during 1973. At the end of the year, major consuming countries such as the United States, Japan, and some European countries had adequate supplies. The 1973 output by the United States and the world showed no appreciable change from 1972. However, from the 1971 production (U.S. 272,000 tons and world 5,007,390 tons), which represented a 14-year peak, U.S. production in 1973 decreased about 9% and world production about 1%.

In 1973 most of the large producing companies were not operating at full capacity. Consequently, any emergency or uniform price increase could readily increase production. Some of the companies that discovered large deposits during the 1968–72 boom exploration years decided to continue development operations and bring these mines into production in anticipation of an increase in world consumption.

Overall, U.S. fluorspar consumption has not shown any significant increase since 1969. During this past 5-year period consumption of acid-grade fluorspar by hydrofluoric acid manufacturers decreased 8% to 664,000 tons, consumption of metallurgical-grade fluorspar by the iron and steel industry increased 11% to 649,400 tons, and ceramic-grade fluorspar consumption by the glass and ceramic industries decreased 30% to 18,000 tons.

The trend in consumption of fluorspar in primary aluminum and magnesium production is more difficult to determine. The direct use, shown in table 5, is only a small percentage of the total. Most of the fluorspar used by the aluminum industry is first converted to hydrofluoric acid and then to aluminum fluoride and sodium aluminum fluoride (synthetic cryolite) for use as an electroflux in the aluminum potlines melt to produce aluminum.

Total fluorspar demand by the aluminum industry decreased during 1972 and increased slightly in 1973, as aluminum companies reduced fluorspar consumption per ton of aluminum. Pressure from the Environmental Protection Agency (EPA) and economic changes instituted by the companies helped speed up recycling programs. The major EPA required improvements will probably be completed by the end of 1974.

The 1973, reported consumption of 1,351,700 tons, almost equaled the 1972 reported consumption of 1,352,100 tons. The U.S. output provided 18% of reported U.S. consumption and 17% of apparent consumption. The apparent consumption, which includes U.S. shipments, plus imports, plus a decrease in consumers' stockpiles, minus exports, equaled 1,508,800 tons and exceeded reported consumption by about 157,100 tons.

U.S. shipments of finished fluorspar were about the same as in 1972, totaling about 248,600 tons. Production was almost equally divided between acid-grade fluorspar (acid-spar) and metallurgical-grade fluorspar (met-spar). Producers' and consumers' stockpiles combined were reduced over 56,800 tons, indicating that both producers and consumers realized the availability of adequate supplies.

During the year, eight mines and four flotation concentrating plants were closed down, and one flotation plant in Illinois was placed on a part-time operating basis. These closings could ultimately reduce U.S. output by 80,000 to 90,000 tons in 1974, if production from new or reopened mines or increased production from currently operating mines does not materialize.

[1] Geologist, Division of Nonmetallic Minerals—Mineral Supply.

The available supply of fluosilicic acid, that was converted to aluminum fluoride and sodium aluminum fluoride, continued to increase slightly. Construction of new phosphoric acid plants with built in circuits to recover $H_2S_6F_6$ probably will increase the supply in the near future.

r Revised.

Legislation and Government Programs.—On April 16, 1973, the Office of Management and Budget submitted an "omnibus bill" (OMB No. 5) to the U.S. Congress which proposed disposing of many of the minerals in government stockpiles. Under section 2 of the bill, 890,000 tons of acid-grade fluorspar and 252,800 tons of metallurgical-grade fluorspar, now in government stock, were recommended for sale by the General Services Administration (GSA).

On May 14, 1973, GSA held a meeting with fluorspar producers and consumers in Washington, D.C., and presented a plan to dispose of 1,142,800 tons of fluorspar over a 2-year period. Representatives of the fluorspar industry objected to the proposed plan. Thereupon, GSA agreed to take into consideration industry recommendations for selling the material over a longer period of time (10 to 15 years) and to present a revised disposal plan to industry before implementation. As of the yearend, no action had been taken on OMB No. 5.

DOMESTIC PRODUCTION

U.S. shipments of finished fluorspar totaled 248,601 tons, of which 47% was acid grade and 53% metallurgical grade. Although overall output showed little change from 1972, acid-spar production decreased 13% whereas met-spar increased 13%. Mine stocks of finished fluorspar were down 6,600 tons, leaving less than 8,700 tons in stock at yearend. Mine production, material beneficiated, and material recovered were all down appreciably.

The fluorspar industry started to slow down production before the year was half over. At the start of 1973, there were 23 mines and 7 froth flotation plants in operation; during the year 8 mines and 4 flotation plants closed down. These included the Pennwalt Corp. Calvert City Chemical Co. plant in Kentucky, the Ozark-Mahoning Co. Cowdrey (Northgate) plant in Colorado, the Allied Chemical Corp. Boulder City plant in Colorado, and the Tonto Mining and Milling Co., Inc. Tonto Basin (Pumpkin Center) plant in Arizona. The Minerva Oil Co. flotation unit of the Crystal mill in Illinois was placed on an intermittent operating schedule. Three mines were closed down in Kentucky, three in Colorado and two in Arizona. Although Roberts Mining Co. shipped ore from its stockpiles near Darby, Mont., their open pit mine has not operated since 1971. Cumulatively, over 140,000 tons of flotation milling capacity was lost; but during the past 2 years the output from these plants has only averaged about 90,000 tons annually, mainly because the mines could not supply the mills.

On the favorable side of the output picture, the Knight mine and heavy-media plant went onstream in Illinois, the Lafayette mine was reactivated in Kentucky, and Cerro Spar Corp. near Salem, Ky. continued to develop the Babb-Barnes mine and to build a flotation plant with a potential output capacity of 60,000 tons annually. No new mine openings were reported from the West. Reactivation of Minerva's Crystal mill and new production from the Babb-Barnes mine and others may add another 40,000 tons by the end of 1974.

In Illinois, exploration and development drilling continued on the Hicks Dome property in Hardin County. Some exploration and reevaluation studies were performed. Minerva Oil is now a steady producer of barite, for use in drilling muds and paint pigments, as a byproduct from the Minerva No. 1 mine. Income from this byproduct barite, allows a reduction in mill input grade to about 28% CaF_2. In Kentucky, Cerro Spar Corp., continued developing the Babb-Barnes mine while building the new flotation plant. Also in Kentucky near Salem, Minerva Oil Co. reactivated the old Wheatcroft shaft at the Lafayette mine, and Don Grahm, an independent operator, started trucking crude ore from the Midway mine to the Babb-Barnes mill. In Tennessee, exploration drilling by U.S. Borax and Chemical Corp.

and Amoco Minerals Co. continued on a fluorspar prospect in the Sweetwater barite district near Sweetwater in Monroe County.

In Colorado extensive prospecting, drifting, and drilling were performed on numerous prospects, but no firm production announcements were made on new prospects. The Industrial Chemicals Division of Allied Chemical Corp. sealed the shafts of the Burlington and Yellow Bird mines near Jamestown and placed the Boulder flotation plant on standby. In Salida, Colo., Allied continued exploration drilling on the westerly vein of the old Colorado-American mine in the Browns Canyon fluorspar belt. Also, Kalium Chemical Co. in 1972 and 1973 performed exploration drilling on its claims which cover the northern extension of the Browns Canyon fluorite fault-contact zone. Ozark-Mahoning Co. in the Northgate Area at the end of 1973 placed its three fluorspar mines and the Cowdrey flotation and briquetting plant on a standby basis. In the Jamestown Area Inexco Inc. continued active exploration drifting at its Escanaba mine. In Idaho NL Industries, Inc. completed exploration drilling, drifting, and ore testing on the Bayhorse fluorspar mine near Challis and was completing feasibility and environmental impact studies. In Montana Roberts Mining Co. continued to ship met-spar from its stockpile.

In Nevada J. Irving Crowell continued to produce met-spar from the Daisy mine and ship ore to Monolith Cement Co. at Tehachapi, Calif., and to Geneva Works of U.S. Steel Co. near Salt Lake City, Utah.

In New Mexico at least four companies were actively drilling and increasing the reserves at some prospects, but no production announcements were made. Mining and Milling Co. of America continued construction of its flotation plant located 32 miles south of Hachita, on the east side of the Hachet Mountains. Reportedly, both their heavy-media and flotation plants were onstream at the end of the year. The most extensive exploration was performed by Allied Chemical, on the Lyda-K. prospect, located southeast of Truth or Consequences, and by the joint venture of Midwest Oil and Perry-Knox and Kaufman on the Salado prospect, located southwest of Truth or Consequences.

Near Rome in Malheur County, Oregon, Aluminum Company of America (Alcoa) did some more exploration drilling and sampling, mainly for assessment purposes, on its Crooked Creek claims.

In Texas exploration drilling was performed on a fluorspar prospect in the Eagle Mountains near Van Horn in Hudspeth County. In the Christmas Mountains north of the Big Bend country, D & F Minerals Co. continued operating the La Paisano mine and trucking subgrade met-spar to Marathon for screening and then transhipment by Bailey Fluorspar Co. to steel companies. Bailey Fluorspar Co. also continued to receive ore from its mine (Mal Abrigo) in Coahuila, Mexico, and from other privately owned mines in Chihuahua, and Durango, Mexico. The ore is screened and sized at Marathon before transhipment.

In Utah, Willden Fluorspar Co., Spor Brothers, and U.S. Energy Corp. continued to produce met-spar. No new significant activity was reported from Alaska or Arizona, where prospecting and drilling have been active in recent years.

During 1973 there were seven fluorspar briqueting plants known to be operating in the United States. In addition there was one plant known to be making a 2 by 8 inch fluorspar brick for use as a furnace liner. Concentrate fines containing 93% CaF_2 were used to make the bricks, which act as a flux and metal purifier. There were also two clay brick plants which added 100 to 200 pounds of 95% CaF_2 concentrate to every ton of clay brick kilned.

During 1973 approximately 280,000 tons of fluorspar briquets. ½- to 1½-inch size, were produced by the seven plants and sold to steel companies. In making briquets, some companies used only acid-spar concentrate and diluted it with molasses binder, lime, and a large portion of limestone to about 70% effective CaF_2. Other companies mixed together everything from low grade met-spar fines to gravel and acid-grade concentrate. The different mixes and grades were prepared to conform with customer specifications. Most of the briquetting plants were built during the 1968-70 period when prices were rising rapidly. There are three plants at Brownsville, Tex., and one each at Dearborn, Mich., Pittsburgh, Pa., Rosiclare, Ill., and Cowdrey, Colo. The Cowdrey, Colo., plant, owned by Ozark-Mahoning, was closed down at the end of 1973. The two clay-fluorspar brick plants are at East Canton and Nelsonville, Ohio. The fluorspar brick plant is in Cleveland, Ohio.

In February 1973 at the AIME Society of Mining Engineers meeting in Chicago, Ill., a special session was held on a world review of fluorspar. Five excellent papers were presented discussing U.S. and world reserves and production capabilities and uses in the chemical and aluminum industries.

In April 1973 at the Annual Forum on the Geology of Industrial Minerals held at Paducah, Kentucky, a symposium was held on the geology of fluorspar. Ten papers covering various geological aspects of both U.S. and foreign fluorspar deposits were presented. Proceedings of the forum were published by the Kentucky Geological Survey.

Reserves.—U.S. fluorspar reserves totaled about 25 million tons of ore containing about 35% CaF_2 or 4,100,000 tons of fluorine. Also, 28 million tons of submarginal material analyzing about 17% CaF_2, have been developed at the Lost River Mining Co. claims on Seward Peninsula, Alaska. Near Rome in southeastern Oregon there is another 12 million tons of tufaceous siltstone and claystone containing 8% to 10% CaF_2 that may be classified as a resource. U.S. reserves are mainly in Illinois, Kentucky, Tennessee, Colorado, Montana, Idaho, Texas, Nevada, Utah, Arizona, and New Mexico. These reserves occur in small isolated ore bodies or clusters of ore bodies, and as irregularly shaped pods or veins within localized mining districts. The mined rock generally contains from 25% to 70% CaF_2. Most of the deposits are of less than 500,000 tons, but there are a few larger low-grade deposits that may become commercially attractive if they can be mined by open pit methods and if the rock is amenable to beneficiation.

Table 5.—U.S. consumption of fluorspar by end use and by grade in 1973
(Short tons)

End use or product	Containing more than 97% calcium fluoride	Containing not more than 97% calcium fluoride	Total

CONSUMPTION AND USES

In the United States, fluorspar of varied specifications was used by the steel, glass, ceramic, brick, and cement industries. Fluorine derived from fluorspar and manufactured into hydrofluoric acid (HF) is essential to the chemical, aluminum, airplane, medicinal, oil, and nuclear reactor industries and for fluoridating drinking water. Consumption trends for fluorspar depend directly on the growth of the above industries. The domestic steel industry consumed about 45% of the total fluorspar, the chemical industry about 33%, the aluminum and nonferrous industry about 19%, and other industries about 3%.

The share of total consumption used by the iron and steel industry increased from 43% in 1969 to 45% in 1973. Conversely the share of total consumption used to manufacture hydrofluoric acid decreased from 53% to 49%. During this same 1969–73 period, reported consumption of all grades of fluorspar has remained steady at about 1,355,000 tons annually.

Demand by miscellaneous consumers has broadened considerably in the past few years, although actual consumption remained small. Major uses in this category include catalysts in the oil industry, additives for calcining in the cement industry, storage of radioactive uranium as UF_4 for the nuclear reactor industry, and the manufacture of permanent self-sealing lubricants impregnated in movable parts.

Production of fluorocarbon 11 and 12, which is commonly used in home and automobile refrigeration, decreased notably during the energy shortage in the second half of 1973 when air conditioners were slowed down or shutoff. Union Carbide Corp. enlarged the capacity of its plant at Institute, W. Va., by 30% to about 200 million pounds annually of fluorocarbon 11 and 12. In 1973, Buss Ltd. of Basel, Switzerland was awarded a contract by Companhia Nitro Quimica Brasileira to build three plants a 8,500-ton-per-year hydrofluoric acid plant, a 6,000-ton-per-year aluminum fluoride plant, and a 6,000-ton-per-year cryolite (sodium aluminum fluoride) plant to be located at São Miguel Paulista, Brazil. The plants are due for completion by yearend 1975.[2]

Finally in 1973 the State of Georgia General Assembly passed into law a bill requiring fluoridation of all public drinking water in incorporated communities, thereby eliminating one of the last strongholds against water fluoridation. No action is anticipated in 1973 and 1974, since the State must pay for all equipment and installation and no funds have as yet been provided. Furthermore, any local government can remove itself from the provision by a referendum vote.

STOCKS

U.S. producers reported a 43% decrease in their stock of finished fluorspar from 15,294 tons in 1972 to 8,675 tons in 1973, an alltime low since complete records were started in 1940. U.S. consumers stocks decreased 13% (50,239 tons) in 1973, which indicated that consumers were not worried about an adequate supply. Excess stocks of finished fluorspar were reported in the producing countries of Mexico, Thailand, Kenya, and the Republic of South Africa.

PRICES

Prices of finished fluorspar ready for use varied according to specifications and location. The Engineering and Mining Journal (E/MJ) notes that acid-spar prices were mostly in the \$78.50- to \$87-per-short-ton range; same as in 1972. However, some spot sales were reported at \$70 per ton and others at \$87.50 per ton. Domestic 70% CaF_2 met-spar pellet prices were standardized at \$65.50 per ton, but 88% CaF_2 pellets were priced at \$76.50 per ton. Most briquets varied considerably in price, since their effective CaF_2 content ranged from 65% to 94% CaF_2. The gravel met-spar price reported in E/MJ at the Mexican border was \$48.50. However, a quality-grade gravel met-spar of 70% to 75% effective CaF_2, as produced by the larger

[2] European Chemical News. Business World. Jan. 25, 1974, p. 18.

companies, was reported during 1972 and 1973 to be $60 per ton, f.o.b., c.i.f. included, midstream at the Mexican border.

Drastic fluctuations in European prices were caused by the changing value of the U.S. dollar and by sharp increases in ocean freight costs, which occurred during the last quarter of 1973. Most of the freight increase was absorbed by the European producer, but some was absorbed by the U.S. buyer. Prices in Europe temporarily soared to $97 per ton for acid-spar, f.o.b. U.S. port.

Prices at South African ports ranged from $37 to $40 per ton for acid-spar during 1972, but none was exported to the U.S. during 1973. Met-spar prices in Thailand held at $32 to $35 per metric ton and acid-spar prices were quoted at $65 per metric ton, f.o.b. Bangkok.

Although price rises in 1973 were restrained because of the plentiful supply in Thailand, Mexico, the Republic of South Africa, and some European countries, the cost of producing fluorspar throughout the world has been going up.

Table 7.—U.S. prices of fluorspar

	1972	1973
Domestic, f.o.b. Illinois-Kentucky:		
Pellets, (briquets) 70% effective CaF_2	$68.50	$65.50
Pellets, (briquets) 88% effective CaF_2	76.50	76.50
Ceramic-grade, 88% to 97% CaF_2	$76.50–82.00	$76.50–87.00

Source: As listed in the December issues of Engineering and Mining Journal, 1972 and 1973.

FOREIGN TRADE

U.S. imports for consumption totaled 1,212,347 tons or about 90% of the U.S. total reported consumption of 1,351,705 tons. On the other hand, U.S. imports totaled only 80% of the apparent consumption, which is a more realistic percentage. The downward trend in U.S. exports, which started in 1970 continued through 1973. Fluorspar exports in 1973 decreased 12% below the 1972 tonnage of 2,764 tons. About 87% of the total exports moved across the northern border into Canada. U.S. foreign trade, as in the past, continued to be with free world countries.

Table 8.—U.S. exports of fluorspar

Year and country	Quantity (short tons)	Value
1970	14,952	$1,144,861

WORLD REVIEW

Canada.—In 1973, Canada produced 151,000 tons of fluorspar, almost all acid-spar. This was 16% lower than in 1972, and the reason for the decline was a 1-month labor strike. Less than 1% of Canada's production was met-spar, which was used locally at a Newfoundland steel plant. The following tabulation shows Canada's imports of all grades of fluorspar during the first 9 months of 1973, at the Canadian port of entry.

Country	Quantity (short tons)	Total value	Average per ton
Mexico	69,776	$3,527,000	$50.55
United Kingdom	26,071	1,070,000	41.04
Spain	18,595	516,000	27.75
United States	3,218	216,000	67.12
Total and average	117,660	5,329,000	45.29

Imports of fluorspar from Mexico, the United Kingdom, and the United States accelerated in the last quarter of the year. Based on Canada's imports in the first 11 months of 1973, a total import of 161,470 tons is estimated for the year. This would be a 55% increase over the tonnage imported during 1972. Most of the increase was in met-spar.

All of the fluorspar produced in Canada was mined by one company, Aluminum Company of Canada Ltd. (Alcan), from three mines in the Burin Peninsula of Newfoundland. Alcan started in 1973 to develop a new mine near St. Lawrence, and work continued throughout the year.

During 1973, a new evaluation and feasibility study was underway on the Rock Candy mine near Grand Forks, British Columbia, which is owned by Cominco Ltd., and leased by Alcan. Fluorspar had been produced from this mine during the 1918 to 1942 period, and large reserves of 60% CaF_2 were reported as still remaining.

The Birch Island fluorspar prospect of Consolidated Rexspar Minerals & Chemicals Ltd., located about 60 miles north of Kamloops, British Columbia, was subjected to additional exploration drilling, geochemical soil sampling, and feasibility studies during 1972 and 1973. About 1 million tons of proven and 500,000 tons of possible ore containing an average of 29% CaF_2 were delineated. According to Denison Mines Ltd., which has a 44% interest in Consolidated Rexspar, activity was temporarily suspended so as to evaluate preliminary findings.[3] Exploration activity in the Madoc district of Southern Ontario has also been temporarily suspended by some of the companies that were active during 1972.

Huntington Fluorspar Mines Ltd. continued to make fluorspar bricks at its plant near North Brook, Ontario. Imported met-spar was used to make the bricks for iron foundries.

e Estimate. p Preliminary. r Revised.

[1] In addition to the countries listed, Bulgaria and Morocco are also believed to have produced fluorspar, but production is not reported and available information is inadequate to make reliable estimates of output levels.

[2] In those cases where official production statistics of the respective countries are reported subdivided by grade (acid, ceramic, and/or metallurgical), this breakdown has been reported. No attempt has been made to separate by grade the output of countries which have not officially reported their production on this basis, although some information on such a breakdown may be available from unofficial sources.

[3] Totals reported represent marketable product, a combination of directly salable mine product and concentrate produced from ores that are not usable without beneficiation. In 1971 (the only year for which full detail is available), direct shipping ore totaled 129,747 short tons, while concentrates produced totaled 141,045 short tons, these concentrates being produced from 456,622 short tons of crude ore. The latter figure includes both newly mined domestic ore and additional material of unspecified origin, with actual 1971 mine output of ore for concentration totaling only 379,742 short tons. Total actual ore output (direct shipping ore plus ore for concentration) was 509,490 short tons in 1971; comparable total ore output figures for later years are: 1972—602,168 short tons (provisional) and 1973—610,000 short tons (estimated). The distribution of total salable product into acid-grade and metallurgical-grade is based on information on chemical-grade output reported in Annales des Mines, August-September 1973, p. 67.

[4] Data presented includes recorded production of salable acid-grade fluorspar from both fluorspar mines and lead-zinc-fluorspar mines plus an estimate for the production of salable acid-grade fluorspar obtained by beneficiating a portion of total reported salable metallurgical-grade fluorspar output. Total reported production of acid-grade fluorspar was as follows in short tons: 1971—270,697; 1972—279,843; 1973—263,145. Estimated production of acid-grade fluorspar from beneficiation of metallurgical-grade fluorspar was as follows in short tons (with quantity of metallurgical grade fluorspar reported as being processed in this manner given in parentheses following estimated acid-grade output): 1971—44,575 (111,438); 1972—64,832 (162,080); 1973 (all estimated)—54,000 (136,000).

[5] Data presented are the difference resulting from the subtraction of that quantity of metallurgical-grade fluorspar reportedly consumed for the production of acid-grade fluorspar (see footnote 4) from the total reported metallurgical-grade fluorspar output.

[6] Includes materials recovered from lead-zinc mine dumps.

[7] Sales only.

[8] Data are for year ending June 30 of that stated.

[9] Excludes so-called low grade ore (1971 quantity not available, 1972—22,575 short tons and 1973—61,646 short tons) which apparently was not used for traditional fluorspar uses.

NA Not available.

[1] Detail on sources, unless otherwise specified, are from import data of countries listed as destinations, and figures in the total receipts column for each listed source are summations of reported imports of the listed destinations. Figures in the column headed total recorded exports are from the export statistics of the listed source countries. Differences between total receipts and total recorded exports are attributed chiefly to the time lag between date of shipment and the date of receipt, but some differences may result from either (1) concealment policies of some countries, and/or (2) reshipment of material by intermediate countries which may be credited as the origin in the trade returns of final receipt countries.

[2] Data are for year beginning July 1, 1972.

[3] Mozambique reports no production or exports of fluorspar; apparently the imports recorded by three nations from Mozambique were shipped from other countries by way of Mozambique.

[4] India records 4,853 short tons as being imported from Switzerland.

[5] West Germany records 109,691 short tons total imports from undisclosed origins (plus 297 short tons from countries specifically identified but not listed in this table).

[6] Countries included and total imports by each in short tons are: Denmark 3,078; Finland 5,648; France 4,162; Yugoslavia 5,116.

[7] Includes feldspar.

China People's Republoc of.—Fluorspar production in the People's Republic of China (PRC), was officially reported to be 280,000 tons in 1972 and 1973 but was verbally reported to be in excess of 300,000 tons in 1973. Chekiang, Hopeh, and Kwangsi Chuang Provinces were historically the principal sources of fluorspar. However, the largest single producing mine in recent years has been Tauling in Hunan Province where ore assaying about 12% fluorspar, 2% zinc, and 1% lead is mined and upgraded in a flotation plant. Concentrate assaying 95% to 97% CaF_2 is produced, and apparently used domestically in the chemical and aluminum industries.

Production from the older mining districts is mostly met-spar. PRC exported about 175,000 tons of fluorspar to Japan during 1973, all met-spar. In 1972 and 1973 a total of about 55,000 tons of met-spar was exported annually to various other countries such as the U.S.S.R., Belgium, West Germany, Poland, Finland, and Australia.

The iron and steel industry of the PRC consumes large quantities of met-spar, although the tonnage is difficult to estimate. The aluminum industry may have used 12,000 tons of acid-spar in 1973. Another 12,000 tons of acid-spar might also have been consumed by the chemical industry.

At the Chanchiang chemical fertilizer plant in South China's Kwangtung Province, where phosphate products were produced, sodium fluosilicate reportedly was also recovered from hitherto discarded waste materials. This additional fluorine supply is probably used in the PRC chemical industry.

Italy.—Italy has the capacity to produce over 330,000 tons of acid-spar and met-spar annually, but production in 1973 was only 259,630 tons, a 15% drop from 1972 and about 20% drop from the 1971 peak production of about 326,000 tons. Acid-grade fluorspar exports to the United States declined from 74,000 in 1972 to 58,000 in 1973.

In the past 3 years, extensive exploration for fluorspar has been underway, particularly on Sardinia. At the beginning of the year, there were about 10 companies actively mining, developing, or exploring for fluorspar including one major Australian company, Southland Mining Ltd., which controls Società Richerche Coltivazione Minerarie, (SRCM). Normally over 20 mines operated on the mainland and Sardinia.

Southland Mining announced that it is heading a consortium to exploit the Pianciano fluorspar deposit located about 25 miles north of Rome.[4] Reserves of this high clay and carbonate fluorspar ore, in pyroclastic lacustrine sediments, were reported at 8 million tons containing about 55% CaF_2, 9% barite and celestite, and 6% apatite. The matrix is predominantly kaolinite of pyroclastic origin. Numerous companies have made feasibility studies of this deposit, but to date the ore has defied conventional means of heavy-media or froth-flotation processing. SRCM plans to process this pyroclastic material using a hydrocycloning technique and then make a briquet of about 70% CaF_2.

Italy's consumption of met-spar in steel manufacture peaked at about 120,000 tons annually; but due to the recent slump in steel output, consumption was probably less than 100,000 tons in 1973. The country has a plentiful supply of acid-spar but is short of met-spar. Italy requires supplementary imports from France, Mexico, the United Kingdom, the Republic of South Africa, and Tunisia. The physical and mineralogic character of the fluorspar deposits in Italy require flotation plant processing. Consequently, acid-spar production is in excess of internal needs.

Japan.—Japan continues to be the second largest fluorspar consumer in the free world, and is presently twenty-third on the list of fluorspar-producing countries. Japan's 1973 imports totaled about 631,000 tons. About 265,700 tons was imported from Thailand, 174,500 tons from PRC, about 125,200 tons from Republic of South Africa, 26,600 tons from Kenya, and 19,300 tons from Republic of Korea (South), mostly as met-spar. Japan's production totaled about 9,000 tons, all from one mine with dwindling ore reserves.

Japan's consumption totaled about 596,000 tons of all grades of fluorspar. As reported in the Japan Metal Journal, 381,830 tons of fluorspar or about 64% of the imports was used in the iron and steel industry. This indicates that the iron and steel industry, which produced about 132 million tons of primary steel in 1973, used 5.8 pounds of met-spar per ton of steel. Japanese steel companies continued their search for a substitute flux to use in steel furnaces, but to date no satisfactory universal substitute has been developed. Japanese companies have learned to use some of the new cheaper substitutes for starting a steel melt intended for certain types of steel products, and to use fluorspar flux more sparingly, thereby reducing the pounds of fluorspar used per ton of steel.

About 101,400 tons, mostly acid-spar, re-

[4] Industrial Minerals. Southland Takes Control of Fluorite Deposit. July 1973, p. 22.

presenting about 17% of the total, was directed into the aluminum industry. About 1,209,000 tons of aluminum was produced in 1973, indicating that about 168 pounds of acid-spar was used per ton of aluminum metal. This consumption rate confirms the reported consumption rate of aluminum fluoride and synthetic cryolite.[5] In addition Japanese aluminum companies recovered and recycled 26,300 tons of synthetic cryolite particulates, equivalent to about 31,500 tons of acid-spar. The use of recycled particulates has softened demand for synthetic cryolite produced from hydrofluosilicic acid (H_2SiF_6). About 90,900 tons of acid-spar was used in the inorganic chemical industry, and the balance was used in other unspecified industries.[6]

The Japanese fluorspar industry has both upgrading and froth flotation plants for processing imported ore. The chemical industry also has plants making hydrofluoric acid, sodium aluminum fluoride and aluminum fluoride from acid-spar, and a new processing plant for making sodium aluminum fluoride from imported sodium fluosilicate (silicofluoride.) Although the aluminum industry has been the largest consumer of acid-spar, the demands of the expanding fluorocarbon industry may soon surpass aluminum industry demands.

The Environmental Agency (EA) of Japan began studies aimed at establishing new environmental quality standards for all fluorides, based on their adverse effects on plant life. Present fluoride controls were restricted to airborne emissions from aluminum refining plants, glass factories, and brickyards. At midyear, the Chiba Prefectural Pollution Countermeasures Bureau announced that fluoride pollution in the Keiyo Coastal Zone has increased to 3.6 times the 1972 pollution. The EA planned to set the standard low enough to preclude damage to farm products, which are most susceptible to this air pollutant.[7]

Kenya.—Production of met-spar in Kenya increased 18,000 tons in 1973 to about 29,500 tons. A further increase of about 10,000 tons is expected in 1974. The Fluorspar Co. of Kenya, 51% owned by the Government of Kenya, 24.5% by Bamburi Portland Cement Co., and 24.5% by Continental Ore Corp., started construction of a froth flotation plant with a planned output of 120,000 tons annually, which is scheduled to go onstream in late 1975 or early 1976. Continental Ore Corp., a subsidiary of International Minerals and Chemical Corp., is the mine and mill operator.

Export shipments from Kenya have gone to many different countries. However, Japan contracted to purchase 10,000 tons of met-spar in 1973, and intends to buy even larger quantities of both met-spar and acid-spar in the future.

Proven ore reserves in the Rift Valley are said to exceed 6 million tons. Ore was reportedly high grade, although exact quality has not been divulged. It is estimated that another 9 million tons of so-called fluorspar resources will be available for future development.

Mexico.—Mexico maintained its position as the leading world producer and exporter of fluorspar and the foremost supplier to the United States. Although most Mexican companies expanded capacity considerably in 1971–72, the country's 1973 production only increased 4% to 1,197,000 tons, which is still below the peak of 1,302,000 tons in 1971. The majority of the larger companies increased output capacity in 1973. As a result six major companies produced about 79% of the national total.[8]

Mexico's exports of met-spar to the U.S. in 1973 exceeded the acid-spar exports by 21% whereas in 1972 the exports of these two grades were about equal. Mexico provided 74% of U.S. imports in 1973, a decrease of about 3.5% from 1972. Mexico exported over 90% of its production, and fluorspar continued to be Mexico's single most important mineral export. The value of Mexican fluorspar exports increased about 4.7% even though there was an increase in met-spar exports and a decrease in acid-spar exports.

No significant increase in Mexican fluorspar consumption was reported for 1973. The steel industry remained the largest consumer. The chemical and aluminum industries used much smaller amounts. Two small plants were reported to have a com-

bined output of 20,000 tons annually of hydrofluoric acid: One is controlled by Allied Chemical Corp. and the other by Industrias Químicas.

Progress continued on construction of the 70,000-ton-per-year hydrofluoric acid plant being built west of Matamoros by Química Fluor, S.A. de C.V. The plant is jointly owned by the Mexican Government (Comisíon de Fomento Minero), E. I. du Pont de Nemours & Co., Minera Frisco, S. A., and Banco de Commerico. Du Pont is the plant builder and operator and expects to have the plant onstream by mid-1975.

The Las Cuevas mine in San Luis Potosí is the largest fluorspar mine in the world. It is owned by Cía. Minera Las Cuevas S.A., an affiliate of Empressa Fluorspar, which is a subsidiary of Noranda, Mines Ltd. Toronto, Canada. In 1973 they shipped about 338,000 tons of met-spar, including 79,000 tons of met-spar fines that were sold to fluorspar briquetting companies in the United States.[9] During 1973 Las Cuevas operated its new flotation plant, which has a 50,000-ton-per-year capacity, but the concentrate was stockpiled at the mine and not sold. About half of its ore was shipped from Tampico to U.S. and Canadian ports, and the other half was freighted to the Port of Brownsville, Tex., for subsequent distribution.

Other major producing companies included Industrias Peñoles, S.A., in San Luis Potosí and Guanajuato; Fluorita de Mexico, S.A., in Coahuila and San Luis Potosí; Minera Frisco, S.A., in Chihuahua; Reynolds Fluorspar, S.A., in Coahuila; Compania Minera Domincia, S.A., in Coahuila; Asarco Mexicana, S.A., in Chihuahua; and Compania Minera Rio Colorado, S.A., in Guanajuato.

During 1973, the Mexican fluorspar miners wage scale was increased 37% by order of the Mexican Government. Although smaller companies have been forced to raise prices on exported fluorspar, the major met-spar producing companies were able to hold prices fairly steady, in spite of rising production costs, and pressure from the smaller producers to raise the price.

Morocco.—Although no production was reported from Morocco during 1973, it was reported that development of a fluorspar deposit in the El Hammam region, 31 miles southwest of Meknes, and the construction of an acid-spar flotation plant with a 60,000 ton per year output capacity, were underway. Production from this 3 million ton deposit is expected late in 1974.

Production of hydrofluosilicic acid (H_2SiF_6) is planned for 1974. Both the Maroc-Chimie and the Maroc–Phosphore phosphoric acid plants, controlled by the Office Cherifien des Phosphates (OCP) are expected to produce H_2SiF_6 as a byproduct. The H_2SiF_6 by-product potential of the phosphate industry in Morocco could total 100,000 tons annually within a few years.

South Africa, Republic of.—Fluorspar production showed little change from the 1972 level, registering about 232,000 tons. Export sales of acid-spar, however, increased sharply during the last quarter of 1973. Probably some of the oversupply that had accumulated during 1972 was sold in 1973. Local sales were made mainly to the steadily expanding steel and aluminum industries.

At the Buffalo fluorspar mine of General Mining and Finance Corp. Ltd., it was announced that a new flotation plant designed to increase the company's output from 40,000 to 150,000 tons of acid-spar per year was operating at near capacity. However, due to a weak market, the old 40,000-ton-per-year mill was placed on standby. The 20-million-ton ore body averages 70 meters (210 feet) in width and was reported minable by open pit methods. The ore ranges from 13% to 25% CaF_2. Due to the limited supply of water and fears of fluorine pollution, even tailings are filtered for maximum recovery and reuse of water.[10]

A verbal source of information reported that the Phelps Dodge Co. of South Africa had reactivated an old flotation plant south of Zeerust in West Transvaal. Original annual capacity of 20,000 tons will be expanded to 30,000 tons of acid-spar through modernization of facilities. The company's deposit can be mined by open pit methods and reportedly the ore averages 29% CaF_2.

It was evident from the notable increases in production and export of acid-spar, predictions, the possibility of expanding exports, and favorable geological reports of fluorspar occurrences, that the future of the industry depends on the marketability of

[9] Noranda 1973 Annual Report. Empressa Fluorspar. p. 12.

[10] Mining Magazine. South Africa's Buffalo Fluorspar in Full Production. V. 129, No. 6, December 1973, p. 501.

flotation concentrates. It was questioned whether world acid-spar markets could absorb, by the end of 1975, a predicted production increase of 200,000 tons from South Africa, Europe and Kenya, and another 50,000 tons from Mexico. Therefore, it has been suggested that South African companies may be forced to briquet their oversupply of concentrates and sell fluorspar briquets to the growing world iron and steel industry.

Fluorspar reserves in the Republic of South Africa and the Territory of South-West Africa are still reported to be equivalent to about 40 million tons of 35% CaF_2. Although their largest deposits are low grade, ranging from 15% to 20% CaF_2, they are minable by open pit methods and are economically exploitable on today's market.

Spain.—At the start of 1973, there was a large oversupply of fluorspar ore in the stockpiles of Spanish producers. This oversupply was caused by accelerated production in 1972 and a soft European market during the latter part of 1972. In spite of a soft market during 1973, most of the stockpiles were reduced to reasonable tonnages by yearend. Spain's overall production was down from 444,290 tons in 1972 to about 430,000 tons in 1973. The reported 1971 and 1972 production data on fluorspar were questioned. Later it was determined that some of the production of crude ore, containing less than 50% CaF_2, had been incorrectly reported as a finished salable product containing an equivalent of 70% to 75% CaF_2 [11] and some had been processed in a flotation plant to produce acid-spar. Table 11 shows the adjusted acid-spar and met-spar production for 1971 and 1972 and the estimated production for 1973.

Spain's exports of all grades of fluorspar to the United States increased 31% from 135,000 to 177,000 tons. Total exports reported by the Spanish Customs Office increased 36% from 195,000 in 1972 to 264,000 tons in 1973.

Consumption of met-spar in Spain increased slightly, although consumption of all grades of fluorspar was about the same as in 1972. The hydrofluoric acid plant of Minerales y Productos Derivados, S.A. (Minersa) near the Port of Castro-Urdiales continued to increase its consumption of acid-grade fluorspar and output of cryolite and aluminum fluoride. Preliminary estimates indicate that Spain's total consumption of fluorspar probably was close to 200,000 tons for 1973.

Prices of some fluorspar products were temporarily down about 5% to 10% the first part of the year. Met-spar prices were a little stronger than acid-spar prices due to increased demand by the steel industry. The decrease in the peseta-to-dollar exchange ratio and the increase in shipping costs hurt the Spanish producers.

During the first part of 1973 Fluoruros S.A., 49% owned by the Bethlehem Steel Co., put into operation a new fluorspar concentration unit at the Espasa plant in the Asturias region. The input capacity of the unit was reported at 100 tons an hour, which should add about 20,000 tons annually to the 1972 output capacity of about 111,000 tons. A pelletizing or briquetting unit was put in operation at Mineraria Silius' flotation mill at Assemini to make use of the waste fines. It was announced that Fluoruros S.A. was also planning to add a briquetting unit to their flotation plant at Pinzales, Spain, during 1974.

Thailand.—During 1973, about 439,000 tons of fluorspar was produced, less than 1% increase over 1972. Most of the Thai production is exported. About 265,700 tons, 60% of the production, was shipped to Japan, and the rest went to the U.S.S.R., Australia, West Germany, and India.

The value of met-spar, f.o.b. Bangkok, decreased from an average of $36 per ton in 1972 to an average of $32.14 per ton in 1973. The price of acid-grade fluorspar remained unchanged at $65 per ton, f.o.b. Bangkok.

The Thai Fluorite Processing Co. Ltd. continued to operate its flotation plant at Ban Lard and produced about 50,000 tons of acid-spar of which about 30,000 tons was shipped to Japan. Universal Mining Co. Ltd. continued to operate its heavy-media separating plant in the Ban Hong district near Chiengmai, Lamphun Province.

Production in Thailand would probably have been larger if a few suppressing factors had not affected production. Heavy rains in the Lamphun district of northern Thailand destroyed roads and temporarily suspended fluorspar rail and truck shipments to Bangkok. Worldwide shortages of diesel fuel for freighters forced buyers to stockpile met-spar in the Bangkok area

[11] U.S. Embassy Madrid, Spain. Minerals Questionnaire, A-118, May 23, 1972, and A-99, May 9, 1973.

until lower priced shipping facilities could be obtained. Also, deposits that have been mined by cheap surface mining methods are becoming scarce in some of the older districts.

In January 1974, it was announced that a Thai-Australian enterprise intended to build in the Cha-am Area a $2 million froth flotation plant to produce 150,000 tons annually of chemical grade fluorite.[12]

Tunisia.—Fluorspar output from Tunisia remained the same as in 1972 at 51,000 tons. Value per ton of exports increased about 5% but the quantity exported remained the same at about 46,000 tons. The fluorspar mines are located in the Zaghouan region of central Tunisia. Two new mines at Sta and Jebel Ouest started production in 1973. Fluorspar reserves in Tunisia were reported to be 6 million tons, currently minable on today's market, and 5 million tons of potential ore.

A French company, Huertey, and its Swiss associate, Buss, signed an agreement with the Tunisian Government to build an aluminum fluoride plant located in Gabes. The company will be controlled by Industries Chimiques de Fluor and construction will start in 1974.

United Kingdom.—Production continued at the same level as during 1972 and was estimated at 220,000 tons. The closing of the coal mines by labor strikes and a general business slump caused a weakness in internal demand. The United Kingdom was still self-sufficient in fluorspar. Exports dropped notably.

A conservative estimate of fluorspar ore reserves for 1973 was reported to be about 28.5 million tons of 35% CaF_2. A thorough evaluation of fluorspar deposits in the United Kingdom would probably increase reserves by an additional 15 million tons; but until the deposits can be more closely identified and evaluated, the additional tonnage must be treated as a resource. The largest fluorspar deposits are located in the Derbyshire Area of the southern Pennines in northern England. Most of the fluorspar produced in the past 10 years has come from this area. The deposits occur as nearly vertical replacement veins up to 80 feet (25 meters) in thickness. A few stratiform-type deposits containing large tonnages were among the first to be mined primarily for fluorspar. Lead and zinc sulfides and some barite are scattered through the matrix. For many years, starting at the beginning of the twentieth century when fluorspar first came into demand for the steel industry, the waste dumps of the old lead-zinc mines in the Derbyshire Area were the main source of fluorspar.

In the Pennines, barite, galena, and sphalerite commonly occur in sufficient quantities as secondary minerals to be recovered as byproducts from the fluorspar flotation plants. In the southwest England fluorspar area, fluorite is a common mineral constituent of primary lead and copper lodes. This area promises to be a potential producer of fluorspar as a byproduct.

Froth flotation plants in the United Kingdom have the capacity to produce over 200,000 tons annually of acid-grade fluorspar. If the demand were sufficient, the mines have the capacity to produce over 150,000 tons of metallurgical-grade fluorspar per year.

TECHNOLOGY

In September 1973, it was announced that Alcoa had broken ground near Palestine, Tex., for a commercial aluminum ingot plant using the new Alcoa smelting process. This process is described as a revolutionary energy-saving method. The plant will require about 2 years to build. The annual output of primary aluminum is reported to be 15,000 tons initially and 300,000 tons potentially. The new process combines alumina and chlorine in a reactor unit, forming aluminum chloride, which is processed electrolytically in an enclosed cell. The molten aluminum separates from the chlorine, permitting the chlorine to be recycled. No fluorine or fluorine compounds are used.[13]

Tests continued on synthesizing an artificial blood from fluorocarbons to use as a substitute for blood in animals. Efforts were concentrated on experiments using fluorocarbon compounds mixed with blood plasma and hemoglobin. Upjohn Co. reported a new compound called "Flurbipro-

[12] Modern Asia. Joint Ventures. V. 8, No. 1., January/February 1974, p. 34.

[13] Chemical Marketing Reporter. Alcoa Smelting Process is Getting its First Plant. V. 204, No. 12, Sept. 17, 1973, p. 32.

fen," which effectively reduces platelet aggregation in both human and animal bloods.

A nuclear bombardment method for the recovery of fluorine from waste plastics has been developed by the Takasaki Research Establishment of the Japan Atomic Energy Research Institute. The recovered plastic particles of micron size, contain polytetrafluorethylene, which is reusable for mixing into plastics to make lubricants. This process is attractive because it proposes reuse of the fluorine and eliminates fluorine emissions.[14]

A self-lubricating fluoride metal composite material was licensed by the National Aeronautics and Space Administration (NASA) to Astro-Met-Associates of Cincinnati, Ohio. The fluoride composites are impregnated into porous nickel, cobalt, or iron alloys permitting continuous lubrication.

Fluorosilicone grease, as a sealed lubricant, has found many new uses where the lubricant must be thermally stable, chemically inert, and where the rate that the lubricant is fed into the seal at high process temperatures and rotational speeds must be controlled. New uses for fluorosilicone greases have resulted in new pump designs and new automatic grease applicators.[15]

CRYOLITE

Natural cryolite was imported from Greenland (24 tons) and Denmark (2,200 tons). Although mining at the Ivigtut mine in Greenland stopped in 1962, each year since then, some ore was shipped from stockpiles. In Denmark where large tonnages of Ivigtut ore were stockpiled years ago, there is a modern heavy-media and flotation plant for concentrating the cryolite ore, which contains 60% cryolite, 10% siderite, 20% quartz and topaz, 6% fluorspar, and 2% other sulfides. An elaborate flotation plant separates the sulfides, carbonates, and quartz; but to separate the fluorspar and cryolite, they use a two-stage hydrocyclone installation to achieve about 97% recovery of the cryolite. Each year the tonnage produced becomes smaller as the stockpiles are depleted.[16]

All other cryolite production throughout the world was synthetic cryolite, a sodium aluminum fluoride (Na_3AlF_6). This insoluble inorganic salt, also called sodium fluoaluminate, is manufactured from caustic soda, alumina, and hydrofluoric acid. The output of one ton of synthetic cryolite requires approximately 1.2 tons of fluorspar containing 97% CaF_2, 1.6 tons of H_2SO_4, 0.4 ton of $Al_2O_3 \cdot 3H_2O$, and 0.6 ton of NaOH. During 1973, the price of synthetic cryolite was quoted in the Chemical Marketing Reporter at $336 per ton in bulk quantities. In recent years, consumption of synthetic cryolite, used mostly in the liners of the aluminum electrolytic cell, has been on the decline and more aluminum fluoride than Na_3AlF_6 is added directly in the flux.

Table 13 is no longer representative of a natural mineral or a beneficiated mineral product. It includes a natural and manufactured product and the tonnage represents only a small portion of the total synthetic cryolite that is actually consumed in the United States.

[3] Surinam and Switzerland were deleted because the imports were misclassified.

Gallium

By E. Chin [1]

Domestic production of gallium in 1973 increased. Most of the output continued to be used in producing intermetallic compounds such as gallium arsenide and gallium phosphide, which were used to manufacture light-emitting diodes for optoelectronic visual display panels. Sales of gallium-compounds for optoelectronic devices were estimated at $25 million in 1973, up from $4.5 million in 1972.

Estimated world production of gallium arsenide exceeded 10 metric tons. Almost 1 ton of gallium phosphide was produced. Data on world production of gallium metal are not available.

Table 1.—Salient gallium statistics

Price per kilogram dollars--	750	750	750	750

[e] Estimated. W Withheld to avoid disclosing individual company confidential data.

DOMESTIC PRODUCTION

Production of gallium metal in 1973 by two companies was almost double that in 1972.

Gallium metal was produced as a by-product of alumina production by the Aluminum Co. of America (Alcoa) at its Bauxite, Ark., plant. Gallium metal, oxide, and trichloride were produced by Eagle-Picher Industries, Inc., at its Quapaw, Okla., plant. In addition, gallium metal and compounds derived primarily from imported material were produced by Atomergic Chemetals Co. (Atomergic), Cominco American, Inc., European Electronics, Inc., B. Freudenberg, Inc., Indium Corp. of America, and Kawecki Berylco Industries, Inc. Canyonlands 21st Century Corp. (Canyonlands) produced gallium from processing scrap generated from the production of gallium-arsenide single crystals at Blanding, Utah.

Alcoa began construction of a new gallium extraction and refining plant at Bauxite, Ark. The new facility, which was expected to be completed in mid-1974, will add to the existing gallium production capacity. The $1 million plant is being built to meet the increase in demand from the electronics industry and will use Alcoa proprietary gallium production technology.

CONSUMPTION

The largest use of gallium was in optoelectronic applications, principally in the form of gallium arsenide and gallium phosphide, which are used in light-emitting diodes (LEDS). LEDS emit infrared light, have a long service life, and consume little electrical power. Due to the pronounced trend of the electronics industry towards microminiaturization, LEDS were increasingly used in visual display systems in calculators, digital clocks and watches, medical instrumentation, multiple warning lights, and instrumentation for aircraft and automotive dash panels. More sophisticated monolithic light-emitting structures for full alphabet presentation are being developed which will require even greater quantities of intermetallic materials. Gallium arsenide continued to have extensive application in the field of microwave devices, where it operates efficiently beyond the cutoff frequencies of silicon-base diodes. The manganese-doped magnesium-gallium spinel ($MgGa_2O_4$: Mn) is a green phosphor used in ultraviolet

[1] Physical scientist, Division of Nonferrous Metals—Mineral Supply.

excitation and was used in fluorescent lamps in Xerox copying machines. Gallium compounds were also used in semiconductor applications for microswitching devices and in laser applications. The intermetallic compounds, vanadium-gallium and columbium-gallium, were used as superconductors with a high transition temperature and a high critical field.

Approximately 98% of the gallium consumed in 1973 was for electronic applications. Major consuming firms included Bell & Howell Co., Bell Telephone Laboratories, Inc., Hewlett-Packard Laboratories, Laser/Diode Laboratories, Inc., Litronix Inc., Monsanto Co. (Monsanto), Motorola, Inc., Opoca, Inc., RCA Corp., Texas Instruments, Inc., Texas Materials Laboratories, Inc., and Western Electric Co.

Atomergic at Carle Place, N .Y., in conjunction with BDH Chemicals, Ltd., of the United Kingdom, increased production capacity for epitaxial gallium arsenide. Atomergic offered a comprehensive array of gallium arsenide crystals. Materials Research Corp. (MRC), Orangeburg, N.Y., and Texas Instruments, Inc. (TI), Dallas, Tex., entered into a contract whereby MRC will supply TI with production quantities of high-purity gallium arsenide crystals for use in manufacturing LEDS. Monsanto announced a multimillion-dollar expansion program for its electronic materials and optoelectronics group including the construction of additional facilities at St. Peters, Mo., which will double its capacity to manufacture III–V materials. Monsanto will also establish a new headquarters site for optoelectronic devices in Stanford Industrial Park, Palo Alto, Calif. The new facilities were expected to be in operation in the first quarter of 1974. National Semiconductor Corp. (National), Santa Clara, Calif., manufactured LEDS, transistors, and integrated circuits.

STOCKS

Consumer stocks of gallium metal, low- and high-purity grades, totaled 1,091,203 grams as of December 31, 1973. Stocks a year earlier were 1,141,050 grams. Gallium metal stocks, held by producers and suppliers were as follows:

	Grams
Yearend—	
1971	402,875
1972	1,005,945
1973	948,947

Table 3.—Stocks, receipts, and consumption of gallium

(Grams)

Purity	Beginning stocks	Receipts	Consumption	Ending stocks
1972:				
97.0%–99.9%	16,955	10,591	12,692	14,854
99.99%	4,321	51,000	51,513	3,808
99.999%	615	10,249	1,664	9,200
99.9999%–99.99999%	130,938	5,992,586	5,010,336	1,113,188
Total	152,829	6,064,426	5,076,205	1,141,050
1973: p				
97.0%–99.9%	14,854	9,400	10,342	13,912
99.99%	3,808	8,670	10,759	1,719
99.999%	9,200	42,275	46,422	5,053
99.9999%–99.99999%	1,113,188	8,386,280	8,428,949	1,070,519
Total	1,141,050	8,446,625	8,496,472	1,091,203

p Preliminary.

PRICES

The average price per gram of gallium metal as quoted by domestic producers in 1973 was as follows:

Quantity	Purity		
	99.99%	99.999%	99.9999%–99.99999%
50 to 999 grams	$0.90	$1.05	$1.20
1,000 to 4,999 grams	.60	.65	.80
5,000 to 24,999 grams	.55	.60	.75

As the bulk of the demand for gallium is for high-purity metal (99.9999%+), published price quotations for low-grade materials were eliminated in midyear. Subsequently, prices were published only for dealers' and producers' quotes for high-grade gallium in 5-to-10 kilogram lots. Monsanto announced the reduction in prices for III–V material for the manufacture of LEDS and LED displays. Thin-film gallium arsenide-phosphide epitaxial wafer sold for $14 per square inch and was available for delivery from stock. The price of thicker epitaxial film products was reduced to $16 per square inch. The new prices became effective on November 15, 1973.

FOREIGN TRADE

Exports of gallium are not reported separately and are included in the category base metals and alloys, not elsewhere classified, wrought or unwrought, waste and scrap.

Total U.S. imports of gallium in 1973 were $11,124 kilograms, valued at $6,073,479, compared with 6,066 kilograms, valued at $2,715,179, in 1972. Shipments from Canada, the Netherlands, and Switzerland accounted for 89% of the total U.S. imports of gallium. The unit value of gallium imports ranged from $366 per kilogram for material from Italy to $1,307 per kilogram for gallium from Japan. The average unit value of all gallium imports in 1973 was $546 per kilogram.

Table 4.—U.S. imports for consumption of gallium (unwrought, waste and scrap), by country

Country	1972		1973	
	Kilograms	Value	Kilograms	Value
Canada	1,396	$696,186	2,133	$1,102,332

Total	6,066	2,715,179	11,124	6,073,479

WORLD REVIEW

Canada.—The Manitoba Research Council made a $23,800 grant to the University of Manitoba to study the feasibility of extracing gallium from tantalum tailings generated by Tantalum Mining Corp. of Canada, Ltd. (Tamco) at Bernic Lake. The university research team will work with Tamco on the project. The company will examine its production process to determine at which stage gallium concentration is at its maximum. Tamco mills about 150,000 tons per year of tantalite and estimated that about 1 pound of gallium might be available for each 2 tons of tantalum metal produced.

Cominco Ltd. (Cominco) recovered gallium as a byproduct of zinc refining at its smelting-refining-chemicals-fertilizer complex at Trail, British Columbia. Cominco's Technical Research Centre maintains active interest in electronic materials and directs commercial production of high-purity metals.

High-purity gallium was shipped to the Electronic Materials Division of Cominco Amercan Inc. in Spokane, Wash., for sale to consumers.

China, People's Republic of.—Gallium metal was listed for sale at the Canton Trade Fair in October 1973. However, only limited quantities of the metal were reportly available for trade. Four kilograms of gallium metal, valued at $2,652, was exported to the United States.

Japan.—Sumika Alusuisse Gallium Ltd. (Sumika), a company founded jointly by Sumitomo Chemical Co. and Swiss Aluminium Ltd., completed the construction of a plant in Nijhama on the Island of Shikoku for the production and refining of gallium. The gallium is to be recovered as a byproduct in the production of alumina.

World producers of gallium, by company, location, and raw materials source, are as follows:

Country	Company	Location	Source
Canada	Cominco, Ltd	Trail, British Columbia.	Zinc ore.
China, People's Republic of	NA	NA	NA.
Czechoslovakia	NA	NA	NA.
France	Alusuisse France S.A.	Marseilles	Bauxite.

TECHNOLOGY

The extraction of trivalent gallium from aqueous hydrochloric, nitric, and perchloric acid solutions by 1-phenyl-2-methyl-3-hydroxy-4-pyridone (HX) and 1-(4-tolyl)-2-methyl-3-hydroxy-4-pyridone (HY) dissolved in chloroform was studied.[2] From acid concentrations less than 3×10^{-2} molar (M), gallium was quantitatively extracted by both reagents. Zinc was not extracted by either HX or HY from $10^{-3}M$ to 3 M HCl, HNO_3, or $HClO_4$. On the basis of these differences, a rapid and simple method for the separation of gallium from zinc was described.

The transactions of a conference held at Great Gorge, N.J., on electronic materials processing were published by the Materials Research Corp.[3] Papers on the crystal growth of gallium arsenide and gallium phosphide, production of high-purity materials for electronic uses, and design of a reflective LED digit were included in the transactions.

Reports on the growth of crystals for electronic uses and the comparison of various

[3] Materials Research Corp. Electronic Materials Processing . . . From Substrate to Thin Film Device. Orangeburg, N.Y., 1973, 201 pp.

crystal growth techniques were published.[4] These studies covered the growth of substrate materials, the growth of epitaxial films, and the growth of large metal crystals composed of atoms that are arranged in a precise and periodic manner.

Intermetallic compounds are soft materials, subject to surface damage unless care is exercised in handling them. Techniques of etching and polishing gallium and other semiconductor compounds, currently being employed to produce quality (low-damage) crystal surfaces, were described.[5]

Papers characterizing the physical properties of semiconductor materials were published.[6] The delineation of electronic materials is important to the industry for process design, equipment selection, and economic evaluations.

Significant advances were made in gallium arsenide laser diode fabrication.[7] The width of operation was narrowed, and peak output power was increased. One gallium semiconductor laser was successfully operated for 3,000 hours, and it was expected that this laser would attain at least 10,000 hours of continuous operation.

Canyonlands conducted research to recover gallium from phosphorus dust, using a new hydrometallurgical process under license from Monsanto. The dust, which contains 500 parts per million of gallium, will be obtained from Monsanto and other sources.

Gem Stones

By Robert G. Clarke [1]

The production value of gem stones and mineral specimens in the United States during 1973 was estimated to be $2.7 million, essentially equal to the value of production in 1972. Amateur collectors provided most of the material. A few small companies operated deposits for turquoise, opal, jade, emerald, and sapphire. These small companies sold mostly to wholesale or retail outlets and sometimes to jewelry manufacturers.

DOMESTIC PRODUCTION

Gem stone production was estimated to be $1,000 or more for each of 38 States. The following States accounted for 76% of the total production, in thousands: Oregon, $700; California, $220; Arizona, $170; Texas, $163; Washington, $160; Montana, $150; Wyoming, $142; Nevada, $140; Colorado, $131; and Idaho, $110.

The Yogo mine near Utica, Mont. was reopened by a new firm controlled by Sapphire International Corp.[2] The operation was described as employing 40 miners on two shifts, and daily ore production was 100 to 150 tons yielding 3,000 to 5,000 carats per day of a mix of good gem stones, imperfect stones, and chips. The aboveground washing plant operated about 6 months of the year, depending on the weather. Underground operations continued year-round. The sapphires from Yogo Gulch are a consistent corn-flower blue and are brilliant under artificial light.

Pala Properties, International, continued to work the Stewart Lithia mine and the Tourmaline Queen mine in the Pala district, San Diego County, Calif.[3] Good pockets of tourmaline matrix exhibiting deep rose coloring with green caps were uncovered in the Tourmaline Queen. Large tourmaline crystals, 2 inches in diameter and 4¾ inches long, were accompanied by quartz crystals 4 inches in diameter and 6½ inches long. The company also worked the White Queen mine where morganite was produced on an intermittent schedule and also planned to reopen the Pala Chief, Esmeralda, and the Himalaya mines.

Benitoite, one of the rarest gem stones, was produced from an open-cut mine in San Benito County, Calif.[4] The locality is near the headwaters of the San Benito River, about 25 miles north of Coalinga. Benitoite has a fire and dispersion very close to that of diamond; however, it has a hardness of 6.5 or less on the Mohs' scale.

Seashell and rock collectors at Miami Beach, Fla., found a large new source of material for their hobby.[5] A dredging project to deepen the shipping channel at the Port of Miami yielded about 400,000 tons of mixed material that contained a high percentage of coral and clam shells. The dredgings were put in numerous piles at the southern end of Miami Beach. An abundance of the coral and of the clam shells were infilled with yellow calcite crystals caused by fossilization. A mollusk paleontologist at the Rosenstiel School of Marine and Atmospheric Science, University of Miami, estimated the fossils to have a range in age from 100,000 to 1 million years.

Touchstones were collected from gravel beds of the Coosa River system near Wetumpka, Ala., in Elmore County.[6] Touchstone, which has been used since ancient times by jewelers and goldsmiths, can give a precision of about 1 part in 100 in estimating the gold content of a gold-silver or gold-copper alloy. The stones from the Coosa River are also called tarbaby agates. The touchstone from the Coosa River is a deep velvet black variety of jasper and can be polished to a strikingly beautiful gem stone.

Two gem-quality diamonds, 2 to 2½ carats in weight, were reportedly found at the Crater of Diamonds State Park at Murfreesboro, Ark. Mr. J. Cannon, Superintendent of the Park, commented that the stones were of beautiful gem quality. Finders are keepers at the Park, and hence the value of the stones was unknown until the finders report appraisals.

Descriptions of field trips, events, and mineral and gem stone finds were reported regularly in the following publications: Gems and Minerals, Lapidary Journal, Mineralogical Record, and Rocks and Minerals.

Domestic Gem Stone Producers.—The Department of the Interior has received many inquiries regarding producers of gem stones. In response to these inquiries, the Bureau of Mines started an annual canvass in 1973. Quantity and value data were withheld to maintain confidentiality of the producers who responded to the canvass. The following lists producers by principal gem stone reported:

Emerald.—Big Crabtree mine, Mitchell County, N.C., operated by PBH Emerald Co., P.O. Box 163, Little Switzerland, N.C. 28749.

Jade.—Stewart mine, Kobuk Village, Alaska, operated by Stewart Jewel Jade Co., 531 4th Ave., Anchorage, Alaska 99501.

Opal.—Royal Peacock mine, Humboldt County, Nev., operated by Harry W. Wilson, Denio, Nev. 89404.

Spencer Opal mine, Clark County, Idaho, operated by Mark L. Stetler, 1862 Ranier Street, Idaho Falls, Idaho 83401. Mostly operated on a daily fee digging basis for amateurs.

Sapphire.—Chaussee Sapphire mine, Granite County, Mont., operated by Chaussee Sapphire Corp., P.O. Box 706, Philipsburg, Mont. 59858.

Sapphire Village mine (Yogo Gulch), Judith Basin County, Mont., operated by Sapphire International Corp., Utica, Mont. 59452.

Turquoise.—Blue Eye mine, Lander County, Nev. operated by Elmer F. Schroeder, Roderick Corp., Box 6, Crescent Valley, Nev. 89821.

Blue Jay mine, Esmeralda County, Nev., operated by M. C. Winfield, P.O. Box 813, Tonopah, Nev. 89049.

June #1 mine, Lander County, Nev., operated by W. H. Coplen, Box 301, Sells, Ariz. 85634.

Pinto Valley Turquoise Operation, Gila County, Ariz., operated by L. W. Hardy Co., Inc., 3809 E. Hwy. 66, Kingman, Ariz. 86401.

Tina Gem mine, Lander County, Nev., operated by R. G. Bonner, Box 948, Fallon, Nev. 89406.

Variscite.—Brown Claims, Esmeralda County, Nev., operated by C. R. Barbe, Box 187, Mina, Nev. 89422.

CONSUMPTION

Domestic gem stone output generally went to rock, mineral, and gem stone collections, objects of art, and jewelry. Apparent consumption of gem stones (domestic production plus imports, minus exports and reexports) was $423 million, equal to that of 1972.

PRICES

Prices of all gem stones increased during 1973. Price ranges in February 1973 for first-quality, cut and polished, unmounted gem diamond were as follows: 0.25 carat, $100 to $425; 0.5 carat, $300 to $1,000; 1 carat, $700 to $3,800; 2 carats, $2,300 to $12,000; and 3 carats, $4,100 to $25,000. The median price for each range in Feb-

[6] Mayo, R. Tarbaby Agate. Rocks and Minerals, v. 48, No. 1, January 1973, pp. 63–64.

ruary was 0.25 carat, $225; 0.5 carat, $550; 1 carat, $1,750; 2 carats, $4,750; and 3 carats, $9,500. A similar determination of price ranges in June 1973 was 0.25 carat, $100 to $450; 0.5 carat, $300 to $1,195; 1 carat, $800 to $5,000; 2 carats, $2,200 to $20,000; and 3 carats, $4,500 to $35,000. The median price for each range in June was 0.25 carat, $250; 0.5 carat, $595; 1 carat, $2,000; 2 carats, $4,950; 3 carats $11,950. Price data were not ascertained in the latter part of 1973 because of instability and conflict in international political affairs.

FOREIGN TRADE

Exports of all gem materials amounted to $333.1 million, and reexports to $186.8 million. Diamond comprised 94% of the value of exports and 93% of the value of reexports. U.S. exports of diamond in 1973, on which work was done prior to shipment, amounted to 259,119 carats valued at $314.2 million. Of this, diamond cut but unset, suitable for gem stones, not over 0.5 carat, was 44,714 carats valued at $16.7 million; and cut but unset, over 0.5 carat, was 214,405 carats valued at $297.5 million.

Reexports of diamond, on which no work was done, amounted to 1,467,234 carats valued at $173.9 million in categories as follows: Rough or uncut, suitable for gem stones, not classified by weight, 1,389,340 carats valued at $128.3 million; cut but unset, not over 0.5 carat, 35,579 carats valued at $9.0 million; cut but unset, over 0.5 carat, 42,315 carats valued at $36.6 million.

The six leading recipients of diamond exports accounted for 92% of the carats and 93% of the value and were as follows: Hong Kong, 69,071 carats valued at $97.2 million; Switzerland, 59,126 carats valued at $52.3 million; Japan, 53,592 carats valued at $51.7 million; the Netherlands, 30,037 carats valued at $53.9 million; Belgium, 19,878 carats valued at $30.8 million; and Israel, 7,395 carats valued at $6.3 million. The six leading recipients of diamond reexports accounted for 94% of the carats and 92% of the value and were as follows: Israel, 636,497 carats valued at $70.2 million; Belgium, 403,108 carats valued at $30.7 million; the Netherlands, 194,101 carats valued at $30.4 million; Switzerland, 124,715 carats valued at $19.3 million; Japan, 15,874 carats valued at $5.8 million; and Hong Kong, 9,075 carats valued at $2.8 million.

Exports of all other gem materials amounted to $19.0 million. Of this total, pearls, natural and cultured, not set or strung, were valued at $0.5 million. Natural precious and semiprecious stones, unset, were valued at $16.2 million; and synthetic or reconstructed stones, unset, were valued at $2.3 million. Reexports of all other gem materials amounted to $12.9 million. Reexports of pearls amounted to $0.8 million; of natural precious and semiprecious stones, unset, to $11.6 million; and of synthetic or reconstructed stones, unset, to $0.5 million.

Imports of gem material from 85 countries and territories increased 31% in value compared with that of 1972. Diamond accounted for 86% of the total value of gem material imports.

Most of the rough and uncut diamond imports were from seven countries, which accounted for 98% of this category as follows: the United Kingdom, 978,553 carats, $225.8 million; Sierra Leone, 747,000 carats, $78.9 million; Republic of South Africa, 426,881 carats, $83.7 million; Venezuela, 296,271 carats, $9.8 million; Central African Republic, 190,833 carats, $7.7 million; Belgium-Luxembourg, 68,056 carats, $16.8 million; and the Netherlands, 55,255 carats, $22.2 million. Of the imports of diamond, cut and unset, not over 0.5 carat, 89% was supplied by the following eight countries: Belgium-Luxembourg, 1,016,871 carats, $131.4 million; Israel, 774,090 carats, $106.6 million; India, 211,061 carats, $22.8 million; the U.S.S.R., 27,435 carats, $5.2 million; France, 23,485 carats, $2.4 million; the United Kingdom, 18,511 carats, $1.9 million; the Netherlands 15,158 carats, $1.7 million; the Republic of South Africa, 13,656 carats, $3.9 million. For diamond, cut and unset, over 0.5 carat, 99% came from the following seven countries: Belgium-Luxembourg, 142,001 carats, $45.8 million; Israel, 77,944 carats, $21.6 million; the Republic of South Africa, 10,070 carats, $8.9 million; the Netherlands, 2,832 carats, $2.4 million; India, 2,148 carats, $0.3 million; the U.S.S.R., 1,882 carats, $0.7

million; and the United Kingdom, 1,683 carats, $0.5 million.

Imports of emeralds increased 31% in quantity and 47% in value. Of 28 countries supplying natural emeralds to the United States, 10 countries accounted for 97% of the quantity as follows: India, 412,179 carats, $6.7 million; Brazil, 148,399 carats, $1.2 million; Colombia, 47,524 carats, $15.2 million; Hong Kong, 34,196 carats, $1.0 million; Switzerland, 27,840 carats, $2.9 million; the United Kingdom, 22,651 carats, $2.3 million; Israel, 13,771 carats, $0.6 million; the Netherlands, 9,652 carats, $0.1 million; West Germany, 9,419 carats, $0.2 million; and Belgium-Luxembourg, 3,478 carats, $0.2 million.

Imports of rubies and sapphires increased 47% and came from 30 countries. Eight countries accounted for 90% of the value of rubies and sapphires as follows: Thailand, $11.7 million; Hong Kong, $2.5 million; India, $1.4 million; Switzerland, $0.7 million; the United Kingdom, $0.6 million; France, $0.3 million, and Israel, $0.2 million.

Natural pearls and parts imported from India were valued at $260,000. Other leading suppliers of natural pearls and the value of imports were as follows: Italy, $33,100; Japan, $28,600; Hong Kong, $18,500; Switzerland, $10,500; Burma, $8,300; and Taiwan, $5,300. Imports of cultured pearls from Japan were valued at $8.4 million. Cultured pearls, also imported from Hong Kong were valued at $231,000; from Burma, $348,000; from Switzerland, $101,000; from France, $38,000; from Thailand, $22,000; from Italy, $19,000; from West Germany, $8,000; and from India, $8,000.

The imports of imitation pearls decreased two-thirds. Imports from Japan valued at $1.1 million comprised 85% of the total. Other countries from which imitation pearls were imported included: Spain, $78,000; Taiwan, $27,000; Australia, $7,000; Hong Kong, $5,000; the Republic of Korea, $4,000; and West Germany, $1,000. Smaller values also came from France, Switzerland, and Portugal.

Of 17 countries supplying imitation gem stones to the United States, 6 countries accounted for 78% by value, as follows: Austria, $4.0 million; West Germany, $2.8 million; Czechoslovakia, $0.8 million; Switzerland, $0.5 million; Japan, $0.3 million; and Denmark, $0.1 million.

Synthetic materials, gem-stone quality, cut but not set, and others, decreased about 3% in value. From West Germany, the value of synthetics was $4.8 million; from Switzerland, $1.2 million; from Japan, $1.0 million; from France, $0.8 million; from Taiwan, $0.7 million; from Israel, $0.5 million; from Hong Kong, $0.4 million; from Belgium-Luxembourg, $0.3 million; and from Austria, $0.2 million. These nine countries accounted for 98% of synthetic gem imports.

[1] Less than ½ unit.
[2] Adjusted by the Bureau of Mines.

Marcasites, cut but not set, and suitable for jewelry were imported from four countries: Israel, $23,125; Switzerland, $3,644; Hong Kong, $850; and the United Kingdom, $450.

Precious and semiprecious stones, rough and uncut, amounted to $5.9 million in value of imports. Seven countries accounted for 92% of the value as follows: Colombia, $2.4 million; Brazil, $1.3 million; Australia, $0.8 million; the United Kingdom, $0.3 million; the Republic of South Africa, $0.3 million; Mozambique, $0.2 million; and Hong Kong, $0.1 million.

Precious and semiprecious stones, cut but not set, amounted to $25.0 million. Eleven countries accounted for 94% of the value as follows: Hong Kong, $9.4 million; Australia, $3.4 million; Brazil, $3.1 million; West Germany, $1.9 million; Iran, $1.4 million; Taiwan, $1.4 million; Japan, $1.0 million; Sri Lanka, $0.5 million; Mexico, $0.5 million; India, $0.5 million; and Switzerland, $0.5 million.

Coral and cameos, cut but not set, were imported from Italy, $1.2 million; from Japan, $0.5 million; and from Taiwan, $0.3 million. Minor quantities of coral and cameos were also imported from the United Kingdom, France, West Germany, Switzerland, Israel, Singapore, the Philippine Republic, Hong Kong, the People's Republic of China, Australia, and Egypt.

WORLD REVIEW

Angola.—Companhia de Diamantes de Angola (DIAMANG), the only diamond producer, reported an increase in export value in 1972 of 4% to $63.4 million owing to an increase in the percentage of gem stones produced.[7] The quantity of diamond exported in 1972 decreased 6% to 2.2 million carats. All diamond exports go to metropolitan Portugal. The Consorcio de Diamantes de Angloa, the consortium of DIAMANG and De Beers interests that inherited all but 50,000 square kilometers of DIAMANG's former concession area, continued active exploration. A number of promising kimberlite deposits were found, but no plans were made for immediate exploitation.

Australia.—Large deposits of high-quality nephrite jade were discovered near Cowell, a town in the east coast of Eyre Peninsula, about 125 miles northwest of Adelaide, South Australia.[8] A newly formed company, Jade Australia Proprietary Ltd., Adelaide, was reported to have extensive proven reserves.

According to Australian sources, its 300 sapphire mines produce sapphires valued at $15 million and account for 80% of the world volume of sapphire and 50% of the world sapphire value.[9]

Botswana.—Development of a second large diamond mine is expected.[10] The Government of Botswana and De Beers Botswana Mining Co., discussed development of the DK 1 kimberlite pipe 25 miles southeast of the existing Orapa mine, which currently produces 2.4 million carats worth about $30 million per year. The mine at DK 1 could be operating within 18 months after agreements are reached.

Burma.—Burma's Ninth Annual Gem, Jade, and Pearl Emporium was held February 19–24, 1973. Jade sold amounted to $4,307,000; gems, to $281,000; and pearls, to $1,247,000. The total amounted to $5,835,000, a record high. The increase was due primarily to rising world prices of jade rather than an increase in the quantity of jade, or gems, or pearls. Attendance was by 12 countries, 151 firms, and 219 persons. Hong Kong buyers took 119 lots of jade out of the 156 lots sold. The People's Republic of China delegation bought 27 lots of jade, and Japanese buyers bought 9 lots. One bidder from the United States bought one lot of jade. Neither gems nor pearls were bought by U.S. bidders. Motivated by the success of the Ninth Emporium, the Government held a special emporium in August 1973 for jade and pearls, omitting gem stones. At the special emporium, jade sales amounted to $5.3 million. Hong Kong dealers monopolized the buying of jade, accounting for 72 lots of the 81 sold. Burmese authorities assert that reserves of jadeite are adequate

and that prospects are good for locating additional deposits.

Canada.—Pacific Jade Industries, operators of all nephrite jade mines near Ogden Mountain, British Columbia, reported 1972 jade sales of nearly $200,000, over half of which was sold to the People's Republic of China.[11] Exports to other countries included West Germany, Hong Kong, Singapore, and Japan. The most precious jade is generally apple-green in color, translucent, free of flaws, and free of color variations. Variations in color can be almost white or black and all shades of green in between. The value of jade sold ranged from $1 to $30 per pound, averaging about $3.30 per pound. In addition to selling crude jade, Pacific Industries also marketed finished pieces ranging from inkstands and paper weights to works of art.

Central African Republic.—Cominco, Ltd., a Canadian company and Diamond Distributors, Inc., of New York formed a new company, Société Centraficaine d' Exploitation Diamantifere, to conduct diamond mining and exploration in the Central African Republic.[12] Cominco, which has the majority interest, will manage the new company and provide technical direction; Diamond Distributors, Inc., will be responsible for marketing. In the Central African Republic, 60% of the amount of diamond recovered is from the Upper Sangha (Carnot, Berberati, and Nola regions); the remainder is from the northern (Bamingui-Bangoran) and eastern (Haute-Kotte) areas.[13] About 45,000 workers were employed in 1973 to gather diamond from alluvial deposits.

Colombia.—The Government-owned emerald mines at Muzo, Coscuez, and Peña Blanca were closed in July 1973 and the operations landfilled to conserve the unmined emeralds. The emerald mine areas were placed under Colombian Army control. Negotiations were underway between the Ministry of Mines and private operators to arrange the reopening of the mines. The amount of security to be exercised by the Army to protect the operations was an important item. The export of emeralds accounted for more than half of the value of mineral exports from Colombia up to the time of the mine closures.

Israel.—The growth in the imports and exports of gem stones, particularly diamond, has been explosive. The main reasons have been the continual turmoil in exchange rates, and worldwide inflation. People are actively seeking a reliable item of value and a hedge against inflation. Gem stones, most of all diamond, fill the need. The following tabulation indicates the growth pattern: [14]

Year	Net imports of rough gem diamond		Net exports of polished diamond	
	Carats	Value	Carats	Value
1970	3,624,027	$154,361,873	1,501,265	$202,040,738
1971	5,292,715	224,065,256	1,874,685	265,269,576
1972	6,176,605	316,059,884	2,296,829	385,691,783
1973	6,587,698	448,020,973	2,445,092	556,754,004

The value of diamond exports to the United States increased 78% from $74 million in 1971 to $132 million in 1973; however, the share of the exports to the United States decreased from 28% in 1971 to 24% in 1973. After the United States, Japan, Hong Kong, the Netherlands, Switzerland, Belgium, and West Germany, in that order, were the major recipients of diamond exports for 1971 through 1973. In September 1973, diamond enterprises numbered 649 and the employees numbered 9,857.

Lesotho.—As part of a continuing effort by the Lesotho National Development Corp. (LNDC) to revive commercial interest in diamond mining, De Beers Consolidated Mines, Ltd., was granted permission to conduct a 6-month evaluation of the Letseng-la-Terai diamond pipe in the Mokhotlong District.[15] This site was abandoned by Rio Tinto Zinc Corp. in 1972,

and Newmont Mining Corp. cancelled a similar effort earlier this year at Kao in the Butha Buthe District. However, subsequent evaluations made of the stones in those areas have shown the diamond to be of higher value than originally appraised.

Sierra Leone.—Diamond exports continued to be the main source of revenue for Sierra Leone for 1972 and 1973. World prices which began rising in 1972 were still rising in 1973. The National Diamond Mining Corp. (DIMINCO) increased its work force to recover as much diamond as possible from its alluvial deposits. Diamond production was not tied to long-term price contracts as were other minerals, therefore revenue to the Government of Sierra Leone increased as diamond prices increased.

Sri Lanka.—The State Gem Corp., a Government-owned company, introduced an incentive program to encourage marketing of privately held gem materials. The incentive program was so successful that receipts to the Government increased more than twentyfold for the period January–July 1973 compared with those of the similar period in 1972. Many lovely gem stones are produced in Sri Lanka, but worldwide high prices applied at the source by the State Gem Corp. discouraged buyers from the United States.[16]

South Africa, Republic of.—The Central Selling Organization reported 1973 diamond sales of $1,290 million, an increase

e Estimate. p Preliminary. r Revised.

[1] Total (gem plus industrial) diamond output for each country is actually reported except where indicated to be an estimate by footnote. In contrast, the detailed separate reporting of gem diamond and industrial diamond represents Bureau of Mines estimates in the case of all countries except Lesotho (1971 and 1972), Liberia (1971 and 1972), and Venezuela (1971 and 1972), where sources give both total output and detail. The estimated distribution of total output between gem and industrial diamond is conjectural in the case of a number of countries, based on unofficial information of varying reliability.

[2] Exports of diamond originating in Lesotho; excludes stones imported for cutting and subsequently reexported.

[3] Exports for year ending August 31 of that stated.

[4] Exports.

[5] All company output from the Republic of South Africa except for that from the Premier mine; also excludes company output from the Territory of South West Africa and from Botswana.

of 40% over those of 1972. No breakdown of quantity of gem stones or value of gem stones versus the quantity and value of industrial stones was given. De Beers suspended operations at some mines in favor of operations at other mines to adjust production to meet demand.[17] Consumer demand worldwide in 1973 was mostly for 1.0 carat stones and resulted in a surplus of small stones weighing less than 1/4 carat. A marketing program was developed for use of smaller stones to accentuate other gem stones in jewelry settings.

Zaire.—On November 30, 1973, the Government of Zaire announced that companies formerly operated by a Belgian group, FORMINIERE, would be taken over 100%. Included in this group was the diamond mine of the Société Minière de Bakwanga (MIBA) located at Mbuji Mayi, East Kasai Region. The MIBA mine produces over 12 million carats of diamond annually, nearly all industrial diamond, and is a major foreign exchange earner for Zaire. MIBA employed about 4,000 workers in East Kasai in 1973.

TECHNOLOGY

The Diamond Grading Laboratory, London, England, developed a method for positive identification of individual diamond gems.[18] The method utilizes the range of color in diamond, approximately 1,000 hues, and the characteristics of flaws and inclusions commonly found in all diamond. A full "fingerprint" dossier, including a color photograph, was recommended for all stones 1 carat and over, for an approximate cost of $75 each.

Another utilization of diamond characteristics was developed for identifying the source, or area in the world, from which a diamond came. The De Beers Diamond Research Center, Johannesburg, Republic of South Africa, compiled a set of 150,000 physical observations of diamond from various parts of the world for use in establishing the identifying traits.[19]

Geologists have believed that high pressures and temperatures were necessary for the growth of diamond. Laboratory efforts using high pressure and temperatures were proven successful, first by General Electric Co. research workers and subsequently by many others. However, a review of all available data disclosed that other conditions may foster the growth of diamond.[20] Information gained from patent literature and from laboratory experiments was used to present a new theory on the growth of both natural and synthetic diamond. According to the theory, the essential requirement is a set of conditions that will provide a source of individual carbon atoms that exist in excited states. This theory attempts to explain why diamond is not present in the lower regions of kimberlite pipes, and why some kimberlite pipes have no diamond present. Although high pressure and high temperature used by the earlier experimenters provided a set of conditions that presented carbon atoms in an excited state, the passage of an electric current in the presence of catalytic contaminants was needed to complete the transformation to diamond.

Nephrite jade has a hardness of 6½ on the Mohs' scale and jadeite jade has a hardness of 7. However, the hardness is not an indication of the toughness, or the resistance to breakage. In addition to the two jades, a number of minerals were measured for relative toughness even though no widely accepted scale exists.[21] For comparison, carbonado diamond was found to be the toughest mineral. Of all other natural minerals, nephrite jade measured highest in resistance to breakage, and jadeite was ranked next, a sequence which is the reverse of their accepted relative hardness. In fact, the two jades exceeded most commercially available ceramics. Only ultrahigh strength, hot-pressed oxides and nitrides used for cutting tools and turbine vanes exceeded the two jades in toughness.

The most attractive of current imitation diamonds is a well-made doublet

which combines the virtues of two synthetics.[22] A sapphire crown provides durability to the exposed area, and a strontium titanate pavillion provides fire and brilliance. The juncture may be at the girdle or it may be just below the girdle. The plastic cement used to join the crown and pavillion is resistant to almost anything likely to be encountered except steam cleaning.

All phases of faceting require equipment to be properly prepared and also require a skillful artisan. The proper procedure for dopping gems for facet cutting was described for a variety of minerals.[23]

The term "cameo" applies particularly to a stone, shell, glass or other hard substance upon which a design has been carved. A comparison was made of methods used to carve antique cameos and current methods are thoroughly illustrated by examples in color photography.[24]

Pierre Gilson, one of the leading producers of synthetic emeralds, submitted a 3.5-carat synthetic black opal to the Gemological Institute of America for examination.[25] The specimen was described as "absolutely beautiful." The representatives of Gilson claimed that stones as large as 20 carats may be available in the future.

Gold

By J. M. West [1]

Gold reached a record selling price on U.S. markets of $126.45 per troy ounce about midyear 1973. The price might have been even higher but was held to that level by Federal Government ceilings imposed as a part of economic control measures. From the beginning of the year to yearend gold prices rose $47.20 per ounce, and the average price for the year was up 67%. The official gold price was increased from $38 to $42.22 per ounce by Public Law 93–110, enacted September 21, 1973; however, no gold was exchanged at official prices and U.S. official gold reserves remained at the same quantitative level throughout the year.

Domestic gold production during 1973 declined for the third straight year, dropping 20% to 1.18 million ounces. The leading four producers, Homestake Mining Co., Kennecott Copper Corp., Carlin Gold Mining Co., and Cortez Gold Mines, accounted for nearly 75% of all U.S. gold production. Of the four, Homestake Mining operated the only underground mine; the others were open pit. Virtually all of the Kennecott gold was a copper refinery byproduct from ores of its Utah Copper Division mine (Bingham pit). The Carlin and Cortez operations in Nevada produced gold from ores in part carbonaceous, and containing "submicron" gold particles. At most gold-producing mines the gold was a byproduct. Of the 25 leading mines, 19 were mined principally for metals other than gold. The other six mines were operated for gold alone; of these, five were classified as lode-gold or gold-silver mines, and one was a placer operation in Alaska. The leading gold producers were located in nine Western States: South Dakota, Utah, Nevada, Arizona, Colorado, Washington, Montana, New Mexico, and Alaska. Minor production also came from California, Idaho, Oregon, and Tennessee.

Consumption of gold in the United States declined 8% in 1973, with jewelry and arts accounting for 52% of the total consumed. The quantity of net imports dropped 82%; however, an additional source of industry supply was established through the sale of foreign stocks on deposit at the Federal Reserve Bank in New York, and 25% of consumption came from this source during the year. Industry stocks rose 2% during the year.

World gold output declined again in 1973, dropping 3.7% to 43 million ounces. The Republic of South Africa supplied 64% of the world production, about the same proportion as in 1972. The U.S.S.R. ranked second in production and supplied 16% of the world's output, several percent higher than in 1972. Canada and the United States were third and fourth in order. Past and future world demands for gold were reviewed, and higher gold prices were predicted.[2]

Legislation and Government Programs.—A bill devaluing the dollar by 10% in terms of gold was signed into law September 21, 1973 (Public Law 93–110). The devaluation increased the value of gold reserves in the Treasury by 11.11% to $42.22 per ounce. Included in the bill was a provision giving the President discretion to eliminate regulations on private ownership of gold when this would not adversely affect the U.S. international monetary position. The International Monetary Fund (IMF) was notified of the U.S. devaluation effective at 12:01 a.m., October 18, 1973.

The Office of Domestic Gold and Silver Operations, Department of the Treasury, issued the following notice pertaining to gold coins, effective December 17, 1973:

> All foreign gold coins minted 1934 through 1959, if genuine and of legal issue, are now considered to be of such

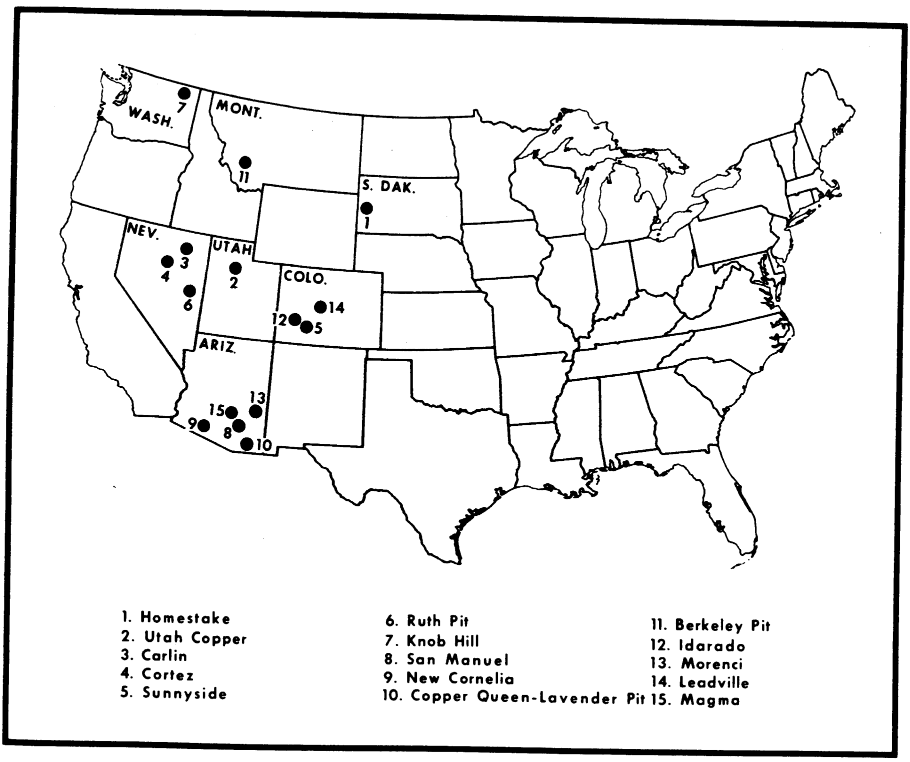

Figure 1.—Major U.S. gold-producing mines.

recognized special value to collectors of rare and unusual coins as to warrant the issuance of a general license for their importation into the United States under section 54.20(e) of the Gold Regulations for numismatic purposes. Genuine gold coins minted prior to 1934 may be imported without a license under section 54.20(d). As provided in section 54.20(e) of the Gold Regulations, modern gold coins minted after 1959 will continue to be prohibited importation into the United States and such coins may not be held outside the United States by persons subject to U.S. jurisdiction.

Under section 54.24(b)3(ii) of the Gold Regulations, gold coins made subsequent to 1933 may be exported from the United States only under license of form TGL–11 issued by the Director, Office of Domestic Gold and Silver Operations.

Gold coins contained in jewelry items are subject to the same regulations which govern the importation/exportation of unmounted gold coins.

Domestic selling prices for gold were frozen on June 13, 1973, and the ceilings established were to be effective for a maximum of 2 months. A base period of June 1–8, 1973, was selected and the ceiling established for each company was at the highest price level at which 10% or more of its sales were made during the base period. The general price freeze lasted through August 13. Controls were also placed on gold products but these were later modified in specific instances by the Cost of Living Council so increased material costs could be passed on to buyers by fabricators who were caught in the middle of the cost-price squeeze.

On November 13, 1973, the two-tier gold price system was terminated by consensus of officials of the seven nations that had initiated the system March 17, 1968. Under the system, the United States and six other nations (the London Gold Pool) had agreed not to sell reserve gold to private parties, nor to buy gold directly from the Republic of South Africa or on the free market. In December, following the system's termination, the IMF and the Republic of South Africa terminated a 1969 gold agreement whereby the IMF would purchase gold from South Africa whenever the price fell below the $35 per ounce official level or whenever South Africa had a payments deficit. No gold had been purchased under the agreement since August 1971.

The Office of Minerals Exploration (OME), U.S. Geological Survey, continued its program of participitory loans for gold exploration covering up to 75% of approved costs. A small number of active contracts were in effect in several Western States.

DOMESTIC PRODUCTION

The drop in domestic gold output during 1973 resulted largely from a phaseout of production at the Cortez mine, Lander County, Nev., the mining of lower grade ores and a 20-day strike at the Carlin mine, Eureka County, Nev., and the mining of lower grade ores at the Homestake mine in Lead, S. Dak. Despite the reduced outputs, gold mining operations were generally more profitable owing to the sharp rise in gold prices during the year. Utah production was down mainly because the Mayflower mine, in the Park City district of Utah, had ceased operations the year before. In Washington, production was lower because the Knob Hill mine produced less from declining reserves. The Knob Hill mine with its 250-ton-per-day mill was expected to close about the end of 1975 unless additional exploration was productive.[3] In Alaska expansions were underway and a revival of gold mining was predicted.[4] Standard Metals Corp. increased ore reserves by core drilling at its Silverton mine in Colorado.[5] Exploration and development activities were reported at a number of California mines.[6] The Cripple Creek, Colorado, district, one of the large past producers of gold, was undergoing renewed development.[7]

Of the total domestic gold produced in 1973, the top 4 producers provided 75% and the 25 leading producers supplied 98%. Placer production accounted for only about 1% as before. Approximately 47% of pro-

[7] World Mining. Cripple Creek's Golden Glamour. V. 26, No. 5, May 1973, pp. 46-48.

duction was a byproduct of mining for other metals. An estimated 1.8 million ounces of secondary gold was treated by refiners, compared with 2.1 million ounces in 1972. Among the largest gold refiners were American Metal Climax, Inc., which reported refinery output of 820,000 ounces in 1973, slightly lower than in 1972, and Kennecott Copper Corp. with 342,284 ounces refined in 1973 versus 350,080 ounces in 1972.

At the Homestake Mining Co. operations, production dropped 12% to 357,634 ounces in 1973. The average price received on sales was $93.36 per ounce, 65% higher than in 1972. The average recovered grade was 0.227 ounce per ton in 1973, compared with 0.278 ounce in 1972, an 18% drop. A total of 1.57 million tons of ore was milled, up 7%; revenues from gold sales, which included gold purchased for resale, were $52.05 million, 55% higher than in 1972. Metallurgical recovery improved following startup of a new "charcoal-in-pulp" treatment plant for handling the slime fraction of the ground ore; recovery averaged 93.63% for the year, and reached 94.6% in December. A shortage of skilled miners continued to hamper production. A contract was let to sink the new No. 7 winze and deepen the No. 8 shaft from the 7,200- to the 8,000-foot level. A major crosscut was being driven on the 5,300-foot level to explore new ground. Several large-tonnage blasthole stopes were prepared for extraction of lower grade ore. This mining method dilutes the ore but provides greater tonnage per man-shift. Ore reserves were estimated at 9.05 million tons proven, averaging 0.249 ounce per ton, a 24% increase in tonnage but a 17% decrease in grade from 1972. Proven reserves included 1.89 million tons averaging 0.148 ounce per ton in blasthole stopes. Additional reserves totaled 6.8 million tons at a grade slightly over 0.3 ounce per ton.

The Carlin mine, Eureka County, Nev., produced 150,000 ounces of gold, compared with 194,000 ounces in 1972, a 23% decline. Sales were valued at $15.0 million, compared with $11.7 million in 1972. Despite less production, net income from the Carlin operations rose 47% to nearly $5.7 million. Waste removal began at the Bootstrap property, where about 50,000 tons of low-grade ore was stockpiled for heap leaching. Other ores were stockpiled to haul to the Carlin mill, 12 miles away. Five miles from the mill the Blue Star property was being drilled. Reserves at the two properties totaled 1.9 million tons, averaging 0.14 ounce per ton. At the Carlin mine reserves amounted to 2.4 million tons averaging 0.319 ounce per ton at the end of 1973. Exploration of areas surrounding the open pit workings and at depth was continuing.

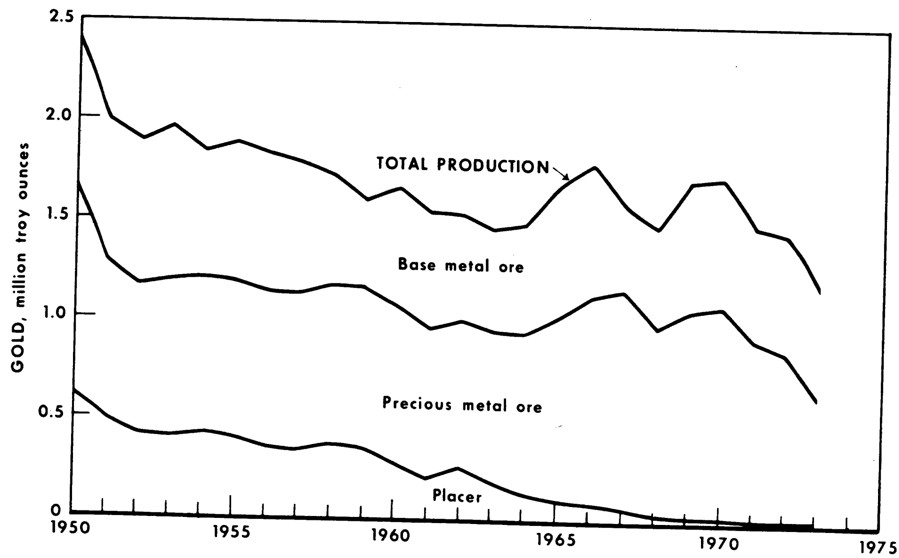

Figure 2.—Sources of U.S. gold production.

At the Cortez mine, Lander County, Nev., mill throughput declined 5% to 762,500 tons in 1973. Production dropped 60% to 75,700 ounces of gold, compared with 190,-600 ounces in 1972. The average grade of ore milled dropped to 0.109 ounce per ton, compared with 0.214 ounce in 1972, and 85.6% of the gold was recovered. Milling of ore from the nearby Gold Acres property began at the Cortez mill in April, and 643,400 tons of ore, over half of the property's reserves, were treated before yearend. The balance of the mill feed came from marginal ores in the Cortez mine. Also in 1973 1.16 million tons of low-grade ores were added to heap leach piles, compared with 0.82 million tons placed in 1972. Gold (included in totals) produced from heap leaching amounted to 10,300 ounces, compared with 37,600 ounces in 1972. At yearend, 1.09 million tons was under leach treatment (which began in October) at the Gold Acres property. Gold Acres was expected to be mined out by the end of 1974.

UV Industries, Inc., formed a new subsidiary, Alaska Gold Co., to manage its gold properties in Alaska and Arizona. During 1973 the firm operated a gold dredge at Hogatza, Alaska, and tested new drilling equipment for thawing operations at Nome, Alaska. From 1974 to 1976, it was planned to activate two dredges in the Nome area where extensive reserves were believed to exist.

The Golden Cycle Gold Corp. continued exploration of its properties and rehabilitation of its 1,000-ton-per-day mill in the Cripple Creek district of Colorado. The mill was last operated in early 1962. According to plans, local dump tailings would be milled pending the start of deep mining scheduled in 1975. Standard Metals Corp. operated its 700-ton-per-day mill at Silverton, Colo., on three shifts and remained Colorado's largest gold producer. About 40% to 45% of its smelter returns were in gold in 1973, and its Sunnyside mine reserves were adequate for 4 to 5 additional years. Many other gold mines throughout the West were explored during the year in anticipation of reopening.

CONSUMPTION AND USES

Domestic consumption of gold, as reported by the Office of Domestic Gold and Silver Operations, U.S. Department of the Treasury, declined 8% to 6.7 million ounces in 1973. Consumption in 1973, according to surveys of fabricators of industrial and other products, was divided, as follows, in thousand ounces (with 1972 figures for comparison): Jewelry and arts, 3,473 (4,344); dental, 679 (750); and industrial, including space and defense, 2,577 (2,191). Increases in the last category were attributed to growing electrical and electronic consumption, which comprises the bulk of this category. Jewelry and dental uses were down owing to consumer resistance to higher gold prices, which were passed on in product prices. Figure 3 shows consumption trends in recent years.

In a study done for the Federal Bureau of Mines, an assessment was made of how much gold would be required for U.S. industry through 1978 based on a variety of data for past years.[8] A general downtrend in consumption was forecast at gold prices of $70 and over per ounce. During 1973, demand for gold coins increased sharply, and supplies in the hands of coin dealers fell short. U.S. coin buyers continued to be limited by Treasury regulations governing purchases, although rules were eased, as noted under Legislation and Government Programs. Purchases of gold coins in 1973 were estimated to have reached a value of $125 million.

In product development, more efficient use of gold was obtained with a clad strip in the form of a tape, which could be attached or welded to electrical contacts.[9] A gold-clad wire was also developed for electrical use utilizing a molecular bonding technique. Growing use of electroplated gold and other precious metal contacts was cited. Several new low-alloy gold electroplating processes were introduced for use on printed circuit boards, contacts, switches,

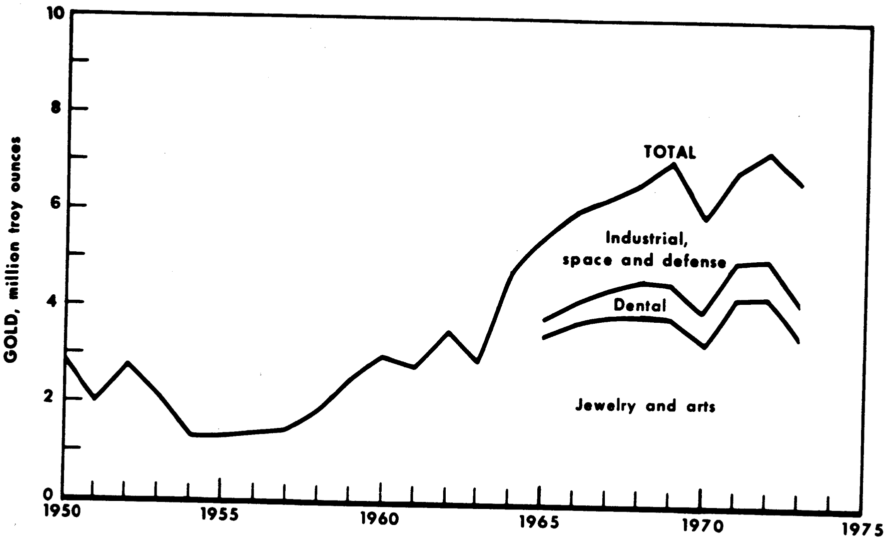

Figure 3.—Gold consumption in the United States.

and electronic parts.[10] In the electronics industry, bright tin, tin-nickel, and palladium were considered as substitutes for gold; however, the high cost of adapting processes keyed to gold was said to be keeping immediate customer interest in substituting less costly materials relatively low.[11] It was estimated that bright tin would be used increasingly in connectors, possibly replacing 10% of the gold being used for this specific purpose.[12] Research efforts of process vendors were said to be directed to developing suitable alloys of 60% to 80% gold combined with copper, cadmium, nickel, and silver. The jewelry industry was said to have used some of the new alloys extensively. One company spokesman did not expect higher gold prices to have a significant impact on the semiconductor industry, the largest single consumer of gold salts, owing to conservation steps underway.[13]

Particularly useful to the jewelry industry was a new series of acid gold-plating solutions which were said to give unvarying reproducibility of color.[14] Also, an electroless process for gold-plating over a variety of substrates was developed for use in the electronics industry.[15] Statues were gilded with a new "brush" electroplating technique,[16] thoria added to gold and platinum gave a superior product for high-temperature electrial uses,[17] and gold was readily mounted on a new vitreous carbon used in dentistry for tooth implants.[18]

STOCKS

Monetary.—Official U.S. gold stocks, including those in the Exchange Stabilization Fund, were valued at $11,652 million based on $42.22-per-ounce gold at the end of 1973, compared with $10,487 million based on $38-per-ounce gold at the end of 1972. The equivalent amount of gold at the end of 1973 was 276.0 million ounces, unchanged from a year earlier. Suspension of the convertibility of dollars to gold, begun August 15, 1971, remained in effect at yearend 1973.

Federal Reserve banks held $17,068 million (404.3 million ounces at $42.22 per ounce) worth of "earmarked" gold for foreign official accounts at the end of 1973, compared with $15,530 million (408.7 million ounces at $38 per ounce) at the end of 1972. Total gold stocks of national monetary authorities and international institutions (excluding Communist countries) were valued at $49,850 million at the end of 1973 ($42.22 per ounce), compared with $44,890 million at the end of 1972 ($38 per ounce). Stocks at the end of 1973 were virtually unchanged from a year earlier at 1,181 million ounces. U.S.S.R. gold reserves were estimated to be worth $2,715 million, equivalent to around 65 million ounces.

World monetary stocks of gold at the end of 1973 were distributed as follows, in million ounces: United States, 276.0; IMF, 153.4; West Germany, 117.6; France, 100.9; Switzerland, 83.2; Italy, 82.5; the Netherlands, 54.3; Belgium, 42.2; Portugal, 27.5; Canada, 22.0; Japan, 21.1; Republic of South Africa, 19.0; Spain, 14.3; Venezuela, 11.2; Bank for International Settlements, 5.6; others, 149.9. Compared with 1972, the greatest changes were shown in stocks of the Republic of South Africa, up 1.1 million ounces; Belgium, down 0.9 million ounces; and Portugal, up 0.6 million ounces. Also, Philippine stocks dropped 0.8 million ounces to 1.07 million ounces. "Paper gold" Special Drawing Rights (SDR's) in the IMF were valued at $10,625 million at the end of 1973. Of this value, $7,963 million was allotted to industrial countries and $1,890 million to less developed areas. U.S. reserves in the form of SDR's were valued at $2,166 million at the end of 1973, compared with $1,958 million at the end of 1972. The unit of SDR remained by definition equivalent to 0.888671 gram of fine gold. IMF dollar values were based on $38-per-ounce gold before February 1973 and on $42.22-per-ounce gold thereafter.

Industrial.—Inventories of gold at domestic refiners and fabricators rose 2% during 1973 to 4.5 million ounces, according to data collected by the Office of Domestic Gold and Silver Operations, U.S. Department of the Treasury.

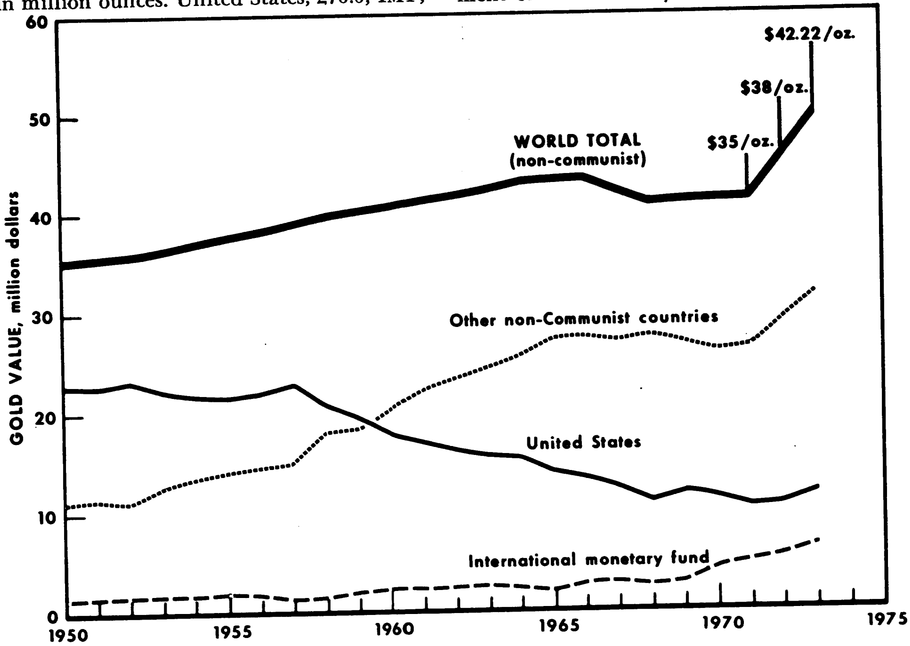

Figure 4.—World monetary gold stocks.

PRICES

During the year, free market gold prices rose from a low of $64.35 per troy ounce (Engelhard Industries selling price) to a record $126.45 about midyear, then declined. The low price was on January 18, and the high price was reached on June 5 and again on July 6 and 9. The high price was the maximum established by Phase III price ceilings, and the ceiling caused Engelhard Industries to suspend buying quotations 1 day on July 6. On January 2, the first trading day of 1973, the price was $65.55 per ounce, and on December 31, the last trading day, it was $112.75, $47.20 or 72% higher. The average price for the year was $97.81 per ounce, 67% higher than in 1972. The rise in prices was international and was generally attributed to less confidence in currency values, inflationary trends, unsettled world trade deficits, and limited supplies of new gold.

The U.S. official gold price was much lower in comparison, and remained at $38 per ounce until October 18, when it was raised to $42.22. October 18 was the date on which a September 21, 1973, devaluation law became effective (Public Law 93–110).

Table 2.—U.S. monthly gold selling prices, per ounce

(Engelhard Industries)

Month	1973		
	Average	Low	High
January	$65.59	$64.35	$66.55
February	74.67	67.05	86.95
March	84.87	80.45	90.45
April	90.96	89.70	91.70
May	102.41	90.75	115.20
June	120.61	116.00	126.45
July	120.46	114.75	126.45
August	107.10	94.50	118.00
September	103.39	100.50	106.60
October	100.58	97.25	104.25
November	95.77	90.50	102.25
December	107.37	100.75	112.75
Year	97.81	64.35	126.45

FOREIGN TRADE

Gold exports in 1973 totaled 2.99 million ounces valued at $146 million and went largely to Switzerland (69%), Uruguay (12%), the United Kingdom (7%), and Canada (6%); the balance went to seven other countries. Scrap comprised 11% of the exports, going to the United Kingdom (46%), Belgium-Luxembourg (44%), and six other countries. About 83% of the exported gold consisted of monetary metal, going to Switzerland, Canada, and Uruguay.

Total imports of 3.84 million ounces of gold were valued at $356.2 million. The bulk of the imports came from Canada (39%), Switzerland (32%), and the U.S.S.R. (21%). The balance was from 31 other countries. Virtually all imported gold was destined for industrial use. In addition to import sources, industry was supplied with 1.70 million ounces from foreign stocks on deposit at the Federal Reserve Bank, New York.

Net imports of gold showed a decline compared with those of 1972 (figure 5). The net value in 1973 was $210.2 million versus $294.6 million in 1972. The 1973 net value was not directly comparable with that of 1972, because reported exports in 1973 included a large quantity of monetary gold (2.21 million ounces), which was shipped at the lower, official monetary value. Net quantities imported in 1973 and 1972 respectively were 0.86 and 4.65 million ounces, showing a much sharper drop in net trade. The inflow of gold in ore, scrap, and base bullion was 70% of the outflow in the form of scrap.

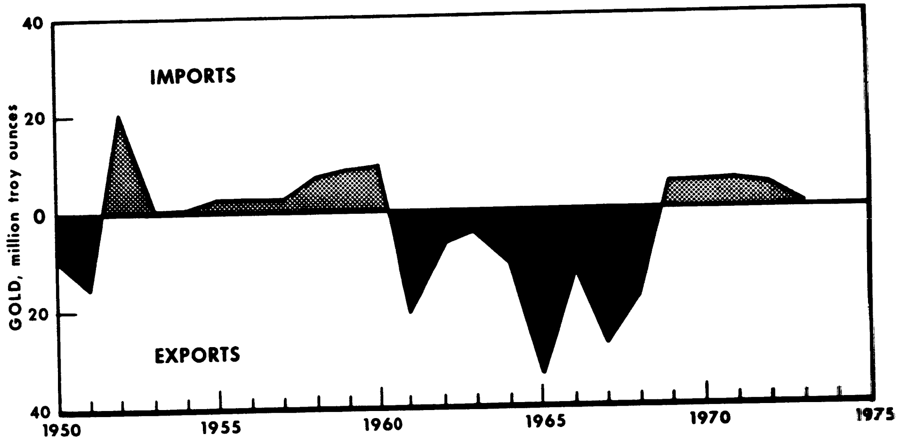

Figure 5.—Net exports or imports of gold.

WORLD REVIEW

World gold production (figure 6 and table 14) declined for the third straight year to 43.1 million ounces, a 3.7% drop. Outputs were lower in major producing countries except the U.S.S.R. where a 3% increase to 7.1 million ounces was estimated. All gold sales from the Republic of South Africa were made by the South African Government, whose selling policies had an important influence on gold markets. The bulk of South African gold was sold in Switzerland and moved from there to other markets. Quantities moving to markets were generally less in the first half of the year than in the second half. For the year, about 4% of South African production went into the Governments' reserves, and the balance was sold at free market prices. According to a major London gold trader, the total European industrial gold offtake in 1973 was 13.8 million ounces, about 2 million ounces less than in 1972. Italy remained the largest consumer with its important jewelry industry. Consumption in West Germany was estimated at 2.9 million ounces; in France consumption was believed to have increased to 1.9 million ounces, and in Spain an estimate of 1.6 million ounces was given. In addition, it was estimated that 12.5 million ounces were added to European speculators' holdings, including 3.2 million ounces to privately owned stocks in France. On balance, then, total European offtake approximately equaled total South African gold sales, and the remaining about 8 to 10 million ounces of non-Communist world production had to supply the rest of the world. U.S.S.R. sales to the free world were estimated between 6 and 9 (probably closer to 6) million ounces in 1973; as a net result, non-European countries probably received about 15 million ounces of gold, about 75% destined for industrial purposes.

Angola.—Negotiations were conducted by the Angolan Sociedade Mineira da Huila, Lda., of Sá da Bandeira to form an international consortium to explore gold deposits in the southern part of the country. Development of deposits near Chipindo was under consideration.

Australia.—Australian gold output rose sharply in 1973 responding to higher prices. Western Australia reopened its state-owned custom gold mill at Laverton early in the year. Gold Mines of Kalgoorlie, owned by Western Mining Corp. Ltd., and the Lake View and Star gold mines, owned by Poseidon Ltd., merged operations under a new company, Kalgoorlie Lake View Pty. Ltd., and planned renewed development work in Western Australia's "Golden Mile." Newmont Mining Co. reported the discovery of gold in a new area about 180 miles from the seacoast in a remote region of the Great Sandy Desert of Western Australia. Exploration and evaluation work was underway.

Bolivia.—Disputes continued in 1973 between the Bolivian Government and South

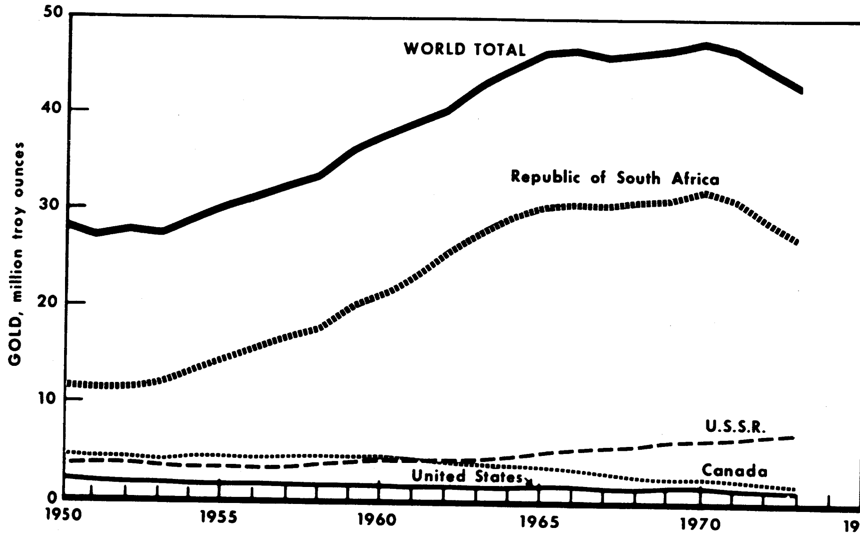

Figure 6.—World production of gold.

American Placers Inc. (United States) over whether past gold production operations in the Teoponte area had been conducted in accordance with expectations. In July, the Government issued a decree that required the U.S. firm to present within 6 months concrete work plans for mining an 11,700-hectare concession area; otherwise, the area would revert to the Government.[19] Continued placer operations on approximately 700 hectares of land would not be affected. A new law was passed regulating exploration and mining of gold in National Reserve areas.[20] A new Canadian company, Camino Gold Mines, Ltd., was formed to explore and develop an area of placer gold deposits 85 miles northeast of LaPaz in the Tipuani River valley. Test equipment was flown to the area about yearend.

Brazil.—Anglo American Corp. and several Brazilian associates entered into agreements to explore for gold in the State of Bahia. Most Brazilian production continued to come from a group of lode mines in the Nova Lima area of Minas Gerais.

Canada.—Gold production dropped 7% in 1973, continuing its long downtrend. Production value rose, however, by 55% owing to higher gold prices. Gold accounted for about 5% of Canada's metal production value and 2% of total mineral production value. Ontario remained the largest gold producing Province with 47% of the total national output, Quebec was next with 25%, and the Northwest Territories and British Columbia followed with 13% and 10%, respectively. Manitoba and Saskatchewan contributed 4% together, and less than 1% came from Newfoundland and New Brunswick. The Yukon supplied a few thousand ounces, and a few ounces were produced in Nova Scotia and in Alberta. The greatest percentage drops in production were in the Northwest Territories (18%), Ontario (12%), and Quebec (11%). Significant increases were shown in British Columbia (64%) and Manitoba (26%). Of all gold produced, quartz lode and placer mines supplied 73.6%; the balance was a byproduct from base metal mines.

In Ontario, plans to expand gold exploration and add production facilities were reported. An optimistic appraisal was made of the outlook for new gold discoveries in the Timmins-Val d'Or region of Ontario and Quebec.[21] An industry opinion survey

[19] U.S. Embassy, LaPaz, Bolivia. State Department Airgram A-165, Aug. 14, 1973, 4 pp.
[20] U.S. Bureau of Mines. Bolivia: Law Governing Gold Mining Concessions in the National Reserve. Mineral Trade Notes, v. 70, No. 12, December 1973, pp. 35-37.
[21] Mineral Resources Branch, Department of Energy, Mines and Resources, Canada. The Timmins-Val d'Or "Gold Belt" of Ontario-Quebec, Can. Min. and Met. Bull., v. 66, No. 730, February 1973, pp. 70-71.

indicated a potential for new discoveries in the area amounting to between 8 and 20 million ounces in gold content in deposits averaging about 0.25 ounce per ton of ore. Dome Mines Ltd. operated its Timmins, Ontario, mill at about full capacity of 2,000 tons per day, milling about 10% more ore at 6% lower grade than in 1972. Pamour Porcupine Mines Ltd. completed its mill expansion and operated at 2,500 tons per day beginning in March 1973. The cost of the 600-ton-per-day expansion was about $450,000. Mill feed was about 75% from the Pamour mine and 25% from the Aunor (No. 3) mine, both operated by the Noranda Group. McIntyre Porcupine Mines Ltd. continued operations at its 62-year-old mine near Timmins, milling about 900 tons per day of gold ore along with a larger tonnage of copper ores from parallel veins. Reserves of gold ore were estimated at a 2-year supply averaging 0.283 ounce per ton, and the company studied marginal ores and adjoining leased properties with the hope of expanding reserves in view of higher prices. On November 27, McIntyre Porcupine sold its Schumacher gold and copper properties to Pamour Porcupine Mines. To sale date, the 1973 production was 69,000 ounces of gold compared with 104,000 ounces for all of 1972.

In the Red Lake area, western Ontario, Dome Mines' Campbell Red Lake operation produced 196,190 ounces of gold compared with 196,855 ounces in 1972. Dickenson Mines Ltd. increased exploration at its extensive holdings in the Red Lake area and began to explore its newly acquired Rowan Gold Mines properties in Ball Township. Cochenour Wilians Gold Mines Ltd. planned to reopen its Wilmar mine, also in the Red Lake area. The deposit was believed to contain a large tonnage of ore grading 0.12 to 0.15 ounce of gold per ton, and plans were considered for a possible 1,000- to 2,000-ton-per-day milling operation. Kerr Addison Mines Ltd. maintained operations in the Larder Lake area, Eastern Ontario, at a milling rate of about 900 tons per day, its main mine at Virginiatown was estimated to have about 4 year's reserves with but little chance for additional marginal ores.

Camflo Mines Ltd. was the leading gold producer in Quebec with bullion output of 98,228 ounces in 1973, compared with 100,101 ounces in 1972. Dome Mines' Sigma Mines Ltd. was second with 78,204 ounces produced in 1973 versus 85,614 ounces in 1972. Other lode gold producers were East Malartic Mines Ltd., Lamaque Mining Co. Ltd., and Marban Gold Mines Ltd. The average grade for lode mines was 0.145 ounce per ton. In addition to 230,005 ounces from Quebec lode mines, 161,641 ounces of gold was produced from base metal mines, 40% of which was from Noranda Mines Ltd. The new $15 million gold operation of Agnico-Eagle Mines Ltd. was scheduled for production at 1,000 tons per day in late 1973. Reserves of 3 million tons averaging 0.29 ounce per ton were expected to be adequate for 10 years of production. The mine is located in Joutel Township. It was developed to the 1,800-foot level and will utilize a trackless haulage combined with sublevel bench mining method. Chibex Ltd. planned to open a mine in the Chibougamau area where ore reserves were estimated at 1.2 million tons grading 0.229 ounce per ton of gold and 0.5% copper. Equipment was being assembled for a 750-ton-per-day mill in late 1973. In Cadillac Township of northwestern Quebec, Gold Hawk Mines Ltd. continued core drilling and prepared to ship ore to a nearby mill. The property was about 17 miles from Malartic on the Noranda-Val d'Or highway. Quebec Sturgeon River Mines Ltd. prepared to mine a nearby 1-million-ton ore body averaging 0.217 ounce of gold per ton at its Batchelor Lake property in northwestern Quebec.

Cominco Ltd. planned a $5 million investment in the Con mine at Yellowknife, Northwest Territories. Mill capacity was about 500 tons per day, and ore reserves included over 1 million tons grading 0.07 ounce per ton. O'Brien Gold Mines Ltd. planned underground development at its Cullaton Lake property in the Northwest Territories, after favorable drill results. In British Columbia, Bralorne Resources Ltd. undertook a major gold exploration program at its Bralorne-Pioneer property.[22] A 200- to 300-ton-per-day operation was foreseen for the Brandywine gold-silver property 70 miles north of Vancouver, British Columbia, by its owner, Northair Mines Ltd. Home Oil Co. Ltd. and Mosquito Creek Gold Mining Co. Ltd. joined to explore and develop gold claims in the Wells-Barkerville area, British Columbia. Kennco Explorations Ltd., a subsidiary of

[22] Western Miner. Bralorne Reborn. V. 46, No. 8, August 1973, pp. 24–25.

Kennecott Copper Corp., continued exploring newly found gold-silver veins averaging 10 feet in width in the Toodoggone area, 170 miles north of Smithers, British Columbia.

Colombia.—Pato Consolidated Gold Dredging Ltd. reported 1972 production at 63,104 ounces of gold from 17.9 million cubic yards of material at its operations near Bagre in Northeast Antioquia, and 1973 output was expected to be higher. A fifth dredge, planned to go into operation in 1974, was expected to increase production about 18%. Proven reserves were estimated to be adequate for continued full-time operations for the next 15 to 20 years. Cia. Minera Chocó Pacifico operated five dredges in the San Juan River basin, near Andagoya, in the Department of Chocó, northwest Colombia, producing gold and platinum. From 1966 to 1971, an estimated 1.1 million ounces of platinum and 2.4 million ounces of gold were produced from 700 million cubic yards of material mined from the Chocó deposits. Output in 1973 was estimated at 9,000 to 10,000 ounces of platinum and about twice that amount of gold. Most of the balance of Colombian gold and platinum production came from operations of Cia. Minera Frontino Gold Mines, with properties in the Department of Narino. During 1973, the Colombian Government took steps that could lead to possible expropriation of foreign company mining rights and properties.[23]

Costa Rica.—Cia. Minera del Guanacaste, which opened the Tres Hermanos gold mine in the Abangares area in April 1972, expanded milling capacity by addition of a 50-ton-per-day ball mill and flotation cells to a stamp mill equipped with two, five-stamp batteries and amalgamation tables. The Bulora Corp. (Canada) reopened the El Libano gold mine near Tilaran and began construction of a 100-ton-per-day cyanide mill to be operative by March 1974.[24] Mining costs at the El Libano were estimated at $15 to $17 per ton of ore, and inferred and indicated reserves totaled about 161,000 tons grading 0.84 ounce of gold and 0.88 ounce of silver per ton.

Dominican Republic.—Gold and silver production was scheduled to begin about yearend 1974 from the Pueblo Viejo mine, under development northwest of Santo Domingo by Rosario Resources Corp. Plant construction costs were expected to exceed $24 million, and planned milling capacity was revised upward from 6,000 to 8,000 tons per day. When fully operating, the mill was expected to produce 350,000 ounces of gold and 1.5 million ounces of silver annually in the form of doré bullion to be refined elsewhere. Ore reserves were increased 50% during the year to 30 million tons as a result of further studies.

El Salvador.—Production was planned by San Sebastian Gold Mines, Inc. (United States) at a rate of 100 tons per day at the company's leased property near Santa Rose de Lima. The mine was scheduled to produce at a rate of 1,200 ounces of gold per month after startup, planned in March 1974. Other deposits in the eastern portion of El Salvador were said to have potential.[25]

Ethiopia.—Virtually all production continued to come from the Government-operated Adola gold mine, a placer producing 20,000 to 30,000 ounces of gold annually; a minor quantity of platinum was produced with gold at the Government Yubdo mine.

France.—The source of most French production, Mines de Salsigne, was slated to change ownership through an agreement to purchase control by two Canadian firms, New Calumet Mines Ltd. and Jorex Ltd. The mine, located near Carcassonne in southern France, produced at a rate of 170,000 tons of ore annually, with resulting output of about 66,000 ounces of gold, 170,000 ounces of silver, 385 short tons of copper, 60 tons of bismuth and arsenic, and sulfuric acid byproducts. Other gold concessions in the Limoges area of central France were included in the agreement. Salsigne ore reserves were estimated at 2.8 million tons averaging 0.38 ounce and 1.34 ounces per ton, respectively, of gold and silver.

Ghana.—The Ghanaian Government continued to control sales of gold and during the year proposed an export duty equivalent to about $2.10 per troy ounce after the first 100,000 fine ounces. The Ashanti goldfields area was the source of most Ghanaian production, with sales mainly in Switzerland. Interest was revived in establishing a gold refinery at Tarkwa.

[24] Northern Miner (Toronto). Canadian Firm Developing Gold Mine in Costa Rica. V. 59, No. 23, Aug. 23, 1973, pp. 1, 6.

[25] U.S. Embassy, San Salvador, El Salvador. State Department Airgram A-166, Nov. 27, 1973, 2 pp.

Honduras.—Rosario Resources Corp. reopened its silver-gold mine at San Juancito and planned gold placer operations in the Mosquitia area of Honduras.

India.—Production in 1973 was slightly higher than in 1972. The Government in April 1972 consolidated its two gold-mining companies, the Kolar and Hutti, into one organization, the Bharat Gold Mines, Ltd., hoping this would encourage modernization and greater efficiency. Annual subsidies of $5.6 million were provided in new budget estimates to offset operating losses. The Kolar mines produced 67,997 ounces of gold in 1972; the Hutti mine produced 37,776 ounces. Average ore grades were 0.17 to 0.18 ounces per ton, respectively. Combined ore reserves were estimated at 4.2 million tons averaging 0.27 ounce per ton, with most of the remaining accessible ore in the Champion Reef at depths in excess of 10,000 feet.[26]

Japan.—Beginning April 1, 1973, all restrictions and duties on the import of gold ingot were removed, and on July 1 restrictions on importing gold products were also removed, although a 20% duty remained. The action stemmed from rapidly expanding Japanese industrial demand and declining production capabilities. Plans were announced by Sumitomo Metal Mining Co. to close its formerly important Konomai gold mine in Hokkaido because of high costs. Output was down to about 10,000 ounces per year.

Mexico.—The Mexican Comisión de Fomento Minero joined with a U.S. firm to explore the possibly large Loma Bonita gold placer in southern Mexico. The Government organization received options and a 20% equity as part of the agreement. The new discovery was believed to be in the State of Guanajuato.

Nicaragua.—Rosario Resources Corp. purchased the Nicaraguan properties and assets of La Luz Mines Ltd. and planned to reactivate gold operations at Siuna, where they were suspended in 1968. An extensive exploration program was planned to develop additional reserves. The purchase included the Rosita copper mine, which has been a consistent source of byproduct gold, supplying about 17,000 ounces in 1970–71.[27]

Panama.—Copper and gold exploration and extraction concessions were offered by the Government in the Río Pito area of Panama. The deposits, originally discovered during a United Nations study, were located in an isolated area on the Caribbean side of Panama in the San Blas region near the Colombian border. Under a new draft of the Minerals Resources Code, requests for exploration concessions were to be accompanied by a $100 payment and those for extraction concessions by a $500 payment. Bison Petroleum & Minerals Ltd. and Pavonia S. A., a subsidiary of Canadian Javelin Ltd., obtained a large concession, which included the El Remance gold deposit estimated to contain 115,000 tons of ore averaging from 0.25 to 0.33 ounce of gold per ton.

Papua-New Guinea, Territory of.—Byproduct gold production at the Bougainville copper mine exceeded expectations. From the second to the fourth quarters 1972, grades increased from 0.019 ounce of gold per ton and 0.67% copper to 0.034 ounce of gold per ton and 0.86% copper. Tonnages produced in 1973 were above forecast rates. Plans were announced by Kimberley Securities Ltd., Rumble Explorations Pty. Ltd., and Mt. Isa Mines Ltd. for a joint gold placer operation of Porgera, New Guinea. Reserves in two areas were estimated at 2.25 million cubic yards averaging 0.0175 ounce of fine gold per yard (April) and 120,000 cubic yards averaging 0.125 ounce per yard (Denys Creek). A 3- to 5-year mining operation was envisaged. Lode deposits were also studied. New Guinea Goldfields, Ltd., continued open pit operations in Papua-New Guinea, treating about 7,000 tons of ore monthly at its Golden Ridges mill. Milling problems reduced output to about 500 fine ounces of gold and 250 ounces of silver per month.

Peru.—Banco Minero del Peru conducted an intensive program to encourage new gold placer mining in the area known as the "selva." In addition to deposits on the Inambari River, the bank promoted mining in the Chinchipe, Perené, Marcapata, Quince Mil, and San Juan de Oro areas. The "selva" was a source of about 4,000 ounces of placer gold in 1972 and was expected by the bank to supply over 20,000 ounces in 1973. Meanwhile, Natomas Company of Peru, subsidiary of Natomas Co. (United States), discontinued operations in

[26] U.S. Embassy, New Delhi, India. State Department Airgram A-191, May 31, 1973, pp. 54–56.

[27] Bevan, P. A. Rosita Mine—A Brief History and Geological Description. Can. Min. and Met. Bull., v. 66, No. 8, August 1973, pp. 81–84.

early 1972 at its gold placer properties about 30 miles north of Lake Titicaca. The bulk of Peruvian gold in 1973 continued to come from six mines of the Cerro de Pasco Corp., the Cobriza, Cerro de Pasco, Yauricocha, San Cristobal, Casapalca, and Morococha. Metals were refined at the La Oroya metallurgical complex.

Philippines.—Gold production was lower in 1973, mainly because of declining byproduct output from copper mining. The Philippine Monetary Board pursued plans for the Central Bank to establish a gold refinery which would treat the country's gold ore products.

Rhodesia, Southern.—The Rhodesian Government introduced an assistance program of "establishment loans" carrying a 6% rate of interest under which the gold miner was not required to repay the loan if the project failed or if the free market gold price fell below U.S. $55 per ounce. By the end of 1972, three loans were granted, two were under final approval, and eight applications were under study. In 1973, four new gold mines were being brought into production and two others were under development. Among gold mines reopened were the Champion, near Odzi, and the Bar-Twenty at Gwanda. As a result of higher gold prices, Falcon Mines Ltd., one of Rhodesia's largest gold-mining groups, increased its ore reserve estimate to 781,000 short tons averaging 0.33 ounce of gold per ton. The group planned renewed operations at its Turkois and Venice mines after dewatering.

South Africa, Republic of.—For the third consecutive year, production dropped, falling 6% to 27.5 million ounces. Comparative data for gold producers reporting to the Chamber of Mines of South Africa (virtually all producers) showed a 4% increase in the tonnage of ore milled to 80.8 million short tons but a 10% decline in the average grade to 0.34 ounce per short ton in 1973. During the year, the grade for all mines including uranium producers dropped from an average 0.342 in the first quarter to 0.318 in the fourth quarter. The drop reflected producers' efforts to prolong effective life of the operations by exploiting lower grade sections of ore bodies.

Working revenue of gold mines rose by more than 53% to R1,754 million ($2,613 million) over the 1972 figure; however, working costs also rose by nearly 25% to R770.3 million ($1,148 million), owing to increased labor and equipment expenses. Moreover, because of greater working depths labor productivity was estimated to have dropped by 10% since 1969, a reference year. Improved productivity and technology were to receive priority attention during 1974 according to the Mine Managers Association meeting in Johannesburg. Capital expenditure on gold mining was reported 115% higher in 1973, increasing by during 1973. Working profits of gold mines associated with the Chamber of Mines rose 88% during 1973 to R983.3 million ($1,466 million). Tax revenues paid from these profits to the South African Government were reported 115% higher in 1973, increasing by R267 million ($398 million). During the year the South African Central Bank increased its gold reserves 6% or 1.08 million ounces to nearly 19 million ounces, in effect withholding about 4% of production from world markets.

As in past years, the bulk of gold production came from the Transvaal region of the country, and 25% to 30% was produced in the Orange Free State. The West Driefontein mine, about 20 miles west of Johannesburg, remained the world's largest and richest gold producer with an output of 2.35 million ounces from ores averaging 0.904 ounce per ton. Other mines producing over 1 million ounces in 1973 included Vaal Reefs, Western Deep Levels, Western Holdings, President Brand, Free State Geduld, Harmony, Hartebeestfontein, Buffelsfontein, Blyvooruitzicht, and President Steyn. The lowest average grade mined by any of 40 principal gold producers was 0.096 ounce per ton at the East Daggafontein mine; the highest average grade was at the West Driefontein.

A tributing agreement between the West and East Driefontein mines, whereby ores were transported through West Driefontein workings, was ended in March, and stoping began in the No. 4 shaft area of the East Driefontein for the first time since 1968 when workings were flooded. A new mill at the East Driefontein mine was scheduled for completion early in 1975 and was to be the largest gold mill in the Republic of South Africa. Operations were to expand from 960,000 tons in 1973 to 2.17 million tons in 1976. At the Western Deep Levels mine, world's deepest, operations were conducted about 12,000 feet below the surface and plans were considered to go to 14,000 feet. The President Steyn No. 4 shaft, 7,750 feet deep and the world's deepest single-lift shaft, was completed, providing new capacity for an additional 246,000 tons of ore per month. On the Buffelsdorn farm, southwest of Western Deep Levels, a drill hole 8,500 feet deep cut the Ventersdorp contact reef, and a 2.3-foot section sampled contained 4.2 ounces of gold and 1.1 pound of uranium per ton of ore. The Vaal Reefs mine operators planned a large capital spending program, with about $37 million budgeted for the 1974 fiscal year. Ore production at Vaal Reefs and at Western Deep Levels was scheduled to rise to 6.1 and 3.2 million tons per year, respectively, by the end of 1974. Gold Fields of South Africa Ltd. planned a large new mine in the Deelkraal area to begin production about 1980. A $150 million capital investment was considered. The Brakpan mine was scheduled to reopen by the end of 1974 with output of 240,000 tons of ore per year and a minimum cutoff grade of 0.14 ounce per ton.

In the Orange Free State, south of the President Brand and President Steyn mines, the new Jurgens Hof mine, a $60 million investment, was under development. The mine was scheduled for production in 1978 at 864,000 tons of ore per year, the ores to be treated at the St. Helena cyanide mill nearby. The Elsberg and Western Areas mines were scheduled to merge operations for efficiency. Several nearby depleted mines had their lives extended as a result of higher gold prices and remained in operation after reassessing of reserves. Total general ore reserves of South African gold mines rose 30% to 182 million tons at the end of 1973. Grades were estimated to be slightly lower for most mines, but stoping widths were slightly greater than in 1972.

U.S.S.R.—Soviet gold sales to other countries were estimated at about 6 million to 9 million ounces in 1973, compared with 5 million to 6 million ounces in 1972. The Government's gold reserves were believed to be about 65 million ounces. In Siberia near the Arctic Circle, new placer gold operations were underway in the Bilibino region, while production declined from the Kolyma region where deposits were approaching exhaustion. A new nuclear powerplant was expected to begin supplying electricity to the Bilibino operations. The bulk of Soviet gold production continued to come from areas east of the Lena River.

TECHNOLOGY

Federal Bureau of Mines scientists assisted mine operators in evaluating the effectiveness of cyanide leaching and activated carbon gold extraction processes on their ores. Investigations of heap-leaching, which entails sprinkling weak cyanide solutions over the top of an open mound or leveled heap of ore and collecting the enriched solutions for gold extraction, revealed that, in general, for amendable ores 67% to 95% of the gold present could be extracted in 4 to 42 days. Extraction rates were dependent on coarseness of both gold and ore. Successful commercial applications of the process have been demonstrated with mine-run stripping waste at the Cortez mine in Nevada and on selected stripping material crushed to ¾-inch at the Carlin mine, also in Nevada.

At the Homestake mine in Lead, S. Dak., a carbon-in-pulp pilot plant, utilizing activated carbon as a gold collector mixed with the cyanide solutions and subsequently screened out, showed that 90% to 95% of the gold in a 0.15-ounce-per-ton slime feed could be successfully extracted this way. In March 1973, a 2,350-ton-per-day plant utilizing the carbon-in-pulp process was placed in operation at Lead, permitting the closure of an outmoded plate-and-frame filter-type leaching plant. After correction of minor problems with aeration, the unit operated fully up to expectations.

Slow stripping of gold from the activated carbon at atmospheric pressure remained a problem, and trials continued at several locations of a Bureau of Mines invented high-temperature stripping process that would significantly reduce stripping time, labor, and reagent requirements. In connection with this, work was in progress to accumulate data on equilibrium loading and desorption isotherms for gold and silver activated-carbon systems.

A sample tested by the Bureau of Mines from the Buckhorn gold mine, which is under development by the Carlin Gold Mining Co., showed 94% recovery of gold after grinding to 35 mesh, using activated carbon in a carbon-in-pulp test. Further tests indicated that heap leaching of the ore sized between minus 2 inches and plus 35 mesh, followed by adsorption on activated carbon, would provide recoveries of 83% of the gold in the coarse fraction and 68% of the total gold in the original ore; 17% of the total gold remained in the minus 35-mesh material.

At the new Gold Acres property of Cortez Gold Mines in north-central Nevada, a Bureau of Mines-type expanded-bed activated-carbon unit consisting of five open columns side-by-side began processing heap-leach solutions from adjacent prepared dumps. A high-temperature stripping unit was operated to remove the gold from the carbon; gold removal from the solution was virtually 100% before recycling to the dumps.

Laboratory investigations were reported using thiourea in an acid system at a pH of 1.0 to extract gold and silver with a view toward application to in situ leaching.[28] The effectiveness of the thiourea was said to be about 75% in comparison with cyanide, but the compound was believed to be more acceptable for in situ leaching for environmental reasons. The precious metals were recovered from solutions by conventional zinc dust precipitation or charcoal adsorption methods. Research was successful on a method of gold recovery from arsenopyrite and carbonaceous and oxidized gold ores employing sulfuric acid in the presence of sodium chloride to form a gold chloride complex.[29] In another process, gold was recovered from ore leaching solutions containing 4% to 80% concentrated hydrochloric acid using tetrahydrofuran to form a gold complex and extracting the complex with either methylene chloride or methylene bromide.[30] Gold was also extracted from gold leach solutions by treating an acidified solution with a chloride ion to form a gold complex, next passing the solution through a resin adsorption bed, and then stripping the resin with acetone, followed by evaporation and electrolysis.[31] A ketonic solvent containing iodine was used in another process to recover gold from ores or gold alloys,[32] and hydrogen sulfide in an oxidizing leach solution followed by aqua regia treatment was used to extract gold and platinum-group metals from copper-bearing mattes and sulfide ores in still another process.[33]

A group of articles was published on the treatment and destruction of cyanide solutions after use.[34] Most Canadian gold mills on which sample data were obtained were found to release cyanide in effluents exceeding 0.1 ppm, the proposed maximum of the Ontario Ministry of the Environment. Of four methods commonly used to dispose of cyanide wastes—oxidation, dilution with water or with other wastes, acidification and dilution or resulting gas with air, and alkaline chlorination—most Canadian operators applied only the first two. In a Film Layer Purification Chamber (FLPC) process, ozone, produced by electric discharge, was contacted with cyanide wastes sprayed into a chamber. Using this process, 91% to 97% of the cyanide present was decomposed in less than 2 minutes contact time. A commercial prototype plant was under construction. The metal-finishing industry produces a wide range of concentrations and volumes of cyanide wastes in periodic discharges. Generally, electrolytic destruction is used for high cyanide concentrations followed by oxidation, but a new system introduces a copper catalyst into the waste stream, the mixture then passing through an oxygen-bearing gas and finally through a carbon tower.

Cyanidation of gold ores following flotation was described at the Giant Yellowknife mine in Canada's Northwest Territories.[35]

Arsenic and antimony were removed by roasting before final cyanidation; Cottrell dusts containing these metals were treated by a cyanide leach-charcoal recovery process for lost gold. Effects of various alkalis and impurities on cyanide dissolution of gold were investigated.[36] Best extraction was achieved with sodium carbonate (soda ash). Lime, which is universally used, was found to have deleterious effects, especially with refractory ore, although its use tended to keep the consumption of cyanide low.

Three reports were completed covering work by the Bureau of Mines under the Heavy Metals Program (1966–70).[37] Work showed that underground mining of the Six-Mile placer gold deposit at Badger Hill, Nevada County, Calif. (selected as an example) would be uneconomical at then-existing prices but that potential existed if marketable gravel products could be produced at the same time. It was concluded that, generally, for the Tertiary channel gravel deposits of northern California, mining could only be conducted with marginal profits unless the price of gold remained substantially above $70 per ounce or there was significant recovery of byproduct materials. Studies at the Badger Hill placer mine indicated that the bulk of the gold is within 40 feet of bedrock and occurs in stacked, lenticular zones of cemented gravel largely confined to the relatively narrow, meandering course of the deepest portion of the bedrock channel. Techniques were suggested for improved drilling, sampling, and delineation of the pay zones.

Research on new gold-mining methods has resulted in development of a swing hammer rock-cutting machine that is particularly adapted to thin continuous veins or reefs such as those in South African gold mines.[38] Nine experimental machines were built and tested at the Doornfontein and Stilfontein gold mines, Republic of South Africa, mining out up to 1,300 square feet of vein area in 1 month, using one machine on a single-shift basis. Stoping widths were maintained by taking alternate top and bottom cuts, leaving the middle ore section, about 1.3 feet thick, to break out by itself. In a related development, a patent was issued on a method by which slots or holes were cut alongside a reef or vein by combined percussive and oscillatory action and the ore extracted by bursting due to natural rock pressures.[39] With a possible view to the future, a patent was issued on a method using a laser beam to fracture a rock face to a depth of several inches.[40] The technique was said to be particularly adapted to mining narrow seams of gold ore. Undersea mining of deposits containing gold and platinum was the subject of another patent.[41]

The Federal Bureau of Mines prepared a report discussing the potential for renewed lode gold mining in central Alaska near Fairbanks.[42] Inferred remaining resources in the area described were estimated at 4 million ounces. Details were given on gold placer deposits in Alaska,[43] Utah,[44] and Nevada[45] in a continuation of a U.S. Geological Survey series started in 1972. The Geological Survey reported on a gold anomaly found by soil sampling near the Yellow Pine tungsten mine in Valley County, Idaho.[46] The mean value of 23 samples

was 0.085 ounce of gold per ton of soil material.

Conglomerates were found to contain possibly significant amounts of gold in another Geological Survey study, which established the approximate ranges of values in the Harebell and Pinyon Formations in Northwestern Wyoming.[47] Preliminary analyses showed an average of 65 and maximum of 1,000 parts per billion (ppb) of gold in the Harebell Formation and an average of 84 and maximum of 8,700 ppb of gold in the Pinyon Formation. It was estimated that a volume of 75 cubic miles of these conglomerates was present in the Jackson Hole region.

In mineralogical studies it was found that gold and arsenic in unoxidized ores of the Carlin and Cortez gold mines in Nevada were the most abundant in pyrite.[48] No association was found between gold and carbonaceous material, which was a particularly interesting revelation because a carbon and gold relationship in these two mines has been widely publicized in the past. Geochemical studies were said to suggest the presence in British Columbia of Carlin and Cortez type gold deposits.[49] Douglas fir needles were included in the evidence. In another study, it was concluded that geochemical abundance data do not provide reliable guides to areas favorable for gold mineralization and, furthermore, such data do not help identify source rocks or clarify natural processes concentrating gold.[50]

The content of gold and molybdenum in a large number of copper deposits was investigated, and it was found that nearly every deposit that contained significant molybdenum produced only relatively small amounts of gold.[51] Age and relationships of mineralization in gold deposits were subjects of other articles.[52]

Mine fires occur periodically in South African gold mines where extensive amounts of timber are used in stoping and for pack supports. Because of increasing concern, the system of rescue and firefighting was examined, and procedures and strategies were reported.[53] Causes of variations in different gold placer sampling techniques were discussed in an article, which favored bulk sampling to reduce error.[54] Increased interest in reclaiming gold from old tailings prompted a report on experiences at the Cornucopia mine in northeastern Oregon.[55]

The subject of byproduct gold production including unit processing costs was studied by the Bureau of Mines.[56] Direct unit costs for byproduct production operations at 1,420 ounces per week were estimated at 25.4 cents per ounce of gold produced; unit depreciation costs for a similar size plant over 10 years were estimated at 2.4 cents per ounce of product. Byproduct gold supply was shown to be relatively unresponsive to gold prices.

Smelting and refining of gold was described at the Rand refinery in the Republic of South Africa.[57] The plant, which is

Table 3.—Mine production of recoverable gold in the United States, by State

(Troy ounces)

State	1969	1970	1971	1972	1973
Alaska	21,227	34,776	13,012	8,639	7,107
Arizona	110,878	109,853	94,038	102,996	102,848
California	7,904	4,999	2,966	3,974	3,647
Colorado	25,777	37,114	42,031	61,100	63,422
Idaho	3,403	3,128	3,596	2,884	2,696
Montana	24,189	22,456	15,613	23,725	27,806
Nevada	456,294	480,144	374,878	419,748	260,437
New Mexico	8,952	8,719	10,681	14,897	13,864
Oregon	875	256	244	(1)	(1)
South Dakota	593,146	578,716	513,427	407,430	357,575
Tennessee	126	124	192	176	68
Utah	433,385	408,029	368,996	362,413	307,080
Washington [1]	47,020	55,008	55,434	41,961	29,200
Total	1,733,176	1,743,322	1,495,108	1,449,943	1,175,750

[1] Production of Pennsylvania, Washington, and Wyoming (1969), North Carolina (1971), and Oregon (1972 and 1973) combined to avoid disclosing individual company confidential data.

Table 4.—Mine production of recoverable gold in the United States, by month

(Troy ounces)

Month	1972	1973
January	117,605	102,252
February	131,733	104,482
March	139,489	102,045
April	131,660	99,336
May	146,182	101,693
June	131,544	102,665
July	106,054	93,537
August	89,035	97,374
September	107,000	87,114
October	123,382	102,554
November	114,031	91,403
December	111,778	91,295
Total	1,449,943	1,175,750

Table 5.—Twenty-five leading gold-producing mines in the United States in 1973, in order of output

Rank	Mine	County and State	Operator	Source of gold
1	Homestake	Lawrence, S. Dak	Homestake Mining Co	Gold ore.
2	Utah Copper	Salt Lake, Utah	Kennecott Copper Corp	Copper, gold ores.
3	Carlin	Eureka, Nev	Carlin Gold Mining Co	Gold ore.
4	Cortez	Lander, Nev	Cortez Gold Mines	Do.
5	Sunnyside	San Juan, Colo	Standard Metals Corp	Lead-zinc ore.
6	Ruth Pit	White Pine, Nev	Kennecott Copper Corp	Copper, gold ores.
7	Knob Hill	Ferry, Wash	Knob Hill Mines, Inc	Gold ore.
8	San Manuel	Pinal, Ariz	Magma Copper Co	Copper ore.
9	New Cornelia	Pima, Ariz	Phelps Dodge Corp	Copper, gold ores.
10	Copper Queen-Lavender Pit	Cochise, Ariz	do	Copper ore.
11	Berkeley Pit	Silver Bow, Mont	The Anaconda Company	Do.
12	Idarado	Ouray and San Miguel, Colo	Idarado Mining Co	Copper-lead-zinc ores.
13	Morenci	Greenlee, Ariz	Phelps Dodge Corp	Copper ore.
14	Leadville	Lake, Colo	American Smelting & Refining Co	Lead-zinc ore.
15	Magma	Pinal, Ariz	Magma Copper Co	Copper ore.
16	Copper Canyon	Lander, Nev	Duval Corp	Do.
17	Continental	Grant, N. Mex	UV Industries, Inc	Do.
18	Hogatza River	Yukon River Region, Alaska	do	Placer.
19	Christmas	Gila, Ariz	Inspiration Consolidated Copper Co	Copper ore.
20	Tyrone	Grant, N. Mex	Phelps Dodge Corp	Do.
21	Trixie	Utah, Utah	Kennecott Copper Corp	Gold-silver ore.
22	Bonney-Misers Chest	Hidalgo, N. Mex	Federal Resources Corp	Copper ore.
23	Pima	Pima, Ariz	Pima Mining Co	Do.
24	Butte Hill Copper Mines	Silver Bow, Mont	The Anaconda Company	Do.
25	Copper Cities	Gila, Ariz	Cities Service Co	Do.

Table 6.—Production of gold in the United States in 1973, by State, type of mine, and class of ore yielding gold, in terms of recoverable metal

1 Included with gold-silver ore.
2 Includes other ore classes to avoid disclosing company confidential information. See additional footnote entries in table.
3 Included with gold ore.
4 Included with copper ore.
5 Included with copper-lead, lead-zinc, copper-zinc, and copper-lead-zinc ores.
6 Includes Oregon, Tennessee, and Washington.
7 Less than ½ unit.
8 Included with zinc ore.
9 Includes byproduct gold recovered from tungsten ore in California, fluorspar ore in Colorado, and uranium ore in Utah.

Table 7.—Gold produced in the United States from ore, old tailings, etc., in 1973, by State and method of recovery, in terms of recoverable metal

State	Total ore, old tailings, etc., treated [1,2] (thousand short tons)	Ore and old tailings to mills					Crude ore, old tailings, etc., to smelters [1]

[1] Includes some non-gold-bearing ores not separable.
[2] Excludes tonnages of fluorspar, tungsten, and uranium ores from which gold was recovered as a byproduct.
[3] Includes tonnages from which gold is heap leached.
[4] Includes tonnages from which gold is vat leached.
[5] Includes Oregon, Tennessee, and Washington.

Table 8.—Gold produced at amalgamation and cyanidation mills in the United States and percentage of gold recoverable from all sources

Year	Bullion and precipitates recoverable (troy ounces)		Gold recoverable from all sources (percent)			
	Amalgamation	Cyanidation	Amalgamation	Cyanidation	Smelting [1]	Placers

e Estimate. p Preliminary. r Revised.
[1] Unless otherwise indicated, production is on the basis of mine output.
[2] Gold is also produced in Bulgaria, Czechoslovakia, Spain, and probably in small quantities in Argentina, Burma, East Germany, Hungary, Thailand, and several other countries. However, available data are insufficient to make reliable output estimates. Data are lacking on clandestine activities.
[3] Bullion only; excludes gold from placer operations for which no data are available.
[4] Purchased by the Bank of Monrovia.
[5] Contained in blister copper, refinery muds, and electrolytic copper.
[6] Refinery production for Japan was as follows: 1971—772,652 ounces; 1972—845,628 ounces; 1973—1,052,775 ounces.

Graphite

By David G. Willard [1]

Crystalline natural graphite remained in short supply throughout 1973, and the market had grown perceptibly tighter by yearend. Prices of imported flake had risen by more than 20% and stocks were being heavily drawn upon. A principal cause of the shortage was a major decline in production in the Malagasy Republic, the main source of crystalline large-flake graphite. Supplies of amorphous graphite, however, remained sufficient, and attempts appeared to have been made to substitute it for the scarce crystalline flake.

Imports of natural graphite were up 21%, but the entire gain was in the amorphous form. Imports of crystalline flake slumped to 53% of the 1972 level. A steady rise continued in exports of natural graphite, which were 9% greater than in the previous year.

Demand continued its strong growth for a third consecutive year, compounding the already difficult supply problem. Some uses, particularly for crucibles, showed declines which appeared to have resulted from the inadequacy of supplies rather than any decline of industrial demand.

The manufactured graphite industry enjoyed another booming year as production registered an 11% gain. Almost all segments of the industry showed improved results compared with 1972 production, and prospects for 1974 remained good.

[1] Economist, Division of Nonmetallic Minerals—Mineral Supply.

[1] Estimated demand has been substituted for the consumption survey results previously published, since the latter are incomplete. A figure comparable to the previous series appears as the total of table 3.
[2] Includes some manufactured graphite.

Legislation and Government Programs.—As part of Administration efforts to reduce strategic stockpile inventories, more than half of the natural graphite in the stockpiles was declared surplus by the General Services Administration (GSA). Of the three types of stockpiled graphite, about half of the Malagasy and Sri Lanka types, and all graphite of other types were placed on the surplus list. However, Congressional authorization for their disposal had not been obtained, and no sales were made. All stockpiled graphite which had previously been authorized for disposal had been sold, although some shipments were still being made during the year.

Responsibility for determining requirements for strategic materials was transferred from the Office of Emergency Preparedness to GSA. Authorization for disposal, however, still required congressional action.

Table 2.—Government yearend stocks of natural graphite

(Short tons)

Types of graphite	National stockpile	Supplemental stockpile	Total all stockpiles
Malagasy crystalline flake:

PRODUCTION

In 1973 natural graphite production in the United States was again from a single location, the Southwestern Graphite Co. mine near Burnet, Tex. Shipments from the mine were slightly lower than in 1972, and continued to account for only a small portion of the domestic supply. Other graphite deposits in New York, Alabama, and Texas continued to draw the interest of investigators contemplating the development or redevelopment of additional mines, but no mine openings occurred or were in prospect at yearend.

Production of manufactured graphite continued its upward trend in 1973. Output of 306,212 tons was up 11% from the 275,311 tons produced in 1972. Total value of production increased 20% to $220.0 million from $183.6 million the previous year. The use of powder and scrap material declined from 29,479 tons and $4.1 million in 1972 to 25,722 tons and $3.7 million in 1973.

Metallurgical use of manufactured graphite again showed advances as the metal industries continued at high rates of production. Other uses, such as mechanical products made of graphite, also continued to advance. Graphite fiber has apparently strengthened its initial commercial acceptance in sporting goods such as golf clubs and tennis rackets. The first experimental applications have been made in the automotive field, particularly in the racing area, where the strength to weight ratio is important. These are the first non-defense applications of the graphite fiber materials.

Table 3.—Production of manufactured graphite in the United States in 1973, by use

(Short tons and thousand dollars)

Use	Quantity	Value
Synthetic Graphite Products		
Electrodes	216,043	147,240
Crucibles & vessels	5,971	11,650

Total	306,212	219,966
Synthetic Graphite Powder & Scrap	25,722	3,742
Grand total	331,934	223,708

[1] Quantity includes anodes, high modulus fibers & other. Value includes anodes, unmachined shapes, cloth, fiber, high modules fibers & other.

Manufactured graphite was produced at 25 plants in 1973, and some additional production for in-house use was likely. Therefore, the following list is probably not complete:

Company	Plant location
Airco, Inc., Speer Div	Niagara Falls, N.Y.
Do	Punxsutawney, Pa.
Do	St. Marys, Pa.
Avco Corp., Avco Systems Div	Lowell, Mass.
The Carborundum Co., Graphite Products Div	Hickman, Ky.
Do	Sanborn, N.Y.
Celanese Corp., Celanese Research Lab	Summit, N.J.
Fiber Materials, Inc	Graniteville, Mass.
Great Lakes Carbon Corp	Rosamond, Calif.
Do	Niagara Falls, N.Y.
Do	Morganton, N.C.
Hercules, Inc	Bacchus, Utah
HITCO	Gardena, Calif.
Morganite Modmor, Inc	Costa Mesa, Calif.
Ohio Carbon Co	Cleveland, Ohio
Pfizer, Inc.; Minerals Pigments & Metals Div	Easton, Pa.
Poco Graphite, Inc	Decatur, Tex.
Polycarbon, Inc	No. Hollywood, Calif.
Stackpole Carbon Co	Lowell, Mass.
Do	St. Marys, Pa.
Super Temp Co	Santa Fe Springs, Calif.
Union Carbide Corp	Niagara Falls, N.Y.
Do	Yabucoa, P.R.
Do	Columbia, Tenn.
Wickes Engineered Materials	Saginaw, Mich.

An expansion of the graphite fiber production facility at Bacchus, Utah, was announced by Hercules, Inc. New equipment will enable a doubling of the plant's output.[2]

CONSUMPTION AND USES

Demand for natural graphite remained on a strong uptrend in 1973, and the growth pattern was similar to that of 1972. Consumption in steel mills and foundries exhibited continued strength and again accounted for most of the increase. Use of graphite in brake and clutch linings and powdered metals was also considerably higher than in 1972. Consumption in the manufacture of crucibles and associated products declined sharply, probably resulting from the difficulty in obtaining Malagasy flake which is particularly important to that industry.

Total consumption of natural graphite was considerably greater than that shown in table 4, which reports only the results of a survey of known graphite consumers. Total graphite consumption is estimated to have been in the neighborhood of 79,000 tons in 1973.

[2] Includes mixtures of natural and manufactured graphite.
[3] Includes bearings and carbon brushes. Previously titled "Other mechanical products."
[4] Includes ammunition, packings, and seed coating.
[5] Includes paints and polishes, antiknock and other compounds, drilling mud, electrical and electronic products, insulation, magnetic tape, small packages, and miscellaneous and proprietary uses.

PRICES

Impelled by the continuing world shortage, graphite prices rose sharply in 1973. Since most of the U.S. supply is imported, domestic prices responded to the higher cost of foreign supplies. Prices of all the principal types of crystalline flake graphite imported by the United States were significantly above their 1972 levels, with increases ranging from 20% to 35%. Malagasy crystalline flake, the most important type of flake graphite and the one with the greatest decline in production, rose an average of 35% in price during the year. Mexican graphite, however, the principal amorphous type imported, remained unchanged in price. As a consequence, imports of Mexican graphite were up 33% in quantity compared with those of 1972.

Price quotations represent a range of prices. Actual prices are often on a negotiated basis between the buyer and seller. Therefore, the quotations which follow provide only a general guide to graphite prices and their trends. Another source of information, for imported graphite, is the average value per ton of the different classes of imports, which can be computed from table 6, although it should be kept in mind that these represent mainly shipments of unprocessed graphite.

No published source of domestic price quotations has been found which reflects the increases that have taken place in the last couple of years. Price information can be obtained from the companies which produce and import natural graphite. Representative prices of several types of imported graphite, published in the Engineering and Mining Journal, are shown below. All prices are f.o.b. the foreign port or border station and have been converted from metric tons.

	Per short ton	
	1972	1973
Flake and crystalline graphite, bags:		
Germany, West	$163–$929	$204–$1,179
Malagasy Republic	122– 336	159– 476
Norway	91– 145	109– 181
Sri Lanka	152– 259	181– 318
Amorphous, nonflake cryptocrystalline graphite (80% to 85% carbon):		
Korea, Republic of (bags)	22	27
Mexico (bulk)	22	22

FOREIGN TRADE

A further rise in exports of natural graphite occurred in 1973, continuing the uptrend begun the year before. Exports gained 9% to 7,953 tons compared with 7,289 tons in 1972. The principal buyer again was Canada which took 3,793 tons. Other countries purchasing several hundred tons apiece were the United Kingdom, Mexico, and Japan; and graphite was exported to 28 additional countries.

Imports of natural graphite increased sharply, but the rise did not signal an end to the graphite supply problem. The entire increase occurred in amorphous graphite imports from Mexico, while imports of crystalline graphite fell by more than 3,000 tons due to a 53% decline in receipts from the Malagasy Republic. The figures would appear to indicate an attempt on the part of industry to substitute the more plentiful amorphous graphite in products normally requiring crystalline flake, with a consequent increase in the quantities needed. Small increases occurred in imports of crystalline and amorphous graphite from the People's Republic of China and lump graphite from Sri Lanka, but the amounts were insignificant beside the shortfall in Malagasy flake.

Tables 5 and 6 give statistics on U.S. exports and imports of natural graphite in 1973.

WORLD REVIEW

World production of natural graphite increased slightly in 1973, but the gain was not sufficient either to overcome the decline of the previous year or to keep pace with the growing international market. Furthermore, a large part of the increase was in the amorphous form of graphite in Mexico and the Republic of Korea, while a crucial decline in output of the shortage-plagued crystalline graphite occurred in the Malagasy Republic. As a result, the overall situation in world markets was little changed from that which prevailed in 1972. Crystalline graphite remained in short supply and became increasingly costly, while supplies of amorphous graphite continued to be adequate.

India.—Plans to set up a graphite beneficiation plant in the Palamau district of Bihar State were announced by the Bihar Mineral Development Corp. No further details on the plant or its source of ore were given.[3]

Malagasy Republic.—Problems stemming from the continuing tense political climate in the country as a whole, and particularly in the graphite-producing region around Tamatave, caused a sharp drop in output during the year. Inability of the French-owned and relatively low-paying graphite mines to obtain sufficient labor was a major cause of the production decline and tended to discourage owners from undertaking needed expansion projects. Despite recurrent rumors, however, the government still showed no inclination to nationalize the industry. An additional serious difficulty arose when an ocean-shipping line refused to handle graphite shipments because of the risk of contaminating other cargo. Negotiations were under way at yearend, but the problem had not been resolved.[4]

Sri Lanka.—Production rose toward its former level as industry adjusted to government ownership. In addition, shipments to the United States became more regular, in contrast to the erratic pattern of receipts in 1972.

Other countries.—No further announcements were made concerning graphite discoveries near Niteroi, Brazil, and Razanj, Yugoslavia, that were reported a year ago, indicating that development of the deposits had not taken place.

[1] In addition to the countries listed, Czechoslovakia, India, Southern Rhodesia, and the Territory of South-West Africa produce graphite, but available information is inadequate to make reliable estimates of output levels.

[2] In part produced from imported crude graphite.

[3] Output of A/S Skaland Grafitverk only.

TECHNOLOGY

While research efforts continued to be concentrated on manufactured graphite and its uses in 1973, several new developments occurred either pertaining to natural graphite or applicable to both natural and manufactured graphite.

Graphite fluoride is one of many materials being studied as a solid lubricant and shows promise of being useful under high-temperature conditions. Tests of the wear life of graphite fluoride were described in a research report,[5] and a new product consisting of graphite fluoride with polyimide varnish as a binder was announced.[6] A new water-based forging lubricant, consisting primarily of graphite, was also described,[7] and the addition of graphite to an iron base cermet material will allow it to function in conditions of dry friction.[8]

The increasing importance of powder metallurgy was stressed in several speeches and articles during the year, with particular emphasis on its application to the automotive industry.[9] Much speculation centered on its possible use in parts for the new rotary engine.[10] Graphite is frequently used to supply the carbon in powdered steels. A research study of a powdered material containing graphite and tantalum carbide was also described.[11]

Also in the area of new materials, several processes for coating or impregnating graphite were announced.[12] These processes yielded graphites of higher strength and possibly improved resistance to oxidation. A patented refractory compound containing graphite, alumina, and silicon carbide, developed in Japan, was claimed to have good resistance to erosion, spalling, and oxidation.[13]

Fiber-reinforced composite materials once again held the center of attention for researchers in manufactured graphite during 1973. Graphite fiber costs dropped as low as the $40 to $50 per pound range, opening up new opportunities for commercial applications outside the aerospace field.[14] Improved types were also offered, including graphite ribbon.[15] However, research also moved forward on competing materials, and the future prospects of these graphitic materials remained uncertain.[16]

Graphite fiber composites have found several applications in the sporting goods area. Graphite golf club shafts have proved popular,[17] and graphite tennis racket frames are also in use. Racing car builders have taken advantage of the weight-reducing feature of composites in such components as wheels, bumpers, and dashboards,[18] and the horse racing industry has found an application for graphite shafts in sulky rigs.[19] Additional potential uses may be developed for various types of machinery.[20]

Numerous studies of new composite materials and processing methods were conducted. These studies covered a wide range of subjects including basic physical

analysis of graphite,[21] the properties obtained by combining various materials in composites,[22] and new methods of processing and fabrication.[23] The development of composites containing graphite and a metal continued to pose problems, but research results with aluminum looked promising.[24] One potential approach under study is that of bonding a graphite-epoxy composite to a metal.[25]

In addition to fibers and composites, other types of manufactured graphite materials were developed during the year. One was a carbon-graphite composition for use in making seal rings, bearings, and rotor vanes usable at elevated temperatures.[26] Other types were developed for mold materials in the casting of glass, ceramics, and metals.[27] A laminate containing steel, graphite and asbestos, which is expected to withstand the high temperatures of rocket nozzles, was also patented.[28] Finally, a product combining graphite ribbon with other forms of the material is expected to alleviate certain problems encountered in oxidative electrosyntheses.[29]

Gypsum

By Avery H. Reed [1]

The gypsum industry continued to operate at record levels in 1973. Output of crude and calcined gypsum set new annual records. Imports were about the same as in 1972. Sales of gypsum products were a record 20.6 million tons.

American Cyanamid Co. planned to build a $16 million plant at Savannah, Ga., to recover byproduct gypsum from its ilmenite plant sludge wastes. The gypsum will be made into wallboard. The Flintkote Co. purchased the Florence, Colo., mine and plant of Johns-Manville Corp. Kaiser Gypsum Co. Inc. planned to expand its New Jersey and Florida plants 30%. National Gypsum Co. planned to build a $60 million wallboard plant at Wilmington, N.C.

Energy.—The Bureau of Mines completed a comprehensive canvass of energy used in the mineral industries in 1973. All gypsum mines and calcining plants were covered.

The canvass showed that the gypsum industry depended on the use of natural gas and petroleum products for most of its energy requirements. Neither coal nor coke was used. Only 7% of the total energy used was purchased electricity.

At gypsum mines, 51% of the energy used was from diesel fuel, and 38% was purchased electricity. Most of this was used by heavy excavating equipment. At calcining plants, 73% of the energy used was from natural gas and 15% was from heavy fuel oil. Most of this was used for heat in the calciners. Total energy used was 14.8 billion kilowatt-hours.

The gypsum industry used 35 billion cubic feet of natural gas, 51 million gallons of heavy fuel oil, 991 million kilowatt-hours of purchased electricity, 18 million gallons of diesel oil, 8 million gallons of liquefied petroleum gases (LPG), and 1 million gallons of gasoline. On a total energy basis, only 3% was used in mining.

Petroleum products required for mining crude gypsum were 392 gallons of diesel fuel, 49 gallons of heavy fuel oil, 29 gallons of gasoline, and 7 gallons of LPG for each thousand tons produced. For calcining gypsum requirements were 3,696 gallons of heavy fuel oil, 961 gallons of diesel oil, 566 gallons of propane, and 69 gallons of gasoline for each thousand tons of calcined gypsum produced. In addition, 2.6 million

cubic feet of natural gas was required per thousand tons calcined.

Cost of energy used in the gypsum industry was estimated at $2.3 million for mining and $30.8 million for calcining. Energy cost per ton of crude gypsum was estimated at $0.17 per ton; the cost per ton of calcined gypsum was $2.45.

Each ton of gypsum mined required 32 kilowatt-hours of energy, and each ton of gypsum calcined required 1,142 kilowatt-hours.

DOMESTIC PRODUCTION

Thirty-nine companies mined crude gypsum at 69 mines in 22 States. Of these mines, 57 were open pit and 12 were underground mines. Crude output increased 10% to 13,558,000 tons, a new annual record. Leading States were Michigan, California, Texas, Iowa, and Oklahoma. These 5 States, with 29 mines, accounted for 60% of the total domestic production.

Leading companies were United States Gypsum Co. (13 mines), National Gypsum Co. (8 mines), Georgia-Pacific Corp. (7 mines), The Flintkote Co. (3 mines), and H. M. Holloway Inc. (1 mine). These 5 companies, operating 32 mines, produced 73% of the total output of crude gypsum. Leading individual mines were U.S. Gypsum's Plaster City mine in California, U.S. Gypsum's Alabaster mine in Michigan, National's Tawas City mine in Michigan, Holloway's Lost Hills mine in California, and U.S. Gypsum's Southard mine in Oklahoma. These five mines accounted for 26% of the national total.

Fourteen companies calcined gypsum at 76 plants in 30 States. Output was a record high of 12,592,000 tons, an increase of 5% over that of 1972. Leading States were Texas, California, New York, Iowa, and Indiana. These 5 States, with 29 plants, accounted for 44% of the total output.

Leading companies were U.S. Gypsum Co. (23 plants), National Gypsum Co. (19 plants), The Flintkote Co. (6 plants), Georgia-Pacific Corp. (10 plants), and Kaiser Cement & Gypsum Co. (5 plants). These 5 companies, operating 63 plants, accounted for 87% of the total domestic calcined output. Leading individual plants were U.S. Gypsum's Plaster City plant in California, Georgia-Pacific's Acme plant in Texas, U.S. Gypsum's Shoals plant in Indiana, Weyerhaeuser Co.'s Hot Springs plant in Arkansas, and U.S. Gypsum's Fort Dodge plant in Kansas. These five plants accounted for 14% of the national total.

Valley Nitrogen Producers Inc., Occidental Petroleum Corp., and Collier Carbon & Chemical Corp. sold 322,000 tons of byproduct gypsum valued at $1,931,000 for use in agriculture, in California.

The United States is the world's leading producer of gypsum, accounting for 20% of the total world output.

CONSUMPTION AND USES

Apparent consumption of gypsum (production plus imports minus exports) was 21.2 million tons, an increase of 6% and a new annual record. Imports were 36% of the total apparent consumption.

Of the total gypsum sold or used, 5.7 million tons (28%) was uncalcined. Of the total uncalcined gypsum, 4.1 million tons (73%) was used for portland cement, and 1.5 million tons (25%) was used in agriculture. The leading sales regions for gypsum consumed in cement were the West South-Central and the Middle Atlantic, which accounted for 34% of the total. For agricultural gypsum, the Pacific sales region accounted for 84% of the total.

Grand total [2]	14,184,059	13,078	497,744	15,004,025	13,793	563,594

[1] Includes weight of paper, metal, or other material.
[2] Data may not add to totals shown because of independent rounding.
[3] Includes ¼-inch, 5/16-inch, and ¾-inch gypsumboard.

Of the total calcined gypsum, 92% was used for prefabricated products and 8% was used for plasters. Of the prefabricated products, 72% was regular wallboard, 20% was Type X wallboard, and 2% was lath.

The leading sales regions for prefabricated products were the South Atlantic and the East North-Central, which accounted for 36% of the total. For plaster, the East North-Central and the South Atlantic accounted for 48% of the total.

PRICES

The value of crude gypsum increased from $3.93 per ton in 1972 to $4.18. The value of calcined gypsum decreased from $16.32 in 1972 to $16.31. The average value of byproduct gypsum sold was $6 per ton.

The average value of gypsum products increased from $28.88 in 1972 to $30.67. Prefabricated products were valued at $40.86, plasters at $33.94, and uncalcined products at $5.43 per ton.

Quoted prices for gypsum are published monthly in the Engineering News-Record. Prices at yearend showed a wide range, based on delivered prices. Regular ½-inch wallboard prices ranged from $41 per thousand square feet at Dallas to $86 at Chicago.

FOREIGN TRADE

The gypsum industry depends on imports. Imports of crude gypsum from Canada (78%), Mexico (16%), Jamaica (4%), the Dominican Republic and Italy (2%), totaled 7.7 million tons and supplied 36% of domestic consumption. Exports of crude gypsum were 63,000 tons.

WORLD REVIEW

Botswana.—Minerals Research Inc. planned to mine gypsum at Foley for use in cement. Deposits containing 3 million tons have been proved.

Canada.—Canada was the second leading producer of crude gypsum, accounting for 12% of the world total. Truroc Gypsum Products Ltd. planned to build a new wallboard plant at Vancouver.

France.—France was the third leading gypsum producer, accounting for 10% of the world total. Lambert Industries planned to build a new wallboard plant at Grand Quevilly.

Greece.—Reserves of gypsum in Greece amount to hundreds of millions of tons. They are located in the western part of the country, on the Ionian Islands, on Crete, and on some of the Dodecanese Islands.

Netherlands.—Rigips Baustoffwerke GmbH and the Dutch State Mines plan to build a wallboard plant at Born, using by-product phospho-gypsum.

Pakistan.—The West Pakistan Industrial Development Corp. announced the discovery of a 1-million-ton, 99% pure gypsum deposit near Sanghar.

U.S.S.R.—The U.S.S.R. ranked fourth in world gypsum output, accounting for 8% of the total.

United Kingdom.—The United Kingdom ranked fifth in world gypsum production with 6% of the total output.

TECHNOLOGY

United States Gypsum Co. developed a new process for granulating gypsum into granules of any size. A plant will be built at Sperry, Ohio, to make the new product. The gypsum will be compressed into sheet form, then broken up. The main use of the granules will be in agriculture. Farm use of gypsum has been limited owing to its fine texture which makes it difficult to handle and spread.

Helium

By Gordon W. Koelling [1]

Sales of high-purity helium (99.995% purity) in the United States during 1973 increased 2% to a total of 497 million cubic feet.[2] Approximately 36% of this total was sold by the Bureau of Mines and 64% was accounted for by private industry plant sales. Exports of high-purity helium, all by private industry, totaled 150 million cubic feet in 1973. The Bureau of Mines f.o.b. plant price for high-purity helium sold during the year remained at $35 per thousand cubic feet while private industry plant prices averaged $21 per thousand cubic feet.

In compliance with an order of the U.S. District Court for the District of Kansas issued on March 27, 1971, the Bureau of Mines continued to accept helium during 1972 under three of four conservation contracts whose termination provisions had been invoked by the U.S. Department of the Interior. This order rested on the ground that the Department had not filed an environmental impact statement on termination as required by the National Environmental Policy Act.

Following the release of an environmental impact statement by the U.S. Department of the Interior and an evaluation of the environmental consequences of terminating the contracts and careful consideration of options provided the Government under the contracts, the Secretary of the Interior, on February 2, 1973, issued notices terminating the three contracts in question. A further injunction against termination was granted by the District Court on the ground that the impact statement was unsatisfactory. The District Court order was reversed on appeal by the U.S. Court of Appeals for the Tenth Circuit in October 1973 and on November 12, 1973, the Department ceased the physical acceptance of helium for conservation storage. However, one of the companies involved in the litigation continued to deliver helium for 1 month to the Bureau of Mines for storage to its own account.

The issue of damages was pending in connection with a ruling made by the U.S. Court of Claims which held that the Government had materially breached its contract with the fourth contractor not involved in the above litigation.

DOMESTIC PRODUCTION

A total of 12 helium extraction plants were in operation during 1973. Of these, 2 were owned by the Federal Government and operated by the Bureau of Mines and 10 were owned by private industry.

Total helium extracted from natural gas during 1973 declined approximately 22% to 3,205 million cubic feet, despite a 3% increase in the output of high-purity helium to 647 million cubic feet. Approximately 80% of total helium extracted was crude helium[3] and 20% was high-purity helium produced for sale. About 93% of crude helium production and 72% of high purity output was from private industry plants producing for sale to commercial customers. The remaining 7% of crude and 28% of high-purity helium produced was extracted at Bureau of Mines plants.

Of the 357 million cubic feet of helium

[1] Geographer, Division of Fossil Fuels—Mineral Supply.
[2] All helium statistics in this chapter are reported in terms of contained helium measured at 14.7 pounds per square inch absolute and 70° F.
[3] Helium mixed with various quantities of other light gases, mostly nitrogen.

produced at the Bureau of Mines Keyes and Exell plants in 1973, approximately 83% was extracted from natural gas supplied by a private natural gas pipeline company on a gas processing contract basis. The remaining 17% was extracted from natural gas produced from the Bureau of Mines Cliffside gasfield primarily to create additional reservoir space for helium conservation storage. Almost all helium extraction from Cliffside natural gas occurred at the Exell plant.

Extensive modernization of the Exell plant was incomplete at the end of 1973 because of delays caused by technical problems. During the latter part of the year, the M. W. Kellog Co. submitted its engineering evaluation and recommendation of alternate concepts to correct purification deficiencies at unit IB. Kellog considered four concepts in its evaluation and recommended utilizing a pressure swing adsorption system in combination with the existing warm-end cold box equipment. This recommendation was under consideration at yearend. Kellog also completed engineering work for modifying enrichment unit IA and was planning to issue bid invitations for the necessary construction.

[4] Excludes return of conservation helium produced as indicated in footnote 2 to conservation storage system.

CONSUMPTION AND USES

Domestic sales of high-purity helium rose only about 2% during 1973, considerably less than the 9% increase registered in 1972.

Bureau of Mines helium sales, which accounted for 36% of the domestic market increased at a slightly higher rate than total domestic sales in 1973. This was a moderate reversal of a 6-year declining trend in the need for helium by Federal agencies, which are required by law to purchase all of their major requirements from the U.S. Department of the Interior. The Bureau of Mines f.o.b. plant price, which is set at $35 per thousand cubic feet for the purpose of financing the long-range helium conservation program, was not competitive with the 1973 average private f.o.b. plant price of $21 per thousand cubic feet.

Approximately 41% of Bureau sales in 1973 were through purchases by Federal agencies from private distributors under General Services Administration contracts, which required the distributors to purchase equivalent quantities from the Bureau of Mines. These contracts made relatively small quantities of helium readily available to Federal installations and reduced freight charges for small purchases. The quantity of Bureau helium sales distributed in this manner increased 40% during 1973.

Domestic consumption of helium during 1973 was primarily for purging and pressurizing rockets and spacecraft, research, welding, maintenance of controlled atmospheres, leak detection, and cryogenics. Demand occurred principally in the States along the west and gulf coasts.

All helium sold by the Bureau of Mines was shipped in gaseous form in cylinders, highway semitrailers, or railway tank cars. Private industry plants shipped helium in both gaseous and liquid form. Much of the helium transported in liquid form was delivered by semitrailers and containerized dewars to distribution centers, where most of the product was gasified and compressed into small cylinders and trailers for delivery to consumers.

[1] Includes quantities used by Bureau of Mines.
[2] Most of this was purchased in bulk by commercial firms, repackaged in smaller containers, and then sold to Federal installations under contract arrangements with the General Services Administration.

CONSERVATION

The purchase of crude helium by the Bureau of Mines, under the terms of contracts entered into with three private producers in 1961, continued during most of 1973 in compliance with court orders obtained during 1971 and early 1973 by Cities Service Helex, Inc., National Helium Corp., and Phillips Petroleum Co. As a result of the decision of the U.S. Court of Appeals for the Tenth Circuit in October, 1973, crude helium deliveries to the Bureau from Cities Service Helex, Inc., and National Helium Corp. ceased on November 12, 1973. However, Phillips Petroleum Co. opted to continue helium storage deliveries for its own account pending the outcome of negotiations on a long-term storage contract. These negotiations were unsuccessful and Phillips Petroleum Co. ceased deliveries for storage on December 12, 1973.

Helium held in the Bureau of Mines conservation storage system, which includes the conservation pipeline system and the partially depleted Cliffside gasfield near Amarillo, Tex., increased 7% during 1973 to a yearend total of 38,201 million cubic feet. Of this total, 97% was stored under the Bureau's conservation program (including that accepted under court order after March 28, 1971) and the remaining 3% was stored under contract for private producer's own accounts. Approximately 7% of the net addition to the helium conservation system in 1973 was accounted for by deliveries from Bureau plants, 89% was acquired from private industry plants for the conservation program, and 4% was added to storage under contract for private producers' own accounts.

[1] Includes some helium stored for the account of Cities Service Cryogenics, Inc., which pipes its output to Cities Service Helex, Inc., for purification.

RESOURCES

Proved and probable helium reserves (in natural gas with a minimum helium content of 0.3%) in the United States, exclusive of those quantities in conservation storage at the Cliffside field, were estimated at 114,090 and 41,298 million cubic feet respectively, as of December 31, 1973. The total 155,388 million cubic feet of proved and probable reserves available at yearend was 14% higher than at the beginning of the year. This increase resulted entirely from revisions to probable reserves.

Although proved and probable helium reserves were contained in the natural gas reservoirs of 86 gasfields located in 10 States, the bulk of reserves were in four fields: the Greenwood field in Kansas and Colorado; the Hugoton field in Kansas, Oklahoma, and Texas; the Keyes field in Oklahoma; and the West Panhandle field in Texas. Almost 66% of proved and probable reserves were in fields being produced at yearend 1973. Approximately 38% of the helium-rich (0.3% helium content) natural gas produced was being processed for helium extraction, and helium contained in the remaining helium-rich natural gas output was being wasted incident to the consumption of the gas.

The Bureau of Mines continued its efforts to identify helium resources in the United States and other parts of the world. A total of 348 natural gas samples from 17 States and Australia were collected and analyzed for helium content during 1973. None of these samples indicated the occurrence of significant helium resources.

FOREIGN TRADE

Exports of high-purity helium in 1973 increased almost 9% and comprised 23% of the U.S. helium industry's total high purity sales compared with 22% during 1972. All exports were from private industry extraction plants which depended on foreign markets for 32% of their total high purity sales in 1973. Most of the quantity shipped was destined for Western Europe.

WORLD REVIEW

Helium produced outside the United States during 1973 totaled an estimated 132 million cubic feet. Canada produced approximately 35 million cubic feet from a single plant in Saskatchewan, mostly for export to Japan and other Asian countries, although some was used in Canada. A plant in France produced about 7 million cubic feet of helium as a byproduct of nitrogen removal operations. The countries of Eastern Europe extracted an estimated 90 million cubic feet during the year.

During 1973, Petrocarbon Developments, Ltd., of the United Kingdom began construction, under contract, of a helium and nitrogen extraction plant in Poland. This plant will separate helium and nitrogen from natural gas which has about a 45% nitrogen content. A helium purification and liquefaction unit to be integrated with the nitrogen removal process will have a high-purity helium output capacity of 150 million cubic feet per year. Completion of this project was expected by 1975.

TECHNOLOGY

During 1973 the world's largest containerized liquid helium dewar was placed in service. This dewar, designed and built by the Gardner Cryogenics Division of Carpenter Technology Corp., has a capacity of 11,000 gallons of liquid helium (approximately 1.1 million cubic feet of gas equivalent) as compared with an 8,500-gallon capacity (approximately 860,000 cubic feet of gas equivalent) of the largest units previously placed in service. At yearend several additional 11,000-gallon dewars were under construction.

Gulf General Atomic Co., a subsidiary of Gulf Oil Corp., continued work on a preliminary planning study of a helium gas-turbine for the Atomic Energy Commission. This study will assess the commercial feasibility of developing a helium-cooled nuclear reactor and employing the same helium in a closed cycle to drive the gas-turbine generator. This would eliminate the steam-turbine cycle ordinarily used in powerplants and allow heat rejection to take place directly to air in dry cooling towers, thereby eliminating thermal pollution of streams and allowing utility companies more flexibility in picking powerplant sites. The gas turbines themselves could be located inside the same containment vessel that housed the reactor core, thus offering a capital cost savings.

Iron Ore

By F. L. Klinger [1]

With strong demand for iron and steel throughout 1973, world production of iron ore increased to an estimated 850 million long tons,[2] about 11% more than in 1972. The increase in world exports was estimated at 15% to 20%, with major increases reported from Australia and Brazil. Imports of iron ore by Japan, the European Economic Community (EEC), and the United States totaled 133 million tons, 117 million tons, and 43 million tons, respectively, and consumption in most industrialized countries rose to record levels.

World output of pellets was estimated at 150 million tons, about 18% more than in 1972, and continued rapid growth in this sector was expected. New pellet plants were completed, under construction, or contracted for in more than a dozen countries in 1973. Several new direct-reduction projects were also begun, notably in fuel-rich countries such as Iran, Venezuela, and Saudi Arabia.

Large beneficiation plants based on flotation or high-intensity magnetic separation came on stream in Canada and Brazil. These installations were the first commercial-scale plants of their kind. Another large flotation plant was due to begin production in the United States in 1974.

Iron ore prices in most countries increased during 1973. Increases in contract prices allowed by Japanese buyers ranged from about 10% to 15% and were made retroactive to April 1, 1973. The increases were allowed mainly to compensate for devaluations of the U.S. dollar in 1971 and 1973. By yearend, indications were that prices would rise further in 1974.

In transportation of iron ore, the average size of vessels and individual cargoes continued to increase on the Great Lakes as well as in ocean trade. The largest ocean cargo was 218,000 tons. A second port facility capable of accommodating 250,000-ton carriers was completed in Brazil, and a new receiving terminal capable of handling 100,000-ton vessels was completed in the United Kingdom. Ocean freight rates continued to rise during most of 1973; some reduction was apparent by yearend, but rising fuel costs due to large increases in crude oil prices were expected to drive freight rates still higher in 1974.

EMPLOYMENT

Due to changes in procedures of reporting or tabulation of statistics, aggregate data on employment at U.S. iron ore mines and mills in 1973 were not comparable to data reported for 1972. Consequently, publication of employment statistics for 1973 will be deferred until these differences can be resolved.

DOMESTIC PRODUCTION

As a result of strong demand for iron and steel, and a relatively low level of iron ore stocks at the beginning of 1973, U.S. mine production of usable ore increased to 87.7 million tons, 16% more than in 1972 and the highest since 1970. Mine shipments exceeded production by 3 million tons and were the highest since 1957. Vessel shipments of iron ore from U.S. ports on the Great Lakes in 1973 totaled 73.8 million tons, an increase of 10.2 million tons compared with those of 1972.

Pellets made up 70% of mine production and shipments of iron ore in 1973. Although the proportion was slightly less than in 1972, the actual output of pellets increased by 14% in 1973 to 61.2 million tons. Shipments of pellets totaled 63.7 million tons. Most of the increase in production came from the Minntac plant in Minnesota.

Production of crude ore in 1973 totaled 218.7 million tons, of which 95.6% was produced from 59 open pit mines and 4.4% was produced from 7 underground mines. The proportion of direct-shipping ore continued to decline and made up only 1.7% of the total output. The average iron content of crude ore produced was estimated at 33.9%. The average iron content of all usable ore produced was slightly higher than 60.5%, ranging from about 55% in direct-shipping ore and concentrates to about 63% in pellets. Nationwide, the ratio of crude ore mined to usable ore produced in 1973 (excluding byproduct ore) was approximately 2.50:1, the same as in 1972.

The Lake Superior district accounted for 84% of all crude ore mined in 1973 and 82.6% of all usable ore produced. Minnesota produced 68% of the total usable ore; Michigan produced 13% and the remainder was produced in 18 other States. Five mines were closed by yearend: two in Alabama and one each in Minnesota, Pennsylvania and North Carolina.

In Minnesota, production of iron ore pellets totaled 41.6 million tons in 1973, a 20% increase compared with 1972. The increase was mainly due to the first full year of production from new facilities at the Minntac operation of United States Steel Corp. Production capacity at Minntac was raised to 12 million tons per year in mid-1972. In mid-1973, Bethlehem Steel Corp. and Pickands Mather & Co. (PM) announced plans to construct a taconite mining and processing complex near Hibbing by 1977. Initial production capacity of the facility will be 5.4 million tons of pellets per year. Cost of the project, which was expected to employ more than 1,000 persons during the construction period, was estimated at $150 million. The Mahoning natural-ore mine was closed by PM in August due to exhaustion of ore reserves. The mine formed part of the famous Hull-Rust-Mahoning open pit and had been in almost continuous production since 1895. Also near Hibbing, the Hanna Mining Co. began stripping operations at the Whitney natural-ore mine in 1973. Ore from the Whitney mine will be processed at the Pierce concentrator. The Pierce mine was expected to be closed in 1974. Near Eveleth, nominal production capacity for iron ore pellets at the Fairlane plant of Eveleth Taconite Co. was increased about 10% to 2.4 million tons annually. On the western Mesabi range, parts of the Trout Lake concentrator were being dismantled and the plant was expected to be inactive in 1974. In the suit filed against Reserve Mining Co. by the U.S. Department of Justice, alleging pollution of Lake Superior by taconite tailings discharged from the company's Silver Bay plant, trial began in the U.S. District Court at Minneapolis on August 1, 1973. The trial continued into 1974.

In Michigan, construction of the Tilden taconite facility was continued. The project is designed to produce 4 million tons of pellets per year from 10 million tons of low-grade hematite ore. Production was scheduled to begin by the fall of 1974. At the Empire magnetic taconite facility, expansion of production capacity to 5.2 million tons of pellets per year was expected to be completed by mid-1974. Both projects are managed by The Cleveland-Cliffs Iron Co.

In Pennsylvania, the Cornwall mine near Lebanon was finally closed by Bethlehem Steel Corp. in 1973 after the open pit ore was mined out. The underground portion of the mine was closed in 1972. The mine was the oldest operating iron mine in the United States, having been in continuous production since 1742. During that time about 100 million tons of ore were produced.

In Alabama, production of brown-ore concentrates was terminated by two companies, due to lack of adequate markets. The Blackburn mine and plant, operated by Shook & Fletcher Supply Co. near Russellville in Franklin County, were apparently closed late in 1972. Davis Mining Co. stopped mining in Crenshaw County in mid-1973. United States Pipe and Foundry Co. continued to operate the Russellville No. 15 mine in Franklin County and appeared to be the only remaining producer of iron ore in Alabama.

In North Carolina, the Cranberry mine and concentrator in Avery County were closed at yearend by Greenback Industries, Inc. This operation had produced small quantities of high-purity magnetite concentrate which was partly used as heavy-media material and partly in manufacture of ferrites.

CONSUMPTION

Consumption of iron ore and agglomerates in 1973 was 15.7% more than in 1972 and was the highest on record. Of the total quantity, 98.2% was consumed in blast furnaces, 1.4% was consumed in steelmaking furnaces, and 0.4% was used for manufacture of miscellaneous products consisting mostly of cement and heavy-media materials. Consumption in steelmaking furnaces increased for the first time in several years; this appeared to be due mainly to a 14% increase in output of open-hearth steel in 1973 as compared with 1972. Consumption in blast furnaces increased 15.5%. In blast furnaces, the weight ratio of iron ore and agglomerates consumed to hot metal produced was approximately 1.58:1 in 1973, compared with 1.55 in 1972.

Pellets made up about 52% of all iron ore and agglomerates consumed in 1973, and 65.5% of all agglomerates consumed. The respective shares contributed by domestically produced pellets were 44% and 56%. These proportions were essentially the same as in 1972.

Consumption data are shown in tables 10 and 11. In these tables, iron ore concentrate used to produce pellets and other agglomerates at mine sites is not reported as iron ore consumed; its consumption was reported only when such agglomerate was shipped to the furnace site and used (table 10). Iron ore concentrates and fines used to produce agglomerates (such as sinter) at iron and steel plants is reported as iron ore consumed (table 11), and consumption of agglomerates derived from this source is included in table 10. In table 11, the difference in weight between iron ore consumed and agglomerate produced is due to additives such as mill scale, flue dust, lime, coke, and other materials.

STOCKS

Stocks of iron ore and agglomerates at U.S. mines, docks, and consuming plants totaled 59.9 million tons on December 31, 1973. The total was 11% less than a year earlier and was the lowest since 1956. Yearend stocks represented about a 5-month supply at the average rate of consumption in 1973. The 49 million tons on hand at U.S. docks and consuming plants at yearend included 30 million tons of domestic ores, 8.5 million tons of Canadian ores, and 10.5 million tons of other foreign ores.

PRICES

Published prices for Lake Superior iron ores increased in 1973. In March, prices for natural ores rose by 20 cents per gross ton and the price of iron ore pellets rose by 0.3 cent per long ton unit of iron, compared to the prices in effect on January 1. At the beginning of the 1973 lake shipping season, prices for natural ores, per gross ton, basis 51.5% Fe natural, delivered rail-of-vessel at lower lake ports, were: Mesabi non-Bessemer, $11.91; Mesabi Bessemer, $12.06; Old Range non-Bessemer, $12.16; and Old Range Bessemer, $12.31. The price of iron ore pellets was 29.4 cents per long ton unit of contained iron. These prices were 5% to 6.6% higher than those in effect 1 year earlier. Any increase in transportation or handling costs was to be borne by the buyer.

Effective October 1, 1973, the price of iron ore pellets delivered to Lake Erie ports by the Hanna Mining Co. was increased 2.2%, to 30.019 cents per long ton unit of contained iron. Prices for natural ores marketed by the company were unchanged.

The average value (f.o.b. mine or concentrating plant) of usable iron ore shipped from domestic mines in 1973 was $12.84 per long ton compared with $12.20 in 1972 and $11.55 in 1971. These values were calculated from producers' statements and approximated the commercial selling price less the cost of mine-to-market transportation.

Prices for most foreign iron ores during the first half of 1973 appeared to be unchanged or only slightly higher compared with 1972 levels. Exceptions to this were evident in Sweden, where the average export price in 1973 was 7% less than 1972, and in Canada and Venezuela where the value of iron ore exported to the United States increased due to the rise in U.S. Lake Superior prices.

Strong pressure for upward revision of foreign prices was generated by devaluation of the U.S. dollar in February, as most prices for foreign ores are quoted in dollars. By November, Japanese buyers had agreed to raise the prices stipulated in many contracts with foreign ore producers, retroactive to April 1, 1973. Compared with contract prices prevailing in the first quarter, the increases averaged about 13% for Indian ores and 15% for Australian and Brazilian ores.

Nominal prices quoted for certain foreign iron ores at Atlantic ports late in 1973[3] were about 20% higher than prices quoted earlier in the year. The price of Swedish pellets, basis 68% Fe, rose from $14.25 per ton to $17.00 per ton. Brazilian iron ore, basis 68% to 69% Fe, increased from $10.00 per long ton to $12.00.

Revised 1973 f.o.b. prices for iron ore products under Japanese contracts[4] indicated ranges as follows (dry long ton basis): For run-of-mine ore, 60% to 66% Fe, $8.96 to $9.75; for lump ore (including sized lump), 64% to 65% Fe, $10.35 to $11.60; 60% to 62% Fe, $6.40 to $6.80 (India) to $7.50 to $8.12 (Chile) to $10.13 (Australia); for fines, 64% to 66% Fe, $5.25 to $8.68; 60% to 62% Fe, $5.45 to $8.40; 57% Fe, $4.40 to $5.88; for iron sand concentrates, 59% to 60% Fe and 6% to 7% TiO_2, $6.10 to $6.65; for iron ore pellets, per dry long ton unit of contained Fe, 21.5 to 24.3 cents (Australia), 19.3 cents (India), and 25.35 cents (Canada).[5]

TRANSPORTATION

The iron ore shipping season on the Great Lakes started relatively early in 1973. Vessel shipments from most U.S. ports had begun by April 2. By yearend, nearly 65 million gross tons of ore had passed through the Soo Locks compared with 54.3 million tons during 1972. All lake shipments totaled about 74 million tons in 1973.

With strong demand for ore at consuming centers, and continued aids to winter navigation, shipments from all U.S. ports continued beyond normal closing dates for the season. Shipments of ore were made in January from all ports except Duluth, Minn., and the last cargo of the season left Two Harbors, Minn., on February 5. Navigational aids in the winter of 1973–74 included, for the first time, daily ice-distribution maps delivered electronically to vessels. The maps were images obtained from aerial surveys using side-looking radar.

Lake freight rates at the start of the 1973 shipping season were about 9% higher than those in effect 1 year earlier although less than half of this increase took place in 1973. Basic rates in effect in March 1973 were as follows, per gross ton: from the head of the lakes to lower lake ports, $2.45; from Marquette, Mich., to lower lake ports, $2.20; from Escanaba, Mich., to Lake Erie ports, $1.84; and from Escanaba to lower Lake Michigan ports, $1.47. No further increases were reported by yearend. Handling charges at discharging ports during the 1973 season were 5% to 6% higher than 1 year earlier, but charges at upper lake ports were unchanged.

Some statistics on lake shipments of iron ore, by port, during the 1973 season are shown in the following tabulation.

[3] Includes shipments in early 1974.

Principal source: Skillings' Mining Review, various issues, 1973 and 1974.

Rail freight rates for iron ore at the beginning of the 1973 shipping season on the Great Lakes were 4% to 6% higher than those in effect 1 year earlier. Some published rates[6] for selected routes were as follows (per gross ton): From Mesabi and Cuyuna ranges to Two Harbors, Minn., and Superior, Wis., $1.92; for pellets from McKinley and Mt. Iron, Minn., to Duluth, Minn., $1.70; for pellets from Marquette range to Escanaba, Mich., $0.95. The freight rate from Lake Erie ports to the Pittsburgh and Wheeling districts was $3.69 and that from Baltimore to the Pittsburgh district was $5.30. Rates for all-rail hauls from mines to consuming districts included Mesabi range to Chicago $6.98 and to the Pittsburgh and Wheeling districts, $13.91; Marquette and Menominee ranges to Chicago, $5.68, and to the Pittsburgh district $11.40; Pea Ridge, Mo., to Chicago $4.76; Black River Falls, Wis., to Chicago, $2.85; and Benson Mines, N.Y., to Cleveland, $6.48. No further increases were reported by yearend.

The size of ore-carrying vessels and the efficiency of materials handling systems on the Great Lakes continued to increase. The 1,000-foot, self-unloading tug-barge unit "Presque Isle," with cargo capacity of up to 59,000 gross tons of iron ore pellets, began service on December 16. The vessel will be used to transport pellets between Two Harbors, Minn., and the Gary, Ind., works of United States Steel Corp. Two 1,000-foot self-unloading bulk carriers were ordered in November by Pickands Mather & Co. The vessels were scheduled for delivery in 1976 and 1977 and will cost a total of about $75 million. The *Stewart J. Cort* and *Roger Blough*, having cargo capacities of up to 59,000 tons and 45,000 tons, respectively, transported a total of about 4.5 million tons of iron ore pellets on the lakes in 1973. Other new self-unloaders with cargo capacities ranging between 27,000 to 35,000 tons began service or were under construction. Other carriers were being lengthened to increase cargo capacity up to 28%.

Improved storage and materials handling facilities for iron ore and limestone were completed early in 1973 at the port of Conneaut, Ohio, by Pittsburgh & Conneaut Dock Co. The new facilities include a storage area for up to 3.2 million tons of material, a traveling stacker capable of stockpiling 10,000 tons per hour (tph), and two bucket-wheel reclaimers having a combined handling capacity of 5,000 tph. The system has an annual throughput capacity of 9.1 million tons in-and-out of storage. Formerly, there was little storage space and all iron ore had to be loaded directly into railway cars from the vessels. This required close scheduling of car availability with vessel arrivals and resulted in a heavy concentration of cars during 8 months of the year which caused traffic congestion during vessel delays.

In July, the Burlington Northern Railway Co. began a unit train operation between Hibbing, Minn., and Minnequa. Colo., a round-trip distance of about 2,400 miles. Trains of 110 cars, carrying 6,000 tons of iron ore, were scheduled to leave Hibbing every 173 hours. Initial plans called for shipment of 80,000 tons. The ore came from the Sherman mine and was destined for CF & I Steel Corp. Burlington Northern

[6] Skillings' Mining Review. V. 62, No. 51, Dec. 22, 1973, p. 2.

was also planning to expand its ore-handling facilities at Allouez, Wis., to accommodate future shipments of pellets from the new taconite project at Hibbing.

In foreign transport developments, shipments of iron ore began in November from the Minerações Brasileiras Reunidas (MBR) terminal at Guaiba Island in Sepetiba Bay, Brazil. The initial shipment was a cargo of 155,000 tons. The facility can load vessels of up to 300,000 deadweight tons (dwt) at rates up to 7,000 tons per hour. In Norway, bids were invited by the Swedish firm of Luossavaara-Kiirunavaara AB (LKAB) for expansion of iron ore shipping facilities at Narvik. Plans were to increase the maximum loading rate to 11,000 tph (7,200 tph for pellets) and to accommodate vessels of up to 400,000 dwt. In the United Kingdom, the Redcar iron ore terminal at Teesside was completed by the British Steel Corporation. The terminal can accommodate vessels up to 150,000 dwt and received its first 100,000-ton cargo of pellets in September. At other receiving ports, 13.8 million tons of iron ore were unloaded at Rotterdam (Europoort) in 1973, mostly for transshipment to West Germany. The largest incoming cargo was 151,000 long tons. About 3.4 million tons were unloaded at Port Talbot including one cargo of 105,000 tons.

Some statistics on foreign shipments of iron ore, by port, in 1973 are shown in the following tabulation.

Ocean shipping port	Number of vessels loaded	Total tonnage shipped (thousand long tons)	Average cargo (long tons [1])	Largest cargo (long tons [1])

[3] Excludes shipments by Liberia Mining Co. (LMC), for which data were not available. Total tonnage shipped includes IMC.
[4] Also known as Port Etienne or Point Central.

Principal source: Skillings' Mining Review, various issues, 1974.

Ocean-freight rates for iron ore continued to increase in 1973, partly because of devaluation of the dollar and increased demand for iron ore and other bulk commodities, and partly because a large number of vessels were occupied in the grain trade, particularly between the United States and the Soviet Union. Although freight rates for most of the iron ore shipped by sea were probably controlled under long-term contracts, spot rates published in various issues of "Metal Bulletin" indicated that freight charges for individual shipments in 1973 were often 40% to 75% higher than those charged for similar shipments late in 1972, and some were two to three times higher. There was a sharp drop in rates for some shipments of iron ore from South America and West Africa late in 1973, when the Arab oil embargoes increased the number of vessels available for dry cargo trade, but in general the rates remained much higher than those of late 1972.

Late in 1973, published freight rates for individual shipments of iron ore to West European and Japanese destinations showed the following approximate ranges: To West Europe from Brazil and Canada, $7.50 to $11.00 per ton for cargoes of 28,000 to 135,000 tons; from Venezuela, $12.50 to $14.00 per ton for cargoes of 34,000 to 40,000 tons; from West Africa, $5.00 to $9.00 per ton for cargoes of 55,000 to

90,000 tons; and from Australia, $11.00 to $12.00 per ton for cargoes of 50,000 to 110,000 tons; to Japan from Australia, $9.00 to $11.00 for cargoes of 110,000 to 137,000 tons; from Brazil, $15.50 for 95,000 tons; from Liberia, $16.75 for 57,000 tons; and from eastern Canada, $14.25 for 140,000 tons.[7] Published freight rates under some Japanese long-term contracts[8] ranged from about $4.00 to $8.00 per ton for Brazilian ore (vessels of 50,000 to 125,000 dwt) and for Indian ore (vessels up to 35,000 dwt), and $5.23 to $6.25 per ton for Swaziland ore (vessels of 80,000 to 90,000 dwt).

FOREIGN TRADE

U.S. exports of iron ore increased by 31% compared with those of 1972 but the total remained well below the levels of 1951–71. Exports to Canada via Great Lakes ports accounted for 82% of the total.

U.S. imports of iron ore for consumption in 1973 increased by 21% compared with those of 1972 but the total was 1.6 million tons less than in 1970. The increase was due to strong demand at consuming plants throughout 1973. The principal countries of origin were Canada, which supplied 50% of the total quantity, Venezuela (30%), Brazil (7%), Liberia (6%), and Peru (3%). Imports from Brazil increased by 2 million tons compared with 1972 and were the highest on record. Of the total quantity imported, 63% was landed at U.S. ocean ports and 37% was landed at Great Lakes ports. Philadelphia, Baltimore, Cleveland, Chicago, Mobile, and Buffalo continued to be the principal ports of entry.

The average f.o.b. value of imported ore in 1973 was $12.32 per long ton, compared with $11.63 in 1972. The average value of ore exported was $13.80 per ton compared with $12.78 in the previous year.

WORLD REVIEW

Angola.—Iron ore exports in 1973 by Cia. Mineira do Lobito (CML) totaled about 6.1 million tons, 23% more than in 1972. Of total shipments, 47% was destined for Japan, 25% for West Germany, and 14% for seven other countries.

CML, currently the only Angolan producer of iron ore, announced plans to build a pelletizing plant for ore from the Cassinga deposits. The plant will have a production capacity of 3 million tons of pellets per year and may be completed by 1977. Cost of the project was estimated at $87 million, of which 35% was to be provided by CML, 51% by two South African companies, and 14% by a group of British, West German, and French companies.

Cia. do Manganês de Angola, which formerly produced iron ore from deposits at Cassala, also announced plans to build a pelletizing plant and stated that the project would be managed by the Japanese firm of C. Itoh and Co. Exports of pellets were scheduled to start in 1976. The project includes construction of a pellet plant having production capacity of about 2 million tons per year, extension and improvement of the railway from Cassala to Luanda, and construction of loading facilities at the port of Luanda. Estimated total cost of the project was not announced.

Australia.—Production, shipments, and exports of iron ore set new records in 1973. Shipments totaled 86 million tons, of which about 72 million tons were exported. Exports to Japan totaled 65 million tons. Company shipments in 1972 and 1973, in thousand long tons, were as follows:

Producer	1972	1973
Hamersley Iron Pty. Ltd	22,117	27,268
Mt. Newman Mining Co. Pty. Ltd	21,443	26,316
Goldsworthy Mining Ltd	6,465	8,469
Broken Hill Pty. Co. Ltd	8,891	11,979
Cliffs Robe River Iron Associates	1,369	8,333
Savage River Mines	2,306	2,334
Frances Creek Iron Mining Corp	823	835
Western Mining Corp. Ltd	610	800
Total	64,024	86,334

Shipments of iron ore from the Paraburdoo mine were begun by Hamersley Iron Pty. Ltd. in 1973. Mt. Newman Mining Co.

[7] Metal Bulletin (London). Various issues, November–December 1973 and January 1974.

[8] The TEX Report Co. Ltd. (Tokyo). Iron Ore Import '73. Pages 96–146.

Pty. Ltd. and Goldsworthy Mining Ltd. also had expanded production capacity. Iron ore shipments from the Robe River project increased sharply as planned production facilities were completed early in the year. By yearend, total productive capacity of all Australian producers of iron ore was estimated at 115 million tons per year.

An estimated 9.15 million tons of iron ore pellets were shipped in 1973, compared with about 6 million tons in 1972. The Robe River project accounted for most of the increase. Hamersley was raising its productive capacity for pellets by 20%, to 3 million tons annually.

Kaiser Steel Corp. sold part of its interest in the Hamersley venture to a Japanese group in 1973. The sale reduced Kaiser's ownership share to 28.3%, from 34.5%. Hamersley was reported to have contracted to supply 3 million tons of iron ore during a period of 3 years to the People's Republic of China. Trial shipments to Chinese consumers were also reported by the Mt. Newman and Goldsworthy companies during 1973.

Bolivia.—Efforts were continued to utilize the iron deposits at Mutún. An agreement was signed in February 1973 to supply 50,000 tons of ore to the Argentine government for blast furnace tests at San Nicolás, Argentina. A second agreement, for 100,000 tons may be made if test results are favorable. Transportation facilities were limited, however, and only 15,000 tons of ore had been shipped to San Nicolás by yearend. The ore had to be hauled in 10-ton trucks about 75 miles from Mutún to a river loading point at Puerto Busch, from where it was carried by barge 1,250 miles to San Nicolás. For the river haul, a maximum draft of 9 feet was reportedly available for only about 4 months per year.

The possibility of constructing a direct-reduction plant near Mutún, to be fueled by natural gas from Bolivian fields, was being discussed with Brazilian authorities during negotiations for the sale of Bolivian gas to Brazil.

Brazil.—Production and exports of iron ore in 1973 were more than 30% greater than in previous years. Exports were estimated at 43 million tons, of which 24 million tons were destined for Europe and 14 million tons were destined for Japan.

Shipments of iron ore from the Aguas Claras mine of Mineraçoes Brasileiras Reunidas (MBR) began in July and the first export cargo (155,000 tons) was shipped from the Guaiba Island terminal late in November. The mine was expected to produce ore at the rate of about 11.3 million tons per year. At least 80% of planned production has already been sold under long term contracts with buyers in Europe, Japan, and Argentina. In 1973, MBR shipped 811,000 tons of ore from Aguas Claras and 1.4 million tons from other properties. The company was owned 51% by Empreendimentos Brasileiros de Mineração S.A. and 49% by St. John del Rey Mining Co. In the latter company, 66% of the ordinary shares was owned by the Hanna Mining Co.

Completion of the port facility at Guaiba Island, about 40 miles west of Rio de Janeiro, gave Brazil two iron ore ports capable of loading 250,000 dwt carriers. The other facility was operated by Companhia Vale do Rio Doce (CVRD) at Tubarão.

CVRD completed its second pelletizing plant at Tubarão early in 1973. The plant has a production capacity of 3 million tons of pellets per year and raised the total capacity of CVRD, the only producer of pellets, to 5 million tons annually. A third pellet plant, with production capacity of 3 million tons per year, was scheduled for completion at Tubarão by 1976. Sales of pellets reported by CVRD in 1973 totaled 4.4 million tons including 3.7 million tons for export. Sales in 1972 totaled about 2.5 million tons.

In Minas Gerais, the high-intensity wet magnetic separation plant being built by CVRD at the Caué mine was nearly completed by yearend. Twenty-six Jones-type separators have been installed at the plant, which was designed to produce 12 million tons of hematite concentrate per year from 20 million tons of crude ore. The plant is the first of its type to be built in the world.

In northern Brazil, feasibility studies for economic development of the Serra dos Carajas iron deposits were continued. Advanced engineering studies and related field work were expected to be completed in 1974. The deposits were reported to contain 1.87 billion tons of proved iron ore reserves averaging about 67% Fe. Amazônia Mineração S.A., the development company, was owned 51% by CVRD and 49% by a subsidiary of United States Steel Corp. The participating companies said that, depending on the results of these studies, initial shipments of ore could begin in 1978.

Canada.—Canadian production and exports of iron ore increased sharply in 1973 compared with the previous year. The greatly improved performance was largely due to the virtual absence of strikes, which had crippled production during the summer of 1972, but it was also due to strong demand for ore in foreign and domestic markets in 1973. Production set a new record, while exports, though 30% higher than in 1972, were less than in 1970. Production in 1973 totaled 48.9 million tons including 24.4 million tons of pellets. Exports totaled 37.9 million tons including 21.6 million tons to the United States, 11.8 million tons to the European Economic Community, and 3.8 million tons to Japan.

Two significant projects were completed by Iron Ore Co. of Canada late in 1973. Production capacity for concentrates at Labrador City was increased by 10 million tons per year, and production capacity for pellets was increased by 6 million tons with completion of a plant at Sept-Îles. Feed for the latter plant was flotation concentrates produced from Schefferville natural ores. With completion of these projects, Canadian production capacity for iron ore at yearend was 63.35 million tons per year, including 31 million tons of pellet capacity.

Quebec Cartier Mining Co. (QCM) continued construction of a major concentrating facility at Mt. Wright in northern Quebec. Initial production was scheduled to begin early in 1975. The project was designed to produce 16 million tons of concentrate per year. QCM was also developing deposits at Fire Lake, north of Gagnon, for production by 1976. Ore from the Fire Lake mine will be hauled on the Mt. Wright railways to the concentrator at Gagnon. The latter plant will continue to process ore from the Lac Jeannine deposits until 1976, when ore reserves at Lac Jeannine were expected to be exhausted.

The direct-reduction plant of Falconbridge Nickel Mines Ltd. at Sudbury was closed early in 1973 due to technical problems. The plant used the SL-RN process and had a production capacity of 300,000 tons of metallized pellets per year. Construction of a new SL-RN plant was begun in 1973 by the Steel Co. of Canada Ltd. The plant will process pellets produced at the Griffith mine and will have a production capacity of 400,000 tons of metallized product per year. At Contrecoeur, Quebec, a 400,000-ton-per-year direct reduction facility began regular production in May 1973. The plant employs the Midland-Ross process and was built for Siderurgie de Québec (Sidbec). Sidbec was using the product for feed to electric steel furnaces.

Iron ore shipments by the principal Canadian producers in 1973, in million long tons, were as follows:

Iron Ore Co. of Canada	20.5
Quebec Cartier Mining Co	9.0
Wabush Mines	5.4
Caland Ore Co. Ltd	2.1
Steep Rock Iron Mines Ltd	1.4
Griffith Mine	1.5
Algoma Steel Corp. Ltd	2.0
Adams Mine	1.2
National Steel Corp. of Canada Ltd. (Moose Mountain)	.7
Sherman Mine	1.0
Marmoraton Mining Co	.5

Chile.—Production and exports of iron ore in 1973 appeared to be about 9% and 15%, respectively, above 1972 levels. Exports in 1973 totaled 7,993,000 tons of which 95% was destined for Japan. Mine shipments by Compañía Acero del Pacífico S.A., the principal producer, totaled 9.28 million tons of which 35% originated at Romeral, 33% at Santa Barbara and Santa Fe, and 32% at Algorrobo. The company's shipments to Chile's iron and steel works at Huachipato totaled 919,000 tons.

China, People's Republic of.—Revised estimates of production of iron ore in China in 1971–73 (see table 20) are substantially greater than those previously published. This also applies to estimated production of pig iron (see table 14 in chapter on Iron and Steel). While the revised estimates may appear relatively high, and are considerably larger than those published elsewhere,[9] they are judged to be reasonably accurate by Bureau country specialists for China, considering the scarcity of information available.

European Economic Community (EEC).—Low-grade iron ore (25% to 32% Fe) continued to be produced by EEC countries in 1973 although it was significant mainly in France and Luxembourg. Domestic production continued to decline in West Germany, the United Kingdom, and Italy.

Imports of high-grade foreign ores by the EEC in 1973 were estimated to total 117 million tons. West Germany was the principal importer, with 46.2 million tons,

[9] Statistisches Bundesamt (Duesseldorf). Insert in Eisen und Stahl, 4. Vierteljahresheft 1973.

followed by the United Kingdom (22.8), Belgium-Luxembourg (17.8), Italy (estimated 13.5), France (9.8), and the Netherlands (6.9).

The major suppliers of iron ore to the EEC in 1973 were Sweden, with 27.2 million tons, followed by Brazil (19.8), Liberia (14.4), and Canada (11.2).

In the United Kingdom, the British Steel Corp. (BSC) contracted with a subsidiary of Allis-Chalmers Corp. for construction of a pelletizing plant at the Redcar steelworks. The plant will have a production capacity of 3 million tons of pellets per year and was scheduled for completion in 1975. The only large pelletizing plant known to be operating in the EEC in 1973 was at the Hoogovens-Hoesch steelworks in the Netherlands. This facility had a production capacity of about 3.5 million tons of pellets per year and was fed by imported ores. Other pelletizing plants were located at Hamburg, West Germany, where a direct-reduction plant of the Midland-Ross type was operated by Korf Industrie und Handel G.m.b. H., and at Scarlino, Italy, where iron oxide residues from pyrite were pelletized by Montedison S.p.A.

The Redcar iron ore terminal at Teesside was also completed by BSC in 1973 and the first 100,000-ton cargo of pellets was received in September. Completion of the Redcar terminal gave Britain two iron-ore ports capable of accommodating 100,000-dwt vessels. The other facility was located at Port Talbot. BSC also planned another deep-water terminal in Scotland. The company's terminal at Immingham, completed in 1972, may eventually accommodate 100,000-ton vessels.

Finland.—An agreement was signed October 31, 1973, by the Governments of Finland and the Soviet Union concerning development of the Kostomus iron deposits in Soviet Karelia. The project was planned to eventually produce about 8 million tons of iron ore pellets per year, with production beginning in 1978 at the rate of 2.7 million tons per year. Construction of the facilities will be done mostly by Finnish companies, with the Soviet Union supplying most of the machinery. Part of the ore produced would be consumed in Finland, and part would be exported from Finnish ports.

Finland's annual requirements for iron ore were expected to increase to more than 2 million tons by 1980. Domestic mines were not expected to supply more than one third of this total. Construction of a second blast furnace, with a production capacity of about 600,000 tons of pig iron per year, was started at Raahe in 1973. Completion was scheduled by 1976. The Raajärvi mine, which currently accounts for most of the iron ore mined in Finland, was expected to be depleted in 1975. Its production will be replaced by output from the Rautuvaara underground mine, now under construction near Kolari. Imports of iron ore by Finland in 1973 totaled 948,000 tons, 23% more than in 1972.

India.—Exports of iron ore in 1973 totaled about 23.2 million tons, of which 83% was shipped to Japan. This included about 400,000 tons of pellets from the plant of Chowgule & Co. Ltd. in Goa. Domestic consumption of iron ore was approximately 11 million tons, an increase of 2.8% compared with 1972.

Indian production of pellets was estimated at 1.5 million tons in 1973. Two-thirds of the output were produced by Tata Iron & Steel Co. Ltd. at Naomundi, where a plant was reportedly completed late in 1972. Chowgule & Co. planned to increase pellet production capacity in Goa by about 1.2 million tons per year, but no construction contracts were announced by yearend.

Iran.—Under a project announced in 1973, production of prereduced iron ore was scheduled to begin at Ahvaz in mid-1975. Three reduction plants of the Midland-Ross type, each with a production capacity of 400,000 tons of prereduced iron ore or pellets per year, were scheduled to be built. Design and construction of the plants will be supervised by Korf Engineering G.m.b.H. of West Germany, under license from the Midland-Ross Corp. Construction of additional direct-reduction plants, not necessarily of the Midrex type, was being considered at Ahvaz, Bandar Abbas, Mashhad, and Isfahan.

Iron ore to supply the reduction plants at Ahvaz was expected to be imported. Iranian authorities were reportedly considering investment of $300 million for development of iron deposits and port facilities in the Indian state of Mysore.

Iron ore for the Iranian steelworks at Isfahan was being supplied from deposits at Bafq. The feasibility of developing additional deposits, south of Kerman, was being investigated by the Swedish firm of Gränges AB.

Japan.—Imports of iron ore by Japan

in 1973 totaled nearly 133 million tons, 21% more than in 1972. Australia was the major supplying country, accounting for 49% of the total, followed by India (14%) and Brazil (9%). The remaining 28% was supplied by Chile, Peru, and 19 other countries.

Production of pellets, mostly from imported ore, was 6.2 million tons in 1973, an increase of nearly 2.4 million tons compared with 1972. The increase appeared to be due to production at Hirohata, where a new pelletizing facility was completed in January. Imports of pellets were estimated at 11 million tons.

Consumption of iron ore, excluding manganiferous ores, was approximately 128 million tons including about 900,000 tons of iron ore produced in Japan and an estimated 17 million tons of pellets from all sources.

Liberia.—Exports of iron ore from Liberia in 1973 totaled nearly 25 million tons, an increase of 11% compared with 1972. Of the total quantity, 76% was shipped to EEC countries, 11% to the United States, 10% to Japan, and the remainder to Spain and Romania. Three of the four producing companies increased production and exports in 1973. A decline was registered by National Iron Ore Co. due to startup problems at its new concentrator. Shipments of iron ore, by company, in thousand tons, were as follows:

Liberian-American Swedish Minerals Co. (LAMCO)	[1] 12,584
Bong Mining Co	[2] 6,792
National Iron Ore Co	[e] 3,300
Liberia Mining Co	[e] 2,300
Total	24,976

[e] Author's estimate.
[1] Including 1,685,000 tons of pellets.
[2] Including 2,274,000 tons of pellets.

Sources: U.S. Embassy, Monrovia, Liberia. State Department Airgram A–18, Mar. 5, 1974, and Skillings' Mining Review, various issues, 1974.

Mexico.—Cia. Fundidora de Fierro y Acero de Monterrey, S.A. contracted with the Allis-Chalmers Co. of Milwaukee, Wis., for construction of an iron ore pelletizing plant at Monterrey. Production capacity of the plant will be about 1.5 million tons of self-fluxing pellets per year. Completion was planned for 1976. Fundidora shipped 1.3 million tons of iron ore to Monterrey in 1973 from its four mines in Durango, Coahuila, Oaxaca, and Colima.

Construction of a 600,000-ton-per-year pelletizing plant was underway at the La Perla mine in Chihuahua. Completion of the plant was expected early in 1974. Output of iron ore at La Perla in 1973 was 2.55 million tons, with about 2 million tons shipped to the steelworks of Altos Hornos de Mexico S.A. at Monclova.

Siderúrgica Lázaro Cardenas-Las Truchas, S.A. (SICARTSA) ordered a pelletizing plant from Lürgi Chemie und Hüttentechnik G.m.b.H. in 1973. The plant will be built near Lázaro Cardenas on the Michoacan coast and will have a production capacity of 2 million tons of self-fluxing pellets per year. Iron ore fed to the plant will be magnetite concentrate, delivered in slurry form through a 9-mile pipeline. A date for completion was not announced.

The pelletizing plants described above are in addition to the 1.5-million-ton plant under construction at Manzanillo by Consorcio Minero Peña Colorada S.A.

Shipments of iron ore pellets by Las Encinas S.A. from its mine and plant near Alzada, Colima, totaled about 1.15 million tons in 1973.

Norway.—The second iron ore pelletizing line of A/S Sydvaranger at Kirkenes was scheduled to begin production by mid-1974. The company's production capacity for pellets will then be 2.4 million tons per year.

Increased requirements for rock stripping and crude ore production at the Sydvaranger and Rana operations led to purchases of large mining equipment in 1973. Five 150-ton trucks were scheduled for delivery to A/S Sydvaranger in 1974. A/S Norsk Jernverk purchased three 150-ton trucks and an electric shovel with 15-cubic-yard bucket for the Rana mine.

Panama.—Shipments of iron concentrates to Japan, halted in mid-1972 owing to berth trouble at Isla Bona, were expected to resume in the spring of 1974. The concentrates are produced from Pacific beach sands in the Balboa district by Hierro Panama, S.A. The scheduled rate of shipments was 300,000 tons per year.

Peru.—Shipments of iron ore products in 1973 by Marcona Mining Co. totaled 9.4 million tons, an increase of 3.6% compared with 1972. Exports totaled 9.0 million tons, of which 65% was destined for Japan, 18% for the United States, and 17% for countries of the EEC. Exports included 3.8 million tons of iron ore pellets and 1.2 million tons of slurry and filter cake.

Negotiations between the Marcona Co. and

Japanese interests for expanding production capacity of pelletizing facilities at San Nicolas were continued in 1973. Production capacity was expected to be increased to 7.5 million tons per year by 1976 at a cost of about $72 million. The project was being reviewed by the Peruvian Government.

Saudi Arabia.—The Marcona Corp. concluded an arrangement with Petromin, a Saudi Arabian Government company, for a joint study of the feasibility of establishing a steelmaking plant on the Arabian Gulf coast. The proposed plant would include facilities for receiving slurried iron ore concentrate, as well as for pelletizing and direct-reduction of the ore using natural gas. Other companies involved in the study are Gilmore Steel Corp. of San Francisco and Midland-Ross Corp. of Cleveland.

South Africa, Republic of.—Although iron ore export contracts necessary to support the Sishen-Saldanha Bay export project were not yet negotiated, the Government approved the project in April and construction of the 530-mile railroad reportedly began in 1973. The project was designed for export of 15 million tons of iron ore per year. At Sishen, a new open pit mine was being developed to raise production capacity to 9 million tons annually.

Production of iron ore declined slightly in 1973 compared with that of 1972, but exports increased 28% to 6.3 million tons. Sales of ore to domestic consumers totaled about 6.6 million tons, slightly less than in 1972.

Sweden.—Production of iron ore in 1973 increased 5% compared with that of 1972, but exports increased by nearly 20% to 32.4 million tons as Swedish producers drew heavily on stockpiles. Total shipments of iron ore and pellets to domestic and foreign markets by the principal producers in 1973, in thousand long tons, were as follows:

	Pellets	Other	Total
Luossavaara-Kiirunavaara AB (LKAB)	5,926	23,219	29,145
Gränges AB	1,191	2,586	3,777
Stora Kopparbergs Bergslags AB	--	861	861
Total	7,117	26,666	33,783

At the Malmberget operations of LKAB, production capacity of the concentrator was increased to 8 million tons per year, and capacity of the pelletizing plant was increased to 4 million tons per year. At Grängesberg, Gränges AB planned to invest about $9 million to raise production capacity for low-phosphorus concentrates to 2.5 million tons per year.

Tunisia.—The Tunisian Government signed a letter of intent in 1973 concerning plans to construct a direct-reduction iron ore plant at Gabes. The proposed plant, believed to be of the Midland-Ross type, would have an initial production capacity of 1 million tons of metallized ore per year. Iron ore for the project would be imported from Brazil. A completion date for the project was not announced. The companies involved were Korf Industrie und Handel G.m.b.H., C. Itoh and Co. Ltd., and CVRD.

Production of iron ore continued to decline in 1973 due to depletion of reserves at the Djerissa and Tamera mines. Exports reportedly declined 30% to 383,000 tons owing to increased requirements for ore at the El Fouladh steel plant.

U.S.S.R.—Exports of iron ore from the Soviet Union in 1973 totaled approximately 40.7 million tons, of which about 10% was shipped to Japan and West Europe.

The Soviet firm V/O Metallurgimport awarded a contract in 1973 to Allis-Chalmers Co. for construction of a two-line pelletizing facility for iron ore near Kremchug in the Ukraine. The plant will have a production capacity of 6 million tons of pellets per year. Production of pellets was scheduled to start in 1977. An agreement was also made with Finnish authorities for construction of pellet plants in Karelia (see Finland).

Soviet production of pellets in 1973 was reported to be about 21 million tons. This was equivalent to about 10% of the reported output of usable iron ore. Pellet production in 1971 and 1972 was 13.25 and 17.2 million long tons, respectively.

Negotiations between Korf Industrie und Handel G.m.b.H. and Soviet authorities, concerning establishment of a large direct-reduction facility, were reported in 1973 but no contracts were announced by year-end.

Venezuela.—Production and exports of iron ore increased about 20% in 1973, compared with those of 1972. Shipments by Orinoco Mining Co. and Iron Mines Co. of Venezuela totaled 21.4 million tons, of which about 21.1 million tons was exported and the remainder was destined for consumption in Venezuela. Of the quantity exported, approximately 63% was sent to the United States and 37% was shipped to

European consumers. Data on production or shipments of iron ore in 1973 by the State-owned Siderúrgica del Orinoco S.A. were not available.

Expansion of production facilities by Orinoco Mining Co. was nearly completed in 1973. The company's production capacity for iron ore will be 25 million tons per year early in 1974. Output capacity of Iron Mines Co. of Venezuela was believed to be 4 million tons per year.

Output of prereduced iron ore briquets at Puerto Ordaz was less than expected in 1973, owing to temporary technical difficulties. Production amounted to about 122,000 tons, of which 9,300 tons was shipped to the United States and the remainder was shipped to Venezuelan consumers.

A project to build a direct-reduction plant in the Guayana region was announced in 1973. The plant will employ the Fior process developed by Exxon Research & Engineering Co. and will have a production capacity of 400,000 tons of briquetted, prereduced ore per year. Completion was planned by mid-1975. Arthur G. McKee & Co. was in charge of construction. Participants in the venture included Lukens Steel Co. of Coatesville, Pa., and two Venezuelan companies.

TECHNOLOGY

Trends toward increasing size and productive capacity of iron ore mining, processing, and handling equipment, previously noted in this and other publications[10] of the Bureau of Mines, continued in 1973.

Large rotary drills with bits 12 to 15 inches in diameter were already in use or planned for blast-hole drilling at most taconite operations in the Lake Superior district in 1973. The models used were either the Gardner-Denver GD–120 or Bucyrus-Erie 61–R. These drills will also be used at the Hibbing and Tilden taconite projects. Jet-piercing drills continued to be used at several locations for all production drilling or in conjunction with rotary units.

A medium-size rotary drill (GD–80), using a table-drive instead of conventional top-drive mechanism, was tested for 3 months in 1973 at the McKinley natural-ore mine by Jones & Laughlin Steel Corp. The drill was said to have several advantages over top-driven machines including greater down-pressure and penetration rate, less vibration and stem-wear, and lower maintenance costs.

The number of autogenous grinding mills used in taconite processing was also increasing. Autogenous grinding will be used at the Hibbing and Tilden concentrators scheduled to start operating in 1976 and 1974, respectively. The method is currently used at the National, Butler, and Empire operations. Two new mills were installed in 1973 at the Empire concentrator where production capacity was being increased by 50%.

High-intensity magnetic separation continued to be a subject of wide interest because of its potential use in beneficiating low-grade hematite materials such as oxidized taconite. A new type of separator, using a continuous-flow process capable of processing large volumes of material, was developed at the Massachusetts Institute of Technology.[11] Known as the "Carousel" separator, the device uses stainless steel wool as the collector of ferromagnetic particles. This was said to increase the working volume of the magnetic field compared with machines previously built. The separator was scheduled to be tested on the Mesabi range in 1974 at the Hibbing laboratory of Hanna Mining Co. A method of high-intensity separation was also being investigated at the University of Wisconsin in 1973, under a grant by the National Science Foundation. The latter tests would be made on iron-bearing materials from the Black River Falls area of Wisconsin. The application of pulsed magnetic fields to matrix-type separators was described in a Bureau of Mines publication.[12]

In Brazil, the first commercial-scale beneficiation plant using high-intensity wet magnetic separation was nearing comple-

tion. Most of the 26 Jones-type separators scheduled to be installed were already oprating in 1973. The plant was designed to process 20 million tons of medium-grade hematite ore per year. The plant is located at the Caué mine near Belo Horizonte and is owned by CVRD.

Laboratory research was reported on recovery of specular hematite from spiral tailings in which a Lamflo sluice was used in conjunction with high-intensity magnetic separation or flotation equipment.[13] It was estimated that about 60% of the iron units presently lost in such tailings can be recovered at a grade of about 66% Fe by a variety of methods, although more data are needed to estimate costs of such recovery. It was also stated that high-intensity magnetic separation is now competitive with froth flotation due to pollution control regulations.

Demand for iron ore pellets at iron and steelmaking centers continued to grow. New pelletizing plants comprising about 45 million tons of annual production capacity were completed, under construction, or announced as new projects in the United States and 11 other countries during 1973. Pelletizing of furnace dust and mill scale was being investigated by some U.S. and foreign steel companies as well as by the Bureau of Mines. The Swedish "Grängcold" cold-bonding pelletizing process was being applied to agglomeration of steel mill wastes.[14]

Direct reduction of iron ore also increased. Armco Steel Corp. began full production at its Houston, Tex. plant in 1973. The plant has a production capacity of about 1,000 tons of metallized ore per day. In Venezuela, all units of United States Steel Corp.'s large reduction facility at Puerto Ordaz were operated during the year although production of briquets was restricted by temporary problems. In Canada, regular production of metallized pellets was begun in May at the Contrecoeur plant of Sidbec. The plant uses the Midrex process and has a production capacity of 400,000 tons of metallized pellets per year. In Iran, a project to build three 400,000-ton-per-year Midrex plants was begun at Ahvāz. A 1-million-ton facility was planned in Tunisia, and another was proposed for Saudi Arabia.

A comprehensive survey of the iron industry of the United States and the world was published by the Bureau of Mines.[15] The survey includes a section on technology of iron ore mining and beneficiation, including pelletizing and direct-reduction processes.

The Bureau of Mines continued research on beneficiation of nonmagnetic taconite and on methods of production and metallization of iron ore pellets. The processes of selective flocculation-desliming-flotation and reduction roasting-magnetic separation-flotation were being tested on hematitic and goethitic taconite from the western Mesabi range. The use of western lignite and subbituminous coal as reductants for taconite roasting or as fuel for induration of pellets, was being studied as a possible alternative to natural gas and fuel oil. Research was also being conducted on solid-liquid separation processes for reclamation of process water; the use of plastic refuse materials as binders for agglomerating fine materials such as iron and steel plant dusts and for coating metallized pellets; and utilization of magnetic fluids for beneficiation of ores. Publications issued during the year described the effects of thermal treatment on concentratability of oxidized taconite from the western Mesabi;[16] anionic flotation of nonmagnetic taconite from the Marquette range and some advantages of autogenous grinding;[17] the production of iron oxide superconcentrates by caustic leaching;[18] and attempts to reduce the phosphorus content of Alabama hematite ore.[19] Two publications on materials handling research, including a study of bucket-wheel excavators, were also released.[20]

In the iron ore industry, as in other industries, much money and manpower were being directed toward design and installation of adequate methods and equipment to meet increasingly stringent environmental control regulations. This was generating new technology in the fields of dust control and reclamation of water and land. Methods of stabilizing and vegetating tailings were being developed, and wholly closed or nearly closed systems were being designed for water supplies to taconite concentrators. Methods of dust control at iron ore shipping and receiving terminals included a fogging system for ship-unloading at Europoort, the Netherlands and telescoping chutes for shiploading at Palua, Venezuela.[21] There was also a need for better measuring techniques and equipment and coordination of standards for air and water quality.

[1] Insofar as availability of sources permit, data in this table represent the nonduplicative sum of marketable iron ore, iron ore concentrates and iron ore agglomerates produced by each of the listed countries. Moreover, concentrate and agglomerates produced from imported ores are excluded, under the assumption that the ore from which they are produced has been credited as marketable ore in the country where it was mined.

[2] In addition to the countries listed, Cuba and North Vietnam may produce iron ore but definitive information on output, if any, is not available.

[3] Shipments, dry tons, including byproduct ore.

[4] Calculated from reported iron content assuming a grade of 60% iron.

[5] Includes byproduct ore.

[6] Nickeliferous iron ore.

[7] Includes magnetite concentrate, pelletized iron oxide (from pyrite sinter) and roasted pyrite (purple ore).

[8] Includes "roasted ore", presumably pyrite sinter, not separable from available sources.

[9] Excludes iron oxide pellets produced from pyrite sinter.

[10] Includes manganiferous iron ore.

[11] Includes byproduct magnetite as follows in thousand long tons: 1971—2,193, 1972—2,952, 1973—2,958; and manganiferous iron ore (20% to 35% iron, 15% to 30% manganese) as follows in thousand long tons: 1971—179, 1972—100, 1973—65.

[12] Year beginning March 21 of that stated.

[13] Concentrates including concentrate derived from iron sand as follows in thousand long tons: 1971—581, 1972—539, 1973—274.

[14] Largely concentrates from magnetite-titanium sands.

Iron and Steel

By Horace T. Reno [1]

The iron and steel industry of the world operated at practical capacity throughout 1973. World production of raw steel [2] ingots and castings reached a record 766 million tons. The United States regained its lead as the world's leading steel producer as it produced a record 151 million tons compared with the 144 million tons produced in the Soviet Union. Demand for steel exceeded the supply in all parts of the world, and, except in the United States, the United Kingdom, and other countries where prices were controlled, prices advanced substantially as sellers' markets developed.

According to the American Iron and Steel Institute (AISI), domestic steel mill shipments totaled a record 111 million tons, 17 million more than the record set in 1969. Shipments to all major markets exceeded those of 1972. Steel service centers and the automobile and construction industries received 20% more steel in 1973 than they did in 1972, and shipments to makers of containers and capital goods producers were nearly 18% more. The largest increase in shipments to any single market was a 53% increase to oil and gas drillers.

U.S. exports of steel mill products increased 40% compared with those of 1972; steel mill imports decreased 14%. It was apparent that the reversal in the U.S. foreign trade pattern would have been even more marked had U.S. producers been able to increase their output. AISI reported the steel industry's total revenue at $21 billion, an increase of 32% compared with revenue in 1972, and net income totaled $924 million, an increase of 77% from the $523 million net income in 1972. Net income in 1973 was 4.4% of total revenue compared with 3.3% in 1972. Despite the improved financial position of the domestic steel industry, the shortage of capital available for expanding productive capacity continued.

The high production rate for steel in 1973 brought many problems. The coke supply, which was already curtailed by inability of producers to meet environmental standards, did not equal the demand, and the quality of coke available on the market was not up to standard. In many instances steel output was limited by the supply of fuel oil, natural gas and railroad cars, and there was not enough zinc to produce all the galvanized steel needed to meet demand. Many producers resorted to rationing their output among regular customers and selectively adjusted their product mix to emphasize high-profit items. A shortage of steel to make roof bolts for use in coal mines and of steel to make drill stems and oil well casings caused most concern.

---

[1] Physical scientist, Division of Ferrous Metals—Mineral Supply.

[2] The term raw steel, as used by the American Iron and Steel Institute, includes ingots, steel castings, and continuously cast steel. It corresponds to the term crude steel as used by the United Nations.

[2] Based on average production in 1967 as 100.
[3] Data not comparable for all years.

PRODUCTION AND SHIPMENTS OF PIG IRON

Domestic production of pig iron totaled 100.9 million tons in 1973, an increase of 12 million tons or 13.6% more than that produced in 1972. Average production of pig iron per blast-furnace-day decreased to 1,771.7 tons compared with 1,789.6 tons in 1972 and 1,654.3 tons in 1971 according to AISI. A total of 143 blast furnaces were in blast at the beginning of the year, including 2 that produced ferroalloys. At yearend the total number in blast had increased to 164, with 2 producing ferroalloys. There were 214 producing furnaces at the beginning of the year, and 203 at yearend, of which 3 were being relined and 1 was rebuilt.

Metalliferous Materials Consumed in Blast Furnaces.—For each ton of pig iron produced in 1973, an average of 1.676 tons of metalliferous materials was consumed in blast furnaces. Total net iron ore consumed in blast furnaces including agglomerates was 159.2 million short tons. The total tonnage of iron ore including manganiferous ore consumed by agglomerating plants at or near the blast furnaces in producing 41.3 million tons of agglomerates was 34.9 million tons. The remainder consisted of mill scale, coke, limestone, dolomite, and small amounts of other materials. Domestic pellets charged to the blast furnaces totaled 72.5 million tons, and sinter charged was 44.4 million tons. Pellets and other agglomerates from foreign sources added an additional 11.7 million tons.

Blast furnace oxygen consumption totaled 21.0 billion cubic feet according to the AISI, compared with 15.5 billion cubic feet in 1972 and 13.3 billion cubic feet in 1971.

Data reported to the U.S. Bureau of Mines by the iron and steel industry showed that blast furnaces, through tuyere injection, consumed 13.3 billion cubic feet of natural gas, 4.7 billion cubic feet of coke oven gas, 270.3 million gallons of oil, 94.6 million gallons of tar, pitch, and miscellaneous fuels, and 130,608 tons of bituminous and 10,397 tons of anthracite coal in 1973.

PRODUCTION AND SHIPMENTS OF STEEL

Domestic raw steel production reached a record 151 million tons in 1973, 13% more than in 1972. The steel industry worked at practical capacity throughout most of the year.

The 1973 steel index, based on production in 1967 as 100, was 118.5 compared with 104.5 in 1972 and 94.7 in 1971. Of the total, 55.2% was produced by the basic oxygen process (BOP), 26.4% by open-hearth furnaces, and 18.4% by electric furnaces.

Shipments of steel products for the year were up 21.4%, from 91.8 million tons in 1972 to 111.4 million tons in 1973. The distribution of steel shipments to markets was changed little from the distribution in 1972, with service centers and the automotive industry each accounting for approximately 20% of the total.

Materials Used in Steelmaking.—Metallics charged to domestic steel furnaces in 1973, per ton of steel produced, averaged 1,259 pounds of pig iron, 1,104 pounds of scrap, and 32 pounds of iron ore, including agglomerates. In 1972, comparable quantities were 1,246 pounds of pig iron, 1,103 pounds of scrap, and 32 pounds of iron ore.

According to AISI, steelmaking furnaces consumed 618,268 tons of fluorspar, 2.4 million tons of limestone, 7.8 million tons of lime, and 0.9 million tons of other fluxes. Oxygen consumption in steelmaking totaled the equivalent of 215.1 billion cubic feet compared with 189.5 billion in 1972.

CONSUMPTION OF PIG IRON

Pig iron consumed in steelmaking totaled 94.9 million tons. Basic oxygen converters consumed 68.08 million tons; open hearths, 25.48 million tons; and electric furnaces, 1.38 million tons. An additional 2.74 million tons was consumed by iron foundries and miscellaneous users, primarily for charging cupola furnaces. Also, approximately 2.2 million tons in the form of molten metal was used in making ingot molds and direct castings.

PRICES

At the beginning of 1973, steel prices were beginning to reflect a worldwide boom in the industry. European steel prices rose at a record rate. Reinforcing bars that had sold in European markets for approximately $115 per ton early in December 1972 were selling for $150 per ton by the end of January. Price increases in the United Kingdom and Japan lagged behind the rapid increase in the European Common Market countries; but the Japanese raised their steel export prices in February to offset the 10% devaluation of the dollar, and the British Steel Corp. raised its steel prices 9.5% in mid-April. Canadian steel prices in general followed the upward trend of steel on the world market although apparently moderated somewhat by proximity to the United States.

Prices quoted by domestic steel producers were governed by phase 2 price controls. In January, the Price Commission approved a weighted average 4½% increase in the price of steel plates at the request of National Steel Corp. Leading producers increased the price of tinplate about 4% as phase 2 ended and five producers increased the quoted price of merchant basic iron to $82.75 per net ton f.o.b. the plant. Producers of stainless tool and high-speed steels increased their prices 4% to 8% in March to recover the cost resulting from rising scrap, ferroalloy, and energy prices.

Most of the major steel producers planned to raise the base price of steel $8 to $12 per ton on June 15 to 17 but were prevented from doing so by the Cost of Living Council issuing a 60-day price freeze which was to end August 12. Essentially all producers gave 30-day notice to the Cost of Living Council in August that they planned to increase steel prices when permitted to do so in the middle of September. The Council approved only a 2½% increase effective October 1 and another 2½% effective January 1, 1974.

The price control action of the Cost of Living Council triggered widespread reevaluation by steel producers of their product mix. Seeking greater profitability, producers eliminated many low-profit forms of steel from their operations. Rod stock to make roof bolts used in coal mines and tubular steel used in casing oil wells were among the low-profit steels eliminated. The Cost of Living Council granted an exception on the price of rods to make roof bolts on November 20, and a petition for exemption from price controls for oil country goods was pending at the end of the year.

On November 30, major steel producers gave a 30-day notice of intention to increase their prices approximately 6½% on January 1, 1974. Late in December the Council agreed to adjustment of price freezes for certain steel items to reflect increased costs in iron and steel scrap incurred between June 1, 1973, and December 31, 1973.

The composite price of pig iron, according to Iron Age, increased from $71.96 per short ton at the end of January 1973 to $78.16 at the end of December, and the composite price for finished steel increased slightly from $187.26 in January to $188.64 per short ton in December.

FOREIGN TRADE

United States trade in steel mill products at the beginning of 1973 was not greatly affected by the worldwide boom in the steel industry. According to AISI, steel imports into the United States in the first month established a January record, but after the first month, the pattern of U.S. foreign trade in steel reversed, and for the entire year exports of steel mill products were 41% more than in 1972, while imports were 14% less. Some U.S. mills refused orders from foreign companies. Devaluation of the dollar on February 9 accelerated the changing pattern of U.S. steel foreign trade, and by March, Japanese and European steel producers reportedly were pricing themselves out of U.S. markets.

The changing trade pattern greatly eased the burden imposed by the voluntary restraint arrangement which limited steel exports to the United States from Japan, the United Kingdom, and European Community (EC) countries. Officials of some U.S. companies discussed formation of a United States trading combine to promote steel trade in a manner similar to that or the equivalent of Japanese trading companies which have successfully promoted Japanese steel throughout the world. Opening of the Soviet Union and the People's Republic of China to steel imports may have been the first step in steel trade between the United States and Communist countries. The Soviets sought help in providing steels suitable for consumer goods and the worldwide shortage of steel provided the economic climate in which U.S. trade with the Soviet Union could develop and flourish.

Data compiled by AISI indicated that U.S. imports of steel mill products from Japan were 12½% less than in 1972. Total steel imports from EC countries were 16% less; from Belgium-Luxembourg imports decreased 22.8%; from France 20%; from West Germany 7%; from the Netherlands 3%; from Italy 49%; and from the United Kingdom 18%. Steel mill products imported from Canada for consumption in the United States in 1973 were 7% less than in 1972.

The U.S. Tariff Commission closed six cases brought under the Anti-Dumping Act of 1921 relating to iron and steel products being sold in U.S. markets at less than fair value: (1) It determined there was no injury or likelihood of injury to domestic industry from deformed concrete reinforcing bars from Mexico, which were being sold, or likely to be sold, at less than fair value within the meaning of the Anti-Dumping Act of 1921; (2) the Commission, on being advised by the Treasury Department that iron and sponge iron powders from Canada were being, or likely to be, sold in the United States at less than fair value, scheduled public hearings December 11 to determine whether an industry in the United States was being, or was likely to be, injured, by reason of such importation; (3) the Commission determined that stainless steel wire rod imported from France was being, or was likely to be, sold at less than fair value, to injure an industry in the United States; (4) the Commission determined that the domestic industry was not injured, or likely to be injured, by cold-rolled stainless steel, sheet and strip from France; (5) the Commission discontinued its antidumping investigation of injury to domestic industry from high-speed tool steel from Sweden being sold at less than fair value; and (6) the Commission determined that a domestic industry was being injured by sale of stainless steel plate from Sweden which was being sold in the United States at less than fair value.

In investigations preliminary to Tariff Commission actions, the U.S. Treasury Department determined that pig iron from Brazil was not being sold in the United States at less than fair value, but that steel wire rope from Japan had been sold in the United States for less than fair value.

WORLD REVIEW

The steel industry of the world, with very few exceptions, operated at practical capacity throughout most of 1973. The industry produced 765.8 million tons of raw steel—a record. Record production was matched by a record demand. Shortages of steel mill products developed in most marketing areas. The steel industry of North America was at the forefront in producing steel as the industries of Canada and Mexico were as active as those of the United States, continuing the high production rate started in 1972. In South America, the steel boom was not as noticeable as in other parts of the world because the newly developing steel industries had not yet produced sufficient steel to meet demand. Steel supply in the EC and Other Western European countries, as in North America, did not meet demand. Labor troubles and a fuel shortage in the United Kingdom prevented the British Steel Corp. from contributing to continental European markets. State-owned steel producers in Eastern European countries operated as usual on their planned schedule, but the steel industry of Asia, dominated by producers in Japan, lagged somewhat behind the rest of the world in reaching capacity output.

NORTH AMERICA

Canada.—Canadian steel companies produced almost 15 million tons of crude steel—a record. Its steel imports exceeded exports by approximately 1 million tons; so the Canadian indicated crude steel equivalent consumption in 1973 was a record 15.6 million tons. Reportedly, Canadian shipments of rolled steel products were up for most categories compared with those for 1972. Notable increases were to building contractors, up 49%; automotive and aircraft industries, up 29%; natural resources and extractive industries, up 24%; and the railway industry, other than cars and locomotives, up 18%.

All Canadian steel producers modernized or expanded their iron and steelmaking facilities.[3]

Algoma Steel Corp. Ltd. installed its second basic oxygen steelmaking furnace. It had a continuous slab-casting plant under construction and installed various new finishing facilities and ancillary equipment for the new facilities.

Dominion Foundries & Steel Ltd. (DOFASCO) was in the process of rebuilding and recommissioning its No. 1 blast furnace, rebuilding stoves for the No. 2 blast furnace, and a back-draft stack for the No. 3 blast furnace. The company installed fast-roll change equipment on seven finishing stands at the hot mill with various ancillary and emission control equipment.

Interprovincial Steel & Pipe Corp. Ltd. installed a new melt shop and a 125-ton ultra-high-power furnace split shell. It added two soaking pits and a spiral pipe mill.

Sidbec-Dosco Ltd. started operating its Midrex reduction plant on April 11.[4]

The Steel Co. of Canada, Ltd. (STELCO), completed an 80-ton electric arc furnace at its McMaster works and installed a 4-strand continuous casting machine. At its Swanson works it added two heat-treating lines, and constructed numerous ancillary equipment. At its Hilton works, it constructed additional gas-cleaning equipment, a BOF shop, and an addition to BOF teaming facilities and provided oxygen enrichment for its E blast furnace.

Mexico.—The Mexican iron and steel industry produced 5.2 million tons of steel in 1973, an increase of 6% compared with that in 1972. The industry was plagued by shortages of iron, fuel, and electric power, and therefore did not grow at the rate experienced since World War II. Demand for all steel products throughout the year was at a high level, and in the last quarter of the year, delivery schedules were delayed from 75 to 90 days, and several

[3] Iron and Steel Engineer. Annual Review Issue. V. 50, No. 1, January 1974, p. D8.
[4] Schneider, V. B. Iron and Steel. Can. Min. J., v. 95, No. 2, February 1974, pp. 124–126.

fabricating concerns shutdown their plants because they could not obtain steel.

Planning of the Las Truchas complex at Melchor Ocampo in the State of Michoacán continued as bids were asked for basic oxygen and blast furnaces and for continuous casting equipment.

The expansion program of Hojalata y Lámina, S.A. (HYLSA), in Monterrey also progressed as planned. Its new direct reduction plant was scheduled to begin operation to produce 457,000 tons of sponge iron per year early in 1974.

Fundidora de Monterrey reviewed bids for its $110 million expansion program including a basic oxygen furnace, an iron ore pelletizing plant, a reheating furnace, and new rolling mill equipment.[5]

Officials of Altos Hornos de Mexico S.A. (AHMSA) visted Japan seeking financial and technical cooperation to expand AHMSA steelmaking operations, establish a new integrated steelworks on the Pacific Coast, and acquire a stainless steel line.[6]

SOUTH AMERICA

The Thirteenth Latin American Iron and Steel Congress and the Fourteenth General Assembly of the Latin American Iron and Steel Institute (ILAFA) met in Buenos Aires, Argentina, November 12–15. The meeting had been planned for October 22–25 in Santiago, Chile, but was rescheduled because of the economic and political turmoil in that country. The Congress and ILAFA have the common objective of taking advantage of the potentials that Latin American countries have to construct steel complexes which will provide the impetus for a more vigorous economic and social environment in all of South America.

The Congress was of particular significance to Latin American countries. It enabled the participants to discuss mutual problems and obtain information on the most advanced techniques which could be adapted for future installations in their countries. It was organized under three general themes to develop these objectives: (1) A technical session devoted to examining trends in the expansion of Latin American steel plants; (2) a study of methods for combating pollution of the atmosphere and of the seas and rivers; and (3) a review of general industrial engineering problems oriented to maximum production and optimum working conditions without inconvenience to the surrounding life.

Argentina.—Demand for steel mill products in Argentina continued to increase at a rapid rate. The domestic steel industry could not supply the needed steel, so a purchasing team of officials from the Government-owned Sociedad Mixta Siderúrgica Argentina (SOMISA) was formed to seek steel in European countries, the United States, and Japan.

The Argentine Government authorized SOMISA to expand raw steel production to 4 million tons.[7] The expansion program was to involve modifying an existing blast furnace, redesigning of a planned furnace for increased volume, adding an additional Linz-Donawitz (LD) converter and a wide plate mill. Total cost was estimated at $200 million.

SOMISA contracted with Corporacion Minera de Bolivia (COMIBOL) for 50,000 tons of iron ore from the Mutún deposits in southeast Bolivia. Reportedly 15,000 tons of Mutún iron ore concentrate tested satisfactorily at the SOMISA San Nicolas works.[8]

Bolivia.—The Bolivian Government and Bolivia's national iron and steel company Empresa Siderurgica Boliviana S.A. (SIDERSA) actively promoted exploitation of the Mutún iron ore deposits. Through trade with Argentina and Brazil, the Government was considering a three-country cooperative project to build an iron ore mining and iron and steel plant industrial complex which would involve Bolivian iron ore and natural gas, electric power from major dams planned on the Paraguayan-Argentine and Paraguayan-Brazilian borders, and Brazilian markets.[9]

Brazil.—Despite the rapidly expanding iron and steel industry in Brazil, the supply of iron and steel products was not keeping

[8] U.S. Embassy, La Paz, Bolivia. State Department Airgram A–32, Feb. 15, 1974, 2 pp.

[9] U.S. Embassy, La Paz, Bolivia. State Department Airgrams A–369, Jan. 10, 1974; 10 pp.; A–074, Apr. 26, 1974, 2 pp.; and A–117, June 1, 1973, 4 pp.

pace with demand in 1973, and it became apparent that this situation would continue to erode the Nation's international reserve position. Brazil's need for iron and steel has been underestimated in the past, but the shortage and new forecasts resulted in the Government taking steps to increase Brazil's iron and steel productive capacity rapidly.

Plans were announced to build an integrated steel plant to produce 1 million tons of raw steel per year by 1978 and 2 million tons per year by 1980.[10]

A plant to produce semifinished steel at Tubarão was planned by Kawasaki Steel Corp. of Japan at the request of the Brazilian Government. The proposed plant was to be owned 51% by the Government with the remainder being owned by Kawasaki Steel Corp. and one other foreign concern.

The Brazilian Government officially asked Nippon Steel Corp. and Kawasaki Steel Corp. to consider establishing large integrated steelworks at São Luís and at Tubarão. The projects suggest a 3-million-ton steelworks at Tubarão and an initial 5-million-ton mill at São Luìs with Italian and Brazilian partners.[11]

Brazilian officials negotiated with the Bolivian Government to participate in establishing an industrial development center in southeastern Bolivia to take advantage of existing natural gas and raw material deposits. In return for obtaining Bolivian natural gas, Brazil agreed to provide a market for some of the steel mill products.

Among expansion programs at existing steel plants, Cia. Siderúrgica Paulista (COSIPA) was building a second blast furnace at Piassaguara near Santos; Usina Siderúrgica de Bahia S.A. (USIBA) was engaged in an expansion program that will eventually include three electric-arc furnaces and two or three sponge iron plants. The first electric arc furnace was started early in the year. A HyL plant to produce sponge iron was under construction. Aços Finos Piratini S.A. at Porto Alegre began producing steel with two new electric-arc furnaces operating on scrap. An SL-RN rotary kiln was under construction.[12]

Chile.—The iron and steel industry of Chile did not follow the pattern of rapidly increasing production experienced in other steel-producing Latin American countries in 1973. A 12-day strike at Cía. de Acero del Pacífico (CAP) and economic and political turmoil in the first three quarters of the year were the principal reasons for the lessening in steel output. There was marked improvement in CAP operations in the last quarter. Company officials attributed the improvement to comparative stability and labor discipline which followed the change of Government in September.[13]

EUROPEAN COMMUNITY

France.—The French iron and steel industry produced 27,849,000 tons of raw steel in 1973, about 5% more than in 1972. Production in oxygen furnaces continued to increase as 14,488,000 tons was produced, and production by the Thomas process continued to decline as only 6,788,000 tons was produced in Thomas steel furnaces and 3,608,000 tons was produced in open-hearth furnaces, about the same as in 1972. Electric steelmaking continued to increase; 2,922,000 tons was produced in electric-arc furnaces, and 35,000 tons was produced in electric-induction furnaces.

The No. 4 blast furnace of Union Sidérurgique du Nord de la France (Usinor) at Dunkirk was blown in. The No. 4 furnace is the largest in France with a capacity of 10,000 tons per day. It raised Dunkirk's ironmaking capacity to 6.9 million tons per year. In view of this large supply of hot metal, Creusot-Loire added a sixth hot-metal transfer car for transferring hot metal between Usinor's Dunkirk blast furnaces and Les Dunes steelworks at Creusot-Loire.[14]

Construction of the integrated steel complex at Fos proceeded on schedule. A slabbing mill was completed in October, and the 83-inch continuous hot-strip mill was completed early in December. The French Government provided additional funds to assure success of the projects. Additional funding brought the Government's total share in the project to about one-third.[15]

[15] Page D5 of work cited in footnote 12.

Italy.—The Italian steel industry produced 23 million tons of raw steel in 1973, 6% more than it produced in 1972. The record output did not meet demand by more than a million tons. The imbalance strengthened plans for construction of the fifth integrated steel plant to be built in Kioia Tauro (Calabria) in southern Italy. The proposed plant would be operated by Finanziaria Siderurgica (Finsider) whose officials apparently have decided that the plant will use prereduced iron ore from Brazil.[16]

Italian steelmakers, despite being principally Government-owned, continued to experience difficulty with the environmentalists. Most of the opposition to the plant at Gioia Tauro came because it was to be in an area primarily agricultural. Ecologists opposed expansion of Italsider's steel mill at Bagnoli because of gas emissions from sintering plants and coke ovens.[17]

Luxembourg.—Luxembourg's iron and steel industry produced a record 6.5 million tons of steel in 1973. The industry continued to be the driving force in the Luxembourg economy. It accounted for 25% of the gross national product, 45% of industrial production, and 69% of industrial exports. The industry is the largest single employer in Luxembourg. Approximately 95% of the steel produced in Luxembourg was exported.[18]

Luxembourg's labor unions and its steel industry signed a 2-year contract providing a 13.6% increase in average wages. The contract was signed on the last day of 1973.[19]

Netherlands.—The steel industry of the Netherlands produced 6.2 million tons of steel in 1973 approximately the same as in 1972. The industry was caught in the energy crisis and asked U.S. Government assistance in determining the status of its orders for coking coal in the United States. Energy was only one of the steel industry problems, the Hoogovens-IJmuiden works was closed by a labor strike in the first part of the year, and environmentalists continued to oppose expansion on the reclaimed Maasvlakte area near Rotterdam.

United Kingdom.—The British steel industry produced 29 million tons of steel in 1973, thus continuing its recovery from the trauma of nationalization and founding of the British Steel Corp. (BSC) in April 1967. BSC had a profitable year, the first in its existence; nevertheless, the industry fell far short of meeting demand, and its operations were seriously interrupted by major strikes. Many consumers were forced to buy imported steel at prices $50 to $100 per ton higher than quoted by BSC.

BSC and the independent steelmakers of Great Britain became members of the European Coal and Steel Community on January 1. Under Community regulations national governments cannot subsidize their steel industries, but the United Kingdom was allowed until April 30 to withdraw its support from the industry and thus permit prices to reflect a nonsubsidized operation. British steel prices were increased an average of 9½% effective May 1. Nevertheless, British steel remained the least expensive in the world markets as BSC operated at the approximate break-even point.

The British Government released a 10-year development program for BSC which will involve investment of more than $7 billion over the next 10 years and give the corporation raw steelmaking capacity of 39 million tons per year early in the 1980's. Specific details of the plan were not released, but the general program was to expand and modernize the steel industries in Scotland and Wales, close some of the smaller operations in the northern region of England, and concentrate the bulk of the steelmaking at Port Talbot in South Wales, Ravenscraig in Scotland, Llanwern in Wales, and Scunthrope and Teeside in England.

The market for steel in the United Kingdom was exceptionally strong throughout the year, and there were reports of a steel black market wherein domestic consumers bought British steel and resold it abroad. The rapidly developing need for steel in offshore oil and gas platforms in the North Sea amplified the shortage.

Independent steel producers in Great Britain have been closely affected by the

[16] U.S. Embassy, Rome, Italy. State Department Airgram A-508, Aug. 29, 1973, 16 pp.
[17] U.S. Consulate, Naples, Italy. State Department, Airgram A-11, July 9, 1973, 3 pp.
[18] U.S. Embassy, Luxembourg, Luxembourg. State Department Airgram A-22, Apr. 10, 1974, 9 pp.
[19] U.S. Embassy, Luxembourg, Luxembourg. State Department Airgram A-1, Jan. 8, 1974, 5 pp.

position and policies of BSC and its treatment by the Government. Rational planning by independent steelmakers has been prevented because they do not know whether they would remain as private companies or be brought into the nationalized combine. Nevertheless, the private sector of the steel industry has grown and prospered since 1967. Production of high-speed and tool steels was completely in the private sector in 1973 as BSC had relinquished its interest in 1972. The nature of the private sector made it the leader in developing iron and steel scrap supplies and alternate sources of iron raw materials. Moreover, steelmakers in the private sector took the lead in investigating direct reduction and pelletization of iron ore for use principally in electric-arc furnaces.[20]

West Germany.—West German steelmakers completely recovered from the depression of 1971 and 1972. In 1973 they produced almost 55 million short tons of raw steel, 40 million tons of pig iron, and 40 million tons of finished steel.

West German steel mill operators and the Metalworkers Union for Land Nord Rhine-Westphalia, the principal steel producing area of the Federal Republic of Germany, approved a new wage contract December 31, 1973, wherein the steelworkers obtained a pay raise of 11% plus additional fringe benefits. Owing to economic uncertainty, the new contract was to be only 10½ months.

Iron ore smelting in West Germany followed the pattern of large blast furnaces similar to that in Japan and the U.S.S.R. as four large blast furnaces were blown in during the year. The largest was the 45.9 foot (14 meter) hearth-diameter stack blown in early February at the August Thyssen-Hütte's Schwelgern works; however, operation of the furnace has caused trouble with the environmentalists because of the noise and fume emmision problems. A 39.3 foot (12 meter) diameter hearth furnace was blown in at the Bremen works of Klöckner Werke A.G. That furnace and a hot strip mill was built with the cooperation of the Nippon Steel Co. of Japan. The fourth largest furnace in West Germany with a hearth diameter of 37.7 feet (11.5 meters) was blown in by Friedrich Krupp Hüttenwerke A.G. at Rheinhausen.

WESTERN EUROPE

Austria.—The Austrian iron and steel industry operated at capacity throughout 1973, producing 4,672,000 short tons of steel compared with the 4,486,000 short tons produced in 1972. The Austrian Parliament approved a merger of Austria's two major nationalized steel concerns effective January 1. Vereinigte Österreichische Eisen und Stahlwerke, A.G. (Vöest) and Österreichische-Alpine Montangesellschaft A.G. were merged into one company, and two specialty steel producers, Gebrüder Böhler & Co. A.G. and Schoeller-Bleckmann Stahlwerke A.G., became wholly-owned subsidiaries of the new company.[21]

A third LD section with three 110-ton vessels was started up at the Linz works of Austria's Vöest-Alpine.[22]

Portugal.—The Government of Portugal authorized construction of a ministeel mill near Oporto.[23]

Sweden.—The steel industry in Sweden should be considered in two segments—one producing ordinary carbon steel and the other specialty steels. The carbon steel segment did not keep pace with the overall world activity in 1973, but the specialty steel segment improved its position as a supplier of stainless and alloy steels.

Despite the unimpressive record of Swedish steel industry, the Government announced plans for a large new steelworks to be constructed at Luleå on the northeast coast at an estimated cost between $500 and $600 million. It was expected that most of the plant's steel would be exported to continental European countries. As Sweden affiliated with the EC and the Coal and Steel Community in 1972, the new plant might benefit from Sweden's agreements with the Community.[24]

EASTERN EUROPE

U.S.S.R.—The U.S.S.R. produced a record 144 million tons of raw steel in 1973

---

[20] Steel Times. BISPA—The Private Sector Reports. V. 202, No. 3, March 1974, pp. 218–240.

but lost its place as the world's largest producer to the United States. Steel demand in the U.S.S.R. continued to exceed supply. According to the Soviet news agency, Novosti Press, the Communist Council for Mutual Economic Assistance planned an integrated steel plant with a 10-million-ton-per-year capacity in the Kursk basin of central U.S.S.R.

The Soviet Union's largest blast furnace at Lipetsk, in the center of European Russia, was lit in February 1973. Reportedly, the furnace had a working volume of 4,185 cubic yards (3,200 cubic meters) and capacity to produce 2.2 million tons of pig iron annually.

AFRICA

Egypt, Arab Republic of.—The technical and commercial directors of Arab iron and steel member companies of the Arab Iron and Steel Union met at Khartoum, Sudan, to study the present and future situation of the iron and steel industry in the Arab world and to lay the foundations of cooperation and coordination between the Arabic companies.[25] The Soviet Union continued its interest and help to Arabic steel industries by providing assistance for installing a third blast furnace at the Helwan Iron and Steel Mill in the Arab Republic of Egypt.[26]

South Africa, Republic of.—The iron and steel industry of South Africa operated at capacity throughout 1973 producing 6,207,000 short tons compared with 5,886,000 tons produced in 1972. The South African Iron and Steel Industrial Corp. (ISCOR) decided to delay planned expansion of its Newcastle steelworks 5 or 6 years and meet the shortfall by expanding the existing Vanderbijlpark plant. Under the new plans the Vanderbijlpark mill will be producing 6 million tons of steel annually by 1983, while Newcastle will produce only 3 million tons.

Highveld Steel and Vanadium Corp. Ltd. announced plans to expand its Witbank works in the Transvaal by adding a sixth kiln, a fifth submerged arc-smelting furnace, and a fourth continuous casting machine.[27]

Japanese and U.S. steel companies negotiated with ISCOR to produce semifinished steel for export.

ASIA

A meeting of the Sub-Committee on Metals and Engineering of the Committee on Industry and Natural Resources of the United Nations, Economic Commission for Asia and the Far East (ECAFE) was held August 22 to 28, 1973, in New Delhi, India. It reviewed the development and growth of the iron and steel industry of the ECAFE region and noted the rapid growth of the industry in Japan, Australia, and New Zealand which accounted for 26 million tons in 1960 and 100 million tons in 1970. The developing countries increased output of iron and steel from 12 million tons to only 25 million tons during the same period. ECAFE developing countries continued to be net importers of steel, but Malaysia, Indonesia, and the Republic of Korea planned possible expansion. Scarcity of raw materials—iron ore, coking coal, limestone, dolomite, and power—restrict development of steel industries in other ECAFE developing countries.[28]

China, People's Republic of.—Apparently China's iron and steel industry operated at a high level of activity in 1973 following the pattern of the industries in the Western World. Similarly, China's domestic industry was unable to meet the demand. The Chinese imported increasing quantities of foreign steel and negotiated with the Japanese to supply steel rolling mills and continuous casting equipment to increase their own output.[29]

India.—The iron and steel industry of India produced only slightly more steel in 1973 than it did in 1972 despite the addition of the Bokaro plant to list of active producers. The five major steel plants, Bhilai (Madhya Pradesh), Durgapur (West Bengal), Rourkela (Orissa), Tata Iron and Steel Co. (Bihar), and the Indian Iron and Steel Co. (West Bengal) produced at less than 70%

[29] American Metal Market. Japan-China Pact Is Near on Rolling Mills for Latter. V. 80, No. 196, Oct. 9, 1973, p. 7.

of capacity. However, plants of the Hindustan Steel Co. (Rourkela, Bhilai, and Durgapur) produced 12% more steel in 1973 than they did in 1972.[30]

The major causes for underutilization of the steel plants were shortages of power, coking coal, and coke-oven gas; technical problems and lack of coordination in supply; transportation problems in coal, iron ore, limestone; and labor problems (particularly at Durgapur and West Bengal). The severity of the transportation problem forced the Tata steel plant at Jamshedpur to shutdown some production units because coal was not being delivered owing to a slowdown by railway workers.[31]

There was a serious shortage of steel mill products, and according to the steel ministry, industrial concerns held large stocks of steel in their inventories. The severity of the shortage was indicated by the disparity between free market and controlled prices. Prices for plates, joists, and channels in the free market were more than twice the controlled prices.

The iron section at the Bokaro steel plant operated throughout the year and at yearend had produced more than 800,000 tons of pig iron. Steel production in a 100-ton converter started on December 27, 1973.[32]

The Steel Authority of India Limited (established in 1972 as part of an effort to reshape and revitalize the steel industry) was registered in New Delhi on January 24, 1973.

An international symposium on "Science and Technology of Sponge Iron and Its Conversion to Steel" was held at the National Metallurgical Laboratory, Jamshedpur, February 19 to 21, 1973. The symposium may have instigated a Government decision to license more ministeelworks and not to impose regulations on ministeelworks using electric-arc furnaces.

Indonesia.—The Indonesian Government approved an $18 million joint venture between Marubeni Corp. and Toshin Steel Co. Ltd. of Japan, Sims Consolidated Ltd. of Australia, and N. V. Sumera to establish an integrated steel mill in Jakarta.[33]

Iran.—The Iranian Government actively promoted its domestic steel industry to take advantage of a surplus of inexpensive natural gas. The National Iranian Steel Corp. commissioned its first integrated steel plant at Isfahan. The Isfahan plant was built with the assistance of the Soviet Union. Its blast furnace was lit in December 1971. The corporation contracted with the Korf Co. of West Germany for a 1.2-million-ton Midrex direct-iron reduction plant to be built at Ahwaz in South Iran. Meanwhile, the Iranian Government negotiated with Swindell-Dressler Corp., a division of Pullman Inc., to construct and equip a direct-reduction plant at Isfahan. Swindell-Dressler is the agent for the HyL process developed in Mexico.

Japan.—The Japanese iron and steel industry produced 132 million tons of crude steel in 1973, 23% more than in 1972. Basic oxygen furnaces produced 81% of the total, electric furnaces 18%, and open-hearth furnaces 2%. Ninety-nine million tons of pig iron was produced, 22% more than in 1972. According to the Japanese Iron and Steel Federation, iron and steel exports in 1973 totaled 25.6 million tons, 16% more than in 1972.[34] In the first part of the year the industry seemed to retreat from the high rate of steel production established in the last few months of 1972, but after a 2-month pause, the trend of increasing output continued. For the first time in the Japanese steel industry's history, shortage of water forced some producers to curtail their output.

Domestic demand for steel, which may have been responsible for the decreased production in the first part of the year increased rapidly. The Japanese Ministry of International Trade and Industry (MITI) asked steelmakers to restrict exports and give priority to the backlog of domestic orders. Steel prices increased markedly, responding to the imbalance between supply and demand. The Government initiated allocation to prevent domestic buyers from bidding up prices, but formal restraints were not placed on exports. It became apparent that the pattern of the industry, which had been wholly growth and export oriented, could not continue. The pricing system which

had encouraged exports, was changed to favor domestic consumers and the industry, prodded by the Government, sought opportunities to participate in foreign steelmaking enterprises.

The Steel Committee of the Industrial Structure Council, in an interim report to MITI, advised that the iron and steel industry must redirect its investment policies.[35] The Committee recommended that the industry must strive ceaselessly to become eventually a clean industry and fit into the Nation's resources and energy plans; moreover, that in the face of the environmental and energy problems, steel exports must be moderated; and furthermore, that new steel plants in overseas locations must be positively considered. Apparently the change in policy had been expected as Japanese participation in foreign steelmaking enterprises was reported as follows: (1) Kawasaki Steel Corp. reached basic agreement with the Brazilian Government to construct a 6-million-ton-per-year steel plant in Brazil jointly with Brazilian and Italian companies; (2) Mitsubishi International, Kawasaki Steel. and Nippon Kokan Co. agreed to participate in a steel venture in Jamaica; (3) Mitsui and Co. scheduled a steel wire and rod manufacturing enterprise in Nigeria with British Ropes Ltd. of Doncaster, England; (4) Sumitomo Metal Industries Ltd. announced plans to set up a company in Saudi Arabia jointly with Nippon Steel Corp. and the Alireza group in that country to produce large-diameter welded steel pipes and to participate in Confab Industrial S.A. of São Paulo, Brazil, in a similar operation.

The Japanese steel industry lit four large blast furnaces of more than 5,232 cubic yards (4,000 cubic meters) inner volume in 1973: (1) No. 5 furnace at Fukuyama Works, Nippon Kokan KK, 47.2 feet (14.4 meters) hearth diameter, 6,039 cubic yards (4,617 cubic meters) inner volume, lit November 1973; (2) No. 4 furnace, Mizushima Works, Kawasaki Steel Corp., 47.2 feet (14.4 meters) hearth diameter, 5,651 cubic yards (4,320 cubic meters) inner volume, lit April 1973; (3) Kashima Works, Sumitomo Metal Industries, No. 2 furnace, 45.3 feet (13.8 meters) hearth diameter, 5,337 cubic yards (4,080 cubic meters) inner volume, lit March 1973; and (4) Kimitsu Works, Nippon Steel Corp., No. 3 furnace 44 feet (13.4 meters), hearth diameter, 5,314 cubic yards (4,063 cubic meters) inner volume, lit September 1973.

The No. 5 blast furnace at the Fukuyama Works was reportedly the world's largest, with expected average daily pig iron output of over 11,000 tons. Planned steelmaking facilities at the Fukuyama plant will increase its annual capacity to 13.3 million tons of pig iron and 15 million tons of crude steel, by far the largest steelmaking plant in the world.

Kawasaki Steel Corp. announced that it was operating a new prereduced pelletizing plant at its Mizushima Works. The plant recycles iron dust and scale from blast and oxygen furnaces and rolling mills to produce prereduced pellets. Reported plant capacity was 40,000 tons per month of raw pellet mix.

Saudi Arabia.—The Saudi Arabian Government and Marcona Corp. of San Francisco conducted a feasibility study of the possibility of building a steel mill on the Arabian Gulf coast which would be based on Brazilian high-grade iron ore reduced by natural gas.

Taiwan.—The Government of Taiwan announced its intention to construct a 1.5-million-ton-per-year integrated steel mill at Kaohsiung. United States Steel Engineers & Consultants, through a contract with the China Steel Corp. of Taiwan, was to provide technical services for construction of the project.[36]

OCEANIA

Australia.—Broken Hill Proprietary Co. Ltd., the only integrated steel company in Australia, produced at capacity throughout the year but was unable to cope with the rising demand of the automobile and appliance industries for hot- and cold-rolled strip and plate. Despite the shortage of steel in Australian markets, the Australian Mining & Steel Pty. Ltd. (ASM), owned equally by Armco Steel Corp. and Kaiser Steel Corp. of the United States and August Thyssen Hütte of West Germany, decided to modify plans to erect an integrated steel mill to produce 2.9 million tons of slab and 500,000 tons of plate annually. ASM's

new plans were to construct a smaller electric furnace mill based on direct reduction of beneficiated ore at Jervis Bay in New South Wales.[37]

TECHNOLOGY

Blast Furnace.—The world's largest blast furnace was lit on November 8 at the Nippon Kokan Fukuyama Works in Japan. It had a 47.2 foot (14.4-meter) hearth diameter, was 318 feet (97 meters) high, and had 6,039 cubic yards (4,617 cubic meters) volume from stock to tap lines. The largest blast furnace in France was lit at Dunkirk on May 18 and held the world's record as the largest from May to November. It was a year of large furnaces. The largest furnace in the U.S.S.R. was lit in February. The Soviet furnace, however, did not compare with the others, having only 4,186 cubic yards (3,200 cubic meters) in working volume.

Bethlehem Steel Corp. patented a baffle nose tuyère, claimed to help solve burnout and wear problems in iron-making blast furnaces.[38]

Direct Reduction.—Direct reduction was the subject of a panel discussion at the International Iron & Steel Institute meeting held at Johannesburg, Republic of South Africa, in October. Although there was a great deal of interest in direct reduction and successful operations of direct reduction plants were reported, the consensus at the meeting was that a large-scale blast furnace is the most economical source of hot metal.

Armco Steel Corp. reported that its direct reduction plant at Houston, Tex., was completely debugged and producing at the rate of 900 tons per day. United States Steel's briquetting plant at Porto Ardaz, Venezuela, was inaugurated October 27, but Venezuelan Government officials declared that the briquets would not be permitted to leave the country while a need for them existed in Venezuela.

Fior de Venezuela S.A., (Fior) of which the Venezuelan Government was majority owner, and Lukens Steel Corp. which holds a minority interest in Fior contracted for design of a 44,000 ton-per-year fluidized bed iron ore reduction plant. The process to be used was developed by Esso Research and Engineering Co., a subsidiary of the Exxon Corp.

Swindell-Dressler Corp. contracted with the National Iranian Steel Industries Co. to design, build, and equip a plant to produce more than 1 million tons of sponge iron per year. The plant will use the HyL direct reduction process first developed and proved in Monterrey, Mexico.

Sidbec-Dosco Ltd. of Quebec commissioned a direct reduction plant, designed by the Midrex Corp., in April. The plant produced approximately 1,000 tons of direct reduced ore per day. The reduced product was fed directly to electric-arc furnaces.

Basic Oxygen Steelmaking Processes (BOP).—Steelmakers continued to favor basic oxygen steelmaking processes as a means of producing large quantities of steel, but the share of domestic BOP steel production decreased from 56% in 1972 to 55% in 1973 as the high production rate brought many open hearths back into service. United States Steel Corp. started its first bottom blown oxygen converter (Q–BOP) at the Gary, Ind., works early in the year; by May, the corporation reported the Q–BOP to be a complete success.[39] One advantage claimed for its operation was easier control of air pollution.

A study of slag-making reactions in the BOF process indicated that careful control of the flux minimizes refractory wear and slag buildup while maintaining a normal degree of desulfurization.[40]

Electric-Arc Furnaces.—Production of raw steel in the United States by electric arc furnaces in 1973 totaled 27,759,000 tons, an increase of 17% compared with production of 23,721,000 tons by electric furnaces in 1972. It is believed that most electric-furnace steelmaking operations in the United States operated at practical capacity throughout the year, although the

quality of scrap for feed undoubtedly decreased steel output somewhat. An estimated capacity of 32 million tons in 1972 in all probability included some furnaces under construction.

The pattern of increased use of electric-arc furnaces to make steel extended throughout the world. New furnaces were under construction in Canada, West Germany, France, and Japan. The Japanese led the world in increasing use of electric-arc furnaces, producing approximately 20 million tons of raw steel in electric furnaces, more than doubling their electric furnace output in the last 6 years.

Continuous Casting.—Continuous casting equipment in the United States apparently had marked effect on the ratio between raw steel production and steel mill shipments. Shipments in 1973 were 74% of raw steel production while they were only 69% of production in 1972. A large part of this difference was probably the result of steel mills shipping from inventory and the normal practice of not adhering to strict specifications during times of high production. Nevertheless, increased use of continuous casting in 1973 definitely improved the efficiency of the domestic steel industry.

Iron and Steel Refining.—Vacuum degassing of steel continued to receive increasing attention throughout the steel industry as consumers narrowed the tolerances allowable for alloy steels. For specialty applications, argon-oxygen decarburization (AOD) and electroslag remelting (ESR) processes were used for steels which require uniform mechanical properties throughout.

Test data on steels produced in the Lukens Steel Co.'s new ESR facility indicated that the method improved uniformity, tensile strength, ductility, and notch toughness. Lowering the concentrations of small inclusions could be directly attributable to the ESR process. The AOD process was the subject of the Extractive Metallurgy Lecture at the Annual Meeting of the Metallurgical Society of AIME.[41] An AOD vessel with sliding refractory gates to permit pouring through the bottom of the charge was commissioned at the Cabot Corp.'s Stellite Division, Kokomo, Ind.[42] Bottom pouring reportedly minimizes reentrainment of gases that had been removed previously.

Foundry.—The domestic foundry industry operated at its practical capacity throughout the year. Many founders were unable to obtain all the coke, pig iron, and scrap they needed and petitioned the Department of Commerce for priority to buy raw materials.

Research and Development.—U.S. Bureau of Mines researchers made a survey of underground injection of waste-pickle liquor from steel processing.[43] They determined that the average depth of waste pickle liquor injection wells is 4,000 feet and that injection is mostly by gravity flow. In other iron- and steel-related research at the Twin Cities Metallurgy Research Center, Bureau metallurgists investigated the fluorspar requirements in BOF steelmaking and fluorspar substitutes, and determined distribution of fluorspar in BOF products. At the Rolla Metallurgy Research Center, the use of ferrous wastes in cupola electric arc furnaces and BOF operations was studied. Studies were underway to improve utilization of ferrous metals with the general objective of producing ductile iron from blast furnace pig iron suitable for replacing steel in applications where lower strength and ductility could be tolerated. The Rolla studies included an investigation of possible methods for utilization or recovery of valuable alloy metals from stainless steel, ferroalloys, and steel wastes such as flue dust, mill scale, and grinding swarfs. At the Albany Metallurgy Research Center, continuous electric furnace steelmaking was studied to improve efficiency through the use of continuous charging and preheating of charge materials. Recycling of automotive and other ferrous scrap was investigated at the Salt Lake City Metallurgy Research Center.

Industrial researchers directed their attention to devising means of controlling steelmaking functions with computers and finding some way of overcoming the poor quality of steelmaking raw materials, principally coke and scrap iron and steel. The foundry industry was the hardest hit by poor scrap quality. Inasmuch as reactants were in short supply, the only method

devised by the foundrymen to overcome poor quality was to use less scrap and more foundry iron. Others researched desulfurizing iron with magnesium and use of mag-coke for desulfurizing.[44] The mag-coke apparently solved differential density problems in getting magnesium into molten iron. Reportedly, mag-coke (approximately 45% by weight magnesium) is immersed in molten iron and the thermal shielding effect of the coke controls the rate of magnesium vapor evolution, thus effectively lowering the sulfur content. Armco Steel Corporation reported that injection of powdered coal into its furnace in Ashland, Ky., was so successful that it planned to install injection equipment at its other blast furnaces. According to American Metal Market, Armco was satisfied with the coal injection. It plans to adapt other furnaces to it.[45] Experimental injection of coal into the smelting zone of a blast furnace was reported by the Bureau of Mines and others late in the 1960's. At that time, availability of inexpensive fuel oil and natural gas made coal injection economically unattractive.

An iron information center was established by Battelle Memorial Institute at its Columbus, Ohio, laboratories to serve the needs of industry in the fields of iron ore agglomeration and iron making.

[2] Excludes home scrap produced at blast furnaces.

[3] Does not include recycled material.

[4] Fluxes consisted of the following: 6,391 limestone, 198 burnt lime, 6,104 dolomite, and 338 other fluxes excluding 4,803 limestone, 13 burnt lime, 3,418 dolomite, and 113 other fluxes used in agglomerate production at or near steel plants and an unknown quantity used in making agglomerates at mines.

[5] Fluxes consisted of the following: 7,588 limestone, 51 burnt lime, 6,557 dolomite, and 471 other fluxes excluding 5,490 limestone, 3,437 dolomite, and 155 other fluxes used in agglomerate production at or near steel plants and an unknown quantity used in making agglomerates at mines.

Table 7.—Steel production in the United States, by type of furnace[1]

(Thousand short tons)

Year	Open hearth[2]	Basic oxygen converter	Electric	Total
1969	60,894	60,236	20,132	141,262
1970	48,022	63,330	20,162	131,514
1971	35,559	63,943	20,941	120,443
1972	34,936	74,584	23,721	133,241
1973	39,780	83,260	27,759	150,799

[1] Excludes castings produced by foundries not covered by AISI.
[2] Basic and acid open-hearth production data reported separately in previous years.

Source: American Iron and Steel Institute.

Table 8.—Metalliferous materials consumed in steel furnaces[1] in the United States

(Thousand short tons)

Year	Iron ore		Agglomerates		Pig iron	Ferro-alloys[2]	Iron and steel scrap
	Domestic	Foreign	Domestic	Foreign			
1969	710	2,121	487	512	84,187	1,775	74,343

1973	163	1,320	656	243	94,933	1,907	83,228

r Revised.
[1] Basic oxygen converter, open-hearth furnace, and electric furnace.
[2] Includes ferromanganese, spiegeleisen, silicomanganese, manganese metal, ferrosilicon, ferrochromium alloys, and ferromolybdenum.

Table 9.—Consumption of pig iron[1] in the United States, by type of furnace

Type of furnace or equipment	1971		1972		1973	
	Thousand short tons	Percent of total	Thousand short tons	Percent of total	Thousand short tons	Percent of total
Basic oxygen converter	52,023	66.2	60,233	69.9	68,077	69.7
Open hearth	23,574	30.0	22,375	25.9	25,477	26.1

e Estimate. p Preliminary. r Revised.
[1] Steel formed in first solid state after melting suitable for further processing or sale.
[2] In addition to the countries listed, North Vietnam produces raw steel, but information is inadequate to make reliable estimates of output levels.
[3] Data from American Iron and Steel Institute (AISI). Excludes steel produced by foundries not reporting output to AISI but reported to Bureau of Census as follows (in thousand tons): 1971—1,583; 1972—1,607; 1973—1,880.
[4] Ingots only.
[5] Apparently excludes shipyards' production of steel castings.

Iron and Steel Scrap

By D. H. Desy [1]

Consumption of iron and steel scrap reached a record high in 1973, reflecting record production of raw steel. Strong domestic and foreign demand for scrap drove prices to new highs and prompted the Department of Commerce to impose export controls in the latter half of the year. In spite of these controls, exports also reached record levels in 1973.

Research and development, both by the Bureau of Mines and by industry, continued on the utilization of the ferrous fraction of municipal scrap for making iron and steel. A small quantity of this material was recycled by the steel industry.

Legislation and Government Programs.—Because of rising prices and very high domestic and foreign demand for ferrous scrap during the year, representatives of the steel industry requested the Department of Commerce to impose export restrictions on that commodity. On May 22, 1973, the Department of Commerce imposed reporting requirements on all ferrous scrap exports to provide a basis for an estimate of demand levels for the balance of 1973. This estimate indicated a continuing high demand for ferrous scrap.

Under the authority of the Export Administration Act of 1969, the Department of Commerce on July 2, 1973, imposed licensing requirements on all exports of ferrous scrap. Licenses valid for 60 days were granted for orders of 500 tons or over that were accepted before July 2, 1973 for delivery during the balance of 1973. Licenses for orders under 500 tons were at first granted for export to all countries regardless of when these orders were accepted. These licenses were later restricted to Canada and Mexico for the months of October, November, and December 1973, and monthly quotas were established.

In December 1973, an overall export quota for ferrous scrap of 2,100,000 short tons for the first quarter of 1974 was announced by the Department of Commerce. Of this amount, 100,000 short tons were set aside for contingencies and hardships, and the balance was allocated by country following historical trade patterns.

Table 1.—Salient iron and steel scrap, and pig iron statistics in the United States

(Thousand short tons and thousand dollars)

	1972	1973
Stocks Dec. 31:		
Scrap at consumer plants	8,169	7,092
Pig iron at consumer and supplier plants	1,660	1,215
Total	9,829	8,307
Consumption:		
Scrap	93,371	103,589
Pig iron	89,140	99,816
Exports:		
Scrap (excludes rerolling material)	7,177	10,874
Value	233,395	570,011
Imports for consumption:		
Scrap (includes tinplate and terneplate scrap)	312	349
Value	14,741	19,100

AVAILABLE SUPPLY

The new supply of iron and steel scrap available for consumption at consumers' plants in 1973 was 102.5 million short tons. It consisted of 57.8 million tons of home scrap and 44.7 million tons of purchased scrap (net receipts). Compared with 1972 figures, home scrap production was up 13% and net receipts were up 11%.

[1] Physical scientist, Division of Ferrous Metals—Mineral Supply.

CONSUMPTION

Consumption of iron and steel scrap in 1973 reached a record high of 103.6 million short tons. This was an increase of 10.9% over consumption in 1972 and 9.3% above the previous high established in 1969. Manufacturers of steel ingots and castings took 82.5 million tons or 79.6% of the total. Iron foundries and miscellaneous users consumed 18.2 million tons or 17.5%, and manufacturers of steel castings consumed the remainder.

STOCKS

Consumers' stocks reported on hand as of December 31, 1973, were 7.1 million short tons, down 13% from 8.2 million tons at the end of 1972. Stocks remained between 7.8 and 8.0 million tons through August 1973, then declined to the yearend figure of 7.1 million tons.

PRICES

Prices of scrap iron and steel rose sharply during the year. At the end of November, the Iron Age composite price (Chicago, Pittsburgh, and Philadelphia) for No. 1 heavy melting steel scrap reached a record high of $81.83 per long ton, exceeding the record of $64.97 in December 1956. The composite price dropped slightly to $75.17 at the end of December 1973; this was 62.8% above the price of $46.17 at the end of December 1972.

FOREIGN TRADE

Exports of iron and steel scrap (excluding rerolling material, and ships, boats, and other vessels for scrapping) reached a record high of 10.9 million short tons in 1973, exceeding the 1970 record of 10.1 million tons by 8%, and the 7.2 million tons in 1972 by 52%. The total would probably have been higher if export licensing had not been instituted in mid-1973.

The largest exports went to Japan,

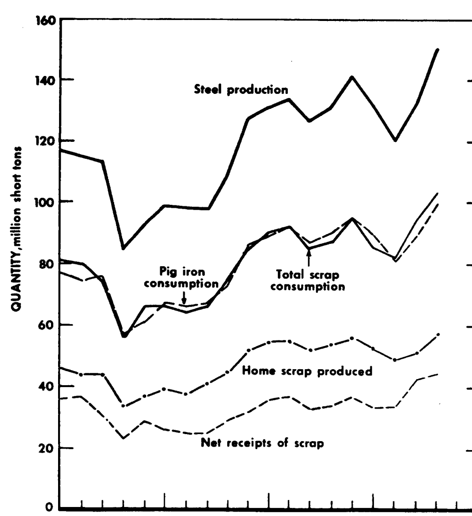

Figure 1.—Steel production (AISI); total iron and steel scrap consumption; pig iron consumption; home scrap production; and net scrap receipts.

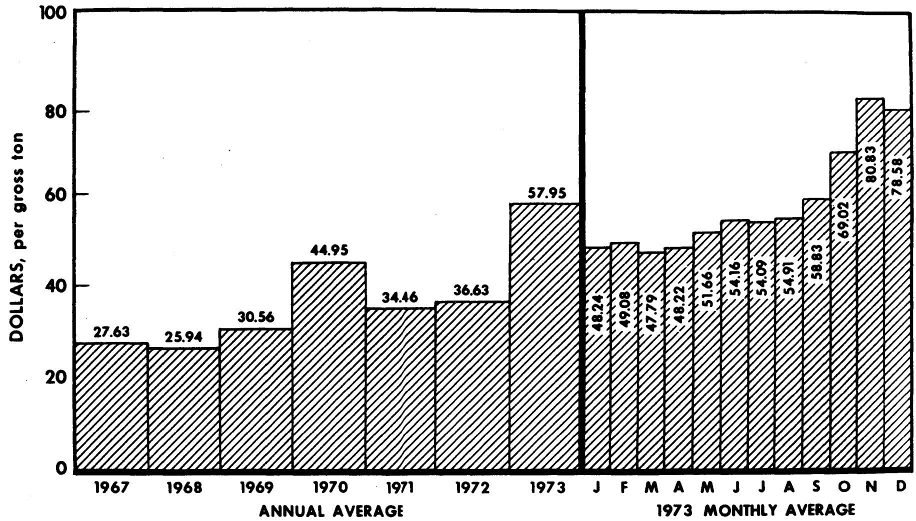

Figure 2.—Composite prices for No. 1 heavy melting scrap (Chicago, Pittsburgh, Philadelphia).

which received 42% of the total; next largest exports went to Spain and Mexico, which received 10% and 9%, respectively. Exports of ferrous scrap went to the People's Republic of China for the first time in 1973, amounting to 428,000 tons or 3.9% of the total.

No. 1 heavy melting steel scrap continued as the largest export grade, accounting for 35% of the total. Next largest export grades were shredded steel scrap and No. 2 bundles, which accounted for 19% and 11%, respectively.

WORLD REVIEW

Austria.—Domestic scrap supplies decreased about 50,000 tons from those of 1972 because of low price levels and the fact that the Government delayed approval of price increases as an anti-inflation measure.

Belgium.—High steel production, short supplies of coal, and high transportation costs have kept the demand for and price of scrap high. Scrap was imported at a rate equal to that of West Germany, about 1.5 million short tons annually.

Canada.—Because of U.S. restrictions on scrap exports, Canada canceled all export permits in August and introduced new procedures that limited scrap exports to a minimum. The Quebec Government-owned steel company, Sidbec-Dosco Ltd., has set up a subsidiary, Sidbec-Unifer, to supply it with steel scrap. The company will have authority to buy, sell, export, and process metal of all kinds. Scrap will be obtained from junk autos among other resources.

France.—Increased steel production brought consumption of scrap to an estimated 3.3 million short tons for the year compared with just over 2.2 million in 1972.

Germany, West.—Demand for scrap was high in this year of record steel production. Crude steel output rose to 54.2 million short tons, 13% over 1972; consumption of scrap was 27.6 million short tons, a 10% increase over that of 1972.

Italy.—New electric steel furnaces with total capacity of 800,000 tons per year are expected to start up by the end of 1973. Thus, demand for scrap will continue to increase.

Japan.—When export licensing of scrap iron and steel was imposed by the United States, Japan voluntarily reduced total imports from the United States in 1973 by 1 million tons (from 6.5 to 5.5 million, including scrap for reexport). The 1 million tons would be deferred to 1974. In addition, Japan agreed to spread imports evenly over the remainder of 1973. Domestic scrap prices declined somewhat at the end of the year as a result of the oil shortage. Steelmakers sought to stabilize the market by a series of measures including a coordinated import policy, a domestic distribution organization, and intermill cooperation over scrap stocks. The construction of 10 cryogenic plants for processing baled auto scrap by a Belgian process is being considered. There were approximately 10 large shredders in Japan in 1973.

Netherlands.—This country is a net exporter of scrap, most going to West Germany, France, and Belgium. With the entry of the United Kingdom into the European Community (EC), the Netherlands will be in a good position to transfer British export scrap arriving in Holland by ship to barges for shipment up the Rhine to West Germany.

Spain.—This country's expanding steel industry, which depends largely on imported scrap for its raw material, was adversely affected by restrictions on scrap exports from the U.S.A. in the second half of the year, as well as Britain's earlier export ban.

Sweden.—Scrap consumption was higher than 1972 levels, requiring increased imports, mainly from the U.S.S.R. and Poland. About 50 percent of all scrap automobile bodies are now being shredded.

United Kingdom.—Britain entered the EC on January 1, 1973; however, there will be a 2-year transition period during which some controls will be maintained on exports of ferrous scrap. One consequence of Britain's entry into the EC was the termination on July 1 of the long-standing pricing agreement between the steel industry and the scrap dealers. Export controls were tightened throughout the year, culminating on October 1 in a ban on exports of all but the lowest grades of scrap under strict licensing and quota regulations. Exports to countries outside the EC had been prohibited on May 21. Despite export controls, strong domestic demand kept prices up, though lower than in the rest of Europe.

TECHNOLOGY

The ferrous fraction of municipal waste, consisting mainly of tin-plated steel cans, is being increasingly recycled in ironmaking and steelmaking, although the percentage of the total is still small. Among the latest entries in the field is Granite City (Illinois) Steel Co., a division of National Steel, which is using cans from shredded municipal waste from St. Louis, Mo., in its blast furnace charge, at the rate of 15 pounds of scrap per ton of hot metal.[2] In New Orleans, La., steel cans obtained from a facility to be in operation in 1974 will

[2] Industry Week. Blast Furnace Joins Steel Recycling Effort. V. 176, No. 13, Mar. 26, 1973, p. 20.

be used by United States Steel in its new QBOP (bottom-blown basic oxygen process) furnace facility at Fairfield, Ala.[3]

General Motors' Central Foundry Division in Danville, Ill., has developed a method for melting bundled auto hulks without removing combustible material. The method can be used in cupolas with modern air pollution controls. The percentage of bundles used must be controlled to assure the quality of the metal produced.[4]

A cryogenic method that employs liquid nitrogen is being used in a pilot plant in Chicago to separate mixed scrap containing a significant percentage of copper, aluminum, and other nonferrous metals along with the ferrous portion.[5]

A new type of magnetic separator, specifically designed for separation of the ferrous fraction of municipal scrap has recently been made available. The new system is said to produce a much cleaner ferrous fraction than conventional magnetic separators.[6]

The Bureau of Mines continued its research efforts in the area of improving utilization of ferrous scrap and waste materials. Metallurgists at the Bureau's Albany (Oregon) Metallurgy Research Center completed a project to test the feasibility of producing electric furnace steel from the ferrous fraction of municipal waste, principally steel cans. The material was tested in the as-received, detinned, or incinerated condition; some was shredded or briquetted. Melting conditions, yield, and chemical composition were determined. Another project was concerned with the preheating and continuous charging into the electric furnace of shredded auto scrap and mixtures of scrap and prereduced iron pellets. Energy consumption, melting rate, yield, and ingot chemistry were being determined.

Scientists from the Bureau's College Park (Maryland) Metallurgy Research Center were acting as consultants to the contractors in the design and construction of a demonstration plant for the City of Lowell, Mass., to process 250 tons of incinerator residues per day. The plant is a scaled-up version of the pilot plant developed at this center, and was partially funded by a grant from the Environmental Protection Agency (EPA). Work was also continuing on refinements to the pilot plant, and residues from the Lowell, Mass., area were processed to provide data for the new plant there. Studies were continuing on methods of removing impurities from the ferrous fraction of the residues. A pilot plant for the treatment of raw refuse was essentially completed. A large number of processing tests were run and cost evaluations were made. Tin-plated cans from the treated refuse were evaluated by commercial detinning companies.

At the Bureau's Rolla (Missouri) Metallurgy Research Center, metallurgists continued to study the effects of impurities such as copper, tin, and lead in ductile cast iron (nodular cast iron). Such impurities are normally present in higher-than-desirable quantities in the ferrous fraction of municipal waste and other low grades of iron and steel scrap, and cannot be economically removed with present technology. The effects of combinations of tin and copper on the strength, ductility, and microstructure of ductile cast iron and the maximum levels and relative potency of these elements were being determined. Studies on the effects of small amounts of lead were initiated.

At the Bureau's Twin Cities Metallurgy Research Center in Minnesota, the use of ferrous waste in the cupola, electric arc furnace, and basic oxygen furnace (BOF) was being investigated. Various types of automotive scrap, including bundled, incinerated, and shredded material, were being evaluated for melting in the electric arc furnace. Yields and chemical content of harmful impurities in the product were determined. Iron-aluminum bimetallic cans were melted in the cupola, alone or in combination with shredded auto scrap, to produce a synthetic pig iron. The effect on fuel requirements, melting rates, and resid-

[6] Secondary Raw Materials. New Magnetic System To Revolutionize Recycling of Steel Cans. V. 11, No. 11, November 1973, pp. 98–99.

ual sulfur and aluminum content of the pig iron were being determined. Preheating of shredded scrap by BOF offgases was being studied as a means of increasing the percentage of scrap that can be added to the BOF charge. A method for preparing purified iron oxide pellets suitable for blast furnace use from impure oxides from incinerator residues and incinerated automotive scrap was also being investigated.

Electric furnace	28,615	904	2,496	41	4,242	434	35,353	1,379
Cupola furnace	1,621	311	286	8	13,345	1,957	15,252	2,276
Air furnace	30	6	27	5	121	46	178	57
Other furnaces [6]	218	220	2	--	465	182	685	402
Total	82,467	94,935	2,949	64	18,173	2,619	103,589	[7] 97,618

[1] Excludes molten pig iron used for ingot molds and direct castings.
[2] Includes only those castings made by companies producing steel ingots.
[3] Excludes companies that produce both steel ingots and steel castings.
[4] Includes consumption in all blast furnaces producing pig iron.
[5] Includes scrap and pig iron processed in metallurgical blast cupolas and used in oxygen converters.
[6] Includes vacuum melting furnaces and miscellaneous melting processes.
[7] Excludes pig iron used in making molds and poured directly into castings.

Table 4.—Proportion of iron and steel scrap and pig iron used in furnaces in the United States

(Percent)

Type of furnace	1973	
	Scrap	Pig iron
Basic oxygen converter	28.7	71.3
Open-hearth furnace	44.7	55.3
Electric furnace	96.2	3.8
Cupola furnace	87.0	13.0
Air furnace	75.7	24.3
Other	63.0	37.0

[1] New supply available for consumption is a net figure computed by adding production to receipts and deducting scrap shipped during the year. The plus or minus difference in stock levels at the beginning and end of year is not taken into consideration.

[2] Includes scrap shipped, transferred, or otherwise disposed of during the year.

Iron Oxide Pigments

By Henry E. Stipp [1]

Iron oxide pigments were in short supply during 1973 despite record high domestic production and increased imports, mainly of synthetic iron oxide pigments. Domestic demand for iron oxide pigments increased susbstantially because of a high level of paint, varnish, and lacquer sales for use mainly in the housing, automobile, and durable goods industries. Iron oxide pigments also were used for preparing materials for magnetic applications. Increased foreign demand for iron oxide pigments, as a result of a worldwide economic expansion, reduced the quantity of iron oxide material that normally could have been imported into the United States. Although U.S. imports of synthetic iron oxide pigments were larger than those in 1972, they were insufficient for domestic demand, and together with low inventories incurred in previous years, limited the ability of suppliers to satisfy total domestic requirements. However, the outlook for sluggish economic activity in 1974, particularly in the construction and automobile industries, should give producers an opportunity to catch up with domestic iron oxide pigment demand.

Legislation and Government Programs.—The U.S. Department of the Treasury issued a ruling that permanent magnets of ceramic material (ferrites) and alnico from Japan were not being sold in the United States at less than fair value.[2] In 1972, Japanese magnets totaling $3.3 million were imported into the United States.

r Revised. W Withheld to avoid disclosing individual company confidential data.

DOMESTIC PRODUCTION

Finished iron oxide pigments production (as indicated by sales) in 1973 increased, for the third consecutive year, to 178,788 short tons, a 2.5% rise over the 174,392 short tons of 1972. Some increase in plant capacity and more efficient operation of existing plants were considered to be the principal factors involved in producers' ability to raise domestic output. Yellow iron oxide production in 1973 posted the largest percentage increase (8.6%) in the manufactured category; natural metallic brown iron oxide increased 7.3% in output. Production of manufactured pure red iron oxide by other chemical processes increased 19.9% over that of 1972, whereas production of pure red iron oxide from calcined copperas decreased 16.3% from that of 1972. Output of natural red iron oxide in 1973 decreased 9.1% from that of 1972.

[2] Wall Street Journal. U.S. Finds No Dumping of Japanese Magnets. V. 181, No. 55, Mar. 21, 1973, p. 30.

The total value of finished iron oxide pigments increased 14.6% in 1973 to $46.2 million, compared with $40.3 million in 1972. In 1973, 14 companies operated 19 plants in 10 States. Pfizer Inc. was the major producer of finished iron oxides with plants in California, Illinois, and Pennsylvania.

Crude iron oxide pigment production and value increased sharply over that of 1972. Figures on production of crude pigments were withheld to avoid disclosing confidential company data. In 1973 crude iron oxide pigments shipments were valued at $770,000, an 84% increase over the $418,000 value in 1972. Six companies operating mines or plants in six States reported production of crude iron oxide pigments in 1973. The Cleveland-Cliffs Iron Co. produced the largest quantity from mines in Michigan.

CONSUMPTION AND USES

Apparent domestic consumption of iron oxide pigments[3] increased 1.2% to 220,083 short tons in 1973, compared with 217,395 short tons in 1972. Consumption probably was curtailed by supply shortages of several types of iron oxide pigments that occurred throughout the year. Reportedly, red and yellow manufactured iron oxide pigments were scarce. One of the factors said to be responsible for shortages of manufactured iron oxide pigments was lack of plant capacity. Capital investment was not attracitve during the previous 5 years because of the low price for iron oxide pigments. Thus there was little incentive for constructing new plants and installing new equipment. The added investment required for pollution control also was reported as contributing to the lack of capacity.[4]

Another factor contributing to domestic shortages was reportedly the devaluation of the U.S. dollar. This made it possible for foreign consumers to offer attractive prices for U.S. products. Exports of iron oxide pigments in 1973 were more than double those of 1972. Iron oxide pigments were used in paints, rubber, plastics, concrete products, paper, magnetic ink, fertilizers, and animal food. They were used also in preparing ferrities for applications as television components, filters in radio equipment, computer memory cores, door latches and seals, small electric motors, and inductor and microwave devices. Iron oxide was used in miscellaneous applications such as abrasives, welding rod coatings, soil conditioners, foundary sands, and automobile brake linings. Iron oxides combined with aluminum in paint formulations produce paints described as metallic for use in protecting automobiles from corrosion and enhancing their beauty. It was estimated that in 1972 the automobile industry used about $200 million worth of paint products in producing about 10 million vehicles.

Data are not collected by the Bureau of Mines on specific uses for iron oxide pigments, and the figures given in table 2 do not necessarily reflect all sales of iron oxide pigment material for uses other than pigments.

[3] Indicated by quantity of finished iron oxide pigments sold plus imports of natural and synthetic iron oxide pigments minus exports of pigment-grade iron oxides and hydroxides.

[1] Includes black magnetite and vandyke brown.
[2] Includes pyrite cinder.
[3] Includes yellow iron oxide.
[4] Includes other manufactured red iron oxide.

PRICES

Most synthetic grades of iron oxide pigments experienced price increases ranging from 1 cent to 1½ cents per pound effective from May 7 to May 11. Synthetic red iron oxides advanced from ½ cent to 2 cents per pound. Synthetic brown increased 1 cent per pound. Most synthetic yellow iron oxide was increased from 1 to 1½ cents per pound; light lemon advanced 2½ cents per pound.

FOREIGN TRADE

The quantity of natural and manufactured iron oxide pigments imported into the United States for consumption in 1973 increased 8.3% to 51,183 short tons, compared with 47,271 short tons in 1972. The value of iron oxide pigments imported in 1973 increased 40.8% to $12 million compared with $8.5 million in 1972. Manufactured (synthetic) iron oxide pigments comprised 73% of total imports of iron oxide materials in 1973. Approximately 70.3% of the natural iron oxide pigments imported in 1973 consisted of crude and refined umber.

The major share of synthetic iron oxide pigments imported in 1973 came from West Germany, Canada, and the United Kingdom. Synthetic imports from Canada increased 32% in quantity and 48% in value compared with those of 1972. Imports of synthetic material from West Germany and the United Kingdom decreased 5% and 42%, respectively, in quantity compared with imports in 1972. Natural iron oxides imported from Spain decreased 42% in quantity, whereas those imported from West Germany increased substantially. Imports of Persian Gulf red iron oxide ceased in 1973, reportedly because of a 300% increase in price, which placed its delivered U.S. price near that of comparable synthetic oxides.

A large West German producer began operating major new facilities for producing iron oxide pigments in 1973. Reportedly, large quantities were slated to be shipped to the United States; however, allocations were not increased owing to a high level of back orders.[5]

The quantity of pigment-grade iron oxide and hydroxides exported from the United States in 1973 increased 132% to 9,888 short tons, compared with exports of 4,268 short tons in 1972. Canada received the major share of U.S. exports. The value of pigment-grade iron oxide and hydroxides exported in 1973 increased 61% to $3.101 million, compared with $1.926 million in 1972.

TECHNOLOGY

Several new technological processes that produce iron oxide as a byproduct of their main operations have been reported. These processes could furnish crude iron oxide material for further refinement by producers to finished iron oxide pigments. One of these is a chemical process that removes sulfur from coal before it is burned and also produces iron oxide and iron sulfate in salable product form.[6]

The removal of impurities from water can be accomplished by seeding the effluent with iron oxide particles and treating the resulting solution with a high gradient magnetic separation machine.[7] Also weakly magnetic iron oxide and other minerals can be recovered, using the high gradient magnetic separation device.

A new high-intensity wet magnetic separator that can be used to remove iron oxides from ground fuel ash and quenched blast furnace flue gases has been introduced in England.[8]

Ilmenite ore was leached with ferric chloride solution; the resulting liquor was oxygenated to obtain a titanium dioxide concentrate and a substantially pure iron oxide byproduct.[9]

Titanium and iron oxides were prepared from red mud obtained as a byproduct of a process to produce alumina from bauxite.[10]

A lithim oxide—iron oxide—silicon dioxide ferrite material was studied to determine regions where $LiFe_5O_8$ could be formed as a crystalline phase.[11] The material was investigated also to determine how magnetic, electrical, and physical properties were related to composition, heat-treatment time, and temperature. Saturation magnetization, remanence, coercivity, and alternating current resistivities data were reported. The dielectric properties gave large dispersion effects. A limited substitution of silicon into the $LiFe_5O_8$ structure was indicated.

A possible successor to ferrite-core computer memory devices was reported with the discovery of a cheaper and easier method to make bubble memories for computer information storage systems.[12] Bubble memories have the capacity to store very much more data in less space and to function much more rapidly and reliably than mechanical and ferrite core devices. In addition, bubble memories are less costly to produce than ferrite-core memories. However, until bubble memory devices are perfected and gain acceptance by computer producers, ferrite materials will continue to be used in computers for information storage.

In March, the commercial production of samarium-cobalt magnets signaled the loss of a part of the market for ferrite permanent magnets.[13] The samarium-cobalt magnets are about three to four times stronger than most other permanent magnets; however, ferrite magnets will continue to be used in those applications, where cost is a factor. Ferrite magnets are significantly less costly to produce than samarium-cobalt magnets. The new magnets will be used in applications where size and field strength are the main factors to be considered.

A steam and heat treatment process applied to iron powder increased the corrosion resistance of the powder because of a film of oxide deposited on the exposed surface of the iron particles.[14] The iron oxide also improves the breaking-in condition of the part, and oxide in the pores space gives a network of hard, wear-resistant material after the surface film wears away. The treatment also imparts an attractive blue-black color to the iron particle and possibly could be used for pigment purposes.

Kyanite and Related Materials

By J. Robert Wells [1]

Kyanite, andalusite, and sillimanite are anhydrous aluminum silicate minerals that are alike in both composition and use patterns and have the same chemical formula, $Al_2O_3 \cdot SiO_2$. Related materials include synthetic mullite, dumortierite, and topaz, also classified as aluminum silicates, although the last two additionally contain substantial proportions of boron and fluorine, respectively. All of these kyanite-group substances have the capability of serving as raw materials for manufacturing special-duty refractories in the high-alumina caetgory, but there has been no record in recent years of significant utilization of either dumortierite or topaz for this purpose in the United States.

Although published statistics are not sufficiently complete to be wholly conclusive, it appears that the United States, India, and the Republic of South Africa are the leading world producers of kyanite-group minerals and that they may not be far from evenly matched in this regard. It can be presumed that the U.S.S.R. and perhaps a few other industrialized nations also produce significant quantities of these materials.

Consumption of the more sophisticated refractories, after a 2-year decline that occasioned a small decrease in domestic kyanite production (1972) and substantial curtailments abroad (1971 and 1972), recovered notably in 1973, pushing U.S. demand for kyanite-group materials to a level reportedly as much as 15% above the available supply. The conspicuous fact that U.S. exports of these materials increased 27% in 1973 over those of 1972 was evidence, furthermore, that they were being eagerly sought by the rest of the world. In August 1973, reflecting the kyanite seller's-market situation, one of the two major U.S. producers, C–E Minerals Inc., announced the launching of an immediate 30,000-ton-per-year expansion of its kyanite mining and processing facilities in Georgia.

Although no curtailment of operations explicitly attributable to fuel shortages had been reported by kyanite producers through yearend 1973 there may have been a portent in one firm's magazine advertisement that included an appeal to customers for tolerance because of "problems and delays from our many suppliers."

Legislation and Government Programs.—The allowable depletion rates for kyanite, established by the Tax Reform Act of 1969 and unchanged through 1973, were 22% for domestic production and 14% for foreign operations.

Revision in 1970 of the list of strategic materials for stockpiling excluded kyanite-mullite, and Congress accordingly authorized a sealed-bid sale of the Government holdings (2,816 tons of Indian lump kyanite and 2,004 tons of fused synthetic mullite). The entire quantity of mullite was sold in June 1973 for $160,320; the stockpiled kyanite, for which no bids had been received through December 1973, was scheduled to be re-offered at a future date.

The U.S. Geological Survey's Office of Minerals Exploration provides Government loans of up to 50% of approved costs for the exploration of eligible kyanite deposits; no loans for that purpose were made in 1973.

[1] Physical scientist, Division of Nonmetallic Minerals—Mineral Supply.

DOMESTIC PRODUCTION

Production of kyanite in the United States increased notably in 1973, surpassing the previous record (1971) by 10% in tonnage and by 11% in terms of total value thus reaching the highest point in history. All but a small fraction of the domestic kyanite produced in 1973 came from three hard-rock openpit operations in two eastern States. Kyanite Mining Corp. used a froth-flotation process to extract the mineral from kyanite-quartzite ore mined at two locations in Virginia—Willis Mountain in Buckingham County and Baker Mountain in Prince Edward County; in Georgia, C–E

Minerals, Inc., treated the same type of ore in a similar operation at Graves Mountain, Lincoln County. The comparatively small remainder of the 1973 total in the form of kyanite-sillimanite concentrate was obtained by E. I. du Pont de Nemours & Co., Inc. as a byproduct from the recovery of titanium and zirconium minerals from a sand deposit at Trail Ridge, Clay County, Fla.

Synthetic mullite was produced in 1973 at six locations in the eastern United States, and although higher total values were reported for some previous years, the 1973 tonnage was the highest on record. Electric-furnace fused mullite was produced by Babcock & Wilcox Co. at Augusta, Richmond County, Ga. High-temperature sintered material was produced by A. P. Green Refractories Co. at Philadelphia, Pa.; Harbison-Walker Refractories Co. at Eufala, Henry County, Ala.; Mullite Corp. of America at Amercius, Sumter County, Ga.; Chas. Taylor Sons Co. at Taylor, Greenup County, Ky.; and H. K. Porter Co., Inc. at Shelton, Fairfield County, Conn. Operation of the H. K. Porter plant in Connecticut was terminated in May 1973, the property was sold, and it was reported that resumption of mullite production at that location is not expected.

Table 1.—Synthetic mullite production in the United States

(Short tons and thousand dollars)

Year	Quantity	Value
1969	48,588	6,847
1970	55,516	8,840
1971	55,077	4,945
1972	46,389	4,080
1973	58,176	5,211

CONSUMPTION AND USES

Kyanite and related materials, conforming to the established end-use pattern, were consumed in 1973 mostly in the manufacture of high-alumina or mullite class refractories and in lesser quantities as ingredients in some ceramic compositions. Imported Indian kyanite was calcined in its natural lump form, after which it was usually separated into designated particle-size ranges for use chiefly as a grog. Domestic kyanite, already ground to minus 35 mesh as required by the flotation process used in its separation and recovery, was marketed in the raw form or after heat treatment, that is, as mullite, which was sometimes further reduced in particle size before use. In the 35- to 48-mesh range, the mineral was used mostly in refractories applications such as for high-temperature mortars or cements, ramming mixes, and castable refractories, or with clays and other ingredients in refractory compositions for making kiln furniture, insulating brick, firebrick, and a wide variety of other refractory articles. More finely ground material, minus 200 mesh for example, was used in body mixes for sanitary porcelains, wall tile, precision casting molds, and miscellaneous special-purpose ceramics.

PRICES

Engineering and Mining Journal, December 1973, listed prices for kyanite, f.o.b. Georgia, ranging from $58 to $73 per short ton in bags and $2 less per ton for bulk shipments.

Prices ranges quoted for kyanite-group materials in Ceramic Industry Magazine, January 1974, were as follows:

	Per short ton
Andalusite	$30–$60
Kyanite	63–116
Mullite, calcined	82–135
Mullite, fused	160–450

The December 1973 issue of Industrial Minerals (London), quoted kyanite-group price ranges approximately equivalent (with some uncertainty due to a floating exchange rate) to the following:

	Per short ton
Andalusite, Transvaal, c.i.f. main European port	$45–$54
Kyanite, Indian, c.i.f. main European port	64– 83
Sillimanite, Indian, natural bagged, f.o.b.	73– 79
Sillimanite, Indian, calcined, f.o.b. Calcutta	83– 90

FOREIGN TRADE

For many years U.S. kyanite-group foreign trade could be presented by plotting the annual export and import statistics to the same scale, but the two sets of data have become so increasingly disparate in recent years, that such a graphic comparison is now of little value. Exports, formerly in a subordinate position, have registered a spectacular increase, while imports have fallen almost to the point of disappearance. The export/import tonnage ratio, which had averaged on the low side of 1 to 1 since records were first kept, decisively crossed over that line in 1963, and the reported figures are no longer of comparable magnitude; in both 1972 and 1973 exports were hundreds of times greater than imports. It was stated that only about 15% of the domestic kyanite output is shipped abroad,[2] so that it can be supposed that the greater part of the material currently being exported consists of mullite. It is to be noted, however, that some element of uncertainty is inherent in such conclusions because the Bureau of the Census export figures on which they are based do not clearly distinguish synthetic mullite from some other mullite-containing materials prepared by high-temperature processing of certain bauxitic and kaolinitic minerals.

WORLD REVIEW

France.—Although at present France is a substantial net importer of kyanite-group minerals for making high-alumina refractories, it was predicted that increased production of andalusite from the relatively new mining operation of Denain-Anzin Minéraux at Glomel will be capable of meeting a major part of the nation's future requirements of those materials.[3]

Guyana.—The Guyanan Geological Society, in a program aimed at diversification of the domestic mining industry, launched a study of recorded occurrences of a number of minerals not presently being exploited. It was stated that a known deposit of kyanite was determined to contain 2.2 million tons of ore, presumably of workable grade. Successful commercialization of this mineral, providing an advantageous

[3] Industrial Minerals (London). Refractories in Western Europe. No. 65, February 1973, pp. 9–11, 13–15, 17–19, 21, 23, 25, 27.

complement for the already established bauxite industry, would help to bring Guyana into a favorable position as a world supplier of high-alumina raw materials for the manufacture of refractories.[4]

India.—Lump kyanite from India has long had an international reputation for superiority as a raw material able to serve in a number of exacting applications. Although that mineral has been a significant item in India's export trade for nearly 50 years, there have been until recently no reliable estimates of available reserves in even the best-known deposits. To remedy that deficiency, the Geological Survey of India launched a study in 1970 aimed at a definitive evaluation of those resources; a preliminary report issued in 1971 pointed to the existence in the States of Bihar, Maharashtra, Mysore, and Orissa of 3.8 million tons of recoverable kyanite ore. The average grade of the material was not specified, but pure kyanite, $Al_2O_3 \cdot SiO_2$, theoretically contains 62.9% alumina, and material produced in the named areas in the past has been predominantly in the range from 60% to 62% Al_2O_3. The Survey also identified, in addition to the presumably high-grade mineral referred to, approximately 67 million tons of kyanite-quartzite material in Bihar probably rating a classification of subeconomic under present circumstances. India's kyanite production was in private hands until March 10, 1972, when the Indian Central Government nationalized the holdings of the then principal producer, the Indian Copper Corp., owner of the famous Lapsa Buru alluvial deposits, said to hold at least nine-tenths of the nation's kyanite reserves. Compounding the uncertainty of the situation, it was announced early in 1973 that the State Government of Bihar has decided "in principle" to take over all kyanite mining operations in that State.

Japan.—High-alumina raw materials for making refractories are not available in sufficient quantities from indigenous sources, and the nation's requirements must be imported; India, the Republic of South Africa, and the United States are the principal suppliers. Imports of kyanite, andalusite, and sillimanite amounted to 43,100 tons in 1970, 28,800 tons in 1971, and about 23,700 tons in 1972 with exports averaging about 4,000 tons annually.[5] Total figures for Japanese consumption of kyanite-group minerals plus synthetic mullite in those same 3 years were 90,200 tons, 48,700 tons, and 51,700 tons, respectively.[6]

South Africa, Republic of.—South Africa's output of andalusite in 1972 (latest figure available) amounted to 50,500 tons, 3% more than the figure for the previous year. Production of sillimanite, on the contrary, dropped sharply in 1972, reaching only 10,500 tons, 46% less than the 1971 total and 73% below that for 1970, apparently reflecting falling demand for export, the customary outlet for about 90% of the yearly total. In comparison, only 30% to 50% of the andalusite produced in South Africa is shipped to foreign markets.[7]

Tanzania.—Kyanite, in association with at least four other nonmetallic minerals of actual or potential commercial importance, was found to exist in Tanzania's residual beach sands along the Indian Ocean coastline. A report by the Tanzanian State Mining Corp. pointed out that, although a conclusive survey of the Continental Shelf is not yet available, it is inferrable that extensive marine deposits of those minerals will be found at dredgeable depths at a number of offshore locations.

1 Owing to incomplete reporting, this table has not been totaled.

2 In addition to the countries listed, a number of other countries presumably produce kyanite and related minerals, but output data are not reported and no basis is available for estimation of output levels.

3 In addition, sillimanite clay (also called kaolinized sillimanite) is produced; output in 1971 totaled 11,229 short tons. (Data for 1972 and 1973 not available.)

TECHNOLOGY

Refractories, both those of the fire clay type and those based on such nonclay materials as mullite, are indispensably involved in all ramifications of today's complex industrial structure and thus exert a pervasive influence upon practically every aspect of modern living. Availability of suitable furnace refractories, for example, is a vital prerequisite for the generation of steam power and for the smelting and refining of copper for which there is no acceptable substitute in the generation of electricity. A report was published pointing out that an inadequate allocation of energy to the refractories industry would inevitably precipitate profound changes in the established technology of refractories production and utilization, seriously hampering the general economy and, in a synergistic repercussion, contributing to an even further restriction of the energy supply itself.[8]

In a patented procedure for beneficiation of kyanite and other specified silicate ores in which iron is subordinate but not absent, undesirable overgrinding is minimized by first pre-crushing the material and then heating it in air to a temperature in the range of 1,100° C to 1,400° C. The calcination is said to have an agglomerating effect on the siderite, goethite, or other iron minerals present, and it is claimed that the proportion of fines generated in the subsequent reduction of the ore to the desired particle size is substantially less than when the same material is comparably ground in an uncalcined condition.[9]

A patent was issued for producing glass-ceramic compositions in the Cs_2O-Al_2O_3-SiO_2 system, in which the principal crystalline phase consists essentially of mullite. Such materials are described as translucent to transparent and dimensionally stable at temperatures up to 1,250° C, which properties enable them to serve advantageously for high-temperature lamp envelopes.[10]

A journal article dealing especially with the high-alumina refractory materials, of which kyanite, andalusite, sillimanite, and mullite are examples, contained a discussion of various criteria other than chemical analysis that should be taken into consideration in selecting refractories for specific applications. Hot modulus of rupture, room-temperature modulus of rupture, fracture toughness, and deformation at high temperature were among the properties mentioned. Examples were cited in support of the conclusion that chemical composition alone should be regarded as no more than a partial guide to a refractory's performance.[11]

Although mullite-based ceramics offer a number of advantages (notably superior mechanical stability and resistance to thermal shock), development of such products has been hampered by inadequacies, both qualitative and quantitative, in the available supply of requisite constituents. Preparation of appropriate ceramic powders of suitable purity by organo-metallic and freeze-dry techniques is costly, tedious, and often hazardous due to the use of volatile solvents that may be both flammable and toxic. Direct mixtures of alpha-alumina and silica do not react readily to form mullite, while those of amorphous alumina and silica, although highly reactive, generally produce mullite with an unacceptable proportion of residual corundum. In the course of research directed toward the processing of aluminosilicate ceramics, an improved method was developed for preparing mullite powder. A weakly acidified colloidal suspension of gamma-alumina was mixed with similarly dispersed amorphous silica, and the resulting hydrosol mixture was then caused to gel by gradually increasing the pH by dropwise addition of aqueous ammonia. Subsequent drying of the gelled material, followed by grinding and firing, yielded a fine-grained product that was shown by chemical and spectrographic analysis and X-ray diffraction to be mullite of theoretical composition and outstanding purity. A feature of the powder was the globular form of the particles, notably different from the acicular habit of mullite obtained in other procedures.

In a subsequent phase of the same research, experiments were carried out on the sintering of the newly available mullite powder under high pressure in an evacuated and induction-heated graphite die. Two journal articles were published presenting information on this experimental work and its conclusions.[12]

Orifice rings, vital components in automatic machines for mass production of glass containers, used to be fabricated from clay-bonded sillimanite or mullite, but the parts so obtained were often deficient in resistance to wear and thermal shock. A switch to harder high-alumina materials for this purpose has posed difficult machining problems with additional complications from the increasing demand for single-, double-, and triple-gob orifices in a profusion of shapes and sizes. Diamond-tool techniques in use by Emhart Corp., Hartford, Conn., for the precision coring of orifice blanks formed by slip casting or press extrusion of the newer materials were described in an industrial journal.[13]

Lead

By J. Patrick Ryan [1]

World production and consumption of lead, continuing an upward trend, again reached record high levels in 1973. Free world mine production increased about 1%, with most of the net gain coming from Canada, Mexico and Peru. Refined lead production also was up about 1%. Consumption of metal rose nearly 5% and exceeded production, the deficit being balanced essentially by withdrawals from producers and Government stocks. The world production deficit and continued strong demand was reflected in rising prices. The monthly average London Metal Exchange (LME) cash price increased 86% and exceeded the U.S. producers average price during most of the year. The average equivalent LME price in 1973 was 19.47 cents. The average domestic price of lead on a nationwide basis in 1973 was 16.29 cents per pound.

Both domestic mine and smelter production of lead were down slightly in 1973 from the 43-year record high levels achieved in 1972. Output from the new Brushy Creek mine, which began production at midyear, was not enough to offset losses due to closure of the Federal and Mayflower mines late in 1972. Secondary smelter output increased 6% to 654,300 tons, a new record that amounted to nearly 49% of total smelter and refinery production of lead.

Demand for lead in the transportation field continued to grow as requirements for batteries and gasoline antiknock compounds together increased nearly 4%. The quantity of lead used in battery manufacture again reached a new record high, and lead used in antiknock additives was only slightly less than in 1972. Lead used in pigments increased 22%. Of the total lead consumption of 1.54 million tons, batteries accounted for 50%; antiknock compounds, 18%; pigments, 7%; ammunition, 5%; and solder, 5%.

Stocks of refined and antimonial lead at primary plants dropped from 64,500 tons at the beginning of the year to 26,100 tons at yearend. Consumer stocks increased from 118,500 tons at the beginning of the year to 124,000 tons at yearend. Commercial sales and transfers for Government use, totaling about 248,500 tons, reduced the total uncommitted Government stockpile inventory of lead to 829,100 tons at yearend.

American Smelting and Refining Company (ASARCO) and The Anaconda Company announced in August joint plans to accelerate development and bring the Ontario lead-zinc-silver mine at Park City, Utah, into production. Annual production of concentrates containing approximately 15,000 tons of lead, 25,000 tons of zinc, and 1.2 million ounces of silver is scheduled to begin in 1975.

Legislation and Government Programs.—The General Services Administration (GSA) reported that commitments to purchase surplus lead from the Government stockpile totaled 248,552 tons in 1973. Of the total, 238,913 tons represented commercial commitments through producers and the set-aside program; the remaining 9,639 tons represented transfers for Government use. The stockpile objective for lead was reduced to 65,100 tons by Excutive Order on April 12, 1973, thereby increasing the uncommitted surplus to 763,963 tons at yearend, of which 299,063 tons was available for disposal under legislation enacted in 1972. Actual physical drawdown of Government stocks during 1973 was 211,541 tons, leaving a total inventory in storage

[1] Physical scientist, Division of Nonferrous Metals—Mineral Supply.

of 874,330 tons on December 31.

Following reduction of the stockpile objective, an omnibus bill (H.R. 7153) was introduced in the Congress which would authorize the General Services Administrator to dispose of various materials from the national and supplemental stockpiles, including 464,900 tons of lead representing the difference between the old and new objectives. By yearend, no further action had been taken on the bill.

Bills (H.R. 3743, S607) to amend the Lead-Base Paint Poisoning Prevention Act were introduced in the 93d Congress, 1st session. These bills essentially provide for reducing the lead content of paints, conducting research to determine the safe level of lead in residential paint products, and would prohibit the use of lead-base paint in some consumer products and in future housing built with Federal aid. A compromise bill won final Congressional approval in October and became Public Law 93–151 on November 9. The lead and zinc flexible tariff bill (H.R. 6437) reintroduced in Congress in March contained a provision for increasing tariffs on lead in imported concentrates, unwrought and wrought metals, waste and scrap, and on manufactures of lead when exceeding specified limiting quantities. No further action was taken on the bill by the 93d Congress, 1st session.

On December 9, the Environmental Protection Agency (EPA) published revised regulations applicable to gasoline refiners designed to reduce the lead content of gasoline 60%–65% over a 5-year period, 1975–79. The new schedule, based on the total pool average lead content per gallon for each 3-month period, is as follows:

January 1, 1975	1.7 grams per gallon
January 1, 1976	1.4 grams per gallon
January 1, 1977	1.0 gram per gallon
January 1, 1978	.8 gram per gallon
January 1, 1979	.5 gram per gallon

The provision that at least one grade of lead-free gasoline—0.05 gram per gallon—be made available by July 1, 1974, remained unchanged.

Responding to lead dumping charges by the Bunker Hill Company, the U.S. Treasury Department made a determination in October that primary lead metal from Australia and Canada was being sold in the United States at less than fair market value within the meaning of the Antidumping Act. Following the determination by Treasury, the U.S. Tariff Commission instituted an investigation and held hearings in December on the question of injury, and on January 10, 1974, the Commission ruled that the dumping had caused or threatened injury to the domestic primary lead industry. As a result of the Commission's ruling, imports of primary lead from Australia and Canada sold at less than fair value will become subject to special dumping duties. On December 7, the Cost of Living Council removed its price control on lead and several other nonferrous metals to assure adequate domestic supplies of the metals vital for many capital-goods producers. The Council's action was said to be sufficient to encourage expansion of domestic capacity and supply as well as to bring domestic prices closer into line with world market prices.
