After rising for 5 consecutive years to a 43-year high in 1972, mine production dropped about 3% in 1973 to 603,000 tons. Monthly production reached a maximum of 55,900 tons in May, slightly less than the maximum achieved in 1972. Production from Missouri mines, which accounted for 81% of the Nation's total, was down slightly. Output in Idaho, which provided 10% of the total, was virtually unchanged. Utah's output dropped sharply following the closure of the Mayflower mine at year-end 1972. Output of lead at Kennecott's Burgin mine also was lower than in 1972 due to a shortage of skilled miners together with delays attributed to adverse underground mining conditions.[2]

The Buick mine jointly owned by Amax Lead Co. of Missouri (AMAX) and Homestake Mining Co. was again the leading lead producer with an output of 1.6 million tons of ore, an increase of 10% over that of 1972. Production of lead concentrate was up 19% to 225,000 tons. The six leading mines, all in Missouri, contributed 75% of the total U.S. mine production of lead. The 10 leading mines produced 86%, and the 25 leading mines contributed 99%. About 4,900 persons were employed in the Nation's lead, lead-silver, and lead-zinc mines and mills in 1973. Output of lead and zinc from these mines per man year was approximately 150 tons. Average grade of lead ore mined was 6.55% lead and 1.08% zinc compared with 5.89% lead and 0.73% of zinc in 1972.

St. Joe Minerals Corp. reported that output from its southeast Missouri mines declined 29,000 tons to 283,602 tons owing to the phasing-in of its new production facilities at Brushy Creek, which replaced the Federal mine in the Old Lead Belt that closed in October 1972. St. Joe, the Nation's largest lead mining company has four mine-mill operations in the New Lead Belt of southeast Missouri: Fletcher, Viburnum, Indian Creek, and Brushy Creek. The company stated that the higher grade ore (4%–8%) and improved mining and milling technology in the New Lead Belt operations has brought a substantial increase in productivity compared with operations in the Old Lead Belt. St. Joe estimates its proven

[2] Kennecott Copper Corp. 1973 Annual Report. P. 11.

lead reserves at 50 million tons—enough for 15 years production at the current rate of mining—and its probable ore reserves at an additional 100 million tons, or 30 years of production.[3]

Ozark Lead Co. produced 59,199 tons of lead in concentrate from its Ozark mine operations compared with 69,100 tons in 1972. The falloff in production resulted from a 2-month labor strike and a shortage of skilled underground maintenance personnel.[4]

The Bunker Hill Company reported that production of lead from company owned and controlled mines in Idaho aggregrated 31,000 tons, about the same as in 1972. The company reported that proven and probable ore reserves at yearend in the Bunker Hill mine totaled 2.01 million tons averaging about 3.6% lead, 5.1% zinc, and 2.1 ounces of silver per ton.[5] Hecla Mining Co. reported that ore production at the Star-Morning mine, jointly owned by Hecla (30%) and Bunker Hill (70%), increased 2,200 tons to 265,780 tons. Hecla's share of the 1973 production of lead-zinc-silver ore was 79,734 tons assaying 5.18% lead, 6.68% zinc, and 2.79 ounces of silver per ton. Hecla's share of the computed ore reserves increased 21,000 tons to 286,000 tons at yearend. Hecla's Lucky Friday mine produced 176,859 tons of silver-lead-zinc ore assaying 11.2% lead, compared with 192,020 tons assaying 10.4% lead in 1972. The decline in 1973 mine output was attributed largely to a continued shortage of skilled underground miners. Ore reserves at Lucky Friday at yearend totaled 510,000 tons, about 74,000 tons less than a year earlier.[6]

Lead output in Colorado, reversing the rising trend of the preceding 5 years, declined about 3,200 tons to 28,100 tons in 1973. Both the Leadville unit (Resurrection mine) and the Idarado Mines reported lower production during the year. The Leadville unit, a joint venture of ASARCO and Newmont Mining Corp., produced 199,000 tons of lead-zinc-silver ore and recovered 7,200 tons of lead.[7] Owing largely to a manpower shortage, the mine did not produce at more than about 75% of its rated capacity of 700 tons of ore per day during the year. Ore reserves at yearend were estimated at 2.62 million tons averaging 4.98% lead, 9.71% zinc, 2.53 ounces of silver and 0.067 ounce of gold per ton. Idarado Mining Co. mined and milled 378,200 tons of lead-zinc-copper ore in 1973 compared with 386,500 tons in 1972. Ore reserves at yearend 1973 were 3.24 million tons averaging 3.36% lead, 4.61% zinc, 0.77% copper, 1.77 ounces of silver and 0.02 ounce of gold per ton.

Park City Ventures, jointly owned by The Anaconda Company and ASARCO, announced in August plans to continue development and to commence operations at the Ontario lead-zinc-silver mine at Park City, Utah. Development plans include deepening the production shaft to the 2,500-foot level and construction of a 700-ton-per-day flotation concentrator. Mine production at a rate of 5,000 tons of ore per week is scheduled to commence in early 1975. Officials estimated that 43,000 tons of zinc concentrate, 25,000 tons of lead concentrate and 1.2 million ounces of silver will be produced annually. The Ontario was the original mine in the Park City district and operated more or less continuously from 1872 until 1970.

SMELTER AND REFINERY PRODUCTION

Reversing the rising trend since 1967, output of lead at the four primary refineries in 1973 was slightly less than the 43-year record high production established in 1972. The gain in metal recovered from foreign ores and concentrates did not fully offset the decline in metal recovered from domestic concentrates. Production from domestic primary sources was down about 7,300 tons; the gain from foreign sources was about 6,400 tons. About 84% of the 674,500 tons of primary lead produced was derived from domestic ores compared with 85% in 1972. Antimonial lead production at primary refineries, after declining for 4 consecutive years, increased slightly to nearly 14,300 tons because the average antimony content of ores increased 0.5% to 7.5%.

The Herculaneum, Mo., smelter of St. Joe Minerals Corp. produced 215,000 tons of lead metal and alloys, about 7,100 tons more than in 1972. The smelter operated below its 230,000-ton rated capacity because

of a planned 3-week shutdown to install new environmental control equipment.[8]

ASARCO reported that its lead smelters maintained production at 1972 rates but continued to operate below capacity owing to environmental restrictions. The Glover, Mo., custom smelting and refining plant produced 82,300 tons of lead compared with 86,400 tons in 1972. Most of the concentrate treated at the Glover plant continued to come from the Ozark mine at Sweetwater, Mo. Concentrates from nine other domestic mines in four States and from one mine in Honduras also were treated at Glover. The East Helena, Mont., smelter operated continuously during the year processing crude ore and concentrates from about 94 domestic mines in 9 States and from mines in Canada, Peru, Colombia, and Australia. The El Paso, Tex., lead smelter processed ores and concentrates from approximately 24 domestic mines in 6 States and from mines in Peru, Canada, Honduras, Nicaragua, Australia, and Mexico. Refined metal output at the company's Omaha, Nebr., refinery, which processed lead bullion from the East Helena and El Paso smelters, totaled 165,100 tons, 22,400 more than in 1972.

AMAX reported that its smelter at Buick, Mo., produced 135,000 tons of refined lead in 1973, about 2,000 tons more than in 1972. About 57% of the total production was for the owners' account, and the remainder was refined on toll for other producers.[9]

The Bunker Hill smelter-refinery of Gulf Resources & Chemical Corp. at Kellogg, Idaho, operated continuously, except for a 4-day strike shutdown, and produced 130,200 tons of lead in all forms, about 1,600 tons less than in 1972. The reduction in output was due in part to the work stoppage and partly to efforts to comply with air pollution standards.[10] The company treated concentrates from nine domestic mines in five States and from mines in Canada.

Secondary smelter production of lead from recycled materials increased about 37,700 tons to a new record output of 654,300 tons, about 49% of the total smelter and refinery production. Approximately 140 secondary plants were engaged in recovery of lead and lead alloys from scrap materials during the year. Secondary output represented about 42% of total lead consumption in 1973.

RAW MATERIAL SOURCES

Domestic mines delivered 603,000 tons of recoverable lead in concentrates to six domestic primary smelters. This represented 88% of the total production of 687,700 tons of primary refined lead and antimonial lead, about the same proportion as in 1972. Lead recovered from imported concentrates smelted during the year amounted to nearly 111,500 tons, about 6,500 tons more than in 1972. Lead recovered from lead scrap processed at primary plants dropped to about 1,100 tons contained in antimonial lead compared with a total of 7,000 tons in 1972. Raw material stocks at the beginning of the year at primary plants totaled 197,300, of which 101,900 tons was in process and 2,500 tons was in secondary materials. At yearend, stocks of primary materials awaiting process contained 88,500 tons of lead, material in process 78,200 tons, and secondary material 2,800 tons, a total of 169,500 tons.

Scrap materials consumed in 1973 totaled 867,800 tons, 53,400 tons more than in 1972. About 98 secondary smelters accounted for nearly all of the total scrap consumed. New scrap in the form of purchased drosses and residues from a wide variety of sources aggregated 154,700 tons, about 18% of the total input. The remainder, old scrap, was predominantly battery scrap, with lesser quantities of cable lead, type metal, solder, babbitt, and soft and hard lead. Nearly all of the scrap processed originated from domestic sources. General imports of reclaimed scrap, mainly from Australia, totaled nearly 2,700 tons (lead content), about 17% less than in 1972, but exports of lead scrap totaled nearly 60,000 tons, about 24,700 tons more than in 1972. Stocks of scrap at smelters increased 18,000 in 1973 tons to 84,300 tons at yearend.

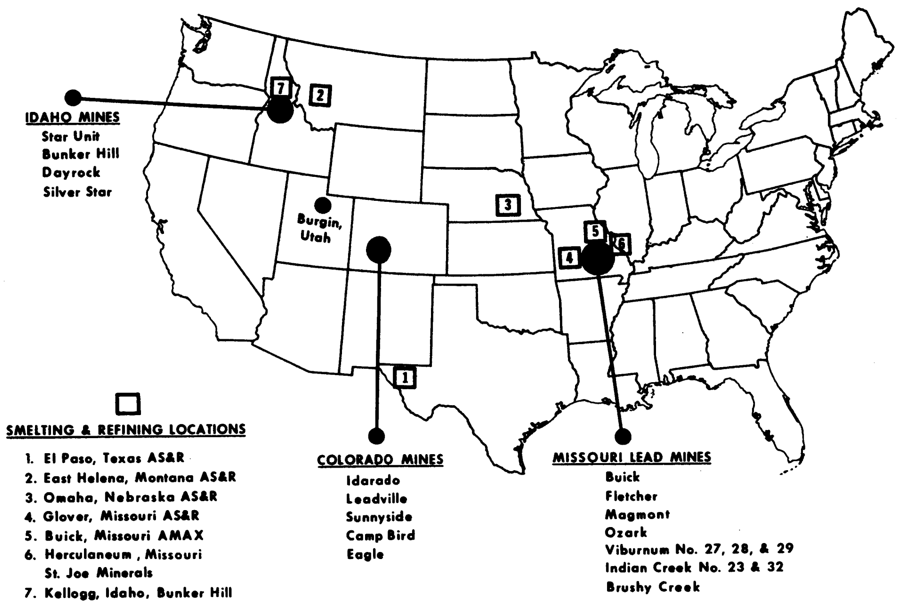

Figure 2.—Lead mines and smelters in the United States.

CONSUMPTION AND USES

Lead consumption in the United States increased nearly 4% in 1973 to a new record of 1.54 million tons. Monthly requirements ranged from a new record high of 143,200 tons in March to a low of 101,900 tons in July. In the metal products category, which accounted for 72% of the total lead consumption, the 6% increase in battery requirements more than offset combined decreases in ammunition, cables, calking, and tubes. Significant gains also were recorded in the quantity of lead used in brass, pipes, terne and type metals. The growth in requirements for battery lead largely reflected the continued increase in the number of both on-the-road and off-the-road motor vehicles that use battery power for starting, lighting, ignition (SLI), and traction. A total of 57.1 million SLI-type batteries were produced in 1973, about 43.4 million of which were for replacement, 12.6 million were original equipment, and the remainder were exported. The quantity of lead used in gasoline antiknock compounds decreased 1.4%, reflecting a reduction in the average lead content per gallon of gasoline from about 2.6 grams per gallon in 1972 to about 2.2 grams per gallon in 1973.

Soft refined lead represented 66% of the total consumption, antimonial lead accounted for 29%, and lead in other alloys mainly solders and bearing metals, accounted for 4% of the total. Lead in copper-base scrap accounted for 1% of consumption.

The domestic supply of lead metal from all sources—primary and secondary production, imports for consumption, stock changes, and stockpile releases—totaled about 157,000 tons more than reported consumption and exports. The apparent excess supply in 1973 amounting to about 10% of reported consumption was attributed partly to unreported consumption and stock buildup, especially by small producers and dealers that do not report to the Bureau of Mines.

The compound annual growth rate in lead consumption during the 10-year period 1964–73 averaged about 2.5% owing largely to increased demand for batteries, which showed an annual growth of 6% during the period and accounted for approximately 50% of the total domestic consumption in 1973 but only 37% in 1964. Per capita lead consumption was 14.6 pounds compared with 14.2 pounds in 1972.

Lead used in pigments, particularly red lead and litharge, increased 28% and accounted for 7% of the total consumption in 1973. Lead antiknock compounds, and miscellaneous and other unclassified uses decreased slightly and accounted for 18% and 3% of the total, respectively. Lead used in other metal products, virtually the same as in 1972, accounted for 22% of the total.

The Lead Industries Association (LIA) reported the expanding use of terne-coated stainless steel in exposed architectural applications for protection against corrosion. The terne metal alloy coating is 80% lead and 20% tin. LIA also reported the increasing use of sheet lead in sound barrier applications such as accoustical polyurethane foam material used in machinery noise control panels designed to meet Occupational Safety and Health Administration (OSHA) standards.

LEAD PIGMENTS

Lead requirements for the production of lead oxides and pigments totaled 510,000 tons, about 13% more than in 1972. The quantity of lead used in making both white and red lead decreased and constituted only 4% of the total lead consumed in pigments and oxides. Litharge production used about 32% of the total lead requirements, and black oxide production used 64% of the total. Most of the litharge shipments went to battery manufacturers and is included in "Other" in table 20. Litharge shipments increased nearly 31,500 tons and comprised 75% of the total shipments in 1973. Litharge shipped for use in the ceramics industry increased 55% in 1973 and amounted to 20% of the total shipments for the year.

Prices.—The price of basic carbonate white lead in carload lots, freight allowed, remained unchanged at 23.9 cents per pound. The quoted price of red lead oxide (Pb_3O_4) 95%, in carload lots at works, was advanced from 18.75–18.90 cents per pound in January to 19.25 cents in February, 20.25–20.45 cents in April, 20.75–21.20 cents in May, to 21–21.20 cents in June, and remained unchanged thereafter to yearend. The price quotation on lead silicate ($PbSiO_2$) ranged upward from 20.75–21.75 cents per pound in January, 21.75 cents in April, to 23.0 cents in June and was unchanged thereafter. The price quotation of commercial-grade litharge, powdered, in carload lots at works ranged upward from 18 cents per pound in January to 19.5 cents in April, 20–20.25 cents in May, to 20.25 cents in June, and remained unchanged to December when the price quotation was advanced to 21.25–22.75 cents.

The value of shipments of white lead, red lead, and litharge amounted to $72.9 million in 1973, an average of $356 per ton compared with $61.1 million and $344 per ton in 1972.

Foreign Trade.—Exports of pigment-grade lead oxides totaled 290 tons valued at $132,700 and exports of lead oxides other than pigment grade amounted to 61 tons valued at $60,500. Shipments went to 36 countries.

Imports for consumption of lead pigments and compounds decreased 23% in quantity and 7% in value to $8.6 million. Litharge, which comprised 70% of the total imports, decreased 7%; imports of chrome yellow, comprising 22% of the total, were 40% less than in 1972. Mexico supplied virtually all the imports of litharge; most of the chrome yellow came from Japan.

STOCKS

Inventories of refined and antimonial lead at primary refineries declined steadily through the first 7 months then trended upward in the last 5 months from the July low. Metal stocks totaling 64,500 tons at the beginning of the year decreased to about 26,100 tons at yearend. Stocks of lead in base bullion declined about 2,700 tons during the year, but the lead content of ore and matte stocks declined nearly 14,700 tons.

Stocks of lead in all forms at consumer and secondary smelting plants totaled 124,100 tons at yearend, indicating an increase of about 5,600 tons during the year. Refined soft lead constituted 68% of the total compared with 62% of the total in 1972.

Stocks of lead at producers and consumers plants totaling about 214,000 tons represented less than a 2-month domestic consumption.

PRICES

The U.S. producer price for common-grade lead on a nationwide basis was reported by Metals Week at 14.50 cents per pound on January 1, was advanced 0.5 cent to 15.0 cents on January 12, to 15.5 cents on February 6, and 16.0 cents on March 6. On April 30, the price quotation became split at 16.0–16.5 cents continuing unchanged at 16.5 cents per pound to June 1. Thereafter, the price was frozen at this level under price control regulations until December 6 when the controls on lead were lifted by the Cost of Living Council. On December 10, the producers quoted price was increased to a range of 18–19 cents per pound. The average monthly producer price increased from 14.50 cents in December 1972 to 17.72 cents in December 1973, a 22% gain during the year. The average price for the year was 16.29 cents compared with 15.03 cents in 1972.

The London Metal Exchange (LME) price, in terms of U.S. currency, reflected strong world demand and increased steadily from a low average of 14.42 cents in January to 22.13 cents in November, rising sharply early in December to a high of 30.28 cents and averaging 26.84 cents for the month. The average LME cash price for the year was 19.47 cents, based on the monthly average Sterling Exchange rate of 245.10 cents, compared with an average price of 13.68 cents in 1972. The LME quotation exceeded the U.S. price for the first time in 8 years.

FOREIGN TRADE

Exports of lead metal and scrap materials increased sharply due principally to world prices being substantially higher than domestic prices, which were frozen for most of the year. The outflow of lead materials and scrap (126,450 tons) was nearly 3 times the quantity exported in 1972 and a new record. Wrought and unwrought metal constituted 53% of the total exports, most of which went to Japan, the Netherlands, and Italy; the remaining 47% was contained in scrap materials, most of which was shipped to Canada, Japan, and Brazil.

General imports of lead materials into the United States dropped nearly 19% to a total of 283,300 tons valued at $76.1 million. Receipts of lead in concentrates and other crude materials were near the same level as in 1972, but metal receipts dropped nearly 27% to about 178,096 tons, the smallest quantity of metal imports since 1951. The decline in lead imports was attributed partly to price regulations in the United States and partly to the effect of dumping charges filed against Canadian and Australian exporters by a major domestic producer and the subsequent determination by the U.S. Treasury Department sustaining such charges. Peru was the leading supplier of crude lead materials with nearly 23% of the total, followed by Australia, Honduras, and Canada. Canada continued to be the leading metal supplier with 35% of the total, followed by Australia 26%, Peru 24%, and Mexico 11%.

WORLD REVIEW

In 1973 mine production of lead in non-Communist countries (which includes Yugoslavia) based on data compiled by the Bureau of Mines totaled 2.95 million tons, about 7% more than in 1972. The Bureau estimated mine production in Communist countries at 0.87 million tons. Smelter output of lead in 1973 in non-Communist countries, reported as primary metal insofar as possible to determine by the Bureau, totaled 2.92 million tons. In addition, the Bureau of Mines estimated 0.88 million tons of metal produced in Communist countries to provide a world total of 3.80 million tons of primary lead, about 1% more than in 1972.

The United States maintained its rank as the leading mine producer of lead in 1973, accounting for approximately 16% of the world total, followed by the U.S.S.R., Australia, Canada, Peru, Mexico, and Yugoslavia, each with production exceeding 100,000 tons of lead in ore mined; these seven countries produced 67% of the world total. The 1% gain in the non-Communist country lead output was largely due to production gains in Mexico, Peru, Canada, Yugoslavia, Morocco and Australia, which more than offset losses in Japan, Spain, and the United States. The North America area increase was about 1% and the 1.21 million tons produced represented 41% of the non-Communist country total and 31% of the estimated world total.

The United States also continued to be the leading producer of primary lead metal as well as secondary lead. The U.S.S.R. again ranked second, followed by Australia, Japan, Canada, Mexico, France, the People's Republic of China and Bulgaria. The nine countries each produced more than 100,000 tons and together accounted for 69% of the world total. The North America area accounted for 37% of the non-Communist country metal output and 28% of the estimated world output (excluding U.S. secondary production). The 1% gain in primary metal output by non-Communist countries came chiefly from increases in Australia, Mexico, and Japan. The smelter output data for some countries, particularly France, Japan, and West Germany, includes secondary metal.

According to preliminary data compiled by the International Lead and Zinc Study Group (ILZSG), consumption of refined lead in 1973 by non-Communist countries amounted to 3.8 million tons, about 5% more than in 1972. Most of the increase came from West European countries and Japan. The U.S. accounted for about 40% of the non-communist total consumption. ILZSG comparative statistics on metal production and consumption in non-Communist countries indicate a new supply deficit of about 90,400 tons in 1973, compared with an indicated surplus of 33,000 tons in 1972. The indicated deficit was reflected in producers stocks, which declined about 106,000 tons during the year to nearly 160,000 tons at yearend. Consumers' stocks in the United States, the United Kingdom, and Japan combined decreased about 23,700 tons to 172,000 tons at yearend.

Trade data for the first 9 months of 1973 compiled by ILZSG disclosed that imports of lead bullion and refined lead into Communist countries from the rest of the world totaled about 58,200 tons, 19,700 tons more than exports compared with 40,800 and 11,000 tons, respectively, in the corresponding period of 1972.

Australia.—Mine output of lead increased nearly 1% to 447,000 tons, and Australia maintained its rank as the world's third ranking lead-producing country.

M.I.M. Holdings Limited treated 2.26 million tons of silver-lead-zinc ore at its Mount Isa operations averaging 6.6% lead and recovered 124,000 tons of lead bullion, 3,800 tons less than in 1972. In June 1973, the company reported primary silver-lead-zinc ore reserves at the Mount Isa mine at 60.6 million tons averaging 6.9% lead, 6.4% zinc, and 4.8 ounces of silver per ton. At the Hilton mine primary silver-lead-zinc ore reserves were estimated at 40.8 million tons averaging 5.8 ounces of silver per ton, 7.7% lead, and 9.6% zinc.[11]

Lead production at the Port Pirie smelter operated by Broken Hill Associated Smelter, Pty. Ltd. was 201,660 tons, nearly 19,000 tons less than in 1972.

E.Z. Industries Ltd. continued to expand productive capacity at its West Coast mines in Tasmania. During the year, the company milled 546,600 tons of zinc-lead-copper ore chiefly from the Rosebery and Hercules mines containing 5.3% lead and recovered nearly 25,200 tons of lead concentrate, a 15% gain in ore milled and a 5% gain in output of lead concentrate compared with production in 1972. The higher mine output achieved under the double production capacity plan was partially offset by the effects of a 5-week labor strike. The adoption of long-hole open stope drilling and improved loading equipment contributed to the increased tonnage mined at the Rosebery mine compared with that of the preceding year. Ore reserves totaled 10.3 million tons at fiscal yearend. About 96% of the total reserve was in the Rosebery mine; the remainder was in the Hercules and Farrell mines.[12]

North Broken Hill Ltd. reported that it mined 556,700 tons of lead-zinc-silver ore, about 6,000 tons less than in 1972. The grade of ore was 12.4% lead, 9.20% zinc, and 6.2 ounces of silver per ton, and production was 91,700 tons of lead concentrate containing 67,250 tons of lead and 29.2 million ounces of silver. Ore reserves on June 30 totaled 5.0 million tons, about the same as last year.[13]

Canada.—Canadian mine output of lead contained in ores and concentrates increased 2% in 1973 to 427,400 tons. The gain in output came chiefly from increases at mines in the Yukon and Northwest Territories and British Columbia, which together accounted for about 84% of the total production.

Cominco, Ltd. reopened its H.B. mine in British Columbia in February and brought output up to rated capacity of 1,000 tons per day in March. The mine had been closed since 1965. Cominco also continued development of the Polaris mine, which is jointly owned by Cominco (75%) and Bankeno Mines Ltd. (25%), on Little Cornwallis Island in the Northwest Territories and shipped 3,600 tons of ore for metallurgical tests. Nigadoo River Mines Ltd. began unwatering its New Brunswick mine in preparation for resuming operations that were discontinued in 1971. The 1,000-ton-per-day concentrator is scheduled for capacity production by mid-1974. Ore reserves were estimated at 1.2 million tons averaging 3.2% lead, 3.2% zinc, 0.2% copper, and 4.0 ounces of silver per ton.

Cominco, Ltd. continued to operate its Sullivan mine in British Columbia, the Pine Point mine in the Northwest Territories, and the Trail smelter which treated company and custom lead-zinc ores. Ore production at the Sullivan mine was increased about 15% to 2.21 million tons with a combined lead-zinc content of 10.0%; Pine Point ore production was 3.90 million tons averaging 8.9% combined lead-zinc and yielding 131,400 tons of lead concentrate. Lead produced at Trail from all sources totaled 172,000 tons, about 2,000 tons more than in 1972. Ore reserves at the Sullivan and H.B. mines totaled 62.0 million tons containing 6.7 million tons combined lead and zinc. Pine Point reserves totaled 38.0 million tons containing 3.1 million tons of zinc and lead. The company also reported zinc-lead ore reserves at the Polaris mine of 25.0 million tons containing 4.7 million tons of combined zinc and lead.[14]

Brunswick Mining and Smelting Corp. Ltd. reported that it milled 3,288,100 tons of lead-zinc ore yielding 153,500 tons of lead concentrate, about 19,400 tons less than in 1972. Preliminary conversion of the Imperial Smelting Process (ISP) lead-zinc smelter to a smelter treating lead con-

centrate only was completed in the second quarter, and 34,450 tons of refined lead was produced compared with 35,980 tons in 1972 (including 7,100 tons of lead purchased and upgraded). Reserves of lead-zinc ore in the No. 12 mine at yearend were 84.7 million tons averaging about 3.8% lead, 9.4% zinc, 0.27% copper, and 2.8 ounces of silver per ton. An additional 3.4 million tons of proven reserves were in the No. 6 mine.[15]

Primary lead output from Canada's two refineries, one at Trail, British Columbia, operated by Cominco, Ltd, and one at Belladune, New Brunswick, operated by Brunswick Mining and Smelting Corp. Ltd., decreased about 3,400 tons to 202,500 tons. Conversion of Brunswick's ISP plant to a straight lead blast furnace and the addition of new refining equipment are expected to increase capacity from 33,000 to 70,000 tons per year when fully operative.

Anvil Mining Corp., a 60%-owned subsidiary of Cyprus Mines Corp., mined 2.90 million tons of lead-zinc-silver ore averaging 4.9% lead, 6.4% zinc, and 1.6 ounces of silver per ton from its open pit mine and concentrating facility in the Yukon Territory. Concentrates produced contained 111,700 tons of lead, 118,100 tons of zinc and 2.58 million ounces of silver. Ore reserves at yearend were estimated at 52.6 million tons with an average grade of 3.1% lead, 5.5% zinc, and 1.1 ounces of silver per ton. At the current mining rate, reserves will last about 14 years.[16] Most of Anvil Mining production is sold in Japan and West Germany.

Exports of lead in ores and concentrates increased 8% to 193,400 tons. Refined metal exports totaling 113,600 tons were about 19% less than in 1972. Shipments to the United States accounted for 42% of the total; 44% went to the United Kingdom, and the remaining 14% was shipped to 19 other countries.

Greenland.—Vestgron Mines Ltd., a 63%-owned subsidiary of Cominco, Ltd., began production at the Black Angel mine near Marmorilik in October at the rate of 1,800 tons of ore per day. One shipment of about 20,000 tons of concentrate was made before the fiord was closed by ice. Concentrates were stockpiled for shipment to European smelters in the spring of 1974.[17]

Honduras.—Rosario Resources Corporation reported that it processed 311,600 tons of ore averaging 8.4% lead, 10.0% zinc, and 11.9 ounces of silver per ton in 1973 and recovered lead concentrates containing 21,160 tons of lead along with silver, gold, and zinc. The quantity of ore treated in 1973 was slightly less than in 1972, but average ore grade and metals recovered were greater than in 1972. Assured and probable ore reserves in the main mine area decreased by 153,200 tons to 1.79 million tons grading 10.5% lead, 10.9% zinc, 12.2 ounces of silver, and 0.008 ounce gold per ton. Ore reserves developed in the San Juan ore body increased to 3.05 million tons grading 2.8% lead, 7.5% zinc, 0.3% copper, 2.9 ounces of silver, and 0.002 ounce of gold per ton. Total reserves for both mine areas increased by 54,700 tons to 4.88 million tons averaging 5.6% lead, 8.8% zinc, 0.4% copper, 6.3 ounces of silver, and 0.005 ounce of gold per ton.[18] Mine expansion in progress in 1973 included extending the main production shaft 500 feet to the 2,225 level and the development of the San Juan ore body scheduled for initial production in 1974.

Ireland.—Tara Exploration and Development Co. Ltd. reported that its target date for initial production at its Navan mine was revised to late 1975 as a result of delays in obtaining final planning permission to construct surface facilities and the issue of a State mining license. The company reported that the development shaft was advanced to 1,105 feet, only 15 feet short of its target depth of 1,120 feet and that it expected to begin hoisting development ore in July 1974. About 250 feet was raised in the production shaft, which was scheduled to be completed and fully equipped by October 1975. The underground decline tunnel system has now advanced over 6,000 feet.[19]

At the Tynah mine, Irish Base Metals Ltd. milled 529,400 tons of ore yielding concentrates containing 45,000 tons of lead, 16,400 tons of zinc, 1,350 tons of copper, and 1.46 million ounces of silver. Open pit ore was completely extracted and mine operations were wholly underground at yearend.

The new Irish Government announced that it will withdraw the 20-year tax exemption on mineral deposits brought into production before 1986.

Mexico.—ASARCO Mexicana, S.A., 49%-owned by ASARCO, reported normal operations at its mines and improved operations at the Chihuahua lead smelter in 1973. Production of refined lead increased 10,700 tons to 86,300 tons.[20]

The Fresnillo Co. reported that it mined a total of 1.5 million tons of lead-zinc-silver ore at its Mexican properties and recovered 40,967 tons of lead, 43,000 tons of zinc, and 4.3 million ounces of silver. Most of the metal production came from the Naica and Fresnillo units. Ore reserves at yearend declined about 3% to 4.9 million tons averaging 4.0% lead, 4.4% zinc, and 4.8 ounces of silver per ton.[21]

Peru.—Cerro Corp. reported that its Peruvian operations continued at near record levels during 1973. Refined lead production was 91,300 tons, about 3,000 tons less than in 1972. Approximately 25% of the total lead output came from purchased ores, compared with 47% in 1973. Cerro's subsidiary, Cerro de Pasco Corp., which operated the mines and smelter complex in Peru for 72 years, was expropriated by the Peruvian government effective at yearend.[22]

Lead production in Peru, comprising lead in concentrate for export plus refined lead and lead alloys in smelter products, increased nearly 5% to 218,800 tons.

Nicaragua.—Neptune Mining Co., operated by ASARCO, treated 177,500 tons of ore at the Vesubio lead-zinc mine, and recovered concentrates containing 3,000 tons of lead and 20,600 tons of zinc, an increase of 37% and 26%, respectively, over output in 1972. Development work resulted in increased ore reserves.

Tunisia.—Production of lead ore from Tunisian mines dropped 22% in 1973 to 28,430 tons. However, both production and export of refined lead increased slightly. Imported lead ore, primarily from Algeria and Morocco, totaling 27,950 tons (60% to 70% lead), was blended with domestic ores, which average 40% to 50% lead. Exports of refined lead totaled 25,990 tons, most of which went to Italy and Greece.

Yugoslavia.—Trepca Corp. continued expansion and modernization at its Stari Trg mine scheduled for initial operations in 1975 at a rate of 1 million tons per year. Output of 3 million tons of lead-zinc ore per year is planned by 1977. Annual output from the Trepca complex will be increased to 167,000 tons of lead. The new Zletovo ISP zinc-lead smelter at Titov Veles, Macedonia began production in May. The smelter complex consists of a sinter plant, sulfuric acid plant, an Imperial Smelting furnace plant, and zinc and lead refineries. Output of lead at the plant is expected to total 35,000 tons, which will increase Yugoslavia's smelting capacity to 210,000 tons of lead per year.

TECHNOLOGY

Research and development activities in the lead industry were primarily directed toward improving and expanding current applications of the metal to maintain optimum growth.

The International Lead Zinc Research Organization (ILZRO) continued its cooperative research in such general areas as architectural applications, wrought lead applications, cable sheathing, batteries, organolead chemicals, ceramics, and environmental health. A major effort in the architectural area resulted in the development of single-family dwelling concepts featuring new and conventional applications of lead. The prototype house will be capable of quick assembly by unskilled labor using a few simple tools; it will be expandable and contractible and will be thermally and acoustically efficient. The ILZRO house of modular design is primarily metal and the materials are recyclable, thus minimizing pollution and promoting conservation. Research continued on developing lead-plastic laminates suitable for all types of packaging applications and for possible use as cable sheathing where resistance to water vapor penetration is required. In the battery field ILZRO, in cooperation with a manufacturer, designed and constructed prototype test vans powered by lead-acid batteries that may establish the advantages and prac-

[22] Cerro Corp. 1973 Annual Report. Pp. 16–17.

ticability of using electric vehicles in the transportation field. In the ceramics area, ILZRO research efforts developed basic information on the structure, composition and properties of leaded-glass systems. ILZRO participated in various environmental health projects dealing with the effects of lead on biological organisms. In one such project, ILZRO reported that a comparison of the health of workers in the lead industries demonstrated that lead workers had a longevity better than that of the general population.

Cominco, the largest Canadian lead and zinc producer, reported substantial progress in the pilot-plant study of its new process that could make present conventional lead smelting operations obsolete. The new process, which has already cost $1.5 million, would eliminate the need for blast furnaces and sinter plants, a constant source of air pollution.

Chrysler Corp. disclosed that early test results of laboratory research indicated that a gasoline additive, ethylene dibromide, and not lead may be primarily responsible for poisoning noble oxidation catalysts. The early results, subject to verification in road tests, indicated that leaded gasoline without ethylene dibromide could be used successfully with platinum-palladium catalysts.

Bureau of Mines investigators at Rolla, Mo., reported significant progress in laboratory research to develop new technology for recovering lead from flotation concentrates to replace present sintering and blast furnace reduction. The new technique, using a vapor phase reduction of lead sulfide, permits recovery of lead metal and elemental sulfur rather than SO_2. A new hydrometallurgical process for recovering lead from scrap batteries that would eliminate SO_2 pollution tested by Bureau metallurgists at College Park, Md. achieved a 98% reduction and a 94% recovery of lead. The process converts $PbSO_4$, Pb_0, and $CaSO_4$ by mixing with a slurry of $Ca(OH)_2$. Continued progress was reported by Bureau metallurgists on developing an aqueous chlorine and electrolytic oxidation leaching process for extracting metals from lead-zinc sulfide concentrates. Extractions in the range of 95% to 99% of the contained lead, zinc, copper, and silver were achieved, and 85% of the sulfide content of the concentrate was converted to elemental sulfur.

Cooperative research by the Naval Research Laboratory (NRL) and ILZRO, in conjunction with battery manufacturers, were directed essentially toward improving battery performance and life. Investigations encompassed the effects of charge and discharge on lead plate microstructure, the causes of capacity loss, and the influence of antimony on the morphology of the lead dioxide.[23]

The joint abstracting service of Lead Industries Association and Lead Development Association afforded researchers a worldwide coverage of new research developments in reports and patents classified under such headings as: analysis, batteries, cables, casting, ceramics, chemicals, coatings, composites, electrochemistry, extraction, health and safety, paints and pigments, physical metallurgy and production.[24]

The Geological Survey issued a comprehensive report on U.S. Mineral Resources which included a review of world lead deposits and reserves.[25]

Table 10.—Secondary lead recovered in the United States

(Short tons)

	1969	1970	1971	1972	1973
As metal:					
At primary plants	4,966	4,367	1,223	1,189	--
At other plants	149,344	154,800	148,911	172,168	186,124
Total	154,310	159,167	150,134	173,357	186,124
In antimonial lead:					
At primary plants	6,409	7,599	2,379	5,816	1,065
At other plants	336,066	340,759	340,333	340,066	374,713
Total	342,475	348,358	342,712	345,882	375,778
In other alloys	107,120	89,865	103,951	97,358	92,384
Grand total:					
Quantity	603,905	597,390	596,797	616,597	654,286
Value (thousands)	$180,326	$187,461	$165,790	$185,349	$213,166

Table 11.—Lead recovered from scrap processed in the United States, by kind of scrap and form of recovery

(Short tons)

Kind of scrap	1972	1973	Form of recovery	1972	1973
New scrap:			As soft lead:		
Lead-base	113,795	110,787	At primary plants	1,189	--
Copper-base	4,669	4,506	At other plants	172,168	186,124
Tin-base	421	403	Total	173,357	186,124
Total	118,885	115,696			
Old scrap:			In antimonial lead [1]	345,882	375,778
Battery-lead plates	347,881	369,819	In other lead alloys	82,725	75,545
All other lead-base	134,209	153,938	In copper-base alloys	14,614	16,805
Copper-base	15,620	14,831	In tin-base alloys	19	34
Tin-base	2	2	Total	443,240	468,162
Total	497,712	538,590	Grand total	616,597	654,286
Grand total	616,597	654,286			

[1] Includes 5,816 tons of lead recovered in antimonial lead from secondary sources at primary plants in 1972 and 1,065 in 1973.

Table 12.—Lead consumption in the United States, by product

(Short tons)

Product	1972	1973	Product	1972	1973
Metal products:			Pigments—Continued:		
Ammunition	84,699	81,479	Pigment colors	16,264	16,963
Bearing metals	15,915	15,657	Other [1]	337	477
Brass and bronze	19,805	22,735	Total	89,214	108,766
Cable covering	45,930	43,005			
Calking lead	22,483	20,057	Chemicals:		
Casting metals	7,139	7,220	Gasoline antiknock		
Collapsible tubes	4,020	2,860	additives	278,340	274,410
Foil	4,592	4,985	Miscellaneous		
Pipes, traps, bends	17,780	21,291	chemicals	849	944
Sheet lead	23,667	23,394	Total	279,189	275,354
Solder	71,289	71,770			
Storage batteries:			Miscellaneous uses:		
Battery grids,			Annealing	4,329	3,974
posts, etc	347,225	365,557	Galvanizing	1,397	1,294
Battery oxides	379,367	403,890	Lead plating	638	744
Terne metal	504	2,658	Weights and ballast	21,302	20,848
Type metal	19,944	21,922	Total	27,666	26,860
Total	1,064,359	1,108,480	Other, unclassified uses	24,826	21,749
Pigments:			Grand total [2]	1,485,254	1,541,209
White lead	2,814	1,749			
Red lead and					
litharge	69,799	89,577			

[1] Includes lead content of leaded zinc oxide and other pigments.
[2] Includes lead which went directly from scrap to fabricated products.

Table 13.—Lead consumption in the United States, by month

(Short tons)

Month	1972	1973	Month	1972	1973
January	122,272	135,308	August	127,368	125,707
February	123,671	131,695	September	125,984	124,793
March	132,311	143,197	October	132,241	140,655
April	122,367	128,432	November	131,438	131,420

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, Uganda and Arab Republic of Egypt may produce lead, but available information is inadequate to make reliable estimates of output levels.

[2] Recoverable metal content of lead in concentrates for export plus lead content of domestic products (refined lead, antimonial lead, mixed bars, and other unspecified items).

[3] Recoverable metal.

[4] Recoverable metal; content of lead in concentrates for exports plus lead content of domestic smelter products (refined lead, antimonial lead, and bismuth-lead bars).

[5] All data for 1971 are for fiscal year ending June 30, 1971; data for 1972 and 1973 are a summation of company figures for calendar year 1972 and 1973 for Tsumeb Corp. Limited and for fiscal year ending June 30, 1972, and June 30, 1973, for South-West Africa Co. Limited, South African Iron and Steel Industrial Corporation Ltd., and Rosh Pinah mine. Output of Tsumeb Corp. Limited for period July 1, 1971, through December 31, 1971 (which is not otherwise covered in table), was 30,590 short tons.

[6] Year beginning March 21 of that stated.

[7] Content of concentrates.

[8] Less than ½ unit.

[9] Contained in lead-copper concentrate.

[1] Primary except as noted, or where source does not differentiate.
[2] Includes recovery from secondary materials.
[3] Refined from domestic and foreign ores; excludes lead refined from imported base bullion.
[4] Includes primary lead content of antimonial lead.
[5] Lead bullion from imported ores and concentrates.
[6] Data for 1971 are for years ended June 30, 1971. Data for 1972 and 1973 are for calendar years. Output for the last 6 months of 1971 was 36,506 short tons.
[7] Pig lead only (excludes lead content of antimonial lead).
[8] Year beginning March 21 of year stated.

Lime

By Avery H. Reed[1]

Lime output in 1973 increased 4% to 21.1 million tons, a new annual record. Total value was a record $368.1 million, 8% above 1972.

Other highlights of the year included plans by J. E. Baker Co. to install a gas-cleaning scrubber system at its Millersville, Ohio plant. Black River Mining Co. was doubling its plant at Carntown, Ky., to a total capacity of 700,000 tons per year by late 1975. Colorado Lien Co. planned to build a $3 million lime plant near Buena Vista, Colo.; a vertical kiln will produce quicklime. Dravo Corp. organized a new company, Dravo Lime Co., which planned to construct a 3,000-ton-per-day lime plant near Maysville, Ky.

The Flintkoke Co. planned to replace its 80-ton-per-day limekiln at Nelson, Ariz. with a new 800-ton-per-day, $10 million plant.

A strike at Mississippi Lime Co.'s Missouri plant caused serious shortages of lime in the Midwest. This is the largest limekiln in the country. Rangaire Corp. purchased the Tennessee and Virginia lime plants of Foote Mineral Co.; they will operate as Tennessee Lime Co. and Virginia Lime Co. Southern Industries formed a new company, SI Lime Co., which will operate the Longview plant in Alabama and the Pelican State Lime Co. plant in Louisiana.

Energy.—The Bureau of Mines completed a comprehensive canvass of energy used in the mineral industries in 1973. All lime plants were covered.

The canvass showed that the lime industry depended on the use of coal and natural gas for most of its energy requirements. Only 2% of the total energy was purchased electricity. Total energy used was 39.9 billion kilowatt-hours.

Coal supplied 46% and natural gas 45% of the total energy used, mostly for heat in the calciners. The choice of fuel for individual plants was usually based on geographic proximity to supplies; leading coal-using States were Ohio, Pennsylvania, Missouri, Indiana, and Illinois, which together consumed 69% of the coal; leading natural-gas-using States were Ohio, Texas, Pennsylvania, Michigan, and New York, which together consumed 54% of the natural gas.

The lime industry used 2.6 million tons

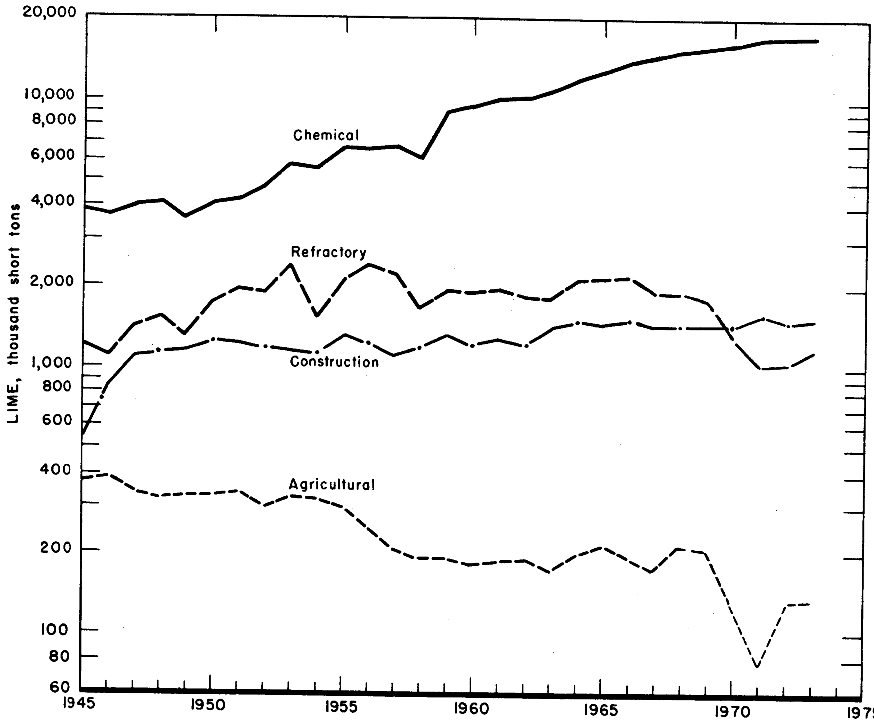

Figure 1.—Trends in major uses of lime.

of coal, 59.6 billion cubic feet of natural gas, 186,000 tons of coke, 848 million kilowatt-hours of purchased electricity, 16.4 million gallons of heavy fuel oil, 9.8 million gallons of diesel oil, 686,000 gallons of gasoline, and 127,000 gallons of propane.

Requirements for each thousand tons of lime produced were 124 tons of bituminous coal, 2.8 million cubic feet of natural gas, 9 tons of coke, 774 gallons of heavy fuel oil, 465 gallons of diesel fuel, 32 gallons of gasoline, and 6 gallons of propane.

Cost of energy used in the lime-manufacturing industry was estimated at $67.8 million, or $3.21 per ton of lime produced. Each ton of lime required 1,890 kilowatt-hours of energy.

DOMESTIC PRODUCTION

Lime producers sold or used 21.1 million tons, compared with 20.3 million tons in 1972. Sales of lime increased 8% to 14.4 million tons for a new annual record. Captive lime used by producers decreased 4% and was 8% below the 1971 record. Output of refractory dolomite increased 16% but was 48% below the 1956 record. The number of plants decreased from 186 to 176, and the average output per plant increased from 109,300 tons per year to 120,100 tons.

Five States, Ohio, Pennsylvania, Texas, Missouri, and Michigan, accounted for 54% of the total output.

Leading producing companies were Marblehead Lime Co. with four plants in Illinois, one in Indiana, and one each in Michigan, Pennsylvania, and Missouri; Mississippi Lime Co. in Missouri; Allied Chemical Corp. in New York and Louisiana; Bethlehem Steel Corp. with two plants in Pennsylvania and one in New York; Martin-Marietta Chemicals in Ohio and Alabama; Pfizer, Inc., in Ohio, Massachusetts, California, and Connecticut; Warner Co. with two plants in Pennsylvania; United States Gypsum Co. with two plants in Texas and one each in Ohio and Louisiana; Diamond Shamrock Chemical Co. in Ohio; and United States Steel Corp. in Ohio. These 10 companies, operating 28 plants, accounted for 42% of the total lime production.

The 12 largest lime plants, each producing more than 400,000 tons per year, accounted for 32% of the total production. There were 39 plants which produced more than 200,000 tons per year and accounted for 67% of the total output.

Leading individual plants were Mississippi Lime's Ste. Genevieve plant, Marblehead's Buffington plant, Allied Chemical Corp.'s Syracuse plant, Bethlehem's Annville plant, and Diamond Shamrock's Painesville plant.

CONSUMPTION AND USES

Lime was consumed in every State. Leading consuming States were Ohio, Pennsylvania, Michigan, Indiana, Texas, Illinois, and New York. These seven States, each of which consumed more than 1 million tons, accounted for 64% of the total lime consumed.

Leading quicklime-consuming States were Ohio, Pennsylvania, Michigan, Indiana, Illinois, and Texas, each of which consumed more than 1 million tons. These six States accounted for 60% of the quicklime consumed.

Leading hydrate-consuming States were Texas, Pennsylvania, Ohio, Illinois, Louisiana, and California, each of which consumed more than 100,000 tons. These six States accounted for 54% of the hydrate consumed.

Lime sold by producers was used for chemicals, 80%; construction, 11%; refractories, 8%; and agriculture, 1%. Captive lime used by producers was 32% of the total, compared with 34% in 1972 and 37% in 1971.

Leading individual uses were basic oxygen steel furnaces, alkalies, water purification, refractories, and paper, which together accounted for 63% of the total consumption, compared with 62% in 1972.

Lime used in agriculture increased 2%. Lime used for refractory dolomite increased 16%. Construction uses continued to expand, increasing 2%. Lime for chemical and industrial use also continued to expand, increasing 3%.

[1] Excludes regenerated lime. Includes Puerto Rico.
[2] Includes New Hampshire, Vermont, and States indicated by symbol W.

PRICES

The average value of lime sold or used by producers in 1973 was $17.42 per ton, an increase of 4% over the 1972 value of $16.78 per ton.

Values for quicklime sold ranged from $15.69 for chemical lime to $16.20 for agricultural lime, $18.71 for construction, and $20.70 for refractory dolomite, and averaged $16.21 per ton.

Values for hydrated lime sold ranged from $20.33 for construction lime to $21.72 for chemical lime and $22.39 for agricultural lime, and averaged $20.59 per ton.

FOREIGN TRADE

Exports of lime decreased 2% to 36,914 tons and were 46% below the 1968 record. Of the total quantity exported, Canada received 64%, Mexico 12%, and the United Kingdom 10%. The remaining 14% went to 32 countries, listed in order: Jamaica, Surinam, British Bahamas, West Germany, Dominican Republic, Brazil, Panama, New Zealand, Saudi Arabia, Nicaragua, Bermuda, Ethiopia, Australia, Denmark, Austria, Japan, Leeward and Windward Islands, Sweden, Argentina, Honduras, Pacific Trust Islands, Venezuela, Liberia, Antilles, Nigeria, British Honduras, Belgium, Tanzania, Philippines, Chile, Angola, and the Netherlands.

WORLD REVIEW

Lime is produced all over the world, mainly in the heavily industrialized areas. Source materials are plentiful. The United States ranks second in world production, with 18% of the total; foreign production is reviewed in the following paragraphs.

Canada.—Beachville Lime Ltd., a subsidiary of Dominion Foundries and Steel Ltd., purchased the Beachville, Ontario, lime plant of Cyanamid of Canada Ltd.

Germany, West.—West Germany ranked fourth in world lime output, with 10% of the total production.

Japan.—Japan produced 11% of the world's lime, ranking third. Most of the lime was used in steel mills.

Poland.—Poland produced 7% of the world's lime and ranked fifth among the countries.

U.S.S.R.—The U.S.S.R. was the leading lime-producing country in the world, with 20% of the total output.

United Kingdom.—Tilling Construction Services Ltd. installed a new lime plant with two rotary kilns and preheaters at Swinden.

Zambia.—Ndola Lime Co. was building a lime plant, to produce 550 tons of lime per day.

[e] Estimate. [p] Preliminary. [r] Revised.

[1] Lime is produced in many other countries besides those listed. Mexico, Venezuela, and the United Kingdom are among the more important countries for which official data are unavailable.

[2] Excludes output by small producers.

[3] Includes burnt dolomite which was excluded in previous editions.

[4] Data for 1971 may be incomplete. Figures for 1972 and 1973 include production in Eritrea.

[5] Year ending June 30 of that stated.

TECHNOLOGY

The National Lime Association developed a new scrubber for removing sulfur from stack gases. Blaw-Knox Co. has been licensed to produce the scrubber.

The U.S. Army Corps of Engineers successfully injected lime slurry under pressure to a depth of 6 feet over a large area. The building erected at the site has shown no signs of settling, while adjacent buildings on unstabilized ground have settled drastically.

The Bureau of Reclamation completed a canal-lining project using lime. The canal bank was stabilized to a depth of 4 feet with 4% quicklime. After 10 months under 18 feet of water, the stabilized soil is hard and strong. Adjacent unstabilized sections have failed.

The Environmental Protection Agency was developing standards for air pollution in the lime industry.

Magnesium

By E. Chin [1]

Production and shipments of magnesium metal by The Dow Chemical Co. were 122,431 short tons and 137,277 short tons, respectively, in 1973. NL Industries, Inc. produced some metal at Rowley, Utah. The magnesium metal plant of American Magnesium Co. at Snyder, Tex., was not in operation throughout the year.

Legislation and Government Programs.—The General Services Administration (GSA) continued to dispose of all the magnesium remaining in the national stockpile. In 1972, GSA sold 7,737 short tons of metal from the Government stockpile, compared with 710 tons in 1971. A total of 66,638 short tons was sold during 1973. At yearend, the uncommitted excess in the stockpile was 23,205 short tons of magnesium metal.

DOMESTIC PRODUCTION

During the year, The Dow Chemical Co. completed an expansion program for producing metal at its plant in Freeport, Tex. Process modifications and improvements added 10 million pounds of annual capacity to its existing magnesium metal production capacity of 240 million pounds of metal. NL Industries, Inc., produced some metal in 1973 at Rowley, Utah, and was expected to produce magnesium at full rated capacity by late 1974. American Magnesium Co. was closed down throughout 1973, but was expected to resume production in mid-1974.

Northwest Alloys, Inc., a subsidiary of the Aluminum Co. of America (Alcoa), began constructing a new magnesium facility at Addy, Wash. Northwest Alloys will use the Magnetherm process for producing magnesium metal. Startup of this plant, with an intial capacity of 24,000 tons per year of magnesium and an ultimate capacity of 40,000 tons per year, was scheduled for late 1975.

CONSUMPTION AND USES

Consumption of magnesium in the United States increased over that in 1972 to 115,558 short tons. Magnesium was consumed in two broad categories: Structural products such as castings and wrought products, and distributive or sacrificial applications where advantage is taken of the chemical properties of the metal. Useful structural properties of magnesium include low specific weight, good machinability, hot formability, and high strength. The principal structural applications, which account for about 23% of the total use, are in aircraft, automotive, and other types of transportation equipment, in materials handling, and in power tools, such as powersaws and lawnmowers. The remainder of the consumption is for sacrificial uses, primarily in alloying with other metals, especially aluminum, cathodic protection, production of nodular iron and the desulfurization of steel, and as a reducing agent in the production of titanium, beryllium, and other metals.

PRICES

During 1973, the quoted base price for primary magnesium pig and ingot in 10,000-pound lots, 99.8% magnesium f.o.b. plant, was 38.25 and 39.00 cents per pounds, respectively, compared with corresponding prices of 37.25 and 38.00 cents per pound, respectively, during 1972.

Depending upon the state of preservation of the metal available from the national stockpile, GSA accepted bids for primary magnesium ranging from 31.75 to 39.30 cents per pound, f.o.b. storage locations. The average price of metal sold by GSA during the year, excluding the negotiated sales of magnesium, was 34.167 cents per pound.

STOCKS

Producer and consumer stocks of primary magnesium totaled 17,188 short tons as of December 31, 1973. Yearend stocks of primary magnesium alloy ingot were 1,706 tons. Stocks a year earlier were 22,011 short tons of primary metal and 986 short tons of alloy ingot.

FOREIGN TRADE

U.S. exports of magnesium increased from 17,556 short tons, valued at $11.7 million in 1972, to 39,585 tons, valued at $28.2 million in 1973. Shipments to West Germany, Brazil, the Netherlands, Canada, and Japan accounted for 19%, 17%, 15%, 14%, and 10%, respectively, of the total U.S. exports of magnesium. The remaining 10,399 tons were exported to approximately 20 countries.

Total magnesium imports for consumption decreased 27% from that of 1972. Canada, by far the largest of U.S. sources, contributed 27% of the metal imported. Receipts from the Netherlands and West Germany constituted 18% and 16%, respectively, of the magnesium imports. The remainder of U.S. imports, 1,280 tons, was contributed by 19 other nations.

WORLD REVIEW

World production of magnesium metal in 1973 was 261,110 short tons, an increase of 51,500 tons over world production in 1972. The United States produced 47% of the world magnesium output, followed by the U.S.S.R. 24%, and Norway 16%. The remainder of the world production was by Canada, the People's Republic of China, France, Italy, and Japan.

World producers of magnesium in 1973 with annual capacities, processes, and plant locations were as follows:

Country	Company	Capacity (short tons)	Process	Plant location
Canada	Chromasco Corporation Limited	12,000	Silicothermic	Haley, Ontario.
China, People's Republic of	NA	5,000	do	Ying-kou, Liaoning.
France	Société Générale du Magnesium Péchiney Ugine Kuhlmann S.A. (70%) Société des Produits Azotes (SPA) (30%).	9,000	do	Marignac.
Italy	Societá Italiana per il Magnesio e Leghe di Magnesio.	7,700	do	Bolzano.

NA Not available.

Japan.—Consumption of magnesium in Japan was estimated to be about 17,500 short tons in 1973 compared with 15,400 tons in 1972. Production was estimated to be 12,239 tons in 1973, compared with 12,004 tons in 1972. Imports of magnesium metal into Japan were expected to remain around 3,300 tons in 1973.

Norway.—Norsk Hydro-Elektrisk A/S (Norsk Hydro) announced that it will construct a magnesium production facility at Mongstad. The electrolytic plant will have an annual capacity of 55,100 short tons of metal per year and will be in operation about 1980. Additionally, Norsk Hydro developed a new magnesium chlo-

ride production process which will be tried in a plant at Heroya, scheduled to be built for the production of anhydrous magnesium chloride, and which would supply sufficient cell feed for the production of 16,500 short tons of metal.

United Kingdom.—The Minor Metals Traders' Association was formed in London in August 1973. Metals included in the association's groupings are magnesium, antimony, bismuth, cadmium, mercury, nickel, and selenium. The association, composed of 21 founding members, hopes to promote the interests of minor metal traders and give dealers in minor metals an entity separate from the London Metal Exchange.

U.S.S.R.—The All-Union Institute of Aluminum, Magnesium, and Electrolysis Industries announced the construction of a new electrolytic pilot plant for the production of magnesium metal and chlorine from magnesium chloride without the use of diaphragms. The new pilot plant, which produces about 2,200 pounds of magnesium and 6,000 pounds of chlorine per day, reportedly uses less floor space and lower power consumption.

TECHNOLOGY

Joseph Lucas Industries, Ltd., developed a system of dual sheet electrodes for multicell batteries.[2] A valuable characteristic of thin-film batteries is that thin sheets or strips can be stacked in electrical series so that high voltages can be produced from units with very small overall dimensions. A sheet of silver chloride is treated photographically to convert the silver chloride on one surface to metallic silver. When the silver chloride side of the sheet is juxtaposed with the face of a sheet of magnesium, the latter becomes an anode and a single cell is formed. The thin pairs of sheets can then be stacked to obtain whatever voltage is desired.

The 29th Annual Meeting of the International Magnesium Association was held at Cherry Hill, N.J., May 6–8, 1973. Papers on the uses of magnesium in steel desulfurization, in alloying, in potential uses by the automotive industry, and on the fluxless melting of magnesium and electrochemical applications for magnesium were presented.

Heretofore, magnesium has not been competitive with aluminum and zinc diecastings which are produced by the cold-chamber process. However, a hot chamber process has been developed for use with magnesium.[3] Equipment was designed for working temperatures of about 650° C and provisions were made to prevent the magnesium from oxidizing by blanketing the hot metal with a protective gas containing SO_2. The hot-chamber process offers a number of significant advantages. Production rates are high; the process lends itself to automation; air inclusions are less of a problem; and the temperature of injected molten metal is not only higher but more uniform in the hot-chamber process than in the cold-chamber process.

Magnesium has been traditionally used in the treatment of cast iron to produce spheroidal graphite iron, in which desulfurization by magnesium is an essential

chemical reaction.[4] However, magnesium has the potential to be a major ingredient in the desulfurization of steel by the Mag-Coke process.[5] Based on metallurgical coke infiltrated with 45% by weight of magnesium, Mag-Coke is introduced into torpedo cars which are used to transfer hot molten iron from the blast furnace to the basic oxygen furnace. By this approach, the sulfur content of steel can be reduced to 0.01% by weight and thus improve the fracture toughness and formability of the end product.

Patents on the purification of magnesium chloride solutions to be used in the electrowinning of magnesium metal and on the purification of magnesium metal obtained from electrolytic cells were issued.[6]

Magnesium Compounds

By E. Chin [1]

World production of magnesite in 1973, excluding output in the United States was about 9,900,000 short tons, slightly higher than that in 1972. Magnesite production in Austria, Greece, North Korea, People's Republic of China, and the U.S.S.R. accounted for 74% of the world total.

The increasing worldwide trend toward greater production of magnesium compounds from sea water, well and lake brines, and dry lake deposits continued to exert competitive pressure on producers of magnesite. During 1973, two domestic companies, one using sea water as a raw material source and the other using well brines, announced the expansion of production capacity for magnesium compounds. A Japanese firm announced plans to produce magnesium hydroxide from a salt lake in Mexico.

Refractory magnesia, and caustic-calcined and specified magnesias, sold or used by domestic producers in 1973 were 17% above that in 1972. The value of domestic shipments of magnesias rose 27% to nearly $97,000,000 in 1973.

U.S. imports for consumption of processed magnesite in 1973 were about 158,000 short tons, with Greece accounting for 44% of the total. Exports of magnesite and magnesia were about 60,000 tons in 1973, and as in the 1970–72 period they were primarily to Canada.

[2] Caustic-calcined magnesia only.

DOMESTIC PRODUCTION

Magnesium hydroxide was produced from sea water and well brines, by Barcroft Co., Basic Magnesia, Inc., Corhart Refractories Co. Inc., The Dow Chemical Co., Harbison-Walker Refractories Co., Kaiser Aluminum & Chemical Corp., Martin Marietta Chemicals, Merck & Co., Inc., and Michigan Chemical Corp. Most of the magnesium hydroxide produced was used in the production of magnesia for basic refractories. Producers of refractory magnesia were Basic Inc., Basic Magnesia, Inc., Corhart Refractories Co., A. P. Green Refractories Co., Harbison-Walker Refractories Co., Kaiser Aluminum & Chemical Corp., and Martin Marietta Chemicals Corp. Total production of refractory magnesia in 1973 was 702,278 tons.

Caustic-calcined magnesia was produced by Basic Inc., Basic Magnesia, Inc., The Dow Chemical Co., Kaiser Aluminum & Chemical Corp., Martin Marietta Chemicals Corp., and Michigan Chemical Corp. Merck & Co., Inc., Morton Chemical Co., and Michigan Chemical Corp., produced 12,532 tons of specified magnesia. The Dow Chemical Co., Giles Chemical Corp., and Philadelphia Quartz Co., produced 64,566 tons of magnesium sulfate (hydrous). During the year, 10,657 tons of magnesium carbonate were produced by Merck & Co., Inc. Morton Chemical Co., and Michigan Chemical Corp.

Magnesium chloride was produced by The Dow Chemical Co., FMC Corp., Great Salt Lake Minerals & Chemicals Corp., (GSL), and Kaiser Aluminum & Chemical Corp. Most of the magnesium chloride production was used for magnesium metal cell feed.

Early in 1973, Gulf Resources and Chemical Corp. acquired all of theh stock of GSL Corp. from its former German partner, Kali & Salz A.G. GSL produces magnesium chloride brines, potash, sodium sulfate, and industrial salt. In July, GSL began construction of a 3,500-acre addition to its existing solar evaporation ponds, costing $1.2 million. The completion of the expansion program was scheduled for 1974.

The Dow Chemical Co. announced an expansion of magnesium oxide production capacity at its facilities in Freeport, Tex. Completion, scheduled for mid-1974, will boost its magnesium oxide capacity by approximately 35,000 tons per year.

The U.S. Atomic Energy Commission approved the Consumers Power petition for a proposed nuclear powerplant at Midland, Mich. The 1.3 million-kilowatt installation was designed to deliver up to 4 million pounds per hour of steam for industrial use by The Dow Chemical Co. at its Midland, Mich., installation.

1973 p	1,191	22,335

p Preliminary.

Martin Marietta began an expansion of its Manistee, Mich., chemical plant, which will result in a 50,000-ton-per-year increase in the production capacity for periclase and a 30,000-ton-per-year increase in the production of magnesium chemicals. The Manistee plant is a unit of the Refractories Division of Martin Marietta. Plans for the Manistee expansion provide for a complete, new, high-purity periclase plant, which is a duplication of the periclase manufacturing plant that Martin Marietta placed on-line there in 1969. The plans also include the installation of a multiple-hearth calcining furnace, briquetting presses, and a high-temperature shaft kiln. In addition, new brine wells, hydrate facilities, and extensive water and air emission controls are included. Completion of the Manistee plant expansion program was scheduled for early in 1975.

Kaiser Aluminum & Chemical Corp. completed the installation of three wet scrubbers on its kiln air discharge system to prevent dust emission at its sea water magnesia plant at Moss Landing, Calif. The first wet scrubber was placed in operation in March 1972, the second in December 1972, and the third in June 1973. The scrubbers replaced the precipitator used formerly and reportedly will improve plant efficiency and air pollution control effectiveness.

Domestic producers of magnesium compounds by raw material source, location, and capacity are as follows:

Raw material source and producing company	Location	Capacity (short tons MgO equivalent)
Magnesite:		
Basic, Inc	Gabbs, Nev	150,000
Lake brines:		
Great Salt Lake Minerals & Chemicals Corp	Ogden, Utah	100,000
NL Industries, Inc	Rowley, Utah	75,000
Kaiser Aluminum & Chemical Corp	Wendover, Utah	50,000
Well brines:		
American Magnesium Co	Snyder, Tex	50,000
The Dow Chemical Co	Ludington, Mich	250,000
Martin Marietta Chemicals Corp	Manistee, Mich	180,000
Michigan Chemical Corp	St. Louis, Mich	25,000
Morton Chemical Co	Manistee, Mich	5,000
Seawater:		
Basic Magnesia, Inc	Port St. Joe, Fla	100,000
Barcroft Co	Lewes, Del	5,000
Cohart Refractories Co., Inc	Pascagoula, Miss	40,000
The Dow Chemical Co	Freeport, Tex	285,000
FMC Corp	Chula Vista, Calif	5,000
Kaiser Aluminum & Chemical Corp	Moss Landing, Calif	150,000
Merck & Co., Inc	Cape May, N.J	100,000
Harbison-Walker Refractories Co	Cape May, N.J	100,000
Total		1,580,000

CONSUMPTION AND USES

In 1973 magnesia used in the production of basic refractories increased 16% over that in 1972. Consumption of caustic-calcined magnesia for uses other than the production of refractory magnesia also increased significantly.

Magnesia is used as a fuel additive in burning heavy fuel at steam generating plants to prevent corrosion and acid smut fallout. It is also used for stack gas scrubbing. As an additive to animal feed, magnesia prevents grass tetany in cattle and sheep, promotes increased egg laying, and increases the butterfat content of milk. In sugar cane processing mills, magnesia prevents scale formation in the evaporators. As an additive in rubber, magnesia is used to neutralize acidity, to keep the molds cleaner, and to improve the rubber cure rate. Other uses for magnesia are in chemicals, construction materials such as plaster and cement, cosmetics, electrical heating rods, fertilizers, medicinals and pharmaceuticals, and pulp and paper.

Other magnesium compounds are used in candy, wine, and water processing; in tannery applications; and in cosmetics and pharmaceuticals.

Table 3.—Magnesium compounds shipped and used in the United States

Year and product	Shipped and used: Quantity (short tons)	Shipped and used: Value (thousands)
1972

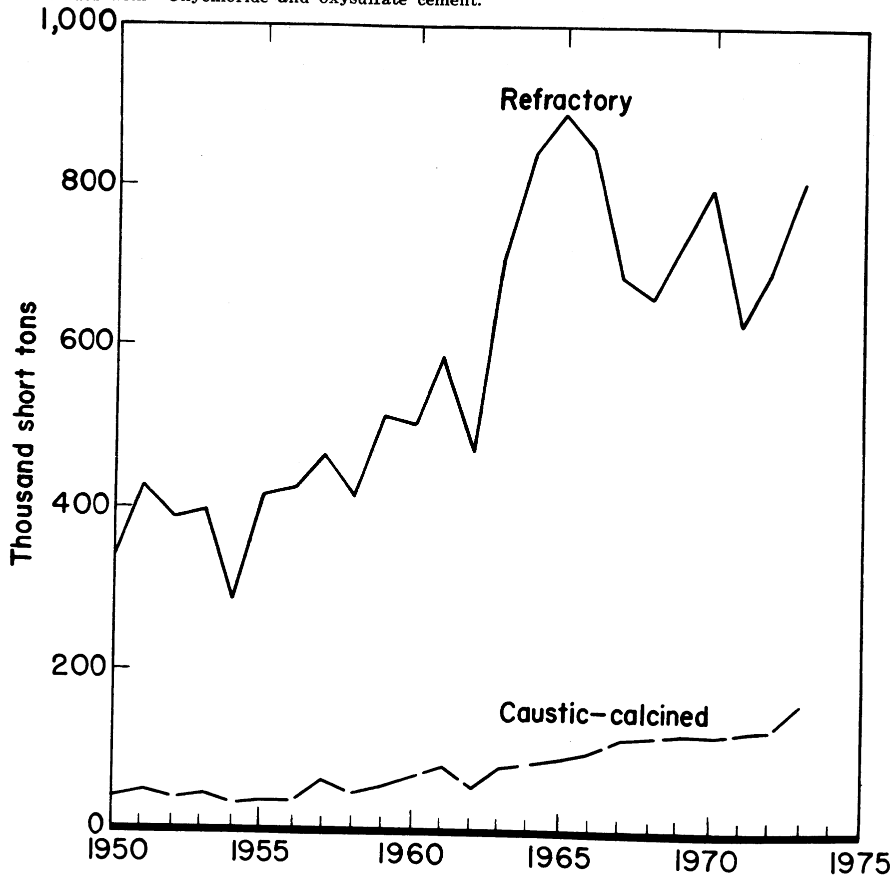

Figure 1.—Consumption and shipments of magnesia in the United States.

PRICES

Prices for magnesia, calcined, technical, heavy, 85% and 90% (bags, carlot, f.o.b. Luning, Nev.) were quoted during the year at $50 and $60 per short ton, respectively, according to the Chemical Marketing Reporter. Magnesia, technical, synthetic rubber–grade, neoprene-grade, light, was quoted at $0.25 per pound (bags, carlot, freight-equalized).

Prices throughout the year for magnesium carbonate, technical (bags, carlot, freight-equalized), remained the same as in 1972 at $0.16 per pound and for truckload quantities at $0.18 to $0.185 per pound with no change from the 1972 rate. During the year, the price for magnesium hydroxide, NF, powder (drums, carlot, and truckload, works) was $0.30 per pound. Magnesium chloride, hydrous, 99%, flakes, bags, carlot, works, was quoted at $80 per ton. The price for magnesium lauryl sulfate, tanks freight-allowed, remained the same as in 1972, at $0.175 per pound.

FOREIGN TRADE

Exports of dead-burned magnesite and magnesia in 1973 totaled 50,760 short tons compared with 54,159 tons in 1972. Exports to the principal destination, Canada, were 42,540 tons, 18% lower than in 1972. However, shipments to Mexico, the Netherlands, and West Germany in 1973 were substantially higher than in the previous year.

Exports of magnesite, including crude, caustic-calcined, lump or ground, increased over exports in 1972 and totaled 9,304 tons. Deliveries to Australia, Canada, Italy, Mexico, and West Germany accounted for over 61% of the exports in this class.

Lump or ground caustic-calcined magnesia imports for consumption increased slightly in 1973 to 10,967 tons and were principally from India and Turkey.

Imports of dead-burned and grain magnesia and periclase containing a maximum of 4% lime increased 17% to 149,051 short tons in 1973. Imports for the same class of material but containing over 4% lime increased from 5,958 tons in 1972 to 8,956 tons in 1973. Total imports of crude and processed magnesite increased 17% over those in 1972 to 168,974 short tons.

Imports of specified magnesium compounds and compounds, not specifically provided for, were valued at $1,880,000 in 1973 compared with $1,111,000 in 1972.

WORLD REVIEW

Brazil.—A new project to produce dead-burned magnesite for basic refractories was to be established in northeast Brazil. The facilities, which will be operated by Refractories do Nordeste S.A. of Fortaleza in Ceará State, were expected to cost over $13.6 million. The Export-Import Bank was to partly finance a $4.9 million loan to cover the design, construction, and equipment for the project.

Kalium Mineraçãos announced it will develop a magnesium, potassium, and rock salt deposit in Sergipe. Initial plans called for the installation of a potassium treatment plant with a capacity of 500,000 short tons per year; this phase was scheduled for completion by yearend 1973. Total cost of the project was estimated at $300 million and was reportedly to be raised by local financing.

Canada.—Canadian Johns-Manville Co., Ltd., terminated its agreement with Canadian Magnesite Mines, Ltd., to assist in the development of a mining operation at Timmins, Ontario. The original plans called for the production of magnesite and talc.

Lundigran Ltd., in conjunction with prospective U.S. partners, announced that it hoped to reopen the Aguaguntha magnesia plant in west Newfoundland. The plant, which was built in 1968, has been shutdown since August 1970.

Greece.—Société Financière de Grèce (Scalistiri) started operation of its first magnesite brick plant at Fourni (near Mantoudi), on the island of Euboea. Scalistiri, which produces over 70% of Greek magnesite exports, began mining magnesite in Euboea in 1959. Initially, raw magnesite was exported, but in 1967 rotary kilns were installed to produce dead-burned magnesite. In 1970, a dressing plant with a capacity of 100,000 short tons per year was installed

e Estimate. p Preliminary. r Revised. W Withheld to avoid disclosing individual company confidential data.

[1] Figures represent crude salable magnesite. In addition to the countries listed, Bulgaria, Canada, and Colombia produce magnesite, but output is not reported and available information is inadequate to make reliable estimates of output levels.

[2] Year beginning March 21 of that stated.

to maximize recovery of the magnesite from the mining operation. The new refractory brick plant has an annual capacity of 42,000 tons; 18,000 tons will be either white or tar-impregnated fire bricks and the remainder tar bonded brick. Additionally, Scalistiri was conducting research to increase the use of process fines from ore only amenable to fine grinding.

India.—The Uttar Pradesh State Industrial Corp. and Belpahar Refractories Ltd. of Jamshedpur have jointly subscribed to the construction of a magnesite operation at Kafligarh in the Almora district of Uttar Pradesh. The project, which will cost 23 million Rupees,[2] was designed to produce approximately 110 short tons of deadburned magnesite per day.

Mexico.—Mitsubishi Corp. agreed to pay $20 million to Seatankers, Inc., the owner of Exportadora de Sal S.A., for the salt field in Baja California, Mexico. Seatankers, Inc., is a subsidiary of the U.S. firm National Bulk Carriers, Inc. The Japanese trading firm planned to product and export magnesium hydroxide, bromine, and salt.

Nepal.—The Nepal Bureau of Mines announced the location of a large, high-grade magnesite deposit at Kharidhunga, a village in the Sindupalchock district, approximately 60 miles northeast of Kathmandu. The deposit was estimated to contain approximately 180 millon short tons of magnesite. Results of core drilling to determine the extent of mineralization and beneficiation tests of the ore were favorable and indicated that a mining operation and prodution facilities for basic refractory brick should be established.

Sea water magnesia production facilities throughout the world by country, location, company, and capacity are as follows:

[2] Because of fluctuating exchange rates, a meaningful conversion to U.S. dollars is impractical.

Country	Location	Company	Capacity (short tons MgO)
Canada	Aguathuna, Newfoundland	Lundrigan's Ltd	30,000

TECHNOLOGY

The first large-scale test of the patented process developed by Chemical Construction Corp. and Basic Chemicals of Cleveland (Chemico/Basic), which uses magnesium hydrate to recover sulfur dioxide from powerplant emissions, was in operation at the Mystic station of Boston Edison Co.[3] Results demonstrated that over 90% of the sulfur dioxide gases previously emitted from one of the 150-megawatt oil-fired boilers could be converted to marketable sulfuric acid. The stack gases were scrubbed in a large tower containing hydrated magnesium oxide. The sulfur gases reacted with the magnesium hydroxide to form magnesium sulfite, which was then dried. The sulfite was reduced to the oxide of magnesium and sulfur; the former was recycled for use in the scrubbing tower and the latter was converted into sulfuric acid.

The Mystic station test, which is being conducted in cooperation with the U.S. Environmental Protection Agency, will also include a series of experiments to determine the effectiveness of the Chemicó/Basic process under various operating conditions. Additionally, Chemico/Basic was installing a similar recovery system at a coal-fired powerplant operated by Potomac Edison Co. in Maryland.

Other methods for removing sulfur dioxide from emissions using magnesium oxide were described.[4] A summary of patents on refractories issued between November 14, 1972, and March 27, 1973, was published by The Refractories Institute production of basic refractory products containing magnesium oxide and magnesite.

Carboline Co. has developed a proprietary catalyst that controls the stability and setting speed of magnesium oxychloride plaster used for fireproofing structural steel.[5] The catalyst enables the plaster to be sprayed onto the surface about 1½ hours after the material has been mixed. Advantages of this plaster material include the lower cost compared with other types of structural steel fireproofing materials; its ability to generate water when exposed to high heat; the ease with which it can be removed after being exposed to fire so that fresh plaster can be applied; and its suitability for weathering in exterior applications.

The Chemicotechnological Institute in the Soviet Union developed a technique that results in a silver electroplate which is more resistant to tarnish.[6] By adding magnesium sulfate to an aqueous silver nitrate electrolyte, the resultant silver electroplate was found to be five times more resistant to tarnish than usual.

Manganese

By Gilbert L. DeHuff [1]

Although a small quantity of manganese nodules was shipped from stocks, there was no actual domestic production of manganese ore, concentrate, or nodules, containing 35% or more manganese, in 1973. With demand high, imports of ferromanganese exceeded the record high established in the previous year, while domestic production dropped and prices of ore, alloy, and metal increased. The General Services Administration (GSA) pressed its sales of surplus stockpile manganese ores, alloys, and metal; and private industry actively continued research that it hoped would lead to commercially mining the nodules of the deep-sea floors.

Legislation and Government Programs.—The Acting Director, Office of Emergency Preparedness, on April 12 revised downward all manganese stockpile objectives. The new objectives were established as follows, in short tons: Natural battery ore, 10,700; synthetic dioxide, none; type A chemical ore, 12,800; type B chemical ore, 12,800; metallurgical ore, 750,500; high-carbon ferromanganese, 200,000; medium-carbon ferromanganese, 10,500; low-carbon ferromanganese, zero; silicomanganese, 15,900; and electrolytic metal, 4,750.

Cumulative sales of stockpiled manganese items for the calendar year, as reported by GSA, were as follows (short tons): Synthetic dioxide, 1,681; type B chemical ore, 600; metallurgical ore, 2,406,617 of stockpile grade and 315,484 of nonstockpile grade; high-carbon ferromanganese, 342,148; and electrolytic metal 7,351.

In June, GSA increased its limit for deliveries of metallurgical ore to 500,000 tons for each of fiscal years 1973 and 1974. In December, the limit for fiscal year 1974 was increased to 750,000 tons. Manganese stockpile inventory changes in calendar year 1973 consisted of the following: Synthetic dioxide decreased 2,481 short tons to 14,538 tons; type A chemical ore decreased 328 tons to 146,586 tons; type B chemical ore decreased 167 tons to 100,671 tons; metallurgical ore, stockpile grade, decreased 423,502 tons to 7,249,034 tons; metallurgical ore, nonstockpile grade decreased 11,889 tons to 1,377,882 tons; high-carbon ferromanganese was down 64,536 tons to 1,111,525 tons; medium-carbon ferromanganese down 1 ton to 28,920 tons; and electrolytic metal decreased 3,358 tons to 18,153 tons.

DOMESTIC PRODUCTION

Except for a small quantity of metallurgical oxide nodules shipped from old stocks by The Anaconda Company, there was neither production nor shipment of manganese ore, concentrate, or nodules, containing 35% or more manganese, in the United States in 1973.

Ferruginous manganese ores or concentrates containing 10% to 35% manganese were produced and shipped from New Mexico, and shipments continued from the Cuyuna Range of Minnesota. Manganiferous iron ore containing 5% to 10% manganese was neither produced nor shipped in either 1973 or 1972. Manganiferous zinc residuum continued to be recovered from New Jersey zinc ores.

Table 2.—Manganese and manganiferous ore shipped [1] in the United States, by State

Total	147,161	18,727	203,055	25,697
Manganiferous iron ore (5% to 10% Mn, natural)	--	--	--	--
Total manganiferous ore	147,161	18,727	203,055	25,697
Value manganese and manganiferous ore	$1,040,000	--	$1,531,390	--

[1] Shipments are used as the measure of manganese production for compiling U.S. mineral production value. They are taken at the point at which the material is considered to be in marketable form for the consumer. Besides direct shipping ore, they include, without duplication, concentrate and nodules made from domestic ores.

CONSUMPTION, USES, AND STOCKS

In the production of raw steel (ingots, continuous- or pressure-cast blooms, billets, slabs, etc., and including steel castings), consumption of manganese as ferroalloys, metal, and direct-charged ore was 12.9 pounds per short ton of raw steel produced. Of this total, 11.1 pounds was ferromanganese; 1.3 pounds, silicomanganese; 0.05 pound, spiegeleisen; 0.25 pound, manganese metal; and 0.2 pound, manganese ore. The comparable 1972 total, on the same basis, was 12.6 pounds with ferromanganese at 11.0, silicomanganese at 1.2, spiegeleisen at 0.05, metal at 0.25, and ore at 0.1. In addition to the aforementioned consumption of manganese in 1973, there was consumed per short ton of raw steel produced approximately 1.1 pounds of manganese contained in manganese ore used in making pig iron. In 1972, the quantity was approximately 1.2 pounds.

Domestic producers of manganese ferroalloys continued their capital expenditures for pollution controls, and continued to have problems of power supply. Union Carbide Corp. converted a ferrochromium furnace at its Marietta, Ohio, plant to the production of standard ferromanganese, reportedly making this the first furnace in the country of 35,000 kilovolt-ampere or larger size used for producing standard ferromanganese. The company stopped production of both ferromanganese and silicomanganese at the Ashtabula, Ohio, plant, apparently converting those furnaces to production of silicon ferroalloys.

Electrolytic Manganese Metal.—All of the manganese metal produced domestically was electrolytic, and it is certain that virtually all of that imported was electrolytic metal. Virtually all of the metal consumed was electrolytic metal, but it is possible that some low-carbon ferromanganese, and possibly some manganese-aluminum additives, may have been erroneously reported by consumers as manganese metal.

Table 3.—Consumption and industry stocks of manganese ore [1] in the United States

W Withheld to avoid disclosing individual company confidential data; included in "Miscellaneous and unspecified."
[1] Virtually all electrolytic.

The metal used to make manganese-aluminum additives is included in table 4 under the "Alloys (excludes alloy steels and superalloys)" category. Production of electrolytic metal in 1973 was 26,175 short tons, compared with 23,200 tons in 1972, and was by the same three companies: Foote Mineral Co., New Johnsonville, Tenn.; Kerr-McGee Chemical Corp., Hamilton (Aberdeen) Miss.; and Union Carbide Corp., Marietta, Ohio. Foote Mineral Co. signed an agreement to become the distributor for the United States and Mexico of the electrolytic manganese metal that will be produced by Delta Manganese (Pty) Ltd., the prospective new producer in the Republic of South Africa.

Ferromanganese.—Bethlehem Steel Co., at Johnstown, Pa., and United States Steel Corp., in the Pittsburg area, continued to be the only domestic ferromanganese producers using blast furnaces. Electric furnaces were used to produce ferromanganese by five other companies in eight plants: Airco Alloys Div., Airco Inc., Calvert City, Ky.; Ohio Ferro-Alloys Corp., Philo, Ohio; Roane Electric Furnace Div. of Woodward Corp., a Division of Mead Corp., Rockwood, Tenn.; Tenn-Tex Alloy Corp. of Houston, Houston, Tex.; and Union Carbide Corp., Ferroalloys Div., Alloy, W. Va., Ashtabula and Marietta, Ohio, and Portland, Oreg. Fused salt electrolysis continued to be used by Chemetals Div., Diamond Shamrock Chemical Co., Kingwood, W. Va., to make low-carbon ferromanganese sold under the trade name of Massive Manganese. U.S. shipments of ferromanganese from furnaces totaled 779,000 short tons compared with 727,000 tons in 1972.

Table 5.—Ferromanganese produced in the United States and manganese ore [1] consumed in its manufacture

Year	Ferromanganese produced			Manganese ore [1] consumed (short tons)		
	Gross weight (short tons)	Manganese content		Gross weight [2]		Per ton of ferromanganese [3] made

U.S.S.R. [1]	23,013	48
Other or unidentified	48,181	--
Total	1,674,718	47

[1] From U.S. Government surplus stockpile disposals, except for possibly a small tonnage of domestic ore.

Silicomanganese.—Production of silicomanganese in the United States was 184,000 short tons, compared with 153,000 tons in 1972. Shipments from furnaces were 196,000 tons, compared with 146,000 tons in 1972. In 1973, six companies used nine plants to produce silicomanganese: Airco Alloys Div., Airco Inc., Calvert City, Ky., and Theodore (Mobile); Ala.; Interlake Inc., Beverly Ohio; Ohio Ferro-Alloys Corp. Philo, Ohio; Roane Electric Furnace Div., of Woodward Corp., a Division of Mead Corp., Rockwood, Tenn.; Tenn-Tex Alloy Corp. of Houston, Houston, Tex.; and Union Carbide Corp., Alloy, W. Va., Marietta, Ohio, and Portland, Oreg. Consumption of silicomanganese was 14.2% that of ferromanganese, compared with 12.8% in 1972.

Spiegeleisen.—The New Jersey Zinc Co. continued to produce spiegeleisen in electric furnaces at Palmerton, Pa.

Pig Iron.—A total of 354,000 short tons of manganese-bearing ores containing over 5% manganese (natural) was consumed in the production of pig iron (or its equivalent hot metal). Domestic sources supplied 150,000 tons, of which 115,000 tons was manganiferous iron ore containing 5% to 10% manganese, and 35,000 tons was ferruginous manganese ore containing 10% to 35% manganese. Foreign sources supplied 204,000 tons, of which 10,000 tons was manganiferous iron ore, and 194,000 tons contained more than 35% manganese.

Battery and Miscellaneous Industries.—The ore reported in table 3 includes that consumed in making synthetic manganese dioxide by either electrolytic or chemical means, but it does not include consumption of the synthetic dioxide. Although some synthetic dioxide is used for chemical purposes, most of it is used in the manufacture of dry cell batteries, particularly for the manganese-alkaline battery, premium or heavy-duty Leclanché (manganese dioxide-ammonium chloride-zinc) cells, and as a blend with natural ore in the ordinary Leclanché cell.

The domestic ore and much of the foreign ore used for chemical and miscellaneous purposes did not meet national stockpile specification P-81-R for chemical-grade ore.

ESB Inc. purchased the Covington, Tenn. synthetic manganese dioxide plant of Lavino Div., International Minerals & Chemical Corp., and resumed production of electrolytic dioxide late in 1973. The plant had been idle for more than a year. ESB has no plans to resume production of synthetic dioxide by chemical means but has moved its grinding operations for natural battery ores from its Ray-O-Vac dry cell plants to Covington.

The long association of the Lavino name with the manganese business came to an end March 30 when the Lavino Div. (formerly E. J. Lavino & Co.) of International Minerals & Chemical Corp. terminated its business of importing, grinding, and blending battery- and chemical-grade ores.

Kerr-McGee Chemical Corp. increased the capacity of its Henderson, Nev., plant to 8,700 short tons of synthetic manganese dioxide per year, and planned a further increase to 12,000 tons per year by early 1975.

PRICES

Manganese Ore.—All manganese ore prices are negotiated, dependent in part on the characteristics and quantity of ore offered, delivery terms, and fluctuating ocean shipping rates. Trade journal quotations reflect the paper's feel for the market. American Metal Market quotes for metallurgical-grade manganese ore containing 46% to 48% manganese carried over from 1972 at 58 to 61 cents, nominal, per long ton unit, c.i.f. eastern seaboard and Gulf ports. In August, they were increased to 61 to 71 cents, nominal, and carried to the end of the year. The quotations for metallurgical ore containing 48% to 50% manganese were 61 to 64 cents, nominal, at the beginning of 1973, and 74 to 84 cents. nominal, at yearend. The Metals Week quotation for metallurgical-grade manganese ore with a minimum manganese content of 48% carried over from 1972 at 63 to 68 cents, same basis. Although some spot sales were reported as appreciably higher, an increase in June to 68 to 75 cents was credited largely to adjustment for February's devaluation of the dollar. In mid-July, the quote was moved to 75 to 85 cents for a "thin market," in mid-November, to 85 to 95 cents, and in mid-December, to $1.05 to $1.15, at which it closed the year. The last two ranges were a measure of the contract prices that are normally negotiated toward the end of the year.

Manganese Alloys.—The domestic producer price for standard high-carbon ferromanganese having a minimum manganese content of 78% remained at $190 per long ton, f.o.b. producer plant or shipping point, until the middle of April when it was increased $10 to $200 per long ton, same basis, at which price it remained for the remainder of the year. Early in May, Metals Week increased its quote for imported alloy of this grade to $190 to $197 per long ton, delivered in Pittsburgh or Chicago. This remained unchanged to yearend.

Manganese Metal.—The price of standard electrolytic manganese metal held through the first quarter of the year at 33.25 cents per pound, f.o.b. producer plant, for shipments of 30,000 pounds or more. An increase in price of 2 cents became effective for Foote Mineral Co. as of June 1, and earlier for Kerr-McGee Chemical Co. A similar increase announced by Union Carbide Corp. to be effective July 2 was negated by imposition of Government price controls before it could be effected. The result was a dual price, 33.25 and 35.25 cents, for more than half of the year.

FOREIGN TRADE

Ferromanganese exports totaled 8,574 short tons valued at $2,136,917, compared with 6,842 tons valued at $1,511,864 in 1972. Of the 1973 total, Canada took 6,637 tons; Switzerland, 988 tons; Mexico, 309 tons; Dominican Republic, 252 tons; El Salvador, 160 tons; Colombia, 93 tons; Republic of South Africa, 66 tons; Brazil, 31 tons; and six other countries received small quantities. Exports classified as "manganese and manganese alloys, wrought or unwrought, and waste and scrap" totaled 4,660 tons valued at $3,108,688 in 1973. The previous year's exports were 1,504 tons valued at $1,020,743. This classification includes electrolytic manganese metal and manganese-copper alloys, but it does not include ferromanganese. Exports of ore and concentrate containing more than 10% manganese totaled 57,448 tons valued at $4,535,463, compared with 25,108 tons at $3,137,104 in 1972. Most of the 1973 exports were probably imported manganese dioxide ore that may or may not have been subjected to grinding, blending, or otherwise classifying.

The average grade of imported manganese ore was 48% manganese in 1973, compared with 49% in 1972. Brazil supplied 42% of the U.S. total in 1973, while Gabon's portion dropped to 26%. Imports of manganiferous ore (more than 10% but less than 35% manganese) consisted of 110 short tons from Mexico, having an average manganese content of 34%.

Ferromanganese imports for consumption exceeded the previous year's record high, and a good portion of the total continued to come from foreign companies in which U.S. producers or consumers have substantial interest. Silicomanganese imports for consumption totaled 44,759 short tons containing 30,061 tons of manganese. Sources and tonnage (gross weight) were as follows: Norway, 27,882; Yugoslavia, 5,382; Mexico, 4,832; Spain, 3,417; Japan, 1,323; Sweden, 829; France 498; the United Kingdom, 335; and Canada, 261, Imports for consumption classified as unwrought manganese metal, except alloys, and waste and scrap of such metal, totaled 2,452 short tons, compared with 4,121 tons in 1972. Of the 1973 total, 2,100 tons came from the Republic of South Africa, and 352 tons came from Japan. A small quantity, 11 pounds with a value of $132.73 per pound, came from Italy.

Imports for consumption classified as "manganese compounds, other" totaled 4,355 short tons in 1973, compared with 7,937 tons in 1972. The sources, gross weights, and values per pound in 1973 were as follows: Japan, 2,784 tons (19.8 cents); West Germany, 1,123 tons (0.6 cents); Belgium-Luxembourg, 300 tons (17.8 cents); the United Kingdom, 147 tons (6.2 cents); and Sweden, less than half a ton ($1.55). The imports from Japan and Belgium-Luxembourg appear to have consisted largely, if not entirely, of synthetic manganese dioxide.

Tariffs.—Suspension of the duty on manganese ore from most nations, Rate 1, was extended another 3 years (through June 30, 1976) by Public Law 93-99. If duties were in effect, the rate would have been 0.12 cent per pound of contained manganese, the last of the five annual General Agreement on Tariffs and Trade (GATT) reductions effected by Presidential Proclamation 3822 of December 16, 1967. Ore from the U.S.S.R., the People's Republic of China, and certain other specified Communist countries, continued to be subjected to the statutory rate of 1 cent per pound of contained manganese.

Table 7.—U.S. imports [1] of manganese ore (35% or more Mn), by country

Country	1972			1973		
	Gross weight (short tons)	Mn content (short tons)	Value (thousands)	Gross weight (short tons)	Mn content (short tons)	Value (thousands)
Angola [2]	35,570	17,160	$1,244	--	--	--
Australia	82,587	40,261	1,575	123,813	61,458	$2,760
Brazil	[3] 404,972	192,827	8,217	629,833	299,402	15,767
Canada	11	5	(4)	611	354	51
Congo (Brazzaville) [5]	33,521	16,760	64	--	--	--
Gabon [6]	473,142	236,821	10,669	393,037	196,114	10,007
Ghana	46,940	22,062	1,237	38,965	18,601	1,076
India	25,593	12,400	620	--	--	--
Mexico	70,655	32,731	1,803	105,019	41,206	2,616
Morocco	26,309	13,936	1,277	26,427	13,923	1,343
South Africa, Republic of	142,354	65,742	2,715	119,038	55,920	2,002
Zaire [7]	278,598	141,990	4,894	73,050	35,657	1,781
Total	[3] 1,620,252	792,695	34,315	1,509,793	722,635	37,403

[1] Quantities for general imports and imports for consumption were identical.
[2] Part or all of the ore reported to have come from Angola is believed to have originated in Gabon.
[3] It appears that up to 225,000 additional tons (gross weight) may have come from Brazil in 1972.
[4] Less than ½ unit.
[5] Actually from Gabon.
[6] In addition in 1972, Gabon imports reported as Congo (Brazzaville) were approximately 35,000 tons (gross weight), Gabon imports reported as Zaire were approximately 130,000 tons (gross weight), and some or all of the imports reported as Angola probably originated in Gabon.
[7] In 1972, actual imports originating in Zaire were approximately 150,000 tons (gross weight); see footnote 6.

Table 8.—U.S. imports for consumption of ferromanganese, by country

Country	1972			1973

WORLD REVIEW

Under United Nations auspices, a Georgetown, Guyana, April 30 to May 2 meeting of representatives from developing countries was reported to have favored the development of producer associations for different ores including those of manganese. Bauxite, copper, iron, nickel, and cobalt were other likely candidates.

Worldwide interest in deep-sea manganese nodules continued unabated, with the various active groups firming plans for increased testing in 1974. Summa Corp., Houston, Tex., an affiliate of Hughes Tool Co., took delivery of a 618-foot, 36,000-ton surface ship, the Hughes *Glomar Explorer*. A huge 324-foot-long barge, resembling a floating drydock, will be sunk to the ocean floor at a suitable Pacific site. Nodules collected by it from the bottom then will be passed through a pipe to the surface-ship. Tests of the Japanese continuous bucket line (CBL) system of nodule recovery were reported to have met with problems under conditions of rough ocean-floor topography and rapidly changing currents but were reported to have been favorable otherwise.

Argentina.—Manganese ore produced in 1972 had an average manganese content of 28%. Ferromanganese production in 1972 totaled 18,000 short tons compared with 10,000 tons in 1971.

Australia.—The manganese mine of Bell Brothers at Woodie Woodie, Pilbara District, Western Australia, closed. The only other significant producer of manganese ore in Western Australia in recent years, the Longreach group, stopped producing in 1971.[2] Calendar year 1973 production data released by the Minister of Mines of Western Australia, totaled 29,000 short tons as measured by sales realized during the period. The ore was metallurgical ore from the Pilbara District, averaging 48.31% manganese. The mining firm of Hancock and Wright was considering a synthetic manganese dioxide plant at Bunbury, Western Australia. It would use Pilbara manganese ore and ferrous sulfate contained in the effluent from a nearby titanium dioxide plant. Ferric hydroxide would be a product of the plant.

On January 31, 1973, the Australian Minister for Minerals and Energy announced that export controls were being imposed on all minerals to be exported in raw or semiprocessed form. One objective was to encourage more processing in Australia.

Belgium.—Société Europenne des Derives du Manganese (SEDEMA) will increase its synthetic manganese dioxide production capacity to 22,000 short tons per year by the end of 1974. SEDEMA uses the chemical process of the former Manganese Chemicals Corp., Baltimore, Md., now Chemetals Div., Diamond Shamrock Chemical Co.[3]

Brazil.—Production of Amapá mine-run manganese ore in 1973 by Indústria e Comércio de Minerios, S.A (ICOMI) was 2,293,000 short tons. Washed ore produced

e Estimate. p Preliminary. r Revised. NA Not available.

[1] In addition to the countries listed, Cuba, Territory of South-West Africa, and Malaysia also may have produced manganese ore and/or manganiferous ore but information is inadequate to make reliable estimates of output levels. Low grade ore not included in this table has been reported as follows in short tons: Czechoslovakia (about 17% Mn) 1971—53,000; 1972—nil; 1973—1,100; Romania (about 22% Mn) approximately 140,000 tons in each year; Republic of South Africa (15%–30% Mn, in addition to material listed in table) 1971—200,220; 1972—112,058; 1973—73,333.

[2] Estimated on the basis of reported contained manganese.

[3] Exports.

[4] Grade unreported. Source: The National Economy of the U.S.S.R., Central Statistical Administration, Moscow.

[5] Of total 1972 output, 57.6% graded below 35% Mn and of total 1973 output 64% graded below 35% Mn, with the balance in each year grading 35% Mn to 48% or more. (Comparable 1971 production breakdown not available, but export figures give 67% below 35% Mn.)

[6] Iranian calendar year beginning March 21 of year stated; all figures apparently are mine run ore.

amounted to 1,744,000 tons having a manganese content of approximately 48%. Production of pellets by the new pelletizing plant, which continued to have problems, was 60,000 tons. Exports of washed metallurgical ore by ICOMI were 1,330,000 tons. Brazil produced 85,000 short tons of ferromanganese and 26,000 tons of silicomanganese in 1973.

Canada.—In the latter part of the year, Union Carbide Canada Ltd. started its new 38,000 kilovolt-ampere closed ferromanganese furnace at Beauharnois, Quebec. It was reported to have a capacity of 100,000 tons of high-carbon ferromanganese per year.[4]

China People's Republic of.—A survey of the People's Republic of China's mineral resources published by the West German Institute for Economic Research concluded,

[4] American Metal Market. V. 80, No. 240, Dec. 12, 1973, p. 16.

with respect to manganese, that of the annual output of 1 million metric tons 90% is consumed domestically and most of the 100,000 tons exported goes to Japan.[5]

Gabon.—Battery and chemical-grade ore produced in 1973 totaled 46,000 short tons.

Ghana.—In September, the Government of Ghana assumed control of all export sales of manganese ore. In November, an agreement was signed with Caemi International, The Hague, the Netherlands, appointing that firm the sole worldwide sales agent for Ghana manganese ore. Caemi International is worldwide sales agent for Brazilian Amapá ore. Ghana ore is marketed in the following grades: Battery grade, containing better than 50% manganese; high-grade lump, containing approximately 49% to 50% manganese; high-grade fines, having a similar manganese content; two lower grades, B and C; and carbonate ore, with a manganese content of approximately 32%. Some of the carbonate ore is used in Europe in electric furnaces for metallurgical purposes, but most of it goes to Japan for use in making synthetic manganese dioxide.

Greece.—An agreement was signed November 8 for construction of a 12,000-ton-per-year synthetic (electrolytic) manganese dioxide plant as a joint venture of two Japanese firms, Tekkosha Co. Ltd. (65%) and Mitsubishi Corporation (35%). Plans called for operation to begin by mid-1975, with a goal to supply the local market and export the balance. Exports of pyrolusite in 1972, apparently battery-grade, totaled 5,700 short tons, of which 2,900 tons went to West Germany and 2,400 tons went to France,

India.—Central Provinces Manganese Ore Co. (C.P.M.O.) continued to operate its one remaining mining property, the Balapur Hamesha (Dongri Buzurg) mine in the State of Maharashtra, although uncertainties surrounded legal status of the property. Although all of the company's remaining ore was apparently sold, the company was hindered in making deliveries by a lack of railway wagons.[6]

The Government of India was reported to have accepted recommendations of the National Committee on Science and Technology (NCST) for construction of a 4,000-short-ton-per-year synthetic (electrolytic) manganese dioxide plant to meet domestic needs. The NCST also was reported to have recommended a plant for manganese metal and for manganese-based chemicals, apparently for export.[7]

To conserve resources and assist in meeting increasing internal demand, the Government of India on April 1 banned the export of First Grade manganese ore (48% or more manganese), except for previous commitments, and decided to reduce exports of Second Grade ores (35% to 48% manganese).

Of the 1,692,000 short tons of manganese ore reported as production for 1973, 1,083,000 tons or 64% was ferruginous ore containing less than 35% manganese, 499,000 tons or 29.5% was classified as Second Grade manganese ore containing 35% to 48% manganese, 108,000 tons or 6.4% was First Grade manganese ore, and 1,700 tons or 0.1% was peroxide ore having a maximum manganese dioxide content of 86%. Exports totaled 814,000 tons divided as follows: Ferruginous, 546,000 tons (all to Japan); First Grade, 37,000 tons (Spain, 18,000; Japan, 13,000; South Korea, 7,000); Second Grade, 230,000 tons (Japan, 190,000; Bulgaria, 14,000; Czechoslovakia, 14,000; South Korea, 12,000); Peroxide, 1,400 (all to Japan). Domestic consumption of manganese ore totaled 826,000 tons, of which 380,000 tons was for ferromanganese production, 430,000 tons for iron and steel, 13,000 tons for dry cell manufacture, and 2,000 tons for miscellaneous uses. Imports were 6,000 tons, presumably all of battery grade.

Production of ferromanganese was 152,000 short tons, compared with 179,000 tons in 1972. Capacity of India's seven plants, all of which produced in 1973, remained unchanged at 215,000 tons. Domestic consumption was approximately 91,000 tons according to preliminary reports from consumers. Exports totaled 60,000 tons, with the United States taking 38,000 tons; Egypt, 18,000 tons; and Japan, 3,700 tons.

Indonesia.—Reported production of manganese ore in 1973 contained more than 75% manganese dioxide.

Iran.—Manganese ore produced in 1972 had an average manganese content of 33%.

Ireland.—Mitsui Denman, Ltd., Irish subsidiary of the Japanese firm Mitsui Mining & Smelting Co. Ltd., contracted

[5] Metals Week. V. 44, No. 35, Aug. 27, 1973, p. 6.
[6] Mining Journal (London). V. 281, No. 7218, Dec. 21, 1973, p. 514.
[7] Mining Journal (London). V. 280, No. 7181, Apr. 6, 1973, p. 275.

with Lummus Co., Ltd. (LCL), for the construction of a $15 million synthetic (electrolytic) manganese dioxide plant on Little Island, County Cork. The plant will use a proprietary Mitsui process and have a productive capacity of 12,000 tons per year, with completion of construction expected by mid-1975. The product will be exported to dry cell manufacturers in the European Common Market. LCL is a London-based affiliate of Combustion Engineering Inc.[8]

Italy.—The manganese ore produced in 1973 averaged 27% manganese content.

Japan.—Tekkosha Co. Ltd. ceased production of electrolytic manganese metal at its 6,000 metric ton per-year Yamagata plant. This dropped the country's annual production capacity to 10,600 from 17,200 short tons.[9] Company plans were to double production capacity of its synthetic manganese dioxide plant at Yamagata to 13,200 short tons per year, reportedly by conversion of the metal facility.[10] Japanese demand for synthetic manganese dioxide in 1973 was 50,000 short tons, of which 33,000 tons was for the export market.[11]

Production of natural dioxide ore or concentrate in 1973 was only 100 short tons, averaging 70% manganese dioxide; metallurgical ore or concentrate produced averaged 28.1% manganese. Production of ferromanganese was 680,000 short tons in 1973 and 610,000 tons in 1972; silicomanganese, 415,000 tons in 1973 and 378,000 tons in 1972; electrolytic manganese metal, 11,111 tons in 1973 and 8,456 in 1972; and synthetic manganese dioxide, 41,338 in 1973 and 43,440 in 1972.

Mexico.—Mexico's principal manganese ore producer, Cia. Minera Autlán, was nationalized through the purchase of the substantial minority interest held by Bethlehem Steel Corp. A $15.5 million loan was obtained from First National City Bank, New York, and construction was to start on a new 50,000-ton-per-year ferromanganese plant near Tampico with the possibility for production to start sometime in 1975. The loan was guaranteed by the State Development Bank, Nacional Financiera, S.A. (NAFINSA). The company's several mines are located in the Molango district of the State of Hidalgo. The deposit from which Autlán has mined battery-grade dioxide ore is approximately 20 miles distant from the larger deposit where its carbonate ore is mined and beneficiated to an oxide nodule for metallurgical use. ESB Incorporated mines battery-grade dioxide ore from a mine in the same part of the district as Autlán's dioxide mine. ESB reports that it has started a calcining operation that will allow the use of lower grade ores than have been mined to date.

Morocco.—All manganese ore produced in 1973 was chemical-grade concentrate having an average manganese dioxide content of 84%.

Philippines.—The manganese ore produced in both 1973 and 1972 was reported to have an average manganese content of 52%.

Portugal.—According to preliminary data, the manganese ore produced in 1973 averaged 37% manganese. In addition, 38,000 short tons of manganiferous iron ore was produced analyzing 42.4% iron and 7.8% manganese.

South Africa, Republic of.—Electrolytic Metal Corp. (Pty) Ltd. (EMCOR) completed its planned expansion of capacity to produce electrolytic manganese metal, and was considering the possibility of a further expansion. Delta Manganese (Pty) Ltd., however, experienced startup problems with its new plant and did not get into production. South African Manganese Ltd., the country's largest producer of manganese ore, reported increased production and shipments, but earnings remained at the same level as those of 1972. High transport costs were largely held responsible for the poor profit showing. In 1972, The Associated Manganese Mines of S.A. Ltd., the second largest producer, made capital expenditures on a new manganese ore mine at NChwaning and on expansion of other manganese mines in the Blackrock area.

Spain.—The manganese ore produced in 1973 had an average manganese content of 30.0%.

Thailand.—Metallurgical-grade manganese ore produced in 1973 was of a 46% to 50% manganese grade, and the battery ore was of a 75% manganese dioxide grade.

Yugoslavia.—Estimated production of ferromanganese in 1973 was 28,000 short tons.

TECHNOLOGY

Laboratory investigations of the previously reported sulfatization-reduction modification of the Bureau's high-temperature differential sulfatization process for utilizing low-grade manganiferous iron ores of the Cuyuna Range, Minn., recovered more than 90% of the manganese as an oxide containing 65% manganese, and 75% of the iron as an oxide concentrate containing 60% iron.[12]

In a review of U.S. mineral resources geologists of the U.S. Geological Survey set forth the following among their conclusions: There are virtually no domestic reserves of manganese ore, and known resources are very low grade and refractory; the best possibilities for discovery of domestic reserves or resources of "conventional type" would seem to be in finding the source of the manganese of the Pierre Shale (possibly buried under Pleistocene sedimentary rocks in Minnesota or nearby areas), finding a Molango-type (Mexico) deposit, or finding the source of the manganese that is concentrated in the Salton Sea brines.[13]

The literature on the natural and manmade occurrences of manganese and its biologic effects was critically evaluated by a Panel on Manganese, Div. of Medical Science, National Research Council—National Academy of Sciences. The report was prepared for the Environmental Protection Agency to assist that agency in making its decisions concerning pollutants and their regulation. Average urban ambient-air concentration in the United States for a 12-year period ending in 1965 was approximately 0.10 $\mu g/m^3$; maximum ambient-air concentrations, occuring almost exclusively at industrial locations, exceeded 10$\mu g/m^3$ but were apparently of that order of magnitude. The threshold limit value (TLV) recommended by the American Conference of Governmental Industrial Hygienists is 5 mg/m^3. This is generally believed to constitute a low factor of safety for occupationally-exposed susceptible persons when consideration is given to duration and degree of exposure. However, present concentrations in ambient air would appear to provide a substantial margin of safety for the general population. It does not appear that manganese pollution of water can be expected to be a problem, except locally under very unusual circumstances. The report concludes, "The long-term toxicology of manganese, including fetal effects, still presents a collection of ambiguous answers. For this reason, special care must be exercised before substantial additional sources of manganese are introduced into the environment." The possibility that future widespread use of manganese organometallic fuel additives might create an ambient-air problem requires objective evaluation.[14]

Experimental work under the Environmental Engineering Programs, University of Southern California, Los Angeles, Calif. showed that manganese dioxide has a large adsorption capacity with respect to mercury, up to 10% mercury by weight, provided chloride concentrations are below those of seawater. It was concluded that manganese dioxide might be important as a mercury scavenger in fresh or brackish water, suggesting the possibility for its application to the treatment of waste waters.[15]

A new copper-nickel-zinc-manganese alloy, designated IN629, has been developed by the laboratory of International Nickel Ltd., Birmingham, England. It was claimed that this copper-based spring alloy, analyzing 15% nickel, 13% manganese, and 28% zinc, offers considerable improvement in mechanical properties over copper-nickel-zinc (so-called nickel-silver) alloys that are currently used by the electrical and electronics industries for relay springs. Changes in structure, composition, and annealing treatment gave only small variations in the mechanical properties of the alloy.[16]

Several patents were issued in connection with the Toth process for production of

aluminum metal by the reaction of aluminum trichloride with molten manganese as described in U.S. patent No. 3,615,359, dated October 26, 1971.[17] Basically, the process consists of the chlorination of calcined clay by chemical means, with reduction of the resultant aluminum chloride by manganese metal. The manganese is recycled by oxidation of the manganese chloride generated by the aforementioned reduction step and subsequent reduction of the manganese oxide to manganese metal in a blast or shaft furnace. If both the manganese and the chlorine can be recycled as claimed, the process should be relatively pollution-free; because a thermal reaction is used rather than electrolysis, requirements for electricity should be only one-tenth those of the current Bayer-Hall techniques. Capital costs per ton of aluminum have been estimated 50% to 75% less. Applied Aluminum Research Corp. (AARC), New Orleans, together with Bremar Holdings, London merchant bankers, announced plans for a semicommercial plant to be constructed somewhere in Europe to test the technical and economic feasibility of the process. AARC claimed that costs for a commercial operation would be approximately half of those for producing aluminum electrolytically.[18]

Mercury

By V. Anthony Cammarota, Jr.[1]

Primary mercury production of 2,171 flasks[2] in 1973, valued at $621,405, was the lowest since recordkeeping began in 1850. Of the 24 active mines only five produced over 100 flasks, compared with 12 in 1972. Fourteen mines produced less than 10 flasks each from mined ore, dumps, cleanup operations, or as a byproduct. During the year, only about six mines could be classified as consistent producers.

Secondary production of 10,329 flasks was down from the 1972 level. Some of this material represented mercury released by the General Services Administration (GSA) and some came from the closed mercury-cell chlor-alkali plant of Olin Corp. at Saltville, Va. The company used the mercury at its other plants.

The consumption of 54,283 flasks in 1973 was 2.6% higher than the previous year. Increases were registered for usage in electrical apparatus, electrolytic preparation of chlorine and caustic soda, and industrial and control instruments, but usage in mildew-proofing paint declined.

The average New York price, after falling 59% over the past 4 years to $218.28 per flask in 1972, recovered to $286.23 per flask. Efforts by major mercury-producing countries to establish floor prices apparently were effective in stabilizing prices.

Imports were up sharply from 1972, with Algeria supplying about one-quarter of the total. World production of mercury in 1973 decreased less than 1% from that of 1972, although Spain increased production by 11%.

Government actions during the year included reduction of the mercury objective for the strategic stockpile, the banning of mercury from cosmetics, the promulgation of an air emission standard for mercury plants, and the inclusion of mercury and its compounds in a list of toxic water pollutants.

Legislation and Government Programs.—Government financial assistance on a participatory basis was available for mercury exploration projects through the Office of Minerals Exploration, U.S. Geological Survey, to the extent of 75% of the acceptable costs. No contracts were executed during 1973.

GSA continued its sale of surplus mercury on a sealed-bid basis at the rate of 500 flasks per month. Sales totaled 2,000 flasks, with prices ranging from $302 per flask in January to $268 per flasks in July. Total releases for the year were 2,583 flasks, including 583 flasks transferred to other Government agencies. At the end of the year 4,628 flasks remained available for disposal.

In April, the mercury objective for the strategic stockpile was reduced from 126,500 flasks to 42,700 flasks. A bill (H.R. 7153) was introduced into Congress on April 18 to grant authorization for release of the total surplus of 157,362 flasks, but by yearend no action had been taken. As of December 31, 1973, total strategic stockpile accumulations from all programs stood at 200,062 flasks.

The Food and Drug Administration banned the use of mercury in skin-bleaching preparations and in cosmetics except as a preservative in certain eye-area cosmetics.[3]

The Environmental Protection Agency (EPA) published a national emission standard for mercury applicable to stationary sources that process mercury ore to recover mercury, and to those that use the mercury cell to produce chlorine and caustic soda.[4] Emissions to the atmosphere from each source cannot exceed 2,300 grams (5.1 pounds) of mercury per 24-hour period.

The regulations require that an existing plant must comply with the standard within 90 days after promulgation, unless a waiver is granted. If the Administrator of EPA grants a waiver, a period of up to 2 years for compliance is allowed.

Also, EPA issued a proposed list of toxic pollutants as required by the Federal Water Pollution Control Act Amendments of 1972. Mercury and all its compounds were included. The proposed standards applicable to industrial point sources were designed to protect a variety of water uses.[5] Final guidelines establishing test procedures for the analysis of pollutants were issued by EPA.[6] The approved analytical method for mercury, flameless atomic absorption, must be used when applying for discharge permits or certification by a State. A daily maximum of 0.00014 pound of mercury per 1,000 pounds of product was the proposed limitation set by EPA for the amount of mercury that could be discharged from a mercury-cell chlor-alkali plant after application of the best practicable technology currently available.[7] Another regulation by EPA prohibited the dumping or transportation for dumping of wastes containing more than trace concentrations of toxic materials including mercury and its compounds.[8]

r Revised.

DOMESTIC PRODUCTION

Production came from 24 mines in 1973, down from 37 in 1972. Revisions for 1972 added 16 producers to the 21 previously reported in 1972. The additional producers accounted for an increase of 47 flasks in 1972 production; none of the 16 produced more than 10 flasks.

By yearend 1973, six of the largest operations remained active and were expected to continue into 1974. Seven mines reported production exclusively from dumps, cleanup operations, or as a byproduct. An additional 7 mines each showed production of 10 flasks or less. Some exploration and development work was conducted by several small operators. The number of mines reporting outputs of 500 to 999 flasks decreased from four to one, and properties producing 100 to 499 flasks decreased from seven to four. Of the total production of 2,171 flasks, 83% came from producers of over 100 flasks. Principal mines in 1973 were as follows:

State	County	Mine
Properties producing 500 to 999 flasks		
Nevada	Pershing	Red Bird.
Properties producing 100 to 499 flasks		
Alaska	Kuskokwim River Region	White Mountain.
California	Sonoma	Culver-Baer.
Do	Santa Clara	Guadalupe.
Do	do	New Almaden.

California produced 56% of the total mercury production, down from 80% in 1972. New Idria Mining and Chemical Co. sold all its equipment but retained the reduction plant at the New Idria mine in San Benito County, Calif. Until its closing in 1972, the mine was one of the largest producers of mercury with employment of about 160. At the New Almaden property, the company sold all its equipment at auction, and sold six parcels of its 3,500-acre site to Santa Clara County. The company retained three parcels of land on which the Santa Clara Quicksilver Co. operated a mine and a 30-ton-per-day furnace. At the Knoxville mine ore was stockpiled and a small amount of metal was produced from dump material. The Culver-Baer mine closed early in the year and sold its property.

Nevada, with only three mines operating, produced 32% of the total mercury, mostly from the Red Bird mine. In addition, the Carlin Gold Mining Co. continued to recover mercury as a byproduct at its gold mine in Eureka County.

The White Mountain mine in Alaska shipped most of its cinnabar concentrate to Oregon for retorting, but exported a small quantity to the Orient. The Whit-Roy mine in Texas was active for a short time.

The average grade of all ore processed in 1973, including ore treated in concentrators, decreased to 5.9 pounds of mercury per ton. Because of the insufficiency of reported data in 1973, the amount of ore treated and ore grade were based to a large extent on knowledge of producing areas and their historical data.

In spite of a higher level of GSA releases, secondary production of mercury fell to 10,329 flasks from 12,651 flasks in 1972. Dental amalgams, scrap batteries, various types of sludges, mercury from a dismantled chlor-alkali plant, and discarded mercury-containing instruments were the major sources of secondary mercury.

1973	7,746	2,583	10,329

CONSUMPTION AND USES

Consumption continued to climb for the second consecutive year, to 54,283 flasks. The largest gains were noted for use in electrical apparatus (16%), electrolytic preparation of chlorine and caustic soda (13%), and industrial and control instruments (9%). The use of mercury in batteries, which accounts for the major part of consumption in electrical apparatus, was responsible for much of the increase in that sector. After a 3-year decline, mercury usage in the chlor-alkali industry increased. The major uses for mercury were electrical apparatus (33%), electrolytic preparation of chlorine and caustic soda (24%), mildew-proofing paint (14%), and industrial and control instruments (13%).

Mercury consumption in mildew-proofing paint fell 8% from that of 1972. Although the use of mercurials in paint has not been banned, pending the outcome of a final decision by EPA, it was reported that many companies have switched to new nonmercurial mildewcides. They have done so not only to avoid last-minute reformulation problems, in the event mercurials are banned, but also because laboratory tests have indicated that these compounds could be satisfactory substitutes.

Chlorine production increased 4% to 10.3 million short tons, but only 24.6% of the total was produced in mercury cells, up slightly from 24.2% in 1972. Consumption of mercury per ton of chlorine produced edged up to 0.39 pound from 0.37 pound in 1972. Linden Chlorine Products Inc. reactivated its mercury-cell plant at Linden, N.J. With the closing of the Olin Corp.'s Ecusta plant in Pisgah Forest, N.C., the number of chlorine plants using mercury cells was reduced to 28.

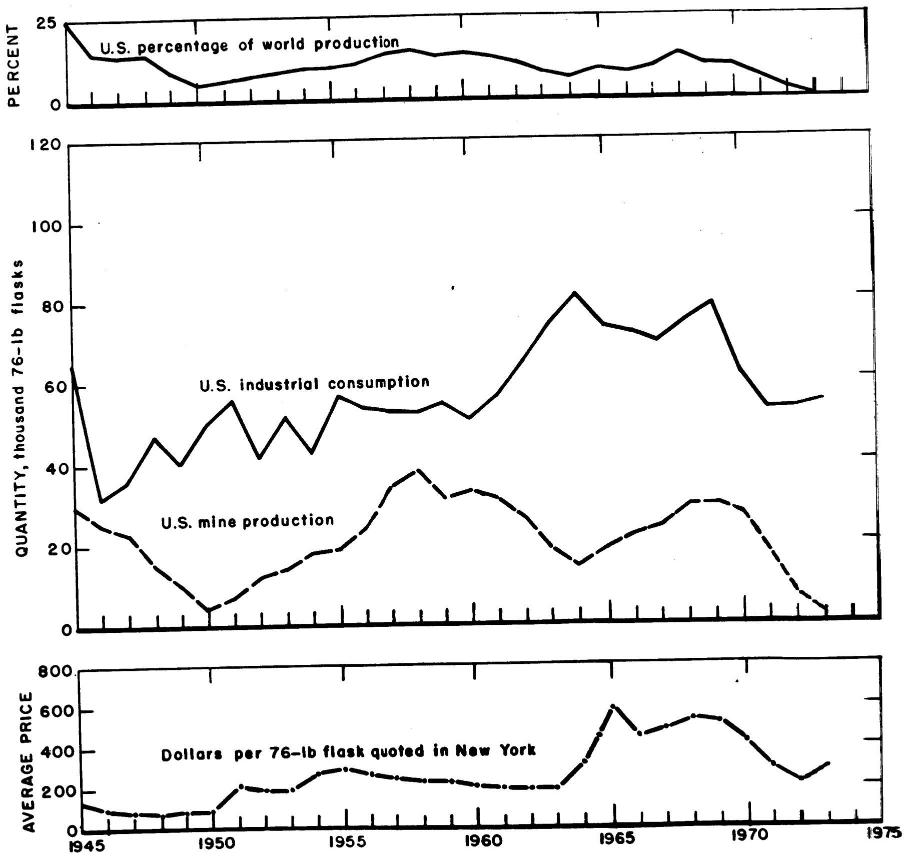

Figure 1.—Trends in production, consumption, and price of mercury.

PRICES

The price of mercury showed signs of settling down from the erratic movements of the past several years. From a January price of $280 to $285 per flask, the price rose to $318 to $330 per flask in late February with the devaluation of the dollar. By midyear the price had fallen to about $250 per flask with the news of a possible stockpile release and the promulgation of emission standards by EPA. In June, prices began an uptrend that reached $310 to $312 per flask in August. The firmer tone was attributed to a hold-back by foreign sources in order to gain greater control over the market. The yearend price was $282 to $288 per flasks. The average price at New York was $286.23 per flask in 1973.

On December 6 the Cost of Living Council amended the phase 4 price regulations on nonferrous metals, thereby removing the price control on mercury. The control was a moot point for mercury because the price during the period never approached the freeze base of $450 to $460 per flask on May 25, 1970.

Although prices on the London market were below New York prices by as much as $24 per flask in October, the gap narrowed by yearend to $5 per flask. Supporting factors for a strengthened foreign market were tenders for mercury from Colombia, India, Taiwan, and Venezuela, and increased Japanese inquiries.

Representatives of the major mercury-producing countries met several times during the year in January, July, and October to exchange views on market developments and to formulate price policies. At the October meeting in Mexico City, Algeria, Italy, Mexico, Spain, Turkey, and Yugoslavia for the first time signed an agreement to pursue market stability by establishing floor prices and selling only to agents that would follow their marketing policy. It was reported that the producers were looking for a minimum price of $280 per flask as a base for future long-term contracts.

Table 8.—Average monthly prices of mercury at New York and London

(Per flask)

Month	1972		1973	
	New York [1]	London [2]	New York [1]	London [2]
January	$213.24	$208.13	$282.50	$260.72
February	207.75	198.84	304.78	289.38

FOREIGN TRADE

Mercury exports decreased to 342 flasks from 400 flasks in 1972. The major recipients were Canada, the Republic of Korea, and Taiwan.

Imports for consumption, which include mercury imported for immediate consumption plus material withdrawn from bonded warehouses, increased by 60% to 46,026 flasks. General imports, which include mercury imported for immediate consumption plus material entering the country under bond, totaled 46,076 flasks. The major suppliers, who accounted for 88% of the total, were Canada (38%), Algeria (26%), Spain (16%), and Yugoslavia (8%). Included in the import figures are 998 flasks entering the country as secondary metal from Canada and Mexico. Imports of mercury compounds, mainly as mercury cyanide from Japan, were equivalent to 34 flasks of metal.

The U.S. rate of duty on mercury imports during the year was $9.50 per flask.

WORLD REVIEW

World mercury production decreased to 276,203 flasks from 277,584 flasks in 1972. Italy, Mexico, Spain, and Yugoslavia accounted for 49% of the total. Mercury producers who met during the year to discuss prices also suggested the possibility of establishing a mercury institute to promote mercury uses and to handle producer marketing.

The Organization for Economic Cooperation and Development (OECD), whose 24 member countries include most of the industrialized non-Communist nations of the world, including the United States, recommended elimination of alkyl mercury compounds in agriculture, elimination of mercury compounds from use in the pulp and paper industry, and maximum possible reduction in discharges of mercury from mercury-cell chlor-alkali plants. In 1973, member countries of OECD produced about 46% of the world total.

The Italian Ministry of Public Health has forbidden entirely the use of organic mercury compounds in agriculture. The Soda Industry Association of Japan revealed a plan to reduce chlorine production from mercury cells from the current 95% down to 60% of the country's capacity. In Canada, mercury cells accounted for 46.8% of total chlorine capacity compared with 60.5% in 1972. On the other hand, the U.S.S.R. is expected to have a 140,000-ton-per-year chlorine plant onstream by 1976 that will use De Nora mercury cells.

Mining operations in Yugoslavia were reviewed.[9]

e Estimate. p Preliminary. r Revised.
[1] Output of Cominco Ltd.; excludes production (if any) by minor producers.

Algeria.—The mercury plant at Ismail produced at full capacity during 1973. A new plant about 50 miles from Annaba was expected to be onstream by the end of 1974.

Canada.—Cominco, Ltd., produced 12,500 flasks, 14% less than in 1972. Ore production at its Pinchi Lake mine amounted to 163,000 tons, compared with 203,000 tons in 1972. Assuming that all the ore mined was treated to produce metal, the ore grade increased from 5.5 pounds of mercury per ton in 1972 to 5.8 pounds in 1973. Ore reserves at yearend were reported by Cominco to be 1,600,000 tons containing 120,000 flasks of mercury. Mining operations at the Pinchi Lake mine, the only mercury mine in Canada, were reviewed.[10]

Italy.—Mercury production fell 23% but exports declined only slightly. Ore grade dropped to 9 pounds of mercury per ton of ore mined, from 10 pounds in 1972. Ore is becoming more difficult and costly to extract as the working levels extend deeper underground. An official Government announcement stated that Italian mines could maintain their present rate of production for another 12 to 15 years.

Lower demand and falling prices in recent years have brought losses to Italian producers, consequently, production was cut to prevent adding to already substantial stocks. Based on production and trade data of the past several years, the apparent mercury stockpile was about 90,000 flasks at yearend.

Spain.—Production increased 11% to 60,076 flasks. Minas de Almadén, the State-owned company, ordered a complete new mercury plant from the U.S.S.R. The plant will be used to process low-grade ore, tailings, and old dump material. Almadén started a 9-month exploration program in the Almadenejos region.

Early in the year, the Spanish Government approved an agreement for the reorganization of the Mieres and Pola de Lena mines in Asturias. The two mines should be able to supply Spain's domestic mercury requirements. To keep the mines in operation, the Government has guaranteed a minimum price for their output.

[1] Identified resources: Specific identified mineral deposits that may or may not be evaluated as to extent and grade, and whose contained minerals may or may not be profitably recoverable with existing technology and economic conditions.

The U.S. Geological Survey updated its assessment of U.S. and world mercury resources as shown in tables 13 and 14.[11] The Survey stated that at most mercury mines no effort has been made to ascertain the ultimate reserve of the deposit in advance of exploitation. Hence, the total reserves or resources at major world mercury deposits are unknown, but estimates based on production records and geologic information can be made.

TECHNOLOGY

A new mineral, balkanite ($Cu_9Ag_5HgS_8$), from the Sedmochislenitsi mine in Bulgaria was reportedly the only known sulfide of copper, silver, and mercury, either as a mineral or as a synthetic product.[12]

Bacteria capable of degrading methylmercury in aquatic sediments were isolated.[13] These organisms may serve a useful purpose in maintaining environmental methylmercury concentrations at a minimum.

Methods for removing mercury from industrial plant effluents and natural waters received widespread attention. Treating solutions containing mercury (II) ions with a starch xanthatepolycation complex, reduced residual mercury (II) content to extremely low levels.[14] Other techniques reported include the absorbtion of mercury on chemically modified cotton cellulose containing amines[15] and by hydrous manganese oxides suspended in solution.[16] Laboratory experiments and small-scale field tests were performed to investigate some possible methods, such as dredging and chemical deactivation, to restore mercury-contaminated lakes and rivers.[17]

A flameless atomic absorption system was developed to analyze ambient mercury levels from 15 nanograms per cubic meter to 10 micrograms per cubic meter by using in-series silver wool collectors.[18] Ambient levels of dimethylmercury, sulfur dioxide, hydrogen sulfide, and nitrogen dioxide did not seriously interfere with the analytical scheme. Another method was described for determining mercury in a variety of matrices including coal and fly ash, which achieves the advantages of a strictly instrumental technique with no chemical manipulations.[19] In a typical coal matrix, the sensitivity is about 10 nanograms of mercury per gram of coal, with a precision of about 10% at 100 parts per billion.

Mercury recovery and recycling processes advanced from the laboratory to the pilot plant or commercial use. Rockwell International Corp. reported excellent results in a pilot plant for removing mercury or other metals from wastewaters using a fluidized bed of conductive particles across which a low-voltage, direct current is applied.[20] Chemical or electrochemical stripping of the metals from the particles can be used to recover the metals and regenerate the bed. The Georgia-Pacific Corp. put into operation at its Bellingham, Wash., chlorine plant a chemical process to reclaim mercury from its effluent.[21] The mercury is recycled back to the mercury cells. The FMC Corp. uses a process at its Squamish, British Columbia, plant to precipitate mercury from the effluent.[22] An extractor solubilizes the mercury in a brine solution, which returns to the plant's mercury cells where elemental mercury is produced and recovered.

At the Bureau of Mines College Park Metallurgy Research Center, a method was developed with the capability of distinguishing between organic and inorganic forms of mercury by using resin-loaded papers.[23] Paper chromatography followed by X-ray spectrography or neutron activation analysis found the mercury content of tap water to be 0.1 to 0.2 part per billion compared with 0.1 to 0.3 part per billion using flameless atomic absorption. The

Bureau of Mines' Reno Metallurgy Research Center, Reno, Nev., published a report describing the electrooxidation process for extracting mercury from cinnabar ore.[24] Power consumption ranged from 10 to 50 kilowatt-hours per ton of ore. Mercury recovery from the pregnant solution was 99.9% pure using 1.5 to 2.0 pounds of zinc and iron, respectively, per pound of mercury contained in solution.

Mica

By Benjamin Petkof [1]

For the second time since 1970, there was no reported domestic production of any form of sheet mica. The domestic production of scrap and flake mica continued to rise, and in 1973 output reached the highest ever recorded. Ground mica production increased in both quantity and value. Total exports of mica increased in quantity and value. Imports of processed (including manufactured) and unprocessed (unmanufactured) sheet mica declined in quantity but increased in value. Imports of scrap increased in both quantity and value. The domestic consumption of block and film mica varied little from that of the previous year, but the consumption of mica splittings increased significantly.

Legislation and Government Programs.—During the year, the Government lowered the Defense Material Inventory stockpile objective for all categories of stockpiled sheet mica. The various objectives were reduced as follows: Muscovite block (stained and better), 6 million pounds to 1.6 million pounds; muscovite film (first and second quality), 2 million pounds to 413,000 pounds; muscovite splittings from 19 million pounds to 2.2 million pounds; phlogopite block, 150,000 pounds to 51,000 pounds; and phlogopite splittings, 950,000 pounds to 200,000 pounds. At the end of 1973, the Defense Materials Inventory contained the following quantities of stockpile-grade material: Muscovite block, 10.6 million pounds; muscovite film, 1.4 million pounds; muscovite splittings, 35.8 million pounds; and phlogopite splittings, 4.1 million pounds. The stockpile also contained some nonstockpile-grade material. The General Services Administration continued to dispose of mica from the stockpile.

DOMESTIC PRODUCTION

Sheet Mica.—There was no reported domestic production of any form of sheet mica and the outlook for any future domestic sheet mica mining remained unpromising.

Scrap and Flake Mica.—The production of scrap and flake mica surpassed that of the previous year and reached a new

[1] Physical scientist, Division of Nonmetallic Minerals—Mineral Supply.

alltime high of 177,076 short tons valued at $6,081,893. This was an increase of 11% in quantity and 40% in value. North Carolina retained its position as the largest scrap- and flake-producing State with 60% of total production. The remaining output of scrap and flake mica came from Alabama, Arizona, Connecticut, Georgia, New Mexico, and South Carolina. Flake mica was obtained primarily by the beneficiation of material from pegmatite and clay deposits. The domestic output of scrap and flake was processed into small-particle-sized mica for various industrial end uses.

Ground Mica.—Sales of ground mica increased 5% in quantity and 6% in value over those of 1972. Dry-ground mica accounted for 88% of total sales. Fifteen companies, operating a total of 19 plants, processed scrap and flake mica to a small-particle size; of these plants, 15 produced dry-ground mica; 3 produced wet-ground; and 1 produced both wet- and dry-ground.

[1] Domestic and some imported scrap.
[2] Data may not add to total shown because of independent rounding.

CONSUMPTION AND USES

Sheet Mica.—Consumption of all forms of sheet mica, consisting of block, film, and splittings, showed a significant increase due to greater consumption of splittings, the major form of sheet mica consumed.

Almost 1.2 million pounds of block mica was consumed for the fabrication of vacuum tubes, capacitors, and various other electrical and nonelectrical items. Of the total consumption of block, vacuum tubes required 68% and capacitors accounted for less than 2%. Lower than Stained quality was in greatest demand and accounted for 64% of total consumption; Stained, 36%; and Good Stained or better, the remainder. Only a small quantity of film was consumed, primarily for the fabrication of capacitors.

Muscovite block and film were consumed by 14 companies in 7 States: New Jersey with four consuming plants, New York with three, North Carolina with two, and Pennsylvania with one, consumed 74% of domestically fabricated block and film. The consumption of phlogopite block decreased 6% from 74,199 pounds in 1972 to 69,899 pounds in 1973.

Consumption of splittings increased 20% from that of 1972. India and the Malagasy Republic continued to supply the bulk of the splittings consumed domestically. Splittings were fabricated into various built-up mica products by 11 companies with 12 plants in 7 States. Seven companies with eight plants located in New Hampshire, New York, Ohio, and Pennsylvania consumed almost 4.7 million pounds of splittings or 90% of total consumption.

Built-up Mica.—This mica-based alternate material was produced in various forms, primarily for use as an electrical insulating material. The production of built-up mica products in 1973 increased 21% in quantity and 10% in value from that of the previous year. The forms of built-up mica in greatest demand were molding plate (24%), and segment plate (24%).

Reconstituted Mica.—Three companies continued to manufacture this mica-based alternate material from good-quality delaminated scrap mica. The manufacturing companies were the General Electric Co. at Schenectady, N.Y., the Samica Corp. at Rutland. Vt., and the Acim Paper Corp. at New Hyde Park, N.Y. There were no published data available relating to the quantity and value of the reconstituted mica produced during the year.

[2] Data does not add to total shown because of independent rounding.

STOCKS

At yearend there was about 2.02 million pounds of sheet mica in fabricators' stocks. Of this quantity, 64% was splittings and the remainder almost entirely block. Only a minor quantity consisted of film. This information was obtained by direct canvass of sheet mica fabricators. Similar information is unavailable for scrap and flake mica, but it is thought that producers maintain stock inventories equal to 5% to 10% of domestic production.

PRICES

The average value of imported muscovite sheet in 1973, based on consumption data, was as follows: Block, $1.63 per pound; film, $5.84 per pound; and splittings $0.33 per pound. The average value of phlogopite sheet mica, also based on consumption data was as follows: Phlogopite block, $1.72 per pound; and phlogopite splittings, $0.95 per pound.

The average value of scrap and flake mica produced during the year was $34.36 per ton. Prices for ground mica, prepared from scrap and flake, quoted in the Chemical Marketing Reporter show slight increases over those of the previous year. Yearend prices are shown in table 9.

Table 9.—Price of dry- or wet-ground mica in the United States in 1973 [1]

	Cents per pound
Dry-ground:	
Joint cement, 100 mesh	4–5
Plastic, 100 mesh	4–5
Roofing, 20 to 80 mesh	2–3
Wet-ground: [2]	
Paint or lacquer, 325 mesh	9½–10
Rubber	9½–10
Wall paper	10½–11

[1] In bags at works, carlots, unless otherwise noted.
[2] Freight allowed east of the Mississippi River.

Source: Chemical Marketing Reporter. V. 204, No. 27, Dec. 31, 1973.

FOREIGN TRADE

All classes of mica exports increased 5% in quantity and 11% in value from that of the previous year. About one-half of the sheet, scrap and flake, and ground mica exported was shipped to Canada, France, and the United Kingdom. Exports of mica manufactures increased in both quantity and value. Reported export data did not provide information on the grade or type of mica exported, but it is assumed the major portion of the material exported was ground mica.

Imports of scrap and waste mica almost doubled from those of the previous year. There were no imports of phlogopite mica. Imports of sheet mica declined 22% in quantity, but increased 9% in value. Processed mica imports declined 15% in quantity and increased 36% in value.

WORLD REVIEW

World mica production showed some variation from that of previous years, but the major production of sheet muscovite and phlogopite occurred in India and the Malagasy Republic respectively. The United States remained the major world producer of scrap and flake mica.

India.—The pattern of Indian mica production remained unchanged from the previous year. Production was dependent on output from 100 regularly operated mines. Other mines continued to operate intermittently as small cottage industries with small, individual outputs.

Exports of mica continued under the direct control of the Minerals and Metals and Trading Corp. (MMTC). It is anticipated that the MMTC will endeavor to exert control over the mica industry from production to domestic consumption and export.

Indian mica consumption continued to increase for the manufacture of items such as refractories, rubber products, built-up mica, paints, and electronic and electrical apparatus.

Malagasy Republic.—The country remained the major world source of all forms of phlogopite mica with production of almost 2 million pounds of block, splitings, and scrap during the year. Almost two-thirds of production consisted of splittings; the remainder, block and scrap. Exports of phlogopite mica reached 2.2 million pounds, with splittings accounting for slightly over one-half of the total quantity exported.

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, the People's Republic of China, Romania, Southern Rhodesia, South-West Africa, and Sweden are known to produce mica, but available information is inadequate to make reliable estimates of output levels.

[2] Exports.

[3] Includes micanite and other built-up.

[4] Includes condenser film, washer, and discs.

[5] Includes sheet, strips, and powder.

[6] Less than ½ unit.

TECHNOLOGY

A recent government publication reviewed the resource position of mica and concluded that although the United States had undiscovered and paramarginal resources of sheet mica, the necessary hand labor required to mine and prepare sheet mica deterred any exploration, development, or mining. The report concluded that reserves and resources of flake mica were adequate to meet future demand.[2]

Experimental work was conducted to observe the effect on reinforcement capability of adding mica, which has a high aspect ratio (flake equivalent diameter to thickness ratio), to polystyrene copolymer and polyester resin. Mica flakes with aspect ratios above 100 imparted a high degree of reinforcement to thermoplastic or thermosetting materials under a given set of conditions.[3]

Molybdenum

By Andrew Kuklis [1]

World molybdenum output increased slightly above that of 1972. Consumption, on the other hand, rose significantly in response to a strong worldwide demand for molybdenum. Consumption exceeded production for the first time since 1965. World industrial inventories of molybdenum declined to 129.8 million pounds or approximately normal requirements.

In response to greater demand for molybdenum, several mines reopened, others resumed producing at capacity, and some expanded mining operations. However, some molybdenum mines remained marginal operations because of low prices resulting from an oversupplied and competitive market. Prices on foreign markets began to improve at midyear and at yearend domestic prices returned to their higher published level.

2 Non-communist countries.

Legislation and Government Programs.—President Nixon signed into law a Congressional bill (S2551) authorizing the General Services Administration (GSA) to dispose of 36.5 million pounds of molybdenum from the national stockpile. Previous legislative action by Congress released 4.3 million pounds of molybdenum for sale. Most of the material will be sold to domestic producers under a long-term buyback contract. Also, GSA was expected to offer approximately 8 million pounds of molybdenum over an extended period, initially on a sealed-bid basis and later (depending on market conditions) on a shelf-item basis.

At yearend, molybdenum in the national stockpile totaled 38.0 million pounds. During the year, GSA sold more than 5.8 million pounds. Approximately 2.9 million pounds of molybdenum was classed as sold but unshipped.

Table 2.—U.S. Government molybdenum stockpile material inventories on Dec. 31, 1973

(Thousand pounds contained molybdenum)

Type material	National (stragetic) stockpile
Molybdenum, disulfide	24,416
Molybdenum, ferro	4,980
Molybdenum oxide	8,651
Total	38,047

DOMESTIC PRODUCTION

Domestic production of molybdenum increased 3.7 million pounds in 1973 and was over 3% higher than in 1972. For the molybdenum producing industry, 1973 was another record year. Higher production rates at byproduct operations accounted for the increased output. Ores processed at concentrators for recovery of molybdenum totaled 204.5 million tons; of which, the bulk was byproduct ores. Mines producing only molybdenum reduced their output over 5% in 1973 compared with 1972 output. Molybdenum output from byproduct sources rose to 42% of total production from the 37% reported in 1972, continuing the upward trend of past years.

Demand for molybdenum was strong during 1973 because of record consumption by the steel industry. Mine and plant inventories were reduced significantly. The domestic molybdenum industry enjoyed continuous operations during 1973 as no serious labor problems interrupted production schedules.

Three mines produced over 67 million pounds of molybdenum from primary ores; of these, two were in Colorado and one was in New Mexico. As in past years, the Climax mine of American Metal Climax, Inc. (AMAX), was the world's largest producer with over 29% of the total.

The 48.8 million pounds of molybdenum produced at byproduct plants increased 18% over 1972 figures. The increase was due to a strong demand for copper and other byproduct minerals. Of the 14 plants processing copper porphyry ore containing molybdenum, 10 increased their output, 3 had lower production, and 1 previously closed plant resumed operating in 1973. The Silver Bell facility of American Smelting and Refining Co. (Asarco) did not recover molybdenum during 1973.

Molybdenum recovered from uranium ores declined 23,600 pounds and that from tungsten ores declined 93,995 pounds compared with 1972 figures.

According to 1973 data, Pennzoil Co., parent company of Duval Corp. and Duval Sierrita Corp., was the leading domestic producer of byproduct molybdenum. Kennecott Copper Corp., with four operations, remained in second place. Other large producers of byproduct molybdenum were, in order of quantity, Magma Copper Co. and Anamax Mining Co. Six companies, four byproduct producers and two primary producers, accounted for over 96% of the United States output of molybdenum, or over 63% of the world's production in 1973.

The marked improvement in demand for molybdenum resulted in increased activities associated with expanding current production facilities, and increased exploration for molybdenum minerals and exploitation of new molybdenum deposits.

Development of an open pit mine at

Climax by AMAX was completed by yearend. The initial production rate ranged from 3,000 to 4,000 tons, but was expected to increase eventually to 25,000 tons of molybdenum ore per day. The open pit mine will provide flexibility in operation at the Climax property to meet changing market conditions and offset production losses due to gradual closing of the Urad mine. During 1973, an additional flotation stage was added to the regrind circuit at the Climax mill to improve concentrate grade. Also, it enabled the company's conversion plant to upgrade technical grade oxide products.

AMAX continued development of the Henderson molybdenum mine near Empire, Colo. Major work projects underway in 1973 were driving a haulage tunnel through the Continental Divide and construction of a concentrator. Approximately one-half of the 9.3-mile-long tunnel was completed at yearend. Satisfactory progress was made on the concentrator but its completion was not expected until late in 1974. Production at the Henderson mine was scheduled to begin in 1976 at a rate of about 30,000 tons of ore per day. Ultimately, the mine was expected to produce about 50 million pounds of molybdenum annually.

AMAX mined the 300 millionth ton of molybdenum ore at the Climax operation on January 11, 1973. Published information indicated that more ore had been produced at the Climax mine than at any underground mine in North America. According to production data, the record "ore ton" came from the Phillipson level of the mine, a producing area in operation for over 40 years. The 200 millionth "ore ton" was reached on January 27, 1966, less than 7 years ago. Estimated ore reserves at Climax are considered sufficient to operate the mine for an additional 40 years. To maintain the current underground production rate of 43,000 tons per day, a new 600 level was developed at a cost of over $50 million.

AMAX Specialty Metals Corp., a division of AMAX, announced plans for construction of a molybdenum conversion plant at Fort Madison, Iowa. The facility will produce crystalline ammonium molybdate and derivative products for use in the chemical, metallurgical, and petrochemical industries. Also, the molybdenum conversion plant at Langeloth, Pa., will be modernized. It was estimated that total expenditures for both projects would exceed $25 million.

The Fort Madison facility eventually will be expanded to roast molybdenite concentrate and produce a complete line of molybdenum products. Additional plant capacity will be necessary because of expansion of mining operations at Climax and development of new molybdenum production at the Henderson mine. The Iowa location was selected because of developing markets in the Midwest, availability of railroad and water transportation, and proximity to the company's mining operations in Colorado. Construction of the new Iowa facility and expansion of the existing Langeloth plant were scheduled for completion in 1975.

Cyprus Mines Corp. reported reserves of 100 million tons of ore having an average grade of 0.148% molybdenite at the Thompson Creek deposit near Clayton, Idaho. The company has conducted considerable exploratory work in the area since 1967. To date, an incline to the ore body and extensive footage of drifts and crosscuts were completed. Company officials approved additional expenditures of $1.3 million for continuation of development and related work on the deposit. Final studies were underway to determine the economic potential of the deposit at mining rates of 20,000 tons per day and upward. An estimated $70 to $75 million would be required to develop the deposit.

The Esperanza copper-molybdenum mine of Duval Corp. near Tucson, Ariz., resumed production in January. Operations were suspended at yearend 1971 because of mounting inventories of copper and molybdenum concentrate. A cutback in smelter throughput by Asarco, processor of Duval's copper concentrate, caused the accumulation of a large inventory of copper concentrate which contributed to the mine shutdown. The inventory was reduced to manageable levels by exports of 36,000 tons of copper concentrate to foreign markets, principally Japan. Employment of approximately 350 workers was expected to have a beneficial effect on the area's economy. Modification in processing at the concentrator was completed during shutdown and resulted in a 25% increase in throughput.

Molybdenum output at the operations of

Duval Sierrita Corp. rose 22% over that of 1972. Molybdenum recovery was expected to continue to increase in 1974. Throughput of 89,000 tons of ore per day was reached in the concentrator during December, an increase of 5,000 tons compared with previous months of 1973.

Molybdenum Corp. of America (Molycorp) terminated about 20% of its work force at the Questa mine early in the year. It was the second cutback in employment at the facility in 2 years. The first cutback was in July 1971 when the firm laid off 250 workers. Curtailment of production effected approximately 100 employees, principally open pit miners. The concentrator was expected to operate at current production levels. Management stated that the weakness in demand for molybdenum had resulted in low prices for the mineral and related products and subsequently rising inventories at the plant.

CONSUMPTION AND USES

Domestic consumption of molybdenum in concentrate form increased 32% compared with that of 1972. The 82.5 million pounds consumed was the highest on record and exceeded the previous high in 1968 by nearly 7 million pounds. Virtually, all the concentrate consumed was converted to molybdic oxide at plants in Arizona, Colorado, New Jersey, Ohio, Pennsylvania, and Utah. A small quantity of the concentrate was used in producing purified molybdenum disulfide for lubricant purposes; output of purified molybdenum disulfide increased for the second consecutive year.

Domestic consumption of molybdenum materials by end uses rose significantly in 1972 (table 5). The 25% increase over 1972 figures was the highest reported since 1959. Consumption increased because heavy demand for capital goods resulted in higher production levels for general purpose alloy, stainless and tool steels. Molybdic oxide accounted for over 68% of the molybdenum products consumed in 1973 compared with 66% in 1972. The remaining molybdenum products were ferromolybdenum (18%), ammonium and sodium molybdate (2%), and other molybdenum materials (12%).

Of the reported consumption 70% was used in steel production, 8% was used in cast irons, 5% in super alloys, 3% in alloys, and 5% in mill products such as

Table 5.—Consumption of molybdenum materials, by end use in 1973

(Thousand pounds contained molybdenum)

[3] Includes magnetic and nonferrous alloys.

sheet, rod, and wire. The chemical industry consumed 8% for use in making pigments, catalysts, and other uses.

Research was continued in an effort to develop new uses for molybdenum products such as catalysts for car emission controls and coal gasification. Other new applications of molybdenum under investigation included high-strength steels for stronger automobile bumpers and oil well casing in drill holes of great depth, and an improved super alloy for aircraft and industrial gas turbine engines.

Since 1971, over 200,000 tons of high-strength steel containing molybdenum have been consumed to manufacture oil and gas transmission pipe for service in geographical areas of subzero temperature. With new pipeline projects scheduled in Alaska and the U.S.S.R., a market estimated at 20 million pounds of molybdenum was projected for this requirement in the next decade.

STOCKS

The industrial inventory of molybdenum in concentrate and compounds totaled 52.5 million pounds, 34% less than at yearend 1972. Molybdenum in stocks at mines dropped 51%, those at producer plants decreased 23%, but those at consumer plants increased 66% compared with 1972 figures.

PRICES

Published prices for high-quality molybdenum concentrate and compounds, which were established in May 1969, remained unchanged throughout the year. Because there was some discounting in 1972, domestic producers announced at year end resumption of sales at published prices. The Cost of Living Council removed molybdenum from price control on December 7, 1973. The following tabulation shows published domestic prices at yearend 1973 for molybdenum and related products per pound of contained molybdenum:

Climax concentrate	$1.72
Byproduct concentrate	1.40–1.65
Climax oxide/bags	1.91
Climax oxide/cans	1.92
Dealers oxide	1.86
K–1 oxide	1.78
K–2 oxide	1.71
Ferromolybdenum (Climax lump)	2.21
Ferromolybdenum (Climax powder)	2.27
Ferromolybdenum (Dealer)	2.10

Source: Metals Week, Dec. 31, 1973.

FOREIGN TRADE

U.S. exports of molybdenum concentrate and oxide were the highest on record and exceeded the previous record high in 1969 by 28%. The Nation shipped to foreign markets an equivalent of 64% of the 1973 domestic output, principally to industrialized countries of the world. The 1973 record high in exports was due to an increase in world demand and relatively low prices for U.S. products on foreign markets caused by the de-valued and downward floating dollar.

The Netherlands again was the principal recipient, receiving over 40% of the total. Most of the material entering the Netherlands was converted to other molybdenum products and re-shipped to other European countries.

Ferromolybdenum valued at $3.2 million was exported to 16 countries; Japan received nearly 61% of total value of shipments. Other molybdenum materials exported included metal and alloys in crude form and scrap, wire, powder, and semifabricated forms. Total value of this material was reported at $5.2 million, significantly higher than in 1972.

U.S. exports are summarized in tables 6, 7, and 8.

1 Ferromolybdenum contains about 60% to 65% molybdenum.
2 Less than ½ unit.

Although the Nation is self-sufficient in molybdenum materials, a small quantity of concentrate, manufactured molybdenum products, and waste and scrap enters the United States from numerous countries throughout the free world. High tariff rates preclude the importation of such materials in large quantities.

Molybdenum concentrate containing 458,315 pounds of molybdenum valued at $962,904 was received from three countries, namely, Canada, Peru, and France. Canada supplied nearly all the material. The gross weight of scrap imported from six countries totaled 94,961 pounds, valued at $197,424. The Netherlands supplied nearly 35% of the valued shipments. Imports of 36,400 pounds (gross weight) of wrought and unwrought metal valued at $373,935 came from nine countries. Austria and Sweden were the principal suppliers.

Molybdenum chemicals and related products entering the United States include ammonium molybdate containing 395,577 pounds of molybdenum valued at $826,481; molybdenum compounds containing 297,760 pounds of molybdenum valued at $614,066; potassium molybdate containing 115 pounds of molybdenum valued at $1,404; mixtures of inorganic compounds containing 2,586 pounds of molybdenum valued at $23,134; and molybdenum orange totaling 1,062,721 pounds, valued at $528,690.

WORLD REVIEW

No official statistics were available on molybdenum output in the U.S.S.R., the People's Republic of China, and other Communist nations, but estimates for those countries were included in the world total in table 9. Non-communist world production of 158.8 million pounds was principally from the United States (73%), Canada (17%), Chile (8%), with Japan and Peru accounting for virtually all the remainder.

Australia.—Mt. Arthur Molybdenum NL conducted geological exploration on mineral leases in Queensland. Also, the company obtained a prospecting lease in the Westmoreland district and exploratory work was underway. The Wolfram Camp facility processed some tungsten-molybdenum ores during the year.

Canada.—Molybdenum output increased 3 million pounds in 1973 and was 10% over that of 1972. A higher production rate at the Endako mine and completion of the first full year of operation at two byproduct molybdenum mines accounted for most of the rise in Canadian output. Record yearend 1972 stocks estimated at 20 million pounds were reduced over 50% in 1973.

Canada ranked second to the United States among world producers of molybdenum and supplied approximately 15% of 1973 world production, an increase of 1% over that of 1972.

Improvement in the world molybdenum demand situation resulted in reopening of mines, expansion of existing operations, and active exploration programs, principally in British Columbia. A number of geological reports describing molybdenum mineralization in Canada and the western Cordilleran Belt of North and South America were published.[2]

Gibraltar Mines Ltd., a subsidiary of Placer Development Ltd., completed the first full year of operation at its copper-molybdenum mine near McLeese Lake, British Columbia. The concentrator processed over 15 million tons of ore from which 122 million pounds of copper and one-half million pounds of molybdenum were recovered. The average daily throughput at the mill was 41,300 tons com-

[1] In addition to the countries listed, Argentina, North Korea, Nigeria, Romania, South-West Africa, and Spain also produce molybdenum, but information is inadequate to make reliable estimates of output levels.

pared with 39,500 tons in 1972. The installation of automatic control systems on three grinding circuits accounted for improved concentrator throughput.

Additional mining equipment was placed in service to compensate for increasing stripping ratio and haulage distance. Ore was mined principally from the Gibraltar East Stage Pit. Development of the Granite Lake Stage Pit was continued during the year. The project included removal of overburden by a contractor, drainage of a nearby lake, and dredging of nearly 1 million cubic yards of silt. Mine production at the Granite Lake Stage Pit was scheduled to start at midyear 1974.

Lornex Mining Corp. Ltd. completed the first full year of operations at its open pit copper-molybdenum mine, 33 miles south of Ashcroft in the Highland Valley area, British Columbia. Approximately 14 million tons of ore was processed at the concentrator. The milling rate averaged over 38,000 tons daily. Molybdenum output amounted to nearly 3.5 million pounds. The molybdenum concentrate was sold to Phillip Brothers, New York, a division of Engelhard Minerals & Chemicals Corp. Ore reserves were estimated at 292.8 million tons averaging 0.42% copper and 0.014% molybdenite. A report describing the unique operation was published.[3]

Bethlehem Copper Corp. Ltd. spent $3.6 million for a detailed engineering study of the J-A copper-molybdenum ore deposit, 25 miles southeast of Ashcroft also in the Highland Valley area of British Columbia. The deposit is in close proximity to the company's existing copper mine and milling operations. The study recommended a mining operation having a capacity of 25,000 tons of ore per day. An estimated $60 million would be required to develop the ore body. The deposit contains proven ore reserves totaling 286 million tons having an average grade of 0.43% copper and 0.017% molybdenite. The mine was scheduled for production in 1976.

At midyear, operation of the Endako mine, Placer Development Ltd., reached designed capacity of 15 million pounds of molybdenum per year. The mine operated at reduced capacity since August 1971 because of an oversupply of molybdenum. The return to full production resulted in employment of 70 additional workers hence increasing the work force to over 400 employees. Additional production equipment was placed in service at the facility to improve metallurgical recovery and increase roasting and mining capacity. An expansion program at the facility will be continued during 1974 and 1975. Proven and probable ore reserves at the Endako pit at yearend 1973 totaled 153 million tons grading 0.143% molybdenite and at the adjacent Denak pit 21 million tons grading 0.159 molybdenite. At yearend, the company announced an intensive exploration program for 1974 in order to increase molybdenum reserves.

The Endako concentrator processed 8.4 million tons of ore from which nearly 12 million pounds of molybdenum was recovered. Approximately 8.5 million pounds of molybdic oxide was produced at the roasting plant. The company reported inventory of molybdenum at yearend totaling 5.7 million pounds, a decline of 2.2 million pounds from yearend 1972.

Highmont Mining Corp. Ltd., operated by Teck Corp. Ltd., continued development of copper-molybdenum mineralization in the Highland Valley district of British Columbia. The deposit will be developed as two open pit mines and will produce at a rate of 25,000 to 27,000 tons of ore per day. Mineralization extends close to the surface, hence overburden removal costs were expected to be minimal. The deposit contains an estimated 150 million tons of ore having an average grade of 0.28% copper and 0.051% molybdenite. Pilot plant testing of the ore in 1968 resulted in metallurgical recoveries of 92% for copper and 83% for molybdenum. An estimated $70 million was expected to be spent on the mine and concentrator facility.

Hecla Operating Co. Ltd., Canadian exploration subsidiary of Hecla Mining Co., U.S.A., continued exploration and metallurgical testing at the Liard-Schaft Creek copper-molybdenum deposit owned by Silver Standard Mines Ltd. in northwestern British Columbia. Work projects underway and/or completed during 1973 included additional exploratory drilling, bulk sampling, and pilot plant testing of ore. Also, a road was constructed to the property. A detailed feasibility study also was prepared to ascertain the economic potential of the

[3] Mamen, Chris. Lornex–300M Tons on Tap. Can. Min. J., v. 94, No. 8, August 1973, pp. 23–26.

deposit at a mining rate of 25,000 to 40,000 tons per day. The deposit contains an estimated 300 million tons of ore grading 0.40% copper and 0.036% molybdenite.

Brynnor Mines Ltd., a subsidiary of Noranda Mines Ltd., was expected to reopen the Boss Mountain molybdenum mine early in 1974 because of increasing worldwide demand for the mineral. The mine, located near Williams Lake, British Columbia, commenced production in May 1965. The mill was designed to process ore at a rate of 1,700 tons per day. Owing to an oversupply of molybdenum in the early 1970's, the mine suspended production on December 3, 1971. Mine production for the last year of operation totaled 534,500 tons of ore from which over 2 million pounds of molybdenum was recovered. At yearend 1971, ore reserves were reported at nearly 3 million tons, having an average grade of 0.40% molybdenite.

Deep Grid Analysis Ltd. conducted detailed geophysical exploration of two molybdenum targets in the St. Lawrence area, Newfoundland. A systematic drilling program was planned to evaluate positive vibrations received during the study. The molybdenum targets, buried under Pleistocene sediments, cover an area of about 500 acres. Results of soil sampling conducted in past years inferred the presence of significant molybdenum mineralization in the area. Funds for additional investigative work was authorized by Radex Minerals Ltd., owner of the property.

Climax Molybdenum Corp. of British Columbia, subsidiary of AMAX, U.S.A., conducted a feasibility study on the Ruby Creek molybdenum deposit near Atlin, British Columbia, owned by Adanac Mining & Exploration Ltd. Work completed in 1973 included two diamond drill holes totaling 5,000 feet, relogging split cores of previous drilling projects, and collection of rock specimen for thin section and petrographic study. One hole drilled to a depth of 3,000 feet showed good molybdenum for the first 600 feet. The other hole drilled to a depth of 2,000 feet had molybdenum mineralization between 170 and 420 feet. Should the investigation conclude that the deposit can be mined profitably, then AMAX would provide the necessary funds for its development.

Kerr Addison Mines Ltd. made a similar study of the deposit in 1970 and dropped its option in 1971. The company spent nearly $3 million on underground exploration, diamond drilling, and other related work. The study resulted in increasing ore reserves from 70 million tons grading 0.141% molybdenite at a stripping ratio of 1.3 to 1, to ore reserves of over 104 million tons grading 0.16% molybdenite and a stripping ratio in the order of 0.63 to 1. The improvement in demand for molybdenum accounted for the renewed interest in the deposit.

AMAX purchased the assets and property of British Columbia Molybdenum Ltd., owned by Kennecott Copper Corp., at Kitsault, British Columbia. The mine and mill, having a capacity of 6,000 tons of ore per day, commenced operation early in 1968 and was closed on April 28, 1972, because of weak molybdenum prices and high operating cost. Approximately 22 million pounds of molybdenum were produced during the period. Ore reserves were reported at 40 million tons grading 0.23% molybdenite.

Greenland.—Arktish Minekompagni A/S, a joint venture of Nordisk Mineselskab A/S and AMAX, conducted exploration on a large molybdenite deposit north of Scoresbysund, eastern Greenland. The deposit (Malmberg) contains an estimated 120 million tons of ore grading 0.25% molybdenite and another 100 million tons of ore grading 0.20% molybdenite.

Iran.—The Sar-Cheshmeh Copper Mining Co. continued development of a vast copper-molybdenum deposit near Kerman, south-central Iran. Ralph M. Parsons Co. was awarded a $400 million contract to provide project management, engineering design and related work, and construction and associated services for the mine site, crushing plant, concentrator, and smelter. The facility was expected to process approximately 42,000 tons of ore per day to produce 145,000 tons of blister copper annually and an undisclosed amount of molybdenum. Operations were scheduled to reach full production during 1977.

Mexico.—Asarco Mexicana S.A. and Cía. Mexicana de Cobre S.A. continued engineering studies in preparation for development of the La Caridad copper-molybdenum deposit in the Province of Sonora, Mexico. An open pit mine, mill, smelter, and refinery (costing $300 million) with a throughput of 250,000 tons of metal annually was contemplated. Some 40 million tons of overburden will be removed to reach the ore deposit. Ore reserves were estimated at 700 million tons having an average grade of 0.76% copper and 0.016% molybdenite. Parson-Jurden Corp., a Division of Ralph M. Parsons Co., was the contractor on the project. At yearend, company officials reported obtaining $150 million to initiate construction of the facility.

Tormex Mining Developers Inc. and Industrias Peñoles S.A. negotiated a conditional purchase contract for the Santo Tomás mineral property near Choix from a group of Mexican and American vendors. Santo Tomás consists of 23,000 acres of land and a porphyry copper deposit containing molybdenum and other minerals. The ore deposit, amendable to open pit mining, was discovered in 1970. Some 40 diamond drill holes were completed which outlined 200 million tons of ore averaging about 0.4% copper and an undisclosed amount of molybdenum, gold, and silver. The ore deposit is about 5,000 feet long and 1,000 feet wide. It is adjacent to the Reforma silver-lead-zinc mine which produces ore at a rate of 500 tons per day.

Mongolia.—Development was underway of the vast Erdentyin-Owo copper-molybdenum deposit located 150 miles northwest of Ulan Bator, Mongolia. To date, an electric powerline (connected to the Soviet grid system) and a 105 mile railroad to the Trans-Mongolian line were completed. An open pit mine, concentrator, and townsite were in various stages of construction. The project was receiving financial assistance from U.S.S.R. and the mine-mill facility was expected to provide copper and molybdenum concentrate for export markets.

Norway.—A/S Knaben Molybdaengruber suspended operations at the underground Knaben mine Kvinesdal, Norway, because of rising production costs, weakness in the demand for molybdenum and subsequent low prices, and increasing inventories. The Knaben mine, Europe's only molybdenum producer, has been in operation since 1885, except for the years 1919 and 1923, and a short period during World War II. Production was rather stable during recent years and for 1971 (latest figures available) amounted to 344,252 short tons of ore from which 646,270 pounds of molybdenum were recovered.

Panama.—Cobre Panama S.A., a subsidiary formed by a Japanese consortium composed of Mitsui Mining & Smelting Co. Ltd., Dowa Mining Co. Ltd., Mitsubishi Metal Corp., and Nittetsu Mining Co. Ltd., signed a 4-year exploration contract with the Government of Panama. The company will make a feasibility study and conduct exploration work for copper, molybdenum, tin, lead, and zinc over an area totaling nearly 100,000 acres near Petaquilla in the Donoso District of Colón. A vast copper-molybdenum deposit was discovered in the area by a United Nation's financed exploration project for underdeveloped countries in 1968. Some 5,000 feet of diamond drilling was completed during the initial study which outlined a mineralized belt containing an estimated 300 million tons of copper-molybdenum ore. Cobre Panama S.A. will spend about $1.5 million for additional diamond drilling over a period of 2 years. The company negotiated an option to develop the mineral deposit in the area at the conclusion of its investigation.

Peru.—Cía. Minera Cerros Negros, a subsidiary of Homestake Mining Co. (U.S.A.) and Mitsubishi Mining Co. Ltd. (Japan), agreed to conduct additional exploration work and make a feasibility study of the Pashpap copper-molybdenum deposit situated in the Province of Huaylas. Ore reserves were estimated at 53 million tons having an average grade of 0.86% copper and 0.03% molybdenite. Should the study conclude that the deposit is economically minable, the company would invest $22 million for development of a mine and concentrator having a capacity to process 6,000 tons of ore per day. Approximately 48,000 tons of copper concentrate and 1.7 million pounds of molybdenum would be produced annually.

A consortium which included Empresa Minera del Perú (Minero Perú) and five Japanese companies agreed to conduct a $2 million feasibility investigation of the Michiquillay copper-molybdenum deposit east of the city of Cajamarca, northern Peru. In recent years, Asarco spent several million dollars on diamond drilling of the deposit and on construction of access roads. A principal feature of the study will be to estimate construction and operating costs of slurry pipelining the concentrate from the mill to the coast, a distance of 184 miles. The ore reserves at Michiquillay were estimated at 628 million tons having an average grade of 0.72% copper and an undisclosed amount of molybdenum. It was reported that an estimated $457 million would be required to develop the deposit. Minero Perú engineers anticipate construction of a mine-mill facility with a capacity to process about 40,000 tons of ore per day.

Southern Peru Copper Corp. (SPCC) obtained financing of $200 million from a number of United States, Canadian, European, and Japanese banks to continue development of the Cuajone copper-molybdenum deposit located some 550 miles southeast of Lima. The property has been under development since 1969 when it was estimated that about $500 million would be required to complete the project. Work underway during 1973 included overburden stripping and construction of a railroad tunnel. Some 200 million tons of overburden must be removed to expose the ore body. To date, SPCC expenditures amounted to over $160 million and they expect to spend an additional $152.4 million of company funds to complete the project. Company officials were negotiating long-term sales contracts for the planned output of 180,000 tons of blister copper annually to assure completion of the project in 1976. Work projects scheduled for 1974 included construction of a concentrator, expansion of the Ilo smelter, and building new townsite and ancillary facilities.

Sweden.—Molyscand AB, a joint venture of Kema Nord AB, A. Johnson & Co. and Höganäs AB, conducted research and development on a process for the production of molybdic oxide by a chemical extraction method. The process would eliminate pollution problems associated with traditional methods of oxide production. A pilot plant was expected to commence operation early in 1974.

TECHNOLOGY

The effects of varying amounts of molybdenum, carbon, chromium, and cobalt on yield strength, toughness, and tempering behavior of martensitic steels were described.[4] Maximum toughness at a given yield strength was obtained when steel was tempered until the carbides were completely dissolved. Molybdenum was primarily responsible for secondary hardening. Dispersion of the carbides accounted for the excellent combination of strength and toughness exhibited by these steels.

Tensile strength tests were conducted on oxidized and unoxidized polycrystalline molybdenum specimens and results described.[5] A surface oxidation treatment by heating at 500° C resulted in producing a thin oxide film on the specimens. Tensile tests performed on both of these polycrystalline molybdenum specimens proved that the oxide film had no effect on the ductile-brittle transition temperature. Embrittlement by surface oxidation is characteristic of group V elements of the periodic table, but not of those in group VI in which oxygen is almost completely insoluble.

A process for extracting molybdenum metal from calcium molybdate by aluminothermic reduction was investigated.[6] Calcium molybdate was reduced with aluminum in a refractory-lined open-top vessel to produce aluminothermic molybdenum. The material was then processed by electron-beam melting and by molten salt electrorefining to remove the aluminum. The final molybdenum metal compared favorable with that produced by other processes.

Pitting, stress corrosion, and general corrosion in ferritic stainless steels and other alloys were investigated.[7] Defects in metals have been a continuing problem in many industrial and chemical plants, especially those utilizing a corrosive process. A new ferritic stainless steel was developed which overcomes the disadvantage of many austenitic and ferritic stainless steels. The material has the traditional immunity of ferritic stainless steel to stress-corrosion

resistance and fabricability. The latter physical property was obtained by the addition of chromium and molybdenum.

The production of molybdenum carbide by electrolysis of sodium molybdate was described.[8] Sodium molybdate was dissolved in a fused bath of sodium carbonate, sodium tetraborate, sodium fluoride, and potassium fluoride and the carbide produced by molten salt electrolysis. Under optimum conditions of bath composition, bath temperature, and cathode current density, a maximum electrodeposition rate of the carbide was obtained. The carbide was then admixed with a controlled amount of molybdenum dioxide for vacuum thermal sintering treatment to yield molybdenum metal of purity comparable to conventional extraction processes.

An inert gas fusion method to determine oxygen in molybdenum metal using a limited platinum bath was described.[9] In addition to its economical advantage, the method had higher sensitivity, and greater precision and accuracy. Since molybdenum often contains oxygen concentrations of only a few ppm, a high bath-to-metal ratio had an adverse influence on sensitivity and precision. The reduction in cost of the analysis was due to smaller amounts of the noble metal required for the method.

The sintering properties and chemical stability of molybdenum in the presence of an organic binder and a reducing atmosphere was investigated.[10] Molybdenum powders sintered under constant rates of heating resulted in an effective activation energy of 37 kilocalories per mole. A thermochemical diagram showed the carbonization or oxidation of molybdenum during the sintering process under various dew points. By proper control of the atmosphere and particle size, shrinkage limited to 20% was achieved in molybdenum powder sintered to 1,550° C. Nitridization did not occur in the forming gas atmosphere in the presence of carbon.

Elevated temperature strength of chromium-molybdenum steel with varying carbon contents was investigated because of its potential use in liquid-metal fast breeder reactors.[11] Reducing carbon content had little influence on elevated-temperature tensile strength of annealed steel. Creep-rupture strength of the annealed material decreased as the carbon content was lowered. The combined effects of carbide coarsening and decarburization during exposure of fine-grained commercial steel to liquid sodium caused substantial reductions in elevated temperature tensile strength and moderate reductions in rupture strength. Lubricating properties of solid lubricant was described.[12]

Molybdenum disulfide and graphite are the most commonly used lubricants. Their outstanding lubricating properties are obtained from the layered crystal structure of the minerals. In general, molybdenum lubricants have the advantage of good stability at high temperatures and in a chemically reactive environment. They also have design advantageous of lighter weight, improved dynamic and mechanical stability, and more simplified design than conventional oil and grease lubricants.

Gamma coarsening and elevated-temperature hardness was investigated as a function of molybdenum content, time, and temperature in superalloys and results published.[13] The alloys were selected from specimens containing 1, 3, 4½, and 6 weight-percent aluminum, 3½ weight-percent titanium, and 0, 2, 5, and 8 weight-percent molybdenum. The alloy specimens were solution-treated, thence aged to 112 hours at 1,700° F and to 1,000 hours at 1,400° F. Molybdenum retarded the coarsening of gamma on aging; this retarding effect was most pronounced in alloys containing 6 weight-percent aluminum. Hardness testing in a vacuum at temperatures to 1,750° F showed that molybdenum also

increased the elevated temperature hardness.

The effect of corrosion on iron-chromium alloys containing 2, 4, 6, and 8% molybdenum in a solution of sulfuric acid at a temperature of 77° F were described.[14] The effect of molybdenum on potential current density curves was determined potentiostatically. Increasing molybdenum content caused the critical current density to decrease and the open circuit potential to become increasingly noble. Alloys with 8% molybdenum did not show any anodic dissolution and passivated spontaneously. Some theoretical considerations of the passivation mechanism were discussed in connection with additional electrochemical measurements.

Natural Gas

By William B. Harper,[1] Robert J. Jaske,[2] and Leonard L. Fanelli [3]

Natural gas consumption of nearly 23 trillion cubic feet (Tcf) in 1973 was slightly below that of 1972. The largest decrease in consumption was a 373-billion-cubic-feet (Bcf) reduction by electric utility companies. This was due to curtailment of both interruptible and firm deliveries by pipeline companies. These curtailments were most significant during the summer months when peak power demand occurs. The next largest reduction was in residential usage amounting to 247 Bcf. This was attributed to warmer than normal weather during the 1973 heating season months. These decreases were almost offset by increased demand by industrial users whose consumption increased 7% or almost 0.6 Tcf. Marketed production totaled 22.65 Tcf in 1973, a volume nearly 0.116 Tcf, or 0.5% higher than that of 1972.

Approximately 29 Bcf of natural gas was exported by pipeline, of which 51.4% was moved to Canada. Mexico received the remaining 14 Bcf of natural gas exported by pipeline. In addition, 48.3 Bcf of LNG was exported to Japan from Alaska during 1973.

Net pipeline imports exceeded 1 Tcf in 1973 for the second consecutive year. Canada accounted for all but 0.1% of pipeline imports in 1973. Imports from Mexico dropped 80%, from 8.1 Bcf in 1972 to 1.6 Bcf in 1973. In addition, 1,167,000 barrels of liquefied natural gas (LNG), equivalent to just over 4 Bcf, were imported from Algeria and Canada.

Proved reserves of natural gas declined again as withdrawals (production) exceeded, by a wide margin, additions to reserves from new discoveries and extensions of known fields. Also, previous estimates of reserves were revised downward, particularly in Texas. The decrease for Texas was 4.7 Tcf in 1973 following a 1.5 Tcf decrease in 1972.

The average value of natural gas at the wellhead moved upward 3.0 cents from 18.6 cents to 21.6 cents per thousand cubic feet (Mcf).

r Revised.
[1] Marketed production of natural gas represents gross withdrawals less gas used for repressuring and quantities vented and flared.

Pipeline networks were expanded again in 1973. Specific figures on line additions are not available. Construction of new synthetic gas (SNG) plants using liquid hydrocarbons, such as naphtha and natural gas liquids, for feedstocks advanced in 1973. There were 3 SNG plants operating, 4 in the startup and testing stage, and 14 under construction.

Coal gasification received additional impetus as the result of an agreement between the U.S. Department of the Interior and the American Gas Association (AGA) to jointly finance a pilot plant program that will cost about $120 million over a 4-year period. This project is being funded through the Department of the Interior's Office of Coal Research. Pilot plants include the Institute of Gas Technology's HYGAS process at Chicago, Ill., and the Consolidation Coal Co.'s CO_2-Acceptor process at Rapid City, S. Dak. A third plant, Bituminous Coal Research's BI-GAS process, is being constructed at Homer City, Pa., and should be finished during 1974.

The Bureau of Mines is developing a synthane process with emphasis on producing more methane directly in the gasifier, thus reducing the load in the methanation step. A pilot plant at Bruceton, Pa., is scheduled to be completed in 1974.

Lack of additional gas supplies has created problems for both transmission companies and distributors. Firm volume curtailments for the period April 1973-March 1974, reported by 42 pipeline transmission companies, totaled 1.19 Tcf according to the Federal Power Commission.

Legislation and Government Programs.—Federal Power Commission (FPC) Area Rate Proceedings:

South Louisiana Area.—Subsequent to affirmation by the Fifth Circuit Court of FPC Opinion 598, the Supreme Court was petitioned by the New York Public Service Commission and others to review the Fifth Circuit Court's decision. By way of background, FPC Opinion 598 accepted the United Distribution Companies Settlement Proposal in the Area Rate Proceeding (AR 61-2 et al, AR 69-1). The Settlement Proposal provided for a new gas price of 26.0 cents per Mcf on contracts dated since October 1, 1968; flowing gas prices were 22.375 cents onshore and 21.375 cents offshore on contracts dated prior to October 1, 1968. Also in the proposal were provisions for contingent price escalations of 0.5 cents, 1.0 cents, and 1.5 cents per Mcf upon a total commitment of 7.5 Tcf, 11.25 Tcf, and 15.0 Tcf, respectively, of new gas reserves to interstate pipelines in South Louisiana prior to October 1, 1977. The Settlement Proposal included a moratorium on further rate increases until October 1, 1977 for new gas and until October 1, 1976 for flowing gas. Also involved were refunds of approximately $150 million, but with provision for work-off at a rate of 1 cent per Mcf upon commitment of new gas reserves to interstate pipelines in South Louisiana over a 5-year period.

Other Southwest Area.—FPC Opinion 607 determined rates in the area ranging from 19.4 cents to 20.6 cents per Mcf for gas produced under contracts dated before October 1, 1968. The area includes Mississippi, Arkansas, 4 counties in northwest Alabama, northern Louisiana, Texas Railroad Commission Districts 5, 6, and 9, and 56 counties in eastern and southeastern Oklahoma.

For production under contracts dated after October 1, 1968, rates ranged from 22.5 cents to 26.0 cents. In January 1972, the FPC issued an opinion on rehearing (No. 607-A) that included a proviso giving natural gas producers the option of meeting their refund responsibilities by the dedication of new reserves to interstate commerce. This opinion was sent on appeal to the U.S. Court of the Fifth Circuit, and the Court upheld the FPC decision in Opinion 607, establishing rates for pre-1961 contracts, 1961–68 contracts, and post-October 1, 1968, "new" gas contracts.

A petition was filed on September 6, 1973, by the Mobil Oil Corp. for a writ of certiorari to review the Fifth Circuit decision. Subsequently, the Supreme Court affirmed the Fifth Circuit decision upholding the FPC decision in Opinion 607.

Appalachian and Illinois Basin Areas.—Four natural gas companies filed a petition in January 1972, asking that ceiling rates for gas purchases from the Appalachian Basin be increased to at least 50 cents per Mcf. Because the four companies faced a severe shortage of natural gas, they requested the increase. The FPC, in Opinion 639, denied the request to increase the price of gas in the Appalachian Area to 50 cents for Mcf on contracts dated after February 1, 1972, in order to not perpetuate and extend the contract vintage system of producer pricing.

Pipeline Safety.—Based on failure reports from which table 2 was developed, the Office of Pipeline Safety (OPS) estimated that 67.4% of the gas distribution incidents and 57.7% of the transmission line failures during 1973 resulted from outside force damage. In 1973, an amendment to the Federal Gas Pipeline Safety Standards revised the term "service line" and resulted in the regulation of certain service lines in distribution systems not previously regulated by the U.S. Department of Transportation. Another amendment was the extension in 49 CFR Part 190 on odorization of gas. This allowed for time to complete a separate rule-making proceeding on transmission line odorizing, initiated by notice of proposed rule making on August 15, 1973. Another amendment in 1973 concerned flexibility in qualifying pipe for use in gas pipelines.

DOMESTIC PRODUCTION

Gross production of natural gas represents the total amount produced, including marketed production of gas, gas returned to the formation for pressure maintenance, and the gas vented or flared. In 1973, gross production aggregated nearly 24.1 Tcf, slightly above the 24.0 Tcf produced in 1972. However, marketed production increased 115.8 Bcf, or approximately 0.5%, during 1973 as the quantity of gas used for repressuring declined.

There was a 1.7% increase in the gross production from gas wells, from 19.04 Tcf in 1972 to 19.37 Tcf in 1973. This more than offset a reduction of 0.278 Tcf in gas produced from oil wells. Increased gross production occurred in Louisiana, New Mexico, Colorado, Michigan, Montana, Ohio, Utah, Pennsylvania, and Virginia. Significant gains also occurred in some of the smaller gas producing States which includes Alabama and Florida. Availability and the startup of new natural gas processing plants in Alabama and Florida in which sulfur recovery units are incorporated were the prime causes for these production increases. Much of the natural gas in this region has a high sulfur content. Higher prices for gas, however, provided an incentive to extract the sulfur so that the gas would be acceptable for pipeline transmission. The sulfur extracted from the gas is sold to fertilizer manufacturers.

On the negative side, there was a sizable reduction in gross withdrawals of gas in Texas. However, this was more than offset by the gain in gross withdrawals in Louisiana. A decrease in withdrawals from both gas wells and oil wells resulted in a drop in Texas gas production of 0.26 Tcf in 1973. There was, however, a reduction in gas used for repressuring and gas vented and flared so that the drop in marketed production was narrowed to 0.144 Tcf or a 1.6% net decrease. Marketed production in Louisiana was 3.4% higher in 1973 largely because of a 6% increase in withdrawals from gas wells.

In California, marketed production of gas declined 7.8% in 1973 following a 20.5% drop that occurred in 1972. In the last 2 years the total drop in marketed California production amounts to 163.3 Bcf. Similar to that in 1972, the decrease during 1973 was primarily in gas withdrawals from oil wells. This was coupled with some decrease in withdrawals from gas wells. The 1973 volume changes from 1972 were a decrease of 12.1 Bcf for gas wells and a decrease of 29.7 Bcf for oil wells. The latter shows a leveling off from the 134.6 Bcf drop in gas withdrawals from oil wells experienced in 1972. However, the decreased withdrawals from gas wells reversed a 1972 gain of 10.8 Bcf. The established trend over the last 6 years has been a steady drop in gross withdrawals from both oil and gas wells. The average decrease was 58 Bcf per year for the last 6 years. An unusually large drop of 123.8 Bcf was reported in 1972 and is included in the 6-year average. There are no indications of a reversal of the declining trend. Some lessening in the drop in California could come about if the Kettleman Hills field were utilized to a greater degree. Kettleman now is basically a gasfield with relatively high reservoir pressures and only minimal oil production.

Rising prices for natural gas and the endorsement by the Courts, of FPC Area Rate Proceedings Opinions, encouraged gas exploration and production. During 1973, there were 7,169 gas wells drilled and completed compared with 4,928 gas wells in 1972 or a gain of 45.4% as shown in table

4. There were 900 exploratory gas well completions in 1973 as compared with 601 similar wells in 1972, a gain of 49.8%.

Likewise, higher prices for natural gas have made it economical to build natural gas processing plants with sulfur recovery units. As a result, efforts are being made to drill and explore for gas whether it be sweet or sour. This effort was noticeable in States where production has been small, such as in Alabama. Production in that State in 1973 approximately tripled; proved reserves increased from 245.7 Bcf as of December 31, 1972, to 327.4 Bcf as of December 31, 1973, an increase of 33.2%.

Gas wells also include condensate wells producing from high-pressure natural gas reservoirs. Some of these reservoirs produce considerable quantities of liquid hydrocarbons such as pentanes and heavier, described generically as "condensate."

Significant increases in gas well completions in 1973 were widespread. Reduced activity occurred in only six States: Illinois, Kentucky, Louisiana, Montana, Nebraska, and Virginia.

It is interesting to note, however, that the accelerated pace of gas well drilling activity is taking place primarily onshore. Offshore gas well exploratory drilling in 1973 was far below that of 1972. However, offshore development well drilling increased sharply in Louisiana in 1973.

There has been a steady increase in the number of gas and condensate wells producing. In 1968, for example, there were 114,391 producing wells, and by the end of 1973, there were 124,168 wells producing. Most of this increase has occurred after 1970.

CONSUMPTION AND USES

Consumption of natural gas in 1973 totaled 22.966 Tcf a slight decrease from 1972. Gas delivered to consumers aggregated 19.825 Tcf, a small decline from the comparable total of 19.880 Tcf in 1972.

Residential use in 1973 decreased by 4.8% to 4.879 Tcf. The decrease was due to warmer than normal temperatures in the heating season months. The decrease in use was accompanied by a 1.9% increase in number of residential users.

Over the decade 1963–73, the number of househeating customers grew from 33.45 million to 40.65 million or at an annual growth rate of 2.15%. Between 1972 and 1973 growth contracted to 1.9%. Trends in the number of househeating accounts by Census Regions for the years 1963, 1972, and 1973 are shown in the following tabulation:

Census regions	Gas househeating customers (thousands)		
	1963	1972 r	1973
New England	1,476	1,616	1,603
Middle Atlantic	7,272	7,699	7,713
East North Central	7,487	9,152	9,386
West North Central	2,692	3,309	3,399
South Atlantic	2,723	3,387	3,513
East South Central	1,628	1,848	1,959
West South Central	3,877	4,599	4,575
Mountain	1,357	1,939	2,021
Pacific	4,939	6,322	6,476
Total	33,451	39,871	40,645

r Revised.

By far the largest segment in the consumer-use category is the industrial group. About 44.1% of the gas delivered to consumers is used by industry. Industrial uses in 1973 accounted for 8.74 Tcf, a 7% increase over that of 1972. Most of the gas used by industry is consumed as fuel, and more than 1.07 Tcf was used as refinery fuel as indicated in the footnote in table 8. Natural gas is also an important petrochemical feedstock. Most of the ammonia produced in the United States is obtained by reforming natural gas to produce the hydrogen-nitrogen mix required for ammonia synthesis. It is calculated that, on the average, natural gas consumed per ton of ammonia amounts to about 37 Mcf. This would mean that more than 0.57 Tcf of natural gas was used to produce the 15.4 million tons of synthetic ammonia made in 1973. Methanol production is another important petrochemical industry consumer of natural gas. There were nearly 7.2 million short tons of methanol produced in 1973. Using 36 Mcf per short ton as a yardstick, it is calculated that 0.26 Tcf of natural gas was consumed in methanol production. Data necessary for the calculation of other petrochemical feedstock consumption are not available.

The downtrend in natural gas consumption by electric utilities that started in 1972 continued in 1973 when use de-

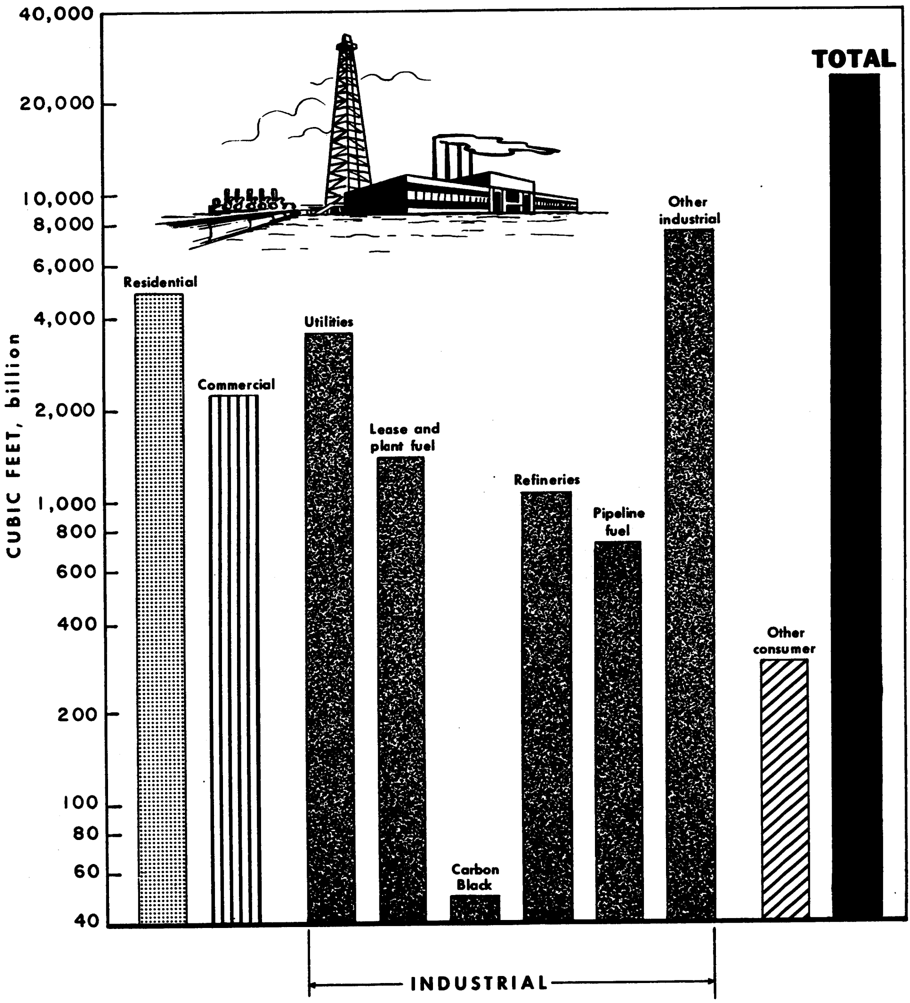

Figure 1.—Disposition of natural gas consumed in the United States by principal use.

clined slightly, to 3.60 Tcf from 3.98 Tcf. All areas showed a decrease except West North Central, which increased consumption slightly.

There was a slight decrease in the number of commercial consumers in 1973 from 3,357,000 to 3,335,000. Use of gas in this category, however, increased very slightly to 2.288 Tcf from 2.286 Tcf.

In addition to gas delivered to consumers, there are three categories of gas-use separately classified; namely, lease and plant fuel, pipeline fuel, and extraction losses. The loss in gas processing plants (shrinkage) increased 0.9% in 1973. In 1973, these plants processed 19.68 Tcf of natural gas (86.9% of marketed production), a decrease of 1.1% from the 19.91 Tcf processed in 1972.

Although there has been a marked growth in natural gas use ever since long-distance natural gas transmission lines became a reality, the tight supply situation is becoming more and more critical for pipeline transmission companies. In fact, the shortage of gas forced major interstate gas pipeline companies to curtail service. During the April 1973-March 1974 season, 17 of the 42 major pipelines listed in table 10, reported firm total volume curtailments aggregating almost 1.57 Tcf or 8.3% of their firm requirements of nearly 18.8 Tcf of natural gas. Table 10 is based on data submitted to the FPC. A breakdown of actual interruptible sales and curtailments for the period April 1973 through March 1974 is shown in table 11.

The uncertainties as to the availability of new gas supplies is also having an impact on expansion of pipeline networks. Data showing the growth of the pipeline networks is shown in the following tabulation:

Mileage, natural gas pipelines

	1961	1971	1972	1973
Field and gathering	56.7	66.5	67.1	NA
Transmission	191.9	256.9	260.2	NA
Distribution	410.4	611.3	623.9	NA
Total	659.0	934.7	951.2	NA

RESERVES

Production of natural gas has exceeded discoveries of new gas during 5 of the last 6 years, and 1973 proved to be no exception. During 1973, production exceeded discoveries by a wide margin, and proved reserves of natural gas dropped from 266.1 Tcf at yearend 1972 to 250.0 Tcf at yearend 1973, or a decline of 6.1%, according to the Natural Gas Reserves Committee of AGA.

Net additions to reserves reported for the United States in 1973 aggregated nearly 6.5 Tcf. The largest segment, some 6.2 Tcf, was derived from extensions to known fields. More than one-half of the 2.0 Tcf total for new reservoir discoveries in oilfields came from Louisiana. In addition, discoveries of new fields totaled almost 2.15 Tcf of reserves. On the negative side, however, previous estimates or reserves in some States were revised. On balance, there was a revision reduction for the United States, as a whole, of nearly 3.5 Tcf.

There were some increases in the reserves of natural gas in 13 States. However, significant increases occurred in only seven States. Michigan had the largest increase, 0.25 Tcf. Next in order were Colorado, Alaska, New Mexico, Pennsylvania, Alabama, and Mississippi. These increases aggregated about 1 Tcf. On the negative side, reserves in major gas-producing States declined sharply. Texas gas reserves dropped from 95.0 Tcf to 84.9 Tcf, a decline of more than 10 Tcf. Likewise, in Louisiana, proved reserves decreased 5.8 Tcf or 7.8% to 69.15 Tcf.

Natural gas reserves committed to interstate pipelines declined in 1973 for the sixth consecutive year. Committed dedicated domestic reserves fell by 12.4 Tcf in 1973, declining from 146.9 Tcf to 134.4 Tcf. Gas produced and purchased by pipelines amounted to 13.7 Tcf, which is 3.6% down from the 14.2 Tcf reported in both 1971 and 1972. The reserve-production ratio for interstate reserves dropped from 10.3 at the end of 1972 to 9.8 by the yearend 1973. These data are shown in the following tabulations:

1973 Yearend domestic reserves, production, and purchases of interstate natural gas pipeline companies

(Billion cubic feet at 14.73 psia at 60° F)

	Major supply companies	Minor supply companies	Total
Number of companies	25	38	63
Gas reserves at yearend:			
Company owned	12,453	721	13,174
Independent producer contracts	119,568	1,704	121,272
Total	132,021	2,425	134,446
Percent of total	98.2	1.8	100.0
Annual production and purchases:			
Company owned	766	64	830

Total	13,418	277	13,695
Percent of total	98.0	2.0	100.0

Preliminary summary of domestic natural gas reserves of interstate natural gas pipeline companies

(Billion cubic feet at 14.73 psia at 60° F)

1. Total dedicated gas reserves as of Dec. 31, 1972	146,894
2. Revisions and additions during 1973 (item 1 minus item 3)	1,247
3. Gas reserves as of Dec. 31, 1972 and changes during 1973 (item 4 plus item 5)	148,141
4. Gas produced during 1972	13,695
5. Total dedicated gas reserves as of Dec. 31, 1973	134,446

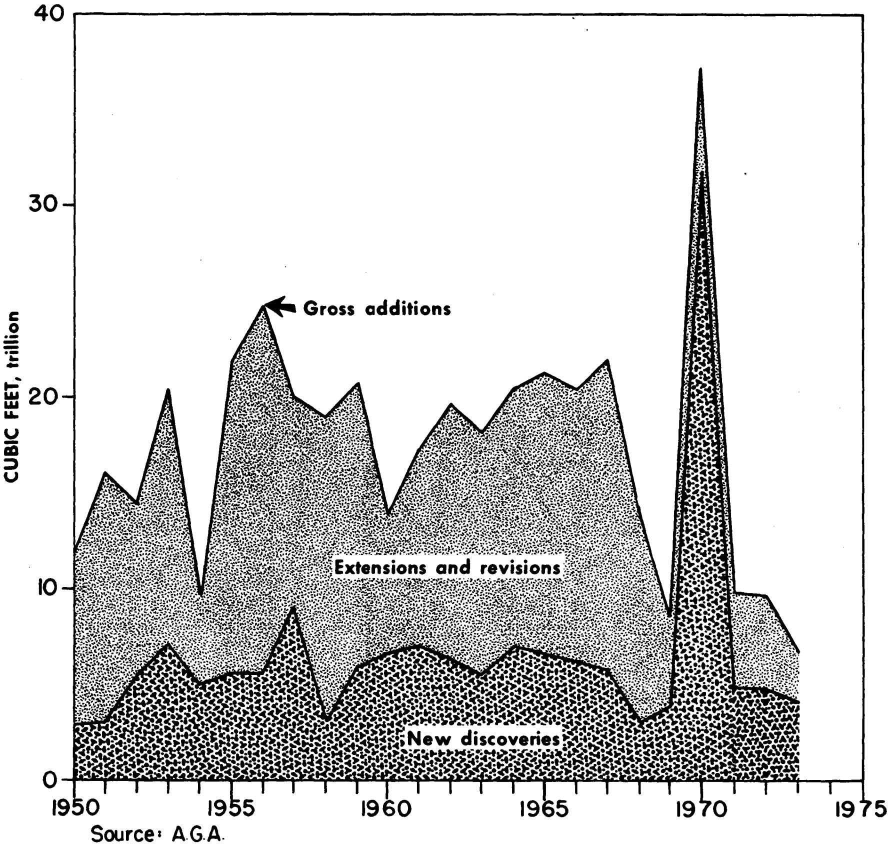

Figure 2.—Trends in annual gross additions to natural gas reserves.

In addition to exploration for new resources in the United States, American companies are involved, either independently or with Canadian companies, in exploring and drilling for oil and gas in Canada's Arctic Islands, the Maritime Provinces, and in the Mackenzie Delta. By the end of 1973, Canada's gas reserves had increased by 2.5 Tcf, which is approximately equal to current production rates. Gas reserves by the end of 1973 were calculated to be adequate for a 23-year supply. Alberta continued to be the primary supplier of oil and gas. The contribution by other areas such as the Mackenzie Delta and the Arctic Islands is anticipated to be significant by the end of the decade; by then Alberta's resources will have reached peak development.

PRODUCTIVE CAPACITY

The daily productive capacity for natural gas at the end of 1973 was estimated to be 78,231 MMcf, according to the AGA, compared with 85,998 MMcf per day as of December 31, 1972, a decline of 7,767 MMcf per day or almost 9%. Productive capacity in nonassociated gas fell to 64,160 MMcf from 69,144 MMcf. Likewise, capacity in associated-dissolved gas was reduced to 14,071 MMcf from 16,854 MMcf per day as of December 31, 1972.[4]

STORAGE

The development of additional underground storage capacity for natural gas, after slackening in 1970, moved at a faster pace in subsequent years. Total reservoir capacity increased 239 Bcf, or 4.0%, from 6.040 Tcf in 1972 to 6.279 Tcf by yearend 1973. The number of underground storage facilities expanded from 348 in 1972 to 360 in 1973. These storage facilities are located in 26 States.

Most storage reservoirs are depleted fields that originally contained dry gas. Of the 360 reservoirs, for example, 284 or nearly 79% were the dry-gas type. Most of these dry-gas reservoirs are located in the northeastern United States, primarily in the oldest petroleum provinces. The second largest concentration is found in the Midwest, in Michigan, where there are 32 such reservoirs. In Pennsylvania, where oil production dates back to 1859, some 68 dry-gas fields have been converted to storage facilities. West Virginia has 34 dry-gas reservoirs.

---

[4] The productive capacity of natural gas from nonassociated reservoirs is defined as the maximum daily rate at which such gas can be produced from natural reservoirs under specified conditions on March 31 of any given year. The determination of productive capacity on March 31 of any given year is based on proved reserves of nonassociated gas reservoirs as of the preceding December 31. The productive capacity of associated-dissolved gas is based on the productive capacity of crude oil and the estimated producing gas-oil ratios that would result from such capacity operation during the first 90 days of a given year. The productive capacity of associated gas from gas wells is usually based on the volumetric withdrawal of crude oil from related oil wells at capacity rates during the first 90 days of a given year as determined by the American Petroleum Institute (API) Committee on Reserves and Productive Capacity.

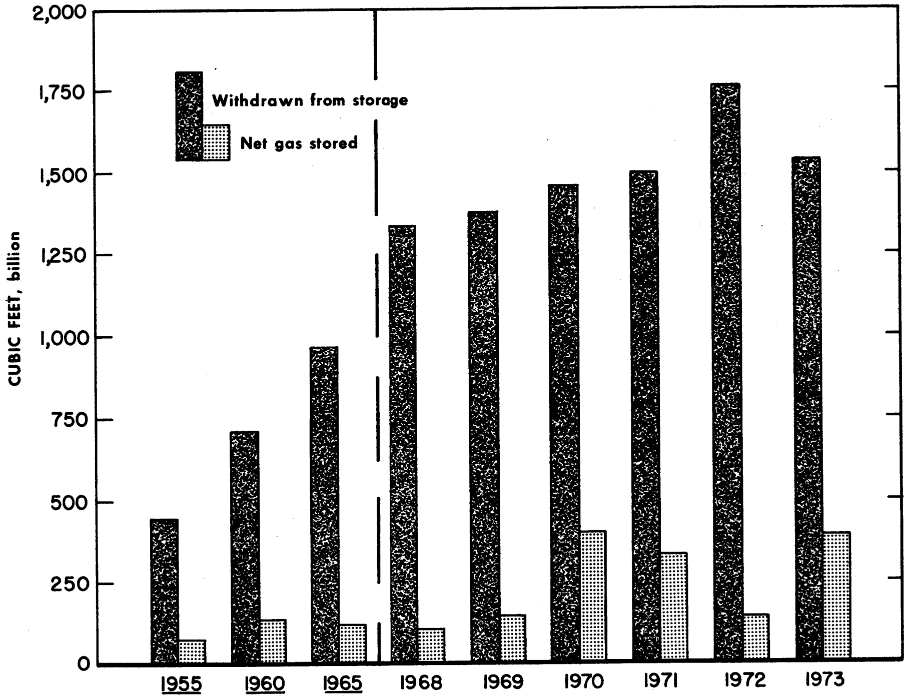

Figure 3.—Trends in net gas stored underground in U.S. storage fields.

Where depleted fields, whether oil or gas, are not available, other types of underground storage come into use. For example, there are 49 acquifers in 9 States in which natural gas is stored. Illinois is the leader with 20 acquifers. Indiana ranks second with 11. Acquifer storage accounts for 29.4% of the total storage capacity.

In addition to storage underground, there is a marked growth in the storage aboveground of natural gas liquefied by lowering temperatures. When natural gas is converted to a liquid by reducing its temperature to —258° F (—161° C) it occupies only 1/620th the space necessary for conventional vapor storage. Liquefied natural gas (LNG) storage is used for peak shaving purposes during the high-consumption, winter months.

During 1973, the total amount of gas moved into storage aggregated 1.974 Tcf as shown in table 17. Over the same period, 1.533 Tcf was drawn down, leaving a net stored of 442 Bcf for 1973.

The following table summarizes LNG facility type and storage capacity:

Facility	Status	Capacity (Bcf)	Number of plants
Peak shaving	Operational	35.571	38
Do	Under construction	13.615	12
Large satellite	Operational	5.757	18
Do	Under construction	6.400	2
Small satellite	Operational	.139	26

The development of storage reservoirs has been an important factor in meeting peak natural gas demand, particularly in the residential househeating market in which there is a high degree of seasonal variation. There is a concentration of underground storage facilities relatively close to the largest markets for residential heating. Illinois, for example, had 571 Bcf of natural gas stored in 29 reservoirs at the end of 1973. In Pennsylvania, there were 614 Bcf stored in 68 dry-gas reservoirs. These two States accounted for 1.185 Tcf or 30.3% of the total stored gas in underground reservoirs.

VALUE AND PRICE

Marketed production of natural gas again increased in value during 1973. Values totaled $4,894,072,000 as compared with a revised figure of $4,180,462,000 in 1972, or an increase of 17%. These values are based on marketed production of 22.648 Tcf in 1973 with an average value of 21.6 cents per Mcf. In 1972, marketed production totaled 22.532 Tcf with an average value of 18.6 cents per Mcf. Two States, Texas and Louisiana, accounted for 74.0% of the total marketed production. These two States plus Oklahoma and New Mexico accounted for 87% of production and 85.9% of total value.

Average values increased in those States close to markets or doing a sizable intrastate volume relative to total marketed production. In the intrastate category is Alabama where average value of gas at the wellhead advanced from 35.2 cents per Mcf to 38.2 or an increase of 8.5%. In Pennsylvania, value climbed from 30.3 cents per Mcf in 1972 to 42.0 cents in 1973 for a rise of 11.7 cents or 38.6%. In several other States relatively close to large markets, such as New York, Pennsylvania, and West Virginia, unit values also increased.

Wholesale Prices.—Increases in wholesale prices for gas also have been significant, particularly in those markets that have substantial use of gas for residential heating. The FPC collects data on the average wholesale prices in large metropolitan areas. In 12 of the 14 areas surveyed by the FPC, residential heating provides a significant market for natural gas. A 7-year historical series of average wholesale natural gas prices in the 14 large metropolitan areas, in cents per Mcf, is shown in table 19.

Comparing July 1, 1973 prices with those prevailing on July 1, 1972, wholesale rates in 11 of the 14 cities increased by 1 cent to 8 cents or more per Mcf. At the same time there were decreases in the wholesale prices for gas in Cleveland, Ohio, Pittsburgh, Pa., and Washington, D.C.

The wholesale prices for gas for those

cities cited are based on the effective FPC gas tariffs. In cities served by more than one pipeline, prices are based on weighted average charges. Prices reflect deliveries at the city gate except for Los Angeles and San Francisco, where distributors purchase gas at the California-Oregon and California-Arizona State lines.

Retail Prices.—At the retail level, the Bureau of Labor Statistics (BLS) compiles price information for fuels and energy, relative to development of the BLS Consumer Price Index. Average prices for fuels and energy are published monthly for the 20 Standard Metropolitan Statistical Areas.

At retail, gas is sold by gas utilities either in therms or in Mcf units. A therm contains 100,000 Btu. For illustrative purposes, if 1 cubic foot of natural gas contains about 1,000 Btu, 1 therm would be equivalent to about 100 cubic feet of natural gas. Since both the average wellhead value and the FPC wholesale price series are on million-cubic-foot basis, the BLS retail price series shown in table 20 has been converted from 100 therms to 10 therms so that the retail price approximates the cost of 1 Mcf.

Although retail prices of natural gas have been moving upward for some time now, significant increases are a recent development. For example, the price of gas at retail was $1.447 for 10 therms in Boston in 1965. By the end of 1970 that price was $1.568 or 8.4% higher than in 1965. Between the end of 1970 and the end of 1973, however, the retail price of gas in Boston jumped from $1.568 to $2.103, a 34.1% increase. New York prices increased from $1.363 to $1.887 or 38.4% from the end of 1970 to the end of 1973. Further increases are a foregone conclusion in light of actions taken by the FPC in Opinions and Orders related to pricing.

On June 21, 1974 the Federal Power Commission issued opinion No. 699 (R-389B) establishing a single uniform national base rate of 42¢/Mcf at standard conditions of pressure and temperature. Effective date was January 1, 1973 for new gas and new/renewed contracts on old gas.

FOREIGN TRADE

Exports of natural gas totaled 77 Bcf in 1973, and 62.6% of the total volume was shipped in liquid form from Port Nikiski, Alaska.

The LNG exports were to Japan and totaled 48.35 Bcf valued at $27,969,903, as compared with 47.88 Bcf valued at $26,694,585 in 1972.

Exports via pipeline in 1973 were almost equally divided between Canada and Mexico. Pipeline exports to Canada, nearly all of which exited at Detroit, declined 4.7% to 14.8 Bcf in 1973.

Exports of natural gas via pipelines to Mexico had been trending upward from 9.5 Bcf in 1965 to nearly 15.8 Bcf in 1971 but dropped to 14.0 Bcf in 1973.

Imports of natural gas from Canada exceeded the 1 Tcf mark for the second consecutive year in 1973. Imports from Canada by means of pipelines were 1.03 Tcf, a modest increase of 1.9%. Canadian gas imports by pipelines averaged nearly 2,814,000 Mcf per day as compared with almost 2,757,000 Mcf per day in 1972.

The value of natural gas imported from Canada increased 15.2% to $357,750,000 in 1973 from $310,521,000 in 1972, or a rise of 15.2%. This jump in value reflected the overall increase in the price of gas to 34.83 cents per Mcf in 1973 from 30.77 in 1972. Most of these price increases were on gas entering the States of Washington, Idaho, and Montana. There were nine companies importing Canadian gas in 1973.

Although imports from Canada have been growing, imports from Mexico have been decreasing drastically. Imports from Mexico entering the United States at McAllen, Tex., were 79.9% lower in 1973, primarily because supplies available for export to the United States are diminishing rapidly. From 50.97 Bcf in 1967, imports from Mexico had decreased to 1.63 Bcf by the end of 1973.

In addition to pipeline imports, 1,167,387 barrels of LNG were imported. At 14.73 psia, this volume is equivalent to 4.055 Bcf of natural gas. Algeria was the source of 83.5% of the LNG imports. The remainder originated in Canada.

The inability to obtain FPC approvals within a prescribed time resulted in cancellations of contracts for additional supplies of LNG from Algeria. Some of these contracts, however, are being renegotiated, particularly where negotiations are related to provisions on prices.

WORLD REVIEW

Marketed production of natural gas, worldwide, climbed to a record high in 1973. World production totaled 44.917 Tcf according to estimates, and of this figure, the United States accounted for 22.648 Tcf or 50.4%. In 1968, for sample comparison, the United States accounted for 61.5% of the world total marketed production.

The U.S.S.R. was second to the United States, accounting for 18.3% of world production. During 1973, marketed production in the U.S.S.R. was estimated to have been 8.33 Tcf, an increase of 516 Bcf over that of 1972. The completion of a natural gas pipeline across Czechoslovakia paved the way to move Soviet natural gas to Italy and West Germany. The new line connects the U.S.S.R. and Austria and has a flow-through capacity of 990 Bcf. Czechoslovakia will take 13%, or 129 Bcf.

Soviet natural gas began flowing to West Germany in 1973. A proposed 3,000-mile pipeline from the Tyumen gas deposits in western Siberia would carry up to 247 Bcf of gas annually to Germany and Austria by 1980.

Negotiations are under way between some U.S. companies and the U.S.S.R. wherein 2 Bcf of Siberian gas would be delivered to the east coast of the United States. This would be in exchange for financial assistance in connecting the gas reserves with seaports, a distance of about 1,800 miles, where it would be liquefied and transported by a fleet of 20 tankers. Another 2 Bcf of gas would come to the west coast of the United States from Siberian fields situated some 2,000 miles from the eastern Siberian coast. Japan is an interested party in the latter venture and could be a financial contributor and receive some of the gas. Reportedly, 10 tankers would be involved in this operation. Both of the aforementioned projects are 6 or more years distant.

The cooperation of American oil, gas, and engineering companies in assisting in the development of Soviet resources has received impetus from the discussions between the United States and the U.S.S.R. in May 1972.

In July 1972, the Occidental Petroleum Corp. signed a 5-year scientific and technical agreement covering (1) exploration, production, and usage of oil and gas, (2) agricultural fertilizers and chemicals, (3) metal treating and metal plating, and (4) the utilization of solid wastes.

Other American companies, such as El Paso Natural Gas Co., Bechtel Corporation, Texas Eastern Transmission Corp., Tenneco Corp., and Brown & Root, Inc., have been negotiating with the U.S.S.R. relative to development of its oil and gas potential.

Canadian production of natural gas, and natural gas liquids, continued at record-breaking levels through 1973. This reflects in part the sharp increase in prices for petroleum products, including natural gas liquids and synthetic products. Marketed production of natural gas rose about 8.2% during 1973 to just under 8,700 Mcf per day. This is a reduction in the growth rate, compared with that of previous years, and is due to a combination of Provincial royalty increases and Federal export control. As in past years, the bulk of production came from the Provinces of Alberta, Saskatchewan, and British Columbia, which accounted for in excess of 98% of the total production. Small quantities were also produced in Manitoba, Ontario and the Northwest Territories as well as New Brunswick. Developments throughout the world, which led to rising prices and supply shortages, had a direct bearing on the increased demand for Canadian gas by the United States. This in turn contributed to the imposition of export and price controls by the Canadian Government in a conservative move to avert anticipated shortfalls they feel could occur in supply to Canadian consumers. By yearend, a system of absolute quotas had been established, and the Government had levied export taxes which they appear to believe will bring Canadian prices more in line with world prices.

The search for gas in shallow formations continued as a priority exploration target in southern Alberta. A large amount of this activity was centered in an area called the British Block, which was formerly reserved for military testing. Approximately 8,000 square miles were made available for exploration, and considerable drilling was initiated. The area is estimated to contain upwards of 4 Tcf of gas. The first 27 tests of the scheduled 50-well drilling program have been drilled, and all were reported successful. Offshore drilling continued near Sable Island, 175 miles east of Halifax, Nova Scotia. An announcement of a new significant oil discovery was made in mid-1973 by the team of Mobil Oil Canada, and Texas Eastern Transmission Corp. This makes a total of four significant discoveries since 1966 when drilling began in this area. In the MacKenzie Delta, moderate exploration continued through 1973, with announcements of several new oil and gas finds. Very little information has been made available; however, it is felt that this area probably contains a number of major fields.

In the Arctic Islands, exploration also continued at a moderate pace; several new gas finds were made during 1973. However, there are still not enough proven reserves to warrant the building of a pipeline to transport the gas to market areas. It is hoped that continued drilling through 1974 will produce additional reserves.

Canadian Arctic Gas Study Limited (CAGSL) has not yet made any presentation before the National Energy Board (NEB) or the Federal Power Commission (FPC) for its project to move Alaska North Slope and Canadian Arctic gas to the United States and eastern Canadian markets. Resistance by the NEB to further gas-export applications is likely pending a review of gas reserves in Canada.

A major achievement in 1973 was the world's first drilling of an offshore well from a floating ice platform 8 miles off Melville Island.

In the Netherlands, marketed production in 1973 totaled 2.49 Tcf. This is 21.5% greater than that in 1972.

The Netherlands reserves of natural gas were estimated at 84.8 trillion cubic feet as of December 31, 1973. The prior estimate was 70.6 trillion cubic feet. By 1975, production is expected to plateau at from 3.0 to 3.2 Tcf per year. It is expected that about half of the gas will be exported to West Germany, France, and Belgium-Luxembourg. Some gas will go to Italy and Switzerland through a pipeline expected to be completed in 1974. The line will be 34 inches in diameter and just over 500 miles long. It will handle 211.9 billion cubic feet of gas per year.

Romania's 1973 natural gas production is estimated at about 1.03 Tcf or about 8.2% higher than the 0.95 Tcf produced in 1972. Most of the gas produced is used domestically. Industry use, for fuel and petrochemical feedstocks, is an important consumer in Romania.

The North Sea remains one of the most promising natural gas areas of the world outside the U.S.S.R. and the Middle East, and is one of the fastest developing natural gas areas in the world. Estimates of North Sea area reserves, range widely from 70 to 200 Tcf. Production from the United Kingdom gasfields in the southern North Sea have increased one-third from 2,426,000 Mcf per day in 1972 to 3,250,000 Mcf per day in 1973. Exploratory drilling and geological surveys continued in the North Sea waters of Norway, Denmark, West Germany, the Netherlands, and the United Kingdom. The area of interest has expanded to include the Celtic Sea south of Ireland. the Atlantic Ocean north of Scotland, and the Baltic Sea south of Sweden. A newly developed gasfield south of Cork, Ireland, is believed to contain 1 Tcf of natural gas.

Of the 576 wells completed in the North Sea by the end of 1973, 135 were drilled in the last year. The majority of these, 473, are exploratory. By the winter of 1973–74, 38 or more jackup and semisubmersible drilling rigs were operating in the North Sea and adjacent waters. Future drilling should quicken since 50 of the 90 drilling rigs now under construction are slated for North Sea use.

Algeria's marketed production is becoming a progressively more important factor to the United States in view of long-range plans to import natural gas as LNG. El Paso Natural Gas Co.'s plans to import 1 Bcf per day of gas are proceeding, and deliveries are scheduled to start in April 1976. Negotiations on a second agreement were in progress at yearend 1973. A contract already in effect involves imports of 42 MMcf per day by Distrigas of Boston. A third company, Eascogas LNG, Inc., has been granted conditional approval by the FPC to import up to 0.652 Bcf per day.

Algerian sources estimate that nation's gas reserves at 150 Tcf. Further, by 1976 they believe natural gas will be one of Algeria's most important sources of foreign income. U.S. imports of Algerian LNG increased by 66.8%, from 2.032 Bcf in 1972 to 3.388 Bcf in 1973. In addition, Algeria's state-owned company Société Nationale pour las Recherche la Production, le Transport, la Transformation et la Commercialisation des Hydrocarbures (Sonatrach) has been negotiating with companies from West Germany, Belgium, France, Spain, and Britain to provide Europe with long-term supplies of LNG. West Germany is showing interest in financing port facilities to enhance their receiving Algerian LNG.

TECHNOLOGY

The expected long-term scarcity of natural gas has stimulated action on the part of industry and Government to spearhead research in the development of gasification of coal to obtain a high-Btu gas that is virtually the same in characteristics as pipeline-quality natural gas.

Construction of a $12 million Synthane process facility at Bruceton, Pa., to develop the Bureau of Mines coal gasification process is expected to be completed in August 1974. This pilot plant will be the fourth in a series to evaluate coal gasification for high-Btu gas. Currently, plants consist of the Institute of Gas Technology's HYGAS process at Chicago, Ill., and Consolidation Coal Co.'s CO_2-Acceptor process at Rapid City, S. Dak. The third pilot coal gasification plant is being built under a 1971 agreement between the Office of Coal Research and the AGA at Homer City, Pa., and is scheduled for completion in 1974. It will incorporate Bituminous Coal Research's BI-GAS process. A high-Btu gas is to be the end product, although the plant will have built-in design capability to produce low-Btu gas. The Synthane gasifier is designed to operate at 1,000 pounds per square inch and 1,800° F, and to produce 100,000 standard cubic feet per hour (scfh) of coal gas. One-fourth of the raw gas will be further processed to produce 13,000 scfh of pipeline-quality gas. A commercial plant would have a capacity of 250,000 Mcf of pipeline-quality gas per day.

In the low-Btu gas category, a Westinghouse-led team is working to develop the process. A pilot plant is scheduled to be built to handle 15 tons of coal per day and should be completed in 1974.

There are 47 SNG plants in various stages ranging from operational to those projects which have been cancelled. Three plants are operational with work in progress on 19, planning underway on 4, and 21 either suspended or cancelled. The three operational plants have a capacity of 340,000 Mcf per day. Plants now nearing completion and in startup will add another 896,000 Mcf per day.

Subsurface nuclear detonation is another method for augmenting the supply of natural gas. The Atomic Energy Commission has conducted three experiments to determine the feasibility of using nuclear stimulation in the recovery of natural gas in tight formations. The first, the 1967 Gas Buggy experiment in New Mexico, was a 29-kiloton shot. The second, a 43-kiloton shot, was at Rulison, Colo. in 1969. Both proved that the flow of gas could be stimulated, but there was some tritium contamination.

The third experiment, also in Colorado, was the Project Rio Blanco Phase I. This was the near simultaneous detonation of three 30-kiloton nuclear explosives spaced one above the other more than 1 mile underground. The detonation took place on May 17, 1973. Production testing by flaring gas started on November 14, 1973. Results indicated only the top cavity was open to the production well which was drilled to evaluate the results of the stimulation. Production was disappointing with a rapid pressure drop occurring within a very short period of gas flaring. A directed hole is being drilled with the middle cavity as the objective. Status of the lowermost cavity is completely unknown.

Table 2.—Gas pipeline failures reported during 1972–73 [1]

	Total number of failures		Fatalities: Employees		Fatalities: Non-employees		Injuries: Employees		Injuries: Non-employees		Estimated property damage (value)	
	1972	1973	1972	1973	1972	1973	1972	1973	1972	1973	1972	1973
Distribution system:

[1] In addition to this table compiled from written gas pipeline failure reports received by the Office of Pipeline Safety during 1973, there were 7 fatalities and 25 injuries resulting from gas distribution incidents that occurred in 1973 but were not reported until after December 31. Also, additional incidents reported to OPS by telephonic notice during 1973, but which did not require followup written reports, indicated that there were 17 fatalities and 47 injuries from distribution system failures.

[1] Columbia Gas Transmission Corp. states that during the period November 1973 through March 1974 a 2% curtailment was imposed on all CD, WS and G customers; however, due to warmer than normal weather, energy conservation, etc., actual curtailment cannot be ascertained.

[2] Consolidated Gas Supply Corp. data is on an "as measured" basis.

[3] On Jan. 31, 1974, El Paso divested its Northwest Division System properties to Northwest Pipeline Corp. Northwest has filed actual data for February and March 1974, as well as projected data for the period Apr. 1, 1974, through Mar. 31, 1975.

[1] The net difference between gas stored in and gas withdrawn from underground storage reservoirs inclusive of adjustments and native gas transferred from other reserve categories. (Adjustments include change of reporting basis to report only gas reserves considered recoverable with a net result of a 781,819 MMcf reduction.)

[2] Preliminary net production.

[3] Gas held in underground reservoirs (including native and net injected gas) for storage purposes.

[4] Includes offshore reserves.

[5] Includes Arizona, Iowa, Maryland, Minnesota, Missouri, South Dakota, Tennessee, and Washington.

Pittsburgh [3]	39.30	38.85	38.37	43.44	49.78	49.26	48.24
St. Louis (Missouri portion only)	33.60	33.74	33.77	37.26	47.62	49.37	53.96
San Francisco-Oakland [3 4]	31.17	28.68	30.81	33.67	35.17	36.52	39.24
Washington, D.C. [3]	50.09	48.39	47.13	51.06	61.64	60.29	59.74

[1] The prices for July 1, 1965 through July 1, 1969 are from press releases issued by the FPC. The July 1, 1970, July 1, 1971 and Jan. 1, 1972 prices are based on 1970 sales volumes by pipelines to distributors (FPC Form 2). The prices for July 1, 1972 were based on 1971 sales volumes by pipelines to distributors, and the July 1, 1973 prices were based on 1972 sales volumes by pipelines to distributors (FPC Form 2).
[2] Reflects contingent rates in effect subject to subsequent reduction and refunds as of July 1, of year indicated.
[3] Wholesale service furnished by more than one pipeline company. Average prices are computed from the weighted average charges of all suppliers.
[4] Deliveries are not at city gates. Distributors must transport from State lines (California-Oregon and California-Arizona).

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, Cuba, Mongolia, and Thailand produce crude oil and presumably produce natural gas, but available information is inadequate to estimate output levels and the share of gross production that is classifiable as marketed.

[2] Comprises all marketed production (see footnote 3) plus gas vented, flared, reinjected for repressuring, and used to drive turbines (without being burned).

[3] Comprises all gas collected and utilized as fuel or as a chemical industry raw material, including gas used in oilfields and/or gasfields as a fuel by producers, even though it is not actually sold.

[4] Apparently, natural gas that is vented or flared is not included in reported gross production; marketed output presented here is the difference between reported gross production and reported injected into reservoirs.

[5] Gross production not reported; marketed output has been reported in lieu of a gross production estimate because the quantity flared, vented, and/or reinjected is believed to be small.

[6] Total production is obtained from coal mines.

[7] Includes output from coal mines as follows, in million cubic feet: Czechoslovakia: 1971—12,289; 1972—12,000 (estimate); 1973—12,000 (estimate); West Germany: 1971—20,165; 1972—18,646; 1973—18,000 (estimate); Netherlands: 1971—2,013; 1972—1,236; 1973—1,200 (estimate); Poland: 1971—7,734; 1972—7,770 (estimate); 1973—7,800 (estimate); United Kingdom; 1971—4,838; 1972—4,485; 1973—4,400 (estimate); Japan: 1971—10,418; 1972—9,358; 1973—9,200 (estimate).

[8] No marketed production reported; there probably is some small field use in both Denmark and Norway, and in the case of the latter there was extraction of natural gas liquids reported in 1973, but available information is inadequate to make reliable estimates.

[9] Available statistics, used for both gross and marketed production, comprise marketed production plus gas injected into reservoirs for repressuring, but exclude gas vented and/or flared. In 1968 (latest available figure), gas used for repressuring constituted only 0.4% of the total. Information is inadequate to make a reliable estimate of gas vented and/or flared, but it is believed to be small.

[10] Series revised to reflect output in calendar year from that of year beginning March 21 of that stated used in previous editions.

[11] Data are for year ending June 30 of that stated.

[12] Series revised to include output from coal mines, not previously included.

[13] Includes ½ of production reported for the former Kuwait-Saudi Arabia Neutral Zone.

Natural Gas Liquids

By David A. Carleton [1] and Leonard L. Fanelli [2]

Production of natural gas liquids at natural gas processing plants declined for the first time since late in the 1950's. Production of 634.4 million barrels (1.74 million barrels per day was down 0.6% from that of 1972, reflecting primarily a decline in the availability of natural gas for processing. During the summer and fall months, supply shortfalls of some natural gas liquids were created as consumers increased inventories preparatory to anticipated critical shortages during the 1973–74 winter.

Natural gas liquids are products obtained from the processing of natural gas at natural gasoline plants, cycling plants, and fractionators. Included are ethane, the liquefied petroleum gases (LPG—propane, butane, propane-butane mixtures, and isobutane), natural gasoline, isopentane, plant condensate, and finished products including motor gasoline, special naphthas, kerosine, jet fuel, distillate fuel oil, and miscellaneous products.

Natural gas liquids supplied approximately 3.4% of energy requirements, 4.1% of energy production, and 7.4% of petroleum demand in the United States. Their position in the energy market increased slightly in the past decade. The output was valued at $1.86 billion, up 28% from 1972. The unit value rose 29% to $2.93 per barrel compared with $2.28 per barrel in 1972. The 1973 heating seasons were plagued by supply uncertainties and price fluctuations. Supply patterns were further complicated by inventory anomalies, allocation programs, and conservation efforts. Supply complications combined with abnormally warm heating seasons resulted in dislocations in the fuel usage patterns.

The only major natural gas liquids component to increase significantly in production was ethane. This reflected expanded demand for this product as a petrochemical feedstock and increased recovery capability at processing plants. Production rose nearly 8 million barrels, or 7.5%, in 1973, following a 20-million-barrel increase (25%) in 1972.

A series of events that occurred in 1972 led to considerable dislocation in the propane market in 1973. Price controls instituted in July 1972 froze the price that large oil companies (the historic wholesale buyers) could pay for propane. Concomitantly, small companies, those with less than 30 employees could purchase and sell propane without price controls. As a result, the large companies found it difficult in early 1973 to bid successfully for propane. Furthermore, major natural gas consumers (industrial firms, electric powerplants, and natural gas utilities), fearing a shortage of that product, sought propane as a substitute or standby fuel and were active propane purchasers during the spring and summer. This represented a significant demand for propane and resulted in a major diversion of propane from established markets.

Because of lower-than-normal midyear inventories and the prospect that residential and commercial consumers would not have adequate propane supplies during the 1973–74 winter, President Nixon announced a mandatory propane allocation program which became effective on October 3, 1973. This program was generally successful in that propane was available during the heating season; however, several factors had a moderating impact on demand. These included an unusually warm winter, conservation efforts, and resistance to sharply higher consumer prices.

The average unit value of natural gas liquids production was $2.93 per barrel, an

[1] Petroleum specialist, Division of Fossil Fuels—Mineral Supply.
[2] Survey statistician, Division of Fossil Fuels—Mineral Supply.

increase of 29% from the $2.28 per barrel in 1972. LPG, including ethane, exhibited the greatest increase, 39%, by rising to $2.66 per barrel. All other natural gas liquids items increased in unit value except finished gasoline and naphtha which decreased 8%. The general rise in unit value occurred during the middle 6 months of 1973, because of the following: (1) The marketing diversion referred to above, (2) the fear by retailers that they would be unable to obtain adequate supplies, (3) the general fear of a general natural gas shortage, (4) the embargo on exports to the United States by certain Middle East and African nations, and (5) the unilateral increases in foreign crude oil prices, together with the refineries' authorization to "pass on" to consumers a portion of the increase.

Data presented in this chapter were compiled from operating reports of natural gasoline plants, cycling plants, and fractionators that process natural gas. Included are all natural gas liquids except the small volume considered to be insignificant in national and State totals, recovered at pipeline compressor stations and gas dehydration plants. Plant condensate is included in natural gas liquids; field-separated condensate, however, is included with crude oil. Ethane and liquefied gases such as butane and propane, recovered from the crude oil refining operations, are classed as liquefied refinery gases (LRG) and reported as refinery products.

Annual reports were received from all large producers and distributors and from most of the dealers that sell more than 100,000 gallons of LPG per year. To reflect total shipments, the sample of dealer shipments was expanded by Petroleum Administration for Defense (PAD) districts on the basis of domestic demand in the district.

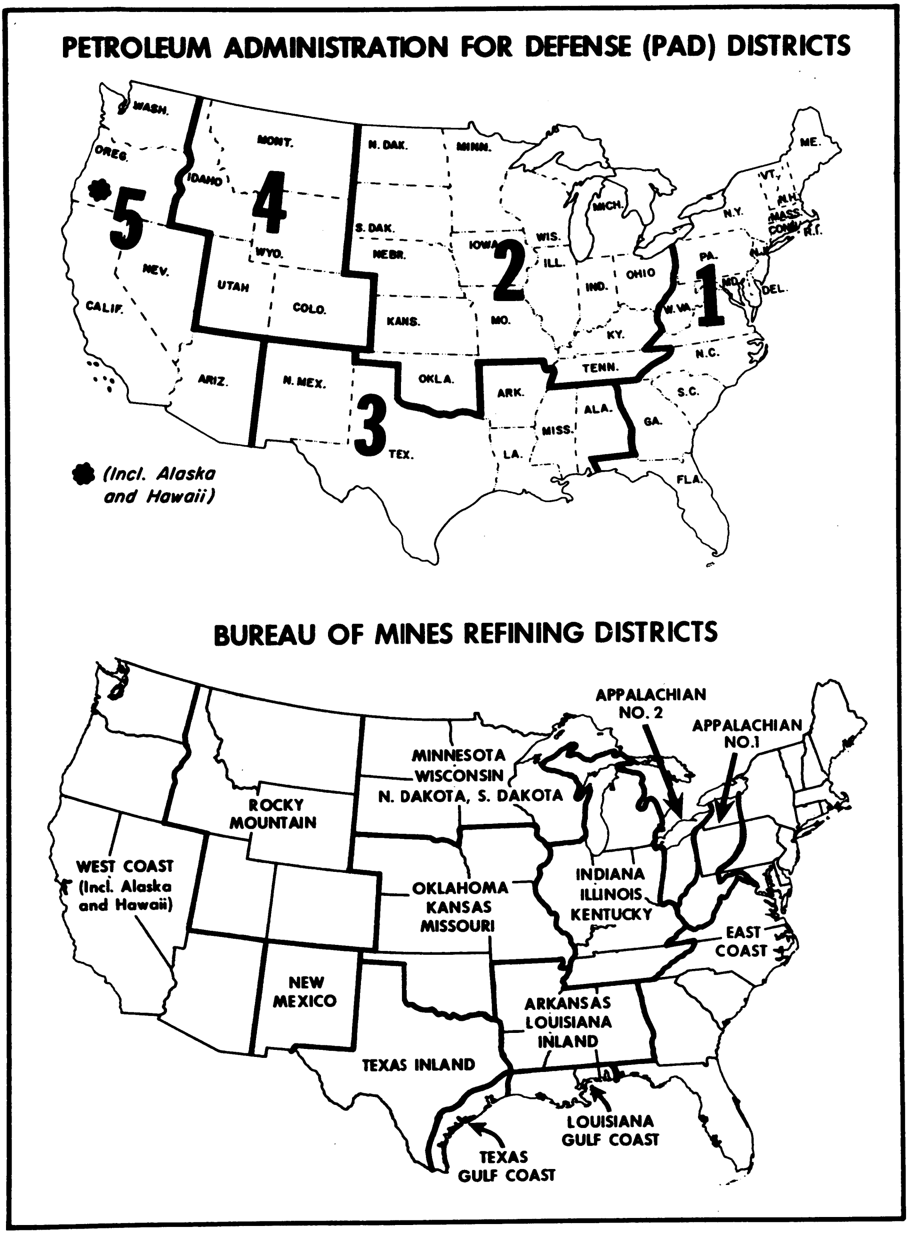

Figure 1.—Maps of PAD Districts and Bureau of Mines Refining Districts.

DOMESTIC PRODUCTION

The overall production of natural gas liquids declined for the first time in over a decade as the availability of natural gas for processing was reduced. Whereas output of most natural gas liquids decreased slightly, the major changes were a 7.5% increase in ethane production and a 2.4% decrease in propane production. The following tabulation presents quantity and percent changes between 1972 and 1973 production of the major natural gas liquids groups:

	Thousand barrels	Percent
Ethane	+7,529	+7.5
LPG:		
Propane	—5,153	—2.4
Other	—79	—.1
Total LPG	—5,232	—1.5
Natural gasoline and isopentane	—1,993	—1.2
Other natural gas liquids	—4,097	—13.8
Total	—3,793	—1.0

There were 786 natural gas processing plants in the United States at the beginning of 1973, down from 805 the previous year. These plants had a natural gas throughput capacity of 73,260 million cubic feet, down 2.5% from 75,137 million cubic feet on January 1, 1972. Nearly 47% of the plants were in Texas, and 17% were in Louisiana.[3] The number of companies operating plants was also down, declining from 131 in 1972 to 125 in 1973.

[3] Oil and Gas Journal. V. 71, No. 28, July 9, 1973, p. 98.

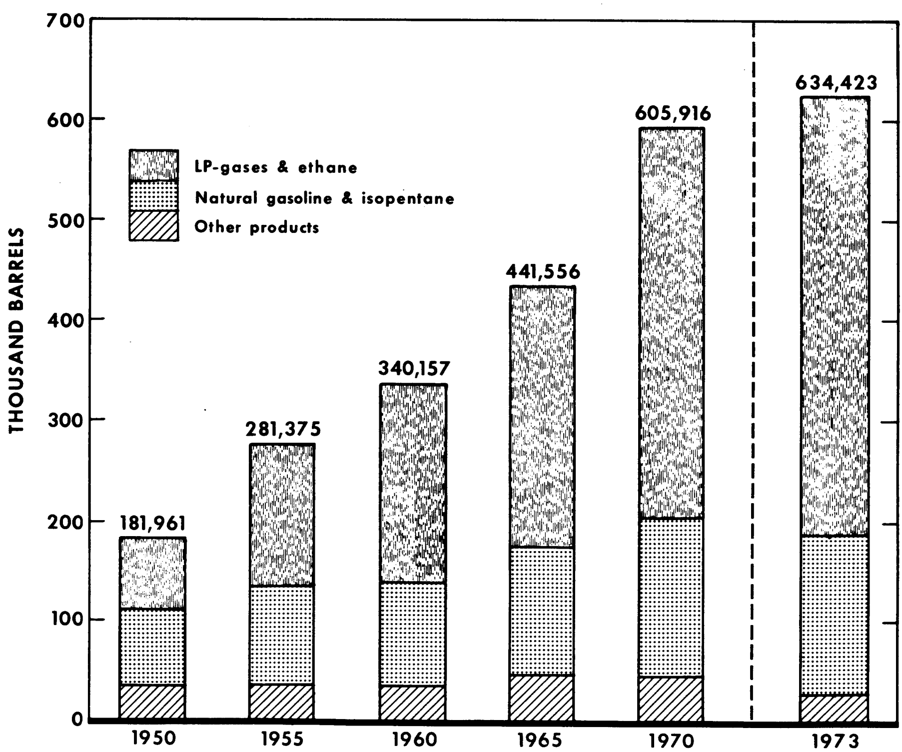

Figure 2.—Production of natural gas liquids in the United States.

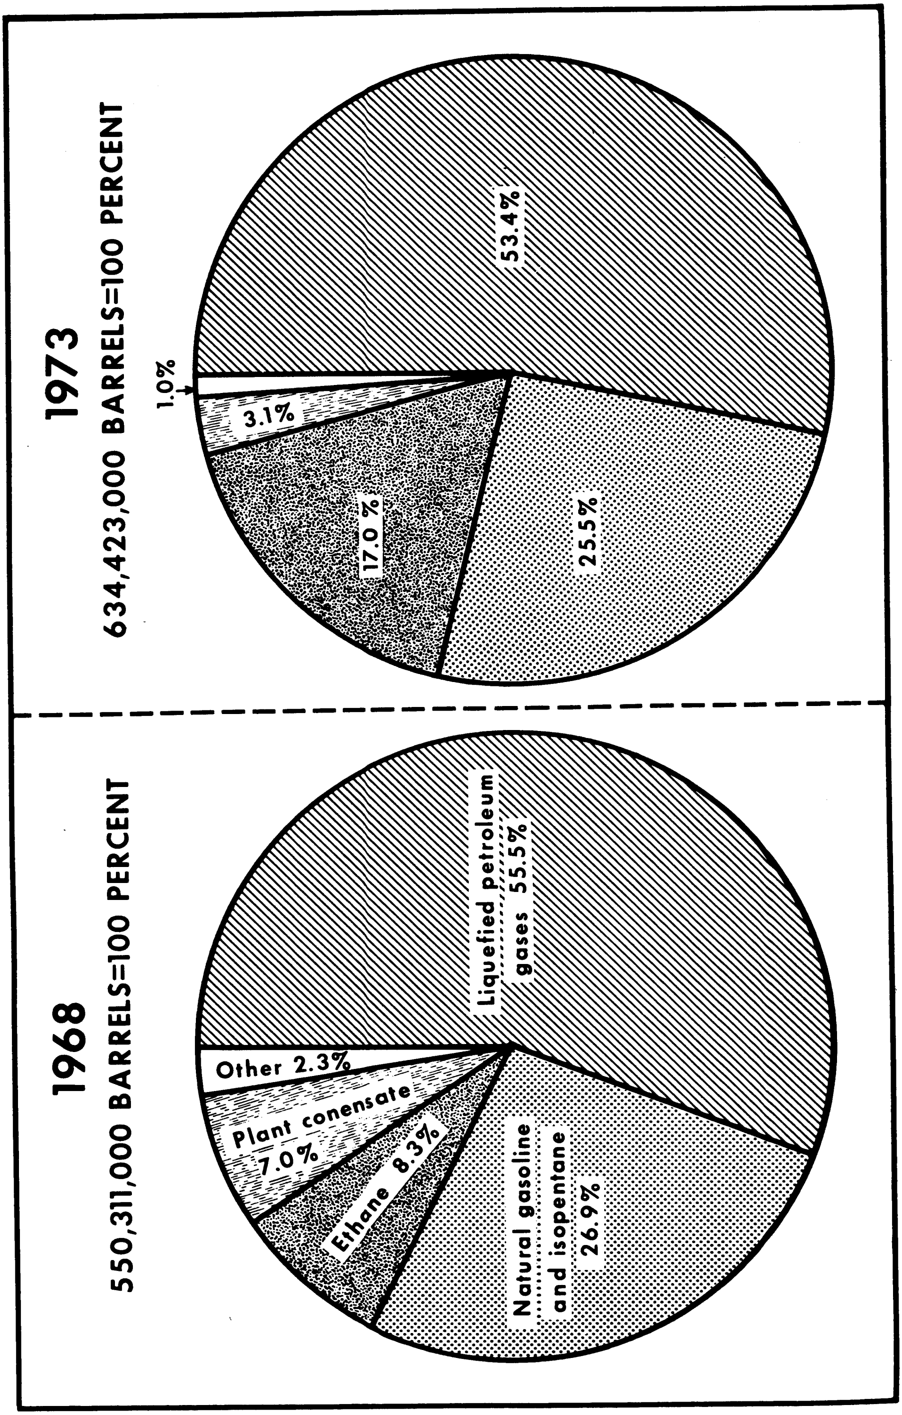

Figure 3.—The relative production of natural gas liquids components, 1968 and 1973.

RESERVES

The American Gas Association (AGA) Reserves Committee estimated that proved reserves of natural gas liquids at yearend 1973 were 6,455 million barrels. This was 5% less than in 1972, and represented the sixth consecutive year in which proved reserves declined since the high of 8,614 million barrels was reached in 1967. Although net changes in reserves by reason of extensions, revisions, and discoveries increased by more than 400 million barrels during the year, this was less than the amount of natural gas liquids produced. According to AGA data, the 1973 reserve-to-production ratio was 8.7:1, compared with 13.4:1 in 1967. A decline in the reserve-to-production ratio from 9.0:1 in 1972 resulted in spite of the greatest increase in new additions to reserves since 1968. Most of the new additions were revisions of estimates of previously proven fields in Texas. States with the largest reserves at yearend 1973 were Texas with 44% of the national total, and Louisiana with 31%. Sizable reserves were also in New Mexico, Kansas and Oklahoma. Louisiana experienced the greatest reduction in reserves, 143 million barrels. Of the States with major reserves, New Mexico had the greatest percentage decline, 18%.

CONSUMPTION AND USES

Liquid products from natural gas liquids plants are generally shipped either to major storage terminals for distribution to retailers and consumers or to refineries for either blending or processing. In 1973, 41% of the natural gas liquids output (about 260.0 million barrels) was shipped to refineries. Inputs to refineries, including 37.5 million barrels of imports, totaled 297.5 million barrels, one-half of which was run to crude oil distillation units and one-half to blending units. The following tabulation shows shipments (inputs) into refineries in 1,000 barrels:

	1972	1973	Percent change
Propane	3,934	2,755	−30.0
Butanes:			
Isobutane	34,629	35,723	+3.2
Normal butane	31,800	25,990	−18.3
Other butanes	11,364	11,267	−8.5
Total butanes	77,793	72,980	−6.2
Butane-propane mix	3,466	4,486	+29.4
Natural gasoline	156,879	154,455	−1.6
Isopentane	7,183	5,895	−17.9
Plant condensate	53,190	56,911	+7.0
Total	302,445	297,482	−1.6

Generally, the lighter natural gas liquids (propane and butane) are blended at refineries, and the heavier items are run to process units. Shipments to storage terminals, including some directly to retailers and consumers, amounted to 374.4 million barrels. Essentially all ethane produced was shipped directly to chemical plants.

PRODUCTIVE CAPACITY

According to the AGA, estimated productive capacity at yearend 1973 was 2,404,000 barrels per day, a decline of 463,000 barrels per day, or 16%, during the year. Each of the top seven States declined in productive capacity during the year. Texas led, losing 190,000 barrels per day (15% of its capacity), followed by Louisiana, 108,000 barrels per day (12%); Kansas, 84,000 barrels per day (37%); New Mexico, 56,000 barrels per day (33%); and Oklahoma 26,000 barrels per day (13%). At yearend the distribution of productive capacity by leading States was: Texas, 43%; Louisiana, 32%; Oklahoma, 7%; Kansas, 6%; and New Mexico, 5%.

As natural gas liquids production is a function of natural gas production and processing, productive capacity is dependent upon rates of gas production from crude oil and natural gas reservoirs. The AGA has defined productive capacity of natural gas liquids as the amount of hydrocarbon liquids that would be produced coincident with the estimated productive capacity of natural gas based on unit recoveries at normal producing rates. Such estimated capacities are not limited by lack of capacity of processing plants or other surface facilities, and it is emphasized that adequate facilities would be required to effect the recovery of liquids from the natural gas produced at these rates. It should also be recognized that such facilities cannot be enlarged quickly. Therefore, the estimated natural gas liquid capacities which relate to increased production of gas from oil and gas wells operating at their productive capacities are theoretical and may not be realized in event of an emergency.[4] Although productive capacity estimates determined in accordance with the above definition are theoretical, they are useful in determining potential availability.

Domestic demand for LPG and liquefied refinery gases (LRG) totaled 409.1 million barrels in 1973, down slightly from 413.6 million barrels in 1972. Of the 1973 domestic demand, 281.4 million barrels was for LPG produced at natural gas processing plants, 89.7 million barrels was for LRG for fuel use and 38.0 million barrels was for LRG for chemical use. Propane (including propylene) demand accounted for 318.0 million barrels, or 77.7% of total LPG and LRG demand. Demand for plant propane was 218.6 million barrels. Refinery propane and propylene demand was 99.4 million barrels, of which 74.1 million barrels was for fuel use and 25.3 million barrels was for chemical use.

Domestic demand for butane (including butylene) increased to 81.7 million barrels. Plant demand was 62.3 million barrels, whereas refinery demand was 19.4 million barrels, of which 12.7 million barrels was for fuel use and 6.7 million barrels was for chemical use.

The domestic demand for ethane (including some ethylene) increased 12% to 119.4 million barrels in 1973. Virtually all ethane was used for petrochemical feedstocks. According to the U.S. Tariff Commission, production of ethylene, the principal use for ethane, increased to a record 22.4 billion pounds in 1973. This compares with 5.9 billion pounds in 1960 and 18.5 billion pounds in 1971.

STOCKS

Stocks of natural gas liquids, which reached a record of 116.2 million barrels on September 30, 1972, fell to critical levels in February 1973. Particularly precarious was propane stocks which totaled 31.7 million barrels and were equivalent to only 24 days of domestic demand. For the corresponding month in 1972, propane stocks were equivalent to 38 days of demand. The February 1973 stocks of propane were of considerable concern since the 1972–73 winter was not exceptionally cold. Propane demand in February 1972 was 14% higher than in February 1973. By yearend 1973, as a result of the demand-constraining factors previously mentioned, stocks had returned to more secure levels, being equivalent to 59 days of December 1973 average daily demand.

Total natural gas liquids stocks at both refineries and plants and bulk terminals at yearend 1973 totaled 98.9 million barrels, 14.7 million barrels more than at yearend 1972. About three-fourths of this total was in underground storage. Natural gas liquids stocks at refineries amounted to 4.8 million barrels, a decrease of 0.2 million barrels from stocks at yearend 1972, whereas stocks at plants and terminals totaled 94.1 million barrels, 14.9 million barrels more than at yearend 1972. By type of liquid, the major yearend stocks changes were for propane, up 11.0 million barrels; butane, up 5.1 million barrels; and ethane, down 2.0 million barrels.

PRICES AND VALUES

The average unit value of natural gas liquids was $2.93 per barrel, up a substantial 29% during the year. The exceptionally large increase resulted from a variety of factors: The general rise in wellhead prices for natural gas, marketing factors resulting from propane shortages during early and mid-1973, efforts to supplement depleted inventories during the

[4] American Gas Association, American Petroleum Institute, and Canadian Petroleum Association. Reserves of Crude Oil, Natural Gas in the United States and Canada and United States Productive Capacity as of December 31, 1973. V. 27, May 1974, p. 108.

Arab embargo on exports to the United States and resultant shortages of petroleum products including liquefied refinery gases, and the diversion of propane and other natural gas liquids into untraditional markets because of the natural gas shortages and the rapidly expanding petrochemical industry.

Future prices for propane increased uniformly throughout the year; however, quotations at supply areas recorded significant increases earlier than those at consuming areas. Average monthly futures increased 9.85 cents per gallon, or 142% at Wood River, Ill., and 8.40 cents per gallon, or 140% at Mt. Belvieu, Tex. New York had the smallest increase; 4.20 cents per gallon, or 46%. Unit price of LPG and ethane increased more than that of other natural gas liquids. The increase was $0.75 per barrel (1.79 cents per gallon), or 39%. The only unit price to decline was that for finished gasoline and naphtha. This suggests that these small amounts were probably contaminated and sold at distressed prices.

FOREIGN TRADE

In 1973 liquefied petroleum gases and plant condensate became the third most important item of liquid hydrocarbon imports, following residual and distillate fuel oils. The 85.3 million barrels imported were 34% greater than 1972 imports. The significant increase was occasioned by the critical shortage in the early part of the year that accompanied efforts to rebuild inventories, and by dwindling supplies associated with the Arab embargo on petroleum exports to the United States. In 1973, the United States imported LPG from 22 countries, compared with only 9 in 1972. Principal among these were Canada and Venezuela which supplied 81% and 15% respectively of the total. Canada accounted for essentially all of the natural gas plant condensate. Canada is providing some of the feedstock for the production of synthetic high Btu gas as shown in plant condensate data in table 17.

Whereas PAD District II was the principal importer of LPG (essentially all from Canada) District III had the greatest increase, rising from 0.8 million barrels in 1972 to 9.1 in 1973. Although some of this was used in the petrochemical industry in PAD III, large amounts were shipped to other districts, principally PAD II and IV for heating and crop drying.

Mexico is the major destination of LPG exports, receiving 92% of the total, followed by Japan (4%) and Canada nearly 4%. Exports were down 13% from 1972, reflecting the propane shortage in the United States. Much of LPG exported to Mexico was used for heating and cooking in border areas. LPG exports comprised butane, 8%; propane, 32%; and butane-propane mixtures, 60%.

WORLD REVIEW

The United States and Canada continued to dominate natural gas plant liquids output, together accounting for an estimated three-fourths of total world production. The U.S.S.R. was also an important producer, ranking third and comprising 8% of the total. Significant gains in output have been made in recent years, especially in major associated natural gas producing countries. Venezuela's production of 33.9 million barrels in 1973 was 33% more than in 1971. Natural gas liquids production from the Middle East's three major producers of associated natural gas, Iran, Kuwait and Saudi Arabia, also reached a record high of 71,259,000 barrels or 36% above 1972. Most of the increase occurred in Saudi Arabia, as evidenced in table 19.

In Canada, the National Energy Board approved a project relating to the export of propane and ethane. Included was a 1.2-billion-pound-per-year ethylene plant located at Fort Saskatchewan using ethane feedstock and two pipelines from Edmonton to Sarnia, one of which is a 12-inch-diameter line for natural gas liquids and the other a 10-inch line for ethylene. Plans are to export over an extended period 169 million barrels of ethane to a synthetic gas plant at Green Springs, Ohio.

Canada, the only foreign country for which natural gas liquid reserves data were available had proved reserves of 1,595 million barrels at the end of 1973. This was down by 108 million barrels and represented the fourth consecutive year of decline.

Atlantic Richfield Co. announced plans to build a $75 million natural gas liquids plant in the Java Sea, offshore Indonesia. The totally offshore plant will process natural gas associated with the offshore Ardjuna oilfield about 90 miles north of Djarkata. Construction was scheduled to begin in mid-1974, and operation was set for 1975.

The National Iranian Oil Co. (NIOC) and Transco Companies, Inc. of the United States will be equal partners in a $650 million natural gas liquids project to be built in southwestern Iran. About 750 million cubic feet per day of associated gas from five oilfields will be run to six extraction plants, which will produce 60,000 barrels per day of natural gas liquids. The product will be one-third propane, one-third butane, and one-third pentane plus. The liquids will be moved in a 12-inch pipeline to Kharg Island where they will be shipped to Transco's previously announced $85 million synthetic gas plant in eastern Pennsylvania.

Plans are underway in Kuwait to double the existing natural gas liquids output, which reached 22.1 million barrels in 1973.

The consortium Santo-Delhi-Vamgos, plans to complete a natural-gas-processing plant at Moomba in Australia in 1977. The output will be feedstock for a petrochemical plant planned by Redcliffs, S.A.

Other natural gas processing plants planned or under construction include expanding the 5.2-million-barrel-per year propane-butane plant at Hassi Messaud Algeria, to 8.6 million barrels per day; completion of a 700,000-barrel-per-year LPG plant in Santa Fe Province in Argentina; increasing the 1.5-million-barrel-per-year processing plant at Nienburg, West Germany, to 4.2 million barrels per year, and expanding and constructing 12 plants in Canada, having a combined capacity of 130 million barrels per year. The largest of these was a 34-million-ton-per-year plant at Brazcau, Alberta.

The joint venture of Broken Hill Pty. Co., Ltd., and ESSO Australia, Ltd., that operates the only natural gas processing plant in Australia at Longford, Victoria, announced that capacity will be doubled. When completed in mid-1975, the plant is expected to produce 53,000 barrels per day of propane and butane and 12,500 barrels per day of ethane.

The Hungarian Oil and Gas Trust completed the first stage of its natural gas-processing plant at Szank. The plant can process 141 million cubic feet per day of associated natural gas from fields in the Szeged area. The plant was built with the assistance of U.S.S.R. technicians. The annual output capacity is as follows:

	Thousand barrels
Propane and butane	1,438
Isobutane	464
Isopentane	418
Natural gasoline	1,800
	4,120

Plans are to double the capacity by 1975.

[1] A producer operating in more than 1 State is counted only once in arriving at U.S. total.
[2] Represents average unit value of sales throughout the year.
[3] Includes kerosine, distillate fuel oil, and miscellaneous products.

People's Republic of China, and Romania, may also produce natural gas plant liquids, but infor-
include in this table only those natural gas liquids produced by natural gas processing plants, and
because the latter are normally blended with crude oil and thus are included in statistics on crude
only output of natural gas processing plants, or if they include field output. Thus, some of the
country has been so footnoted, but it may also be true in the case of other countries.

tries, only total of butane and propane or only total natural gas plant liquids is reported in
type. Summation of totals of propane and butane thus does not equal the reported subtotal, nor
plant liquid total.

Nickel

By John D. Corrick [1]

Nickel supply and demand came into approximate balance throughout the world in the latter part of 1973. Balance was brought about by greatly increased demand in the United States, Western European countries, and Japan. Apparently the 3 years of surplus supply did not alter the course of the nickel industry. The supply base was greatly expanded and the dominance of the International Nickel Co. of Canada Ltd. (Inco) and Société le Nickel S.A. (SLN) of New Caledonia was partly diminished by other nickel producers expanding their production.

Domestic nickel consumption increased 24% in 1973 compared with that of 1972, and exceeded the record consumption in 1966 by 5%. The pattern of nickel consumption was little changed from previous years. However, that portion of nickel consumed in stainless and heat-resisting steels increased at a faster rate in recent years than did nickel consumption in other major end use categories.

The price of nickel in ferronickel was increased 6 to 7 cents per pound at midyear by SLN. Inco followed SLN's lead and increased the price of oxide sinters 90 and 75 by 3 cents per pound. Inco's price was equivalent to those quoted for SLN's ferronickel, recognizing the iron value in ferronickel.

World trade in nickel was singularly marked by the changing supply base. Imports into the United States of Soviet Union nickel for consumption increased nearly fortyfold compared with those of 1972; imports from the Dominican Republic increased about fivefold; and Southern Rhodesian producers supplied nearly 8 million pounds. The United States imported a record 191,000 tons of nickel in 1973.

Legislation and Government Programs.—A proposed rule change regarding rated nickel orders was published in the October 1, 1973, Federal Register. The proposed rule permits nickel producers and distributors to reject rated orders for nickel (other than DX-rated orders and directives issued by the U.S. Department of Commerce, Bureau of Competitive Assessment and Business Policy) that are received by them less than 10 days before the month in which delivery is requested. The proposal also provides that producers and distributors of nickel shall comply with directives, including those that require the set-aside of an individual producer's or distributor's supply of nickel for acceptance of rated orders during specified periods of time.

DOMESTIC PRODUCTION

The Hanna Mining Co. at Riddle, Oreg., was the sole producer of primary nickel in the United States in 1973. By-product nickel salts were produced at copper and other metal refineries; part of the byproduct nickel originated from scrap. Amax Nickel Division of American Metal Climax Inc. began constructing, expanding, and rehabilitating the Port Nickel, La., refinery formerly owned by Freeport Sulphur Co. (Freeport Minerals Co.). The renovated plant will produce 80 million pounds of nickel per year along with varying quantities of copper, cobalt, and ammonium sulfate. Feed material will be in the form of a copper-nickel matte initially imported from Bamangwato Concessions Ltd. (BCL) of Botswana. Considerable interest was expressed in the copper-nickel deposits of Northeastern Minnesota in 1973. Numerous hearings were held by Minnesota's Environmental Quality Council regarding the question of immediate development of the deposits or instituting a moratorium on development. However, at yearend no significant results were reported.

Table 2.—Primary nickel produced in the United States

In nickel-base alloys	2,694	1,192
In copper-base alloys	6,738	11,739
In aluminum-base alloys	1,056	908
In ferrous and high-temperature alloys [1]	24,003	18,025
In chemical compounds	269	73
Total	35,926	33,295

[1] Includes only nonferrous nickel scrap added to ferrous high-temperature alloys.

CONSUMPTION AND USES

Consumption of ferronickel was an even more significant part of total nickel consumption in the United States in 1973, than it was in 1972. However, the increased usage was due more to the availability and price spread between nickel in ferronickel and that of pure nickel than it was to any change in technology of usage as in the past. Nickel in ferronickel accounted for 18% of the total nickel consumed in 1973, compared with 14% in 1972, and was consumed principally in stainless and alloy steels. The pattern of nickel consumption in 1973 was little changed from that of 1972; 33% of the total consumed was used to make stainless steels, 12% was used in alloy steels, 15% was used in nickel plating, 26% was used to make high-nickel alloys and superalloys, and 2% was used in iron castings. End use market data available to the Bureau of Mines did not indicate any significant change in the worldwide pattern of nickel consumption.

Data on secondary nickel reported in table 8 are incomplete and are based on

November and December reports of approximately 200 companies that report monthly, and the 1973 reports of approximately 450 companies that report annually. The information is included in this chapter to acquaint the reader with the type of material that will be available in future publications and to initiate this series of data. It should be used only as an indicator of secondary nickel consumption.

[1] Data should not be considered as annual owing to its incompleteness.
[2] Less than 1 unit.

PRICES

The producer price for electrolytic nickel was unchanged at $1.53 per pound during the year. Prices were unchanged for domestically produced nickel in ferronickel in 1973, the quoted price was $1.38 per pound. The price of foreign produced ferronickel was increased on July 9 by NC Trading Co., the sales agent for SLN, by 6 to 7 cents per pound. The new prices were FN4, $1.43 per pound nickel content; FN3, $1.47 per pound nickel content; and FNC, $1.45 per pound nickel content. Falconbridge Nickel Mines Ltd. increased the price of ferronickel 7 cents per pound to $1.46 effective July 13. Inco, increased prices of nickel oxide sinter-90 to $1.43 per pound nickel content, and nickel oxide sinter-75 to $1.40 per pound nickel content, effective July 20. The new Inco price was equivalent to those quoted for SLN ferronickel, recognizing the iron value in ferronickel. These price changes for nickel produced in foreign countries narrowed the differential between prices quoted for pure nickel and that quoted for nickel in ferronickel and in other forms of nickel suited for steelmaking.

FOREIGN TRADE

U.S. exports of nickel, nickel alloy, and catalysts were 20% more than those of 1972. Exports of nickel waste and scrap decreased 26% from that of 1972.

Canada continued to be the principal supplier of nickel to the United States in 1973 and accounted for 63% of the total nickel imported for consumption. Nevertheless, Canada's portion of the total imports was 10 percentage points less than in 1972. The Dominican Republic nearly replaced Norway as the second most important source of imported nickel. The strong influx of ferronickel that began in 1972 continued through 1973; imports of ferronickel more than doubled. The Dominican Republic and New Caledonia were responsible for the major portion of ferronickel imported into the United States in 1973. The total of nickel in all forms imported for consumption in 1973 was 10% more than was imported in 1972.

WORLD REVIEW

Australia.—At midyear, six nickel mines were operating in Australia. The Redross nickel mining project in Western Australia was reopened in 1973 by the partnership of Anaconda Inc., the Australian subsidiary of The Anaconda Company of the United States, Conzinc Riotinto of Australia, Ltd. (CRA), and New Broken Hill Consolidated Ltd. (NBHC). Anaconda held a 60% interest, CRA 26⅔%, and NBHC 13⅓%. Full production, rated at 10 million pounds per year of nickel concentrate, was expected by 1974 with reserves adequate for 7 years of operation at this rate. Initially the ore was to be toll-milled at Western Mining's Kalgoorlie concentrator. The concentrate was to be shipped from the port of Esperance to Sherritt Gordon Mines Ltd.'s refinery at Fort Saskatchewan, Canada, for toll-refining. At yearend, the partnership was conducting economic feasibility studies to determine if a nickel smelter, using Anaconda's Arbiter process, should be built in Western Australia.

There were only two significant new nickel finds in Australia in 1973. One of the finds was at Forrestania, 170 miles southwest of Kambalda. The discovery was being explored by American Metals Climax Inc., American Oil Co., a subsidiary of Standard Oil Co. (Indiana), and several small Australian companies. The other discovery was near the Pilbara Coast at Sherlock Bay. Texas Gulf, Inc., was exploring the find. Preliminary estimates by company officials were 75 million tons of ore averaging 0.5% nickel.[2]

Western Mining Corporation Ltd. dedicated its new flash smelter at Kalgoorlie in April 1973. The furnace at Kalgoorlie was blown in on December 5, 1972, and had a rated capacity of 25 tons of nickel concentrate per hour utilizing the Outokumpu Oy process. Prior to smelting, the concentrate assayed 11% to 13% nickel and 1.02% to 1.20% copper. Smelting produced a high-grade matte containing approximately 75% nickel plus copper. Western

[e] Estimate. [p] Preliminary. [r] Revised.
[1] Insofar as possible, this table represents mine production of nickel; where data relate to some more highly processed form, the figures given have been used in lieu of unreported actual mine output to provide some indication of the magnitude of mine output and are so noted parenthetically following the country name.
[2] In addition to the countries listed, Albania and East Germany also produce nickel from mines, but available information is inadequate to make reliable estimates of output levels.
[3] Refined nickel and nickel content of oxides and salts produced, plus recoverable nickel in exported mattes and speiss.
[4] Includes a small amount of cobalt not recovered separately.
[5] Nickel-cobalt content of metallurgical plant products, plus recoverable nickel-cobalt in exported ores.

e Estimate. p Preliminary. r Revised.
[1] Refined nickel plus nickel content of ferronickel produced from concentrates unless otherwise specified.
[2] In addition to the countries listed, East Germany and North Korea are believed to produce metallic nickel and/or ferronickel, but information is inadequate to make reliable estimates of output levels.
[3] Includes nickel content of nickel oxide and nickel fonte in addition to metallic nickel and ferronickel.
[4] Nickel content of ferronickel only (no refined nickel is produced).
[5] Includes electrolytic nickel as follows, in short tons: 1971—17,077; 1972—18,189; 1973—23,249; the difference between these figures and the listed total is the nickel content of ferronickel, nickel oxide and nickel fonte.
[6] Nickel-cobalt content of ferronickel and matte.

Mining produces over 70 million pounds of nickel annually, or nearly 8% of the free world's output. The company marketed nickel in the United States, the United Kingdom, other European countries, India, and Japan. In addition to Western Mining's nickel production from the Kambalda region, the company was expanding its exploration activities across Lake Lefroy into the Paris-St. Ives region. At yearend, Western Mining had increased its proven reserves in the Kambalda and St. Ives region from 22.7 million tons containing 3.29% nickel to 24 million tons containing 3.24% nickel.

Development of the Greenvale nickeliferous laterite deposit by Freeport Queensland Nickel Inc., a wholly owned subsidiary of Freeport Minerals Co. of the United States, and Metals Exploration N.L. of Australia continued on schedule during 1973. Early in 1973 a contract was let for the construction of the town of Greenvale in Queensland. At the same time, the treatment plant foundation was poured at Yabulu, near the coast, 140 miles from the mine site. Stripping of mine overburden also began in early 1973 as did construction of a 140-mile-long railway connecting the mine at Greenvale with the Yabulu treatment plant. The plant was designed to treat a million dry tons of ore annually and produce over 50 million pounds of nickel. The hydrometallurgical process was based on ammoniacal leaching of pyrometallurgical reduced ore. Western Europe was to receive the major portion of output; Japan was to receive about 18%.

A joint venture between Poseidon N.L., Western Mining Corporation, Ltd. and Sherritt Gordon Mines, Ltd., of Canada to develop the Windarra nickel deposit in Western Australia gathered momentum in 1973. Ore production was to begin in August 1973, but was unconfirmed at yearend. Nevertheless, Poseidon reportedly awarded, in late 1973, a contract to Ruwolt Pty. Ltd. to supply mineral processing equipment for the Mt. Windarra project. The equipment, valued at $1.4 million, included an apron feeder, a Symons cone crusher, 6 grinding mills, and 13 Paramount vibrating feeders.

Technical feasibility of mining the Agnew nickel deposit in Western Australia was confirmed in 1973. Exploration activities were conducted by Selection Trust Ltd. and Consolidated African Selection Trust Ltd. At yearend, indicated reserves were 40 million tons of ore averaging 2% nickel. Australian participation in the development of the Agnew deposit, through Selcast Exploration Ltd., was 18%.

At yearend, the Australian Government was preparing to reveal a new national petroleum and minerals authority bill.[3] The bill would foster a new Government policy toward insuring maximum Australian ownership of the nation's mineral wealth. Foreign ownership of Australian mineral wealth had been estimated at 62%. The immediate and long-range effects of the bill, should it become law, on foreign investments, mineral exploration, and mining in Australia were uncertain at yearend.

Botswana.—BCL expected to begin mining the Selebi-Pikwe copper-nickel deposits early in 1974. Ore concentrating and smelting facilities reportedly were completed in 1973. The matte produced from the smelting process was to be refined at Amax Nickel's rehabilitated plant in Louisiana, United States. Considerable exploration for copper-nickel deposits was conducted during 1973 with several new discoveries being evaluated at yearend.

Canada.—Canada remained the world's leading producer of nickel accounting for nearly 37% of the total world mine output. Nickel production was reported as 268,908 tons of contained metal, a 3.8% increase over that produced in 1972. The principal producers of nickel in Canada remained Inco, Falconbridge Nickel Mines Ltd., and Sherritt Gordon Mines Ltd.

Inco mined a total of 19.7 million dry tons of ore having an average nickel content of 1.4% in 1973, compared with 19.2 million tons having an average nickel content of 1.3% in 1972. Company officials reported that the higher average grade of ore mined in 1973 over that of 1972 was a result of improved grade control in mining operations and increased production from mines having higher grade ore. In 1973 Inco had 16 mines in full or partial production, 13 in Ontario and 3 in Manitoba. Three mines remained on standby status in 1973. They were the Totten and Murray mines in Ontario and the Soaba in Manitoba. The company expected to reactivate the Crean Hill mine and the Leback West mine early in 1974. Inco officially opened its Copper Cliff nickel refinery in October 1973. The plant was expected to reach its full designed capacity of 125 million pounds of nickel per year in pellet and powder forms by mid-1974. The Copper Cliff facility was the only plant in North America producing nickel pellets.

Falconbridge and Sherritt Gordon remained the No. 2 and No. 3 producers, respectively, of nickel in Canada in 1973. However, Falconbridge, as a result of problems with research and equipment deliveries, coupled with the failure of its nickel-iron pellet refinery in 1972, had to schedule changes in its air pollution abatement plans for the Sudbury area of Northern Ontario. Falconbridge's program called for major revisions to its smelting process and other facilities at a cost estimated at more than $40 million. The revised process was designed to improve working conditions in the plants and bring about a significant reduction in sulfur dioxide emissions to the atmosphere. The revisions were to incorporate fluid-bed roasting, electric smelting, and treatment facilities for roaster gases. These changes would eliminate the need for sintering, which is a source of sulfur dioxide in the existing smelter complex and process, and would replace existing blast furnace operations. According to company officials, production from the processing complex will not be affected during the conversion nor will the capacity of the plant be increased when the revisions are completed. Giant Mascot Mines Ltd., made its first shipment of nickel concentrate from its Hope mine to the Sherritt Gordon refinery near Edmonton in 1973. Giant Mascot was to supply Sherritt Gordon with a nickel concentrate grading 10% to 12% nickel and 2% copper. Exploration to maintain and expand existing ore reserves was begun in 1973.

The principal Canadian nickel producers and their 1973 production, sales or deliv-

[3] Engineering and Mining Journal. Changes in Australia's Minerals Policy to be Revealed by Labor Government. V. 175, No. 1, January 1974, p. 40.

eries to customers as given in their annual report to stockholders were as follows:

Company	Type of operation	Thousand pounds
International Nickel Co. of Canada, Ltd	Delivery	517,000
Falconbridge Nickel Mines Ltd	do	99,408
Sherritt Gordon Mines Ltd	Sales	17,499

Early in 1973 officials of Boliden A.B. of Stockholm, Sweden, announced that the company would invest a second $1 million in a joint venture with Great Lakes Nickel, Ltd., of Toronto, Ontario, to develop the Great Lakes nickel-copper mining property near Thunder Bay, Ontario. The investment was used to complete work on Boliden's feasibility report. The report completed in July 1973, recommended construction of a mine and mill with an initial designed capacity of 1.8 million tons per year. Capital costs of this initial stage were calculated at $31.2 million, with expected startup by mid-1975. The company also recommended that the deposit be mined by the underground room and pillar method in order to obtain minimum dilution and to provide the lowest development and production costs. A two-stage autogenous grinding system and flotation process would be used to separate nickel and copper concentrates. Indicated ore reserves were confirmed at 32.8 million tons averaging 0.36% copper and 0.20% nickel. Potential reserves included an additional 40 million tons of ore. Boliden was to secure markets for the concentrate.

The fuel shortage that occurred late in 1973 required major nickel producers to review their energy requirements. Canadian production was not adversely affected by fuel shortages.[4] Canada not only has large reserves of petroleum but also relies heavily on hydroelectric power for the production of nickel.

Colombia.—Negotiations were carried out during 1973 between the Colombian Nickel Co. (CONICOL) and the Instituto de Fomento Industrial (IFI) of Colombia in an attempt to resolve problem areas that existed between the various parties. Estimates for start up, should all problems be resolved, were from 40 to 45 months.

Cuba.—Cuba rearranged its sales price on nickel to the U.S.S.R. to $2.265 per pound of contained nickel as part of the recent Cuban-U.S.S.R. plan to renovate and modernize both the Moa Bay and Nicaro nickel facilities and develop the new Punta Gorda nickel deposit. The new price was to prevail for a period of 7 years (1973–80). The price was estimated to be about 90 cents per pound more than Inco's price for similar quality material. Work on renovating the Moa Bay and Nicaro nickel facilities was to begin in 1973. Government officials were hopeful that Cuban production would ultimately reach 126,000 tons of nickel per year or an increase of 90,000 tons.

Dominican Republic.—Falconbridge Dominicana C. por A. operated its plant at Bonao at about 87% of designed capacity of 63 million pounds per year of nickel in ferronickel. The plant's designed throughput was not to be sustained until completion of the warranty inspection of three turbine generators, installation of improved metal handling facilities, and modifications to the ore preparation circuit. Falconbridge exported approximately 70,000 tons of nickel in 1973, valued at about $75 million. Nearly 50% of the exports went to Europe, 40% to the United States, and the balance to Japan. Under the company's contract it was obligated to explore an area of 78,000 hectares for additional nickel. The new exploration was to begin in early 1974. At yearend 1972, reserves were reported to be 70.8 million dry tons grading 1.6% nickel.

Finland.—Finland's total productive capacity for nickel ore was increased early in 1972 when the open pit at Keretti, Vuonos became operational. Underground production from the Vuonos nickel ore body began in November 1973. The deposit was discovered in 1965 and developed for initial production in 1972 at a cost of about $27.5 million. Plans were to mine and process 1.6 to 2.0 million tons per year of nickel ore from the two zones. To date the Vuonos operation has shown an efficiency of 80% in recovering nickel contained in a 6% nickel concentrate.

The nickel refining process developed by Outokumpu was a pioneering effort in hydrometallurgy and electrowinning techniques. The nickel refining section of the

[4] International Nickel Co. of Canada, Ltd. 1973 Annual Report. P. 12.

Harjavalta complex was first established as a 3,300-ton-per-year plant in 1959, its 1973 capacity was 11,000 tons per year of electrolytic nickel.

Greece.—Greece's only nickel producer, Société Minière et Métallurgique de Larymna S.A. (LARCO), produced approximately 15,000 tons of nickel in 60,000 tons of ferronickel in 1973. LARCO mined nickel ore from a laterite deposit at Larymna, 71 miles northeast of Athens, Greece. The ore contained 1% to 1.6% nickel. A larger but lower grade lateritic ore body with 1.1% nickel was located on the island of Euboea. Total reserves were estimated at over 240 million tons. LARCO's capacity was to be expanded to 80 million pounds of nickel per year at a later date if warranted by future demand. The company commissioned a new (third) rotary kiln for production of ferronickel at the Larymna plant early in 1973. LARCO's open pit mines on the island of Euboea were being expanded during the year. Studies were being conducted by the company in 1973 to determine the feasibility of converting the Aghios Ioannis mines from underground to open pit. Currently, about 80% of the ore treated comes from Euboea and 20% from the Aghios Ioannis deposit. LARCO has been able to lower the arsenic content of its ferronickel by using larger portions of the virtually arsenic-free ore from Euboea.

Intercontinental Mining and Abrasives, Inc. was constructing a nickel refinery near Lake Ionina. The refinery, costing $30 million, was to produce 12 million pounds of ferronickel per year. The project was to be completed by 1974.

Guatemala.—Exploraciones y Explotaciones Mineras Izabal S.A. (EXMIBAL), completed negotiations in 1973 with the Guatemalan Government for the development of nickel deposits in the country. EXMIBAL owned a lateritic nickel deposit near Lake Izabal. Contracts were let to McKee Latin America, Inc., for designing and constructing the processing plant and related facilities, and to the Montreal Engineering Co., Ltd., for designing the powerplant. Construction began in 1973 on the first phase of the project. The plant was to be commissioned by the end of 1976. Annual production was to be 25 million pounds of nickel in the form of 75% nickel matte. Inco, the principal owner of EXMIBAL, secured loans during the year of $15 million from the World Bank affiliate International Corp. and $13.5 million from the U.S. Export-Import Bank. Total cost of the project was estimated to be $90 million.

Indonesia.—A decision to proceed with the first phase of the lateritic mining and processing project of P.T. International Nickel Indonesia, a wholly owned subsidiary of Inco, was announced in April 1973. At yearend, construction had begun, and contracts were awarded to the Dravo Corp. for general engineering and construction work, to the Montreal Engineering Co., Ltd., for designing the powerplant, and to International Design Consultants of Jakarta for designing the town site in Sulawesi. The plant was to become operational in 1976. Proposed output of nickel, as 75% nickel matte, was increased in 1973 from 30 million to approximately 35 million pounds per year. Company officials estimated that reserves were sufficient to permit production to be increased to more than 100 million pounds of nickel annually at a later date.

The Indonesian Mining Corp., P.N. Aneka Tambang (ANEKA), continued construction of a smelter at Pomalaa, designed to produce 4,000 tons of nickel per year in ferronickel by late 1974 or early 1975. Japan was to import the entire output. In other developments, the Indonesian Nickel Development Co. of Japan began surveying nickel ore deposits in the Halmahera area of the Molucca Islands late in 1973. Preliminary estimates indicated 240 million wet tons of lateritic ore with a nickel content ranging from 1.3% to 1.4%. Company officials expected the survey to take approximately 1 year and that a comprehensive development plan would be drafted by 1975. To date, the largest planned Indonesian nickel operation was that of P.T. Pacific Nickel Indonesia. The company planned to produce 100 million pounds of nickel per year from deposits on Gag Island, Irian Barat. At yearend, pilot plant testing of the ore had been completed, and feasibility studies were being made by Sherritt Gordon, the prime company in this undertaking. Other companies involved in this venture were the United States Steel Corp., Newmont Mining Corp., and Koninklijke Nederlandsche Hoogovens en Staalfabrieken, N.V. The preliminary project completion date was given as 1975. However, at yearend, financing arrangements had not been completed.

New Caledonia.—Production of nickel ore in New Caledonia in 1973 was 11% greater than that produced in 1972. Nickel smelter production increased 2% in 1973 over that of 1972. More specifically, ferronickel output decreased by 1% and matte production increased by 7% compared with that of 1972. With a settlement of price differences between Japanese consumers and the independent mining industry in New Caledonia, exports of nickel ore to Japan increased 26% in 1973 compared with exports in 1972.

New Caledonia's principal nickel producer Société le Nickel, S.A. (SLN) experienced considerable difficulties in 1973. Major problem areas for SLN Caledonia were export taxes, averaging 11% ad valorem, and revaluing of the franc by 20% against the dollar in 1973. At yearend, the French Government had proposed that the New Caledonian administration reduce the tax burden in 1974 on SLN by about $13 million. An additional proposal by the French Government was that the New Caledonian Power Utility (ENERCAL) buy SLN's power station for approximately $45 million. At yearend Kaiser Aluminum & Chemical Corp. announced an agreement whereby SLN would purchase Kaiser's 50% interest in New Caledonian Co. This would give SLN full ownership. The transaction was contingent upon necessary Government approvals and actions. SLN installed its third 33,000-kilowatt furnace at Domiambo at midyear. The new addition increased SLN's smelter capacity to about 85,000 tons per year of nickel contained in ferronickel and matte. A new mine was commissioned at Si Reiss II during 1973. When the new mine reaches capacity, the mining complex will be able to produce 2.4 million tons of ore per year.

A proposal submitted February 1973, by Inco for mining a low-grade lateritic ore body near Goro on the island's southernmost extremity had not been acted upon by the French at yearend. If approved, Inco hoped to produce approximately 20,000 tons per year of nickel and 1,400 tons per year of cobalt by 1978, at an estimated capital investment of $275 million. The company planned to more than double the output of nickel to 45,000 tons per year at a later date. The project was dependent upon Inco acquiring mining rights to the Goro deposits presently held by the French Bureau de Recherches Géologiques et Minières. Another project involving the Goro deposit was submitted by Freeport Minerals Co. of the United States and Société Nationale des Pétroles d'Aquitaine of France.

A third project still active at yearend was the Compagnie Française d'Entreprises Minères Métallurgiques et d'Investissements (COFREMMI), Pechiney Ugine Kuhlmann, Granges Co. proposal to develop garneritic ores at Tiebaghi in the northwestern part of New Caledonia. COFREMMI, a Patiño subsidiary, was to operate the mine, selling the ore at a profit to the smelter, which was to be owned by all three partners. Near yearend Pechiney and Granges withdrew from the Tiebaghi project. Nevertheless, COFREMMI indicated it planned to proceed on its own. Reportedly, Government approval had been received and financing was being arranged at yearend. Tentatively, the project was slated for completion by 1975 and would have a capacity of 36,000 tons per year of nickel in ferronickel.

Philippines.—Construction of the Nonoc nickel refinery by Marinduque Mining & Industrial Corp. made significant progress in 1973 with engineering and equipment procurements being completed. During the year, pier facilities for oceangoing tankers and a tank farm were completed, a ¾-mile long air strip became operational, all-weather roads completed, and housing for senior and junior staff members neared completion. Also nearing completion at yearend was a dam on the Sabang River in northern Dinagat Island designed to provide water and standby power for the Nonoc operation. The first mining block was developed in 1973. Nickel production was expected to begin in August 1974. With a designed capacity of 3.8 million dry tons of ore annually, the refinery will make the Philippines the largest pure nickel producer in Southeast Asia. The Sherritt Gordon ammonium carbonate leach process will be used to extract nickel from the lateritic ore.

The Philippine Government, which until

this year had sought to defer new nickel ventures until the Marinduque project was onstream, reversed itself and gave the go ahead to two potentially important nickel projects. One project, a joint venture between Atlas Consolidated Mining Development Corp. and Mitsubishi Metal Mining Co. Ltd. of Japan to develop laterite deposits on Palawan and build a 35-million-pound-per-year nickel refinery was expected to proceed. Company officials of Atlas stated that pilot plant tests, conducted by Freeport Minerals Co., had confirmed the technical feasibility of utilizing the Freeport process in treatment of the Palawan ore. The second project was to exploit lateritic nickel deposits in northern Luzon. The partners in this venture were New Frontier Mines and Hochmetals of Panama. Annual capacity of the New Frontier operation was to be 33 million pounds of nickel.

In 1973 the Philippine Government altered its export laws covering nickel to permit the shipment of beneficiated ores rather than refined metal. To date, there have been five proposals submitted to the Board of Investments for ore exporting operations. Among companies interested in the recent Government ruling was Pacific Metals Co., Ltd., which agreed to purchase from Universal Oil Products Co. its 40% interest in Rio Tuba Nickel Mining Corp. of the Philippines. Exploration of Rio Tuba deposit has confirmed 32 million dry tons of ore with an average grade of 2.2% nickel. Total ore reserves were estimated at 81 million dry tons averaging about 1.6% nickel. The higher grade nickel ore was suitable for direct shipment to nickel smelters in Japan where Pacific Metals, a subsidiary of Nippon Steel Co., operated plants that produce ferronickel alloys.

TECHNOLOGY

Based on the number of reports and patents issued in 1973, nickel research has slowed somewhat during the past few years. Nevertheless, research can be expected to increase as the need for cryogenic storage vessels and energy related uses grow. Scientists at Bureau of Mines laboratories continued their investigations on methods of recovering nickel and copper from the Duluth gabbro of Minnesota. A reduction-roast, magnetic-separation process, as applied to gabbro flotation concentrate containing 0.9% nickel and 4.2% copper, reportedly yielded more than 95% nickel and copper in a magnetic concentrate.

The Bureau's scientists filed an invention report in 1973 in which they described an efficient extraction treatment process for low-grade lateritic ores. The oxide ore was selectively reduced and leached in an ammonia-ammonium sulfate system to recover 90% of the nickel and more than 80% of the cobalt. The nickel was selectively removed by liquid ion extraction and subsequently recovered by electrolysis; cobalt was precipitated from the leach solution as cobalt sulfide.

A new process for the recovery of nickel and cobalt from limonites by aqueous chlorination in sea water was described in a joint paper by scientists of Dartmouth College, Hanover, N.H. and Delft University of Technology, Delft, the Netherlands.[5] The process was based on selective reduction of the ore pyrometallurgically and aqueous chlorination in sea water. Reportedly, advantages gained from the process were as follows: High recovery of nickel and cobalt, rapid dissolution rates, and the use of saline in place of fresh water. Scientists at Republic Steel Corp. reported on a new process for extracting nickel from laterites, silicates, and sulfides utilizing hydrothermal sulphidization and oxidation steps followed by high-temperature cementation-in-pulp. Reportedly, the process was adaptable to iron-rich laterites, magnesium-rich silicates, and sulfide ores. Company officials reported yield recoveries consistently above 90%.[6]

The ad hoc interdisciplinary panel of experts formed by the Committee of Biological Effects of Atmospheric Pollutants, Division of Medical Sciences of the National Research Council to study nickel as a possible hazardous pollutant and toxic material finished its work. Its report was still being processed at yearend.

---

[5] Roorda, H. J., and P. E. Queneau. Recovery of Nickel and Cobalt From Limonites by Aqueous Chlorination in Sea Water. Inst. Min. and Met. (Sec. C), v. 182, No. 799, June 1973, pp. C79-C87.

[6] Engineering and Mining Journal. Republic's New Nickel Process Digests Laterites, Silicates, or Sulphides. V. 174, No. 5, May 1973, pp. 80-81.

Numerous patents were issued during 1973 on mining deep sea manganese nodules and subsequent recovery of nickel. In general, recovery techniques included both pyrometallurgy and hydrometallurgy to extract the metal values from nodules. Officials of Inco reported that the company's Ocean Mining Development group was continuing to investigate the feasibility of recovering nickel-bearing nodules from the ocean floor.[7] No details regarding the investigations were reported.

The Canadian National Research Council (NRC) in conjunction with its studies relating to the use of hydrogen as a fuel, announced a program directed at developing storage canisters containing metals as sponges. Alloys of nickel were among a list of metals being studied by NRC scientists in 1973. Inco metallurgists developed a copper-nickel-zinc-manganese spring alloy (IN-629) particularly suited for use in relay leaf springs and connectors. The alloy should find applications in the electrical and electronics industries, particularly in telecommuncations where ease of forming, moderate strength with high ductility, and good corrosion resistance are needed.[8] Inco metallurgists also introduced a powder metallurgy steel having excellent physical properties and not requiring heat treatment. The 2% nickel steel (IN-861) in the sintered condition had tensile strengths in the range of 70,000 to 90,000 pounds per square inch. Possible uses for the new nickel steel powder reportedly would be in parts presently cast and machined and as a substitute for other powder metallurgy alloy mixes.[9]

Officials of Latrobe Steel Co. of Latrobe, Pa., announced the development of a new high-temperature, high-strength (super) alloy composed principally of nickel, cobalt, and chromium. Reportedly, the alloy will be suited for jet engine components and high-stress parts as well as in marine and petrochemical machinery and equipment. The alloy was reported to have high corrosion resistance as well as high resistance to crevice corrosion and stress corrosion cracking in hostile environments. The alloy was designated Multiphase MP159 and contained 25.5% nickel, 35.5% cobalt, 19% chromium, 9% iron, 7% molybdenum, 3% titanium, 0.6% columbium and 0.2% aluminum.[10]

National Aeronautics and Space Administration (NASA) scientists reported the development of a nickel base (chromium free) superalloy having twice the strength of the strongest previously available cast nickel base alloy. Designated WAX-20, the alloy was composed of 17% to 20% tungsten, 6% to 7% aluminum, 1.4% to 1.6% zirconium, 0.1% to 0.2% carbon, with the balance nickel. The alloys melting point was reported as 2,375° F with a tensile strength of 20,000 pounds per square inch at 2,200° F.[11]

NASA scientists at the Lewis Research Center's Energy Conversion and Materials Science Section announced the development of a photographic film and processing procedure utilizing nickel in place of silver. The film, used in X-ray and electron beam photography, was insensitive to light. The image was reported to be comparable with those produced by the common silver-based photographic process.[12] General Electric engineers reported on the use of carbonyl nickel powder in the company's first fast-recharge, nickel-cadmium battery. The new batteries were capable of being recharged in less than 15 minutes at low cost compared with nearly 2 hours required by more costly and exotic cells used in space work. Reportedly, the nickel carbonyl permitted the formation of porous nickel battery plates, which was essential for controlling rapid recharging. The nickel-cadmium cells have a long discharge-recharge cycle life and remain viable when not in use. Company officials expect the cells to find use in home tools, two-way radios, medical instruments, photographic equipment, and standby power for lighting.[13]

Nitrogen

By William F. Keyes[1]

Production of fixed nitrogen (that is nitrogen in compounds) increased 2% in 1973. Production of elemental nitrogen continued to grow rapidly, increasing by 17% in 1973. Exports of fixed nitrogen increased 15% during the period and net exports increased from 363,000 to 539,000 short tons of contained nitrogen. Domestic ammonia plants produced at about 95% of capacity during the year and estimated consumption increased 5%. Plans to construct one ammonia plant were announced.

Table 1.—Salient nitrogen statistics

DOMESTIC PRODUCTION

Domestic production of anhydrous ammonia increased nearly 2% in 1973, while production of elemental nitrogen increased 17%. No new ammonia plants were brought into production during the year. Ammonia plants operated at 93% of capacity during the first 6 months of 1973 and at almost 98% of capacity during the last 6 months of 1973, according to The Fertilizer Institute.

Nitrogen is derived from air, and the chief raw material in the production of fixed nitrogen, as ammonia, was natural gas. Local shortages of natural gas caused some curtailment of ammonia production during the year. A survey by The Fertilizer Institute showed that plant days lost because of gas interruption were 605 in 1970, 773 in 1971, and 1,317 in 1972.[2] Industry estimates to the U.S. Department of Commerce in the fall of 1973 indicated a probable loss of 382,000 tons in the 1973–74 fertilizer year. Later estimates cut this figure to 231,000 tons.[3]

Agrico Chemical Co. announced plans to build an ammonia plant with a capacity of 425,000 tons annually to be located on the Verdigris River east of Tulsa, Okla. The plant was to cost $46 million, including a 600,000-ton urea ammonium nitrate solution plant. The complex was scheduled to be in operation in 1975.[4]

W. R. Grace & Co. announced that it would construct a $17 million urea production facility at its Memphis, Tenn., complex. The new facility will have a capacity of 350,000 tons per year when it reaches full production late in 1975 and will replace Grace's current 138,000-ton-per-year Memphis urea facility.[5]

CF Industries, Inc. awarded a contract for a 1,000 short-ton-per-day urea plant at Donaldsonville, La., having settled a dispute over noise pollution.[6]

The urea ammonia facility at St. Helens, Oreg., formerly operated by the Shell Chemical Co. was reopened by Reichhold Chemicals Inc. after having been closed the previous year by Shell.[7]

Phillips Petroleum Co. was expected to close its Cactus Ammonia Plant at Etter, Tex., on Nov. 1, 1973. The plant, which was one of the oldest in the United States was reportedly closed because of mounting costs of operation due to obsolete design.[8]

Plans to construct an air separation plant with an initial capacity of 270 tons per day were announced by Union Carbide Corp. The plant to be located in Garland, Tex., will produce liquid oxygen, nitrogen, and argon and should be onstream by late 1974. Cost will exceed $3 million.[9] A seventh 1,200-ton-per-day plant, to produce high-purity oxygen, nitrogen, an argon at its atmospheric gas complex in East Chicago, Ind., was also announced by Union Carbide.

An air separation facility with a capacity to produce 250 tons per day of oxygen, nitrogen, and argon was to be built by the Industrial Gases Division of Chemitron Corp. near Toledo, Ohio.[10]

Industrial Gases Division of Airco Inc. planned to construct a 400-ton-per-day air separation plant in the Albany, N.Y., area.[11]

Three new industrial gas plants were announced by Air Products & Chemicals Inc. Each will have a capacity of 300 tons daily. They will be located near Toledo, Ohio, Albany, N.Y., and Tulsa, Okla., and will have a combined liquid production capacity in excess of 325,000 tons per year.[12]

The Chemitron Corp. was constructing a $5 million air separation plant to produce 150 tons per day of oxygen, nitrogen, and argon.[13]

CONSUMPTION AND USES

Domestic consumption of fixed nitrogen increased 647,000 tons or about 5% in 1973 compared with 1972 consumption.

Fertilizers were the major use of fixed nitrogen. Approximately three-quarters of the production was used for this purpose. Other uses of nitrogen compounds were in explosives, resins, fibers, animal feed, and plastics.

The two major uses of elemental nitrogen were to exclude air from industrial processes and, in liquid form, to provide low temperatures in food processing and scientific applications. It is estimated that 18% of elemental nitrogen use was in cryogenics.

PRICES

Prices of the major nitrogen compounds remained stable during the year until phase IV controls on fertilizers were lifted by the Cost of Living Council (COLC) in October. It was explained by the COLC that while producers could not justify price increases by COLC guidelines, needed fertilizer was being attracted abroad by higher prices. After exemption of fertilizers, prices of ammonium nitrate, anhydrous ammonia, urea, and diammonium phosphate increased strongly while imported and domestic sodium nitrate prices remained steady, as did the price of ammonium sulfate.

Table 5.—Price quotations for major nitrogen compounds in 1973

(Per short ton)

Compound	Jan. 1	Dec. 31
Ammonium nitrate, domestic, fertilizer-grade, 33.5% nitrogen, bulk, delivered	\$47–\$49	\$47–\$78
Ammonium sulfate, standard-grade, commercial, bulk, f.o.b. works	--	15–25
Anhydrous ammonia, fertilizer, wholesale, tanks, delivered east of Rockies, except East Coast	55–65	60–110
Aqueous ammonia, 29.4% NH_3, anhydrous basis, tanks, freight equalized, east of Rockies	65–70	76–79
Delivered east coast	60–65	60–65
Sodium nitrate, domestic, agricultural, bulk, carlots, f.o.b. works	51.50	51.50
Bags, carlots, f.o.b. works	55.50	55.50
Sodium nitrate, imported, commercial, bulk, carlots, f.o.b. Atlantic and Gulf warehouses	51.50	51.50
100-pound bags, carlot, same basis	55.50	55.50
Urea:		
Industrial, 46% nitrogen, bulk, 50-ton carlots, delivered East	64–76	75–107
Agricultural, 46% nitrogen, bulk, same basis	62–63	73–107
Agricultural, 45% nitrogen, bulk, 50-ton carlots, delivered East	60–61	72–104
Diammonium phosphate, fertilizer grade, 18-46-0, bulk, carlots, f.o.b. Florida works	55–66	75–110
Bags, same basis	61–73.50	--

FOREIGN TRADE

Exports of fixed nitrogen increased 15% in 1973, in terms of nitrogen content, while the value of exports rose 43%. A strong increase was registered in exports of ammonium phosphates which rose 23% in volume and 50% in value. Ammonium phosphates accounted for 59% of the value of fixed nitrogen exports. Urea exports decreased 15% in volume and increased 31% in value compared with 1972. Urea accounted for 10% of the total value of fixed nitrogen exports.

Imports of fixed nitrogen increased 2% in nitrogen content and 17% in value. Most of the increase was accounted for by larger imports of urea. Imports of sodium nitrate, all from Chile, declined 39% in 1973, continuing the decline registered the previous year.

WORLD REVIEW

In recognition of an approaching shortage of nitrogenous fertilizers, plans were announced, and in certain cases construction started on numerous plants to produce the basic material, ammonia, for these products. The People's Republic of China, the U.S.S.R., and India were active in this regard, as well as other countries, particularly those with a ready supply of natural gas.

Angola.—A plan was announced to build a 230,000 short-ton-per-year ammonium sulfate plant as well as other plants for sulfuric acid and superphosphate. A fertilizer plant with a capacity of 250,000 short tons per year was also planned for the Caala region and was expected to be onstream in 1976.[14]

Bahrain.—A project to establish a nitrogenous fertilizer plant to produce 500,000 short tons per year, costing around $115 million, was under study by an Indian technical team.[15] The project would include a 1,100-short-ton-per-day ammonia plant and a 1,650-short-ton-per-day urea facility.

Bangladesh.—A credit of $80 million to construct a new 220,000-short-ton-per-day ammonia plant at Chittagong was authorized by the Indian Government.[16]

Bolivia.—Yacimientos Petrolíferos Fiscales Bolivianos (YPFB) has reached agreement with Yacimientos Petrolíferos Fiscales de Argentina to build a 1,100-short-ton-per-day ammonia plant and a 1,650-ton urea plant, probably at Santa Cruz. The plants will use domestic natural gas.[17]

Brazil.—Petrobrás Química S.A. awarded a contract to Kellogg International Corp. for the design and engineering of a 1,000-

[17] Nitrogen (London). No. 86, November—December 1973, p. 14.

ton-per-day ammonia plant and an 880-ton-per-day urea plant to be built at Camacari, Bahia. Cost of the project was estimated at $60 million and initial production was expected in 1975. The natural gas feedstock will be supplied by Petróleo Brasileiro S.A. from nearby gasfields.[18]

A 1,100-short-ton-per-day ammonia plant, with a 660-ton urea plant, was announced for Rio Grande do Sul State. A new company, Cia Rio Grandense de Nitrogenados S.A., with a 51% participation by the State government, was to operate the ammonia facility.[19]

Canada.—The calcium cyanamide plant of Cyanamid of Canada Ltd. was shutdown after having operated since 1907. Demand for the product as fertilizer had decreased. Other factors, including new technology, increased power costs, and environmental considerations, contributed to the closing.[20]

Allarco Chemicals Ltd. planned to build a 1,100-ton-per-day ammonia plant, with a 1,650-ton-per-day urea plant, at Medicine Hat, Alberta.[21]

Brockville Chemical Industries, Ltd. announced plans to build and operate a 500-ton-per-day plant costing $4 million to produce nitric acid at Maitland, Ontario. The plant was scheduled for startup during the second quarter of 1975. It will raise the productive capacity at Maitland to 1,000 tons per day.[22]

China, People's Republic of.—In the first sale of its kind by a U.S. firm, three 1,100-short-ton-per-day ammonia plants were ordered from the M. W. Kellogg Co. of Houston, Tex. The plants will use natural gas feedstock and the total cost was estimated at more than $70 million. Two ammonia plants sold earlier in the year to the People's Republic of China by Toyo Engineering of Japan also were to use Kellogg's ammonia process.[23]

A Kellogg affiliate, Kellogg Continental (Amsterdam) signed a contract to design, supply materials, and erect five 1,620-ton-per-day urea units. Total cost was estimated at about $55 million. This sale supplemented an earlier contract for three identical plants valued at $37 million. The first unit was slated for startup in late 1976.[24]

Egypt, Arab Republic of.—An agreement was reached between the Egyptian Industrialization Authority, the World Bank, and the Arab Development Fund for constructing a nitrogenous fertilizer plant in the Nile Delta area. The unit, located at Talcha, will have a capacity of 630,000 short tons per year. It is expected to supply the entire nitrogenous fertilizer requirements of lower Egypt.[25]

Hungary.—A 1,100-ton-per-day ammonia plant, being constructed at Pét, was scheduled for commissioning in 1975.[26]

India.—The capacity of the ammonia plant being constructed by Mangalore Chemicals and Fertilizers is to be increased from the originally planned 240,000 short tons per year to a total of 565,000 tons per year. Including additional investment in mixed fertilizers, the total investment was expected to be $150 million in addition to the original $75 million.

The Indian government was planning a 990-short-ton-per-day ammonia plant based on coal. This would be linked to a 1,390-short-ton-per-day urea plant. The technology was expected to be similar to that installed by the contractor, Imperial Chemical Industries, Ltd., at a coal-based urea plant in the Republic of South Africa. In addition, three public sector coal-based urea plants were being constructed in India; at Talcher (Orissa), Korba (Madhya Pradesh), and Ramgundam (Andhra Pradesh).[27]

A new 1,000 short-ton-per-day ammonia plant based on fuel oil was to be built at Nongal, Punjab; a contract for design and construction was signed with Friedrich Uhde GmbH, of West Germany.[28]

Iran.—The Shahpur Chemical Co. awarded Krebs et Cie. a contract to expand their urea plant from 500 to 700 tons per day.[29]

Iraq.—A large fertilizer production complex based on natural gas will be built

at Basrah by the Ministry of Industry under a contract awarded to Mitsubishi Heavy Industries. A urea plant, with a capacity of 1,430 short tons per day, and an ammonia plant, with a capacity of 880 tons per day, will be included in the complex, the total cost of which was estimated to be over $100 million.[30]

Ireland.—The State-sponsored fertilizer company, Nitrigin Eireann Teoranta (NET), announced plans to build a $50 million plant for processing ammonia from natural gas or naphtha in the Cork Harbor area. The capacity of the plant will be 1,100 short tons of ammonia per day. It will employ 350 people and production is expected to start in 1977. If natural gas becomes available from the Irish offshore area, the gas will be used in the plant, although the plant is designed initially to use naphtha as a raw material. Of the total production, about one-third will be exported, one-third will be used at NET's fertilizer plant at Arklow, County Wicklow, and the balance will be processed on the site to manufacture about 500 tons per day of urea.[31]

Italy.—An ammonium nitrate plant with a capacity of 1,100 short tons per day was under construction at the Azienda Nazionale Idrogenazione Combustibili S.p.A. petrochemical complex at Ravenna. The plant is scheduled to begin production at the end of 1974.[32]

Korea, Republic of (South).—As part of its third 5-year plan (1972–76), Korea will build a second petrochemical complex and a $181 million fertilizer operation at Yosu on the southern coast. The complex will include an ammonia plant with a capacity of 550,000 short tons per year, a urea plant with a capacity of 250,000 tons per year, and capacity for 17,000 tons per year of ammonium nitrate. All the fertilizer units will be owned by Korea Integrated Chemicals, a joint venture of Honam Fertilizer and the Korean Government.[33]

The sixth large fertilizer plant at Chung Ju came into operation. The capacity of the new plant is 330,000 short tons per year of ammonia and 255,000 tons per year of urea. The plant which used naphtha feedstock was built with the help of a foreign consortium consisting of the U.S. Agency for International Development, Barclay's Corp., and the Mitsubishi Industrial Group.[34]

Libya.—A 1,100-short-ton-per-day ammonia plant was to be built at Marsa el Brega for Libya's National Oil Corporation. A contract for supply of the plant and offsites was placed with Friedrich Uhde GmbH of Dortmund, West Germany. The plant is due onstream in 1976.[35]

Pakistan.—A urea ammonium phosphate plant will be designed and supplied by Sim Chem, a division of Simon-Carves, for the Pakistan Fertilizer Co., Ltd., at Karachi. The design capacity is 220,000 tons per year and the plant will be financed through a World Bank loan.[36]

The Pakistan Industrial Development Corporation issued a tender for the design and engineering of a fertilizer complex to be built at Multan. It was to include a 1,000-short-ton-per-day ammonia plant.[37]

The National Fertilizer Corp., owned by the Government of Pakistan, decided to build a second major nitrogenous fertilizer plant beside the present plant at Multan. The project will include a 1,000-short-ton-per-day ammonia plant, two nitric acid plants of 660-short-ton-per-day capacity each, one 1,120-ton-per-day prilled nitrophosphate plant and one 1,600-ton-per-day prilled ammonium nitrate plant. The engineering and procurement contract for the ammonia plant was awarded to Kellogg International Corp. Total cost of the entire expansion was expected to be $100 million, approximately $75 million of which will be foreign exchange cost provided by the Asian Development Bank, the World Bank, and the Abu Dhabi National Oil Co. The latter will obtain 30% of the share capital.[38]

Romania.—Expansion of the Azotul Four ammonia unit at Piatra Neamt was completed. The additional capacity will increase nitrogen fertilizer output by 140,000 tons per year.[39]

Spain.—A 330,000-short-ton-per-year am-

monia plant and a 180,000-short-ton-per-year urea plant were under construction by Unión ExplosivosRio Tinto S.A. at Seville. The plants were expected to be completed in 1975.[40]

A $4 million contract for the engineering, procurement and construction of a 330-short-ton-per-day urea plant at Malaga was awarded by Amoniaco Español S.A. to McKee-CTIP Ingenieros of Madrid. When the plant is completed in September 1974, it will produce urea prills for direct use as fertilizer.

Sudan.—The Sudanese Government awarded a $60 million contract to a subsidiary of Compagnie Française des Petroles covering the installation of a plant to produce 440 short tons per day of ammonia and 740 tons per day of urea. Naphtha feedstock was expected to come from a nearby refinery owned by the British Petroleum Co., Ltd. and the Royal Dutch/Shell group.

Taiwan.—A 330,000-short-ton-per-year ammonia plant and a 110,000-ton urea plant were expected to be built by Taiwan Fertilizer Co. at Miaoli.[41]

Trinidad and Tobago.—A project for two-phase construction of a 1,200-ton-per-day ammonia plant, followed by another ammonia unit of the same size and a 3,000-ton-per-day methanol plant was announced. The project will be a fifty-fifty joint venture between W. R. Grace & Co. and the National Petroleum Co., which is controlled by the Trinidad-Tobago Government. The first phase of the project will cost an estimated $50 million and should be in operation in 1976. The second phase will cost $80 million. Natural gas for the plant will be supplied from offshore gas wells. The product will be marketed in the United States, Europe, and South America.[42]

Turkey.—An air separation plant, with a production capacity of 600,000 cubic feet per day of gases, including nitrogen, argon, helium, and acetylene, was opened by Anatolian Industrial Gas at Izmit, near Istanbul.[43]

An ammonia urea complex was also to be built in the Izmit area for Igsas Istanbul Gubre Sanayii A.S. Some 1,100 tons per day of ammonia and 1,100 tons per day of urea will be produced starting late in 1975. Design, construction, and procurement will be carried out by the firm of Friedrich Uhde GmbH. The project is financed in part by a $24 million loan from the International Bank for Reconstruction and Development.[44] Total cost was estimated at $57 million.

U.S.S.R.—A 20-year barter arrangement for the joint production and sale of fertilizers was signed by Occidental Petroleum Corp. of the United States and the Soviet Government. Occidental was to contract for building several ammonia and urea plants in the U.S.S.R. and to supply 1 million tons per year of superphosphoric acid. In return the Soviet Government would supply up to 1 million tons of potash, 1 to 1.5 million tons of urea, and 3 million tons per year of ammonia to Occidental, which would market it in the United States. Total value of the deal was estimated at $8 billion. The ammonia complex would be built at Kuibyshev, southeast of Moscow.[45]

A contract for the construction of seven chemical plants in the Soviet Union was awarded to the Italian firm, Montecatini Edison S.p.A. Included will be two ammonia plants, each of 550,000-short-ton-per-year capacity, and one urea plant, also of 550,000-short-ton-per-year capacity.[46]

TECHNOLOGY

The sulfur-coated urea (SCU) product developed by the Tennessee Valley Authority was intensively studied during the year. Application of molten sulfur was found to be superior to the previous dry application to coat the urea. Improvements included better coating efficiency and uniformity, less dust and mist formation, simplified coating drum design, and decreased requirements for preheating the urea. SCU was originally produced with a sealing coat of wax over the sulfur. During the year progress was made in eliminating the wax coating when desired. It was found that SCU was more effective in rice cultivation where the fields are alternately flooded and drained as in developing nations where water supplies are inadequate. SCU maintains its slow release characteristics. Furthermore, it has the advantage of supplying nitrogen in the ammonium form which suffers less from leaching and volatilization than the nitrate form.[47]

[47] National Fertilizer Development Center, Tennessee Valley Authority. 1973 Annual Report, pp. 3 and 5.

The detection of atmospheric nitrogen compounds, including low concentrations of nitrogen oxides, is of considerable interest in determining air quality. A method of detecting these compounds by flame chemiluminescence was described.[48] A hydrogen-rich oxyhydrogen flame was used as the medium for excitation of characteristic nitrogen bands. The emission observed in the reaction between atomic hydrogen and NO was viewed photometrically. The detection limit was 0.150 parts per million for nitrogen oxides. Sulfur dioxide was also detected in concentrations of 0.004 parts per million.

A method was proposed for analyzing nitric oxide-nitrogen dioxide mixtures by reacting them with iron in sulfolane. The sensitivity of the method is only moderate but it appears to have potentialities for the analysis of grab samples collected at NO_x emission sources.[49] It was reported that nitric oxide can be measured in an air sample with a new laser magnetic resonance device developed by the National Bureau of Standards. The Zeeman effect, a split of molecular energy levels under a magnetic field, is particularly pronounced for nitric oxide at a wave length of 5.307 micrometers. No other contaminant exhibits this effect at this frequency.[50]

NO_x abatement from flue gases in Japan was described.[51] Japanese environmental emission and control standards and measurement methods were covered. Thirteen processes were described for NO_x abatement from waste gases. Two promising developments were a new type of burner for combustion modification and catalytic reduction for NO_x removal from flue gases.

The Arbiter process was developed by The Anaconda Company and a plant to produce 100 tons per day of copper product was under construction at the Anaconda, Montana smelter. The process, which is pollution-free, was essentially an ammonia leach using oxygen but requiring no pressure or elevated temperature. It was claimed that the process can treat lower grade and highly pyritic concentrates such as those from old tailings.[52] The plant was estimated to cost $22 million and will produce 36,000 tons per year of copper. This investment cost was estimated to be about 60% of the investment for a conventional smelter of equivalent capacity.

Peat

By Eugene T. Sheridan [1] and Donald P. Mickelsen [2]

Peat production in the United States increased 10% in 1973, principally because of greater output at several of the larger operations. Although the number of active plants decreased by 5, production increased in 13 States. The largest production gains were recorded in Michigan, Indiana, Pennsylvania, Washington, and South Carolina.

Commercial sales of peat were 2% higher than in 1972, but the total value of peat sold, f.o.b. plant, rose 6% as the average value of all peat sold in 1973 increased $0.44 per ton.

Imports increased 4%, and the quantity of peat imported in 1973 was about one-half the quantity produced domestically. Ninety-five percent of the peat imported was shipped from Canada.

World production was estimated at 106.5 million short tons. The U.S.S.R. was the largest producer with an output estimated at 96 million tons, 90% of the world total.

[2] Statistical assistant, Division of Fossil Fuels —Mineral Supply.

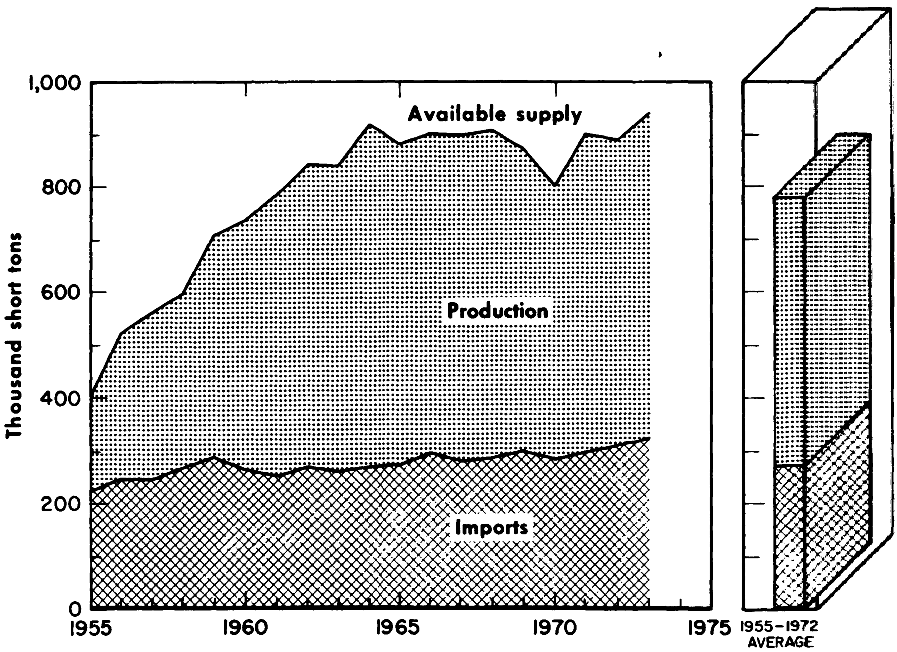

Figure 1.—Production, imports, and available supply of peat in the United States.

DOMESTIC PRODUCTION

The 58,000-ton increase in production resulted mainly from a larger output of humus. Of the reported total production, about one-half was reed-sedge peat, whereas the remainder was about equally divided between moss peat and humus.

Peat was produced in 22 States in 1973. Michigan remained the largest producer, with about one-third of the Nation's output. Illinois, Indiana, New Jersey, Florida, and Pennsylvania followed in output in the order named. These States, with Michigan, had three-fourths of the total production.

Active operations decreased from 103 to 98, but average output per plant increased 16% to 6,475 tons. Three-fourths of the operations, however, had outputs smaller than the average. Only 28 plants had production in excess of 5,000 tons, and only 6 plants produced more than 25,000 tons.

Roughly one-third of the peat was sold as produced with no processing other than air drying. Most of the remainder was shredded, and a small quantity was subjected to thermal drying.

CONSUMPTION AND USES

Commercial sales and imports both increased in 1973, and the amount of peat available for consumption was about 3% greater than in 1972.

Peat was used for a variety of purposes, but 87% of total commercial sales reported by producers was for general soil improvement. Among the principal markets for this peat were nurseries and greenhouses, which used peat as a mulch and a medium for growing plants and shrubs; landscape gardeners and contractors, who used peat for building lawns, golf course greens, and for transplanting trees and shrubs; and garden, hardware, and variety stores, which sold peat to homeowners for mulching and for improving lawn and garden soils. Most of the remaining peat was sold for use in potting soils and for packing flowers and shrubs, but small quantities were used in mushroom beds and mixed fertilizers, and for earthworm culture and seed inoculant.

Fifty-eight percent of the tonnage of peat sold commercially by producers was packaged. Packaged peat, however, accounted for more than two-thirds of the total value of sales. Of the total peat sold in packages, about two-thirds was reed-sedge peat, about one-fifth was moss peat, and the remainder was humus.

States leading in sales of packaged peat were Michigan, Illinois, and Indiana, which, together, reported 80% of the total sales of packaged peat. Michigan was the largest producer of packaged peat with 56% of the total sales.

PRICES AND SPECIFICATIONS

Prices of peat at individual operations varied greatly in 1973, with the price depending mainly upon the kind of peat sold, the amount of processing, and whether the material was sold packaged or in bulk.

The overall average value per ton, f.o.b. plant, for all peat sold in 1973 was $12.16. This was an increase of $0.44 per ton over the average value of 1972. The bulk of the increase was attributed mainly to higher average receipts for peat sold by producers in Minnesota, Illinois, and Iowa.

The average price of bulk peat increased $0.65 per ton to $8.84. Packaged prices, however, decreased an average of $0.11 per ton to $14.57. The average price for bulk peat was influenced mainly by higher overall prices for bulk sales by producers in Florida, New Jersey, Indiana, and Pennsylvania. The decline in the unit value of packaged peat was attributed to generally smaller receipts for each ton of packaged peat sold by Michigan producers.

In a few instances, producers did not report the value of the peat they sold, and a value was assigned to their sales that was based upon the average value of peat sold within the State.

Imported peat had a total value of $18.8 million. The total value of imported peat was 9% greater than in 1972, partially because there was 13,000 tons more peat imported but, also, because the average value per ton increased from $55.30 to $58.00.

Although the average value of imported peat was over four times that of domestically produced packaged peat, their values are not comparable because they are assigned at different marketing levels. Also, imported peat has different physical properties than most of the domestic peat, and it usually is sold on a volume basis rather than by weight. Each 100 pounds of a typical air-dried imported peat will measure approximately 12 bushels, whereas the same quantity of a typical domestic peat will measure 3 to 4 bushels. Only a few domestic operations produced peat with properties similar to those of the imported kind.

Peat is broadly classified in the United States as moss peat, reed-sedge peat, and humus, according to the materials from which it has been formed and its degree of decomposition. Moss peat is a type that has been formed principally from sphagnum, and/or other mosses; reed-sedge peat has originated mainly from reeds, sedges, and other swamp plants; and humus is peat too decomposed for identification of its biological origin.

FOREIGN TRADE

The quantity of peat imported into the United States in 1973 totaled 324,000 short tons. This was 4% more peat than was imported in 1972 and the largest quantity imported in any year to date.

Canada provided the bulk of the imports, supplying 95% of the total peat imported. Virtually all of the remaining foreign peat was supplied by Europe.

European shipments increased 44% principally because of substantially larger shipments from West Germany. West Germany supplied 96% of the peat imported from Europe.

Imported peat was classified according to use as poultry- and stable-grade peat and fertilizer-grade peat. Of the total imported, 98% was fertilizer-grade peat. Except for a duty of $0.50 per long ton levied on poultry- and stable-grade peat from communist countries, there is no tariff on peat.

Foreign peat entered the United States through 29 customs districts in 1973, but 84% of the total was shipped through the Buffalo and Ogdensburg, N.Y.; Detroit, Mich.; Pembina, N. Dak.; St. Albans, Vt.; and Seattle, Wash., customs districts. The largest quantity, 90,000 tons, was shipped through the Ogdensburg district.

WORLD REVIEW

World production of peat in 1973 was estimated at 106 million short tons, 8% less than the revised output reported for 1972.

The U.S.S.R. was by far the largest peat producer with an estimated 90% of the world production. According to published U.S.S.R. figures, 30 million tons of peat was produced by State enterprises for agricultural use, and an estimated 66 million tons was produced for fuel. Agricultural peat was used for general soil improvement and the manufacture of fertilizers, and fuel peat was used for generating electric power and for domestic and industrial heating.

Ireland ranked second in peat production with an estimated output of 6 million short tons. Virtually all of Ireland's production was fuel peat that was used for generating electric power and for heating households. A small amount of agricultural peat was produced, principally, for export.

West Germany, the third-ranking peat producer with 1.9 million short tons, provided about 2% of the world output. Most of the West German production was agricultural peat, with less than one-fifth consumed as a fuel.

Other producers ranking in output in the order named were the United States, the Netherlands, Finland, and Canada. The combined output of these countries was, however, only 2% of the total. Although fourth in world production, output of the United States was only 0.6% of the world total.

[1] In addition to the countries listed, Austria, Canada, Iceland and Italy produce a negligible quantity of fuel peat. No data are available for East Germany, a major producer.

TECHNOLOGY

Experimental research conducted at the University of Sherbrooke, Quebec, Canada,[3] indicated that peat moss, being a highly porous material, can be used as an adsorbing agent for the treatment of polluted water. In one study, moss peat was tested for its adsorbing power for beef extract and an alkyl benzene sulphonate (ABS) solution, contaminants sometimes found in municipally polluted water. Studies on the effects of time of contact, particle size, and concentration of pollutants in adsorption revealed a chemical oxygen demand (COD) reduction of around 27% for beef extract, and 72% to 95% for the ABS solution. The proposed water treatment process would filter polluted water through columns of peat moss to produce a relatively clean water. The peat then, if not toxic, could be used as a fertilizer, formed into building materials, or dewatered and burned.

Field and laboratory studies, also conducted by the University of Sherbrooke[4] have shown that peat moss can be used as an absorbing agent for oil recovery. Laboratory measurements indicate that peat moss has a stronger affinity for oil than straw, the absorbent presently being used for oil spill cleanup. Tests proved that peat moss, because of its highly porous and fibrous nature, can absorb up to eight times its own weight in oil. Field experiments were conducted at actual oil spill sites where, it was found, that peat moss spread before a vertically placed screen, acting as a boom, would easily stop an oil patch. Field tests also proved peat moss to be effective in beach cleanup when, spread on the beach and picked up with rakes, it removed at least 95% of the oil. It is indicated from field and laboratory studies that peat moss is a very effective absorbent for oil cleanup.

Additional research work at the University of Sherbrooke[5] evaluated the use of peat as a building material. Peat, when mixed with portland or other cements, produces a lightweight concrete, which is a good thermal and sound insulator. Through research, a process was developed for fabricating a material called peatcrete. Peatcrete is produced by first screening the peat through a No. 4 seive for better cohesion, then mixing with the cement. The best cement, water, peat mixture was found to be 1:2:2. After mixing, the peat/cement mixture was compacted into cylinders under a pressure of 18 pounds per square inch for 24 hours, after which the cylinders were dried at a temperature of 120° F. for 7 days. The resulting peatcrete had a compressive strength of 250 pounds per square inch and was very light, having a specific gravity of between 0.05 and 0.07. The peatcrete was cohesive enough to be sawed, drilled, nailed, and otherwise worked without disintegrating or splitting. Research is continuing into the development of industrial fabrication of peat-cement panels.

Perlite

By Arthur C. Meisinger [1]

The quantity of crude perlite sold or used in 1973 fell short of the record 545,000 tons established in 1972; however, the 544,000 tons sold or used in 1973 was obtained from a record quantity of 759,000 tons of crude perlite mined. Value of crude perlite sold or used in 1973 was 10% less than the record value set in 1972.

Compared with 1972 production, expanded perlite was produced at six fewer plants, but the quantities produced and sold or used declined only 3,000 tons and 3,500 tons, respectively. The value of expanded perlite ($28.0 million) in 1973 was also just under the record total of $28.4 million set in 1972. New Mexico and Illinois continued to be the leading States in production of crude and expanded perlite, respectively.

r Revised.

DOMESTIC PRODUCTION

Production of crude perlite in 1973 was reported by 11 companies in 7 States. Twelve mines were in operation compared with 13 mines in 1972. A record quantity (759,000 tons) of crude perlite was mined and surpassed the previous record quantity of 1972 by 110,000 tons. New Mexico continued to be the principal producing State with 89% of the U.S. crude perlite mined. Other producing States, in descending order, were Arizona, California, Nevada, Colorado, Idaho, and Texas.

The quantity of crude perlite sold or used to make expanded perlite products in 1973 was only 911 tons under the record total of 545,000 tons established the previous year. Value of crude perlite sold or used, however, declined 10% from the record value of $6.2 million in 1972.

Crude perlite was expanded at 76 plants in 30 States in 1973. The quantity of expanded perlite produced was 424,000 tons, compared with 427,000 tons in 1972. The value of expanded perlite also declined slightly from the record 1972 value of $28.4 million; value of expanded perlite sold and used in 1973 was $28.0 million.

The leading State in production of expanded perlite was Illinois. Other States with significant production in 1973 were California, Colorado, Florida, Indiana, Kentucky, Mississippi, New Jersey, Pennsylvania, and Texas.

[1] Included with "Other States."
[2] Includes Colorado, Georgia, Idaho, Illinois, Iowa, Kentucky, Louisiana, Maine, Maryland (1972 quantity produced only and 1973), Massachusetts, Michigan, Minnesota, Mississippi, Missouri (1972), Nebraska, Nevada, New Hampshire, New Jersey, Oregon, Tennessee, Utah, and Wisconsin.

CONSUMPTION AND USES

Domestic consumption of expanded perlite was nearly 417,800 tons in 1973—only 3,500 tons below the record 421,300 tons consumed in 1972. The percent disposition of expanded perlite in the United States is shown in table 3. Filter aid, plaster and concrete aggregates, formed products, and insulation board (included with "Other" uses) were the principal domestic uses of expanded perlite. Compared with that of 1972, use of expanded perlite in filter aids increased 3%, and use in horticultural aggregates increased 2%. Decreases in expanded perlite for plaster aggregate, concrete aggregate, and low-temperature insulation were 2%, 1%, and 2%, respectively. Other uses totaled 46% and included primarily insulation board, and lesser uses such as paint textures, foundry castables and bonding agents, polishing compounds, and miscellaneous industrial and agricultural products.

[2] Included with "Other" to avoid disclosing individual company confidential data.
[3] Includes insulation board.

PRICES

Producers sold crushed, cleaned, and sized crude perlite to expanding plants at an average price of $11.64 per short ton in 1973, and the portion used by producers in their own expanding plants was valued at an average of $9.21 per ton. The weighted average of both categories was $10.28 per ton—a decrease of $1.16 from the 1972 price.

Expanded perlite sold or used, according to expanders, had an average value of $67.02 compared with $67.40 per ton in 1972. However, average values by States in 1973 ranged from $34 to $151 per ton.

WORLD REVIEW

Greece.—Data on perlite production in 1973 were not available; however, the quantity of crude perlite produced in 1972 was approximately 136,500 tons—a decrease of 20% from the 171,300 tons (revised) reported in 1971. Although crude perlite production in Greece declined in 1972 for the second consecutive year, the quantity of perlite screened and sized (120,300 tons) in 1972 for export increased over that (104,500 tons) produced in 1971.

The country's largest perlite producer, Silver and Barytes Ores Mining Co., Athens, announced plans to enlarge its perlite facilities on the island of Milos with the construction of a new crushing and screening plant at Vouthia Bay. The current plant has a capacity of about 150,000 tons per year. The new plant is expected to increase graded perlite capacity to around 350,000 tons per year by 1975. Crude perlite reserves of Silver and Barytes Ores on Milos was estimated to be 150 million tons.[2] The company also has a small perlite-expanding plant (2,000 tons per year) in Athens that largely supplies expanded perlite for markets in Greece.

Other producers of crude perlite in Greece are N. Buras and Co. with deposits on Kos, and L. K. Sarides Mining Enterprises S. A. The latter company started mining on Milos in 1972 and reportedly shipped 7,000 tons of crude perlite in 1973.[3] The company's mines are at Tsigrado and Vounalia.

Hungary.—Production of crude perlite in Hungary was last reported in 1971 as 67,100 tons. No data were available for 1973, but production has probably averaged 70,000 tons or better for the last 2 years. Production estimates were based on increasing exports and research interest by Hungary in developing new uses for expanded perlite.

Crude perlite from the open pit mine at Pálháza, northern Hungary, was preheated and mixed with bitumen at the Tapolca insulation material plant in 1973. The new insulation product (bituminous perlite) is reportedly resistant to decay and bacterial attack. The plant's production in 1973 was about 247,000 cubic feet.[4]

The Research Institute of the Silicate Industry in Hungary announced a process to produce foam-glass granules from ground crude perlite. The process, using conventional foam-glass techniques, produces a material that has a vesicular structure with high internal strength and low permeability. The foam-glass perlite granules, properly mixed with portland cement and water, reportedly produced an unusually strong lightweight insulation concrete. These lightweight concretes are commercially attractive because the lower permeability of foam-glass perlite granules, compared with expanded perlite, requires less water and up to 30% less cement in formulating.

Also in 1973, a new horticultural use of expanded perlite for propagating tree saplings was developed jointly by the Hungarian Perlite Institute and the Department of Forestry, Budapest University, Budapest, Hungary. The method consists of forming cold beds, about 5 feet wide and 1 to 1½ feet deep, that are filled with an 8- to 10-inch layer of perlite kept moist and enriched with a chemical fertilizer. Each 10.8-square-foot area of the perlite beds is reported to have the capacity of raising up to 2,200 seedbed plants.[5]

Philippines.—The quantity of crude perlite mined by the Trinity Lodge Mining Corp. in 1973 was 909 tons, and represented a substantial increase over that produced in 1972.

Turkey.—Approximately 19,100 tons of crude perlite was produced in 1973, 43% less than the 33,500 tons produced in 1972. Producers and/or expanders of perlite in Turkey are Pabalk Ticaret Limited, Sirketi, Istanbul; Elyafli Çimento Sanayii ve Ticaret, A.S., Istanbul; and Etibank General Management, Ankara.

Crude Petroleum and Petroleum Products

By David A. Carleton,[1] William B. Harper,[2] Bernadette Michalski,[2] and Betty M. Moore [3]

CONTENTS

The United States petroleum industry experienced considerable change and development during 1973, occasioned by additional government involvement and a growing awareness among the public of petroleum industry dynamics. Principal events were the decline in U.S. liquid hydrocarbon production, widespread petroleum product shortages, dwindling inventories, an embargo by some Arab countries on exports to the United States, and substantial price increases. Government activities involved cessation of the mandatory import controls, decontrolling prices, establishing a two-tier pricing system, creating new allocation programs, adopting a new license-fee system to replace import duties, and the issuance of consumption-constraining legislation.

Crude oil production (including lease condensate), which totaled 9.2 million barrels per day (bpd) in 1973, was the lowest since 1968 and 3% lower than that of 1972. The decline resulted from the exhaustion of older fields and the absence of discoveries of new fields. At yearend, final permission was given to construct the Alaska pipeline. When completed, the line will permit production on the North Slope to increase initially by an estimated 600,000 bpd.

Domestic demand for petroleum products, which increased 5.4% during the year, was inhibited during late 1973, particularly by shortages and by conservation efforts. This was the second lowest rate of increase since 1964 reflecting, also, unusually warm winter weather. Domestic demand for refined products, which averaged 17.3 million bpd, might have fallen considerably short of this level had not demand been stimulated in early 1973 by the continued conversion of powerplants from high-sulfur coal use to low-sulfur residual fuel oil use. Further-

more, demand was up because of the substitution of petroleum products for a curtailed use of natural gas. In addition there were higher than normal additions to motor gasoline inventories, both at secondary levels and at the consumer storage level.[4]

The decline in domestic production of liquid hydrocarbons in 1973 made it necessary to meet with imports the rising demand for petroleum products. Imports which totaled 6.2 million bpd, a 30% increase from 1972 levels, consisted of about one-half crude oil and one-half finished and unfinished products. The Western Hemisphere continued as the principal source of imported oil, providing nearly two-thirds of the total.

Inventories of liquid hydrocarbons at primary storage facilities were well below those of 1972 untii near yearend, and throughout most of the year stock levels were of concern. At yearend 1973, however, stocks were equivalent to 58 days of domestic demand or virtually the same as a year earlier. It should be noted that roughly 20% to 30% of these stocks are either tank bottoms or pipeline fill, or are in other equipment in order to assure continuous operations, and are therefore unavailable for shipment.

The lone Federal offshore lease sale took place off Mississippi, Alabama, and Florida on December 20. Total high bids for the sale reached $1.5 billion as companies placed 373 bids on 89 of the 147 tracts available for leasing. The U.S. Department of the Interior also announced that it established lease-sale boundaries containing, for future sale, 6 million acres offshore California. Interior also announced that it plans to speed-up lease sales in areas offshore Alaska, California, Texas, and Louisiana. The California State Lands Commission lifted the moratorium on new oil-well drilling on State-owned offshore land.

Geophysical and geological exploration increased in 1973 as the outlook for petroleum exploration improved over previous years. According to the Hughes Tool Co., an average of 1,373 rotary rigs were active in 1973, the highest since 1966. However, according to the American Petroleum Institute (API), there were 26,592 exploratory and development wells drilled during the year, down 2.6% from the 1972 figures. Factors causing this decline were weather, lack of steel, shortages of drilling crews, and economic conditions.

The API estimated that reserves of crude oil declined for the third consecutive year as production withdrawals continued to outstrip additions to reserves. Reserves of 35.3 billion barrels, at yearend 1973 represented a reserves-to-production ratio for crude oil of 11:1 based on 1973 production. The largest single additions to reserves occurred in 1970 when Alaska's North Slope discoveries were included for the first time. Since World War II, reserves-to-production ratios have trended downward from a high of 13.6:1 in 1949 and to a low of 9.2:1 in 1969.

Refinery throughput capacity at yearend 1973 amounted to 14.2 million barrels per (calendar) day, up 3% from yearend 1972. Following the early 1973 discontinuance of import quotas on crude oil and petroleum products, many refiners announced expansion plans that could have increased throughput capacity by nearly 1.5 million bpd by the end of 1976. Most of the proposed new capacity was scheduled to use imported crude oil. However, at the close of 1973 many of these plans and other longer range projects were either cancelled or suspended because of the uncertainties of supply, characterized by the Arab oil embargo during the latter part of the year. Output of refined products from U.S. refineries accounted for only 75% of total demand for refined petroleum products in 1973. Only 35% of residual fuel oil demand was met with domestic refinery output.

---

[4] Certain terms as used in this chapter are more or less unique to the petroleum industry. Principal terms and their meaning are—

Total demand.—A derived figure representing total new supply plus decreases or minus increases in reported stocks. Because there are substantial secondary and consumers' stocks that are not reported to the Bureau of Mines this figure varies considerably from consumption.

Domestic demand.—Total demand less exports.

New supply of all oils.—The sum of crude oil production, plus production of natural gas liquids, plus benzol (coke-oven) used for motor fuel, hydrogen, and other hydrocarbons, plus imports of crude oil and other petroleum products.

Transfers.—Crude oil conveyed to fuel-oil stocks without processing, or reclassification of products from one product category to another.

All oils.—Crude petroleum, natural gas liquids, and their derivatives.

Exports.—Includes shipments to United States territories, possessions, and free trade zones.

Imports.—Includes receipts from United States territories, possessions, and free trade zones.

CRUDE PETROLEUM

PRODUCTION

Production of crude oil (including lease condensate) declined again in 1973, after recovering slightly in 1972. Total production of 3.36 billion barrels, nearly 9.2 million bpd, 3.0% less than that of 1972. The decline occurred in 18 of the country's 31 producing States. Of these, Louisiana had the greatest loss, 165,214 bpd or down 6.8% from 1972. Others with less production were Oklahoma, 45,011 bpd (—7.9%); California, 29,992 bpd (—3.2%); New Mexico, 26,134 bpd (—8.6%); Texas, 19,216 bpd (—0.5%); Mississippi, 13,693 bpd (—8.2%); and Illinois, 11,521 bpd (—12.1%).

Florida was the only State that recorded significant production gains. Output, mostly from fields in the northwestern part of the

State, averaged 89,575 bpd, up 43,282 bpd or 93.5% from that of 1972. Others with increased production during the year were Utah, up 16,674 bpd (22.9%); Wyoming, 5,214 bpd (1.4%); Colorado, 12,534 bpd (14.3%); Alabama, 4,775 bpd (17.6%); and Michigan, 4,449 bpd (12.5%).

The general decline in output resulted from the exhaustion of many of the older fields, lagging secondary and tertiary programs and the paucity of large discoveries to reverse significantly the declining productive capacity.

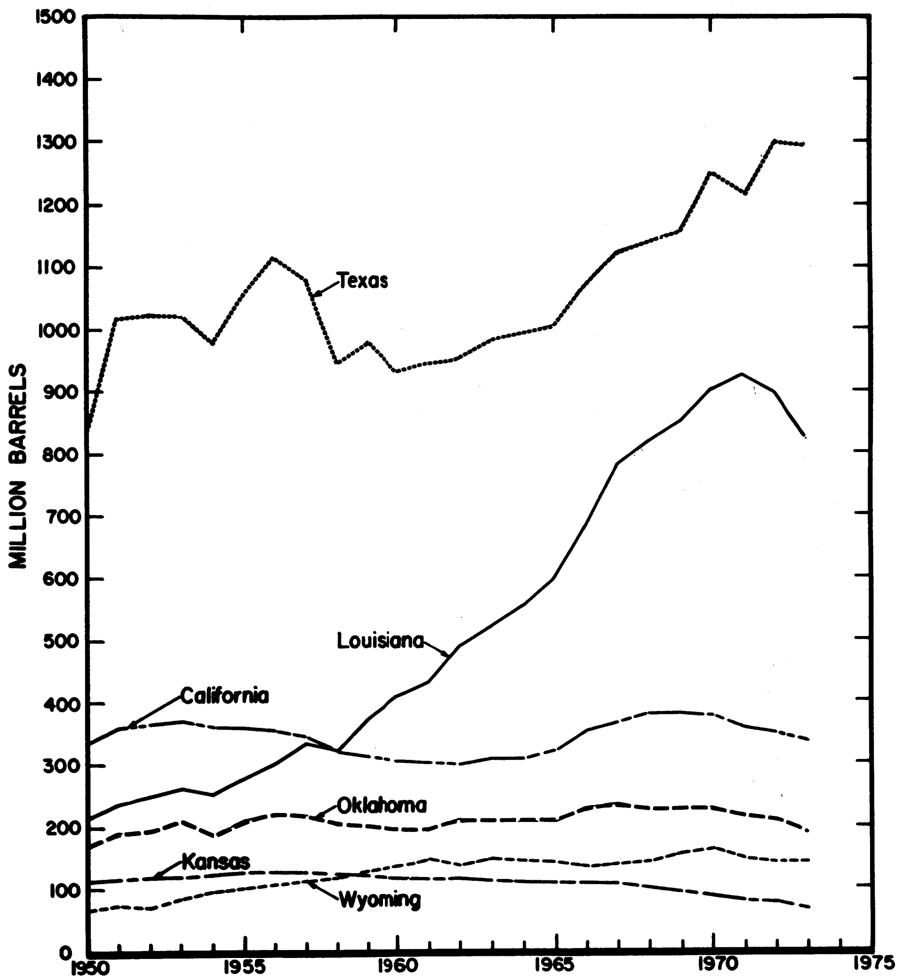

Figure 2.—Production of crude petroleum in the United States, by principal producing States.

CONSUMPTION

Refineries processed 4.5 billion barrels (12.4 million bpd) of crude oil, of which 74% was domestic crude and 26% was from foreign sources. The amount processed was 6% more than that refined in 1972 and represented 91.1% of the January 1, 1973, operable refining capacity of 13.6 million bpd. This was the second highest operating ratio in the past decade.

The highest average monthly operating

ratio was reached in June when 94.3% of the operable throughput capacity was in use. This was the highest monthly rate reached since December 1969 and the fourth highest in the past decade. Refinery input and operating ratios were at record levels during the spring of 1974, because of the summer motor gasoline shortage in 1973. Conversely, the ratio of input to operable capacity in December was among the lowest December operating ratios during the past decade. In December 1973 the government announced plans to allocate crude oil to all refiners at an input ratio of approximately 85% of throughput capacity, owing to the shortage resulting from the Arab embargo on oil shipments to the United States. These were scheduled for adaptation under the mandatory allocation program effective December 27.

PRODUCTIVE CAPACITY

According to the API the maximum crude oil output that could be attained in the United States as of January 1, 1974 was 9.7 million bpd. This was the lowest since 1960 and was 0.6 million bpd or 6% less than that on January 1, 1973. Texas and Louisiana suffered the greatest losses, declining a combined 0.3 million bpd. Colorado and Wyoming had the largest increases totaling 0.03 million bpd. These estimates were based on the assumption that such production could be achieved in 90 days with existing wells, well equipment, and present surface facilities, plus work changes that could be accomplished within that time. No productive capacity was credited to the North Slope of Alaska since there was no way to market the oil, and installation of producing and pipeline facilities were incomplete.

Although the United States had, for many years, a surplus productive capacity that could be called on to meet emergency needs, it became apparent in 1973 that the country no longer has an effective surplus capacity. Most of the surplus capacity is in fields in Eastern Texas.

DRILLING ACTIVITY

Although well completions were up in 1972 after several years of decline, well completions were down again in 1973. The success ratio improved, however, since 61% of the wells completed in 1973 yielded commercial quantities of either oil or gas, compared with 59% in 1972. In 1973, nearly 61% of the successful wells drilled were oil producers compared with 70% in 1972 and 88% in 1954. Of the States having considerable drilling activity, Ohio and California had the best success ratios, 89% and 78% respectively.

In December 1973, the California State Lands Commission ended a 4-year moratorium on new oil well drilling on State-owned offshore lands. The ban on offshore drilling was imposed after a well on federally leased land in the Santa Barbara Channel blew out on January 28, 1969. The lifting of the ban followed the completion of a report which emphasized that equipment and recovery systems not available in 1969 now made the possibility of a similar accident far less likely.

On December 20, the U.S. Department of the Interior held its lone 1973 offshore lease sale. Total high bids for the sale, which covered Federal lands off Mississippi, Alabama, and Florida reached $1.5 billion. Companies placed 373 bids on 89 of the 147 tracts available for leasing, exposing a total of $3.4 billion.

RESERVES

The API Committee on Petroleum Reserves estimated proved recoverable reserves of crude oil as of December 31, 1973, to be 35,300 million barrels, a decline of 1,039 million barrels for the year.

Gains in proved reserves were accomplished in seven States, led by New Mexico, which added 60 million barrels. Losses in proved reserves occurred in 19 States, in those States having significant reserves, the largest losses occurring in Louisiana (452 million barrels), Texas (387 million barrels), California (66 million barrels), and Kansas (52 million barrels).

According to API, indicated additional reserves from known reservoirs amounted to 5,144.4 million barrels. These are potentially available crude oil reserves in known reservoirs expected to respond to fluid injection and other improved recovery techniques. Most of the indicated additional reserves are in Texas (2,083.3 million barrels), California (1,506.6 million barrels), and New Mexico (319.5 million barrels).

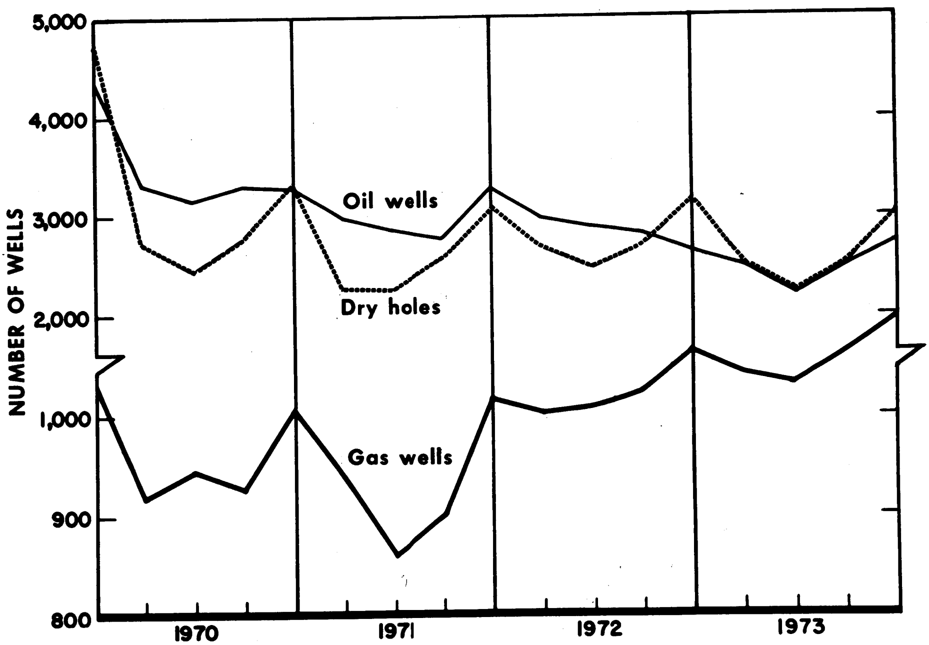

Figure 3.—Wells drilled for oil and gas in the United States, by quarters.

REFINED PRODUCTS

The Arab embargo enacted in October 1973 came too late to arrest a decided uptrend in oil consumption. As a result, domestic demand in 1973 was 17,254,000 bpd, a new record and 5.4% above the 16,367,000 bpd of 1972. Although crude oil production in 1973 was about 3% below the 1972 level, operable refining capacity expanded impressively from 13,641,000 bpd to 14,362,000 bpd, a net increase of 720,000 bpd, or 5.3%. About one-half of this increase in crude oil capacities occurred in refineries in Texas and Louisiana.

GASOLINE

Domestic demand for gasoline increased 4.3% in 1973, to 6,672,606 bpd. This rate was relatively high considering the conservation measures taken near the end of the year. During the first 10 months of 1973, demand increased 5.0%, somewhat less than that of the previous year. A factor affecting demand, especially in early 1973, was the building of secondary (unreported) inventories by many retailers, marketers and bulk consumers in anticipation of summer shortages. As a result stocks at primary (reported) storage terminals were at guarded levels as shown in table 36. In March, these stocks were equivalent to 32 days of demand, compared with 1971 when primary storage facilities held 42 days of demand in storage. Because of the shortages, refiners increased refinery yields of gasoline up to 48.4% of refinery runs in May and June. The previous 3-year average for these months was 45.5%. Ample supplies were available during the summer high-demand period prior to the Arab embargo. Since a greater proportion of automobiles in use have air-emissions-control equipment which reduces miles per gallon, the impact over the previous years' demand was less significant than that of other recent years. During December some service stations curtailed service hours and motorists formed lines at opened stations for restricted quantities of gasoline.

According to data compiled by API based on tax data reported by the States, 6,920,373 bpd of motor gasoline was consumed in the United States in 1973. This differs from demand compiled by the Bureau of Mines, which does not include changes in secondary stocks. At yearend the allocation level for each wholesale purchaser was 100% of requirements for certain priority uses such as energy production, emergency uses, agriculture, and transportation. Other businesses, such as industrial, commercial, governmental and social services agency users, were to receive 100% of 1972 consumption. There was also a 3% set aside for redirection by Federal Energy Administration (FEA).

Aviation gasoline demand in 1973 continued to decline. But the declining demand curve is leveling off since most air lines and air cargo carriers have completed programs for converting their fleets to jet-powered craft. The 1973 demand of 45,290 bpd was only 2.3% less than that of 1972.

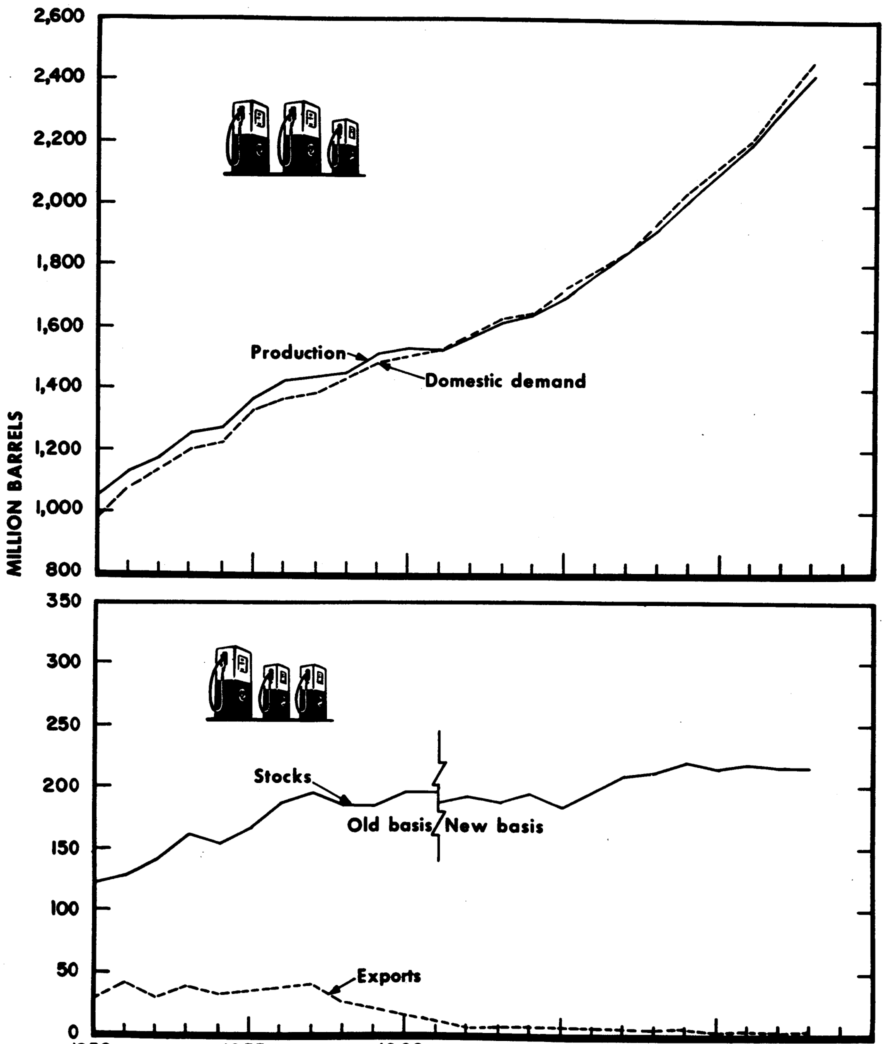

Figure 4.—Production, domestic demand, stocks, and exports of gasoline in the United States.

JET FUEL

By far the greatest use of kerosine is in commercial type jet fuel. This product, a kerosine with restrictions on content of aromatics and naphthenes, has a very low freezing point. The drastic cuts in commercial air lines flights, resulting from the Arab embargo on supplies of petroleum products, came too late to have any impact on the demand for commercial (kerosine) type jet fuel in 1973. Demand for this type averaged 833,247 bpd, a 3.5% increase over the volume used in 1972. The demand of 217,000 bpd, however, for naphtha-type jet fuel, used primarily by the military, was off 10.5% as a result of cutbacks in military flying.

Under the allocation program planned at yearend 1973, emergency flight operations and mercy missions were allotted 100% to 150% of 1972 volumes. The rules applied to both jet fuel and aviation gasoline users. Other users were to be curtailed as follows: Domestic air carriers (air lines), 95% of 1972 use; international air carriers, 100%; commercial and industrial users in general aircraft, 90%; military, 100% of requirements; personal pleasure and other, 70%. Bonded jet fuel users were excluded from the allocation program.

LIQUEFIED GASES, ETHANE, and ETHYLENE

Liquefied gases are derived from two sources. Those produced at refineries are called liquefied refinery gases to distinguish them from liquefied petroleum gases obtained by processing natural gas. The liquefied petroleum gases (LPG) are all parafins (propane, butane, and isobutane). The liquefied refinery gases (LRG) also contain parafins but may also contain unsaturates, that is, the olefins (propylene, butylene, ethylene, etc.). The parafins may be used as fuel including blending with motor gasoline or as feedstock at petrochemical plants. The olefins are used primarily as petrochemical feedstocks.

Demand for ethane (including ethylene) increased a substantial 12.5% in 1973. Use of ethane as petrochemical feedstock raised demand from 290,167 bpd in 1972 to 327,241 bpd in 1973 or an increase of 12.8%.

Domestic demand for LPG and LRG, excluding that blended into other products at refineries or terminals in 1973 was 1,120,866 bpd compared with 1,133,285 bpd in 1972. Nearly 78% of liquefied gas demand was propane. A series of events that occurred in 1972 led to considerable dislocation of the propane market in 1973. Price controls instituted in July 1972 froze the price that large companies (historic wholesale buyers) could pay for propane. Concomitantly, small companies (those with less than 30 employees) could purchase and sell propane without price constraints. As a result, the large companies found it difficult in early 1973 to bid successfully for propane. Furthermore, major natural gas consumers (industrial firms, electric powerplants, and natural gas utilities), fearing a shortage of natural gas, sought propane as a substitute or standby fuel and were active propane purchasers during the spring and summer. This represented a significant demand for propane and resulted in a major diversion of propane from established markets.

Because of the lower-than-normal midyear inventories and the prospect that residential and commercial consumers would not have adequate supplies during the 1973–74 winter, a mandatory propane allocation program was effected on October 3, 1973. This program was generally successful in that propane was available during the heating season; however, several factors had a moderating impact on demand. These included an unusually warm winter, conservation efforts, and resistance to sharply higher prices.

KEROSINE

Demand for kerosine continued to decline, falling 8.1% to 216,205 bpd. The principal use for kerosine was for space heating which represents 77% of domestic demand. Kerosine consumption is expected to continue the downtrend as consumers convert to more convenient forms of energy such as bottled (LPG) gas and electric power.

DISTILLATE FUEL OIL

Despite the warmest year in more than a decade, distillate fuel oil demand increased a moderate 5.5%. The heating degree-day average was about 9% warmer than normal. Although about 50% of the demand of 3,080,296 bpd was for heating, most of the gain over the 1972 level resulted from increased use at powerplants as a substitute for natural gas made unavailable and as an alternative for other fuels in areas where air quality standards restrict the use of high-sulfur content fuels. In some situations distillate fuel oil was used as a blend to reduce the sulfur-content of high-sulfur residual fuel oils. Gains in demand were also significant in the transport and industrial sectors as economic activity improved.

Mild weather, during the early part of the year, eased refinery pressure to maximize distillate fuel oil during the cold months. As a result the percentage yield of distillate fuel oil from the processing of crude oil, especially in March, April, and May were at the lowest levels in more than a decade.

Although stock levels, in terms of days demand, were at alarming low levels in January and February, inventories during the remainder of the year were at or above normal levels.

In October 1973, an Office of Petroleum Allocation was established to govern mandatory allocation of middle distillates including distillate fuel oil. In November it was announced that three categories of distillate fuel oil consumers were given preference in receiving adequate supplies: Farmers-ranchers, mass transit systems, and energy fuel producers.

RESIDUAL FUEL OIL

Residual fuel oil demand continued to be strong as a result of increasing use by electric utilities. Although some of the gain resulted from its use as a substitute fuel for curtailed supplies of natural gas, much of the increase was at new steam-powered plants and as a substitute for high-sulfur bituminous coal at certain locations. Residual fuel oil was able to fill the new market as the sulfur content continued to decline. The 1,437,250 bpd used by electric utilities accounted for 51% of the 2,794,340 bpd of residual fuel oil demand in 1973.

At refineries, the output of residual fuel oil with a sulfur content of less than 0.5% increased from 22.2% of total output in 1972 to 27.3% or 264,904 bpd. Low-sulfur (less than 0.5%) residual fuel oil imports also increased from 31.9% of total residual fuel oil imports or 555,019 bpd in 1972 to 36.6% or 669,277 bpd in 1973. Most of the increase in low-sulfur residual fuel oil came from Caribbean refineries (Venezuela, Netherlands Antilles, and Trinidad), which had recently installed desulfurization facilities, and from Italy, which refines a high proportion of low-sulfur North African crude oil.

A large share of the increase in demand was met by drawing on stocks. Throughout the year, stocks (at primary storage facilities) were at levels below all years since 1965 except 1970. At yearend 1973, these stocks were equivalent to 18 days of December demand. Residual fuel oil allocations established at the end of the year allocated 100% of requirements for priority users such as those engaged in energy production, essential commodities, marine shipping, and heating for health services. Industries were to receive 100% of 1973 consumption. Other space-heating consumers were to receive 100% of needs, but based on reductions of inside temperatures of 6° F for residences and 10° F for others.

ASPHALT AND ROAD OIL

Shipments of asphalt and asphaltic products in the United States in 1973 increased sharply from 31,121,000 short tons to 34,410,000 tons, or 10.6%. Shipments of paving asphalt experienced the sharpest boost increasing to 27,113,000 tons from 24,308,000 tons or 11.5%. Shipments of asphalt for roofing increased but at a slower pace; 6% in 1973 as compared with the spectacular jump of 22.6% in 1972. Production of asphalt in 1973, however, totaled 30,524,000 tons which was only 8% higher than the 28,235,000 tons produced in 1972. Hence it was necessary to make a net draw down on stocks in 1973 of 1,200,000 tons or 30.6%. Imports, likewise, decreased in 1973, from 1,684,000 tons to 1,535,000 tons or 8.9%.

Demand for road oil increased from 7,540,000 barrels in 1972 to 7,832,000 barrels in 1973, or nearly 4%, but production declined so that it was necessary to draw on stocks. These decreased by 38.8% in 1973. Trends in asphalt and road oil demand, as well as other data over a 5-year period, are available in table 48.

OTHER PRODUCTS

Petrochemical Feedstocks.—In addition to the liquefied gases and ethane supplied from natural gas processing, petroleum refineries supplied the petrochemical industry with 132,564,000 barrels of other feedstocks in 1973. This is an increase of nearly 6.9% over the volume supplied in 1972.

Exports increased 25.4% in 1973 to 5,801,000 barrels as shown in table 49.

Special Naphthas.—Special naphthas are used primarily for paint thinners, cleaning agents, and solvents. In 1973, domestic demand was 32,230,000 barrels, slightly higher than a year earlier when volume was 31,866,000 barrels. Exports increased 9.5% to 1,652,000 barrels.

Lubricants.—Demand for lubricants in domestic markets increased to 59,037,000 barrels or 11.8% in 1973, but these gains were modified by a 14.4% drop in exports, to 12.8 million barrels in 1973 from 14.7 million in 1972. As a result, the gains in overall demand in 1973 were modified to 6%.

Waxes.—Demand for wax strengthened in 1973. Production increased about 10% to 947,500 short tons and imports of wax more than tripled to 149,400 short tons. Exports of wax were lower by 23,100 tons or 14.6% but still sizeable at 135,100 tons, so it became necessary to draw on stocks to satisfy domestic needs. Domestic demand in 1973 was 971,700 short tons or up 28.3%.

The annual survey of wax sales made by the API represents 62% of total wax sales in the United States as reported by the Bureau of Mines. A breakdown of the 1973 annual sales of wax by end use in the United States compared with 1972 and 1971, is shown below in short tons:

Item	1971	1972	1973
Paper converting:			
Paper wrappers	93,660	95,678	114,655
Paperboard containers	130,193	122,905	128,999
Corrugated paperboard	71,816	78,163	70,782
Total	295,669	296,746	314,436
Candles, molded novelties, figurines, and decorative items	85,852	103,601	106,524
All other uses	180,216	196,702	180,271
Total reported	561,737	597,049	601,231

Source: American Petroleum Institute.

Petroleum Coke.—Petroleum coke production aggregated 132,290,000 barrels in 1973, a 10.5% increase over the preceding year. About 51%, or 67,527,000 barrels was marketable coke. Exports of marketable coke increased to 35,006,000 barrels or about 12.5%. About 26% of petroleum coke exports were destined for Japan, which received some 9,197,000 barrels in 1973, an increase of 10.7% from the 8,305,000 barrels of the preceding year. Canada participated in these increased exports, receiving 771,000 barrels more than in 1972. Exports to Belgium-Luxembourg increased 1,105,000 barrels or 32.7%.

Still Gas.—Still gas is a mixture of extremely low-boiling hydrocarbons produced during the distillation of crude oil, and may be used as refinery fuel and/or as a petrochemical feedstock. During 1973, refineries used 176,758 thousand barrels of still gas as fuel a 3.4% increase from the 170,993 thousand barrels consumed in 1972. Sizeable increases in the use of still gas occurred at refineries in Illinois, Oklahoma, and in Texas during 1973.

Increased use of still gas for refinery fuel had a noticeable impact on the consumption of still gas as petrochemical feedstock. In 1973, this usage fell to 12,428 thousand barrels or 15% below the 14,678 thousand barrels produced in 1972.

Unfinished Oils.—Unfinished oils are oils that have been partly refined and will be further processed by refiners; examples are unfinished naphtha, gas oil, virgin- or straight-run naphtha, topped crude, cracking stock, etc. All of these oils will be further processed by a refinery. The rerun (net of unfinished oils) represents the receipts of domestic or foreign oil plus or minus changes in stocks.

Miscellaneous Finished Oils.—The petroleum industry produces a variety of miscellaneous products that are sold directly to consumers or in bulk to specialty companies which package and distribute them under various trade names. Included in this category would be absorption oils, medicinal oils, insecticides, petrochemicals, and solvents. The domestic demand for these products in 1973 was 19,861,000 barrels.

TRANSPORTATION AND DISTRIBUTION

CRUDE OIL

A transportation system comprising pipelines, tankers, barges, tank cars, and to a lesser degree, tank trucks move crude petroleum to refineries for processing. Refineries received 72.9% crude oil requirements by pipeline, 25.8% by water, and 1.3% by tank cars and trucks in 1973.

The 17 States which comprise PAD district I accounted for 38.4% of the domestic demand for petroleum products. Refineries in District I, however, supplied only 16% of the demand. Foreign crude oil made up the lion's share 84%; 13% was from other PAD districts and 3% from within the district. Fifteen Midwestern States comprise PAD district II, the second largest consuming district. However, although a deficit producing and refining area, output of refineries in that district provided 78% of demand in 1973. About 27% of the crude oil processed in refineries in PAD district II was produced in that district, 45% was received from PAD district III, and 8% was from PAD district IV; 20% was imported from foreign sources. Both PAD districts III and IV produced and refined petroleum in excess of their demand requirements and thus helped meet the supply deficits of other districts.

Maps delineating PAD districts and Bureau of Mines refining districts are shown in figure 5.

Refined products produced at refineries in PAD district V in 1973 represented 93% of the domestic product demand for that district. Crude oil produced in District V supplied 57% of refinery input and foreign crude oil 41%; 2% was received from other PAD districts.

Data collected on receipts of domestic and foreign crude petroleum at refineries in the United States show receipts from local production (intrastate), receipts from other States (interstate), and receipts of imported crude. These data, by method of transportation, indicate the final receipts by water, pipeline, tank car, and truck. Receipts of domestic crude by water usually are moved by pipeline from the point of production to the point of water shipment. These data are shown in table 14.

Total receipts of crude oil at refineries in 1973 were 4,545.8 million barrels, or 12.4 million bpd, an increase of 266.6 million barrels or 730.4 thousand bpd for the year. Receipts from domestic sources, however, decreased 109 million barrels or 298.6 thousand bpd in 1973. Overland receipts of foreign crude oil (from Canada) were 52.9 million barrels higher in 1973 and foreign receipts from overseas sources increased 322.8 million barrels or 882.2 thousand bpd.

More foreign overseas crude oil entered refineries in all PAD districts in 1973 because domestic crude oil was in short supply. Refineries processed 4,537.3 million barrels of crude oil in 1973, reported a net of 1.9 million barrels used for refinery fuel and as losses, and added 6.6 million barrels to stocks as shown in table 34.

REFINED PRODUCTS

Domestic demand for petroleum products averaged 17,254,000 bpd in 1973, a gain of 5.4% above the 16,367,000 bpd for 1972. The demand broken down by PAD districts is as follows: District I, 6,628,000; district II, 4,649,000; district III, 3,199,000; district IV, 454,000; and district V, 2,324,000.

PAD district I imported an average of 2,358,000 bpd of refined petroleum products in 1973, and received 2,815,000 bpd from other districts. Shipments from PAD district I to PAD district II averaged 165,000 bpd, and 17,000 bpd of petroleum products were exported. PAD district II received an average of 857,000 bpd of refined products from other districts and imported 80,000. The district shipped 63,000 bpd to PAD district I and 73,000 bpd to PAD district III. District II also exported 9,000 bpd.

PAD district III shipped an average of 2,749,000 bpd of refined products to PAD district I, 670,500 bpd to district II, 30,000 bpd to district IV, and 66,000 bpd to district V. PAD district III also exported 103,000 bpd. The district received 73,000 bpd of refined products from district II and imported 123,000 bpd from foreign sources.

As compared with 1972 figures, imports of refined products from foreign sources almost tripled in 1973.

PAD district IV shipped an average of 93,000 bpd of refined petroleum products to other districts and received 55,000 bpd from other districts. District IV also imported 17,000 bpd.

PAD district V received an average of 66,000 bpd of refined products from PAD district III and 61,000 bpd from district IV. They also imported 140,000 bpd. District V shipped 3,000 bpd to PAD district I and 25,000 bpd to PAD district IV. Also, 100,000 bpd of refined products were exported from district V.

PIPELINES

The Bureau of Mines triennial pipeline survey covered pipeline statistics as of January 1, 1971, and the next survey will not be available until 1975. Meanwhile, Pipeline and Underground Utilities, a construction trade publication, estimates that 598 miles of crude oil lines were laid in 1973 as compared with 361 miles in 1972.

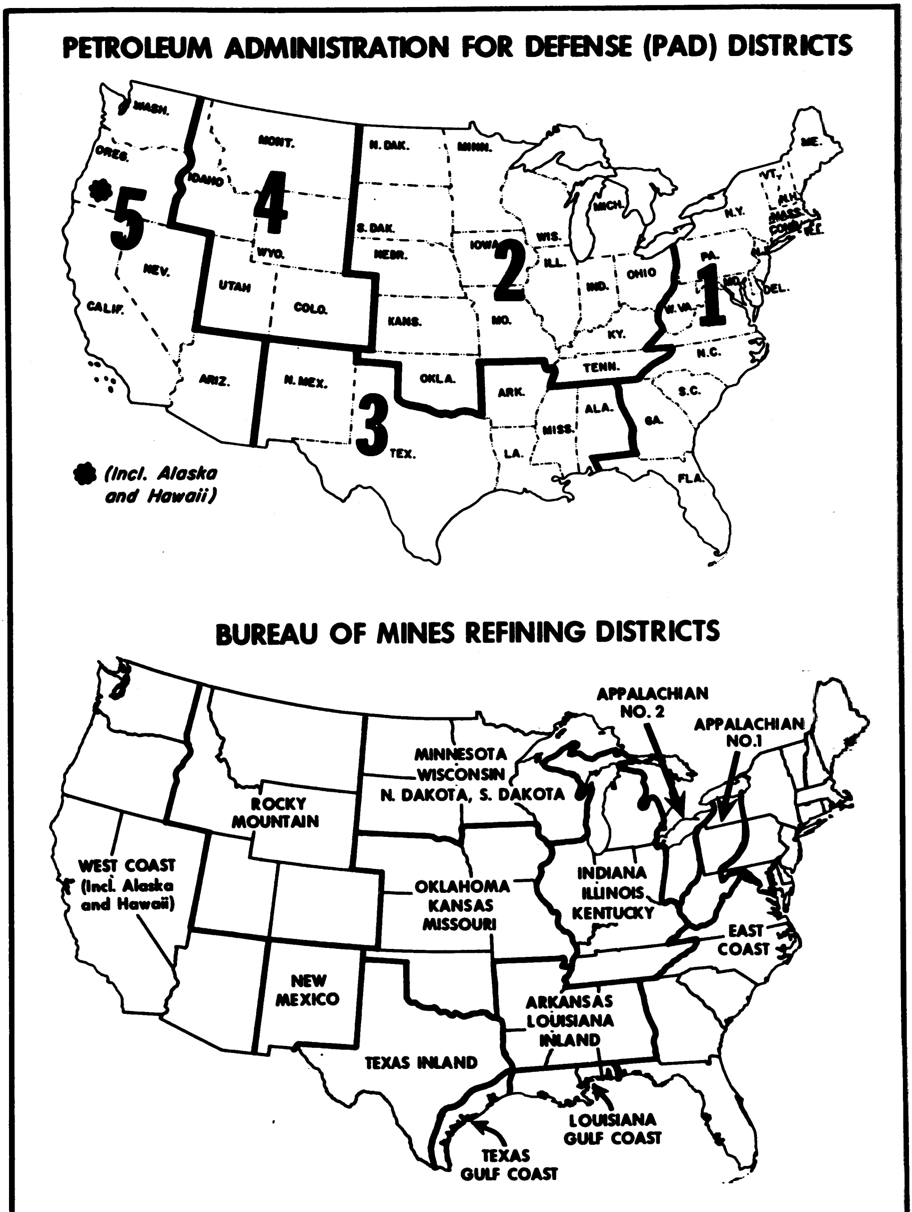

Figure 5.—Maps of Petroleum Administration for Defense (PAD) Districts, and Bureau of Mines Refining Districts.

Crude oil pipelines delivered 3,313.7 million barrels to refineries or 9,078,000 bpd in 1973, a slight increase over the 3,281.6 million barrels or 8,966,000 bpd in 1972, as indicated in table 14. Petroleum product pipelines delivered 3,204.9 million barrels or an average of 8,780,000 bpd in 1973, as compared with 2,967.9 million barrels or 8,109,000 bpd in 1972.

RAIL, TANK TRUCK, BARGE AND TANKERS

The annual survey of the Association of Oil Pipelines estimates that the total tonnage of crude and petroleum products carried was 1.8 billion short tons in 1972. Of this total, 47.53% was transported by pipelines, 23.14% by water carriers, 27.86% by motor carriers, and 1.47% by railroads. On an overall basis, volumes transported in 1972 were 7% greater than those in 1971. Petroleum products accounted for 65% of the volumes transported.

Product pipelines transport only the light products such as gasoline, light fuel oils and heating oils, liquid petroleum gas, kerosine, and jet fuel. These lines transported 1,199,710,500 short tons or 32.39% of the total. Motor carriers transported 462,500,000 or 38.55% of the petroleum products carried. In terms of billions of ton miles, the total aggregated 480.5 of which 40.5% was transported by pipelines and 52.9% by water carriers.

STOCKS

Stocks of all oils have been increasing steadily after touching a low point of 866.9 million barrels in February 1973. This inventory position was the lowest since February 1968, and close to the stock levels during the period when the 1967 Arab-Israeli conflict cut off imports from the Mideast. By the end of 1973, stocks of all oils had recovered to 1,008.3 million barrels or an increase of 49.3 million barrels over the inventory position at the end of 1972. Stocks of refined products were 47.1 million barrels higher at yearend 1973, and the improvement in the stock position in distillate accounted for 89.5% of the gains. Crude oil stocks shrunk from 279.5 million barrels in May of 1972 to a 7-year low of 235.4 million barrels in February 1973. Subsequently, there was some improvement in crude oil supplies throughout most of 1973, but a very sharp drop in crude oil imports in December caused stocks of crude to shrink to the lowest yearend levels since 1966. A drop in domestic production from 9.4 million barrels daily in 1972 to 9.2 million bpd in 1973, was also a contributing factor to the drop in stocks.

PRICES

Crude Oil.—As a result of the embargo by Arab nations of oil shipments to the United States, coupled with sharp rises in prices adopted by the Organization of Petroleum Exporting Countries (OPEC), there were large increases in crude oil and refined products prices in 1973. The uptrend continued in 1974. Six oil-producing countries in the Middle East announced in late December 1973 that they were more than doubling the price of crude oil to $11.651 cents per barrel from $5.11, effective the beginning of the new year. This was the second sharp increase since the price was raised from $3.01 per barrel to $5.11 or nearly 70% in October 1973.

On the domestic scene, the average price of crude oil at the wellhead, which was $3.39 per barrel in 1971 held at that level through 1972. However, in March 1973, the Cost of Living Council (CLC) granted an increase of $0.25 per barrel lifting the price to $3.64 per barrel. On May 15, 1973, the CLC allowed another $0.35 increase. Under phase 4 petroleum regulations, the ceiling price for crude oil was the posted price in each U.S. oilfield plus $0.35 per barrel. The average 1973 price was $3.89 per barrel, according to the Bureau of Mines.

On August 17, 1973, in an effort to stimulate production of domestic crude oil, the CLC enacted under phase 4 Oil Regulations a two-tier pricing system, releasing from ceiling prices "new oil", that is, oil produced above 1972 levels, plus an adjustment for the remainder of current production. The price of new oil produced, which was not covered by the price ceiling, rose steadily to market levels. The ceiling price for domestic crude was about $1 per barrel below the world price at the time phase 4 rules were issued on August 17. Since then, however, world prices have increased sharply and so have prices for new oil or exempt oil, that is, oil exempt from price controls. What constitutes "exempt oil" was broadened as of November 16, 1973, when the CLC exempted prices charged for the first sale of crude petroleum and petroleum condensates, including natural gas liquids produced from any stripper well lease. A "stripper well lease" is defined as a property[5] whose average daily production of crude petroleum, condensates, etc. did not exceed 10 barrels per day during the preceding calendar month.

The impact of exemption on new oil prices was felt almost immediately. Between October 30 and November 30, the price of new or exempt oil rose from an average $5.61 per barrel to $7.85, a jump of 40%. Between August 19 and the end of 1973, the price of new or exempt oil has more than doubled—from $4.05 to $8.70 per barrel and the trend has been upward since then. The prices for old oil, likewise, have been adjusted upward—from $4.05 on August 19, 1973, to $5.10 per barrel for an increase of 25.9% by the end of 1973. A comparison of 1972 prices with 1973 prices of various grades of crude oil is shown in table 28.

Refined Products.—With few exceptions, prices of most refined products in 1973 held close to the 1972 levels throughout the first 9 months. But when most of the OPEC nations raised crude oil prices 70% it was imperative for the CLC to act. In October 1973, the CLC drafted up new regulations. Price controls on refined products were eased under phase 4 to permit refiners, in part at least to pass-through increased costs on gasoline, home heating oil, and diesel fuels. Shown in the following tabulation (in dollars per 100 gallons) are some comparisons of prices in selected cities of No. 2 home heating oil between 1971 and 1973. Data for January 1974 are included to indicate the impact of the pass-through policy on retail prices.

[5] Definitions of "stripper wells" and "property" are available in detail in Title 6 Economic Stabilization, Section 150.54 of the Code of Federal Regulations.

Residual Fuel Oil Prices.—The price of Bunker "C" fuel oil at New York Harbor was depressed throughout 1972 but demand for tankers quickened and fuel oil prices stiffened. From $3.45 a barrel at the end of 1972, prices for Bunker "C" climbed steadily reaching $5.42 per barrel, a year to year increase of $1.97 or nearly 57%. The long-term trend of Bunker "C" prices 1964–73 inclusive is shown in figure 7.

Prices of gasoline in 1973 did not begin to rise until after OPEC action on crude in October, but from then on the climb was rapid. The average service station price of regular grade gasoline including taxes was 38.71 cents per gallon as of September 1. By December 1, the price had risen to 42.26 cents or 9% according to Platt's Oil Price Handbook and Oilmanac 1973.

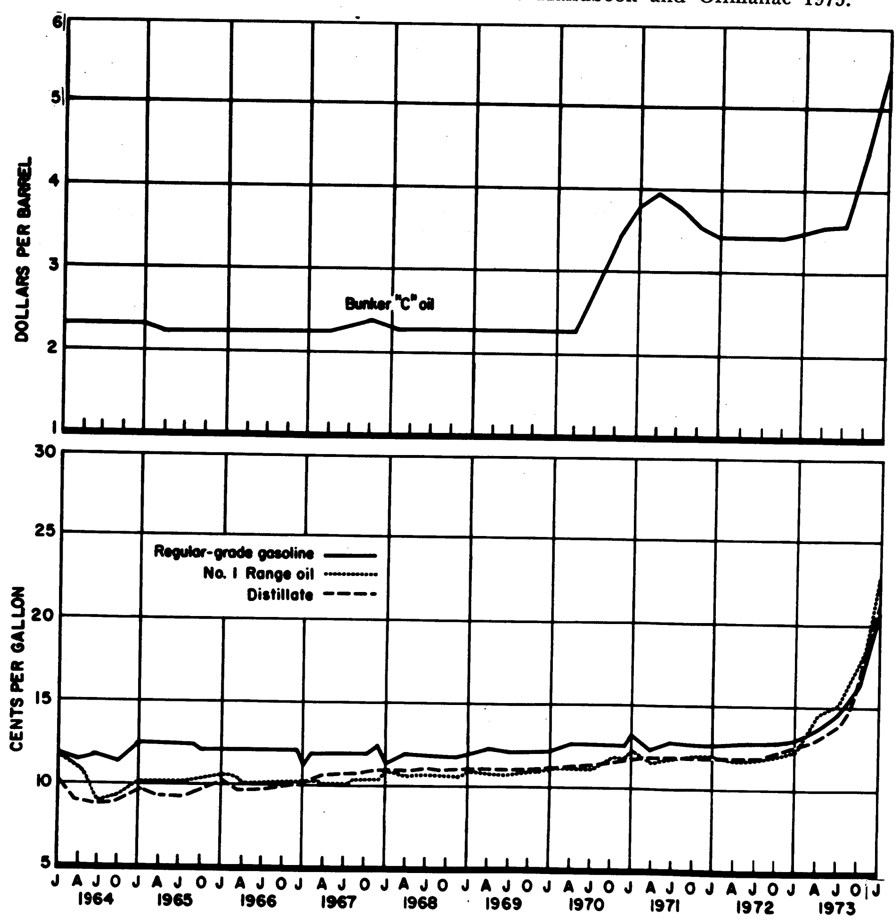

Figure 7.—Quarterly prices of Bunker "C" and No. 2 Distillate Fuel at New York Harbor; No. 1 Range oil at Chicago district, and regular grade gasoline at refineries in Oklahoma.

FOREIGN TRADE

Imports of crude oil and refined products aggregated 2,263.5 million barrels or 6.2 million bpd in 1973 for an overall 30.4% increase. The largest gain was in crude oil imports—372.9 million barrels, or 1.02 million bpd for a 46% increase. Imports of refined products were about 155.3 million barrels higher or 17% above 1973.

Crude oil imports totaled nearly 1,184 million barrels or 3.24 million bpd, and about 1 million bpd or 31% came from Canada as shown in table 58. Venezuela supplied 125.7 million barrels, or nearly one-fourth of the oil imported from Western Hemisphere countries. From the Eastern Hemisphere, nearly 651.8 million barrels or 55% of crude oil imports were obtained. Saudi Arabia supplied 168.5 million barrels, nearly all of which was received in the 10 months through October 1973. Nigeria supplied nearly as much (163.7 million barrels) of crude imports as Saudi Arabia. Refined product imports aggregated 1,079.5 million barrels or 2.96 million bpd, of which 34.4% of all products imported was residual fuel oil from Venezuela and the Netherlands Antilles. Distillate fuel oil imports in 1973 were more than double the volume received in 1972, reflecting the cessation of mandatory import controls. Distillate fuel oil imports from Central America and the Caribbean areas were almost double the 1972 volumes and most of the increases in 1973 originated in the Netherlands Antilles and the Virgin Islands. Imports of distillate from Europe increased almost fivefold, and exceeded those from South America by about 10 million barrels. Most of these increases originated in Italy and the Netherlands. Imports of motor gasoline nearly doubled with most of the increased supply originating in Canada, the Netherlands Antilles, Venezuela and the Virgin Islands. Europe became an important supplier of gasoline in 1973, and 1,122,000 barrels were imported from Turkey in 1973. Other comparisons of 1972 and 1973 imports are available in table 58. Included in the totals for imports of refined products were 3,076,000 barrels of jet fuels, 5,161,000 barrels of distillate fuel oil, and 43,447,000 barrels of residual fuel oil, which were withdrawn from bond for use as fuel for aircraft and vessels engaged in overseas commerce. These imports were exempted from tariff duties. Residual fuel oil imported by the military for offshore use in 1973 totaled 3,350,000 barrels or 33.5% less than the volume used in 1972.

Exports of refined products and crude oil in 1973 were up 2.8 million barrels, or 3.5% as shipments of gasoline, commercial type jet fuel, distillate fuel oil, and coke more than offset a drop in exports of liquefied petroleum gases, residual fuel oil, lubricants, and waxes. Coke accounts for 41.6% of exports from the United States and nearly one-half of this product was destined for Canada, Belgium, Italy, the Netherlands, and West Germany. Japan, however, was the largest single user of coke from the United States, accounting for more than 9 million barrels or nearly one-fourth of all the petroleum coke exported.

The tanker market in most of 1973 continued the uptrend which had begun in mid-1972. The single charter (spot) tanker market for dirty cargoes destined from Persian Gulf to U.S. Gulf climbed steadily and reached a high of 455 Worldscale or $48.96 per long ton, in mid-October 1973, the same month the Arab Embargo began. The impact of the embargo was immediate and demand for tankers shrunk drastically. As a result, the Worldscale tanker rate plummeted to 100, or to $10.68 per long ton in November. The rate then leveled off and by the end of 1973, Worldscale was at 110 or $11.75 per ton. Demand for tankers has since moderated and tanker rates resumed the decline. Average tanker costs, it should be noted, move slowly since they include charters running about 3 years. Also, much of the shipping moves in company-owned vessels.

NATIVE ASPHALT

Bituminous Limestone, Sandstone, and Gilsonite.—Natural rock asphalt and limestone rock asphalt were produced in Alabama, Missouri, and Texas and were used for road building material. Gilsonite was produced in Utah, and most was shipped to a refinery in Colorado and converted into petroleum products. The total production of native asphalts and related bitumens in 1973 was 2,088,657 short tons with a value of $8,464,000.

WORLD REVIEW

The outbreak of Arab-Israeli hostilities on October 6, 1973 created repercussions in world oil supplies. Production cutbacks among Arab producers and Arab embargoes on deliveries to the United States and the Netherlands converted Arab oil into an economic and political weapon.

Many developments in 1972 and early 1973 set an uneasy stage for the yearend crisis. Nationalization of foreign oil company holdings in Algeria, Iraq, Iran, Libya, and Nigeria and a multitude of participation agreements between state-owned companies and foreign operators caused a disruption in normal trading relations and resulted in higher market prices. Revision of the February 1971 Tehran agreement, which provided increases in posted prices through 1975, was under renegotiation in early October. However, by mid-October, negotiations were abandoned and the Persian Gulf States' governments chose to fix prices unilaterally. Libya and Nigeria soon joined the Persian Gulf States in this policy. The initial increases averaged 70%; however on January 1, 1974, posted prices were further raised to double the October 16 levels. Thus, the 1973 Saudi Arabian crude posted price opened at $2.591 per barrel, increasing to $3.011 per barrel by October 1, and increasing to $5.119 per barrel on October 16. The posted price for Saudi Arabian crude on January 1, 1974, was $11.651 per barrel.

The decision for a production cutback was reached in Kuwait on October 17 by the Organization of Arab Petroleum Exporting Countries (OAPEC). Most participants agreed to cut production by 5% (about 1 million bpd) from September production levels and by a further 5% each month until an Israeli "withdrawal is completed from all Arab territories occupied since June 1967 and that legal rights of Palestinians be restored." Military activities resulted in reduced Arabian crude exports even before the OAPEC meeting cutback decision. About ½ million barrels per day of crude had been cut from world markets when the Syrian ports of Baniyas and Tartus were closed because of war damages. A market loss averaging nearly another ½ million barrels per day was realized because hostilities delayed tanker loadings at Mediterranean terminals and Saudi Arabian crude flow through TAPline was reduced to minimize loss in the event of damage.

Crude imports from Arab nations constitute as much as 85% of European demand and 78% of Japanese demand, forcing these as well as all consuming nations to launch emergency petroleum conservation measures.

Although supply shortages and skyrocketing prices had serious effect on the economies of major consuming nations, the developing nations were especially hard hit since their foreign exchange reserves could not absorb higher energy prices placing their development in jeopardy.

Production.—World crude oil production increased by 10.5% over the 1972 level reaching an average production of 56.3 million bpd including an estimated 8.4 million bpd recovered from offshore operations. The United States remained the leading producer followed by the Soviet Union, Saudi Arabia, and Iran.

In spite of production cutbacks, output from the 12 Middle Eastern nations increased from 18.1 million bpd in 1972 to 21.7 million bpd or about 38% of total world crude production in 1973. Output from Saudi Arabia alone increased from 6.0 million bpd to 7.9 million bpd.

The three largest producing nations of North America contributed about 20% of total world crude output in 1973, or about 11.5 million bpd. Production increased in Canada and Mexico, offsetting most of the production decline in the United States.

Crude Oil Movements.—Crude oil movements to the major consuming markets of Western Europe, Japan, and the United States totaled more than 22 million bpd in 1973. European crude imports nearing an average of 14 million bpd were largely supplied by Middle Eastern countries, which provided 9.2 million bpd, an increase of 8.5 million bpd over 1972 levels. Saudi Arabia alone accounted for 3.6 million bpd up from 3.1 million bpd in 1972. Imports from Africa were estimated at 3.9 million bpd. About two-thirds of all African imports originated in Libya and Nigeria.

Japanese crude imports totaled 4.9 million barrels in 1973 up from 4.0 million barrels in the previous year. More than three-quarters of crude imports were obtained from the Middle East with Iran

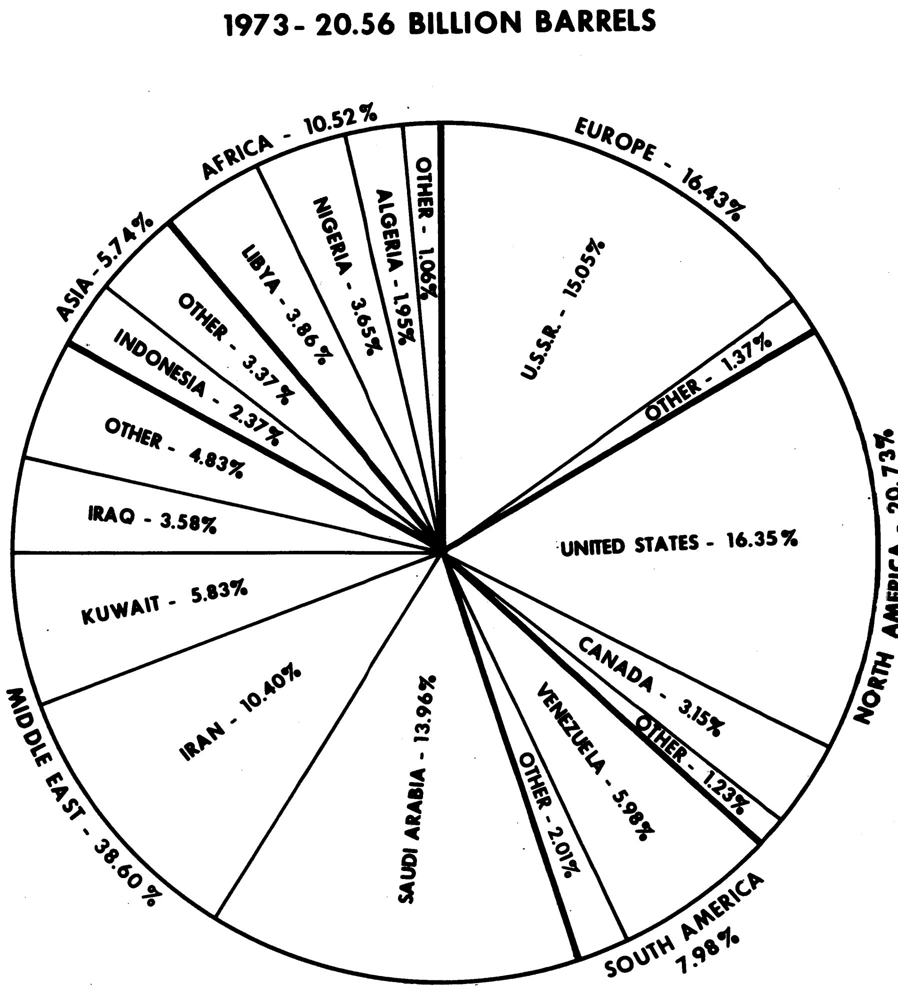

Figure 8.—World share of crude oil production, 1973.

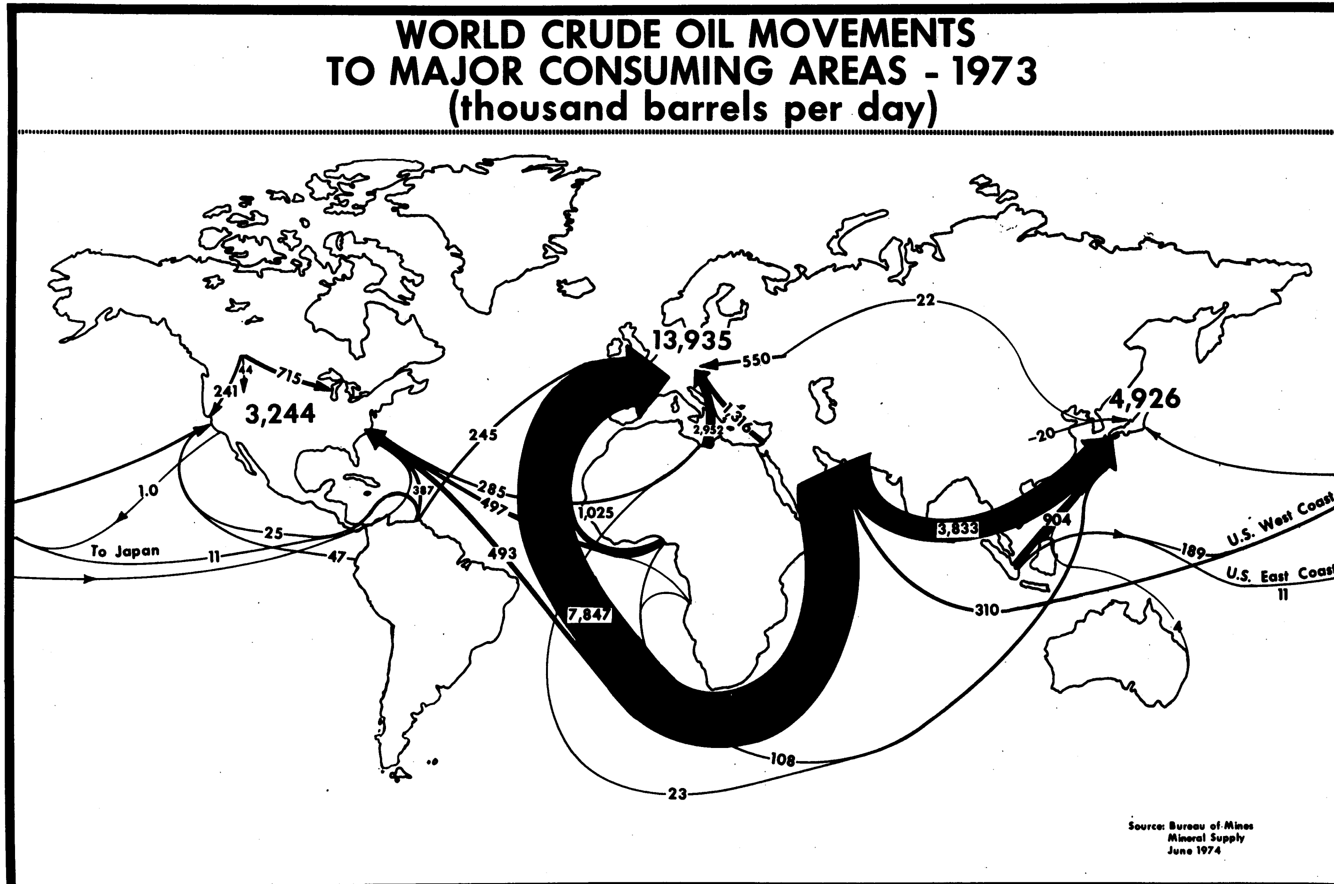
as the major supplier accounting for 1.7 million bpd as compared to 1.6 million bpd in 1972. Crude imports from the neighboring People's Republic of China were inaugurated in 1973. Crude imports from China's Ta-ching field averaged nearly 20,000 bpd in 1973; the volume is expected to increase to 60,000 bpd or better in 1974.

The United States imported 3.2 million bpd in 1973. Canada supplied more than a million bpd, Saudi Arabia, about 462,000 bpd, and Nigeria, 448,000 bpd.

Transportation.—Excluding 37 million deadweight tons in combined carriers, the world tanker fleet at yearend 1973 totaled 220 million deadweight tons, an increase of more than 26% over 1972. About 59 million deadweight tons sail under the Liberian flag, 28 million deadweight tons sail under the United Kingdom flag, about 27 million deadweight tons sail under the Japanese flag, and about 21 million deadweight tons sail under the Norwegian flag. Tankers between 200,000 and 285,000 deadweight tons in size constitute 36% of the total tanker fleet, and tankers of 65 to 125 deadweight tons in size constitute 19% of the total tanker fleet.



(Thousand barrels per day)
Figure 9.—World crude oil movements to major consuming areas, 1973.

Voyages from the Middle East occupied an estimated 75% of the oceangoing fleet. Voyages from the Middle East to Europe and Japan alone occupied about 60% of the total oceangoing fleet.

At yearend, 21 cryogenic ships were in service for the transport of liquid natural gas. Combined capacity totaled 867,000 cubic meters. Liquid petroleum gas vessels numbered 379 with a total carrying capacity of 2.4 million cubic meters.

Refinery Capacity.—Total crude refinery capacity at yearend was estimated at 64.8 million bpd, an increase of 4.95 million bpd over 1972 capacity levels. The Eastern Hemisphere, containing the major refining centers of Europe, the U.S.S.R., and Japan, accounted for nearly 64% of total world refining capacity or 41.4 million bpd. Refining capacity in the Western Hemisphere totaled 23.4 million bpd. Refining capacity in the United States was 14.5 million bpd followed by Canada at 1.8 million bpd and Venezuela at 1.5 million bpd.

Consumption.—World petroleum consumption reached 57.6 million bpd in 1973. Petroleum consumption in the Eastern Hemisphere was estimated at 35.2 million bpd representing an increase of about 12% over the previous year's level. Petroleum consumption in the Western Hemisphere totaled 22.4 million bpd representing an increase of nearly 8% over the 1972 level.

Although total world petroleum consumption increased by less than 12% between 1972 and 1973, several Eastern Hemisphere nations reflected higher percentage increases for the period. These included Spain at 15%, and Japan at 12%.

Algeria.—A slow down in exploration and development programs after the 1971 nationalization as well as the adoption of conservation measures at older fields resulted in a crude production below 1973 anticipated levels. By midyear the Algerian state oil company Société Nationale pour la Recherche, la Production, la Transport, la Transformation, et la Commercialisation des Hydrocarbures (SONATRACH) as well as several minor operators claimed they were over committed in crude exports. Crude exports for the year averaged 945,000 bpd, a decline from the 1972 average of 978,000 bpd. Exploration activities should be intensified as a result of several joint venture agreements signed by SONATRACH with Sun Oil Co. with Compagnie Française des Pétroles, with Hispánica de Petróleos, S.A., with Deutsche Erdölversorgungsgesellschaft mbH and with Société Nationale des Pétroles d'Aquitaine.

Total refining capacity is reported at 115,000 bpd; however, plans for construction of a 175,000 bpd refinery at Skikda were announced.

Austria.—The State company Österreichische Mineral-ölverwaltung, A.G. (ÖMv) reportedly discovered oil and gas deposits near Vienna and at Roseldorf. The discoveries are being studied for commercial potential.

ÖMv produced 82% of total oil output in Austria in 1973 or 40,400 barrels per day. About 175,000 bpd of Austrian and imported crude was processed at the ÖMv refinery at Schwechat. The refinery is to be expanded from present capacity of 210,000 bpd to 280,000 bpd by yearend 1974, satisfying the nation's total product requirements by 1975. A 40,000 bpd products pipeline from the Schwechat refinery to Wels is planned, with completion scheduled for 1975.

Bolivia.—During the year, the state-owned Yacimientos Petrolíferos Fiscales Bolivianos (YPFB) entered into seven operational contracts with foreign companies, mostly American. Each contractor is to finance and undertake exploration of a block of approximately 2.5 million acres. If a block is productive, one-half of the concession reverts to YPFB. The discovery of the Caigua field raised Bolivia's proven reserves to 177 million barrels by yearend 1973. Accelerated exploration activity launched during the year should appreciably augment the nation's petroleum reserves.

In May, YPFB signed service contracts with Universal Oil Products Co., Foster Wheeler Corp., and Lybrand Ross Bros. for expansion of the capacity of the Gualberto Villarrael refinery from 10,000 to 20,000 bpd as well as the construction of a lubricant plant, and expansion of the capacity of the Santa Cruz Refinery from 3,000 to 12,000 bpd.

Expansion plans would raise Bolivian refining capacity to 35,000 bpd. During 1973, a total of 15,160 bpd of crude petroleum was processed in Bolivia's seven refineries.

China, People's Republic of.—Crude production continued to increase sharply, with the bulk of output derived from the north and northeast provinces. China's principal field is Ta-ching, located in the Heilung-

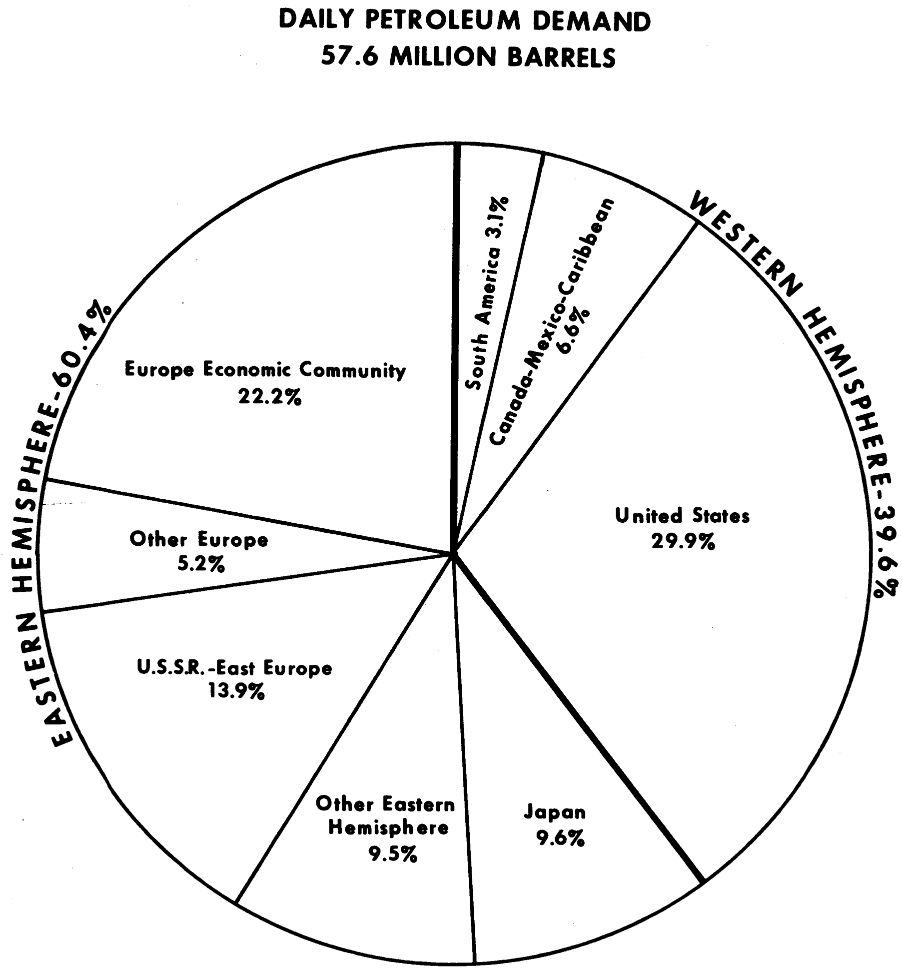


Figure 10.—Daily petroleum demand, 57.6 million barrels.

kiang Province. More than a quarter of the nation's entire output is derived from this field. Pipeline facilities connecting Ta-ching with ports along the Gulf of Liaotung were under consideration and several reports indicated that construction of at least one section had begun during the year. Petroleum storage and shipping facilities were under expansion during 1973 to accommodate increased crude exports. China's petroleum crude and product exports had been directed to North Korea and North Vietnam; however, in early 1973, crude exports to Japan were inaugurated at an average level of 20,000 bpd. By 1974, crude exports to Japan should reach an average of 60,000 bpd or more.

Offshore drilling in the Gulf of Pohai has apparently proved successful. Chinese authorities expressed interest in laying a submarine pipeline from probable fields in the gulf to onshore port facilities.

Refining capacity has historically balanced crude production capacity; however, recent drilling and field development activity have escalated China's crude production beyond refining capacity, and increased crude exports are indicated for the immediate future.

Although primary crude refining reflected only limited growth in 1973, strong activity was reported in the development of the petrochemical industry. Mitsubishi Petrochemical Ltd. (Japan) has received a contract for construction of a 12,000-ton-per-year ethylene plant. Asahi Chemical Industry Co., Ltd. (Japan) will construct a 50,000-ton-per-year acrylonitrile plant utilizing the Standard Oil Co. of Ohio licensed process. Ishikawajima-Harima Heavy Industries Co., Ltd. (Japan) received a contract for construction of a 180,000-ton-per-year low-density polyethylene unit, and a 80,000-ton-per-year polypropylene unit is to be constructed by Mitsui & Co., C. Itoh, and Kosho Corp. (Japan). Other petrochemical plant contracts were awarded to Technip A.T. and Speichim (France), Friedrich Uhde GmbH (West Germany), and Kellogg Continental BV (Netherlands). Completion dates for all plants were scheduled for 1976–77.

Colombia.—Production of crude oil decreased by 6.7% as a result of conservation measures adopted in view of declining reserves. Reserve figures released by the oil ministry were reported at 900 million barrels in 1973. Petroleum exports were to discontinue after 1973 and by 1975–76 Colombia may reverse its role and become a net importer of petroleum.

Drilling activities continued at the Guajira Basin, the Maracaibo Basin, the Llonos Basin, and the Magdalena Basin. Oil was discovered in the Magdalena Basin at a depth of 5,814 feet. The (Tennecol) Tenneco Colombia, Inc. well tested at 675 bpd on a ½-inch choke.

Egypt, Arab Republic of.—Although crude production continued to decline, this trend should be reversed in the near future. Accelerated exploration, field development and secondary recovery operations support the forecast of production levels of 1 million barrels per day by 1980.

The Egyptian General Petroleum Co. (EGPC) issued a series of concession contracts to a number of foreign companies during 1973. Some of the larger concessions included a 18,000-square-kilometer tract in the Nile Valley and Western Desert awarded to Petróleo Brasileiro Internacional, S.A.; a 15,000-square-kilometer offshore tract in the Mediterranean east of Alexandria awarded to Exxon, Egypt, (United States); and a 14,000-square-kilometer tract in the Nile Delta awarded to Continental Oil Co. (United States). Near yearend, the Soviet Union relinquished a 45,000-square-kilometer concession near the Siwa Oasis on the Libyan border. The concession may be reoffered in 1974.

The Gulf of Suez Petroleum Co. (GUPCO) reported a discovery 11 miles northwest of El Morgan field. The new discovery, the "July" field, tested at 5,280 bpd of 32° API crude oil through a ⅜-inch choke. Oil reserves of the 6-square-mile structure were estimated at 300 million barrels. Production at a 30,000 bpd rate is scheduled for early 1974 with expansion to 100,000 or 150,000 bpd by yearend 1974.

A second discovery was reported in 1973. Located offshore near Ras Gharib, the field's initial yields are expected at 50,000 bpd with a potential of 350,000 bpd upon full development.

During 1973, a waterflood pressure maintenance project was under development in the El Morgan field, Egypt's largest producer, with reserves estimated at 1.2 billion barrels. The project operations include the injection of 300,000 to 400,000 bpd of desalinated water from the Gulf of Suez. The cost of the El Morgan waterflood project is more than $30 million; however, a recovery of an estimated additional 1 billion barrels will be realized as a result.

Prior to the October War, Egypt had built up to a 174,400 bpd crude distillation capacity. The Suez Oil Processing Co. began refining operations at the rate of 7,400 bpd at the newly constructed 14,600 bpd capacity Tąntą petroleum refinery in the Nile Delta. The refinery is served by a 112 mile crude pipeline from Suez and a 55 mile products line connecting the refinery to the Musturud storage and distribution area near Cairo. The crude and products pipelines each have a capacity of 40,000 bpd.

During 1973 construction of a 250,000 bpd export refinery was under consideration by the Board of Foreign Investment Authority. The refinery is to be built in the Alexandria free port area at a cost of $400 million. Saudi Arabian and other Persian Gulf crudes will supply the refinery via the proposed Suez-Mediterranean pipeline (Sumed). Refinery products will be marketed in Western Europe.

Contracts for the Sumed line were under negotiation during the year. Bechtel Corp. (United States) signed a preliminary contract for construction of the 210-mile trunkline. At yearend, the Gulf of Suez-Mediterranean Petroleum Pipeline Co. was formed to finance and operate the Sumed pipeline. Construction was to begin in 1974 with the first stage completed in 2 years with an annual throughput capacity of 800,000 bpd through a 42-inch-diameter pipeline. The second stage includes a parallel line to be completed within 6 months of the first stage completion, raising daily throughput capacity to 1.6 million bpd. Additional pump stations and expanded terminal facilities will be required to reach the lines maximum throughput capacity of 2.4 million bpd. During 1973, oil transit agreements were signed with 13 foreign oil companies for a combined 1.67 million bpd of oil shipments via the Sumed pipeline.

Plans to restore the Suez Canal were underway in 1973, with a government allocation of $37.5 million for clearing mines, sunken ships, and bridging. At the time of the closure in 1967, the canal's draught was 38 feet. Deepening the canal to a depth of 70 feet was being considered.

France.—Domestic crude production averaged 0.025 million barrels per day while crude imports averaged 2.7 million barrels per day. Nearly half of total French crude imports are obtained from Saudi Arabia, Iraq, and Kuwait. In a concentrated effort to diversify crude sources, French companies have obtained a variety of concession areas throughout the globe. New concessions obtained in 1973 included areas in North Sea, off the Italian Coast, in Spain, Canada, Peru, and in Colombia. Exploration in France itself is concentrated in the Aquitaine area. Several discoveries were reported in 1973 in the Aquitaine region, in the North Sea, and in Canada.

Crude oil supplies controlled by foreign operations of French companies accounted for ⅔ of crude imports in 1973.

Refinery expansion activities at Fos, Frontigen, Feysin and Donges resulted in nearly a 6% increase in the nation's refining capacity bringing total capacity to 3.2 million bpd in 1973.

Indonesia.—Extensive exploration and development activity continued in 1973, with expenditures estimated at $400 million. Extension and development wells drilled during the year totaled 449. Two hundred exploratory wells were completed, achieving a 1:4 success ratio with the discovery of 50 wells including 28 oil wells, 19 gas wells, and 3 oil and gas wells.

Petroleum production continued to climb, averaging better than 1.3 million bpd in 1973 as compared with 0.9 million bpd in 1970. The bulk of crude output or 0.96 million bpd is recovered by P.T. Caltex Pacific Indonesia (CPI) under a production contract with the state-owned oil company, Pertamina. The production contract calls for a 65% to 35% production ownership in favor of Pertamina.

About three-fourths of Indonesia's crude production is exported, with Japan as the major market receiving 740,000 bpd in 1973. During 1973, eight refineries were in operation with a total capacity of 424,000 bpd. By yearend, construction of a ninth refinery was underway. Constructed by Fluor Engineers & Constructors, Inc., and financed by a $120 million loan from the U.S. Export-Import Bank, the 100,000 bpd Cilacap refinery on the southern coast of Java should be completed by 1976. The refinery will use Persian Gulf crude as feedstock to meet domestic markets for such products as asphalt and lubricants.

Domestic consumption of petroleum products was reported at 170,000 bpd in 1973. The product consumption pattern was 40% kerosine, 25% diesel fuel, 20% gasoline, and 15% other products.

Iran.—In March, Iran assumed ownership and control of all oil installations in the country. The Iranian Oil Participants, Ltd. (IOP) (the Consortium), the largest concessionaire was disbanded but participants were guaranteed supplies of oil for a 20-year period in ratio to their former ownership in IOP. IOP members formed a nonprofit service company, Oil Services Co. of Iran (OSCO), to assist the National Iranian Oil Co. (NIOC) in operations for an initial 5-year period. Production from the former consortium area averaged 5.4 million bpd representing 92% of Iran's crude output in 1973.

Iranian refining operations produced above their designed capacity in 1973. The 40,000 bpd Shiraz refinery was inaugurated in mid-November. Throughput at Shiraz totaled 2.6 million barrels by yearend. Abadan reported an annual throughput of 158.3 million barrels, the Tehran refinery throughput was 34.9 million barrels, the Kermanshah refinery throughput was 6.2 million barrels and a 12.3 million barrel throughput was reported in the topping plant. Expansion of the Tehran refinery to 125,000 bpd was underway as was construction of a second Tehran refinery of 100,000 bpd capacity. Plans were announced for a 100,000 bpd refinery at Isfahan and 130,000 bpd refinery at Neka. The Abadan refinery is to be expanded from 430,000 bpd to 550,000 bpd. Thus, becoming the largest refinery in the world.

Israel.—Israel's second refinery came on stream during the year. The 70,000 bpd refinery at Ashdod brings Israeli refining capacity to well over 200,000 bpd.

Capacity of the Trans-Israeli pipeline (Tipline) was reportedly increased to 900,000 bpd, before the October outbreak of hostilities. The 42-inch line runs 160 miles between the Port of Aqaba on the Red Sea and the port of Ashkelon on the Mediterranean Sea. The eventual capacity of Tipline is projected at 1.2 million bpd.

Italy.—Domestic crude production was limited averaging 19,403 bpd in 1973. Exploration activities continued with several offshore concessions granted in the Sicilian Channel, the Tyrrhenian Sea and in the Adriatic Sea during 1973. Exploratory well completions for the year totaled 63, down from 77 completions reported in 1972.

Italian refining capacity nearing 3.9 million bpd is the largest in Western Europe; however, refineries operated at ⅔ capacity during the year. Major refining operations reported significant losses as a result of prolonged price freezes on petroleum products. British Petroleum Co. sold its 73,000 bpd Volpiano refinery, and more than 3,000 retail outlets along with related transport and distribution equipment to Oil Chemicals and Transport Finance Corp. (Italy). Shell Italiana. S.p.A. sold the 115,000-barrel-per-day-capacity La Spezia refinery, the 100,000 bpd Taranto refinery and the 50,000 bpd Rho refinery along with 4,860 retail outlets and related transportation and distribution equipment to Azienda Generale Italiana Petroli (AGIP).

Price increases for most petroleum products were authorized on September 30. Pump prices were raised by 14 cents to $1.09 and $1.15 per gallon for standard and premium gasoline respectively. Much of the increase was absorbed by an increased manufacturing tax of 10 cents.

Japan.—Domestic production of crude oil has been very limited, ranging from 14,000 to 15,500 bpd in the last decade and peaking in 1970 at 15,500 bpd. Production is derived from fields in the Niigata and Yamagata areas of Honshu Island and from fields near Shiratsukari on Hokkaido Island. A commercial field in the Sea of Japan off Niigata was confirmed and production is scheduled for 1975.

As Japan is dependent upon crude petroleum imports of nearly 5 million bpd, the cutback in receipts of Middle Eastern oil, the source of more than three-fourths of its total crude imports, created a "state of national emergency." An energy saving program went into effect on November 16, 1973, requiring a 10% across-the-board cut in oil and electricity consumption on a government administrative guidance basis. This action was followed by enactment of the Petroleum Supply Adjustment Law and the National Livelihood Stabilization Law both effective on December 22, 1973, which authorized the government to check abnormal commodity price increases and goods shortages arising from oil supply cuts.

Japanese refining capacity was reported at 4.8 million bpd at the close of 1973. Two new refineries were scheduled for operation during the year, the 100,000 bpd Nagoya refinery of Toa Oil Co., Ltd. and the 70,000 bpd Tomakomai refinery of Idemitsu Kosan Co., Ltd. Expansion activities of Nippon Petroleum Refining Co., Ltd. were scheduled for completion near yearend, raising capacity at the Muroran refinery from 10,000 to 110,000 bpd. The Sakai refinery of Kansai Oil Co., Inc., was scheduled for an expansion from 110,000 to 210,000 bpd by the close of 1973. Government authorizations were announced for a 1.4 million bpd additional refining capacity by 1976 and additional authorizations for a total of 1.1 million bpd by 1978.

Several new petroleum companies were formed during the year. On January 31, 1973, Japan Oil Development Co., Ltd., a partnership between Japan Petroleum Development Corp. and nine Japanese oil exploration companies, was formed. The new company purchased 45% of British Petroleum Corp.'s share of Abu Dhabi Marine Areas, Ltd. (ADMA), thus obtaining 30% equity in ADMA which is currently producing a total of 507 bpd from the Umm Shaif and Zakum offshore fields in Abu Dhabi.

The International Oil Co., Ltd. was established March 8, 1973, as a joint venture of 10 private companies. The company arranged for the purchase of nearly 20,000 bpd of crude oil from the Ta-ching field in the People's Republic of China. By 1974 imports of Chinese crude are expected to be 60,000 bpd or more.

Libya.—Crude production continued to decline from the 1970 peak level of 3.31 million bpd. Daily production averaged 2.27 million bpd during the first 10 months of 1973; however, production cutbacks reduced daily output to nearly 1.77 million bpd during November and December, for an overall 1973 daily production average of 2.17 million bpd.

During 1973, Libyan Government activities focused on gaining control of major oil company operations in Libya. In August, Occidental Petroleum Corp. and Oasis Oil Co. signed an agreement accepting 51% government participation in their Libyan operations, at which time the operators were permitted to increase their production rate to 475,000 bpd and 900,000 bpd, respectively. By September the Libyan Government issued a decree unilaterally acquiring 51% participation in the remaining major oil company operations.

The posted price for 40° API gravity Libyan crude was $3.78 per barrel in January. Increments in April, June, July, August, and on October 1 increased the price to $4.60 per barrel, in accordance with OPEC and oil company negotiations that provided price adjustments to compensate for the dollar devaluation. By mid-October prior agreements were abandoned and Libya set posted prices unilaterally. The posted price was nearly doubled at $8.93 per barrel on October 16, increased to $9.06 on November 1, and reached $15.77 by January 1, 1974.

The Libyan Government announced discovery of new oil fields at Ra's al Hilāl in Northeast Libya and near Ghadāmis near the Algerian-Tunisian border. Libyan production has declined steadily since 1970, and extensive exploration and development is necessary if Libya is to maintain her position as the leading African crude producer.

The 60,000 bpd capacity refinery at Az Zawiyah, under contract construction by SNAM Progetti S.A., was near completion by yearend. Doubling of the Az Zawiyah refining capacity was under consideration as well as the construction of a 180,000 bpd refinery at Marsá al Burayqah, a 120,000 bpd refinery at Tobruq, and a jointly owned Libyan-Tunisian refinery at Qabes, Tunisia of 120,000- to 150,000 bpd capacity.

During the year, the Libyan General Organization for Maritime Transport signed agreements for construction of 11 tankers. Nippon Kokan Kabushiki Kaisha (Japan) received a $45.3 million contract for construction of two 118,000-deadweight-ton tankers; the Gotaverken AB shipyard (Sweden) received a $40.8 million contract for three 152,700-deadweight-ton tankers; and two crude tankers of 100,000 to 120,000 deadweight tons each, as well as four 30,000-deadweight-ton product carriers were to be built by Yugoslavia under a barter agreement for 40,000 bpd of Libyan crude for an unreported time period.

Nigeria.—Production continued to climb, increasing from a January 1 production level of 1.91 million bpd to a midyear production level of 2 million bpd, and finally reaching a level of 2.25 million bpd by yearend 1973. Much of the increase was attributable to expanded capacity at the Kolo Creek, Etelbou, and Diebu Creek fields operated by the nation's largest producer, Royal Dutch/Shell and British Petroleum (Shell-BP) in partnership with the Nigerian National Oil Corp. (NNOC). During the year, the Nigerian government represented by the NNOC entered into a participation agreement with Shell-BP acquiring 35% equity in exploration and producing operations. The agreement offers Shell-BP the right to buy back most of the NNOC participation crude. The government engaged in negotiations with other Western operators including Gulf Oil Corp., Mobile Oil Co., and Texaco Overseas (Nigeria) Petroleum Co./Chevron Oil Co. (Nigeria). Although indications were that even higher participation levels were under discussion, no accords were announced by yearend. Government posted prices for 34° API gravity Nigerian crude increased during 1973 from $3.56 per barrel to a high point of $8.40 per barrel and then jumped to $14.69 per barrel on January 1, 1974.

Although the 1973 crude production was obtained essentially from onshore operations, at least eight good test flows were reported during the year from offshore exploratory drilling operations of Japan Petroleum Co. (Nigeria Ltd.), Occidental Petroleum Corp., Deminex and Niger Oil Resources, Texaco Overseas (Nigeria) Petroleum Co., and Chevron Oil Co. (Nigeria). These companies are operating in concession areas awarded in 1972 by an agreement which includes 51% NNOC participation in commercial finds. Promising offshore developments together with expanding onshore operations should in the very near future increase Nigerian crude output to the point of surpassing Libya as the leading African crude producer.

The Nigerian government announced plans for construction of a second refinery. Tentative plans call for construction of a 30,000 bpd capacity refinery at Warri. Proposed completion date is 1976.

Norway.—In spite of a 65-day shutdown because of bad weather conditions in the North Sea during 1973, the Phillips Petroleum Co. group reported production of more than 11 million barrels of crude from four wells in the Ekofisk field. A 1-million-barrel-capacity concrete storage tank was towed to the production site in June 1973 and set in place in 230 feet of water. The tank should be serviceable by mid-1974 permitting crude storage when tanker loadings are prohibited by bad weather. The 34-inch-diameter crude oil pipeline between the Ekofisk field and Teesside, England, a distance of 220 miles was near completion by yearend. Throughput capacity is 1 million barrels per day. Terminal facilities at Teesside are scheduled for completion in 1975.

A 80,000 bpd refinery was under construction at Mongstad, near Bergen under contract to Foster Wheeler Corp. (United States). Completion is scheduled for early 1975.

An agreement reached during 1973 between the government and the Ekofisk producers reserves sufficient amounts of natural gas liquids, landed in Norway free of freight charges, to sustain operations of a 250,000-ton-per-year ethylene plant.

Saudi Arabia.—Saudi Arabia remained the third largest world producer of crude oil. Output for the year averaged 7.9 million bpd including a peak level of 8.4 million bpd in July and a low of 6.1 million bpd in November following the Arab production cutback policy.

The Arabian American Oil Co. (Aramco) reported discovery of a major new offshore field at Maharah. By midyear Aramco's offshore Zuluf field went into production at 80,000 bpd and the onshore Harmaliyah field went into production at 100,000 bpd with output anticipated at 150,000 in 1974. Transportation and loading facilities were under construction. A fourth sea loading berth as well as additional storage capacity of 5.5 million barrels came into service at Ras Tanura. A total of 18 tankers can be loaded simultaneously from the port's two T-head piers and 4 sea berths. Plans were announced for construction of a 46-inch and 48-inch pipeline from Abqaiq to Ju'anura (15 miles northwest of Ras Tanura) with accompanying storage facilities and with offshore loading capacity of 140,000 barrels per hour into tankers as large as 500,000 deadweight tons.

The Saudi Arabian Government acquired 25% participation in Aramco reducing equity holdings of Standard Oil Co. of California, Texaco Inc., and Exxon Corp., to 22.5% with Mobil Oil Corp. holding 7.5%.

United Arab Emirates.—Abu Dhabi, averaging 1.3 million bpd and Dubai averaging 0.2 million bpd were the only producers of commercial crude in the United Arab Emirates. Sharjah will, however, join their ranks when the Mubarek field enters production, possibly by mid-1974. By agreement, Sharjah will share royalties with Iran on production from the Mubarek field. Sharjah's Mubarek crude will be sold to Japan Lines, Ltd.

Several offshore concession agreements were under negotiation during the year. These included concessions totaling 1,650 square miles off the Gulf of Oman in waters of Fujairah and Sharjah as well as 232 square miles of offshore Ajman on the Persian Gulf. Reserve Oil & Gas Co. and United Refining Co. (United States) were included in the negotiations.

Construction plans were affirmed for a 15,000 bpd refinery at Umm al Nar (Abu Dhabi) to be supplied via a 20,000 bpd capacity line running from Habshan (Abu Dhabi) a distance of 76 miles.

Financing for Dubai's massive dry dock project was arranged and construction of facilities for servicing two 500,000 deadweight ton tankers and a million deadweight ton tanker will soon be inaugurated.

U.S.S.R.—Crude production neared an average of 8.5 million bpd in 1973, an increase of 6.9% over the previous year's production level. Tataria, Tyumen, and Bashkiriya were the nation's major producing areas accounting for nearly one-third of total crude output in 1973. Soviet sources report five new discoveries in Tataria during 1973. Two fields in the Bashkiriya area the Teplykovskoye and Burayëvskaya fields entered production during the year. The Samotlor field in Tyumen produced at an average of 340,000 bpd with production averages forecasted at more than 1 million bpd in 1974, as a result of flooding projects. The oil zone is located 8,200 feet below Lake Samotlor.

Negotiations were conducted on the possible Japanese and U.S. participation in development of the Tyumen field. Preliminary discussions indicated a possible export of 800,000 bpd via a pipeline to a Pacific terminal. Subsequent discussions reduced proposed export levels to 500,000 bpd. No agreement was reached by yearend.

Crude and product exports from the U.S.S.R. averaged nearly 2.4 million bpd in 1973. East European nations received nearly 1.4 million barrels per day. To facilitate exports, a 48-inch pipeline was under construction to move crude from the western Siberian fields across the Ural Mountains to Ufa and Kuyibyshev then to Tikhoretsk and the Black Sea port of Novorossiysk.

United Kingdom.—Forty-four exploration wells were drilled in British North Sea waters in 1973, 35 in the North, 8 in the South, and 1 in the Celtic Sea.

In January, the Occidental Group, which holds a production license in the North Sea for 494 square miles, drilled the Piper discovery well in Block 15/17-1A in 475 feet of water. The discovery well was tested at a combined rate of 8,848 bpd of low-sulfur oil averaging 37° API from two zones. In March, a second Piper field well, drilled 2 miles north of the discovery well, tested at a combined rate of 32,129 bpd from the two zones. Four more appraisal wells were drilled confirming the Piper field as a major North Sea oil field. Using a recovery factor of 40%, production potential of the field is estimated at 650 million barrels. Initial production is scheduled for 1975 at 100,000 bpd, building up to 200,000 bpd by 1976. Construction of a 130 mile, 30-inch diameter submarine pipeline connecting the field to an Orkney Island terminal is scheduled for completion in mid-1974.

In early 1973, Phillips Petroleum Co. reported a discovery well in Block 16/29 testing at 3,500 bpd of 36° API crude. The Maureen field lies in 300 feet of water.

By midyear the Shell/Esso group reported a discovery well in Block 211/23, and an appraisal well in Block 211/29 increased recoverable reserve estimates for the Brent field to 1,500 million barrels.

The Total group reported a discovery in Block 3/15 testing at 3,000 bpd of 42° API crude through a ½-inch choke.

Several confirmations and extensions were made on 1972 discoveries. These included the Mobil group's Beryl field in Block 9/13, the Thistle field in Block 211/18, and Shell/Esso's Brent field in 211/29.

Production from Shell/Esso's Auk field discovered in 1970 in Block 30/16 was delayed by 1 year, and production is now anticipated by 1975. Production from the Brent field is anticipated by early 1976, Beryl field is scheduled for production in late 1975, and the Thistle field should be in production by 1976.

The construction of a new refinery and several refinery expansions were reported in 1973. American Oil Co.'s 80,000 bpd Milford Haven refinery was in operation by October. Mobil Oil Co. Ltd.'s Coryton refinery and Texaco Ltd.'s Pennbrook refinery were both expanded from 140,000 bpd to 180,000 bpd.

Zaire.—The nation should enter the ranks of petroleum producers by 1975 when two offshore fields are brought into production by Gulf Oil Zaire which holds 50% equity in a group comprised of Japan Petroleum Zaire with 32.8% equity, and the Belgian firm Ste. du Littoral Zairois Soliza with 17.2% equity. Initial production is anticipated at 25,000 barrels per day.

The government in partnership with Italy's Ente Nazionale Idrocarburi operated a 16,000 bpd capacity refinery at Moanda. Crude petroleum imports from Iran, Saudi Arabia, and Nigeria totaled 14,325 bpd. Petroleum product imports were reported at 2,750 bpd. In December, the government nationalized the marketing facilities of Mobil Oil Co., Texaco, Fina, and Royal Dutch/Shell, placing marketing operations under control of the Ministry of Energy.

TECHNOLOGY

Delta Exploration Co., Inc. was using a patent-pending combination barge and ship to cover both deep and shallow water exploration. The separate 76-foot recording barge is carried on the stern of the 165-foot mother ship which operates well out to sea. Within 10 miles of shore, the barge can be released for operations in water as shallow as 4 feet. Seismic units on the vessel contain Gardner-Denver 2,000-psi compressors powering two 1,000-cubic-inch and two 300-cubic-inch Bolt air guns. Delta's boat and barge system was operating in South America in 1973.[6]

A direct-current electric-power swivel was field tested at Gulf of Mexico locations offshore from Louisiana. Industry's first electrically powered drilling swivel was subjected to a variety of field operating conditions on four recently completed holes. The Bowen Tools, Inc. and Brown Oil Tools, Inc., swivel was installed while working on an Atlantic Richfield Co. platform in Eugene Island Block 175 field.

Specific advantages of the 750-horsepower electric swivel on these wells included the following:

1. Safety, only the driller and one floorman are necessary to make a connection. No spinning chain is needed (the swivel is rotated to make up tool joints) and tongs are not required if the special backup powerslips designed for use with the swivel are installed.
2. Fewer downhole surveys are required to orient the large nozzle in the bit when jetting to establish a directional hole, since reference points to the large nozzle are made on the torque elevators and are always available above the rotary.
3. Weight of the power swivel plus the fact it runs on a guide track allows drilling operations to continue even in high winds, a common occurrence in many offshore areas.
4. Since all swivel operations can be precisely controlled, downhole tools are easier to set.[7]

Contractors and operators are developing and successfully testing new rigs and associated equipment that will allow drilling during the severest weather. Advances in downhole tools are helping to quickly and safely evaluate holes drilled from floating vessels. Recent developments include the following:

1. A procedure for well bore re-entry and drilling in water depths of more than 1,000 feet;
2. A revolutionary deep water jackup;
3. An ice-breaking drillship;
4. Two proposed platforms with ice-cutting equipment; and
5. A drillstem test tool for floating rigs.[8]

An oil recovery system that reportedly can recover oil spills offshore in high seas with 8-foot waves has been developed and tested by Ocean Systems, Inc. The system contains a double flotation arrangement with two weirs arranged in such a way that oil thickens in front of the primary weir, then further thickens in front of the second weir, where it enters a collection tube leading to a floating pump and collector.[9]

A feasibility design has been completed for an Arctic marine, crude oil transportation system consisting of a depth-controlled, submerged barge towed by a powerful, surface icebreaking tug. Continental Oil Co., with assistance from Arctic, Inc., investigated this proposal as a means for transporting crude from Alaska's North Slopes to eastern U.S. markets.

Because the cargo is carried below the ice-water surface, the system can achieve speeds through an ice field greater than a conventional ice breaker of equal power. This feature, combined with low total system costs, can give an economical edge over alternate marine systems. The system is reportedly feasible, and with a suitable development program, an operational system could be realized with existing technology.[10]

The increasing use of reinforced concrete for offshore construction of nearly any type from floating nuclear powerplants to permanent drilling and production platforms is evident. North Sea operators, encouraged by recent studies that indicate stable seafloor conditions in at least some areas of interest, are seriously considering concrete platforms for future installations. Recent tests on concrete installed in the ocean 67 years ago, indicate that compres-

[10] World Oil. New Way to Move Arctic Oil. V. 177, No. 1, July 1973, p. 100.

sive strength, in three cases, had actually increased since a similar test was made 40 years ago. Other core tests made on concrete harbors built in 1942 in Britain revealed superior concrete strength retention and no deterioration of reinforcing metal.[11]

The first concrete production platform has reportedly been ordered by Mobil Producing North Sea, Ltd. for use in the Mobil group's Beryl field located in the United Kingdom North Sea in 380-foot water. The $50 million Condeep design structure is to be built by a Norwegian consortium in Stavanger, Norway for 1975 delivery.[12]

Onsite seismic analysis is being provided by a new Unicomp Inc. system. Integrated with a minicomputer, the Spectar 2000 unit can simultaneously process and display data from 256 sensing stations. The method is claimed to be 10 to 100 times faster than software techniques, and it indicates to crews where further exploration is warranted. The unit also stores data for processing later on a laboratory computer. Digital Resources Corp. will use the system for a massive exploration program in Bolivia.[13]

A new way to make holes, ranging in size from telephone conduit to subway tunnels was demonstrated recently by Los Alamos, N. Mex., Scientific Laboratory and the National Science Foundation. The technique, Subterrene, is an offspring of the atomic energy program and occurred to program managers while components for a new type of nuclear reactor were being tested under high-temperature conditions. Subterrene works by melting rock or soil with an electrically heated element. Few rocks have a melting point high enough to withstand the probe's 2,200° F temperature.

Rock quarry demonstrations at Fort Belvoir, Va., featured two small probes, one less than 2 inches, the other about 2½ inches in diameter. But, larger instruments are feasible. Subterrene's first application was an Indian ruin in the Randelier National Monument near Los Alamos. Archaeologists wanted drainage built into a ruined ceremonial chamber to halt further deterioration, but were afraid vibrations from conventional drilling would damage the site. A 3-inch hole, 8 feet deep, was melted for water drainage and it had its own high-density glass casing created by the melted rock.[14]

The increasing number of directional wells being drilled has accelerated development of cost saving directional drilling equipment. The recent introduction of two new directional tools, available from Dyna-Drill Co., a division of Smith International, Inc., has added measurably to the state-of-the-art of directional drilling.

One tool, a hydraulically actuated bent sub, has proven its ability to cut costs primarily through reducing round trips. With a simple adjustment (made downhole) to the tool, an operator may switch from straight to directional drilling.

The main advantage of the Teleorienter is its ability to transmit orientation data to the surface any time it is required without the need of wireline services. Both tools have been operational for about 1 year and case histories have indicated each to be a useful directional drilling tool.[15]

The immediate need for fuel desulfurization is being stimulated by tight restrictions on sulfur oxide emissions and by expanding fuel oil markets that are becoming more dependent on high-sulfur foreign crude. Hydrocarbon fuels from tar sands, oil shale, and coal, which are expected to ease our impending energy crisis, are all high in sulfur. Moreover, alternative, nonfuel markets for high-sulfur products such as asphalt are rapidly becoming saturated. As a consequence, hydrodesulfurization processes are playing increasingly important roles in refiners' efforts to produce low-sulfur fuels. Amoco Oil Co. has developed a process for the low-pressure hydrodesulfurization of heavy distillates such as vacuum gas oils or decanted oils. The process will operate at total pressures well below those conventionally used and can achieve 90% desulfurization on most feeds. For virgin feedstocks, catalyst life will approach that obtained at high pressure while even with cracked stocks such as decanted oil the catalyst will give satisfactory life. Investments can be reduced by 30% to 40% over conventional designs, leading to substantial savings in the overall cost of preparing low-sulfur blending stocks. Hydrogen consumption is also substantially less for the low-pressure design, leading to

lower heats of reaction and simplified reactor design.[16]

The Dilchill Dewaxing Process was developed for ketone dewaxing based on direct heat exchange with cold solvent in a highly sheared environment. This process produces highly discrete and stable wax crystal agglomerates, thereby facilitating the separation of wax from oil at high yields and high throughput. The process significantly reduces the need for costly and cumbersome scraped surface exchangers, improves operation of those that are needed, and reduces overall filter area requirements. Furthermore, this process allows integration between dewaxing and refined wax manufacture, eliminating the need for a costly, separate recrystallization plant. In combination with either lube or wax hydrofining, this represents a total process package for dewaxing, wax manufacture and lube and wax finishing.[17]

The responsible disposal of used lubricating oils is a serious problem. Recent Impetus on waste recovery leads to renewed interest in re-refining—to convert this waste oil into useful products. Yet conventional rerefining can also lead to waste byproducts: Spent acid, spent caustic, spent clay, sulfur dioxide, and others. Laboratory data show a good quality lube base stock may be prepared from automotive crankcase drainings. The process includes distillation of the used oil to obtain a lube distillate which is then hydrofined.[18]

The Gasynthan Process, developed by Badische Anilin und Soda Fabrik/Lurgi, offers a proven route to synthetic natural gas (SNG). An SNG plant incorporates naphtha desulfurization, naphtha catalytic reforming with steam to methane-rich gas, methanation of rich gas hydrogen and CO_2, and removal of CO_2 to meet the desired gas quality.

A number of process routes are possible by combining single or two-stage gasification with one or more downstream methanation steps. However, one route best suits any particular application depending on feedstock type and availability, plant location, integration with other plant units, and other project criteria. The four basic possibilities are as follows: (1) Single-stage gasification (Standard Gasynthan) followed by one or two methanation steps, (2) two-stage gasification (Advanced Gasynthan) followed by one methanation step, (3) single-stage gasification with one methanation step and recycle of low CO_2-product gas (this route has a lower net stream requirement (about 0.7 lb/lb naphtha) and the highest efficiency), and (4) single-stage gasification at low temperature (low temperature Gasynthan) and low-steam-to-naphtha ratio followed by single-stage methanation.[19]

The Bureau of Mines continued to focus on improved technology for discovery and production of petroleum. Research was directed toward development of methods of stimulating production from oil and gas reservoirs. Laboratory studies were made to improve tertiary oil recovery by injection of fluids supplemented by micellar-polymer solutions to literally scrub the oil from the reservoir rock. Plans were initiated for a field demonstration of micellar-polymer flooding.

Field research continued to determine the potential application of gamma-ray anomalies at the surface and particularly those over known hydrocarbon deposits in petroleum-producing areas.

The Bureau of Mines SolFrac process was field tested in Labette County, Kans., utilizing a combination of chemical explosive fracturing and solvent injection for heavy-oil recovery. The process recovered 40 barrels of viscous immobile oil during the first 5-month test period.

Laboratory equipment was assembled for testing oil recovery from tar sands by the reverse combustion process. Tests were made with tar sands from deposits in Utah to develop data needed for a field demonstration. In a reverse combustion test from a vertical sand pack of tar sand from the P.R. (Pear) Spring deposit, an oil recovery of 47.4 volume-percent was obtained along with a significant increase in gravity of the oil from about 8° to over 22° API.

Research on petroleum composition included a project on the identification of oil spills. A data bank showing unique properties of crude oils that are shipped by

tankers is being developed to provide information for identifying the sources of oil spills.

In research on re-refining waste lubricating oils, a solvent-extraction and distillation procedure was developed that removes contaminants from waste lubricating oils without adversely affecting the hydrocarbon composition of the oil.

The systematic scheme developed by the Bureau of Mines to separate heavy crude oil distillates into compound-type concentrates was applied to five foreign crude oils. Research continued on spectral characterization of these concentrates to provide information needed for efficient processing of these low-grade distillates into quality fuels.

Total	905,711	866,879	887,386	913,300	933,699	958,011	986,298	996,955	1,015,641	1,037,440	1,023,238	1,008,307	1,008,307

[p] Preliminary (except for oil and lease condensate production).
[1] U. S. Department of the Interior data for crude oil, unfinished oils, and plant condensate; U. S. Department of Commerce data for all other imports.
[2] Excludes imports for substitute natural gas (SNG) plant feedstock use.
[3] Represents the difference between supply and indicated demand for crude petroleum.
[4] Minus represents withdrawal from stock, which is added to total disposition; plus represents stocks increase, which is subtracted from total disposition.
[5] U. S. Department of Commerce data.
[6] Liquefied refinery gas.
[7] Liquefied petroleum gas.
[8] Produced at petroleum refineries. Data for LPG for petrochemical feedstocks are included with those for "Liquefied gases."
[9] Includes isopentane.

Total United States	29,632	39,001	38,063	36,339	35,300

[1] From reports of Committee of Petroleum Reserves, American Petroleum Institute. Included are estimated quantities of crude oil which geological and engineering data demonstrate with reasonable certainty to be recoverable from known reservoirs under existing economic and operating conditions.
[2] Included with "Other States."
[3] Includes offshore reserves.
[4] These data include the estimate of proved reserves in the Prudhoe Bay Permo-Triassic reservoir, discovered in 1968. The estimate is based on the analysis of extensive engineering and geologic data; however, revisions may be required when actual production performance becomes available.
[5] Includes Arizona, Missouri, Nevada, South Dakota, Tennessee, and Virginia.

Table 6.—Supply and disposition of crude petroleum (including lease condensate) in the United States

(Thousand barrels)

Supply and disposition	1969	1970	1971	1972	1973 p
Supply:

[1] Includes 308,981,000 barrels in Delaware River Valley.
[2] Includes some Athabasca hydrocarbons.
[3] Includes 28 by trucks.
[4] Alaska, Arizona, Hawaii, Nevada, Oregon, and Washington.
[5] Excludes crude oil imported for direct fuel use by pipeline.

(Thousand barrels)

Product	1970	1971	1972	1973 p
Liquefied gases—Continued				
Propane (including propylene)—Continued				
Domestic demand—Continued				
Refinery propane and/or propylene:				
For fuel use	62,191	71,185	69,129	74,091
For chemical use	20,159	21,395	25,094	25,335
Total refinery propane and/or propylene domestic demand	82,350	92,580	94,223	99,426
Total domestic demand	283,120	289,718	326,816	318,018
Butane (including butylene):				
Production:				
At gas processing plants	87,253	88,544	88,924	88,766
At refineries:				
For fuel use	13,514	13,765	12,940	13,036
For chemical use	8,693	5,886	5,673	6,666
Total production at refineries	22,207	19,651	18,613	19,702
Total production	109,460	108,195	107,537	108,468
Stocks end of year:				
Plant butane stocks:				
At plants	14,397	13,571	10,389	15,289
At refineries	414	1,614	1,425	1,369
Total plant butane stocks	14,811	15,185	11,814	16,658
Refinery butane and/or butylene stocks:				
For fuel use	912	1,448	2,161	2,471
For chemical use	35	11	15	16
Total refinery butane and/or butylene stocks	947	1,459	2,176	2,487
Total stocks	15,758	16,644	13,990	19,145
Imports	9,454	14,049	16,550	22,187
Exports	1,655	4,725	4,967	4,455
Plant butane used at refineries	43,758	46,061	44,512	39,327
Domestic demand:				
Plant butane	50,083	51,433	59,366	62,327
Refinery butane and/or butylene:				
For fuel use	14,050	13,229	12,227	12,726
For chemical use	8,694	5,910	5,669	6,665
Total refinery butane and/or butylene	22,744	19,139	17,896	19,391
Total domestic demand	72,827	70,572	77,262	81,718
Butane-propane mixture:				
Production:				
At gas processing plants	5,677	4,173	3,535	3,509
At refineries:				
For fuel use	3,947	2,949	2,536	3,003
For chemical use	5,353	3,029	3,892	3,491
Total production at refineries	9,300	5,978	6,428	6,494
Total production	14,977	10,151	9,963	10,003
Stocks end of year:				
Plant butane-propane mixture:				
At plants	733	815	944	826
At refineries	35	38	31	128
Total plant butane-propane mixture stocks	768	853	975	954
Refinery butane-propane mixture:				
For fuel use	220	494	367	533
For chemical use	--	3	2	3
Total refinery butane-propane mixture stocks	220	497	369	536
Total stocks	988	1,350	1,344	1,490
Exports	6,135	--	--	--
Plant butane-propane mixture used at refineries	2,822	2,896	2,485	3,027
Domestic demand:				
Plant butane-propane mixture	198	1,192	928	503

See footnotes at end of table.

Table 30.—Salient statistics of the major refined petroleum products in the United States—Continued

(Thousand barrels)

p Preliminary.

[1] Includes underground stocks at plants and refineries, in thousands of barrels. At plants: Ethane, 1972, 6,143; 1973, 3,921; propane, 1972, 39,340; 1973, 52,090; butane, 1972, 7,917; 1973, 12,243; butane-propane mixture, 1972, 324; 1973 192; and isobutane, 1972, 7,407; 1973, 6,341. At refineries (includes LRG): Propane, 1972, 4,427; 1973, 4,074; butane, 1972, 3,176; 1973, 2,725; butane-propane mixture, 1972, 260; 1973, 444; and isobutane, 1972, 1,236; 1973, 765.

[2] Includes No. 4 fuel oil, in thousands of barrels: 1972, 3,723; 1973, 3,449. Data for previous years are not available.

[3] Produced at petroleum refineries. Data for LRG petrochemical feedstocks are included with those for "Liquefied gases."

[4] Includes foreign crude oil to be burned as fuel, in thousands of barrels. 1972, 10,419,000; 1973, 19,105.

Note: "Stocks at refineries" include stocks at refineries and bulk terminals operated by refining and refined products pipeline companies, including pipeline fill. "Stocks at plants" include stocks at plants and terminals operated by natural gas processing companies and natural gas liquids stocks at terminals of pipeline companies, including pipeline fill.

p Preliminary.
[1] Includes some Athabasca hydrocarbons.
[2] "Other hydrocarbons and hydrogen" is defined as including all hydrogen, process natural gas, tar sand bitumen, gilsonite, shale oil, and other naturally occurring hydrocarbon mixtures consumed as raw materials in the production of finished products.
[3] Production at gas-processing plants shown as direct transfers and omitted from the input and output at refineries.
[4] Conversion factors: 280 pounds of wax to the barrel; 5.0 barrels of coke to the short ton; 5.5 barrels of asphalt to the short ton.

[p] Preliminary.
[1] Includes some Athabasca hydrocarbons.
[2] Production at gas-processing plants shown as direct transfers and omitted from the input and output at refineries.
[3] Conversion factors: 280 pounds of wax to the barrel; 5.0 barrels of coke to the short ton; 5.5 barrels of asphalt to the short ton.

p Preliminary.
[1] Represents crude oil used on leases and for general industrial purposes.
[2] Sulfur content in thousands of barrels: 0.50%, 1972; 64,855; 1973: 96,690, 0.51-1.00%, 1972; 70,824; 1973: 82,500, 1.01-2.00%, 1972: 92,652; 1973: 102,842, over 2.00%, 1972: 64,188; 1973: 72,565.
[3] Sulfur content in thousands of barrels: 0.50%, 1972: 203,137; 1973: 244,286, 0.51-1.00%, 1972: 163,764; 1973: 134,557, 1.01-2.00%, 1972: 79,316, 1973: 78,680, over 2.00%, 1972: 191,184; 1973: 163,213.
[4] Includes foreign crude oil to be burned as fuel, in thousands of barrels. Distrct I: 9,939; District II: 480.
[5] Includes foreign crude oil to be burned as fuel, in thousands of barrels. District I: 13,153; District II: 1,916; District V: 4,036.

p Preliminary.

[1] Imports for onshore use of military jet fuel, distillate and residual fuel oils, and receipts from Puerto Rico, the Virgin Islands, and Guam included in these data are based on figures reported to the Department of the Interior. All other import figures are compiled from Department of Commerce data.

[p] Preliminary.
[1] Imports of crude oil and unfinished oils reported to the Bureau of Mines, imports for onshore military jet fuel, distillate and residual fuel oil, and receipts from Puerto Rico, the Virgin Islands, and Guam are based on data reported to the U.S. Department of the Interior.
[2] Includes quantities imported duty-free for supply of vessels and aircraft engaged in foreign trade.
[3] Excludes imports for substitute natural gas (SNG) plant feedstock use.

Phosphate Rock

By W. F. Stowasser [1]

World demand for phosphate rock exceeded production for the third consecutive year. Deliveries exceeded production by at least 2%, further reducing world stocks. Estimated world production in 1973 of approximately 108 million short tons, an increase of about 9% over the 1972 production level, was the highest recorded to date.

The average unit value of domestic phosphate rock increased from $5.09 per ton, f.o.b. plant in 1972, to $5.66 per ton in 1973. The increase in price reflects higher selling prices obtained for phosphate rock from new contracts written in 1972 and 1973. With higher prices posted to become effective after the first of the year, the upward trend of phosphate rock prices is expected to continue into 1974.

The Cost of Living Council removed price controls on domestic fertilizers and phosphate rock used to produce fertilizer and animal feed supplements in October 1973. It was anticipated that domestic prices of phosphate rock and fertilizers would increase and approach the substantially higher world prices when the price controls were lifted. With higher domestic prices, producers agreed to divert exports of phosphate rock and fertilizers into the domestic market to the degree needed to furnish adequate domestic supplies for the record-high acreage that will be planted in 1974.

Construction underway and plans to build significant additional plant capacity for wet-process phosphoric acid will, if projected estimates are correct, raise the 1973 effective capacity of 6.2 million tons of P_2O_5 to about 10.0 million tons of effective capacity by 1980. The growth of this segment of the industry will provide added pressure to increase domestic supplies of phosphate rock. With restrictions on production of phosphate rock expected to continue from factions opposed to strip mining and with limitations on the availability of domestic high-grade reserves for new mines, a gradual reduction in phosphate rock exports appears necessary to furnish sufficient raw materials for future domestic production of phosphate intermediates and fertilizers.

The phosphate rock industry's production capability was affected by shortages of electric power, from unscheduled repair and maintenance, particularly in older plants attempting to produce at consistently high rates, and in several instances, from depletion of high-grade ores. Because of these factors, a sharp downward revision of the capacity of Florida's phosphate rock industry was necessary.

Legislation and Government Programs.—The phosphate rock and fertilizer industries were regulated by a series of economic controls that started with a price freeze in August of 1971, continued with Phase 2 from November 1971 to January 1973, Phase 3 from January 1973 to June 1973, and Phase 4 from June 1973 to October 25, 1973. During Phases 2 and 3, domestic phosphate rock prices were not to increase to permit higher average profit levels than were recorded for the years 1968, 1969, and 1970. Unfortunately, the industry during the reference years was characterized by a surplus in production capacity, and the return on equity relative to net sales was negative. Although demand for phosphate rock increased during the late 1960's, the industry was able to supply the demand without increasing production capacity. The crossover occurred in 1971 and thereafter, when the demand both in the United States and the rest of the world exceeded available supply. With prices regulated in the United States, increasing amounts of phosphate rock and phosphatic fertilizers were diverted into

[1] From table 5.
[2] Measured by sold or used plus imports minus exports.

the strong export market where prices were not controlled. Domestic demand was further strengthened when the U.S. Department of Agriculture released millions of additional acres in 1973 for cultivation. A further release of acreage was authorized for 1974 to stimulate an increase in agricultural exports and to bolster the U.S. balance of trade position. Without price relief prior to October 1973, the phosphate rock industry could not economically justify the investment necessary for new mines and plant expansions.

The pressures on the fertilizer industry increased in 1973 and on October 25, 1973, the Cost of Living Council exempted from Phase 4 controls the sale of fertilizers and nutrient materials used in the production of fertilizers. The Council also established a group composed of both industry and Government representatives to work toward increasing the supply of fertilizer to U.S. farmers by reducing exports. A system was implemented to monitor exports of fertilizer materials shipped under 1973 and 1974 contracts.[2]

The Environmental Protection Agency published proposed effluent limitations guidelines, and new source performance standards for the fertilizer industry.[3] They require achievement by not later than July 1, 1977, of effluent limitations for point sources, other than publicly-owned treatment works, by the application of the best practicable control technology currently available as defined by the Administrator pursuant to Section 304(b) of the Federal Water Pollution Control Act Public Law 92–500. Sec. 301(b) also requires achievement by not later than July 1, 1983, of effluent limitations for point sources, other than publicly-owned treatment works, by requiring the application of the best available technology economically achievable to result in reasonable further progress toward the national goal of eliminating the discharge of all pollutants as determined in accordance with regulations issued by the Administrator pursuant to Sec. 304(b). The phosphate subcategory includes the manufacture of: Sulfuric acid by sulfur burning; wet-process phosphoric acid; normal superphosphate; triple superphosphate; and ammonium phosphate. The manufacture of phosphoric acid includes phosphate rock grinding, acid attack of phosphate rock, phosphoric acid concentration, and phosphoric acid clarification.

The program to study dewatering of Florida phosphate slimes, sponsored by the U.S. Bureau of Mines and the industry-supported Florida Phosphate Council, was continued during 1973. The 1973 program is described in the technology section of this chapter.

Failure to issue mining permits in Hillsborough and Manatee Counties in Florida held up the development of two proposed mines in 1973. Brewster Phosphates was

asked to resubmit mining plans and land reclamation programs in Hillsborough County. Beker Industries Corp.'s lease application in Manatee County was deferred after a 6-month moratorium was placed on the issuance of mining permits.

DOMESTIC PRODUCTION

Domestic production of marketable phosphate rock was 42,137,000 tons, an increase over that of 1972 of 1,306,000 tons or 3.2%. The value of the marketable rock was $238,667,000, an increase of 14.8% over that of 1972. The average grade of phosphate ore mined in the United States was 13.6% P_2O_5, and the average grade of marketable rock was 31.1% P_2O_5. The average weight recovery of concentrate and rock marketable as mined was 30.2%, and the P_2O_5 recovery averaged 68.9%. Of the total marketable production in the United States, Florida and North Carolina produced 34,427,000 tons (81.7%), the Western States produced 5,198,000 tons (12.3%), and Tennessee produced 2,512,000 tons (6.0%).

Florida and North Carolina.—Production of marketable phosphate rock was 34,427,000 tons, an increase over that of 1972 of 306,000 tons or 0.9%. The value of marketable rock was $191,654,000, an increase of $17,744,000 over that of 1972 or 10.2%.

The average grade of phosphate ore mined was 12.8% P_2O_5, and the average grade of marketable rock was 31.9% P_2O_5. The average weight recovery of concentrate and rock marketable as mined was 27%, and the average P_2O_5 recovery was 67.3%. The production capacity of Florida and North Carolina phosphate mines was limited in 1973 to less than 34.5 million tons of marketable rock. This capacity is less than various estimates made in prior years when the pressures to produce were much less, and power interruptions, limited time and capital to accomplish repair and maintenance, and lower grade ores were not factors influencing plant operations and production.

Agrico Chemical Co., Borden, Inc., Brewster Phosphates, Gardinier, Inc., W. R. Grace & Co., International Minerals & Chemical Corp., Mobil Oil Corp., Poseidon Mines, Inc., P.S.A. Enterprises, Occidental Petroleum Corp., U.S.S. Agri-Chemicals, Inc., and Swift Chemical Co. produced marketable rock from Florida land-pebble phosphate fields. Howard Phosphate Co., Kellogg Co., Loncala Phosphate Co., and Manko, Inc. mined 22,000 tons of soft rock in Florida.

Texasgulf, Inc. mined and processed phosphate rock from deposits along the Pamlico River in North Carolina.

Agrico Chemical Co., a subsidiary of the Williams Co. of Tulsa, Okla., awarded contracts for a 400,000-ton-per-year P_2O_5 phosphoric acid plant and a 100-ton-per-hour single train diammonium phosphate granulation plant at Fausta, La. and an 80-ton-per-hour granular triple superphosphate plant in South Pierce, Fla.[4] A contract was also awarded to construct two 1,800-ton-per-day capacity sulfuric acid plants at South Pierce, Fla.[5] Contracts were awarded for plants to produce 1,000 tons per day of ammonia and 1,800 tons per day of urea ammonium nitrate solution at Verdigris, Okla.[6] A contract was awarded for a 1,000-ton-per-day urea plant at Blytheville, Ark.[7] Plans were advanced to open the Fort Green mine and construct a new plant to produce 3.5 million tons per year of marketable phosphate rock in Florida.

Beker Industries Corp., Greenwich, Conn., signed options to purchase from PPG Industries, Inc., Pittsburgh, Pa. 8,000 acres of phosphate reserves in eastern Manatee County, Fla. Beker plans to mine and ship about 3 million tons annually of marketable phosphate rock to their fertilizer operations in Illinois and Louisiana.[8] The company purchased a 100,000-ton-per-year ammonia plant in Iowa and will move the plant to Conda, Idaho. A 180,000-ton-per-year ammonia plant was purchased in Canada and will be relocated near Sarnia, Ontario, Canada. Another 200,000-ton-per-year ammonia plant was purchased in Illinois and will be moved to a Southwest U.S. location. With these ac-

quisitions, Beker Industries will have a total capacity of 480,000 tons of anhydrous ammonia per year.

Conserve, Inc., started operating a modernized plant at Nichols, Fla., and this plant has the distinction of producing the first commercial monoammonium phosphate in the United States.[9]

CF Industries Inc. completed and dedicated a new phosphate terminal on Tampa Bay to ship about 500,000 tons of phosphatic fertilizers annually by water to farm cooperatives in the Midwest and Canada.[10] A new 800-ton-per-day P_2O_5 wet-process phosphoric acid plant will be constructed in Plant City, Fla. The facility is expected to be completed in 1974.

The Cities Service Co. sold its Tampa Agricultural Chemical Operations to Société des Participation Gardinier of Paris, France. The new name will be Gardinier, Inc.—U.S. Phosphoric Products.[11]

W. R. Grace & Co. announced plans to construct a 350,000-ton-per-year urea plant at Memphis, Tenn. The ammonia-producing capacity at this location was increased from 275,000 to 340,000 tons per year.[12] In addition, the agricultural chemical operations at Bartow, Fla., will be expanded with a 250,000-ton-per-year phosphoric acid plant and a 700,000-ton-per-year sulfuric acid plant.[13] Grace has ordered a 60-cubic yard dragline that will be used to mine rock from the Hooker's Prairie property in Polk County in 1977.

International Minerals & Chemical Corp. started construction of their 600,000-ton-per-year, P_2O_5-equivalent fertilizer plant near Bartow, Fla. They also acquired mining rights to 20 million tons of phosphate reserves in Florida.[14] The new washing plant at the Phosphoria mine is scheduled to start producing in 1974. The deslimed ore will be pumped 6 miles to the Noralyn recovery plant.

Occidental Petroleum Corp. purchased 24,000 acres of phosphate reserves from Owens-Illinois Inc. and Monsanto Co. The reserves, estimated by Occidental to be capable of supplying 23 million tons of marketable rock, are located near Occidental's Suwanee River phosphate mine and chemical complex.[15] A 45-cubic yard dragline was assembled at the Suwanee River Phosphate Division to increase production of phosphate rock. Expansion of the washing plant will increase capacity to about 3.5 million tons per year of marketable rock. An increase of 350,000 tons per year of P_2O_5 phosphoric acid capacity was announced for the Suwanee River complex. In addition, the diammonium phosphate capacity will be increased by 350,000 tons per year and a new but unspecified amount of sulfuric acid capacity will be added, all scheduled for operation in 1975. If the Occidental Petroleum Corp.'s trade agreement with the U.S.S.R. develops in 1978, an additional annual 3.5 million tons of marketable phosphate rock will be required to produce 1.1 million tons per year of superphosphoric acid.

A new sales office of the Phosphate Rock Export Assn. was opened in Paris, France at 42, Avenue Montaigne.[16]

The construction of a new phosphoric acid plant and sulfuric acid plant at Texasgulf, Inc.'s Lee Creek mine in North Carolina to increase the P_2O_5 capacity from 340,000 to 510,000 tons per year was completed. Work was started on the fourth phosphoric acid and sulfuric acid train to raise the plant capacity to 680,000 tons per year of P_2O_5. Mining and milling facilities will also be expanded to furnish phosphate rock for the acid plant and for merchant sales. A new terminal at Morehead City, N.C., will store 200,000 tons of phosphoric acid. On nearby Radio Island, a liquid sulfur terminal with a throughput of 600,000 tons per year was under construction.[17]

Western States.—Production of marketable phosphate rock was 5,198,000 tons, an increase of 643,000 tons over that of 1972, or 14.1%. This was the first full year of production for Agricultural Products Corp., and their contribution was a significant factor in the overall increase. The value of the marketable rock increased to $34,214,000 or 47% above that of 1972. The average grade of mined phosphate rock was 21.8% P_2O_5, and the average grade of marketable rock was 28.4% P_2O_5.

[16] Industrial Minerals. No. 64, January 1973, p. 47.
[17] Texasgulf, Inc. 3rd Quarter Report. Oct. 5, 1973 4 pp.

The average grade of mine production used directly in electric furnaces was 26.4% P_2O_5, and the average beneficiated rock grade from washers and mills was 32.2% P_2O_5. It is of interest to note that of the total marketable production in the Western States, 34% was beneficiated and 66% was used directly. The weight recovery of the combined concentrates and rock used as mined was 62.9%, and the average P_2O_5 recovery was 82%.

Agricultural Products Corp., Monsanto Co., J. R. Simplot Co., and Stauffer Chemical Co. mined and processed phosphate rock in Idaho. In Montana, Cominco American, Inc., recovered phosphate rock from the underground Brock mine near Garrison. Stauffer Chemical Co. mined phosphate rock in Wyoming and in two areas in Utah. The Meramec Mining Co., Sullivan, Mo., again recovered apatite concentrate from Pea Ridge iron ore mine tailings.

Cominco American, Inc.'s Brock mine is projected to operate for at least another 10 years with a sustained production rate of 250,000 tons per year.[18] A new mine and adit about 3 miles south of the Brock adit called Warm Spring, will assure production at current levels and minimize operating problems at the Brock mine.

Agricultural Products, Inc.'s planned expansion program to double production capacity of diammonium phosphate at Conda, Idaho, was completed in 1973.

Stauffer Chemical Co. announced an expansion of its Vernal, Utah operation from 300,000 to 400,000 tons per year of phosphate rock. The grinding and railcar loading facilities at Phoston, Utah, will be enlarged to handle the additional tonnage from the Vernal mine.

Tennessee.—Production of marketable phosphate rock was 2,512,000 tons, an increase of 358,000 tons or 16.6% greater than that of 1972. The value of the marketable rock also increased 19.3% over that of 1972.

The average grade of the mined ore was 21.5% P_2O_5, the average weight recovery of concentrates was 60.3%, and recovery of P_2O_5 averaged 73%.

Hooker Chemical Corp., Monsanto Co., Stauffer Chemical Co., and the Tennessee Valley Authority (TVA) mined phosphate rock in Tennessee and reduced the rock in electric furnaces to elemental phosphorus.

Stauffer Chemical Co. plans to double the capacity to produce benzene phosphorus dichloride and benzene phosphorus thio-dichloride at its Mt. Pleasant, Tenn., organic chemicals plant.

TVA will implement a plan to eliminate phosphate mining; production of phosphorus, phosphoric acid, and nitric acid; and the operation of one rather than two granulation plants between 1973 and 1975.[19]

[3] Data may not add to totals shown because of independent rounding.

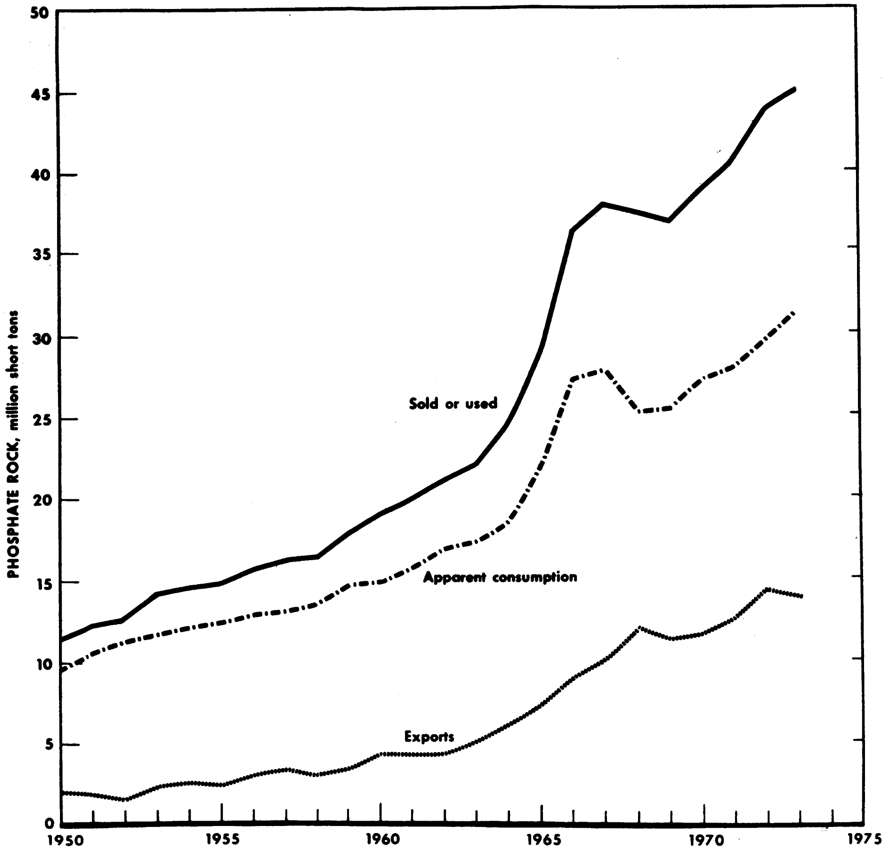

Figure 1.—Phosphate rock (sold or used), apparent consumption, and exports.

CONSUMPTION AND USES

Apparent consumption of marketable phosphate rock increased 5.7% above that reported in 1972. According to producers' reports, the quantity of marketable rock sold or used was 45,043,000 tons. This was an increase of 2.9% over the quantity sold or used in 1972. The domestic market consumed 69% of this total and 31% was exported.

The consumption pattern in the United States was 25,124,000 tons (80.6%) for fertilizer, 5,762,000 tons (18.5%) for elemental phosphorus production, and 282,000 tons (0.9%) was used to produce defluorinated rock and for other purposes.

The percent distribution by grade of marketable rock consumed in the United States is compared with the percent distribution in 1972 in the following tabulation:

Grade, percent BPL [1]	1972 percent distribution	1973 percent distribution
Less than 60	9.5	8.7
60–66	6.3	11.9
66–70	40.5	40.9
70–72	10.3	12.3
72–74	22.1	16.7
Over 74	11.3	9.5

[1] 1.0% BPL (bone phosphate of lime or tricalcium phosphate) = 0.458% P_2O_5.

Florida and North Carolina.—The quantity of phosphate rock sold or used decreased slightly, from 36,934,000 tons in 1972 to 36,916,000 tons in 1973. Of this total sold or used in 1973, 63% was consumed in the domestic fertilizer market and the balance, 37%, exported with a minor quantity used domestically in other applications. The consumption pattern of the overall domestic fraction was 23,421,000 tons (98.6%) for fertilizer, with the balance converted into elemental phosphorus, defluorinated rock, and other minor applications.

The percent distribution by grade of marketable rock sold or used from Florida and North Carolina is compared in the following tabulation for 1972 and 1973:

Grade, percent BPL	1972 percent distribution	1973 percent distribution
Less than 60	0.1	0.3
60–66	5.1	9.7
66–70	44.8	45.9
70–72	11.2	14.1
72–74	25.5	18.5
Over 74	13.3	11.5

Western States.—The quantity of marketable rock sold or used increased 19.2% compared with the quantity sold or used in 1972. Of the total sold or used in the domestic and export markets, about 45% was used for agricultural purposes. The consumption pattern in the domestic market was 35.5% used in fertilizer production and 64.5% was used in electric furnaces. The distribution by grade was 37.7% less than 60% bone phosphate of lime (BPL), 60.5% less than 66% BPL, and the balance was distributed in higher grades.

Tennessee.—The quantity of marketable rock sold or used increased from 2,240,000 tons in 1972 to 2,665,000 tons in 1973, a 19.0% improvement. All of this rock was consumed in domestic electric furnaces to produce elemental phosphorus and industrial chemicals. Most of the elemental phosphorus was burned to produce furnace phosphoric acid which was used to produce sodium tripolyphosphate and dicalcium phosphate. A small amount of elemental phosphorus was used to produce anhydrous derivatives.

Table 3.—Phosphate rock sold or used by producers in the United States, by grade and State in 1973

(Thousand short tons and thousand dollars)

1973	2,665	699	13,812	5.18

[1] Includes Alabama.

STOCKS

Although the phosphate rock mining companies in Tennessee and the Western States do not inventory stocks of marketable rock on an annual basis, the companies in Florida and North Carolina maintain substantial stocks of marketable rock to insure an uninterruptable feed for the fertilizer plants. It is recognized that stocks are accumulated in the Western States during the mild months of the year, when weather conditions permit mining and transportation to consuming electric furnace and fertilizer plants. These stocks are depleted during the winter months. Stocks are not maintained in Tennessee.

In Florida and North Carolina, yearend stocks of marketable phosphate rock declined from 10,501,000 tons in 1972 to 8,482,000 tons in 1973, a decrease of 19.2%. The decline in yearend stocks from 1971 to 1972 was 12%. The significant decline in stocks during 1973 further emphasized the difficulty that the industry experienced in attempting to satisfy demand.

PRICES

The December 10, 1973, issue of the Chemical Marketing Reporter listed prices for various grades of Florida land-pebble phosphate rock. They have not changed since 1971 and are published only as an indication of price levels in 1973. Actual prices negotiated for Florida and North Carolina phosphate rock are not published. The price of phosphate rock produced in Tennessee and the Western States also is not published. Most of this rock is consumed by the producing companies, converted into intermediates or end products, and then marketed.

The average 1973 unit value [20] of marketable rock reported by producers was $5.66 per short ton f.o.b. plant, an increase from the $5.09 per ton value reported in 1972.

The average unit value reported for marketable rock sold or used in the domestic market from Florida and North Carolina increased from $5.10 per ton in 1972 to $5.57 per ton in 1973. In the Western States, the unit value of marketable rock sold or used increased from $5.13 per ton in 1972 to $6.51 per ton in 1973. The unit value of marketable rock sold or used in Tennessee increased slightly from $4.99 per ton in 1972 to $5.18 per ton in 1973.

The average unit value of marketable phosphate rock exported from the United States increased from $5.28 per ton in 1972 to $5.98 per ton in 1973. The unit value of marketable rock exported from Florida and North Carolina increased from $5.10 per ton in 1972 to $5.77 per ton in 1973. The unit value of phosphate rock exported from the Western States increased from $8.76 per ton in 1972 to $9.93 per ton in 1973. Tennessee rock was not exported.

The Phosphate Rock Export Association, Tampa, Fla., publishes export prices. After one price increase on July 1, 1972, the Association issued a new export price schedule on October 1, 1973, that was to be effective on January 1, 1974. This price schedule was superseded on November 16,

[20] Value, if sold, net selling price f.o.b. plant, or if used, estimated value from comparable selling prices or developed price, that is, cost plus overhead and profit.

1973, when a new price schedule was published to take effect on January 1, 1974. The trends in published export prices are shown in the following tabulation with prices converted to a short ton f.o.b. plant basis:

BPL base	Effective date		
	July 1, 1972 [1]	January 1, 1974 [2]	January 1, 1974 [3]
66	--	$9.40	$14.40
68	$6.24	9.94	16.19
70	--	10.92	17.98
72	7.42	11.72	19.76
73	7.67	12.35	21.10
75	8.45	13.69	22.89
77	9.44	15.29	25.12

[1] Issued April 1, 1972.
[2] Issued October 1, 1973; canceled on November 16, 1973. Superseded by schedule issued on November 16, 1973.
[3] Issued November 16, 1973.

The Office Cherifien des Phosphates raised the prices of all grades of Moroccan phosphate rock in October 1973. The new prices were to become effective January 1, 1974. The announced prices, converted to U.S. dollars per short ton, are as follows:

Grade, BPL base	f.o.b. vessel Casablanca
70	$34.82
72	37.01
75	38.83
77 (calcined)	43.59
80	46.08

The stability of these new price levels is not clear at this time, however, it appears that the world demand for phosphate rock is sufficiently strong to support these prices.

The Cost of Living Council removed price controls on phosphate rock in October 1973. Domestic prices of phosphate rock published by several producers after price controls were lifted showed that new contracts for phosphate rock in the domestic market will have prices similar to export prices.

Table 8.—Phosphate rock, Florida land-pebble, run of mine washed, dried, unground, bulk carlots, f.o.b. mine

(Per short ton)

Grade, percent BPL	Price range
66–68	$ 6.50– --
68–70	5.84–$ 7.50
70–72	6.50– 10.65
74–75	7.55– 9.20
76–77	10.20– --

FOREIGN TRADE

Industry reported that 13,875,000 tons of marketable phosphate rock was exported in 1973, 400,000 tons less than that exported in 1972. Although most of the phosphate rock was exported from Florida, Florida exports declined from 1972 levels by 3% in 1973. Exports from the Western States to Canada were essentially unchanged in 1973 from those reported in 1972.

The average calculated unit value of exported phosphate rock increased from $5.28 per ton in 1972 to $5.98 per ton in 1973.

Analysis of import data showed that 65,025 tons of phosphate rock was imported in 1973 compared with 54,738 tons in 1972, an increase of 18.8%. Imports of 1,456 tons and 37,143 tons of low-fluorine phosphate rock were received from Mexico and the Netherlands Antilles, respectively. Shipments of 12,727 tons and 13,699 tons were also received from Spanish Sahara and Morocco, respectively. The value of total imports was $1,288,000, and the average unit value was $19.82 per ton.

WORLD REVIEW

The majority of world phosphate rock production, with the exception of that from the United States, is from Government-owned operations in more than 30 countries.

Angola.—The Companhia de Fosfatos de Angola, which has been seeking financial support for exploitation of phosphate deposits in Cabinda, has reportedly ceased operations. Recent assays have indicated that the phosphate deposits in the company's concession area are not of commercial value. Since this contradicts previous assay reports, the company is in need of additional financial backing for further exploration, but this has not been secured.[21]

Australia.—Potential importers of phosphate rock from the projected Broken Hill South, Ltd. operation are showing interest in the company's progress. Although trials at the Lady Annie pilot plant started in April of this year, it will take several years or longer to develop sufficient production to satisfy the demand from Australia and the Oceania area and also reach levels to permit exporting significant quantities. The question of transport to the Gulf of Carpentaria has to be resolved. A pipeline to move phosphate rock slurry, coupled with a drying plant at the port, has been proposed. The cost of transporting in a pipeline, drying, and port costs will have a strong influence on the f.o.b. vessel price, but in light of the worldwide short supply condition, this is an opportune time to consider this development.[22]

China, The People's Republic of.—According to a study made by the British Sulphur Corp., Ltd., production of phosphate rock will increase from an equivalent 1,290 thousand tons of P_2O_5 in 1973 to an equivalent 2,629 thousand tons of P_2O_5 in 1980.[23]

Egypt, Arab Republic of.—The Abu Tartur phosphate deposits in the Western Desert were estimated to contain reserves of the order of 600 million tons. Mr. Rushdi Saeed, Chairman of the Egyptian Geological Survey and Mining Authority, confirmed the reserves to be 1,000 million tons. If plans materialize in 1979, 10 million tons of concentrates ranging from 72 to 74 BPL will be shipped from this deposit.[24]

India.—The State Government of Rajasthan purchased all outstanding shares in Bikaner Gypsums, Ltd. and it is now a wholly-owned Government company. In 1969, the company was appointed by the Government as the principal mining contractor for phosphate rock deposits in Rajasthan and a production goal of 4,000 tons per day was established for 1974. The Government action was probably taken because of the company's failure to increase its output.

A feasibility report prepared by Parsons Jurden Corp. for the World Bank indicates the phosphate rock deposits discovered near Udaipur are very substantial. A production rate of 1.5 million tons per year of plus 30% P_2O_5 product was recommended.[25]

Israel.—The Arad phosphoric acid plant constructed by the Israeli Government and the Madera Corp. of the United States was shutdown because of fundamental construction problems. The Israeli Government now controls the plant and will determine its future. The original design capacity in 1971 was 183,000 tons per year of P_2O_5. Only 13,000 tons per year has been produced to date.[26]

Jordan.—Because the Lebanon-Syria border was closed early in the year, phosphate rock exports from Jordan were reduced and were estimated to be about 1.3 million tons. Jordan Phosphate Mines Co., Ltd. operates open pit mines at Ruseifa and El Hasa. At El Hasa, an expansion program will raise the country's output to 2 million tons annually.[27]

Morocco.—Preliminary indications are that Morocco produced 18.2 million short tons of phosphate rock and the amount sold or used exceeded 18.8 million short tons. The 1973–77 expansion plan has not been detailed; however, production goals of 26 million annual tons by 1977 and 30 million annual tons in 1980 has been suggested. New open pit mines are planned at Benguerir and Sidi Haggaj. The Office Cherifien des Phosphates hopes to double underground production at Youssoufia to 6 million tons per year. Ore mined from a depth of 166 feet will be calcined to improve the grade from 68% to 75% BPL. A pilot calcination plant is under construction. The Khouribga complex produces about 80% of Morocco's phosphate rock from open pit mines at Sidi Daoui and Merra el-Arech. Layer 2 ore at Sidi Daoui is beneficiated to 72% BPL in a 3–4 million ton-per-year washing plant. Layer 2 at

Merra el-Arech will be processed through a new pilot calcination plant and dry enrichment plant to 78% and 72% BPL products. Future additions to these treatment facilities is contingent on the profitability of these pilot projects.[28]

New Zealand.—Because the high-grade deposits of phosphate rock in the Pacific Islands are likely to be exhausted by 1982, a major search for phosphate rock is underway in New Zealand. Warrants for prospecting near Waibouaiti and Palmerston in North Otago have been granted to Australasian Mining and Oil Investments, Ltd. They have also applied for warrants to prospect at Waihao Downs, near South Canterbury.[29]

Spanish Sahara.—Some shipments were made from the Fosfatos de Bu-Craa S.A. mine in 1973 but they were substantially less than the projected 3.3 million short tons. Startup problems with the ore preparation plant and a new desalinization plant were the principal reasons. Although construction has started on an expansion to increase production to 6.6 million, it is

[3] Revised from crude phosphate basis reported in previous editions to marketable phosphate basis as reported by International Superphosphate Manufacturers Association.

not certain that this production level can be attained by 1975.

Togo.—To meet the expected increase in world phosphate demand in the next few years, Cie. Togolaise des Mines du Bénin (CTMB) will increase production to 2.4 million tons per year and will open a new mine at Kpogame in 1973. The Togolese Government increased its share in CTMB from 20% to 35%. W. R. Grace & Co.'s share declined to 28%, and the French interests declined to 37%. The Government plans to acquire a majority interest by 1987.[30]

U.S.S.R.—Although a comprehensive understanding of new phosphate rock activity in the U.S.S.R. is not readily available, two developments appear noteworthy. On the Kola Peninsula in the North, commercial exploitation of the Koashvinsky deposit has started. Reserves of 500 million tons were reported. About 90% of the phosphate fertilizers produced in the U.S.S.R. use apatite from the Khibiny Mountains on the Kola Peninsula. The incremental production expected from this new deposit was not reported.[31]

Chilisaisk in West Kazakhstan is scheduled to become the third largest mining area in the U.S.S.R. after the Kola area and Karatau in Kazakhstan. Production from Chilisaisk in 1973 was 300,000 tons and in 1975, production will increase to 1,100,000 tons.[32]

A review of available data on the Soviet phosphate rock industry indicates that figures published by the Bureau of Mines in recent years should be revised downward. Corrected figures for 1971 and 1972 have been incorporated in the world production table; corresponding estimates for 1964 to 1970 are as follows, in thousand short tons: 1964—11,750; 1965—14,850; 1966—15,000; 1967—15,150; 1968—16,550; 1969—18,000; 1970—19,600.

TECHNOLOGY

As part of a continuing research program to expand its nitrophosphate technology, the Norwegian company Norsk Hydro A/S has developed a method of manufacturing phosphoric acid from mother liquor obtained after crystallization of calcium nitrate from the solution formed when phosphate rock is acidulated with nitric acid.[33]

Uranium Recovery Corp. has announced the construction of a uranium separation plant that will go onstream in 1975. It will be located in Polk County, close to a number of phosphate mining and chemical plants. Uranium recovery systems will be located at several phosphoric acid plants in the area. Details of the process have not been disclosed but it is known that an organic solvent will be used to extract the uranium values which will then be transported to the central processing plant for refining. Research work on the recovery of uranium from wet process phosphoric acid manufactured from Florida rock was carried out at the Oak Ridge National Laboratory, Oak Ridge, Tenn. A solvent di (two-ethylhexyl) -phosphoric acid and trictylphosphine in a high-boiling aliphatic diluent is used to extract uranium values from the phosphoric acid. The solution is then contacted with phosphoric acid containing ferrous ions to reduce the uranium to the trivalent state in which it is less soluble in the organic solvent and therefore returns to the aqueous phase. The phosphoric acid used in this stage is part of the raffinate from the extraction stage. The tetravalent uranium is then oxidized back to the hexavalent state by bubbling in air or by addition of sodium chlorate, and is then extracted a second time with the same organic solvent. It is finally recovered from the organic solution, with an overall yield of about 95%, by stripping with an aqueous ammonia carbonate solution. Ammonium uranyl tricarbonate is precipitated and after filtration is calcined.[34]

The Albany Metallurgy Research Center, U.S. Bureau of Mines, Albany, Oreg., continued work on a project to demonstrate the feasibility and costs of manufacturing

[33] The British Sulphur Corp., Ltd. Phosphoric Acid Manufacture. No. 64, March/April 1973, p. 43.
[34] The British Sulphur Corp., Ltd. Phosphate Rock Processing. No. 66, July/August 1973, p. 47.

phosphoric acid by acidulating Florida phosphate matrix with sulfuric acid. The research has demonstrated that phosphoric acid can be produced from several different Florida phosphate matrix samples. The principal benefits noted were high P_2O_5 recoveries and a sandy compact solid waste that will permit immediate land reclamation by backfilling mined-out land. Designs for a 100-pound-per-day pilot plant are being prepared.

The Tuscaloosa Metallurgy Research Laboratory, U.S. Bureau of Mines, Tuscaloosa, Ala., has, during 1973, continued the program sponsored by the U.S. Bureau of Mines and The Florida Phosphate Council to develop processes to effect rapid dewatering of phosphate slimes. Programs to characterize Florida phosphate slimes, to study electrophoretic mobilities and ion exchange properties, to develop tests to predetermine the settling rates of slimes, to study the flocculation and agglomeration responses of slimes, to evaluate the settling and dewatering characteristics of sand-slime mixtures, and to study the gelation tendencies of phosphate slimes will continue through 1974.

Platinum-Group Metals

By W. C. Butterman [1]

World production of the platinum-group metals continued its upward trend in 1973, increasing 21% over production in 1972. Republic of South Africa producers, in possession of long-term contracts with United States and Japanese automobile manufacturers, provided most of the increase. Demand, especially from United States and Japanese consumers, remained strong in 1973, and although supplies of most of the metals were adequate, prices rose significantly, partly because of inflationary pressures, devaluation of the U.S. dollar, and the very strong advance in the price of gold. The dealers' prices for rhodium and iridium, which became scarce during the year, increased sharply.

In the United States, significant excesses of platinum, palladium, and iridium were created in Government inventories when stockpile objectives were cut sharply in April; however, none of this metal became available to consumers during the year. Refinery production of primary platinum-group metals rose 29% in 1973, and production of secondary metals rose 4%. Imports were up 27%, and exports increased 16%. Sales to industry were 17% higher than in 1972, and industry stocks increased 11%.

Legislation and Government Programs.—In April the Office of Preparedness set new, sharply reduced, stockpile objectives. As a result, about 265,000 troy ounces of platinum, 926,000 troy ounces of palladium, and 15,000 troy ounces of iridium in inventory became excess to requirements. By yearend, however, congressional authorization for disposal of the excess metal had not been forthcoming. Thus, inventories of the three metals remained unchanged in 1973, except for the disposal of 174 ounces of nonstockpile-grade iridium.

On April 12, the Environmental Protection Agency (EPA) delayed application of the 1975 automobile emission standards for 1 year; instead for 1975, EPA set somewhat relaxed interim standards for California and even less stringent standards for the rest of the Nation. At midyear, EPA, having concluded that the danger from nitrogen oxide emissions had been overstated at the time the Clean Air Act of 1970 was written, recommended to Congress that the law be liberalized with respect to these emissions.

[1] Includes 12 troy ounces nonstockpile-grade material.
[2] Includes 2,204 troy ounces nonstockpile-grade material.
[3] Includes 2,566 troy ounces nonstockpile-grade material.

DOMESTIC PRODUCTION

Domestic mine production of platinum-group metals increased 17% in quantity and 66% in value in 1973. Most of the palladium was recovered as a byproduct of copper refining, and most of the platinum and other metals of the group came from one placer deposit. This deposit, at Goodnews Bay, on the southwest coast of Alaska, is the only deposit in the United States mined primarily for platinum metals.

Refinery production of primary platinum-group metals rose 29% in 1973. Total secondary production rose 4%, owing mainly to a 25% rise in secondary platinum produced. Toll refining increased 4%. Scrap material accounted for 89% of the total material toll-refined; the balance consisted of crude platinum, nickel-copper sulfide matte, and anode slimes derived from the electrolytic refining of sulfide matte. These materials came from Colombia, Canada, Norway, and the Republic of South Africa.

CONSUMPTION AND USES

Sales of the platinum-group metals to consuming industries rose 17% in 1973 to about 1.8 million troy ounces. Sales of four of the metals increased: Platinum 21%, palladium 16%, rhodium 55%, and ruthenium 4%. Sales of iridium and osmium declined 19% and 32%, respectively.

Platinum sales were 658,000 ounces, of which 36% went to the chemical industry, 19% to the petroleum refining industry, 18% to the electrical industry, and 11% to the glass/ceramics industry. The largest increases in sales went to the petroleum, glass, and electrical industries, with more modest gains in the chemical and jewelry industries and the miscellaneous uses category. Only the dental/medical industries used less platinum than in 1972.

Sales of palladium were just over 1 million ounces in 1973. Of this, 52% was used in the electrical industry, 26% in the chemical industry, and 13% in the dental and medical industry. The electrical industry alone consumed 99,000 ounces more in 1973 than in 1972. Dental and medical, jewelry, and miscellaneous uses each consumed substantially more than in 1972, but the chemical, petroleum, and glass industries consumed less than in 1972.

Iridium sales were 31,000 ounces, of which 35% went to the chemical industry, and 44% to the petroleum industry. Sales in each of the seven end-use categories were lower than in 1972.

Sales of osmium declined in 1973 to about 1,600 ounces all of which went to the chemical and dental and medical industries (62% and 38%, respectively).

Rhodium sales were nearly 72,000 ounces, of which 33% went to the chemical industry, 23% to the glass industry, 16% to the electrical industry, and 17% to the jewelry industry. Sales to all industries increased substantially compared with those in 1972.

Sales of ruthenium increased 4% to about 57,000 ounces. About 68% went to the chemical industry and 18% to the electrical industry.

The platinum-group metals are useful because of their extraordinary catalytic properties, resistance to chemical corrosion over a wide temperature range, and unique combination of physicochemical and electrical properties. The pattern of industrial applications in 1973 was similar to patterns in recent years. The patterns for the major metals, platinum and palladium, are shown in figure 1.

Early in the year, the Federal Bureau of Mines issued IC 8565, Demand for Platinum To Reduce Pollution From Automobile Exhausts, which dealt with platinum to be used for catalytic oxidation of hydrocarbons and carbon monoxide in automobile emissions.[2] This report estimated that about 1.4 million ounces of platinum would be needed to equip 1975 model automobiles sold in the United States. After EPA set relaxed interim standards, it became apparent that actual requirements would be lower. For a time after this decision, it was felt that a large percentage of 1975 cars would not need catalytic devices. By yearend, however, the major automobile manufacturers had determined that in order to meet even these relaxed standards, it would be necessary to equip most 1975 model cars with oxidative catalytic exhaust converters. Each

[2] Kusler, D. J. Demand for Platinum To Reduce Pollution From Automobile Exhausts. BuMines IC 8565, 1973, 32 pp.

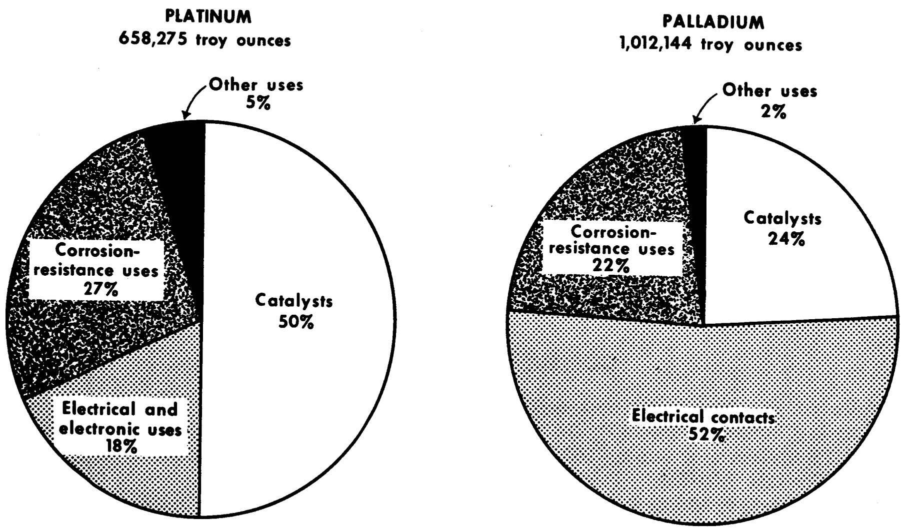

Figure 1.—Uses of platinum and palladium in 1973.

converter would contain, as the active material, between 0.05 and 0.10 troy ounce of a platinum-palladium mixture, the composition of which was expected to range in percent, from 70 platinum- 30 palladium to 80 platinum- 20 palladium.

In other areas of platinum-group metals usage, there were a number of developments in 1973. A special high-purity grade of platinum suitable for use in the production of optical glass fibers became available during the year. The maximum allowed content of metallic impurities in this grade is 10 parts per million.[3] The use of rhodium plated surfaces on electrical components, such as contacts, slip rings, and commutators increased.[4] Dispersion-strengthened platinum, platinum-rhodium, and iridium-rhodium, were developed for use in resistance thermometers, thermocouples, sensor shields, and jet thrusters used for spacecraft attitude control.[5] The use of platinum catalysts to reduce nitrogen oxides in the tail gas from nitric acid plants continued to grow.[6]

STOCKS

Stocks of platinum-group metals held by refiners, importers, and dealers increased 11% to just over 1 million troy ounces at yearend. Palladium stocks increased 22%, platinum stocks rose 5%, and rhodium stocks fell 10%. In addition to these stocks, there were Government stockpile inventories of platinum, palladium, and iridium, and stocks of platinum and palladium held by the New York Mercantile Exchange.

PRICES

Producers' prices for the platinum-group metals, which were under Government controls much of the year, increased 10% to 50% in February, underwent a short-lived 5% fluctuation in June, and then advanced again in late September (palladium, in mid-August) 5% to 14%. After price controls were removed from most nonferrous metals in December, rhodium and iridium prices increased another 14% to 15%. Ruthenium remained unchanged after the February increase to $60 per troy ounce, and osmium stayed at $200 per ounce throughout the year.

The dealers' price for iridium jumped from $250 to $450 per troy ounce in July because that metal became scarce, and ended the year at $525 per troy ounce. The

[1] Stocks of platinum and palladium in the Mercantile Exchange depositories as of December 28, 1973, were 115,200 troy ounces, and palladium 11,500 troy ounces.

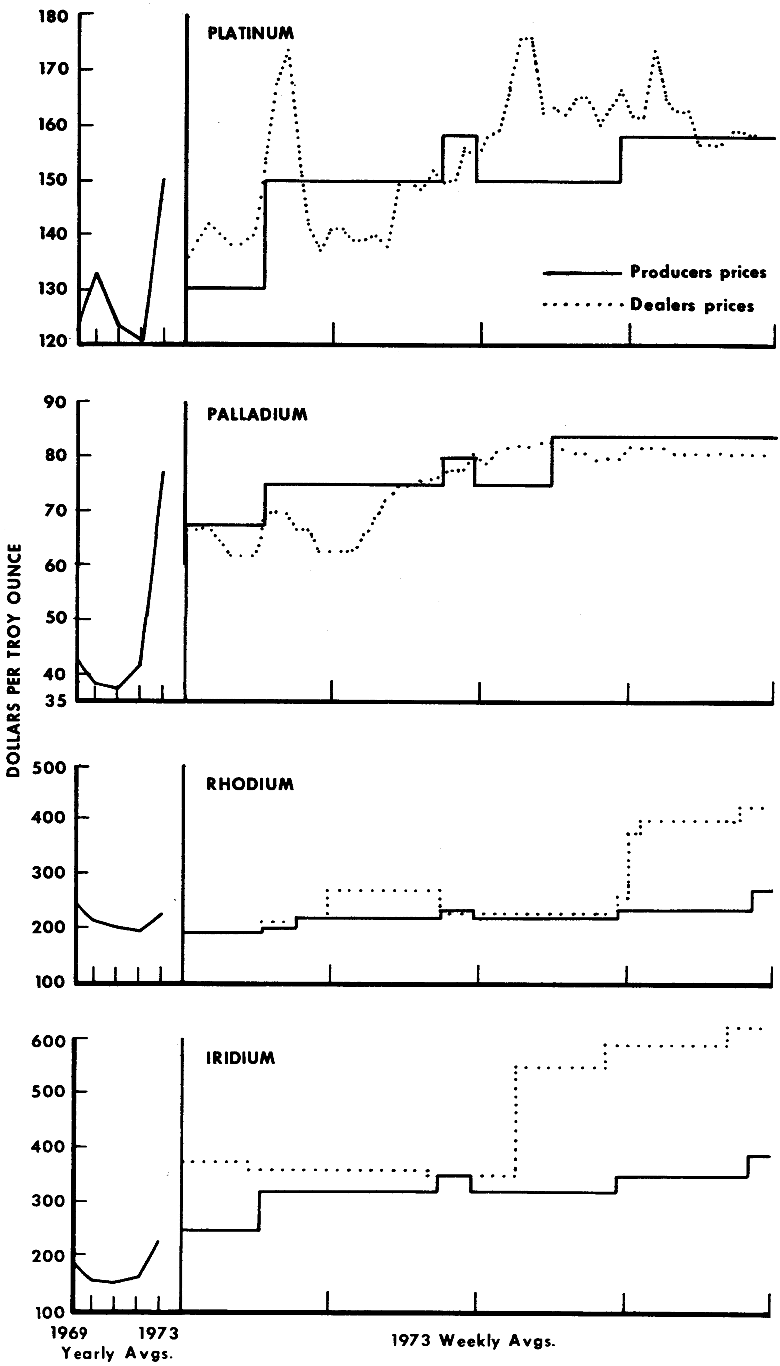

Figure 2.—Prices of four platinum-group metals.

FOREIGN TRADE

Exports of platinum-group metals in 1973 amounted to 628,000 ounces, of which about 439,000 ounces, or 70%, was platinum. Exports of platinum alone increased only 5%, whereas exports of the other metals of the group increased 54%; the increase in total group exports was 16%. As a result of rising prices, value of exports rose 50%, to nearly $78 million. Nearly 80% of the quantity exported went to just three countries: Japan (50%), West Germany (17%), and Belgium-Luxembourg (11%). Seventy-nine percent of the quantity exported to Japan, and 60% of the exports to West Germany, consisted of platinum.

Imports of the platinum-group metals increased 27% in 1973 to 2.3 million ounces valued at $249 million. Platinum comprised 32% of the imports, and palladium 49%. The amounts of platinum, palladium, and rhodium imported were higher than in 1972 by 10%, 28%, and 83%, respectively. The chief sources of platinum-group imports and of the three major metals of the group are shown in table 11.

Table 8.—U.S. imports for consumption of platinum-group metals

Year	Quantity (troy ounces)	Value (thousands)
1971	1,302,740	$93,674
1972	1,836,349	144,092
1973	2,340,491	248,832

WORLD REVIEW

World production of the platinum-group metals increased 21% in 1973 to 5.2 million troy ounces, as demand increased, especially in the United States and Japan. Most of the increment came from Republic of South Africa producers, who were gearing up for anticipated high demand in the United States for platinum and palladium in automobile emissions control catalysts, beginning in 1974. As in the past, virtually all (99%) of the platinum-group metals were mined in just three countries, the U.S.S.R., the Republic of South Africa, and Canada.

In the United States, which imports about 99% of its requirements for primary platinum-group metals, mine production rose 17% to 19,980 troy ounces. Platinum metals were produced in Japan as byproducts of copper refining, and small amounts of platinoid concentrates were produced in the Philippines as byproducts of nickel-cobalt mining. Placer mining continued in Colombia at the same pace that it has for many years, yielding about 26,000 ounces of platinoids, which were refined in the United States.

Canada.—Canadian production of platinum-group concentrates and refined metals fell 29% in 1973, to 288,000 troy ounces in spite of a 4% rise in nickel production. In Canada, the platinum-group metals are produced as byproducts of nickel-copper mining by two companies, The International Nickel Co. Ltd. (INCO), and Falconbridge Nickel Mines, Ltd. The mines are in Sudbury, Ontario, and Thompson, Manitoba. INCO's platinoid-bearing concentrates are refined to metal in the United

e Estimate. p Preliminary. r Revised.
[1] Excludes refined platinum production from Norway, which is derived from imported raw materials, chiefly (if not wholly) of Canadian origin, in order to avoid double counting.

Kingdom, whereas Falconbridge's concentrates are refined in the United States after intermediate processing in Norway.

South Africa, Republic of.—South Africa was the world's largest producer of platinum (1.5 million ounces), and the second largest producer, after the U.S.S.R., of the total platinum-group metals (2.4 million ounces) in 1973. The platinum-group metals were the principal products at five operating mines, all of which were on the Merensky Reef member of the Bushveld Igneous Complex. The Reef, which is in the Transvaal, is a remarkably uniform and extensive orebody in which recoverable values are about 0.2 troy ounce of platinoids per ton of ore. The metals are present in the proportions of platinum 62%, palladium 25%, and the other four metals 13%. (Much of the data available from the Republic of South Africa are in terms of platinum alone. Such data have been converted to platinum-group metals data in this report by applying the 62% factor to all mines.) In addition, a small amount of osmiridium was produced as a byproduct of gold mining. South African reserves of platinum-group metals were estimated at greater than 325 million troy ounces,[7] and resources at between 650 and 1,220 million troy ounces.[8]

Rustenburg Platinum Mines, Ltd., the oldest and largest producer, continued its expansion program, aimed at a capacity of 2.5 million ounces by 1976. By yearend 1973, its production rate was estimated to have reached about 1.6 million troy ounces of platinum-group metals per year. Rustenburg's 3-year contract with Ford Motor Co. for 500,000 ounces of platinum per year, was stretched to 5 years, covering 1975 to 1979, and palladium was substituted for one-fourth of the platinum. Development of the Amandelbult mine continued some 20 miles northeast of the Union mine; it was expected to be operational in 1976. Work also continued on a fivefold expansion of the refinery at Wadeville (jointly owned with Johnson, Matthey & Co.). In the past, virtually all of the refining of Rustenburg concentrates and mattes has been done by Johnson, Matthey & Co. in the United Kingdom.

After signing a 10-year contract with General Motors Corp. in late 1972 to supply 300,000 ounces of platinum and 120,000 ounces of palladium per year, Impala Platinum, Ltd., the second largest producer, announced early in 1973 its intention of expanding production from 560,000 ounces of metals per year to 1.2 million ounces, and later in the year increased the target to 1.5 million ounces to be available by the end of 1974. Impala is a vertically integrated company with its own refinery at Springs, near Johannesburg, and with its own sales organization.

Western Platinum Ltd. completed its second full year of operation, producing on the order of 80,000 ounces of platinum-group metals. Concentrates were smelted to a copper-nickel matte, which was sent to Falconbridge Nickel Mines' electrolytic refinery in Kristiansand, Norway, for processing. The anode slimes from Norway were sent to PGP Industries in California for final refining and distribution. Lonrho, Ltd. (which with Falconbridge and Superior Oil Co., owns Western Platinum), was building a refinery of 150,000-ounce capacity at Brakpan, Transvaal, intended to toll-refine Western's output starting in April 1974.

Atok Platinum Mines, Pty., Ltd., continued its comparatively small-scale operation, producing about 18,000 ounces of platinum-group metals. Concentrates were smelted to matte at Western's smelter and sent to Falconbridge's refinery in Norway. Expansion of capacity to 40,000 ounces of platinum-group metals per year was in progress.

U.S.S.R.—The U.S.S.R. was the world's largest producer of the platinum-group metals in 1973. Nearly 2.5 million troy ounces was mined from placer deposits in the central Urals, and from lode deposits (as a byproduct of nickel and copper mining) in the Norilsk-Talnakh area, of northwestern Siberia, and in the Petsamo district of the Kola Peninsula. Production from placer deposits has been declining for decades, and probably contributed no more than 10% of the national production in 1973. Platinum and palladium comprised about 90% of the output of the refined metals, and the platinum/palladium ratio was estimated to lie between 2 and 3.5 to 1. Expansion of the mining-smelting com-

plex near Talnakh continued in 1973. The Oktyabr'skiy mine was being readied for production in 1974, and development of the Taimyr mine was begun.[9] Work continued on what was reported to be the world's largest nickel smelter.[10] These developments imply a major expansion in platinum-group metals production by the end of the decade.

TECHNOLOGY

In February the National Academy of Sciences issued a report on its study, undertaken at the behest of Congress, on the technological feasibility of meeting the motor vehicle emissions requirements of the Clean Air Act of 1970. The report indicated that the requirements could be met, at least for the 1975 model year, but expressed reservations about catalyst-equipped engines vis à vis other types, as the stratified charge engine, on the grounds of cost, fuel economy, maintainability, and durability.[11] However, the durability of automotive catalysts appeared to be sufficient to satisfy EPA requirements.[12] The National Materials Advisory Board reported on the search for substitutes for platinum in automobile emission control devices and in petroleum refining.[13] They concluded, with respect to automotive emissions that, ". . . at present, no base metal catalyst appears promising for use in the oxidizing reactor." They found also that, ". . . no complete substitutes for platinum in catalytic reforming are currently available and the likelihood of developing sufficiently active and selective catalysts to replace it in existing reforming reactors is extremely remote."

The Second International Symposium on Platinum Coordination Complexes in Cancer Chemotherapy was held in Oxford, England, in April. Clinical trials of the first described cancer inhibitory compound, cis-dichlorodiammine platinum II, were reviewed, and discussions were held on the chemistry and biological effects of platinum compounds.[14] The relationships between certain structural features of platinum complexes and antitumor activity were explored in a paper published earlier in the year.[15]

Interest in ruthenium-molybdenum and ruthenium-tungsten alloys, which in the early 1960's had been studied for possible use in nuclear reactors, was revived when it was found that the temperature coefficients of resistivity of thin films of the alloys could be varied from negative to positive by controlling the temperature of the substrate during deposition. This property suggested use as temperature-compensating components of integrated circuits. The hardness, high melting points, and good resistance to corrosion of these alloys suggested possible uses in electrical contacts operating under severe conditions.

A new family of platinum alloys containing rhodium, tungsten, hafnium, and titanium was developed for the encapsulation of plutonium oxide heat sources used in the thermoelectric power generators of space vehicles.[16]

Considerable experimental work continued on the development of dispersion strengthened (DS) platinum and platinum alloys. The disperse phase, usually with thoria or alumina present in amounts of about 0.5 to 2 volume-percent, hardens the metal and stabilizes its grain structure. The DS metals exhibit superior strength and durability under stress at high temperatures, but at the same time, retain, nearly unchanged, the room-temperature mechanical working properties and electrical properties of the pure metal or alloy. Some possible applications are high-temperature thermocouples and other temperature sensors, spark plugs, high-temperature conductors, and equipment for containing and handling molten glass.[17]

Potash

By William F. Keyes [1]

After a moderate increase in 1972, domestic production of potash declined in 1973. A strong demand during most of the year, particularly in the last 6 months, resulted in a 755,000 ton increase in apparent consumption of K_2O. Exports rose moderately. There was a strong increase in imports, and producers' stocks declined to less than half the level of the previous year. The portion of domestic apparent consumption supplied by imports continued to mount and in 1973 equaled 65%. One mine in the United States ceased operations at midyear, and other mines reported production gains, some of them significantly greater than those in 1972. As the year ended, prorationing and pricing regulations in the Province of Saskatchewan, Canada, were overtaken by a rising demand for potash, and quotas were increased significantly. However, transportation presented a problem, and at yearend, potash was in short or tight supply in many areas of the United States.

DOMESTIC PRODUCTION

Domestic production of marketable potassium salts decreased 2.1% in 1973, compared with that in 1972, in terms of K_2O equivalent. Nevertheless, the value of production increased to a total of $112.6 million. Table 2 provides details of production and sales by product.

During 1973, one company, Teledyne Potash (formerly U.S. Potash and Chemical Co.), ceased operations. Six producers were, therefore, left in operation in New Mexico: AMAX Chemical Corp., Duval Corp., International Minerals & Chemical Corp., Kerr-McGee Corp., National Potash Co., and Potash Co. of America, a division of Ideal Basic Industries, Inc. In Utah three compa-

[1] Physical scientist, Division of Nonmetallic Minerals—Mineral Supply.

nies produced potash: Texas Gulf Inc., which produced potash by solution mining a bedded deposit; Great Salt Lake Minerals and Chemicals Corp., which treated brines from the Great Salt Lake; and Kaiser Aluminum & Chemical Corp., which treated natural brines near Wendover.

Searles Lakes Chemical Corp., a subsidiary of Occidental Petroleum Corp., continued to develop plans for producing potash and other minerals from Searles Lake brines at Trona, Calif. The mining plan was awaiting approval by the U.S. Geological Survey which is required for operations on U.S. Government lands. Output of 100,000 short tons of sodium borate, 150,000 short tons of sodium carbonate, and 115,000 short tons of potassium sulfate annually is envisioned.

Eighty-three percent of the domestic potash was produced in New Mexico. New Mexico's share declined 3% because of the closing of Teledyne Potash and because of production increases in Utah and California. The average K_2O content of crude salts produced at New Mexico mines declined again, to 16.1%. Total plant capacity of potash producers in the United States was about 3.5 million tons of K_2O equivalent prior to the closing of the Teledyne mine.

In 1973 imports of potash were equal to 65% of domestic consumption. This percentage had been increasing for a decade and, given the existence of the huge Canadian industry, it appeared that the trend would not be reversed. These increasing imports, coupled with the lower grade of domestic ore now being mined and the closing of one mine, all indicate continuing relative decline in the domestic potash-producing industry unless potash prices rise more rapidly than the general price level.

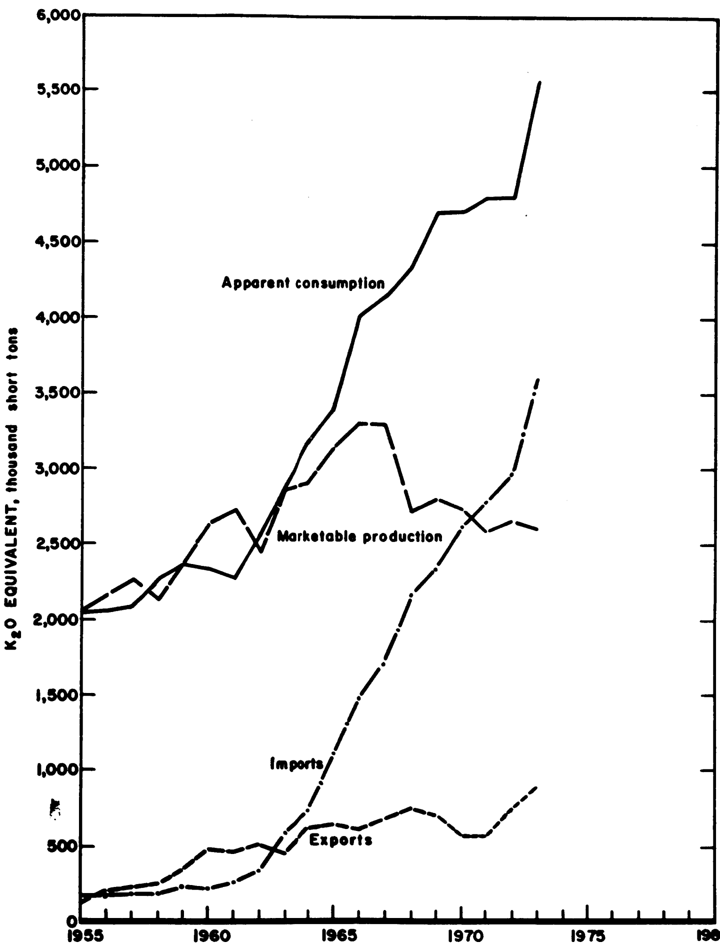

Figure 1.—Marketable production, apparent consumption, exports, and imports of potassium salts measured in K_2O equivalent.

CONSUMPTION AND USES

Apparent consumption of potash in the United States increased to 5.57 million short tons of K_2O in 1973, as measured by sales reported by domestic producers plus imports less exports; this was an increase of 16% over the 1972 level.

The Potash Institute of North America reported (table 4) U.S. sales of domestic and Canadian potash of 5.65 million short tons, in terms of K_2O equivalent, of which 307,000 tons, or 5.4%, was sold as chemical potash. In addition, offshore imports of fertilizer K_2O into the United States were reported as 87,573 tons of K_2O. Some 42% of agricultural potash was consumed in the north central States of Illinois, Indiana, Iowa, Ohio, and Minnesota.

STOCKS

Domestic yearend stocks of marketable potassium salts decreased 56% to 206,000 short tons. This was the lowest level of producers' stocks since the early 1950's when the industry was expanding to its present size.

Table 5.—Yearend stocks of marketable potassium salts in the United States

PRICES

Bulk prices for potash remained relatively steady under Cost of Living Council guidelines until October 25, when fertilizer materials, including potash, were exempted from phase 4 controls. The Council explained its action by pointing out that fertilizer producers had insufficient cost justification to implement price increases under Economic Stabilization Program regulations, and consequently the gap between domestic and world prices was so large that needed domestic supplies were being shipped abroad. Potash prices rose thereafter but at a rate slower than that of other fertilizer materials and slower than raw materials in general.

The Saskatchewan Government continued to maintain a floor price of 33.75 cents per unit of K_2O for all sales of potash. As market demand increased, and as permitted production under the prorationing scheme was also increased, prices rose on the world market, and the floor price became inoperative.

FOREIGN TRADE

Both exports and imports of potash materials increased considerably in 1973 compared with 1972. The relatively small exports and imports of potash materials for chemical purposes showed large percentage increases. Total exports in terms of K_2O content were up 16% and total imports rose 21%. Latin America as a whole took the largest share of U.S. exports. Canada, as usual, was the major supplier, contributing almost 96% of U.S. imports.

WORLD REVIEW

World production increased strongly in 1973, as new mines were opened in Australia and the United Kingdom. Several older European mines were closed.

Australia.—Texada Mines Pty. Ltd. was to begin production of langbeinite from evaporite deposits at Lake McLeod, north of Perth, Western Australia, in the third quarter. A plant was planned with an initial capacity of about 80,000 tons per year, but it was decided to increase this to 200,000 tons, with a possible expansion to 300,000 tons. The bulk of production will be exported, making Australia the world's largest exporter of this product.[2]

Brazil.—Petroquisa and the Lume group announced that they would invest about $120 million over a period of 6 years to produce potash at Carmópolis, in the State of Sergipe, northeastern Brazil. A minority shareholder will be the National Economic Development Bank (BNDE).[3] A local company, Kalium Mineraçãoes, has reportedly received permission to exploit the potash deposit.[4]

Canada.—A study of the Canadian potash industry was issued to serve as background material for an analysis of the transportation of Canadian potash.[5] After an outline of the development and growth of the industry, the basis for prorationing production to market demand was discussed. Prorationing instituted by the Government of Saskatchewan is policed by the producers themselves. All producers operate at a similar capacity level, set to total 95% of the estimated market; the basic industry allowance in the 1973 fertilizer year was 47.7% of capacity, and the total average was about 52%. Excess markets are shared among producers. Exceptions that increased the average above the basic allotment included a special arrangement by one producer to sell 300,000 to 400,000 tons per year to a U.S. firm, a share of which was given to other producers until June 1973, and the building up of stocks by several producers. The minimum price of Can $20.25 per short ton of 60% K_2O product (equivalent to 33.75 cents per unit) may not absorb freight demurrage or storage charges, except storage at Vancouver, which is considered an extension of mine stockpiles.

Prorationing quotas for the fertilizer year 1974, issued late in 1973, allowed the industry to produce 5.6 million tons of K_2O, including 40,000 tons to rebuild inventory, or a rate of about 68% of nominal capacity. This was expected to bring Canadian production in line with its share of world capacity.

France.—Completion of a program of production rationalization in the Alsace potash mines was scheduled to reduce the number of mines to three: Théodore, Amélie, and Marie-Louise, with eventual capacities of 1,760, 1,870, and 2,650 (3,200 by 1974) short tons per day of K_2O in product. Rationalization and modernization were first envisioned in the late 1960's as necessary to meet Canadian expansion into world markets. Total annual capacity of 2.05 to 2.1 million short tons of K_2O will be maintained.[6]

The Anna mine was closed in August, after 51 years of operation. The average grade of ore extracted during the last year was 14% K_2O.[7]

Germany, West.—The Buggingen mine of Kali und Salz AG ceased operations on April 30.[8] The mine in Baden Württemburg was the last remaining in the south German extension of the Alsace deposits; it had a capacity of 495,000 to 550,000 short tons per year.

Italy.—After the Sicilian potash industry was unified late in 1972,[9] two producers, both controlled by the Italian and Sicilian Governments, were in operation. One, SALSI (Societá Salisera Siciliana), produced potassium sulfate from kainite ore, with its principal mine at Palo (San Cataldo), and its refinery at Campofranco; the other, ISPEA (Industria Sali Potassici e Affini, S.p.A.), produced potassium chloride from carnallite, with its principal mine and refinery at Pasquasia. SALSI plans to expand production at Racalmuto, and ISPEA

[9] Phosphorus and Potassium. The Italian Potash Industry. No. 63, January–February 1973, pp. 36–40.

was slated to start potassium sulfate production at Pasquasia in 1973.

Libya.—The Industrial Research Centre of the Libyan Arab Republic issued a tender for technical and marketing know-how to assist with the exploitation of the Marada salt occurrence in central Libya, 120 miles by road south of the Gulf of Sirte. The area is a salt marsh, with a crust varying between 14 and 22 inches in thickness; the brines that form it contain up to 2% potassium. The deposits were worked in 1939–40 by an Italian consortium, when about 23,000 short tons containing 40% to 42% K_2O was produced by fractional recrystallization.[10]

U.S.S.R.—A summary of potash reserves in the U.S.S.R., based on a review of recent Soviet literature, was published.[11] Total reserves of all degrees of confidence were given as 28,410 million short tons containing 16% to 40% K_2O. This includes 17,500 million tons of carnallite and sylvite with 13% to 20% K_2O in the Upper Kama basin in the northern Urals; 5,070 million tons of sylvinite containing 16% to 20% K_2O in Starobinsk, Belorussia; and 3,200 million tons, largely of hartsalz, containing 16% K_2O in L'vov Oblast, Western Ukraine. Other reserves in the Karlyukskoye deposit in the Turkmen SSR were reported as 2,200 million tons and in the Tuva-Gatanskoye deposit, 440 million tons. The Petryakovskoye deposit in Belorussia was under exploration in 1972.

United Kingdom.—Commercial production from Britain's first potash mine began in the second half of 1973.[12] Maximum output at the rate of 1 million tons of K_2O was expected to be reached during 1974 from the Boulby, Yorkshire, mine of Cleveland Potash Co., Ltd.

TECHNOLOGY

A $1 million project to produce alumina and potash from alunite was dedicated at Golden, Colo., by a group composed of Earth Sciences, Inc., Golden, Colo.; National Steel Corp., Pittsburgh, Pa.; and Southwire Co., Carrollton, Ga. The Alunite Metallurgical Center is part of a program to test the process on a pilot-plant scale. If successful, the project could lead to the production of 500,000 tons of alumina, 250,000 tons of potash, and 450,000 tons of sulfuric acid yearly from the joint venture's property near Cedar City, Utah.[13]

The Federal Bureau of Mines continued its investigations of methods to concentrate potash minerals. Tests were made on a flotation process for economically recovering potash from high-clay ores, in a mobile field testing unit at the Duval Corp. mine in New Mexico. Methods were studied at the Tuscaloosa Metallurgy Research Laboratory, Tuscaloosa, Ala., to improve brine recovery from slimes generated in processing potash ore. During the year research was started at the Salt Lake

City Metallurgy Research Center, Salt Lake City, Utah, to prepare chemical plant feed enriched in potassium sulfate from crude salt from Great Salt Lake brine. Bench-scale flotation tests demonstrated the possibility of concentrating the salts from 5% or 6% potassium to 12% or 14% potassium at recoveries ranging from 75% to 90%. Also at Tuscaloosa, the Bureau demonstrated that concentrates containing 59.9% K_2O can be made from New Mexico high-clay sylvinite ores by heavy-liquid separation at recoveries of over 75%[14]

The Office of Coal Research of the Department of the Interior, and the National Aeronautics and Space Administration sponsored research by the General Electric Co. into the use of potassium topping cycles for stationary powerplants. Efficiency of central station powerplants would be increased by boiling potassium instead of water. Maximum steam temperature is limited at present to about 1,000° F.; potassium could permit temperatures as high as 1,700° F., at substantially lower pressures than steam.[15]

It was also reported that an attractive gasification system for magnetohydrodynamic (MHD) power generation consists of a bed of molten potassium carbonate. Some potassium carbonate is carried over to the combustor, where it reduces the need to add potassium carbonate seed.[16]

The Federal Bureau of Mines determined that mixed seedling of 15 mole-percent cesium carbonate and 85 mole-percent potassium carbonate was preferable to either pure cesium or potassium carbonates in open cycle MHD power generation.[17]

In a trial of Lurgi gasification of American coal, in Westfield, Scotland, it was intended to test sulfur purification of the synthesis gas with the Benfield process, using hot potassium carbonate, replacing the Lurgi Rectisol process.[18] The Benfield process is based on the HPC (hot potassium carbonate) process developed by the Federal Bureau of Mines in the 1950's.

Drilling fluids inhibited with potassium chloride were found effective in stabilizing sensitive shales in oil well drilling. Two cations, potassium and ammonium, were found far superior to others as such inhibiting agents, but potassium was preferred for field use because it was less expensive and more temperature stable.[19]

Pumice and Volcanic Cinder

By Arthur C. Meisinger [1]

U.S. production of pumiceous materials in 1973 declined 1% in quantity but increased 34% in value compared with that of 1972. The record value of nearly $8.8 million for pumice, pumicite, and volcanic cinder sold or used by producers in 1973 was due, in large part, to the continued increase in costs for milling. Increased consumption of pumice and volcanic cinder as landscaping material emerged in 1973, and exceeded 150,000 tons, although comprising only 4% of the total use pattern. A record quantity of nearly 3,100 tons of pumice was exported to meet the growing demand in Europe, particularly in West Germany; however, pumice imports declined significantly (48%) in 1973 from that of 1972, primarily because of major price increases for foreign grades.

DOMESTIC PRODUCTION

Domestic production of pumiceous materials was 3,772,000 tons in 1973, down 1% from the 3,813,000 tons in 1972. However, the value increased 34% from $6,539,000 in 1972 to $8,770,000 in 1973. The increase in total value of pumiceous materials was attributed to increased pumice and pumicite production (824,000 tons and $3.6 million) in 1973, which was the highest reported since 1964 when nearly 1.2 million tons of pumice valued at $4.1 million was produced. Although the quantity of volcanic cinder, ash, and scoria was down about 75,000 tons from that of 1972, the value increased 11% in 1973. Volcanic cinder, ash, and scoria comprised 78% of the U.S. output of pumiceous materials.

Domestic output in 1973 came from 88 firms, individuals, and governmental agencies producing from 158 operations in 13 States. Compared with 1972, output of pumiceous materials in 1973 came from 13 less producers and 62 fewer operations. The principal producing States, in order of output as in 1972, were Oregon, Arizona, and California, and their combined output accounted for 70% of the national total. Other States with significant output of pumiceous materials were Hawaii, Nevada, and New Mexico. Of the six leading States, only Arizona and Hawaii showed a decrease in production from that of 1972. California led all the producing States with 56 active operations, followed by Oregon with 31, and Arizona with 28. Volcanic cinder was produced in 11 of the 13 States, and in American Samoa from deposits operated by the Samoan Government.

CONSUMPTION AND USES

Road construction (including ice control and road maintenance) and concrete admixtures and aggregates were again the major end uses of pumiceous materials, and accounted for 44% and 35%, respectively, of U.S. consumption in 1973. Of the remaining 21%, railroad ballast comprised 13%, landscaping 4%, and abrasive materials and other uses, 4%.

Compared with consumption in 1972, use in landscaping increased 33%; use in railroad ballast, 20%; use in concrete admixtures and aggregates, 10%; and other uses, 29%. Use in road construction declined 16% from that of 1972, and use in abrasives declined 5% in 1973. The completion of a number of highway contracts in the western United States at the beginning of 1973 was reflected in a decrease in the use of volcanic cinder for road construction.

Table 3.—Pumice, pumicite, and volcanic cinder sold or used by producers in the United States, by use

PRICES

The average value for crude pumice, pumicite, and volcanic cinder sold and used decreased slightly from $0.98 per ton in 1972 to $0.95 per ton in 1973. Average value for prepared material, however, showed a significant increase—from $2.42 per ton in 1972 to $3.60 per ton. The weighted average value of pumice, pumicite, and volcanic cinder was $2.33 per ton compared with $1.71 per ton in 1972. The continued increased costs in milling was primarily responsible for the rise in weighted average value of pumiceous materials.

The average 1973 price per ton for pumice and volcanic cinder (scoria) used in cleaning and scouring compounds was $27.05, substantially above the 1972 price; for concrete admixtures and aggregates, $2.23, a $0.22 increase; for railroad ballast $1.05, a $0.12 increase; for road construction, $1.27, a $0.09 increase; and for other uses, $15.02, an $8.41 increase. Pumice and volcanic cinder used for landscaping decreased $0.05 in price per ton in 1973 from $5.08 in 1972 to $5.03.

Prices quoted at yearend in the American Paint Journal remained unchanged from 1972, and were as follows for pumice stone per pound, bagged, f.o.b. New York or Chicago: Powdered, $0.0445 to $0.08, and lump, $0.0665 to $0.09.

Price quotations for pumice in Chemical Marketing Reporter were changed on May 21, 1973, and at yearend were as follows: Domestic grades, bagged in ton lots, fine, $0.0765 to $0.1140 per pound; medium, $0.1160 per pound; coarse, $0.094 per pound; imported (Italian) silk-screened, bagged in ton lots, fine, $138 per ton; medium, $150 per ton; and coarse, $140 per ton. Price of imported small and large lump size was reported as $275 per ton.

FOREIGN TRADE

A record quantity of 3,095 tons of pumice was exported in 1973. Since 1965, when export data were first available, the previous record was only 624 tons of pumice in 1968. Pumice was exported to 16 countries in 1973—4 more countries than in 1972—West Germany received 79% (2,457 tons) of the total pumice exported.

Pumice imported for consumption declined in 1973, due primarily to increased shipping rates, higher prices of foreign pumice, and a fuel shortage that reduced cargo shipments at yearend. Compared with 1972, imports of pumice declined 48% in quantity and 24% in value. As in previous years, Italy and Greece supplied nearly all of the imported pumice. Total value of all import classes was $1.1 million in 1973 compared with $1.5 million in 1972.

Imported pumice used in the manufacture of concrete masonry products declined 48% from that of 1972, and imports classed as crude or unmanufactured declined 45%. However, imports classed as wholly or partly manufactured increased 10% from 2,489 tons in 1972 to 2,740 tons in 1973.

Pumice stone, TSUS No. 519.05, for use in concrete products continued to be admitted into the United States duty free. Duties for other products at yearend were as follows: TSUS No. 519.11, crude or crushed pumice, valued not over $15 per ton, 0.02 cent per pound; TSUS No. 519.14, crude or crushed pumice, valued over $15 per ton, 0.04 cent per pound; TSUS No. 519.31, grains or ground, pulverized or refined, 0.17 per pound; and TSUS Nos. 519.93 and 523.61, millstones, abrasive wheels, and abrasive articles n.s.p.f. and articles, n.s.p.f., 7% ad valorem.

Rare-Earth Minerals and Metals

By James H. Jolly [1]

Total world production of rare-earth oxide (REO) contained in concentrates increased about 25% in 1973 despite decreased output by the two leading monazite producing countries, Australia and India. The major factor in the increase was a 64% jump in bastnaesite production at Mountain Pass, Calif., by the Molybdenum Corp. of America (Molycorp). In 1973, Molycorp produced an estimated 60% of the total world REO output. Foreign mine production of rare-earth minerals decreased slightly from last year's level due to power and water shortages and, in part, to decreasing monazite grade at some mines. Monazite was in short supply during the year and prices increased about 15%. Worldwide, the production and consumption of rare-earth compounds and metals increased.

The domestic rare-earth industry was highlighted in 1973 by record production of rare-earth concentrates, increased mine and mill capacity, increased shipments and exports of rare-earth materials, and promising technological developments. The consumption pattern of rare earths changed from that of the previous year. Petroleum catalyst usage was the major consumer of rare earths in 1973, replacing metallurgical applications by a wide margin. Metallurgical uses declined about 20% mainly because rare-earth silicide demand was markedly lower.

U.S. exports of rare-earth products exceeded 8,000 tons contained REO, double the 1972 content. The major importing countries were Japan, West Germany, France, Austria, Canada, and the United Kingdom.

Domestic imports of monazite increased and receipts of yttrium-rich uranium residues from Canada were resumed. Demand for ytruim oxide for use in color television phosphors balanced chronic oversupply conditions for the first time since 1968. U.S. chemical processing capacity decreased during the year because two major rare-earth processors, Lindsay Rare Earths Div. of Kerr-McGee Corp. and Michigan Chemical Co., ceased operations and were dismantling facilities.

Legislation and Government Programs.—At the end of 1973, the General Services Administration (GSA) held a total of 11,677 short tons (dry) of REO equivalent in the national (9,574 tons) and supplemental (2,103 tons) stockpiles. Disposals for the year amounted to 140 tons of contained REO in rare-earth chloride. The Y_2O_3 stockpile remained unchanged at 237 pounds. The rare-earth elements were removed from the list of strategic and critical materials in March 1971 and were authorized for orderly disposal to industry.

During 1973, the Office of Minerals Exploration (OME), U.S. Geological Survey, continued financial assistance of 50% of approved costs for exploration for rare-earth and yttrium resources.

DOMESTIC PRODUCTION

Concentrate.—REO production as measured by output of bastnaesite and monazite was at an alltime high in 1973 and about 60% higher than that of 1972. More than 90% of production was in the form of bastnaesite; the remainder was in the form of monazite.

The Mountain Pass, Calif., operation of Molycorp produced 19,341 tons of REO in flotation concentrate from 305,073 tons of bastnaesite ore mined and milled. A 50% expansion of mill and flotation facilities to

[1] Physical scientist, Division of Nonferrous Metals—Mineral Supply.

30,000 tons REO annually, announced in January, was completed in the fourth quarter.[2]

Molycorp extended its option with Republic Steel Corp. for exclusive purchase rights to heavy rare-earth and yttrium concentrates which may be recovered from the apatite in tailings at Republic's iron ore property at Mineville, N.Y. A low-cost, acid-heap-leaching method to extract yttrium from these tailings was under investigation by the Bureau of Mines.

Humphreys Mining Co. continued to recover byproduct monazite from a beach sand deposit controlled by E. I. du Pont de Nemours & Co., near Folkston, Ga. Ore reserves at the deposit are expected to be exhausted by mid–1974. However, the company planned to continue operations by developing another beach sand deposit located a few miles south, in Florida. The heavy mineral concentrate from the new deposit will be processed at the existing Folkston plant.

Titanium Enterprises, jointly owned by American Cyanamid Co. and Union Camp Corp., was the only other domestic producer of monazite in 1973. The company, which began operations in October 1972, produced monazite as a byproduct in mining Pleistocene beach sands for titanium minerals and zircon near Green Cove Springs, Fla. In the latter part of the year, production decreased due, in part, to energy shortages.

Compounds and Metals.—With the closing of the Lindsay Rare Earths Div. of Kerr-McGee Corp. (Lindsay), West Chicago, Ill., only two volume rare-earth processors, Molycorp and the Davison Chemical Div. of W. R. Grace & Co. (Davison), Chattanooga, Tenn., were operating at the end of 1973. Lindsay, a pioneer in the rare-earth industry, ceased all operations during the year and was dismantling facilities and selling off stocks. The plant, which had an annual capacity of several million pounds, processed monazite into a wide range of rare-earth chemicals and polishing compounds. Michigan Chemical Corp., St. Louis, Mich., specialty producers of yttrium and heavy rare-earth compounds, also ceased rare-earth production in 1973. The company was dismantling all of its ion-exchange facilities and was also selling off rare-earth stocks.

Molycorp, with processing plants at Mountain Pass, Calif., Louviers, Colo., Washington, Pa., and York, Pa., increased production of rare-earth compounds 56% (in terms of REO) over that of 1972. Molycorp resumed importation of yttrium-rich uranium residues from Denison Mines, Ltd., Canada, in 1973 for processing at the Louviers plant after a 3-year suspension of imports because of oversupply conditions. The plant had produced yttrium oxide in the interim from stockpiled residues.

High-purity rare-earth oxides and compounds were produced by Molycorp; Lindsay; Davison ; Michigan Chemical Corp.; Research Chemicals Div., Nucor Corp., Phoenix, Ariz.; Atomergic Chemetals Co., Div. of Gallard-Schlesinger Chemical Manufacturing Corp., Carle Place, N.Y.; and by Transelco Inc., Penn Yan, N.Y. Lindsay, Molycorp, Michigan Chemical, Research Chemicals, and Atomergic produced yttrium oxide and/or metal during the year.

Mischmetal production by the two primary domestic producers—Ronson Metals Corp., Newark, N.J., and Reaction Metals Inc., Newcastle, Pa., a subsidiary of Rare Earth Industries—increased 17% but shipments decreased more than 30% indicating less metallurgical consumption. Rare Earth Metals Co. of America, a joint venture of Aluminum Co. of America (51%) and Molycorp (49%), continued pilot plant testing of a Bureau of Mines-developed electrolytic reduction process to produce mischmetal and rare-earth metals at Molycorp's Washington, Pa., facility. A plant with an annual capacity of 250 tons of metal was planned for 1975.

Rare-earth ferrosilicon alloys consumed primarily by the iron and steel industry in the United States and Canada were produced by four companies: Foote Mineral Co., Ohio Ferro-Alloys Corp., American Metallurgical Products Co., Inc., and Union Carbide Corp. Production and shipments were sharply lower in 1973.

Crucible Magnetics Div. of Colt Industries, Inc., Elizabethtown, Ky., became the fifth domestic producer of rare earth-cobalt magnets in December.[3] Other producers were Raytheon Co., Waltham, Mass.; Spectra-Flux Corp., Watsonville, Calif.; Elec-

tron-Energy Corp., Landisville, Pa.; and Hitachi Magnetics Corp., Edmore, Mich. Hitachi acquired the magnetic materials facilities of General Electric Co. in March and began commercial production at midyear.[4]

CONSUMPTION AND USES

Domestic rare-earth processors consumed an estimated 19,700 tons of REO contained in raw materials during 1973. Bastnaesite consumption increased 45% while monazite consumption decreased by almost 27%. Consumption of monazite by W. R. Grace at Chattanooga, Tenn., declined slightly, whereas bastnaesite consumption, although considerably less than that of monazite, almost tripled.

Shipments of rare-earth and yttrium products from principal processing plants to domestic consumers totaled about 13,400 tons REO, valued at about $23 million. This quantity includes intracompany shipments but does not include products derived from reprocessed shipments at secondary plants. The following estimated quantitative percentage distribution of rare-earth product usage during 1973 was based on information supplied by primary processors and certain consumers: Petroleum cracking catalysts, 43%; metallurgical, including nodular iron and steel, other alloys, magnets, and lighter flints, 35%; ceramics and glass, 17%; electrical and arc light carbons, 4%; and miscellaneous, including research and development, 1%. Shipments of high purity rare-earth and yttrium oxides and metals, although representing less than 1% of the total weight of shipments, accounted for about 30% of the value.

The manufacture of rare-earth zeolites for use in petroleum cracking catalysts replaced metallurgical uses as the major consumer of rare earths in 1973. Metallurgical consumption declined mainly because demand for rare earths used in the production of pipeline steel was significantly lower, owing to continuing delays in construction of the Alaskan pipeline. Most other metallurgical applications, however, continued to increase. Stimulated by the automobile industry's need to reduce the weight of automobiles, the consumption of rare earths in the production of high-strength, low-alloy (HSLA) sheet steels doubled in 1973. Rare earths, in the form of mischmetal or silicide, added to such steels, increase impact and yield strength and improve weldability and formability by beneficially influencing the number, size, shape, and composition of retained inclusions. With proper design, the use of HSLA steels can reduce the weight of some automobile components by as much as 30%.[5] A large increase in metallurgical consumption of rare earths was expected in 1974 owing to large-scale production of HSLA steel for Arctic pipeline construction. Rare-earth treated HSLA steel alloys possess the rigid physical properties required for this pipe to withstand the internal pressures and extreme temperature variations of Arctic regions.

Rare earths were widely used in the production of ductile cast iron because they counteract a number of deleterious elements that interfere with the activity of magnesium in producing nodular graphite. The ductile iron industry continued to grow at a rate of about 15% in 1973, mainly because of strong demand for ductile cast iron pipe for water transmission systems and for quality castings required by the automotive and farm equipment industries.

The production of lighter and striker flints continued to be a major consumer of mischmetal. Other rare-earth alloys and metals were used in the production of high-temperature alloys and superalloys, and nuclear reactor control rods.

Besides the well-known use of cerium oxide for polishing plate glass, eyeglasses, television tubes, and camera lenses, a major and increasing use, worldwide, of cerium oxide was as a decolorizing agent in refining clear glass. Other rare-earth oxides—praseodymium, erbium, holmium, and neodymium—exhibit strong absorption of light and were used as colorants in glass. Lanthanum oxide increases the refractive quality of camera lenses. The Japanese consumed more than 110 tons of La_2O_3 for this purpose in 1973.

Yttrium oxide and europium oxide were

---

[5] Metal Progress. Automakers Turn Weight Watchers, Eye HSLA Grades. V. 103, No. 1, January 1973, pp. 32–33.

important phosphor materials in color television tubes. Crystals of yttrium (or gadolinium)-aluminum (or iron) garnet were used as microwave filters and control devices. The garnets, when doped with small quantities of neodymium or erbium, were used as lasers. Some crystals were grown solely for use as gem stones.

Rare-earth oxides and fluorides added to carbon arc electrodes emit a brilliant white light that is necessary for searchlights and for color motion picture photography and projection. This use continues to grow slowly.

High-energy permanent magnets composed of rare earth-cobalt alloys consumed an estimated 3,000 pounds of rare earths, mostly samarium and mischmetal, in 1973. These magnets, which are two to three times more powerful than previous compositions, were used mainly in electric wrist watches and traveling wave tubes. The high strength of these magnets made it possible to eliminate the bearings in aircraft engine tachometers permitting a 30% saving in weight and improving reliability and service life.[6]

STOCKS

Bastnaesite concentrate stocks held by the principal producer and five other chemical processors at yearend declined 52%; monazite concentrate held by the two producers and three processing companies declined almost 47%. Mischmetal stocks held by two principal producers increased 42% during the year and stocks of high-purity metals held by three firms were 37% higher than at the first of the year.

PRICES

Prices for domestic monazite remained stable during the year, whereas prices of foreign-produced monazite rose 5% to 20% because of continued strong demand and reduced production. The average c.i.f. price per metric ton of Australian monazite (minimum 60% REO plus ThO_2), quoted in Metal Bulletin (London), increased from $187 to $206 at mid-year to $200 to $215. The declared value of imported monazite concentrate from Malaysia averaged $123 per short ton in 1973, 23% higher than the previous year. Malaysian xenotime concentrate with a minimum of 25% yttrium oxide content, as quoted in Industrial Minerals (London), remained unchanged at $3 to $5 per pound.

Unleached, leached, and calcined bastnaesite containing 55% to 60%, 68% to 72%, and 85% to 90% REO remained at 30, 35, and 40 cents per pound REO, respectively, f.o.b. Mountain Pass or Nipton, Calif., in 100-pound paper bags or 55-gallon steel drums in truckload or carload lots.

Rare-earth oxide compound prices, in a downtrend since 1965, firmed in 1973; price increases were expected in many items in the coming year, owing to price hikes in concentrates and higher processing costs. Quoted prices per pound f.o.b. plant, for certain rare-earth compounds were as follows: mixed rare-earth oxides, 97% REO, $1.40 under 500 pounds decreasing

Table 1.—Prices of high-purity oxides, salts, and metals in 1973 [1]

(Dollars per pound)

Element	Oxides [2]	Salts [3]	Metals [4]
Cerium	5.00	14.00	50.00
Dysprosium	40.00	30.00	130.00
Erbium	45.00	30.00	160.00
Europium	450.00	250.00	3,000.00
Gadolinium	45.00	28.00	220.00
Holmium	120.00	90.00	300.00
Lanthanum	4.75	14.00	50.00
Lutetium	2,000.00	1,200.00	6,000.00
Neodymium	12.00	14.00	110.00

to $1.10 for lots over 5 tons; chlorides, $0.29; carbonates, $0.83; fluorides, 84% REO, $0.90; and hydrates, $1.30.

Prices for optical-grade ceric oxide in lot sizes of 50 pounds or more delivered in bags or drums, remained at $2 per pound. Quotations on cerium hydrate, 92% CeO_2 of total REO, increased 5 cents per pound to $1.50 whereas 95% to 98% CeO_2, cerium hydrate, decreased 3 cents per pound to $1.55.

Quoted prices on 1-pound ingots in 50- to 100-pound lots of 97% didymium and cerium-free mischmetal remained at $15 and $5, respectively, f.o.b. plant. Mischmetal 99.8%, was quoted at $3.10 per pound, same basis. Ferrosilicon, containing 30% rare-earth metal, was quoted at $1.45 to $1.50 per pound (contained rare-earth metal). Rare earths for magnet use, 99% purity in 10- to 100-pound amounts, as quoted per pound in American Metal Market were as follows: cerium, $19; lanthanum, $28; praseodymium, $62.50; and samarium, $78.

FOREIGN TRADE

According to the sole domestic producer, Molycorp, exports of bastnaesite concentrate were 4,854 tons contained REO, a 94% increase over those of 1972.

Exports of ferrocerium and other pyrophoric alloys to Sweden, Canada, the Netherlands, Australia, and 18 other countries decreased 46%, totaling 109,766 pounds valued at $285,763. The average unit value of $2.60 per pound was 42 cents less than that of 1972.

Exports of compounds and mixtures of rare-earth metals, including yttrium and scandium, increased from 1,514,605 pounds valued at $3,143,895 in 1972 to 4,047,741 pounds valued at $4,592,374 in 1973. The large quantitative increase was due to shipments of 2,462,597 pounds of rare-earth compounds, valued at $654,567, to Austria.

Imports of monazite concentrate increased substantially from those of the previous year. Shipments from Malaysia more than doubled and imports from Thailand resumed for the first time since 1970.

Cerium oxide imports, predominately from West Germany and Austria, totaled 11,716 pounds, valued at $22,826. Imports of cerium chloride, only from Austria, were one-third of the total imports in 1972 amounting to 1,080 pounds, valued at $1,772. Other cerium compounds, n.s.p.f., from France and Austria totaled 16,575 pounds, valued at $34,503, a 161% increase in quantity but only a small increase in unit value.

Imports of rare-earth metals increased sharply in 1973 due to a more than fourfold increase in shipments from the U.S.S.R. (table 2). Imports of ferrocerium and other pyrophoric alloys increased to 38,206 pounds, valued at $126,631, compared with 1972 receipts of 27,870 pounds, valued at $94,347. France supplied 51% of total shipments, valued at $50,614, followed by Japan with 44%, valued at $66,144. Other suppliers were the United Kingdom, Austria, Spain, and Singapore. No mischmetal was imported during 1973.

The tariffs on rare-earth metals and compounds were the same as in 1972. The tariff was 15% ad valorem on cerium oxide and chloride, $0.50 per pound on rare-earth alloys and mischmetal, $0.50 per pound plus 6% ad valorem on ferrocerium and other pyrophoric alloys, and 5% ad valorem on rare-earth metals and yttrium. Rare-earth ores and concentrates remained duty free.

WORLD REVIEW

Australia.—Production of monazite decreased 12.6% in 1973 from 1972 because of reduced production and leaner monazite contents of the ore. According to the Rutile and Zircon Development Assoc., Ltd., monazite production by members in short tons by State was as follows:

	1972	1973	% Change
New South Wales	1,604	1,076	−32.9
Queensland	121	64	−47.1
Western Australia	3,056	3,087	+1.0
Total	4,781	4,227	−11.6

Western Titanium, Ltd., a subsidiary of Consolidated Gold Fields Australia, Ltd., reported slightly increased production of monazite, 1,817 tons, and a 60% production increase in xenotime for the year ending June 30, 1973. Ore reserves in the Capel area were re-assessed at 7.8 million tons of heavy minerals made up of 6.4 million tons of proved ore and 1.4 tons of probable ore.[7]

Allied Eneabba Pty. Ltd., owned by Allied Minerals N.L. (75%) and DuPont (Australia) Ltd. (25%), planned to construct a 450,000-ton-per-year plant near Eneabba, Western Australia, to process heavy mineral sands for titanium minerals, zircon, and monazite. Full-scale production was scheduled in 1975.[8]

Canada.—Denison Mines, Ltd. resumed recovery of yttrium from uranium waste liquors for the first time since mid-1970. Shipments of yttrium-rich residues were being shipped to Molycorp for processing under a contract that runs to March 1976.

India.—Monazite production by the sole producer, Indian Rare Earths, Ltd. (IRE), decreased 1,388 tons to 3,276 tons in fiscal year 1973 (year ending Mar. 31, 1973). The decreased production was attributed to leaner monazite content in the raw sand and to power shortages at the Manavalakurichi plant. The Alwaye plant of IRE processed 4,350 tons of monazite, producing 4,837 tons of rare-earth chloride, 97 tons of rare-earth fluoride, and 24 tons of REO. Sales of rare-earth compounds declined slightly to 4,815 tons, but the value increased almost 11% to $1,250,000. According to IRE's annual report, the company planned to develop the mineral sand deposits along the Orissa coast. Two Australian firms were preparing a feasibility report on setting up a mineral sand separation plant at Orissa.

Japan.—In 1973 Japanese rare-earth processors consumed increased quantities of bastnaesite concentrate and rare-earth hydrates and reduced amounts of rare-earth chlorides and monazite. Monazite processing continued to diminish because of radioactive pollution problems. Xenotime from Malaysia was the source material for yttrium and heavy rare-earth elements.

Production and demand for rare-earth metals and compounds increased substantially. Imports also increased. Yttrium oxide and mischmetal imports were up 48% to 14 and 11.5 tons, respectively; cerium oxide 54% to 150 tons; and lanthanum oxide 180% to 113 tons.[9] The consumption pattern of rare earths in Japan differs from that of the United States. No rare earths were used in petroleum catalyst manufacture and very little in steel production. Rare earths, consumed by the iron and steel industry, were used mainly in the production of ductile iron. New Japanese steel furnaces are capable of producing very low sulfur steels that do not require rare-earth treatment. Rare-earth consumption in Japan, since 1970, is shown in table 5.

Malawi.—Lonrho Ltd. investigated monazite and strontianite occurrences in the carbonatite veins and dikes at Kangankunde Hill. Subject to satisfactory marketing arrangements, Lonrho planned to develop the deposit which has inferred reserves of more than 15,000 tons of monazite.

Norway.—The Metal Extraction Group (Megon) in association with the Atomic Energy Institute planned to construct a 50-ton-per-year plant at Kjeller, Norway, for commercial production of high-purity yttrium oxide. Trial production in a pilot plant, based on imported 60% yttrium concentrate, successfully produced high-purity material.[10]

South Africa, Republic of.—A pilot plant was under construction by the Industrial Development Corp. of South Africa Ltd. and KRC Resources S.A. Pty. Ltd., a subsidiary of King Resources, to evaluate the feasibility of exploiting a rare-earth, titanium, and zirconium heavy mineral deposit in the Richards Bay area of Natal.[11] Late in the year, KRC's 49% share in the deposit was sold to Quebec Iron & Titanium Corp. for $4 million.[12]

TECHNOLOGY

Research on the uses of rare-earth compounds as potential catalysts in automotive emission control received increasing attention in 1973. In controlled laboratory tests, researchers at Bell Laboratories found that rare-earth lead manganites were effective

[9] Japan Metal Journal. Rare Earth Industry in 1973. V. 4, No. 14, Apr. 8, 1974, p. 7.
[10] Mining Journal. V. 282, No. 7220, Jan. 11, 1974, p. 25.
[11] Engineering and Mining Journal. V. 174, No. 2, February 1973, p. 135.
[12] Metals Sourcebook. V. 11, Jan. 28, 1974, p. 4.

in reducing smog-forming nitrogen oxides to harmless nitrogen.[13] Preliminary results indicated these rare-earth compounds were stable under the oxidation-reduction conditions and the high temperatures encountered in exhaust systems and, also, had some tolerance to lead, a serious problem in noble metal converters. Several test samples of rare-earth lead manganites have been submitted to automotive companies for evaluation. Another series of rare-earth catalysts, lanthanum cobalt oxides, were also reported to be effective in dealing with nitrogen oxides.[14]

The Bureau of Mines investigated the catalytic activity of rare-earth oxides for the cathode reaction of a hydrogen-oxygen fuel cell.[15] The oxides of cerium, praseodymium, and europium were significantly more active than the other elements tested.

Preliminary testing of rare-earth β-ketoenolates as antiknock additives to motor fuels indicated they were as effective or better than tetraethyl lead in some applications.[16] The most effective compounds contained cerium and the best compound discovered was cerium (2, 2, 6, 6-tetramethyl-3, 5-heptanedionate)$_4$. An extra benefit of the rare-earth additive was reduced noxious hydrocarbon emission.

Rare-earth phosphate catalysts for the production of synthetic cresol and xylenols made Industrial Research's list of the top 100 new products introduced during 1973. The new catalysts, composed of lanthanum or cerium phosphate, cut operating costs and eliminate the corrosion and pollution problems associated with the presently used caustic hydrolysis process.[17]

A new class of magnetic bubble material, which may greatly increase the storing and processing of computer data, has been discovered. Magnetic bubbles were observed for the first time in thin films of amorphous gadolinium-iron and gadolinium-cobalt. It was claimed that such films not only are easier and less expensive to fabricate than presently used crystalline films but also that they have potentially greater storage capacity estimated at about 1 billion bits per square inch.[18] In another computer development, bismuth-thulium-garnet films were found to contain magnetic bubbles having greater light sensitivity than earlier films. This makes possible optical readout at about 100 times the rate of nonoptical methods.[19]

Epitaxial films of yttrium-iron garnet and gallium-yttrium-iron garnet for use in magnetic bubble domain applications were grown by chemical vapor deposition at reduced pressure using a system which is simpler and offers more direct control over the process than previous systems.[20]

A magnetically controlled switch which can modulate light passing through a thin, single crystal yttrium-gallium-scandium-iron garnet film has been devised.[21] Such a switch may make possible systems where large amounts of information can be transmitted on laser beams.

Bureau of Mines research continued on developing low-cost technology for recovering yttrium and rare earths from apatite in iron ore tailings from New York State. Because an appreciable portion of the yttrium occurs in more soluble hydrated calcium-yttrium silicates in cracks in the apatite grains, more than half of the yttrium present in a concentrate was leachable with dilute H_2SO_4 without dissolving the apatite itself. Both solvent extraction and ion exchange methods were under investigation to extract the yttrium and rare earths from the leach solution.

High purity magnesium-yttrium alloys containing up to 55% yttrium were prepared by electroreduction of Y_2O_3 dissolved in YF_3–LiF bath.[22] A method to electrore-

fine yttrium metal from low-melting yttrium-base alloys was investigated. Metallic impurities in the cathode products were substantially less than in the anode material when yttrium was refined from alloys containing Fe, Ni, and Mn.[23]

A study of thermochemical data on rare-earth reactions in metallurgical processes was completed by the Rare Earth Information Center, Ames, Iowa, under a Molycorp grant. The study contains data on the free energies of formation of various rare-earth oxides and oxysulfides at temperatures up to 2,200° C and data on formation of rare-earth intermetallics with nine other elements.[24]

Research on rare-earth additives in steelmaking continued to be directed toward improving addition techniques. At the 31st Electrical Furnace Conference in December, the relative merits of using rare-earth silicides versus mischmetal additives[25] and rare-earth additions to electric furnaces at the Houston Works of Armco Steel Corp.[26] were discussed. In another paper, the differences in benefits obtained when rare earths are added to steels by various methods were examined on the basis of available thermodynamic information.[27]

The nonmetallic inclusions in rare earth-treated steels were identified.[28] The composition, number, size, shape, and hardness of the inclusions affect the properties obtained.

A high-speed laser welder based on a neodymium-yttrium-aluminum garnet was developed to make up to 100 spotwelds per second on a variety of metals.[29] A sun-pumped, neodymium laser system was under investigation to determine the feasibility of direct optical communications via satellite. The lasing material can be activated by auxiliary lamps when the sun is not visible.[30] Researchers at Battelle Memorial Institute were exploring the use of a very high-powered neodymium glass laser as a means of strengthening steel and other metals by shock hardening. Hardening of the metal is caused by laser induced microstructual defects.[31]

Rhenium

By Larry J. Alverson [1]

Domestic rhenium production increased 15% and was more than adequate to meet the reduced demand for rhenium, notably in bimetallic platinum-rhenium catalysts. Prices for both metal powder and compounds continued the decline started in 1972. As imports of metal powder and ammonium perrhenate increased significantly during the year, primarily in anticipation of heightened demand for bimetallic catalysts, stocks of rhenium climbed to an all-time high.

Table 1.—Salient rhenium statistics

(Pounds of contained rhenium)

[e] Estimate. [r] Revised.

DOMESTIC PRODUCTION

Production of rhenium, a secondary byproduct material recovered primarily from molybdenite (MoS_2) associated with southwestern United States and Chilean porphyry copper ores, increased in 1973 to an estimated 7,000 pounds of rhenium contained in rhenium salts. Cleveland Refractory Metals (CRM), a subsidiary of Kennecott Copper Corp., was the leading rhenium producer in the United States. CRM processed domestic MoS_2 concentrate from operations of Kennecott and Magma Copper Co., as well as concentrates from Chilean sources, at their Garfield, Utah, roasting facility.

M&R Refractory Metals, Inc., at its Winslow, N.J., plant produced rhenium salts from the MoS_2 recovered at Magma's San Manuel porphyry copper mine for Engelhard Minerals & Chemical Corp. on a contract conversion basis. Shattuck Chemical Co., Denver, Colo., a division of Engelhard Minerals & Chemical Corp., recovered rhenium salts from Arizona molybdenite concentrate. Molybdenum Corp. of America (Molycorp) sold a 50% interest in its new pollution-free hydrometallurgical process for producing molybdenum and rhenium to Cyprus Mines Corp. Cyprus received an undivided interest in the worldwide rights to the process, excluding Japan. The two firms formed a new company, Cymoly Process Corp., to handle the process through construction and/or licensing of processing plants worldwide. Continental Rhenium Corp. closed its commercial pilot plant at Golden, Colo., in the fall of 1973 after operating for about 2 years. Apparently scale-up problems and the soft rhenium market precipitated the shutdown.

Newmont Exploration Ltd., a subsidiary of Newmont Mining Corp., completed installation of a pilot multihearth furnace at its Danbury, Conn., research center. The furnace was used in a research program undertaken to develop a new method to produce salable rhenium from the molybdenite concentrate recovered at Magma's Arizona copper mine.[2]

[1] Industry economist, Division of Ferrous Metals—Mineral Supply.

[2] Newmont Mining Corp. Annual Report, 1973, 32 pp.

CONSUMPTION AND USES

Approximately 75% of the estimated 1973 rhenium metal consumption of 4,400 pounds was used in bimetallic platinum-rhenium catalysts for refining low-lead and no-lead high-octane gasoline. Consumption was down owing mainly to lack of completion of new refineries during the year.

Increases in the compression ratios of automotive engines over the past few years have raised the antiknock requirements of gasoline, resulting in the need for processes to "reform" or improve the octane number of gasoline. One of the most successful of these processes employs a bimetallic platinum-rhenium catalyst. The rhenium inhibits coke formation, making it possible to operate at lower pressures with less frequent catalyst regeneration. Presently, approximately one quarter of all non-Communist countries' bimetallic petroleum reforming catalysts are of the platinum-rhenium variety.

A number of older refineries made conversions from straight platinum to platinum-rhenium catalysts during the year. The Lake Charles, La., refinery of Cities Service Oil Co. made the conversion employing 55,000 pounds of Chevron's Rheniforming catalyst with a rhenium content of about 165 pounds. It was reported that the catalyst functioned well and that the results were very good.

The Los Angeles refinery of Union Oil Co. of California was undergoing a $30 million modification project which included installation of a catalytic reformer employing Universal Oil Products Co.'s R–16 bemetallic platinum-rhenium catalyst for the production of high-octane, lead-free gasoline. Completion was scheduled for sometime in mid-1974.

Standard Oil Co. of California planned to add two large hydrosulfurization units and a catalytic reforming unit to their Richmond, Calif., refinery. Plans called for a 25,000-barrel-per-day Rheniformer aimed at boosting the plant's capacity to produce low-lead gasolines. The project was scheduled for completion in 1976.

The remaining 25% of estimated domestic rhenium consumption was for high-temperature thermocouples, electronic devices, X-ray tubes, electrical contacts, vacuum tube and flashbulb filaments, heating elements, and electromagnets.

CRM sold its X-ray target fabrication facilities to General Electric Co. and sold the rhenium sheet, bar, and tubing fabrication unit to H. Cross of Weehawken, N.J. CRM retained its production facilities for ammonium perrhenate, perrhenic acid, and rhenium metal powder.

Pure rhenium was utilized in filaments for mass spectrographs because it is less affected by many inpurities. Also, if any oxide film forms on the filaments, the conductive rhenium oxide does not increase the filament resistance which would probably lead to overheating and burnouts.

Engelhard Minerals & Chemical Corp. continued to market tungsten-3% rhenium versus tungsten-25% rhenium thermocouples. This couple can accurately measure temperatures up to 2,400° C and is suitable for use in vacuum, hydrogen, and clean inert gases such as argon and helium.

A publication dealing extensively with rhenium was made available during the year by Roskill Information Services, Ltd., of London. It covers information on geology, reserves, producing countries, consumption, uses, prices, and general and specific trends.[3]

A Bureau of Mines publication was issued during the year that discusses rhenium and other metals, primarily from an economic point of view, as byproducts of the copper industry.[4]

PRICES

Prices paid for rhenium metal powder during the year ranged from about $900 to $675 per pound, depending on quantity, decreasing toward the latter by yearend. Prices for perrhenic acid, a starting material used in catalytic applications, ranged from about $875 to $625 per pound, depending on quantity, trending toward the latter in second half of the year. These

[4] Petrick, A., Jr., H. J. Bennett, K. E. Starch, and R. C. Weisner. The Economics of Byproducts Metals (In Two Parts). 1. Copper System. BuMines IC 8569, 1973, 105 pp.

price decreases reflected the soft nature of the rhenium market which was due principally to the lack of new refineries that would utilize bimetallic platinum-rhenium catalysts.

FOREIGN TRADE

Imports for consumption of unwrought rhenium metal during 1973 increased greatly over those of 1972 and totaled 1,437 pounds valued at $1,004,676. These imports, all of which represented rhenium metal powder, came from West Germany (78%), the Netherlands (15%), and Belgium-Luxembourg (7%). There were no imports of scrap or wrought rhenium metal during the year. Unwrought rhenium metal imports are believed to have been recovered from byproduct molybdenite obtained from porphyry copper ore mined in Chile and Peru. The average price of the metal imports, excluding U.S. duty, was $699 per pound, and ranged from $677 per pound (Belgium-Luxembourg) to $701 per pound (West Germany).

Imports of ammonium perrhenate (NH_4ReO_4) salts, all from Sweden and West Germany, nearly doubled during the year to an estimated 3,040 pounds of contained rhenium valued at $3,829,000. This material was imported under the basket classification "Ammonium compounds, not specifically provided for" (TSUS 417.44).

The main reasons for increased imports in the face of decreased consumption were the fulfilling of existing contracts and the stockpiling of rhenium in anticipation of increased demand from the spate of new refineries that were expected to come onstream in 1975–76. Also, as a result of the foregoing, stocks of rhenium were at an alltime high.

The import duty on rhenium metal from non-Communist countries remained at the January 1, 1972 rate of 5% ad valorem for unwrought rhenium metal and scrap, and 9% ad valorem for wrought rhenium metal. The import duty on wrought and unwrought rhenium metal from Communist Bloc countries also remained unchanged at 45% and 25% ad valorem, respectively. The duty on imports of ammonium perrhenate from Communist

and non-Communist countries was 25% and 4% ad valorem, respectively. The import duty on waste and scrap was suspended until June 30, 1975.

WORLD REVIEW

Australia.—Exploration of a copper-molybdenum deposit at Mt. Mulgine in Western Australia by Minefields Exploration N.L. was reported in 1970 to have produced core samples containing rhenium in "relatively high" concentrations. It was announced that the company proposed to spend $300,000 by the end of 1973, to investigate the deposit.

Canada.—The sole source of Canadian rhenium production was copper-molybdenum ore from the Island Copper Mine of Utah International, Inc., at Port Hardy, British Columbia. The ore occurs mainly in altered volcanics, and in this respect, differs from the porphyry copper deposits of the United States and Chile. Molybdenite concentrate was first produced in 1972 when shipments were 400 tons and contained about 1,200 pounds of rhenium. In 1973 shipments were about 1,200 tons containing 3,200 pounds of rhenium. To date, molybdenite purchasers have either paid for the contained rhenium or recovered the rhenium on a toll basis and returned it for direct sale by Utah International, Inc.

The rhenium content of a molybdenite concentrate averaging 95.9% MoS_2 obtained from Brenda Mines Ltd. in south-central British Columbia was found to be less than 10 parts per million (ppm) rhenium; too low to warrant economic recovery.[5]

Chile.—Concomitant to expansion of copper production in Chile, byproduct molybdenite and rhenium output will be greatly increased over the next 2 years. Corporación del Cobre (CODELCO) was constructing a new 30,000,000 pound per year molybdenum concentrate plant at Chuquicamata. A new molybdenum concentrating plant was also being constructed at the Río Blanco mine of Companía Minera Andina, S.A. The substantial rhenium content of the concentrate of these two plants will also be recovered. By 1976, Chile should have a yearly rhenium capacity of 11,000 pounds, thus potentially making her one of the world's leading rhenium producers.[6]

Researchers at the universities of Concepción and Antofagasta were attempting to develop techniques for the recovery of rhenium from copper ore. Experts calculate that commercial extraction of rhenium could earn Chile an extra $2 per ton of copper produced. At present no rhenium is recovered from the copper side of the circuit, but is recovered from the molybdenum circuit.

Detailed studies of the newly discovered porphyry copper ore body, San Jose del Abra (El Abra), about 25 miles north of Chuquicamata, have proven 25,000,000 tons of 0.80% to 1.0% soluble oxide copper and indicated 400,000,000 tons of 0.90% sulfide copper. High rhenium values have been discovered in the deposit now under consideration for development by CODELCO. A 16-mile road was being opened to connect El Abra, at 12,500 feet, with Chuquicamata.[7]

Germany, East.—Rhenium is believed to be produced at the Hettstedt plant of VVB Mansfeld where it is extracted from the copper-bearing slates of the Mansfeld mines. Potassium perrhenate is recovered from which rhenium metal is produced.

U.S.S.R.—Rhenium was being recovered in substantial quantities from MoS_2 concentrates obtained from porphyry copper deposits in the U.S.S.R. The main rhenium production was at the Balkhash copper smelter in Kazakhstan, where an estimated 2,500 pounds per year of rhenium was recovered from all rhenium-bearing materials in different operations. Various reports indicated that the large Dzhezkazgan ore body contained important rhenium values, not necessarily associated with molybde-

num, and that recovery of these values were planned in the future.[8]

A deposit of molybdenite in Transbaikalia was reported to contain economically recoverable quantities of rhenium. A batch of 49 samples was analyzed and shown to contain 21 to 165 ppm of rhenium, the average being 82 ppm. There were other minerals in the deposit, but the rhenium occurred only in the molybdenite.

Yugoslavia.—Ore of the Majdanpek copper mine contains minor amounts of molybdenum and rhenium, however, they apparently exist in quantities currently insufficient for economical recovery.

Zaire, Republic of.—Copper concentrate from the Katanga copper mines, which contains small amounts of rhenium, was exported to Belgium where the contained rhenium was recovered by Métallurgie Hoboken-Overpelt S.A./N.V. Some of this material was then exported to the United States (110 pounds in 1973) in the form of rhenium metal powder.

TECHNOLOGY

The Bureau of Mines pilot plant studies on recovery of molybdenum and rhenium from low-grade molybdenite concentrates were substantially completed during the year. Over-all molybdenum-rhenium recovery using a solvent extraction-carbon absorption system was 98%. Corresponding power consumption ranged between 10 and 13.7 kilowatt hours per pound of molybdenum extracted. A commercial producer of molybdenum and rhenium continued pilot-scale studies of the process.

The Bureau of Mines published the results of a study on extraction of molybdenum and rhenium from low-grade molybdenite concentrates by electrooxidation.[9]

The Bureau continued its research to improve the selectivity and recovery of molybdenum and rhenium during froth flotation of copper sulfide concentrate from disseminated ores.

A study was undertaken to determine the effects of small rhenium additions on low-temperature ductility of molybdenum and to characterize the mechnical properties of dilute molybdenum-rhenium (Mo-Re) alloys. High-purity Mo-Re alloys had ductile-brittle transition temperatures much lower than those for unalloyed molybdenum in both bend and tensile tests and in both recrystallized and worked conditions. At 1,315° C, an alloy of molybdenum with 5.9% rhenium had a 70% greater tensile strength and a 100% greater creep strength than did the unalloyed molybdenum.[10]

A study was conducted on doped tungsten-rhenium alloys which identified the source of the unique interlocked elongated grains responsible for the high-temperature sag resistance of these alloys as bubbles formed by volatilization of potassium during sintering. By pinning grain boundaries, these bubbles raised the recrystallization temperature (from 1,300° to 2,100° C), and their distribution into rows by annealing controlled the recrystallized grain morphology.[11]

In 1970 it was discovered that copper produced from mine water by cementation with iron, contains small but significant quantities of rhenium. It was found that 90% of the contained rhenium could be selectively leached from the precipitate copper and recovered as purified oxide. A process for production of rhenium from the copper was proven on a semicommercial scale (equivalent to about 350 pounds of rhenium oxide per year).[12]

A new method of copper-molybdenum concentration from low-grade porphyry ore (0.005% to 0.006% Mo) was put into practice at the Balkhash dressing plant at Kazakhstan, U.S.S.R. Steam is supplied to each flotation cell tangentially to the impeller, and the temperature is automatically held at the required value. Sodium sulfide (3.7 to 6.6 pounds per ton) is then fed to the cleaning cells. The results of

the process guarantee average molybdenum recovery in the separation cycle of 93% and a 2.6-fold increase in rhenium content in tailings.[13]

The Continental Ore Corp. received a patent for recovery of rhenium and molybdenum from MoS_2 concentrate. The process comprises preheating finely divided MoS_2 concentrate and passing it downward through a vertical reaction zone countercurrently to an upflowing stream of high-temperature oxygen, oxygen enriched air, or oxygen-sulfur dioxide mixture. The rhenium values are collected outside the first oxidation zone and dissolved in water. The process is attractive from a pollution control standpoint because byproduct SO_2, ordinarily released to the atmosphere, is produced in the exhaust gases in concentrations high enough to make its recovery economically feasible.[14]

Molycorp was issued a patent on a solvent extraction process for recovering molybdenum and rhenium from molybdenite. The process involves contacting the solution with an alkyl phosphonate to extract rhenium, organic acids, and other impurities, followed by contacting the extracted solution with an organophosphoric acid and recovering molybdenum and rhenium values by conventional means. The process is applicable to recovery of metal values from leach solutions having a sulfuric acid content of up to 600 grams per liter resulting from nitric acid-oxidation leach of molybdenite.[15]

A patent was issued to Newmont Exploration Ltd., a subsidiary of Newmont Mining Corp., for the recovery of rhenium from molybdenite. The conventional oxidative roasting of MoS_2 concentrate was modified to reduce the dilution of the oxidized rhenium vapor species in the gaseous effluent by substituting a mixture of oxygen and water for air in the roasting reaction, the water serving to maintain roasting zone temperature at about 600° C.[16]

A number of patents dealing with catalytic cracking, hydrocracking, catalytic reforming, and hydrocarbon conversion, employing rhenium in combination with other metals such as gallium, selenium, tungsten, germanium, and iridium in bimetallic, trimetallic and tetrametallic combinations, were issued to various oil and chemical companies.[17]

Salt

By Charles L. Klingman [1]

The quantity of salt used and sold in the United States has not shown any significant movement since 1969. The 1973 figure was 99% of the 1969 quantity. Salt production in 1973 was 95% of the peak production in 1970. Between 1965 and 1970, salt had a growth rate of about 6% per year, so the 1969–73 plateau looked disappointing by comparison.

The largest single factor in the declining salt usage of 1973 was the small requirement for deicing. Rock salt, specified for highway deicing, experienced a 34.6% decline, more than 3 million tons, in the amount sold or used. Stockpiles of salt intended for highway use were large at yearend.

Another factor significantly influencing salt consumption was the large swing from synthetic (Solvay) soda ash manufacture, a process requiring salt as a raw material, to natural soda ash derived from the mineral trona. There was an 18% decline in salt used to make synthetic soda ash in 1973 compared with that of 1972; a reduction equivalent to more than 1 million tons of salt. The future outlook for salt in making soda ash is even lower than it was in 1973.

A third influencing factor on 1973 salt production was a shortage of fuel. Evaporated salt made in vacuum pans is the most energy-intensive of the salt-producing processes. In fact, the reduction in vacuum-pan salt production was attributed to this energy requirement. However, this loss was offset by greater production of solar salt and open-pan (grainer) salt.

Net imports of salt (imports minus exports) amounted to 2,578,000 tons or 6% of the salt sold and used in the United States in 1973. These figures were almost identical to the net import figures of 1972.

The average unit value of various types of salt, as assigned by the manufacturers when ready for sale, showed a 9% increase in 1973 over that of 1972 for both evaporated salt and brine. Rock salt showed less than a 1% increase in value.

DOMESTIC PRODUCTION

Sixteen States recorded production of salt in 1973. Two of the States, Louisiana and Texas, accounted for 54% of the salt sold or used, and three other States, New York, Michigan, and Ohio brought the total up to 87%. Eight of the States, accounting for 96% of the national total, sold or used more than 1 million tons each of salt.

There were 52 salt companies operating 95 plants in the United States and Puerto Rico. Ten of these companies produced over 1 million tons each and accounted for 82% of the U.S. salt production. Eighteen other companies, producing between 100,000 and 1 million tons each, brought the total up to 99% of the U.S. output. Twenty-four other companies whose individual production was under 100,000 tons per year supplied the remaining 1% of the salt output.

A secondary shaft at the Cargill, Inc., salt mine on Belle Isle, La., caved in March 1973,[2] shutting down production for nearly 1 year. The cost of repairing the damage was estimated to be enormous and full operations were not scheduled to resume until mid-1976.

PPG Industries, Inc., closed its synthetic soda ash plant at Barberton, Ohio, in April 1973. This plant was capable of consuming up to 1 million tons of salt per year.

The Leslie Salt Co. announced in December 1973 that it would close its large salt plant in Redwood City, Calif., by the end of 1976. Facilities at Redwood City will be shifted to another Leslie plant at Newark, Calif.

Great Salt Lake Minerals & Chemicals Corp. announced at midyear that it planned to expand operations and that the expansion included facilities for washing and drying 150,000 tons of high quality salt per year.

Cargill, Inc., purchased two salt companies during the year. They were the Barton Salt Co. near Hutchinson, Kan., and the Cayuga Rock Salt Co., Inc., near South Lansing, N.Y. The Cargill mine at South Lansing, N.Y., was modernized with a new underground electrical system and extensions to the main belt conveyor.

Domtar Chemicals, Ltd., of Montreal, Canada, purchased the Carey Salt Co. operation at Louisa (St. Mary Parish), La., in mid-1973.

The International Salt Co. salt mine at Retsof, N.Y., completely replaced its underground railcar hauling complex with 4 miles of conveyor belts.[3] The new conveyor belt installation costing $3.1 million was projected to be amortized in 3 to 5 years. The system was claimed to reduce labor costs 19%, increase production 21%, and reduce maintenance costs 82% in addition to saving $3,000 per month in electricity costs.

At international's Cleveland, Ohio mine, feeder-breakers and a 48-inch-belt conveyor were installed in place of loading machines and trucks to reduce costs from $0.175 per ton to $0.087 per ton.[4]

CONSUMPTION AND USES

Of the total salt consumed in 1973, 59% was distributed as brine, 27% as rock salt, and 14% as evaporated salt. The production of caustic soda and chlorine required 51% of the total salt output, up from 45% in 1972. The amount of salt going into the manufacture of synthetic soda ash, was 11% of the output compared with 13% in 1972. Other miscellaneous chemicals required 3% of the salt, making the total chemical requirements equal to 65% of the salt used and sold in 1973. This was a significant increase from the 60% required for chemical manufacture in 1972.

The salt sold to various governmental agencies, presumed to be used primarily for highway deicing, was down to 14% of the total from 21% in 1972, more than offsetting the gain in chemicals manufacture. Other uses required about the same amount of salt in 1973 as was needed in previous years.

It will be noted that the consumption totals in tables 7 and 8 differ slightly from those in tables 1 through 5. These differences reflect the point at which consumption is reported by salt companies in various sections of the annual salt survey. The Bureau of Mines made no attempt to reconcile these differences, but reported them as received.

The use of salt for deicing and in many other industrial processes came under scrutiny in 1973. For example, its use as a deicing agent on highways and walks, a major salt usage, was attacked because it promoted corrosion of automobile bodies, deteriorated concrete, and either inhibited or prevented plant growth along the salted areas. Objections to salt deicing were tempered by applying a "diluted" salt-sand mixture instead. This mixture not only melted the snow, but the sand embedded itself immediately upon initial melting in the remaining ice forming a continuous skid preventive surface.

The effluent discharged from synthetic (Solvay) soda ash plants into freshwater streams was also contested. These effluents, high in salt and calcium chloride, supposedly affected both the potability of the water and plant growth along the banks. Legislation passed to regulate these effluents were in some instances so stringent that several soda ash plants shut down because of inability to meet the new standards.

The tanning of cattle hides utilizes salt brine to cure and clean the hides, and most of the spent brine is disposed of through sewage treatment plants. Salt is generally not removed by normal sewage treatment and eventually is discharged into freshwater lakes or streams. In 1972, an estimated 260,000 tons of salt was used to preserve cattle hides and two-thirds of this amount was discharged into fresh waters.[5] This condition could be alleviated by either eliminating salt curing or by partially tanning the hides to produce a "blue, chrome-tanned leather." Regardless, either of the proposed methods, which have not been evaluated, would require changes in processing and marketing of hides and would have an adverse impact on salt consumption.

[5] Renderer. Major changes in Store for Tanners. April 1974, pp. 17, 27.

PRICES

Salt prices quoted in Chemical Marketing Reporter were unchanged during 1973 because of Government price regulation. The prices per 100 pounds were as follows:

	1973
Salt, evaporated, common, in bags, carlots, or truck lots, works	$1.43
Salt, chemical-grade, same basis	1.54
Salt, rock, medium, coarse, same basis	.97
Salt, rock, extra coarse, same basis	1.02

The average value of the different classes of salt per ton, as assigned by the salt producers, was as follows:

	1972	1973
Evaporated salt	$21.26	$23.09
Rock salt	6.31	6.36
Salt in brine	3.29	3.57

FOREIGN TRADE

In 1973, exports of salt amounted to 609,000 tons or 1% of salt consumption. This was 30% less than exports in 1972 and 9% less than those of 1971. Over 90% of exports went to Canada, and the only other country receiving more than 1% was Japan at 4%.

Total salt imports into the United States were 7% of apparent salt consumption and 8% less than those of 1972. Net imports (imports minus the exports) were almost identical for the past 2 years.

Salt imports in 1973 were five times the tonnage of exports, and the unfavorable balance of trade in salt amounted to $8.06 million. Thirty-four percent of the salt imports came from Canada, 31% from Mexico, and 27% from the Bahamas. Chile and the Netherlands Antilles each contributed about 4%.

WORLD REVIEW

Canada.—Canada ranked eighth in world production of salt in 1973. Sixty-nine percent of its production was mined in the form of rock salt, 17% as salt in brine, and the remainder was evaporated. Areawise, 75% of the salt production came from the Province of Ontario, 15% from Nova Scotia, 6% from Alberta, and 4% from Saskatchewan. In Ontario, as many as six salt layers have been identified at depths of 900 to 2,700 feet. The total thickness of all beds may be as much as 700 feet. Test drilling in the Magdalen Islands encountered salt at 450 feet and was still in salt at 2,000 feet when the drilling was terminated. The two major uses for salt in Canada were highway deicing at 42% of the production and industrial chemicals at 33%. Hooker Chemical Div. and Dow Chemical of Canada Ltd. each announced plans for expanding their chlorine-alkali production facilities which, of course, will consume more salt.

China, People's Republic of.—Solar evaporation of seawater remained the mainstay of the world's second largest salt-producing country, the People's Republic of China (PRC).[6] The Tung-feng salt Field in Shantung and the Tang-ku Field of Hopeh were major areas for extraction of sea salt. Other salterns were located in Kiangsu, Liaoning, and Hainan Island. Lake salt was treated in Tsinghai where other byproducts such as bromine, borates, potassium and barium salts were also recovered. Rock salt was mined in Yunnan, Kiangsi, and Hunan. Most of the Chinese salt was used in food, but there was an increase in industrial applications. Surplus salt was exported, largely to Japan. During 1973, there were serious negotiations on the price of salt between the PRC and Japan. The Japanese threatened to turn to Australia or Mexico for salt if differences in price could not be resolved.

Japan.—Although Japan produced only 1 million tons of salt in 1973, 7.27 million tons were imported to make the country one of the larger world salt consumers. The three major suppliers of salt to Japan were Australia (44%), Mexico (42%), and PRC (13%). The Australian salt industry was developed primarily to supply the Japanese market. In 1973, Japan produced 3.23 million tons of caustic soda and 1.36 million tons of soda ash, both of which utilize salt as a raw material.

Mexico.—The world's largest solar salt production facility, Exportadora de Sal, S.A., located in the Black Warrior district of Baja California, has been purchased by the Mitsubishi Corp. of Japan for a reported $20 million. The present capacity of the plant is about 5 million tons per year. Mitsubishi may extract bromine, magnesium hydroxide, and other byproducts as well as salt from these fields.

U.S.S.R.—The U.S.S.R. ranks third in world production of salt, but details of its industry are not well known. One of the most enlightening papers on the subject was presented at the 1969 Symposium on Salt in Cleveland, Ohio.[7] The total resources of Soviet salt were placed at 255 trillion (10^9) tons. Two large salt-producing areas were identified as Lake Elton in the northern part of the Caspian depression and Lake Baskunchak. About 36% of the Soviet salt comes from underground mines

e Estimate. p Preliminary. r Revised. NA Not available.

[1] Salt is produced in many other countries, including Cape Verde Islands, Mauritania, and Niger, but quantities are relatively insignificant or reliable data are not available.

[2] 1971 data are sales.

[3] Less than ½ unit.

[4] Revised to include a small quantity of salts produced from brine springs, also includes an average annual production in the Canary Islands of 15,000 metric tons of marine salt.

[5] Year beginning March 21 of year stated.

such as the Solotvinsky mine in the Transcarpathia and the Iletsky mine in the Orenburg Region near the Ural mountains. The mines are well mechanized, and the processing plants are located on the surface near the mine shafts. For home use, the salt is crushed and screened to about 1-millimeter particle size and packed in paper packages weighing 1.5 or 2.2 pounds each. The salt industry of the U.S.S.R. employs about 7,000 workmen. About 1.5 million tons of common salt is used by cattle farmers. The amount going to industry is increasing.

United Kingdom.—An excellent publication of the salt industry of the United Kingdom was issued in 1973 by the Mineral Resources Consultative Committee.[8] It covered the occurrence, reserves, production, industry, uses, trade, prices, technology, and predicted demands for salt. The United Kingdom was the fifth largest salt producer in the world, and its usage pattern was quite similar to that of the United States. Sixty-three percent of the British salt was produced as brine for use primarily in the chemical industry, 19% as evaporated salt for food, agriculture, and other miscellaneous uses, and 18% was mined as rock salt primarily for deicing highways.

TECHNOLOGY

It has recently become recognized that salt domes, such as those along the U.S. coast of the Gulf of Mexico, can be practically inexhaustible sources of heat for power generation.[9] Salt has an unusually high thermal conductivity and can, therefore, be expected to act as an energy conduit to bring heat up from the interior of the earth. Typical temperatures within a salt dome are 330° F at 10,000 feet; 455° F at 15,000 feet; and 580° F at 20,000 feet. These temperatures can be maintained indefinitely, it is believed, regardless of the heat extracted from the salt dome. One possible method of bringing the heat to the surface would be to inject water into the cavity and to direct the steam, thus created, through a turbine which would turn an electric generator. The condensed steam from the turbine could be recycled into the salt cavity.

A 3-year testing program by the Dow Chemical Company at Freeport, Tex., has shown that aluminum alloys have exceptional resistance to corrosion caused by hot brine.[10] The equipment for the test was a multistage, flash-distillation desalting plant of the Materials Test Center for the Office of Saline Water. The alloys tested displayed excellent performance under conditions of low pH, high temperatures, and high flow rates. The tested metals cost about half of that required for comparable cupronickel commonly used for such purposes. National capacity for desalting seawater and brackish inland water is increasing rapidly, therefore the usage of lower cost aluminum should become immediately applicable.

Sand and Gravel

By Walter Pajalich [1]

Sand and gravel production increased about 7% to 984 million short tons. The value of production increased about 13%. Output from commercial operations was 86% of the total output; Government-and-contractor production was 14%. The production of sand and gravel in the Nation's leading State, California, was the same as in 1972, 117 millon short tons.

DOMESTIC PRODUCTION

California, with 117 million tons, ranked first in sand and gravel output and produced about twice as much as second-ranked Michigan. Other States producing substantial quantities of sand and gravel, in descending order of production, were Ohio, Illinois, Wisconsin, Texas, and Minnesota. Combined production from the seven leading States was 389 million tons, about 40% of the total U.S. output. The value of sand and gravel produced in these seven States was $526 million, 39% of the Nation's total. The number of commercial plant operations increased from 5,384 in 1972, to 5,681 in 1973. This was due in part to increased coverage of the industry.

Factors that have added to the consumer cost of sand and gravel included increased labor costs, growing land values, cost of land rehabilitation, and longer haulage distances.

There were 4,496 commercial plant operations with production under 200,000 tons per year. These operations accounted for 30% of the total U.S. commercial production. There were 814 plant operations with production between 200,000 and 500,000 tons, and they accounted for 30% of production. The remaining 371 plant operations, with production over 500,000 tons, accounted for 40% of production.

The use of larger operating units, more efficient portable and semiportable plants, versatility of plant capacity, and greater awareness of pollution control and land rehabilitation were the keynotes of progress in 1973.

Dravo Corp. started constructing a $3.3 million sand and gravel plant at Georgetown, Pa., near the Ohio-West Virginia border. The plant, with an initial capacity of 960,000 tons per year, will process materials dredged from the Ohio River and from the company's 125-acre land deposit in Green Township. The plant will eventually be expanded to 1.5 million tons per year. Reclamation plans for the site include a 100-acre lake and recreation area.[2]

The first phase of Pennsylvania Glass Sand Corp.'s expansion program at its operation at Columbia, S.C., has been completed. The Columbia plant supplies high-quality silica sand for glass, fiberglass, ceramic, and chemical industries in the Southeast. When the $2.5 million expansion is completed, milling capacity will be doubled. The expansion program was to be completed sometime in 1975.[3]

Modernization of the Martin Marietta Corp. silica sand plant at Oregon, Ill., included new features that are becoming part of the sand and gravel industry. Plans called for expansion that would increase the present 200-ton-per-hour capacity of finished product by 50%. The major feature is the attention given to dust and noise control and the protection of operating personnel from these factors, plus the outstanding routine program of housekeeping.

All dust-generating phases of the processing operation are fully enclosed, and all dust is collected by a high-capacity dust-collecting facility. Dust produced by dried material at delivery points is controlled by wet scrubbers. The processed water is recycled from a holding pond from which no water can flow into the area's natural drainage system.[4]

The Herbert Materials Co. of Nashville, Tenn., has modernized its main yard with a new system of aggregate storage and reclamation. Now the company can simultaneously load out aggregates for shipment and feed to a pair of ready-mix plants. Sized sand and gravel is delivered by barges from a dredge in the Tennessee River. The firm has two dredges in operation with a total production capacity of 600 tons per hour.[5]

The problem of clay contamination at the Arena deposit of Thorstenberg Materials Co. of Texas has been solved by a battery of eight washing-classifying units. The deposit contains 35% gravel. The remainder is sand and clay. The clay occurs in erratic seams throughout the deposit. The process of removing clay includes the use of four spiral washers, a 40-foot sand classifier and three log washers. Push-button controls regulate the processing, blending, and loading. The plant produces 750 tons of products per hour. Primary market area for the products is Houston and Harris Counties, Texas.[6]

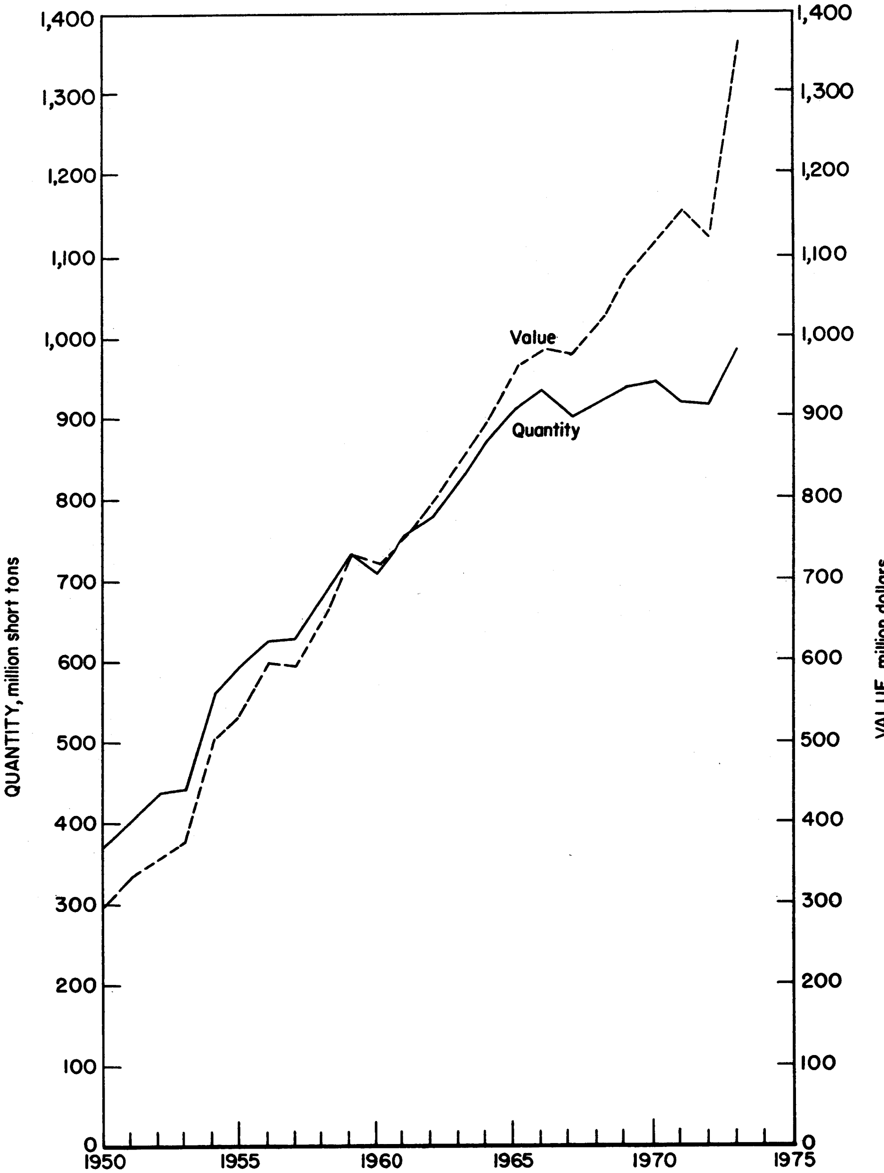

Figure 1.—Production and value of sand and gravel in the United States.

CONSUMPTION AND USES

In 1973, U.S. consumption of sand and gravel amounted to 984 million tons valued at $1.4 billion. The construction industry, the prime user of sand and gravel, consumed 95% of the tonnage, representing 89% of the value of the sand and gravel output in 1973. Of the amount of sand and gravel consumed by the construction industry, 48% went into paving, 38% into building, about 10% into fill, and 4% into other uses. The principal consumers of higher priced industrial sand were the glass and foundry industries.

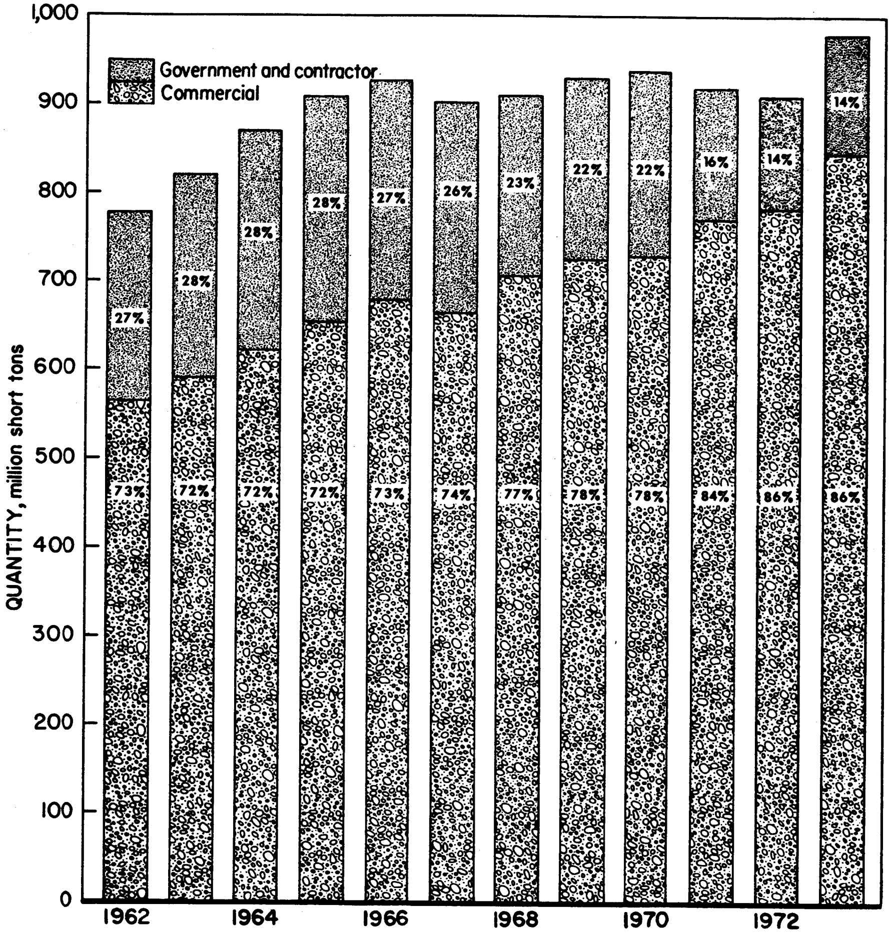

Figure 2.—Sand and gravel sold or used in the United States.

PRICES

Representative carlot-load prices of sand in 18 cities at the end of 1973 ranged from $0.95 per ton in Detroit to $6.45 per ton in Birmingham, according to the Engineering News-Record.[7] The average of the sand prices reported was $3.55 per ton compared with $3.14 per ton in 1972. Prices for either 3/4- or 1 1/2-inch gravel ranged from $1.60 per ton in Birmingham to $5.70 per ton in Los Angeles. The average of the 3/4-inch gravel prices reported for 19 cities was $3.66 per ton, compared with $3.80 per ton in 1972. For 1 1/2-inch gravel, the average for 15 cities was $3.92 per ton compared with $3.74 per ton in 1972.

Based on the Bureau of Mines canvass, the average value of sand and gravel sold or used by producer, f.o.b. plant, was $1.38 per ton; the comparable value in 1972 was $1.31 per ton.

[7] Engineering News-Record. McGraw-Hill Construction Weekly, Dec. 6, 1973, pp. 44–45.

FOREIGN TRADE

Canada received 75% of U.S. exports of construction sand, the Bahamas received 24%, and the Netherlands Antilles received less than 1%. The remainder went to 15 different countries. Exports of construction sand total 422,483 short tons valued at $793,495. Gravel exports totaled 475,894 short tons valued at $666,693. Total exports of common sand and gravel were 898,377 short tons valued at $1,460,168. Canada received 86% of U.S. exports of common sand and gravel, the Bahamas received 12%, and Mexico received 1%. Of U.S. exports of industrial sand, which amounted to 845,359 short tons valued at $7,136,394, Canada received 59%, Mexico 22%, and Japan 13%. The remainder went to 65 different countries.

Most of the crude sand and gravel imported in 1973 was from Canada. Almost all of the imported glass sand was from Australia.

WORLD REVIEW

Denmark.—Hoffman & Sons A/S is one of the suppliers of sand and gravel for the general construction market in the greater Copenhagen area. Mining continues year around despite the rigors of the Danish winter. Fortunately, the material contains only about 2% to 3% moisture and draglines can be used for mining. Average production is 1,000 cubic yards per hour.[8]

Germany, West.—A new, completely enclosed and weatherproof, sand and gravel plant with a 600-ton-per-hour capacity was erected by Gammerer GmbH of Wolfratshausen on a site east of Munich. Two rod mills are part of the installation to produce additional sand.[9]

Japan.—The silica sand resources of Japan are located in a central district including Aichi, Gifu, and Mie Prefectures. Total reserves of the deposits are estimated at 68 million tons. The sand occurs intermixed with clay. Processing involves clay removal by breaking, grinding, water washing, and screening, followed by flotation and magnetic separation. The grade of the sand ranges from 93% to 98% silica. In 1973 production was about 5 million tons. About 2.5 million tons was used in the glass industry and 1.6 million in castings. Selling price ranges from $10 to $13 per ton. About 330,000 tons of silica sand was imported from Australia, South Vietnam, and the Republic of Korea.[10]

Switzerland.—At Bardonnex, a few miles south of Geneva, is an extensive deposit of consolidated glacial gravel. There is also a tile factory at this site. The material for this factory comes from a clay deposit above the glacial gravel. The deposit is so consolidated that blasting is required. Because the natural underground water reservoir for the Geneva public water supply system is below the deposit, careful reclamation of the area had to be considered before permission was granted for gravel extraction. Annual production was about 331,000 tons. As it is generally practiced in Switzerland, the plant is located in a single high building. This gives the operation a neat tidy appearance, facilitates maintenance, and minimizes dust and noise nuisance to the public.[11]

United Kingdom.—Concern has been expressed by the Institute of Geologic Sciences about the size of sand and gravel reserves in the United Kingdom. About 2.5 billion tons has already been excavated. Much of the known reserves are inaccessible. Over the years, construction of new buildings covered up about 49,000 hectares of land around London. This area is estimated to contain about 1 billion tons of sand and gravel. The main concern is the growth in consumption. By contrast, in 1955 annual production was 60 million tons, and in 1973, it was 125 million tons. About 4 million tons of this was exported. Most of the exported material was marine-dredged aggregates. About 12% of the country's sand and gravel is marine dredged, making the United Kingdom the leading country in mining of sand and gravel from the ocean.[12]

[12] Cement Lime and Gravel. Mineral Resources Survey of Sand Gravel. V. 48, No. 1, January 1973, p. 15.

A Government-appointed consultative committee suggested the use of other suitable alternative materials, from sources other than natural sand and gravel. One of the materials suggested was pulverized ash from coal-fired power stations.

About 75% of the sand and gravel produced was used in concrete. Housing, including site roads, and industrial building together account for the largest proportion of the concrete used.[13]

The Queen Mary Reservoir at Staines Middlesex, constructed in the early 1920's, was built over an area that contained a deposit of sand and gravel, under which is a deposit of clay. The area covers 723 acres. Owing to technical considerations, the depth of the water was set at 40 feet. Now equipment is available that assists the thermal circulation of the water from one level to another. This has made it possible to increase the depth of the reservoir. At a safe distance inside the retaining banks, 420 acres of the floor of the reservoir is available for excavation of sand and gravel. An estimated 10 million tons of sand and gravel will be excavated utilizing 3-cubic-yard dragline. The plant will process an average of 180 tons of sand and gravel per hour.[14]

Kennedy Sand Ltd., one of the largest producers of sand and gravel in northwest England, started a new operation at Whiteley Green, near Bollington, about 3 miles north of Macclesfield. The new mine is primarily a sand producer with a plant capacity of 150 tons per hour. Gravel content is about 10% to 15%. The reserves on the 24 acres are about 2.5 million tons. This will keep the plant in operation for 9 years.[15]

In Scotland, a loosely cemented quartz conglomerate deposit located at Douglasmuir Milngavie Dumbartonshire has been developed as a sand and gravel deposit by Amalgamated Quarries (Scotland) Ltd., of North Queensferry, Fife. The initial facilities were handling 65 tons of material per hour. Expansion to 200 tons per hour was planned for 1974. The deposit is located only 5 miles from central Glasgow. The plant is soundproof and occupies only 12,000 square feet. Landscaping and planting will hide the workings from the road. Production of sand and gravel in Scotland has been declining. Production in 1971 was only 9.1 million tons.[16]

TECHNOLOGY

The use of plastic aggregate in highway and building construction is currently undergoing field test investigation in several parts of the United States. The test site is an industrial plant access road in Jamesburg, N.J. The material, called Styropor, was designed as an insulating subbase to reduce frost action. It is also claimed that the inherent structural strength will permit the use of less subbase in road construction. Styropor is produced in the form of polystyrene beads that contain a foaming agent. The beads expand rapidly to 50 times their original size when exposed to heat, forming perfect closed-cell spheres that trap air inside. The expanded beads are coated with a thin layer of epoxy before being mixed with cement as a cover. The cement hardens in a spherical shape around the expanded beads to develop maximum mechanical strength. Because of its low thermal conductivity, it is claimed that 6 to 9 inches of the new Styropor concrete can replace 24 to 36 inches of gravel road foundation for frost protection.

In one experiment, a 38-pound-per-square-foot density Styropor concrete was laid on a 9-inch-thick bed of subbase instead of a conventional 36-inch thickness of gravel. Therefore, a 12-foot-wide lane in 1 mile of highway would require 910 tons of Styropor concrete (24 tons of Styropor beads) instead of 10,450 tons of gravel. The material is being introduced into the United States by a subsidiary of a large German chemical corporation, which has tested the Styropor aggregate at 13 major sites in northern Europe. The tests were conducted under very cold conditions for several years. The results to date are stated to have been successful.

Developed in Denmark, the synthetic aggregate Synopal produces a light-colored

asphalt. It was tested for 7 years as a 1-inch overlay on 1½ miles of U.S. 66 near Pontiac, Ill. The advantages of Synopal are greater light reflectivity, greater hardness, and a more skid-resistant surface texture.

Steel fibers 0.0059 to 0.062 inch in diameter, and 0.25 to 2.5 inches long mixed with any aggregate in amounts varying from 0.2% to 4.0% have been used successfully in concrete. The addition of steel fibers to a mortar or concrete improves the thermal stress and shock resistance, impact strength, abrasion resistance, shear strength, and spalling resistance. These are the findings of numerous applications in various concrete construction projects since 1960 when Battelle Development Corp. took over the development of this material. Battelle Development Corp. of Ohio now holds U.S. patent rights under the trademark Wirand. The U.S. Army Construction Engineers Research Laboratory in Champaign, Ill., tested steel fiber concrete pavement alongside ordinary concrete pavement. The steel fibrous pavement was only one-half as thick as the regular pavement. The results of the test showed the steel fiber concrete pavement was able to withstand twice the load and outlasted the regular pavement.[17]

Asphalt containing asbestos in addition to sand and gravel dates from 1960 when the mixture was given field trials. Asbestos additives, usually 2% to 3% by weight, permit the use of upwards of 50% more asphalt in mixes. According to experts, this additional asphalt, previously impractical, is desirable because it increases pavement cohesion and flexibility, resists abrasion, reduces low-temperature cracking, and decreases water permeability. The cost of the asbestos asphalt mix is 15% to 20% more than the standard asbestos-free mix. Roads paved in Rockville Centre, N.Y., over 10 years ago, with only a ½-inch layer of asbestos asphalt, were claimed to still have 3 to 4 years of use before requiring repaving. Original plans called for repaving these streets every 10 years.[18] Asbestos asphalt has been successfully used at locations such as the George Washington Bridge, New Jersey Turnpike, and other roadways in various parts of the country.

Asphalt mixed with latex and sand and gravel is also being used to extend the life of pavement. A combination of rubberized sealant and rubberized asphalt reportedly reduces maintenance costs, particularly during the winter when deicing chemicals are applied.

Finely ground refuse container glass was used instead of limestone dust in producing asphaltic concrete. It was used primarily where extra hard asphalt was needed, such as curbing.[19]

To replenish the Hawaii beaches, a new system has been developed for mining ocean bottoms using a small vessel and a suction probe that buries itself into thick deposits of sand. The Submarine Sand Recovery System was built and tested under the University of Hawaii's Sea Grant Program. The system is expected to provide more economical and ecologically sound means of recovering offshore sand than the conventional dredging systems. With the aid of scuba divers, a probe with a 6-inch-diameter hose attached to the suction tube is allowed to bury itself about 12 feet into the sand. When suction is applied, a mixture of sand and water enters the inlet valve and is drawn to the surface. Coral or shell fragments, which could obstruct sand flow, are crushed by a 4-inch roller crusher in the probe head.[20]

The combustion roar of an asphalt aggregate drying plant measuring 115 decibles was successfully reduced to an 85-decible level with a specially built enclosure at the Russell Industries, Inc., McKees' Rocks, Pa., plant. The enclosure was designed to handle 71,000 cubic feet per minute of air at a pressure drop of 1½ inches of water. A plenum was installed around the burner. The acoustical panels are 4-inch-thick metallic sandwiches with solid outer surface and perforated inner surface. Between the sheets is an inert, durable, noncombustible acoustic fill. In addition to reducing the noise level, the enclosure prevented the atmospheric loss of burner heat, resulting in hotter air being passed to the rotary dryer. This unexpected benefit reduced gas consumption[21] between 4% to 6%.

A worked-out sand and gravel pit was successfully turned into a sanitary landfill operation. Rockford Black Top Construction Co., of Rockford, Ill., owners of the pit, first graded and then lined the botttom and side slopes of the pit with 2 inches of hot asphalt mix. An asphalt dike along the inside edge of the pavement prevents the leachate from contaminating soil in unpaved areas. Four peripheral wells monitor the ground water for contamination. The landfill, referred to as the Winnebago County Land Reclamation Site, serves a population of 200,000. When the backfill is completed, the pit will become useful level land.[22]

Table 11.—U.S. imports for consumption of sand and gravel, by class
(Thousand short tons and thousand dollars)

Year	Glass sand [1]		Sand, n.s.p.f., crude or manufactured, and gravel		Total	
	Quantity	Value	Quantity	Value	Quantity	Value
1971	48	243	667	984	715	1,227
1972	49	201	712	1,178	761	1,379
1973	48	340	752	1,236	800	1,576

[1] Classification reads: Sands containing 95% or more silica and not more than 0.6% oxide of iron and suitable for manufacturing glass.

Silicon

By E. Shekarchi [1]

The energy shortage had a severe effect on the ferrosilicon industry in 1973. From the beginning of the second quarter the gap between the supply of ferrosilicon and demand began to narrow. Supplies of silicon metal and ferrosilicon products became increasingly tight throughout the year and by yearend were allocated on the basis of the customer's previous order pattern.

Domestic plant expansions and/or modernizations continued as ferroalloy producers moved toward plant specialization and compliance with federal and local government antipollution standards which are to become effective by 1975. In the world market, all grades of ferrosilicon and silicon metal appeared to be in short supply. Prices of silicon metal and ferrosilicon on the international market were substantially higher than the controlled prices in the United States.

DOMESTIC PRODUCTION

Production and shipments of ferrosilicon, and silicon metal and alloys, paralleling those of steel and aluminum, increased 8% and 20% respectively compared with 1972 figures. Yearend stocks had decreased by 65% when compared with those of 1972. With regard to individual ferrosilicon grades, production of nominal 50% ferrosilicon increased 3.6% whereas production of ferrosilicon containing 71% to 80% silicon increased 16.7%. Production of silicon metal increased 14.7% over that of the previous year. Ferrosilicon and silicon metals were produced at 27 plants by 14 companies as shown in table 2.

Northwest Alloy, Inc., a subsidiary of Aluminum Company of America (Alcoa), received final permission from the State of Washington Department of Ecology to start construction on a $50 million magnesium and silicon metal plant at Addy, Wash. Originally, construction of the Addy plant was to begin in April 1973, with completion scheduled for early 1975; however, after the delayed start, no new opening date had been set. Most of the plant's annual 40,000-ton silicon production is to be used by Alcoa although some will be available to other metals producers. The Addy plant will be the first of its kind in the United States to employ the megatherm (electrothermal) process with dolomite as raw material. This process, in operation at Marignac, France, since 1964, involves the reduction of calcium dolomite by ferrosilicon at a temperature in excess of 1,500° C.

Reynolds Metals Co. announced in October plans to more than double the capacity of its silicon plant at Sheffield, Ala. Expansion of the plant, which now produces 7,000 tons of silicon for aluminum casting, is to begin in the fall of 1974 with completion expected by March 1975. Transformer capacity of the new furnace is to be about 1,500 kilovolt-amperes (kVA).

Ohio Ferro-Alloys Corp. announced plans to build in 1974 a new 46,000 kVA electric furnace at the company's Philo plant in Philo, Ohio. The new covered furnace will be installed in an existing building and will be equipped with a modular-constructed bag-house type collector. The company expects new production to begin early in 1975. The total cost of the project was estimated at $4 million.

CONSUMPTION AND USES

Silicon metal continued to be used mainly as an additive to aluminum and for the production of silicon chemicals. It was also used in iron and steel, high-temperature alloys, superalloys, copper base alloys and electrical contact materials. Ferrosilicon was used primarily for deoxidizing steel, and producing silicon alloy steels and cast-irons. The greater part of silvery pig iron was consumed by iron foundries and a sizable quantity was used in the manufacture of steel.

World demand for high-purity silicon increased significantly in 1973 and most consumers felt the pinch of the short supply. In the United States large producers and consumers of polycrystalline and high purity silicon (Texas Instruments, Inc., Motorola Inc., Fairchild Camera & Instruments, Corp., and Dow Corning Corp.) operated at full capacity. Dow Corning announced plans to increase its polycrystalline capacity by another 40% over its 1973 expansion. The new facilities at the company's Hemlock, Mich., plant were scheduled for completion in the latter part of 1975. Monsanto Chemical Co., another polycrystalline silicon producer, planned by 1975 to expand its plant in Missouri.

Demand for polycrystalline silicon in the electronics industry increased with the growing market for personal calculators, and the use of solid state devices in automobiles and in sales and cash registers.

Among more recent developments, polycrystalline silicon furnace tubes and fixtures used in semiconductor processing were found to be much more resistant to high temperatures and sudden temperature changes than those made of quartz.

Table 3.—Consumption, by major end uses and stocks of silicon alloys and metal in the United States in 1973

[1] Includes briquets.
[2] Includes magnesium-ferrosilicon and other silicon alloys.
[3] Included with "Full alloy steel."
[4] Included with "Miscellaneous and unspecified."

PRICES

The prices of ferrosilicon and silicon metals were increased in the second and fourth quarter of the year as allowed by Phase IV price stabilization rules. The f.o.b. price of 50% ferrosilicon increased from 15 cents per pound in 1972 to 18.5 cents per pound contained silicon, bulk, carload lots in 1973. Metallurgical-grade silicon, 98% minimum silicon, 0.35% maximum iron increased from 25.4 in 1972 to 28.4 cents per pound contained silicon in 1973. Amorphous silicon in 50-pound paper bags, 200 mesh, 90% to 95% silicon was increased to $27 per ton in 1973 from $26 per ton in the previous year.

The price increases were attributed to substantially higher costs for scrap iron, metallurgical-grade coal, electric power and to the cost of newly installed devices for environmental control such as bag houses and water purification plants.

FOREIGN TRADE

Exports of ferrosilicon and silicon metal increased 117% in quantity and about 84% in value; major recipients were Sweden, 9,148 tons; Canada, 3,424 tons; and the Netherlands, 833 tons. Twenty countries received shipments ranging from 1 to 100 tons.

The unfavorable trade imbalance in ferrosilicon that was evident in the United States in 1972 continued through 1973, although ferrosilicon imports for consumption leveled off in the fourth quarter. Imports of ferrosilicon and silicon metal for consumption increased 161% in quantity and 130% in value over those of 1972. Major increases in quantity were in the over 60% but less than 80% ferrosilicon category and the not over 99.7% silicon metal category. Total value of imports amounted to $32.9 million in 1973 compared with $14 million in 1972.

WORLD REVIEW

India.—The two major ferrosilicon producers in India were the public sector firm, Mysore Iron and Steel, Ltd., at Bhadravati and the private sector firm, Indian Metals and Ferroalloys, Ltd., at Bhubaneshwar, Orissa. Output of ferrosilicon and silicon metal during 1973 was about 35,000 tons, a 75% increase over 1972 production of 20,000 tons. Two new small companies which contributed about 5,000 tons to the 1973 production were Industrial Development Corp., Ltd., with a plant located in Orissa and Ferroalloy Corp. Ltd., with a plant at Andhra Pradesh.

In 1972 India, for the first time, exported ferrosilicon: 3,000 tons to Sweden and smaller tonnages to New Zealand, Bangladesh, and Sri Lanka.

Italy.—Construction work on a new plant in Sicily, which will produce 148,000 tons per year of ferrosilicon, silicon metal, and ferrochrome, continued in 1973. Production is to begin in mid-1974. It was reported that Montecatini Edison S.p.A. is to build a new plant for the production of silicon metal at Sinigo, Italy. Cost of the plant was estimated at $8.6 million and reportedly production will start in 1975.

Japan.—Production of ferrosilicon and silicon metal in 1973 was reduced 20% due to a severe fuel crisis and several plant shutdowns caused by furnace explosions To overcome the shortage, Japan's steel industry imported 17,000 tons of ferrosilicon from Sweden, Norway, and Yugoslavia. Unless the energy crisis diminishes, Japan is expected to import about 24,000 tons of ferrosilicon in 1974.

Nippon Denko Co., which produced silicon metal in plants at Minamata and Koriyama, announced in 1973 plans to expand production capacity from 20,000 to 28,000 tons per year. The decision was based on Japan's increased aluminum ingot production which consumed most of the silicon metal output.

South Africa, Republic of.—Aluminum Co. of Canada (Alcan) and Foote Mineral Co. of the United States joined with the mining and engineering subsidiary of African Oxygen Co. of South Africa to form a new company—Silicon Smelters (Pty) Ltd. The three partners will have equal shares in the new company. Silicon Smelters will operate a mine and a plant for the manufacture of silicon metal at Pietersburg in northern Transvaal, about 200 miles north of Johannesburg. The plant with an annual capacity of 30,000 tons of silicon metal will cost about $25 million and is expected to go into production in 1975.

Yugoslavia.—The Yugoslavian Economic Organization's (YEO) Electrobosna Co. in Jajce, central Yugoslavia, commissioned its fifth ferrosilicon electric furnace in the latter part of April 1973. The new furnace has a 480 kVA transformer and will increase the company's ferrosilicon productive capacity by 40%. YEO's Jugobrom Company at Jegunovce, in southern Yugoslavia, was constructing a new 30,000-ton capacity ferrosilicon plant that is to begin production in 1976. Most of the expansion programs were aimed at export markets in Europe.

Total production of ferrosilicon and silicon metals and alloys by Yugoslavia was about 65,000 tons in 1973.

Silver

By J. R. Welch [1]

The domestic mine output of silver was 37.8 million troy ounces, nearly 2% higher than in 1972. Imports exceeded exports by 119.5 million ounces, and consumption, including coinage increased 28% to 196.9 million ounces.

There were several significant events in the silver market in 1973. The price of silver set new highs, and industrial consumption, excluding coinage, was greater than in any other single year. The use of silver for all industrial purposes increased sharply, except for use in batteries. Silver used in the manufacture of commemorative medals, embossed bars, and small ingots increased to 21.9 million ounces, 92% more than in 1972. Part of the increase was attributed to coin blanks made for the Canadian Government. Industry stocks (exclusive of trading firms) continued to decline, ending the year at 38.4 million ounces compared with 51.9 million ounces at yearend 1972. Trading volume on the New York Commodity Exchange (COMEX) amounted to 12 billion ounces during 1973, a 52% increase over that traded in 1972. During the year, trading on the Chicago Board of Trade increased to 8 billion ounces, more than double the volume traded in 1972. COMEX stocks decreased from 77.6 million ounces at the end of 1972 to 64.3 million ounces at the end of 1973, and during the same time period, Chicago Board of Trade stocks increased from 22.8 million ounces at the end of 1972 to 27.4 million ounces at the end of 1973.

During the year, the price of silver fluctuated widely and price gains were extensive. A low of 196.2 cents per troy ounce was established on January 24; a high of 328.0 cents per ounce was established on December 27, a difference of 131.8 cents per ounce between the two extremes. As industrial consumption was greater than in any other single year, and this fact, together with the reduction of industry stocks, most probably was one cause for the wide price fluctuations. Another reason for the large price rise during the year was the increasing speculative interest and public desire to own silver and other precious metals.

Net imports of silver rose sharply from 35.7 million ounces in 1972 to 119.5 million ounces in 1973. Most of the imports were in the form of refined bullion, a large percentage of which came from Mexico, Canada, Peru, and the United Kingdom.

During 1973, the Government sold, through the General Services Administration (GSA), 2.0 million ounces of fine silver that had been recovered through reclamation activities of the Department of Defense. The Government also released its stock of uncirculated Carson City silver dollars during 1973.

Stocks (including Chicago and New York exchanges) declined to 130.1 million ounces, compared with 152.3 million ounces (revised) at the end of 1972.

Legislation and Government Programs.—Legislation was enacted in October 1973 authorizing the issuance, beginning July 4, 1975, of up to 45 million silver-clad coins honoring the bicentennial of United States independence. The coins will be 40% silver by weight in a three-layer composite of which the outer cladding will be 800 parts silver with 200 parts copper, bonded to a core of approximately 215 parts silver and 785 parts copper. The coin will consist of the dollar, half-dollar, and quarter.

On April 12, 1973, the Office of Emergency Preparedness announced a revised stockpile objective of 21.7 million ounces of silver, 117.8 million ounces less than the inventory and previous objective. Although the excess silver became available for disposal, it could not be sold without congressional approval, and the total amount remained in the stockpile at yearend.

Silver remained eligible for exploration assistance up to 75% of approved costs under a program conducted by the Office of Minerals Exploration (OME) in the U.S. Geological Survey. A few contracts were active in 1973.

DOMESTIC PRODUCTION

Domestic mine production of silver was 37.8 million ounces, about 2% higher than in 1972. A 4-month strike at the Sunshine Mining Co. in Idaho limited the rise in production. Base-metal ores provided 70% of the total silver output, silver ores provided 28% and the remainder came from gold and gold-silver production.

Idaho's silver output in 1973 declined 4% from 1972 and was 36% of the U.S. production. The combined production of Idaho, Arizona, Montana, Colorado, and Utah was 87% of domestic production.

The 25 leading silver producers contributed 84% of the total output. Four of the producers mined silver ores alone while the rest were base-metal producers. Eight mines produced over 1 million ounces of silver each, their combined output equalling 55% of the total domestic production. Domestic mine output provided 19% of the total silver consumption by industry and the arts.

In 1973, a 4-month strike reduced materially the Sunshine Mining Co. production. This mine has been the country's leading silver producer for several years. Hecla Mining Co. produced 3.9 million ounces, 14% less than 1972 production. Contributing to Hecla's lower production was the December 1972 closing of the Mayflower mine, operated under lease in Utah. The average selling price for Hecla's silver in 1973 was 255.8 cents per ounce, up from the 168.5 cents per ounce in 1972. Hecla's Lucky Friday mine produced 176,859 tons of ore assaying 15.49 ounces of silver per ton, 11.14% lead, and 1.22% zinc, compared with 192,020 (revised) tons of ore assaying 14.62 ounces of silver per ton, 10.43% lead, and 1.32% zinc produced in 1972. Ore reserves at yearend amounted to 510,000 tons, compared with 584,000 tons at the beginning of 1973. Sunshine Mining Co. is the operator of the Sunshine unit area, which produces from properties owned by Hecla Mining Co., Sunshine Mining Co., and Silver Dollar Mining Co. Hecla's 33.25% share of the unit area production was 38,769 tons of ore assaying 25.30 ounces of silver per ton, compared with 33,738 tons of ore assaying 27.32 ounces of silver in 1972. Hecla's share of unit area ore reserves at yearend was 267,000 tons, compared with 258,000 (revised) tons at the beginning of the year.

In addition to the Sunshine mine, Hecla owns a 30% interest in production from the Star-Morning mine. Hecla's share of the 1973 production was 79,734 tons assaying 2.79 ounces of silver per ton, 5.18% lead, and 6.68% zinc, compared with 79,079 tons assaying 2.87 ounces of silver per ton, 5.33% lead, and 7.36% zinc in 1972.

The Bunker Hill Co. produced about 2.6 million ounces of silver in 1973, down from 3.8 million ounces produced in 1972. At the Cresent mine, production of silver was down to 595,000 ounces, which reflected declining ore grades in the lower mine levels. Production in 1972 was 1.53 million ounces. Mine development work underway in the Crescent mine in 1974 was expected to determine future production from this mine.

The Anaconda Company reported silver production of 4.26 million ounces during 1973, up from 4.0 million ounces produced in 1972. The company also reported a partnership in Park City Ventures, owned 60% by Anaconda and 40% by the American Smelting and Refining Co. (ASARCO), which will operate a reactivated lead-silver-zinc mine at Park City, Utah, under lease from the United Park City Mines Co. New reserves were developed, and production was expected to begin in 1975 at an estimated annual rate of 1.2 million ounces of silver and substantial quantities of lead and zinc. A second partnership, on a 50–50 basis, is with Anamax Mining Co. in the operation of the Twin Buttes copper mine in Arizona.

ASARCO operated the Galena mine in the Coeur d'Alene district in Idaho under a lease arrangement from the Callahan Mining Corp. Production from this mine in 1973 was 4.2 million ounces of silver, about the same as 1972. ASARCO also announced an expansion program which included the construction of a new electrolytic copper refinery near Amarillo, Tex. The unit, which was to replace an old refinery at Baltimore, Md., was planned for completion in 1975. The byproducts plant at Amarillo will be capable of producing 60 million ounces of refined silver per year.

Kennecott Copper Corp. reported silver production of 4.2 million ounces of silver in 1973 from the processing of 66.5 million tons of copper ore. This compared with 4.3 million ounces of silver from 58.5 million tons of ore mined in 1972. The average price received for the year was $2.56 per ounce in 1973 compared with $1.68 per ounce in 1972.

Day Mines, Inc., of Wallace, Idaho, operates several mines in Idaho and Washington, and has interests in others. During 1973, silver production from all Day Mines sources amounted to 1.3 million ounces, about an 18% increase over that of 1972.

Smelter and refinery reports show that 34.6 million ounces of silver were generated from old scrap and 41.3 million ounces from new scrap in 1973. These were combined with output from foreign and domestic concentrates and ores for a total refinery production of 151.3 million ounces in 1973, about 8% more than in 1972.

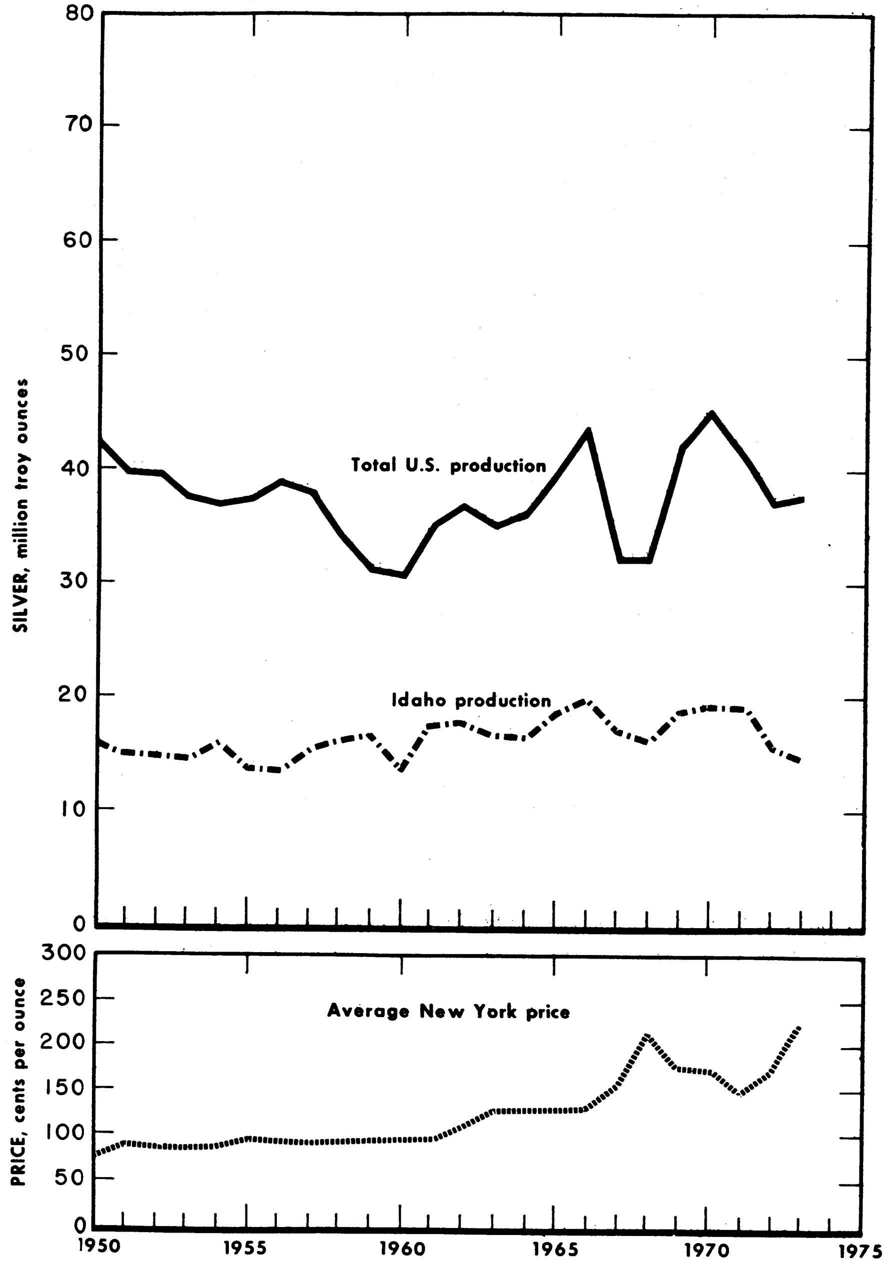

Figure 1.—Silver production in the United States and Idaho and price per ounce.

CONSUMPTION AND USES

Silver consumption in industry and the arts, as reported to the Bureau of Mines by manufacturers and consumers, increased 30% over the quantity consumed in 1972. There were significant percentage increases in use in catalysts (75%), miscellaneous (49%), sterling ware (48%), and brazing alloys and solders (45%). Substantial increases were used in photography (36%) and contacts and conductors (10%). Use in commemorative medals and other collector items was estimated at 21.9 million ounces in 1973 compared with 11.4 million ounces in 1972. Excluding coinage from the totals, the following four categories of use consumed more than 77% of the total silver: photography, 27%; contracts and conductors, 21%; sterling ware, 20%; and brazing alloys and solders, 9%. Consumption in jewelry showed a 19% increase. Sharply expanding uses were shown in dental and medical supplies and in mirrors. Silver used in domestic coinage declined to 0.9 million ounces in 1973 compared with 2.3 million ounces used in 1972.

Silver consumed in commemorative medals, embossed bars, and small ingots rose sharply during 1973, and amounted to 11% of total silver consumption. The 21.9 million ounces used contributed to the increases recorded in the sterling ware and miscellaneous categories shown in table 9.

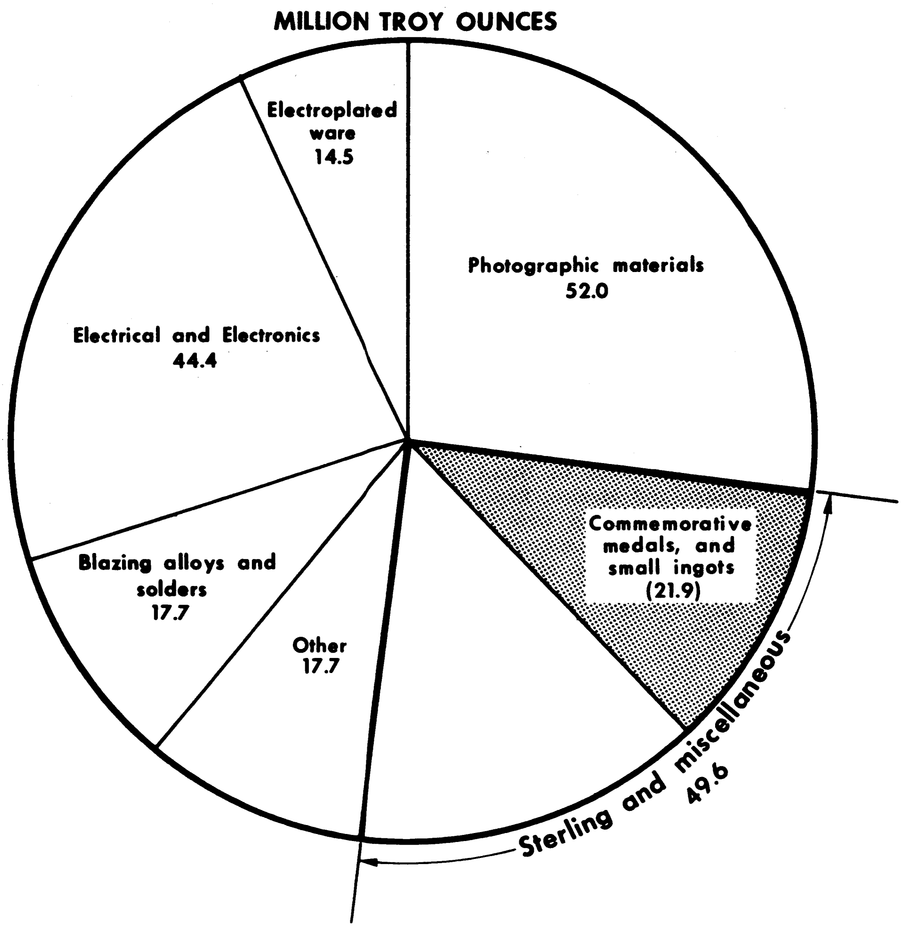

Figure 2.—Silver consumption in the United States, 1973.

STOCKS

The Treasury bullion stock outflow in 1973 totaled 0.7 million ounces, all of which was consumed in U.S. coinage for the continued production of the Eisenhower 40% silver dollar.

Total yearend visible stocks of silver were estimated at 181.3 million ounces, which consisted of industry stocks, 38.4 million ounces; Defense Department stocks, 6.1 million ounces; Treasury bullion, 45.1 million ounces; COMEX, 64.3 million ounces; and Chicago Board of Trade stocks, 27.4 million ounces. Total yearend stocks were 25.8 million ounces less, or 12%, than at the end of 1972.

PRICES

New York prices for silver in 1973, as quoted daily by Handy & Harman, ranged from a low of 196.50 cents per ounce on January 24, 1973, to a high of 328.00 cents per ounce on December 27, 1973. This upward trend extended the advance that began in 1971. Problems of supply and strong industrial demand contributed to the advance. Worldwide inflation and fluctuating international currency values increased the speculative demand for silver. The average price for silver during 1973 was 255.8 cents per ounce in New York.

Prices for spot delivery on the London Bullion Market ranged from a low of 195.5 cents per ounce (U.S. equivalent) on January 23, 1973, to a high of 325.6 cents per ounce on December 31, 1973, and averaged 254.1 cents for the year.

Prices also advanced sharply on the futures markets with increased trading activity. The trading volume on the COMEX increased to 12.4 billion ounces, up from 7.9 billion ounces traded in 1972. A monthly record trading of 1.35 billion ounces took place in December. Silver futures trading was also active on the Chicago Board of Trade, where 8.2 billion ounces were traded in 1973 compared with 3.8 billion ounces in 1972.

FOREIGN TRADE

Silver exports declined sharply in 1973 to 11.2 million ounces, less than half of the total exported in 1972. About 23% went to the Netherlands, 22% to Canada, 17% to West Germany, and 9% each to France and Belgium-Luxembourg. Significant quantities also went to Brazil, the United Kingdom, and Mexico. Exports of waste, scrap, and sweepings went mainly to West Germany, Belgium-Luxembourg, and the United Kingdom; most bullion went to the Netherlands, Canada, France, and West Germany.

Silver imports increased sharply in 1973 to 130.7 million ounces compared with 65.4 million ounces in 1972. About 62% of the imported silver was in refined bullion. The main sources of imports were Mexico (43%), Canada (28%), the United Kingdom (10%), and Peru (10%). Net imports were 119.5 million ounces in 1973 compared with 35.7 million ounces in 1972.

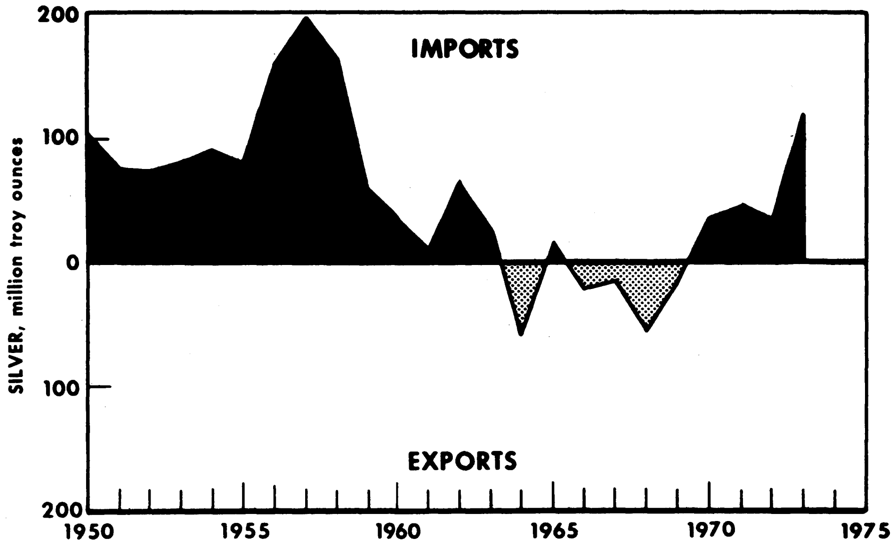

Figure 3.—Net exports or imports of silver, 1950–73.

WORLD REVIEW

World output of silver increased 11.7 million ounces to a total of 305.9 million ounces, an increase of 4% over that produced in 1972. The major increase in 1973 was the Canadian gain of 4.1 million ounces. Mexican and Peruvian silver output was also higher than in 1972, and U.S. production rose about 0.6 million ounces. Australian production increased about 0.4 million ounces in 1973. Western Hemisphere output of silver accounted for about 60% of the world production.

World consumption in arts and industry rose sharply to an estimated 463 million ounces, up about 72 million ounces over that consumed in 1972. The United States had the largest increase in consumption, from 151.1 million ounces in 1972 to 195.9 million ounces in 1973. Coinage requirements for the world declined from 36.5 million ounces in 1972 (revised) to 20.0 million ounces in 1973. Total non-Communist silver consumption exceeded production by 77.1 million ounces. This production and consumption gap was met by secondary recovery and reduction of stocks.

Australia.—Silver output of 23.2 million ounces was 2% more than that produced in 1972. The leading Australian silver producer was Mount Isa Mines, Ltd. (49% owned by ASARCO), which had a 1973 output of 8.8 million ounces, which was slightly below 1972 production. Mount Isa is also a major producer of lead, zinc, and copper.

Canada.—Canada's primary production of silver in 1973 was the highest on record. Reported output of 48.2 million ounces[2] was 3.4 million ounces greater than in 1972. Canada continued as the leading world producer of silver. The increase was mainly attributable to the greater output at several base-metal mines that produce silver as a byproduct, particularly at Mattabi Mines Ltd., which completed its first full year of operation at its zinc-lead-copper-silver property in the Sturgeon Lake area of Northwestern Ontario. Production from the silver-cobalt ores mined in the Cobalt-Gowganda area of northern Ontario was little changed from that of 1972.

Ore production by Texasgulf, Inc. wholly owned subsidiary, Ecstall Mining Ltd., at the Kidd Creek mine in Timmins, Ontario, continued at the rate of 3.6 million tons per year. Work began on plans to expand operations to 5.0 million tons annually. The greatest silver producer in Canada, the

[2] George, J. G. Silver. Can. Min. J., February 1974, p. 103.

Kidd Creek mine, produced about 22% of Canada's total 1973 output. Mine output of 10.7 million ounces in 1973 was about 16% below 1972 production. From the start of operations in 1966 and through 1973, the Kidd Creek mine produced a total of 24.9 million tons of ore averaging 1.53% copper, 0.39% lead, 3.73% zinc, and 4.26 ounces of silver per ton; remaining ore reserves above the 2,800-foot level were reported about 95.0 million tons.[3]

Cominco Ltd., the largest silver producer in British Columbia, derived its output from the lead-zinc-silver ore of its Sullivan mine at Kimberly and from purchased ores and concentrates. Cominco was also one of Canada's leading producers of refined silver and, in 1973 produced 9.6 million ounces at its refinery in Trail, compared with 7.0 million ounces in 1972.

Another mine, in an earlier period (1953–67) was the largest silver producer in Canada. It is owned by United Keno Hill Mines, Ltd. and located in the Yukon Territory. United Keno Hill produced 3.1 million ounces of silver compared with 2.5 million ounces in 1972, with 72% of the production coming from the Husky and No Cash properties. During the year, the Calumet mine, previously a good producer of silver, was closed and the site vacated.

Silver production in the Northwest Territories was significantly higher than in 1972 because of greater output by Echo Bay Mines Ltd. and Terra Mining and Exploration Ltd. Echo Bay, a subsidiary of International Utilities Corp., began operations in 1964. Since then, and operating a 140-ton-per-day mill, it has produced a total of 16 million ounces of silver and a minor amount of copper. It was reported that some of the treated ore had yield values of up to 70 ounces of silver per ton.

Exploration work continued in 1973 by Dynasty Exploration Ltd., and its associate, Atlas Exploration Ltd., on the Plata silver-lead property in the Hess Mountains of the Yukon Territory. In several exposed veins, it was reported that the ore assayed a high percentage of silver and lead.

Dominican Republic.—Rosario Resources Corp. announced it was increasing the production capacity of the gold-silver processing plant, under construction at its Pueblo Viejo mine in the Dominican Republic, from 6,000 to 8,000 tons per day. During 1973, additional exploration increased the estimated oxide ore reserves from 20 million to 30 million tons. Annual production at Pueblo Viejo, an open pit mine, was projected to be about 1.5 million ounces of silver and 350,000 ounces of gold. Plant completion was scheduled for the latter part of 1974. The operation is owned by Rosario Resources (40%), J. R. Simplot and Co. (40%), with a 20% equity participation by the Central Bank of the Dominican Republic.

Honduras.—Silver production from the El Mochito mine of Rosario Resources Corp. (formerly New York and Honduras Rosario Mining Co.) was 3.2 million ounces, about the same as in 1972. The mine produced 311,682 tons of ore and the mill processed 311,576 tons of ore averaging 11.9 ounces of silver per ton, with additional amounts of gold, lead, and zinc. Ore reserves in the main area amounted to 1.8 million tons.

Japan.—Mine production of silver in Japan was 8.5 million ounces, a decrease of 15% from 1972 production. Japanese silver consumption rose from 54.4 million ounces in 1972 to 67.5 million ounces in 1973. No silver was used in coinage. With Mexico, Peru, and Australia as its major suppliers in 1973, Japan imported 32.0 million ounces of silver and exported 100,000 ounces. Japanese Government stocks of silver were reported at 16.0 million ounces, unchanged from 1972.[4]

Mexico.—Silver production in Mexico rose to 38.8 million ounces, 3% higher than in 1972. During the year it was announced that silver output would be increased 10 million ounces in the next 2 years by development of deposits previously disregarded because of low world prices.

Tormex Mining Developers, in which Ducanex Resources and Pure Silver Mines Ltd. (Canadian firms) hold just over 26% interest each, reported that construction was completed on a 500-ton-per-day concentrator at the Encantada mine. The mine is owned by Tormex (40%), and its Mexican partner, Industrias Peñoles, S.A. (60%). It was expected that operators would ship 6,000 tons of concentrate, grading about 40% lead, and 30 ounces per ton of silver, to the smelter each month. This silver-lead property is located in the northern part of the country, 200 miles southeast of Chihuahua.

[4] Handy & Harman. The Silver Market, 1973. 58th Annual Review. 1973, 16 pp.

The surface and underground development work at the Guanajuato, Mexico, silver-gold properties of Pure Silver Mines Ltd. (Canada) and its Mexican partners, Cia. Mineral Fresnillo S.A. and Industrias Peñoles S.A., continued in 1973. An independent feasibility report on the proposed integrated mining and milling operation was expected to be completed by the end of October 1973. The proposed operation, at a rate of 2,000 tons per day, is based on indicated silver-gold ore reserves of approximately 4.4 million short tons at the Mother Lode, Peregrina, and Cebada mines. At the Las Torres mine, the main production shaft was completed to the 2,130-foot level, with most lateral work continuing on the 1,600-foot level. Good values in silver and gold have been reported. At the Peregrina mine, a new 12-foot by 14-foot shaft was scheduled for completion to 1,270 feet at the end of August 1973. Deepening of the Cebada shaft to 1,270 feet was completed.

The American Smelting and Refining Co. subsidiary, ASARCO Mexicana, S.A. (49% owned by ASARCO) produced 14.8 million ounces of silver during 1973, a decrease of 5% from 1972 production. Operations at company mines were normal. Ore reserves were maintained except at Parral, where mining operations were being phased out, with plans to terminate in 1974 owing to exhaustion of ore reserves.

In December 1973 ASARCO reached agreement in principle with the main Mexican stockholders of ASARCO Mexicana to sell an additional 15% of the stock of ASARCO Mexicana to Mexican investors, thus reducing its holdings to 34% of the outstanding stock.[5]

Peru.—Peru was the world's second largest producer of silver in 1973. Output increased to 42.0 million ounces, compared with 40.2 million ounces in 1972. Silver production was primarily a byproduct of base-metal mining.

The largest silver producer and refining company in Peru was the Cerro Corp. Its totally owned subsidiary, Cerro de Pasco Corp., operated six metal mines. The total silver refined in 1973 at Cerro's reduction works at La Oroya from its own and purchased ores was 19.9 million ounces, 47% of the total silver output of Peru. This compared with 23.0 million ounces produced in 1972.

On January 1, 1974, the Peruvian Government expropriated Cerro Corp. holdings in Cerro de Pasco. It was reported that the Peruvian Government would provide compensation for the company's mining, smelting, and refining properties.

TECHNOLOGY

In 1973 the Bureau of Mines reported on its investigation of treating ores in which silver occurs as a sulfide, in jarosite, in iron oxide, and in manganese carbonate-oxide associations.[6] Silver ores from the Candelaria District, Nevada, and Round Mountain District, Colorado, were the subjects of study. Leaching these ores with a sulfurous acid-sodium chloride system increased silver extraction up to 61% over that obtained by conventional cyanidation techniques. The Bureau published a report that described two processes for recovering silver and other metals from the magnetic fraction of waste generated by the primary smelting of zinc in horizontal retort distillation furnaces.[7]

The Calico silver-barite deposits near Barstow, Calif. are a potentially important silver and barite resource. Exploraiton performed in the past by two major mining companies has outlined large tonnages of ore containing 2 to 3 ounces of silver per ton and 7% to 15% barite. Laboratory beneficiation work was done by the Bureau of Mines on four samples to develop methods for recovering the silver and/or barite. Cyanidation recovered from 47% to 60% of the silver, and from 75% to 90% of the barite was recovered from either the natural ore or from cyanidation residues. Salt roasting followed by cyanidation recovered a higher percentage of the silver but precluded recovery of the barite concentrate from the leach tails.[8]

At the Bureau of Mines Intermountain Field Operation center, a study was conducted that gave an economic analysis of copper system byproducts and discussed the identification and classification of byproduct metals, and their supply. The report gave the sources of supply of individual byproduct metals to indicate importance to total supply. The study also included information on the reserves-resource base supporting byproduct output, reserve estimates, and the demand aspects of silver.[9]

The Bureau of Mines continued research on a project entitled, "Extraction of Silver and Other Metals From Refractory Ores, and Mine Wastes." The objective was to develop new or improved extraction processes to recover silver and associated metals from refractory and marginal ores and deposits too small to support amortization of a conventional cyanide plant. Procedures to develop a low-cost pit cyanidation, carbon-in-pulp technique for recovering silver from old mill tailings appeared promising.

Two companies in Japan jointly developed a commercial process for manufacturing the fine silver powder consisting of submicrometer-size particles. The technology involved placing a given metal in a vacuum oven and heating the metal above its melting point in an inert gas atmosphere. The resulting vapor was condensed to obtain metal powder between 0.01 and 0.02 micrometer in diameter. The process was applicable to silver, copper, aluminum, and various other metals and alloys. Fine metal powders are used in electronics (silver pastes), powder metallurgy, and catalysts.[10]

e Estimate. p Preliminary. r Revised.
[1] Recoverable content of ores and concentrates produced unless otherwise noted.
[2] In addition to the countries listed Bulgaria, Thailand, Turkey, and several African countries produce silver, but information is inadequate to make reliable output estimates.
[3] Less than ½ unit.
[4] Includes production by the State mining company COMIBOL plus the exports of medium and small (private sector) mines.
[5] Smelter and/or refinery production.
[6] Output of Inyati mine only.
[7] Data represents recoverable content of Tsumeb Corp. Ltd. concentrates for year ending June 30, 1971, and calendar year production in 1972 and 1973. Silver production from July 1 to December 31, 1971, was 649,343 troy ounces.
[8] Includes recovery from copper refinery sludges.

Slag—Iron and Steel

By Harold J. Drake[1]

Production of processed iron and steel slag, in the aggregate, increased in 1973. Output of iron blast-furnace slag rose 15% in quantity and 18% in value, but output of steel slag decreased 4% in quantity and 2% in value. Nearly all of the increased production of iron slag was accounted for by air-cooled blast-furnace slag. As in past years, a considerable portion of steel slag was recycled to blast furnaces, whereas little, if any, iron slag was so utilized.

Prices of iron and steel slags, continuing the trend of recent years, were stable. The average price for all iron slag was up 2% and that of steel slag was up 3%. Imports of slag declined 13% in quantity and 18% in value. Exports increased 35% in quantity and more than doubled in value, indicating increased shipments of high-value material.

DOMESTIC PRODUCTION

Increased production of iron and steel in 1973 resulted in higher output of iron slag. Production of iron-blast-furnace slag totaled 28.8 million tons valued at $62.9 million. Output of steel slag totaled 9.7 million tons valued at $10.8 million.

Production of air-cooled blast-furnace slag totaled 25 million tons valued at $52.2 million, increases of 14% and 17%, respectively, over the levels of the preceding year. Approximately 95% of this material was crushed and screened to specifications; the remainder was crushed and used without screening. Granulated blast-furnace slag production reached 2 million tons valued at $3.7 million, increases of 21% and 20%, respectively. Production of expanded slag, at 1.9 million tons valued at $6.9 million in 1973, was up 22% in quantity and 25% in value.

The great bulk of the slag was produced in Ohio, Pennsylvania, Illinois, Indiana, and Michigan. A total of 1,713 plant and yard personnel worked 3,797,000 man-hours during 1973 in 90 air-cooled, 16 expanded, and 12 granulated slag plants. A total of 3,465,000 tons of slag-encrusted magnetic iron was recovered at these operations.

CONSUMPTION AND USES

Because stocks of process slag are relatively small and constant from year to year, consumption virtually equals production, excluding the quantities that are recycled to blast-furnaces. The principal market has always been the construction industry which, in 1973, accounted for about 95% of the quantities consumed. Agricultural uses, sewage filtering medium, and mineral wool manufacture utilized the small remainder.

Increased consumption of screened iron-blast-furnace slag was reported in portland cement concrete construction, bituminous construction, and highway and airport construction. In total, these uses accounted for about 73% of the volume of screened air-cooled slag consumed in 1973. Declines in consumption were reported for railroad ballast, roofing granules, and sewage filtering medium. Consumption of unscreened air-cooled slag in highway and airport construction, the principal use, declined slightly. Consumption of granulated and expanded blast-furnace slags was up 21% from 1972. More granulated slag was used in highways and agriculture and less in cement and concrete blocks. Use of expanded slag in concrete blocks increased 23% but decreased 14% in cement manufacture.

Consumption gains were recorded for steel slag in miscellaneous base and fill applications, railroad ballast, bituminous mixes and agriculture, but declines were recorded in highway construction and paved areas.

Use technology was reviewed in a number of important papers in recent years.[2]

PRICES

Iron and steel slag encountered strong price competition from mineral aggregates such as crushed stone and sand and gravel in 1973. Prices of most types of slag were only slightly changed from those of 1972. The unit value of all iron-blast-furnace slag was $2.18 per ton, compared with $2.13 per ton in 1972. Corresponding figures for steel slag were $1.11 per ton in 1973 and $1.08 per ton in 1972.

The price of screened air-cooled blast-furnace slag used for highway and airport construction rose $0.06 to $2.15 per ton, for railroad ballast, up $0.01 to $1.58 per ton, for bituminous construction, up $0.10 to $2.19 per ton, and for portland cement structures, up $0.07 to $2.40 per ton. The price of granulated iron slag used in highway and airport construction, the main use, declined slightly to $1.37 per ton. Prices of steel slag used for highway construction rose $0.03 to $1.01 per ton, for paved areas the price declined $0.02 to $1.02 per ton, and for miscellaneous base and fill, prices declined $0.18 to $0.96 per ton.

FOREIGN TRADE

Exports of iron and steel slag totaled 37,117 tons valued at $734,723, a level well above that of 1972. Canada was the principal export market, receiving 94% of the quantity and 28% of the value of total exports. The United Kingdom received 4% of the quantity and 53% of the value. Australia, the Netherlands, West Germany, and Italy were the principal recipients of the remainder.

Imports totaled 1,268 tons valued at $13,914 all of which came from Canada. Imports supply only a very small share of the U.S. market for iron and steel slag.

WORLD REVIEW

France.—Production of iron-blast-furnaces slag in 1972, the latest year for which detailed statistics are available, totaled 15.1 million tons. Approximately 50% was granulated, 36% was air-cooled; the remainder was utilized either by foaming or deposited in stockpiles. The main uses for granulated slag were in the manufacture of cement, 32%, and in roads and highways, 24%. Approximately 13% was exported, 12% stockpiled, and 8% discarded as waste. Air-cooled slag was used mainly for roads and foundations, 59%, with an additional 19% stockpiled. Both types of slag had many minor uses.

United Kingdom.—Production of iron and steel slag in 1972, the latest year for which data are available, totaled 7.8 million tons. Approximately 72% of the slag was used in road construction; the remainder was used in numerous applications. Of the quantities used in road construction, approximately 58% was used in conjunction with macadam or bituminous materials. More than 96% of the total slag produced was of the air-cooled variety, 3% was foamed, and less than 1% was granulated. Properties, uses, and physical and chemical properties of foamed slag were published.[3]

West Germany.—Production of iron and steel slag in 1972 totaled 11.7 million tons, 50% of which was derived from steel mills. Approximately 80% of that output was used in road building, the remainder for fertilizer, mineral wool, cement, and a few other uses. About 77% of the iron and steel slag was air-cooled, 21% granulated, and 2% foamed.

Sodium and Sodium Compounds

By Charles L. Klingman [1]

Total production of soda ash (sodium carbonate) in the United States in 1973 was almost exactly the same as that of 1972, but demand continued to increase at least as much as the historic 3% growth rate. Exports of soda ash were reduced by 55,000 tons and for the first time, there was an importation of 16,000 tons of soda ash. Even though the supply-demand imbalance was not large, soda ash market conditions were chaotic in 1973.

Construction continued toward increasing productive capacity at the Trona mines of Wyoming, but the actual increase (about 16%) was limited by shortages of fuel and skilled production workers. The increase in naturally derived soda ash production was practically nullified by a 472,000-ton reduction in synthetic soda ash outlet. Synthetic soda ash plants were plagued in 1973 by shortages and poor quality of raw materials.

There was a 7.6% increase in 1973 in total sodium sulfate production in spite of a loss of 4.1% in the production of naturally derived salt cake. Metallic sodium output showed a 10.2% increase in 1973 as compared with a historic growth rate of about 2.0% per annum.

Legislation and Government Programs.—There has been a depletion allowance, for Federal income tax purposes, on the mining of trona since 1946; but in 1970 the U.S. Internal Revenue Service gave notice that it wanted to end this allowance. In 1973, a proposal to this effect was on the verge of adoption when the proposal was introduced in the Senate which, in effect, guaranteed continuation of the depletion allowance. Although the U.S. Department of the Treasury strongly opposed the amendment, the Wyoming soda ash producers said that the depletion allowance was essential to the continuation of their plans to increase trona production.

Federal price controls on soda ash and other sodium compounds were scheduled to end April 1, 1974.

DOMESTIC PRODUCTION

In 1973 there was a surging demand for soda ash but total production increased by only 0.4%. Therefore, the market was in turmoil throughout the year. The shortfall in soda ash was estimated by one writer to be about 350,000 tons.[2]

Soda ash producers were forced to allocate their output to present customers on the basis of 1972 usage, and new customers had practically no chance to obtain supplies. Prices were regulated under phases 3 and 4 of the Economic Stabilization Act, so there was no opportunity for soda ash users to bid against each other for additional shipments. Small tonnages of European soda ash, amounting to 0.2% of U.S. consumption were imported at prices up to four times the prevailing domestic prices. Greater demand also caused a reduction in exports.

[3] Includes glauber salt.
[4] Data does not add to total shown because of independent rounding.

The three producers of natural soda ash at Green River, Wyo., increased their combined output by about 16%, but this was offset by comparable reductions from synthetic soda ash producers. Texas Gulf, Inc., contracted with Stearns-Roger, Inc. of Denver, Colo., to build a fourth soda ash mine and plant near Green River, Wyo. It is scheduled to start producing in 1976. Construction of new facilities for production of natural soda ash was apparently continuing on schedule, but the anticipated increases were not fully realized because of a shortage of skilled production workers and occasional shortages of fuel. Natural soda ash increased to 49.2% of the total production as compared with 42.7% in 1972.

There was a large drop in production of synthetic (Solvay) soda ash. There were no known plant closings during the year, but all plants seemed to be having trouble, especially with raw materials supplies. The anthracite coal or coke used to convert limestone to lime was reported to be in very short supply, was poor in quality, and was higher in price. There were also shortages in fuel for steam generation. Approximately 2.8 tons of steam were required to make one ton of soda ash, so fuel costs made up a significant portion of total production costs. All existing Solvay plants were quite old, so maintenance shutdowns were frequently required, were time consuming, and were expensive. It was believed that some of the existing Solvay plants would close as soon as the present shortage of soda ash eases.

Caustic soda, which was interchangeable with soda ash in certain applications, was also in short supply during 1973. This situation was caused, in part, by the shutdown of some mercury-electrode, chlorine-caustic cells which were under attack by environmentalists for pollution of public water courses. Additional capacity for producing caustic soda was under construction but would not be in full production for 1 or 2 years.

Sodium sulfate, or salt cake, showed a 20.7% increase in production of the synthetic product and a 4.1% decrease in output of the natural sulfate, resulting in an overall increase of 7.6%. Historically, synthetic salt cake production had wide year-to-year variations with no significant growth for more than 20 years. Naturally derived sodium sulfate, on the other hand, displayed an annual growth of about 5%, so the 1973 decrease was disappointing, by comparison. Salt cake derived from natural sources declined to 47.0% of the total output in 1973 compared with 52.8% in 1972. Early in 1973, there seemed to be an ample supply of salt cake, but during the last 2 months of the year demand was apparently greater than supply. This could have been caused by a general tightness in the whole sodium market and more substitution of salt cake for soda ash and caustic soda. There was no lack of source material for natural sodium sulfate in the western part of the country.

Metallic sodium output increased to 176,903 tons, an alltime record and 10.6% above the 1972 production. This was a surprise development, since the historic growth rate was only 2.0% per annum; in addition, over 80% of the metallic sodium was utilized in the manufacture of a compound which was supposed to be on the decrease, tetraethyl lead, a gasoline additive.

A list of U.S. producers of natural sodium compounds and metallic sodium follows:

Product	Company	Plant location	State	Source of sodium
Soda ash	Kerr-McGee Chemical Corp	Trona	California	Dry lake brine.
Do	Stauffer Chemical Co	Westend	do	Do.
Do	Allied Chemical Corp	Green River	Wyoming	Underground trona.
Do	FMC Corp	do	do	Do.
Do	Stauffer Chemical Co	do	do	Do.
Sodium sulfate	do	Trona	California	Dry lake brine.
Do	Kerr-McGee Chemical Corp	do	do	Do.
Do	United States Borax & Chemical Corp.	Boron	do	Open pit mining.
Do	Ozark-Mahoning Co	Brownfield	Texas	Subterranean brine.
Do	do	Seagraves	do	Do.
Do	Great Salt Lake Minerals & Chemicals Corp.	Ogden	Utah	Salt lake brine.
Metallic sodium	E.I. du Pont de Nemours & Co.	Niagara Falls	New York	Salt.
Do	do	Memphis	Tennessee	Do.
Do	Ethyl Corp	Baton Rouge	Louisiana	Do.
Do	do	Houston	Texas	Do.
Do	Reactive Metals Inc	Ashtabula	Ohio	Do.

CONSUMPTION AND USES

The Bureau of Mines does not routinely survey consumers of sodium compounds (except salt), so data on utilization of these products were indirectly obtained from production data on related commodities or from the studies made by other agencies. For example, data on production of glass sand indicated that there was an increase in glass output and from the figures it could be calculated that 51.5% of the total soda ash production went to the making of glass. The higher glass output might have been caused by an increase in the manufacture of expendable (nonreturnable) bottles. Shortages of paper and plastic for containers could have required more glass for this end usage.

Required reductions in the phosphate content of dry detergents in 1973 created an additional outlet for sodium sulfate in these powdered products. In this usage sodium sulfate is not claimed to improve the cleaning characteristics of the detergents but is merely a low-priced extender or diluent for the concentrated detergent. Also, with a decrease in availability of caustic soda and soda ash for the manufacture of pulp and paper, more salt cake might have been required for this specific usage.

Increases in production of tetraethyl and tetramethyl lead did not keep pace with the increased output of metallic sodium, so it might be inferred that the portion of metallic sodium used in tetraethyl and tetramethyl lead manufacture dropped from 83% in 1972 to about 80% in 1973. It also followed that other uses for metallic sodium such as detergent manufacture and the reduction of metallic ores increased.

As far as is known, the remaining usages of sodium compounds remained about the same in 1973 as they were in 1972.

TRANSPORTATION

With the shift in soda ash output from that manufactured at plants in the northeast, to that recovered from natural deposits in the far west, transportation and its costs took on increasing significance for soda ash users. There was only one important route for the movement of soda ash from Green River, Wyo., and that was by Union Pacific Railroad. A railroad strike, a shortage of rail cars, or major equipment failure could virtually shutdown the soda ash industry. If the production could be handled by truck, over 1,000 trucks per day or 42 trucks per hour, each with a 20-ton load, would be required.

A novel soda ash transportation plan was considered by producers. The plan called for a pipeline to convey a water slurry of soda ash from Green River, Wyo., to some central distribution point in the northeast, possibly on a navigable waterway. The pipeline would have to be more than 1,000 miles long and would be expensive, but once installed, would reduce shipping costs, including handling at both ends by perhaps 25%.

PRICES

Market prices quoted at yearend for sodium carbonate, sodium sulfate, and metallic sodium were as follows:

	1972	1973 [1]
Sodium carbonate (soda ash):		
Light, paper bags, carlots, works ____per 100 pounds__	\$2.47½	\$2.47½
Light, bulk, carlots, works ____do____	1.77½	1.77½
Dense, paper bags, carlots, works ____do____	2.47½	2.47½
Dense, bulk, carlots, works ____do____	1.77½	1.77½
Sodium sulfate (100 percent Na_2SO_4):		
Technical detergent, rayon grade, bags, carlots ____per ton__	43.00–46.00	43.00–46.00
Technical detergent, rayon-grade, bulk, works ____do____	33.00	33.00
Domestic salt cake, bulk, works [2] ____do____	28.00	28.00
National Formulary (N.F. XII), drums ____per pound__	.23½	.23½
Metallic sodium:		
Bricks, carlots, works ____do____	.30	.30
Fused, lots 18,000 pounds and more, works ____do____	.26½–.27½	.26½–.27½
Bulk, tank, works ____do____	.18¾	.18¾

[1] Chemical Marketing Reporter. Current prices of chemicals and related materials. V. 204, No. 27, Dec. 31, 1973.
[2] East of Mississippi River; price in the west is \$18.50 per ton, f.o.b. producing point.

FOREIGN TRADE

In 1973, exports of soda ash dropped to 425,000 tons or 5.6% of production, from 480,000 tons or 6.4% of production in 1972. In 1973, there was also a small import of soda ash for the first time, which reduced net exports to 409,000. Over half of the soda ash exported went to Canada and Mexico and over one-fourth was shipped to South American countries. The soda ash imports came almost entirely from European countries.

In sodium sulfate, the United States imported 320,000 tons or 18.9% of domestic total consumption but exported 45,000 tons or 2.7% of the total consumption. The net importation was, therefore 275,000 tons or 16.2% of consumption. These figures are quite similar to those of 1972 except that salt cake exports were slightly higher in 1973. Canada supplied about 48.0% of the imports; Belgium-Luxembourg 41.5%; West Germany 4.5%; East Germany 2.9%; and 3.1% other countries.

The value of exports of all sodium compounds exceeded the value of the imports by 11.4 million.

Tariff rates for sodium compounds remained constant throughout the year as shown by the following tabulation:

	Tariff Jan. 1, 1973 (dollars per short ton)
Sodium carbonate:	
Calcined (soda ash)	2.40
Hydrated and sesquicarbonate	2.00
Sodium sulfate:	
Crude (salt cake)	Free
Anhydrous	.25
Crystallized (glauber salt)	.50

Table 3.—U.S. exports of sodium carbonate and sodium sulfate

(Thousand short tons and thousand dollars)

Year	carbonate Sodium		Sodium sulfate	
	Quantity	Value	Quantity	Value
1971	437	15,400	66	1,825
1972	480	[r] 18,911	29	926
1973	425	16,064	45	2,049

[r] Revised.

Table 4.—U.S. imports for consumption of sodium sulfate

(Thousand short tons and thousand dollars)

Year	Crude (salt cake) [1]		Anhydrous		Total [1]	
	Quantity	Value	Quantity	Value	Quantity	Value
1971	236	4,108	32	559	268	4,667
1972	226	4,082	73	1,275	299	5,357
1973	240	4,054	80	1,602	320	5,656

[1] Includes glauber salt as follows: 1971, none; 1972, 50 long tons ($1,491); 1973, 98 long tons ($2,200).

Table 5.—U.S. imports for consumption of sodium carbonate and bicarbonate in 1973

(Thousand short tons and thousand dollars)

	Quantity	Value
Soda ash	10	756
Sodium bicarbonate	6	260
Total	16	1,016

WORLD REVIEW

Argentina.—The Government of Argentina has exercised controls over the exportation of goods to conserve materials for local utilization if they are in short supply. Specifically mentioned in the order were carbonate and bicarbonate of soda.[3]

The 1971 production of sodium sulfate (mirabilite) was 21,700 short tons.[4] Production in 1973 was estimated at 40,000 tons.

Canada.—Salt cake production in 1973 was 525,000 tons, an increase of 3.6% over that of 1972. Canada consumed 81% of its production, 90% of which went to the making of pulp and paper. The portion going into the manufacture of synthetic detergents however, showed the largest gain. Exports, primarily to the United States, increased 12%. Production for 1974 was predicted to be about 10% above the present rate.

Six producers of natural salt cake in Saskatchewan and Alberta produced 92%

[3] U.S. Embassy, Buenos Aires, Argentina. State Department Telegram, Feb. 15, 1974, p. 1.

[4] U.S. Embassy, Buenos Aires, Argentina. State Department Airgram A-240, May 17, 1973, p. 1.

of the country's output. Three smaller companies produced synthetic or byproduct salt cake in Ontario and Nova Scotia. There were two synthetic soda ash plants in Canada, one in Manitoba and one in Ontario. A new chlorine-caustic plant rated at 65,000 tons of caustic soda per year was being built at Becaneour, Quebec. It is scheduled to be onstream by spring 1975.

Chad.—Lake Chad was a good potential source of trona (termed "natron" in reports from Chad), but the 1973 production from this source was only 7,000 tons. The material was collected by hand from incrustations around the naturally alkaline lake and was continually replaced by solar evaporation of the lake water. Modern extraction equipment and rail transportation were necessary for large-scale exploitation of this source of soda ash.

Chile.—Sodium sulfate production figures for 1972 were published during 1973[5] and are as follows in short tons:

From natural sources	5,413
From the nitrate industry	40,938
Total	46,351

The government-owned nitrate monopoly announced that, it hoped to spend $32.3 million on updating the equipment and plants for producing various chemicals, among them sodium sulfate.[6]

The Central Bank of Chile devalued the bankers rates for selected exports and imports. The list included sodium sufate.[7]

Japan.—All of the soda ash produced in Japan was synthetic rather than natural, but its volume, 1,374,000 tons in 1973,[8] made it a large contributor to world supply. In spite of this large production, soda ash was in short supply in Japan in 1973. Increase in capacity of the Solvay plants was not planned, but importation of naturally derived soda ash from Wyoming was anticipated.

Kenya.—There were extensive trona deposits at Lake Magadi and the 1973 production was estimated at 197,000 tons. Only 16% of this was consumed in Africa and the rest was exported primarily to India, Japan, and the Philippines. The company which extracted the trona was called the Lake Magadi Soda Company Ltd., and was a subsidiary of the British firm, Imperial Chemical Industries, Ltd. (ICI). The raw material from the lake was calcined in Kenya before shipment. Trona reserves in Lake Magadi were estimated at 100 million tons.

Mexico.—The apparent consumption of soda ash in Mexico in 1973 was estimated to be 453,100 short tons. There were two soda ash plants in Mexico and a third being planned at Pajaretos, Vera Cruz.

United Kingdom.—A strike of British coal miners had a direct effect on United Kingdom soda ash output since coal, reduced to coke, was used in calcining limestone to reagent lime for the production of soda ash. The cutback was about 25% of the previous rate, and this had a "domino effect" on the glass and paper industries and subsequently on all products which were packaged in paper or glass. Little relief was obtained from abroad because of the worldwide shortage of soda ash.[9]

The sodium bicarbonate industry of England operated at nearly full capacity throughout 1973.[10]

The Mond Division of ICI, announced a modernization program of its 47-year-old Solvay soda ash works at Northwich, Cheshire. Total expenditure was reported to be £3.25 million ($7.7 million U.S.)[11]

TECHNOLOGY

The Japanese have devised and brought onstream a full-scale plant for producing metallic sodium by an improved method.[12] The process features reduced cost because of (1) lower operating temperature; (2) higher current efficiency; (3) lower labor costs; and (4) almost complete elmination of corrosion. The process starts by the creation of a sodium amalgam in a mercury-electrode electrolytic cell in which brine, instead of fused sodium chloride, is the electrolyte. The sodium amalgam is then transferred to a second cell in which this alloy is used as the anode and a perforated iron plate is

used as the cathode. The second electrolyte is a mixture of fused caustic soda, sodium iodide, and sodium cyanide held at a temperature of about 230° C (446° F) and kept under an atmosphere of hydrogen. The metallic sodium is drawn off continuously and is purified to remove the traces of mercury. Metallic mercury is, of course, recovered and recirculated back to the first electrolytic cell.

Stone

By Harold J. Drake [1]

Production of stone in 1973 totaled 1.1 billion tons valued at $2 billion. The quantity and value were 15% and 19%, respectively, above those of 1972. Most of the rise was attributed to increased output; a lesser share was due to expanded coverage of the crushed stone industry. Production of crushed stone totaled 1.06 billion tons valued at $1.9 billion compared with 919 million tons valued at $1.6 billion in 1972. Approximately 69% was used for construction aggregate, 11% for cement manufacture, 4% for agricultural purposes, and 3% for flux stone. Production of dimension stone rose 6% in quantity to 1.6 million tons but declined 5% in value to $86.0 million. Production of granite rose 15%, and sandstone, quartz, and quartzite, 28%, whereas production of marble was off 32%, and limestone and dolomite declined 10%.

Crushed stone was produced in every State except Delaware. Principal producing States were California, Illinois, Florida, Texas, Ohio, and Missouri, which, in the aggregate, produced 32% of the total U.S. output. Dimension stone was produced in 44 States with Georgia, Indiana, Ohio, Pennsylvania, and Vermont accounting for 55% of the total. Massachusetts, Minnesota, and Wisconsin also accounted for large tonnages.

Price changes for stone were mixed in 1973. The average unit value for all crushed stone rose $0.08 to $1.80 per ton. The corresponding figure for dimension stone was $54.36, off $6.55 per ton. The value of imports of stone was up 12% while that of exports was up 18%.

Legislation and Government Programs.—The National Science Foundation (NSF) announced plans to conduct a study of the crushed stone industry to determine the possibility of applying the sophisticated technology of the aerospace industry to traditional industries. The study will be conducted for NSF by the National Crushed Stone Association, Washington, D.C., and Martin Marietta Corp., Baltimore, Md. In the 1972 National Limestone Institute Safety Competition, top safety honors were awarded to Suwannee Mine, Florida Rock Industries, Inc., Live Oak, Fla.; Monroe Quarry, The France Stone Co., Monroe, Mich.; Pitts Quarry, Pitts Quarry Inc., Ashley, Ill.; Custar Mine, Pugh Quarry Co., Custar, Ohio; and Hillview Quarry and Volstad Quarry, Martin Volstad, Carrollton, Ill. These operations had the best safety records in the five categories of plants comprising the contest conducted by the Bureau of Mines, U.S. Department of the Interior, in cooperation with the National Limestone Institute.

DIMENSION STONE

DOMESTIC PRODUCTION

Production of dimension stone in 1973 increased 6% in quantity but declined 5% in value from the 1972 levels. The advance in volume was attributed to increased construction activity. Output totaled 1.6 million tons valued at $86.0 million. Production of granite totaled 713,000 tons valued at $46 million, rises of 15% in quantity and 8% in value from the preceding year. Dimension limestone and dolomite recorded declines of 10% and 17% in quantity and value, respectively, to 370,000 tons valued at $11.9 million. Production of sandstone, quartz, and quartzite was up 28% in quantity and 10% in value to 296,000 tons valued at $8.4 million. Production of marble totaled 48,000 tons valued at $10.1 million compared with 71,000 tons valued at $16.5 million in 1972. Production of slate rose both in quantity and value whereas that of other types of dimension stone fell 3% in quantity and 21% in value.

CONSUMPTION AND USES

Apparent consumption of dimension stone was valued at $125 million, a level virtually unchanged from the preceding year. A decline in value of domestically produced stone was offset by a 12% increase in the value of imports. The share of the U.S. dimension stone market supplied by U.S. producers was 67%.

In 1973, the domestic market for dimension stone, in terms of value, was divided into 44% granite, 10% limestone and dolomite, 23% marble, 7% sandstone, quartz, and quartzite, and 16% slate and other dimension stone. Apparent consumption of granite totaled $54.5 million, up 5%, and that of marble was $28.6 million, down 12%. Considerable quantities of these kinds of dimension stone are also imported annually. Consumption of limestone and dolomite was valued at $11.5 million, off 20%, and that of sandstone, quartz, and quartzite totaled $8.4 million, up 10%. U.S. producers normally supply the great bulk of these types of stone. Consumption of slate and other kinds of stone rose 11% and 17%, respectively, from the levels of 1972.

The principal uses for domestically produced rough dimension stone were in monumental, architectural, and construction applications. Consumption of monumental stone totaled $12.3 million, that of architectural stone, $6.5 million, and that of construction stone $4.1 million. The remainder went for flagstone and numerous other uses. Consumption of domestically produced dressed stone was valued at $61.5 million, most of which consisted of cut stone ($20.7 million) and monumental stone ($14.2 million). The value of sawed stone totaled $4.5 million. Consumption of dressed house stone veneer was valued at $3.5 million, curbing, at $7.8 million, and roofing and millstock slate, at $5.1 million. The remainder was used principally in construction and flagging.

PRICES

Average values for dimension stone in 1973, as reported to the Bureau of Mines, were as follows, in dollars per ton:

	Building		Monumental, rough and dressed	Flagging
	Rough	Dressed		
Granite	$32.12	$ 86.55	$63.70	--
Marble	54.29	290.24	--	--
Limestone	19.15	51.61	--	$21.50
Sandstone	18.16	50.19	--	39.33
Slate	--	145.43	--	34.77
Miscellaneous	14.42	60.57	--	--

FOREIGN TRADE

U.S. exports of dimension stone declined 5% to $2.8 million. The export market has not been a significant outlet for U.S. producers and in 1973 accounted for only 3% of their output. Canada and countries in South America such as Venezuela and Chile have been the principal foreign markets.

Imports of dimension stone supplied a significant share of the U.S. market for dimension stone. In 1973, imports were valued at $41.5 million, compared with $37.4 in 1972, and supplied 33% of the U.S. market. Increased shipments were recorded for marble, at $18.5 million; travertine, at $3.3 million; slate, at $6.5 million; other stone, at $4.5 million; and limestone at $188,000. Imports of granite, however, declined 9% to $8.6 million. Imports of marble and travertine, which accounted for 45% of the total value of imports, rose 14%, slate rose 15%, and miscellaneous stone rose 40%. The principal marble item, slabs and paving tiles, rose 20%. Imports of whiting rose 57% to $1.2 million.

As in past years, Italy and Portugal supplied most of the marble and travertine imports. Granite was imported principally from Italy and Canada. Numerous other countries supplied the remainder.

WORLD REVIEW

Greece.—An estimated 400 to 500 quarries operated by 250 companies produced marble in 1973. Production has averaged about 200,000 tons in recent years and is expected to be three times greater by 1980. Most of the marble produced goes to the building industry as dimension stone, but some was ground.

United Arab Emirates.—Marble was produced in the Emirate of Ajman not far from the town of Ajman. Output totals about 60 square yards per day but is expected to double during 1974. All of the output is used locally.

CRUSHED STONE

DOMESTIC PRODUCTION

Production of crushed stone in 1973 totaled 1.06 billion tons valued at $1.9 billion compared with 919 million tons valued at $1.6 billion in 1972. The new high in output was attributed in part to increased demand and in part to expanded coverage of crushed stone producers.

The sharp gain in total production was led by limestone and dolomite, which increased 15% in quantity and 21% in value. Granite also recorded sharp production gains of 13% and 19% in quantity and value, respectively. Production of traprock rose 9% in quantity and 11% in value, corresponding figures for sandstone, quartz, and quartzite were 13% and 20%. Other types of stone, which accounted for a lesser portion of total output also recorded gains in output. In quantity and value, shell was up 20% and 27%, respectively, and other stone was up 64% and 89%, respectively. In contrast, marble was off 10% and 6% in quantity and value, respectively, and output of marl was off 12% in quantity and 15% in value.

Domestic producers have encountered some difficulties in meeting the heavy demand in recent years for crushed stone. Shortages in labor and of transportation vehicles were common, and high interest rates have delayed construction of new facilities. Zoning laws and conformance with environmental regulations have served, in many instances, to restrict production.

The problems inherent in the steadily increasing demand for crushed stone must be reconciled with societal demands for environmental quality.[2] Rapid growth and technological development in recent years have created a need for careful internal appraisal of the industry and its place in society. Management science in planning, operating, and evaluating operations in the aggregate industry is a step in this direction.[3] In addition, it is essential to differentiate costs that comprise fixed capital and working capital and how to understand the functions of depreciation for fixed assets.[4]

Several studies were made of the utilization of alternative materials and waste materials for aggregate purposes.[5] Successful utilization of a depleted gravel pit as a sanitary landfill operation may lead one company to utilize an abandoned rock quarry in a similar manner.[6] Key to the success of the operation was the use of a thin layer of asphalt pavement that prevented liquids from permeating into surrounding soils. Perhaps one of the most significant decisions facing crushed stone producers is land reclamation when quarries are depleted. Early planning for industrial or residential use of mined-out areas can lead to considerable savings in time and money.[7]

A number of new plants were planned or opened and numerous existing plants underwent modernization and expansion. Ivy Corp., Atlanta, Ga. announced plans for construction of a major new plant and the expansion of existing operations in

northern Georgia. A new plant opened by Melvin Stone Co., Melvin, Ohio, reportedly uses 40% less labor than its old plant.[8] Erie Stone Co. modernized its crushed stone plant at Huntington, Ind., and now produces over 1 million tons per year of crushed limestone.[9] Other plant expansions were reported by Maule Industries, Inc., Miami, Fla., Southern Illinois Stone Co., Buncombe, Ill., Marblehead Lime Co., Gary, Ind., Florida Mining and Materials Co., Brookville, Fla., and MCQ Industries, Inc., Columbus, Ohio.

Portable crushed stone plants were used widely by the industry. Ivey Construction Co., Mineral Point, Wis., used a 300-ton-per-hour portable crushing and screening plant to service 10 quarries.[10] V. H. Collender Co., Pittsfield, Ill., used a completely roadable crushing and screening plant to supply as much as 900,000 tons of crushed limestone per year from several quarries.[11] Nesbitt Contracting Co., Mesa, Ariz., mounted crushers and screens on a semitrailer frame and, along with other portable equipment, services as many as a dozen different quarries in a year.[12] Gilpatrick Construction Co., Inc., Riverton, Wyo., used specially designed portable equipment to operate at numerous sites.[13]

Gordon H. Ball, Inc., Black Butte, Calif., used a portable plant to process volcanic lava for use as a construction aggregate.[14] Monitoring of portable plants was accomplished using an airplane and a helicopter.[15] One of California's largest aggregate producers. Livingston-Graham, Inc., El Monte, Calif., used a minicomputer-based information-control subsystem to improve profits and the utilization of equipment and manpower.[16]

CONSUMPTION AND USES

Apparent consumption of crushed stone in 1973 totaled 1.06 billion tons valued at $1.9 billion. Consumption was equivalent to production inasmuch as imports and exports were about equal. Consumption of limestone and dolomite totaled 774 million tons valued at $1.3 billion, while that of granite totaled 121 million tons valued at $216.9 million. Comparable data for 1972 for limestone and dolomite were 672 million tons valued at $1.1 billion, and for granite, 106 million tons valued at $182.9 million. Consumption of traprock totaled 84 million tons valued at $177.7 million, up from 77 million tons valued at $159.8 million in 1972. In the aggregate, these three types of crushed stone accounted for 92% of total consumption. Consumption of marl totaled 2.3 million tons valued at $3.0 million, marble, 2 million tons valued at $23.4 million, and other kinds of stone, 23.5 million tons valued at $46.2 million. Consumption of shell increased to 19.9 million tons valued at $37.6 million.

Construction continued to be the principal market for crushed stone. In 1973, approximately 735 million tons, two-thirds of total consumption, was used as aggregate. Roadbase stone accounted for 258 million tons, concrete aggregate, 153 million tons, bituminous aggregate, 102 million tons, and unspecified aggregate, 130 million tons. Consumption in each of the major use categories was well above 1972 levels. Other major uses, apart from aggregate use, recording consumption gains were cement, at 115 million tons, up 6%, agriculture, at 39 million tons, up 39%, lime manufacture, at 34 million tons, up 13%, and fluxstone at 29 million tons, up 12%. The great majority of all other use categories recorded consumption gains.

PRICES

Quotations in Engineering News-Record for carload lots of 1½-inch crushed stone in 1973, exclusive of discounts, ranged from $6.60 per ton in Minneapolis, Minn. and Los Angeles, Calif., to $1.65 per ton in Birmingham, Ala. The average price reported for 12 major cities was $3.44 per ton. Prices for ¾-inch crushed stone ranged from $6.60 per ton in Minneapolis

to $1.65 per ton in Birmingham. The average price for 12 major cities was $3.51 per ton. Prices per ton for industrial fillers and extenders, as reported in the American Paint Journal, were as follows, in dollars:

Silica, amorphous, ultrafine-ground	$69.00
Silica, crystalline	20.50–45.40
Whiting precipitated, surface-treated	48.00
Whiting, dry-ground 325 mesh	14.25–22.00
Whiting, precipitated, U.S.P	50.00–117.00
Whiting, precipitated, technical	33.00–44.00
Whiting, natural, water-ground	39.00

FOREIGN TRADE

Exports of crushed stone in 1973 totaled 3.1 million tons valued at $10.2 million, increases of 11% and 26%, respectively, from the levels in 1972. An increase in shipments of crushed limestone was partially offset by a decline in shipments of other stone. Canada was the principal market with smaller volumes going to countries in Central America.

Imports of crushed stone rose slightly in 1973 to 3.3 million tons valued at $5 million. Of the two principal kinds of stone comprising imports, crushed limestone declined 6% in quantity, and other crushed stone rose 15% in quantity. Imports of dry-ground whiting rose 28% in quantity and 41% in value to 26,653 tons valued at $875,000. Precipitated chalk whiting totaled 3,332 tons valued at $332,000 compared with 1,895 tons valued at $150,000 in 1972.

WORLD REVIEW

Canada.—Production of crushed stone has averaged about 74 million tons valued at $95 million in recent years. Approximately 88% of the total output was limestone; 6%, granite; and 4%, sandstone. The remainder consisted principally of marble, shale, and slate. Roadstone accounted for about 30% of the total output, concrete aggregate about 15%, asphalt aggregate about 9%, and riprap about 3%. A large number of applications accounted for the remainder. Limestone resources of the Province of Alberta were examined, and it was determined that abundant reserves of high-calcium limestone exist in various parts of the Province.[17]

Dominican Republic.—Aluminum Company of America (Alcoa) joined with local business interests to form a company, Complejo Industrial Pedernales, to produce agricultural lime. Initial production, expected in early 1974, will total 60,000 tons. The limestone raw material will be supplied by Alcoa from its mine in Cabo Rojo.

Japan.—Limestone deposits of good quality are widely distributed throughout Japan. Resources were estimated to be about 41 billion tons with an additional 987 million tons of dolomite.[18] In 1972, the latest year for which detailed statistics were available, 277 companies operated 324 quarries and produced 140 million tons of limestone. Of this production, 61% was used in the manufacture of cement; 18%, for flux; 11%, as aggregate; and 6%, for the manufacture of lime. Numerous other uses accounted for the remainder.

South Africa, Republic of.—Coedmore Quarrier, Durban, Natal, in 1973 completed 50 years of crushed stone production.[19] Production, which consisted of quartzite, dolerite, and tillite, was used as concrete aggregate and coarse aggregate for road work. Production in 1972 was about 1.1 million tons.

United Kingdom.—Production of crushed stone aggregate in Great Britain totaled 110 million tons in 1972. Of this tonnage, 35% was used for fill and ballast, 28% for uncoated roadstone, 19% for concrete aggregate, and 18% for coated roadstone. Production of crushed limestone at the Tunstead Quarry owned by Imperial Chemical Industries, Ltd., exceeded 5.5 million tons a year.[20] High-calcium lime was produced for use in ammonia-soda plants and in the manufacture of lime and cement, but lower quality stone was used for roadstone and aggregate.

Amey Roadstone Corporation, Ltd., more than doubled capacity at its Black Rock Quarry near Portishead, Somerset, to 400,000 tons per year.[21] Redland Roadstone, Ltd., and Hoveringham Stone, Ltd., joined together to form R. H. Roadstone, Ltd., to quarry, process, and market dry and coated stone near Nunney, Somerset.[22]

TECHNOLOGY

A study of surveying techniques in the quarrying industry was published.[23] A wide range of methods relating to various situations were outlined to demonstrate the usefulness of minerals surveying. The importance of surge piles between the quarry-primary crushing operation and the remainder of the plant was thoroughly discussed.[24]

It was suggested that an appropriate strength test be employed in conjunction with polished-stone value to determine the suitability of crushed stone as paving aggregate.[25] The aggregate impact test was believed to be the best strength and durability test to use inasmuch as it is simple, rapid, and inexpensive yet is sensitive to variations in fundamental properties of the aggregate. Crushed stone was used to stabilize highway subgrade thus enabling the contractor to use the subgrade as a haul road.[26] The crushed stone was thoroughly mixed with silty, unstable subgrade soil and compacted to form a solid impervious foundation that could be used, prior to paving, as a haul road.

Benefits derived from recycling concrete and asphalt rubble in California included lower costs, saving scarce landfill areas, and extending existing aggregate resources.[27] A method of pelletizing ground limestone, using special clay binders, was developed to allow agricultural limestone to be spread evenly and utilized immediately.[28]

Quarry blasting was the subject of a number of studies. One study developed the basic principles, significant variables and procedures for their integration in designing primary blasts from a widely variable combination of possibilities to achieve safe working and economic production.[29]

Generally accepted rules of thumb on blasting in the quarrying industry and their relationship to hole size and pattern were outlined.[30] More precise blasting designs and patterns were presented to provide quarry operators with an uncomplicated, first-approximation method for designing blast patterns.[31] In southern Florida, a high water table and drilling difficulties led to the development of a unique explosives-loading technique.[32] A metal tube slides down the borehole as it is drilled and remains there until the explosives are loaded, after which it is removed.

Guidelines were set out for selecting primers when blasting with AN-FO.[33] Dewatering of blastholes and the cost reductions inherent thereto were examined.[34]

Factors affecting equipment selection and maintenance were reviewed.[35] Use of hydraulic excavators in quarrying operations has expanded considerably in recent years and real benefits have been gained from their use.[36]

Rippers were used to break up deposits of basaltic and granitic rock,[37] and specially designed trucks were used to reduce the number of trucks required, lower maintenance costs, and speed up the movement of crushed and broken stone during mining and processing operations.[38]

r Revised. W Withheld to avoid disclosing individual company confidential data.
1 Includes irregular shaped stone and rubble.
2 Includes unspecified rough stone for 1972.
3 Less than ½ unit.
4 Includes data for dressed flagging, paving blocks and figure where symbol W appears for granite.
5 Data may not add to totals shown because of independent rounding.
6 Data include small amount of monumental stone (1972), and uses not specified.
7 Includes data for monumental and flagging (1973).
8 Data combined to avoid disclosing individual company confidential data; also include flagging, uses not specified, and figure where symbol W appears for marble.
9 Data include construction stone, flagging and uses not specified.
10 Data include stone used for construction, sawed, uses not specified, and figure where symbol W appears for sandstone, quartz, and quartzite. 1972 data also include monumental stone, and stone used for structural and sanitary purposes.
11 Includes small amount of slate used for house stone veneer.
12 Includes slate used for electrical purposes and where symbol W appears for slate.
13 Includes slate used for aquarium bottoms, building stone, fireplaces, flooring (1972), and uses not specified (1973).
14 Produced by the following States in 1973, in order of value of output and with number of quarries: Hawaii (4), Maryland (4), New Mexico (3), Pennsylvania (3), Virginia (7), California (6), New Jersey (1), Oregon (6), and Washington (3).
15 1972 data include sawed stone and house stone veneer.
16 Data include sawed stone, house stone veneer, flagging and stone used for structural and sanitary purposes.
17 To avoid disclosing confidential data, 1972 figures include stone used for flagging, and structural and sanitary purposes.
18 Includes small amount of uses not specified.
19 Data include stone for paving blocks, structural and sanitary purposes (excluding slate), and uses not specified; slate for aquarium bottoms, building stone, fireplaces, and flooring (1972).

Table 5.—Granite (dimension stone) shipped or used by producers in the United States in 1973, by State

State	Active quarries	Quantity (short tons)	Value (thousands)
California	9	7,764	$591
Georgia	36	244,468	6,884

r Revised. W Withheld to avoid disclosing individual company confidential data.

[1] Produced by the following States in 1973, in order of tonnage: South Carolina, Mississippi, Texas, North Carolina, Michigan, Indiana, and Virginia.

[2] Includes marl used in agricultural limestone, agricultural marl and other soil conditioners and nutrients, and minor amounts of filler.

[3] Data include small amount of fill.

[4] Data include stone used in dense-graded roadbase stone, unspecified aggregate, and fill.

[5] Data may not add to totals shown because of independent rounding.

[6] Includes stone used in manufactured fine aggregate, terrazzo, cement manufacture, asphalt filler, drain fields (1972), fill (1973), roofing aggregate, chips, and granules, waste material, uses not specified, and any data represented by the symbol W in granite.

[7] Includes agricultural limestone, agricultural marl and other soil conditioners, and poultry grit and mineral food.

[8] Includes stone used for abrasives and mine dusting.

[9] Data include stone used in acid neutralization, building products, bedding material (1973) disinfectant and animal sanitation, drain fields, dam construction (1972), magnesium metal manufacture, paper manufacture, roofing aggregates, chips, and granules, stucco, waste material, use not specified, and any data represented by the symbol W in limestone and dolomite.

[10] Data combined to avoid disclosing confidential data. Includes surface treatment and filter stone (1972).

[11] Includes a minor amount of stone used in roofing aggregates, chips, and granules and any data represented by the symbol W in marble.

[12] Includes bituminous aggregate, roofing aggregates, chips, and granules (1973), and any data represented by the symbol W in marble.

[13] Includes ground sandstone, quartz, and quartzite.

[14] Includes stone used in poultry grit and mineral food, building products, drain fields (1973), fill, other filler (1973), roofing aggregates, chips, and granules, waste material (1973), and uses not specified.

[15] Includes stone used for concrete aggregate (1973), bituminous aggregate, and surface treatment aggregate.

[16] Includes stone used for asphalt filler (1973), railroad ballast (1973), riprap and jetty stone (1973), uses not specified and any data represented by the symbol W in shell.

[17] Data include stone used for asphalt filler, bedding material (1973), drain fields, other fillers or extenders, roofing aggregates, chips, and granules, terrazzo (1972), waste material (1973), and uses not specified.

[18] Includes stone used for asphalt and other fillers, cement manufacture, roofing aggregates, chips, and granules, manufactured fine aggregate, abrasives, drain fields, waste material, uses not specified, and data represented by the symbol W in other stone.

[19] Data include stone used in building products, flour (slate), uses not listed in smaller quantities, and uses not specified.

Table 9.—Number and production of crushed-stone quarries in the United States, by size of operation

Sulfur and Pyrites

By Roland W. Merwin [1] and William F. Keyes [2]

Conditions in the sulfur industry improved over those of 1972. Production, shipments, and apparent domestic consumption reached alltime highs. The price position of elemental sulfur increased moderately over that of 1972, reversing the downward trend that had prevailed for several years. Most of the price increases were effective the latter part of 1973, with strong indications at yearend that there would be a substantial improvement in domestic prices in 1974. The improved conditions in the sulfur industry resulted from a continuing upsurge in sulfur demand for fertilizer manufacturing.

There was a substantial increase in the production of both Frasch and recovered sulfur over that of the previous year. However, the production of sulfur in other forms decreased moderately. Shipments of sulfur in all forms by domestic producers increased because of increases in domestic consumption. Production of sulfur in all forms exceeded shipments by a moderate amount, with the excess being placed in Frasch producers' stockpiles as a reserve against forward commitments for this product.

The total value of shipments of sulfur in all forms increased from $194.6 million in 1972 to $207.8 million in 1973. The average net shipment value, f.o.b. mine/plant, for Frasch and recovered elemental sulfur, which accounted for 92% of the total shipments of sulfur in all forms in 1973, increased from $17.03 per long ton in 1972 to $17.84 per long ton in 1973.

The United States maintained its position as a net exporter of sulfur in all forms in 1973. However, net exports were substantially less than those in the previous year as the result of a moderate decrease in exports and a moderate increase in imports as compared to those in 1972. The maintenance of the export-import balance reflected strenuous efforts on the part of domestic producers to maintain their competitive position in both domestic and world markets in the face of strong foreign competition and low price levels.

DOMESTIC PRODUCTION

Frasch Sulfur.—Frasch sulfur accounted for 70% of the domestic production of sulfur in all forms in 1973, compared with 71% in 1972. All of it was produced from Frasch mines in Texas and Louisiana.

In 1973, 12 Frasch mines produced sulfur. The producers and mines in Louisiana were Freeport Minerals Co. at Garden Island Bay, Grand Isle, Grande Ecaille, and Lake Pelto; and Texasgulf, Inc., at Bully Camp. The producers and mines in Texas were Atlantic Richfield Co. at Fort Stockton; Duval Corp. at Culberson; Jefferson Lake Sulphur Co. at Long Point Dome; and Texasgulf, Inc., at Boling Dome, Fannett Dome, Moss Bluff Dome, and Spindletop Dome.

Production of domestic Frasch sulfur increased in 1973, being 4% more than that of 1972 and 2% more than the previous alltime peak production in 1968. This was a reflection of a projected substantial increase in sulfur demand in the domestic fertilizer manufacturing market and an anticipated stable level of demand in foreign markets.

There was a continuing tendency to concentrate production in the larger low-cost mines to counteract the adverse effects of low sulfur prices and increasing production costs. During 1969, 9 producers operated 21 mines. By 1973 this was reduced to 5 producers operating 12 mines. The 12 mines remaining in operation increased their production over that of 1969 by 1,344,000 tons, or 21%. Seven of the mines showed increases in production rates over those during 1969, and the other five registered decreases.

In 1973 the five largest mines, with production rates in excess of one-half million tons per year each, accounted for 78% of the total Frasch sulfur output and 54% of the total production of sulfur in all forms during the year. Three medium-sized mines, with production rates of more than 250,000 tons per year each, contributed an additional 14% of the year's Frasch production. The remaining 8% of the Frasch output came from four smaller mines.

Ten mines, operated by Duval Corp., Freeport Minerals Co., and Texasgulf, Inc., accounted for most of the Frasch production. Only a relatively small portion of the output was obtained from the other two producers, operating one mine each.

Producers' shipments of Frasch sulfur decreased 2% from those in 1972, as a result of slight decreases in demand in both the domestic and export markets. Frasch production exceeded shipments by 167,000 tons, or 2%, with the excess production being placed in producers' stocks as a reserve against forward commitments. Approximately 76% of the shipments were for domestic consumption and 24% for export.

Despite a decline in the quantity shipped, the total value of the shipments, f.o.b. mine, increased by 5% over that of 1972. The average reported unit shipping value, f.o.b. mine, was $18.63 per ton in 1973, compared with $17.39 per ton in 1972. These increases reflected a substantial improvement in sulfur prices in the latter months of 1973.

Recovered Sulfur.—Recovered elemental sulfur accounted for 22% of the total domestic production of sulfur in all forms compared with 19% in 1972. This was a reflection of the rapidly increasing importance of recovered sulfur as a source of U.S. sulfur supply.

Production and shipments of this product in 1973 reached alltime highs with increases of 24% and 27%, respectively, over those in 1972. The total value of shipments increased by 26%. However, the average reported shipment value, f.o.b. plant, declined slightly from $15.60 per ton in 1972 to $15.45 per ton in 1973.

Recovered sulfur was produced at 132 plants in 28 States. Most of the plants were of relatively small size, with only three of them reporting an annual production exceeding 100,000 tons. The 10 largest plants accounted for 37% of the total output, and the combined production of the 5 leading States amounted to 73% of the total. By source, 57% was produced at refineries or at satellite plants treating refinery gases, and 43% was produced at natural gas treatment plants.

The five largest recovered sulfur producers were Exxon Company, U.S.A., Getty Oil Co., Shell Oil Company, Stand-

[2] F.o.b. mine.

ard Oil Co. of California, and Standard Oil Co. (Indiana). Together, their 38 plants accounted for 51% of recovered sulfur production.

The production was nondiscretionary as a byproduct from natural gas and petroleum refinery operations. As such, it was produced and marketed regardless of demand or price and generally sold in close proximity to the points of production. As a result of local competitive factors in the regional markets served by recovered sulfur producers, including competition from Canadian sources in northern areas of the Nation, there were wide variations between the unit sales prices, f.o.b. plant, reported in the different regions of the Nation. This was in marked contrast to the more stable marketing of Frasch sulfur.

The States of Alabama, Florida, and Mississippi continued to emerge as major producers of recovered sulfur. This development was based on the rapidly expanding exploitation of dry sour natural gas and sour natural gas associated with petroleum in the deep Jurassic formations underlying these States. With existing plants increasing their production and with new plants under construction, there was every indication of a substantial increase in recovered sulfur production in this 3-State area within the next few years.

Petroleum refineries, particularly those along the coastal areas of the Nation, continued to install additional sulfur recovery capacity and modify process equipment for the refining of sour crudes in the expectation of increasing imports of this type of petroleum from the Near East. It was anticipated that these actions would sharply increase the production of recovered sulfur from these sources within the next few years.

Byproduct Sulfuric Acid.—The sulfur contained in byproduct sulfuric acid produced at copper, lead, and zinc roasters and smelters during 1973 amounted to 5% of the total domestic production of sulfur in all forms. It was produced at 18 plants in 12 States. Eight acid plants operated in conjunction with copper smelters, and 10 plants operated as accessories to lead and zinc roasting and smelting operations. The five largest acid plants accounted for 57% of the output, and the combined production of five States amounted to 79% of the

[2] Data may not add to totals shown because of independent rounding.

total. The total output was 10% more than that in 1972, and the value of shipments was 6% more than that in 1972.

The five largest producers of byproduct sulfuric acid were American Smelting and Refining Co., The Bunker Hill Co., Kennecott Copper Corp., Phelps Dodge Corporation, and St. Joe Minerals Corp. Together, their 12 plants produced 79% of the output during 1973.

A number of additional byproduct sulfuric acid plants were either under construction in 1973 or in the planning stage. Coupled with increasing production from the existing plants, it was anticipated that this type of production would increase rapidly within the next few years.

Pyrites, Hydrogen Sulfide, and Sulfur Dioxide.—The contained sulfur in these products amounted to 3% of the total domestic production of sulfur in all forms during 1973. Pyrites was produced at three mines in three States, hydrogen sulfide at seven plants in four States, and sulfur dioxide at one plant. Output was 31% less

[1] Includes acid from foreign materials.
[2] Excludes acid made from pyrites concentrates in Arizona, Montana, Tennessee, and Utah.
[3] Excludes acid made from native sulfur.
[4] Data does not add to total shown because of independent rounding.

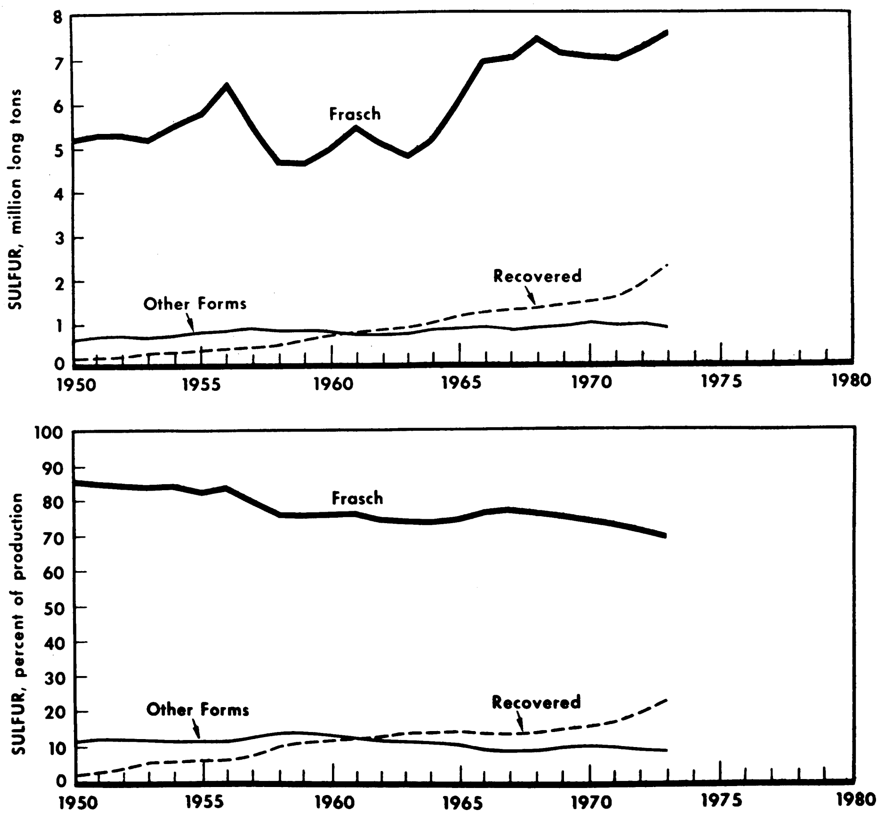

Figure 2.—Trends in the production of sulfur in the United States.

than in 1972. The value of these combined products was 22% less than that in 1972.

The four largest producers of these products were Phillips Petroleum Co. (hydrogen sulfide), Shell Oil Company (hydrogen sulfide), Standard Oil Co. of California (hydrogen sulfide), and Cities Service Co. (pyrites, hydrogen sulfide, and sulfur dioxide). Together, the one mine and seven plants accounted for 97% of the contained sulfur produced in the form of these products.

There was a marked reduction in the production of hydrogen sulfide below that of 1972 as producers found it to be technically and economically more advantageous to directly convert their product to recovered sulfur than to use it as a feedstock to a sulfuric acid plant.

Table 7.—Pyrites, hydrogen sulfide, and sulfur dioxide sold or used in the United States

(Thousand long tons of sulfur content and thousand dollars)

Year	Pyrites	Hydrogen sulfide and sulfur dioxide	Total	Value

1972	283	149	432	9,227
1973	212	88	300	7,188

CONSUMPTION

Apparent consumption of sulfur in all forms reached an alltime high in 1973, being 4% more than that of 1972. This high level of consumption reflected an improvement in demand by the domestic fertilizer industry. With many new phosphoric acid plants either under construction or in the planning stages, there were indications that this condition would continue to improve during the next several years.

Sulfur for domestic consumption was obtained mainly from domestic sources: Frasch 55%, as compared to 58% in 1972; recovered 24%, as compared to 20% in 1972; and combined byproduct sulfuric acid, pyrites, hydrogen sulfide, and sulfur dioxide 9%, as compared to 10% in the previous year. The remaining 12% of the sulfur was obtained by imports of Frasch and recovered sulfur, with the percentage of supply being the same as in 1972. The decrease in the domestic Frasch industry's share of the domestic market and the increase by the domestic recovered sulfur industry continued a long-range trend.

The apparent sales of domestic Frasch sulfur to domestic consumers decreased by 100,000 tons, or 2% below those in 1972. Domestic producers of recovered sulfur increased their apparent sales to domestic consumers by 524,000 tons, or 27% over

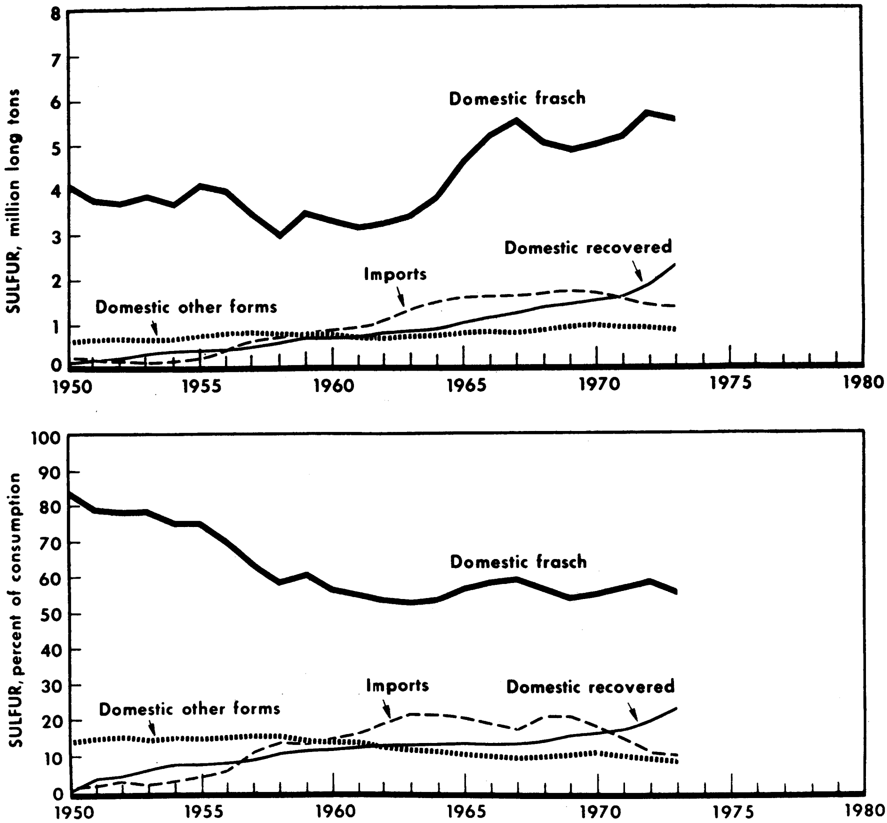

Figure 3.—Trends in the consumption of sulfur in the United States.

those in 1972. The reported sale or use of byproduct sulfuric acid, pyrites, hydrogen sulfide, and sulfur dioxide by domestic producers in the domestic markets decreased by 78,000 tons, or 8%. Imports of elemental sulfur for domestic consumption increased by 34,000 tons, or 3% above imports of elemental sulfur and pyrites for domestic consumption in 1972.

Approximately 90% of the sulfur consumed was in the form of sulfuric acid. The manufacture of fertilizers accounted for approximately 54% of all sulfur consumption. Together, plastic and synthetic products, paper products, paints, nonferrous metal production, and explosives accounted for approximately 21% of demand. The remaining 25% was used for a large number of relatively small individual end uses.

The approximate distribution of consumption was as follows: Southern States (except Florida) 39%; State of Florida 30%; North-Central States 11%; Western States 12%; and Northeastern States 8%.

STOCKS

Yearend producers' stocks of combined Frasch and recovered sulfur were 3% more than those at yearend 1972 because production of Frasch sulfur exceeded combined shipments to the domestic and export markets by 167,000 tons, with the excess being added to the producers' stockpiles. The combined yearend stocks amounted to approximately a 5-month supply based on the 1973 domestic and export demands for domestically produced Frasch and recovered sulfur.

PRICES

Producers of Frasch and recovered elemental sulfur report the value of their shipments f.o.b. mine or plant. Such values vary widely between different mines or plants, depending upon prevailing selling prices in the markets they individually serve and the transportation costs to these markets.

The values f.o.b. mine or plant do not necessarily reflect the ultimate selling prices because most sales of elemental sulfur, generally in the form of molten sulfur, are made ex-terminal near the point of consumption. Due to the highly competitive nature of the transactions, prices are not generally made available. The trade journal, Sulphur, reported bimonthly on sales prices by areas on the basis of the best information available.

Early in 1973 several major Frasch sulfur producers independently announced increases in the price of liquid sulfur ex-terminals, ranging upward to about $3 per ton in the Tampa, Fla., area, to be effective as soon as contractual agreements permitted. Additional price increases of about $3 per ton, under similar conditions, were announced at midyear 1973.

These Frasch sulfur price increases were accepted by major consumers because they recognized that Frasch sulfur production costs had increased, because they were actively seeking assured forward commitments of sulfur to supply large phosphoric acid plants that were either under construction or in the planning stage, and because the greater profitability of the phosphate fertilizer manufacturing industry allowed them to pay higher prices for sulfur.

However, because of contractual agreements, the higher price levels were only partially effective by midyear and did not generally become fully effective until near yearend. As a result, the sales values of shipments of Frasch sulfur f.o.b. mine during 1973 increased only $1.24 per ton, or 7% more than the prices prevailing during 1972.

By the end of 1973, an increasingly strong demand for sulfur by fertilizer manufacturers created a situation in which sulfur was approaching short supply in the major fertilizer-manufacturing areas. It became evident that this situation, coupled with further increasing costs of producing Frasch sulfur, would lead to price increases in Tampa, Fla., and other fertilizer centers in early 1974.

In contrast to the Frasch industry, with a relatively stable marketing pattern, the recovered sulfur industry experienced marketing problems in some areas of the Nation. Because of regional competitive factors, some areas were able to increase their unit shipment values f.o.b. plant, whereas other areas registered sharp decreases. Overall, the reported unit shipment values in 1973 were slightly lower than those reported in 1972.

FOREIGN TRADE

The United States maintained its position as a net exporter of sulfur in 1973. However, net exports were substantially less than in 1972. Exports of sulfur in all forms in 1973 were 4% less than those in 1972, and imports in all forms were 3% more than those in 1972. As a result, total exports of sulfur exceeded total imports by only 555,000 long tons in 1973, as compared to 664,000 tons in 1972, a decrease of 109,000 tons, or 16%.

The maintenance of the export-import balance reflected strenuous efforts on the part of domestic producers to maintain their competitive position in both domestic and world markets in the face of strong foreign competition and low price levels. Favorable factors included limitations on the importation of elemental sulfur from Mexico because of antidumping duties under provisions of the Antidumping Act and a continuing strong demand for sulfur in foreign markets. The European market, in particular, continued to rely upon U.S. Frasch producers as an assured source of supply during a period in which logistic problems limited sulfur exports from Canada, and production problems in Poland made that source of supply uncertain.

Exports were almost entirely in the form of elemental Frasch sulfur. The tonnage of crude sulfur exported during 1973 was 4% less than in 1972. However, the total value increased by 6%, with the average reported value of $17.55 per ton in 1972 increasing to $19.38 per ton in 1973. Together, Belgium and the Netherlands received 63% of these exports, mainly for transshipment to other European Community (EC) countries. Brazil, with 13%, was the third largest customer.

Imports of sulfur consisted largely of recovered sulfur from Canada and Frasch sulfur from Mexico. Imports from Canada in 1973 were 4% more than those in 1972. Imports from Mexico were 12% more than those in 1972, but were only 52% of the average imports during the years 1969 through 1971, prior to the imposition of antidumping duties. However, in the latter part of 1973, with higher prices in the Tampa, Fla., market mitigating the effects of the antidumping duties, imports from Mexico into this area began to increase. There were indications that these conditions would lead to substantial increase in imports from Mexico. The total quantity of elemental sulfur imported in 1973 was 7% more than in 1972, and the total value decreased by 9%. The average declared customs value in 1973 was $12.06 per ton, whereas in 1972 the average was $14.31 per ton.

There were no imports of pyrites from Canada in 1973; shipments were phased out in 1972 because this product was no longer competitive with low-cost domestic elemental sulfur.

Acting under the provisions of the Antidumping Act, the U.S. Government completed an ongoing investigation of the sales of Canadian elemental sulfur within the United States. The investigation was initiated in early 1972, being mainly based on a complaint that sales of Canadian sulfur were being made at less than cost of production.

On January 17, 1973, the U.S. Department of the Treasury announced a 3-month extension of the investigation because certain complex issues had not yet been resolved relating to the treatment of possible sales below cost of production.[3]

On April 19, 1973, the Department of the Treasury announced two determinations.[4] First, the prices at which foreign merchandise is sold in the home market or for exportation to countries other than the United States would be used in determining the "fair value" of such merchandise regardless of whether the prices represented less than the cost of production. Second, it issued a Withholding of Appraisement notice directed against imports of elemental sulfur from Canada on the basis that there were reasonable grounds to believe or suspect that selling prices were below those allowed by the Antidumping Act. The practical effect of these determinations was to limit the investigation to a conventional comparison between purchase prices and home market prices

rather than to consider the cost of production.

On July 20, 1973, the Department of the Treasury announced its determination that elemental sulfur from Canada was being, or was likely to be, sold in the U.S. market at less than fair value within the meaning of the Antidumping Act.[5] On July 26, 1973, the U.S. Tariff Commission announced that, having received this advice from the Department of the Treasury, it was instituting an investigation to determine whether an industry in the United States was being, or was likely to be, injured or prevented from being established by reason of these imports.[6]

The Tariff Commission on October 23, 1973, announced that it had determined by a vote of 3 to 2 that an industry in the United States was likely to be injured by reason of the importation of elemental sulfur from Canada that was being, or was likely to be, sold at less than fair value within the meaning of the Antidumping Act.[7] On December 12, 1973, the Department of the Treasury announced that it was adding elemental sulfur from Canada to the list of findings of dumping currently in effect.[8] These actions made sulfur imports from Canada subject to antidumping duties.

WORLD REVIEW

The world's production of sulfur in all forms increased substantially over that of 1972, mainly because of an increase in the production of Frasch and recovered elemental sulfur. Major increases were shown in the production of Frasch and recovered sulfur in the United States, recovered sulfur in Canada, and Frasch sulfur in Mexico and Poland. Additionally, the U.S.S.R. was reported to have increased its production of sulfur in all forms. For the world as a whole, the production of pyrites remained fairly stable.

World demand for sulfur also increased substantially over that of 1972, primarily because of a continuing upsurge in demand for use in fertilizer manufacturing. However, production exceeded demand by a somewhat wider margin than in 1972 as reflected by an increase in producers' stocks, particularly in the case of Canadian recovered sulfur.

Because of logistic problems that restricted the movement of sulfur from certain major producing areas to world markets, there was more of an effective equilibrium between available supply and consumption than the overall statistics would suggest. These logistic problems, coupled with the increasingly strong demand, created a tight supply position for sulfur in most of the major consuming areas of the world in the latter part of 1973. As a result, sulfur prices began to increase during this period.

There was a continuation of the trend toward a basic restructuring of world sulfur supply sources, with increasingly larger supplies being obtained from secondary sources such as petroleum refineries and plants treating sour natural gas. However, the Frasch sector of the industry, with its well-established production and distribution facilities and ample stocks on hand, continued to maintain its position with consumers as the most reliable source of supply. The pyrites industry continued to become less attractive to the major sulfur-consuming countries of the world as a source of supply.

There was a continuing trend toward the use of liquid sulfur tank ships in international trade and the installation of liquid sulfur terminal facilities at points of consumption.[9] This was being brought about because of environmental problems associated with the storage and shipment of dry bulk elemental sulfur with its associated dust problems, and the preference of consumers for the delivery of liquid sulfur ex-terminals. Further implementation of this method of distribution will require large capital investments by sulfur producers.

Stabilization of conditions in the Middle East and the prospective reopening of the Suez Canal increased the probability that the Persian Gulf area would emerge as a major source of world sulfur supplies. The countries bordering on the Persian Gulf have tremendous reserves of sulfur that could be recovered as a byproduct during the exploitation of their deposits of sour petroleum and sour natural gas. In the past these sulfur resources have only been

[9] Sulphur (London). Seaborne Trade in Liquid Sulphur. No. 108, September–October 1973, pp. 35–40.

exploited to a limited extent. However, with announced plans for large refinery installations, petrochemical complexes, and natural gas liquefaction plants, it appeared inevitable that the production of recovered elemental sulfur would increase very rapidly. Additionally, the reopening of the Suez Canal would permit the marketing of this sulfur in European markets.

Canada.—The Province of Alberta's production of recovered elemental sulfur increased from 6.5 million long tons in 1972 to 7.0 million tons in 1973 as the result of the completion of several new plants. Alberta's shipments of sulfur increased from 3.1 million tons in 1972 to 3.9 million tons in 1973, mainly because of an increase in offshore shipments through the port of Vancouver, British Columbia. With production continuing to exceed shipments by a wide margin, producers' yearend stocks increased from 8.7 million tons in 1972 to 11.8 million tons in 1973. Although producers announced substantial increases in prices in the latter part of 1973, contractual arrangements did not permit them to become effective until after the close of the year. As a result, the value of the marketed sulfur, f.o.b. plant, remained low, in the range of $5.50 to $6.00 per ton for the year as a whole.

With no new major sulfur recovery plant construction currently underway, it appeared that Alberta's recovered sulfur production had leveled off at approximately 7 million tons per year. The rated nameplate capacity of these plants for 1974 was 25,000 tons per day, or approximately 9 million long tons of sulfur per year.[10] However, these plants do not operate at full capacity throughout the year because of the cyclic demand for natural gas and downtime for maintenance.

Efforts were underway to solve logistic problems limiting the shipment of Alberta's sulfur to world markets. One development was the shipment of sulfur to the port of Churchill, Manitoba, for transshipment to Europe during the forthcoming summer shipment season on Hudson Bay. Additionally, consideration was being given to shipping to Great Lake ports, also for transshipment to the European market. It was projected that total sales of Canadian sulfur would reach 4.7 million tons in 1974, with stockpiles accumulating at a slower rate than in previous years and leveling off at around 20 million tons in 1980.[11]

Germany, West.—This nation continued to move toward self-sufficiency in sulfur supply, mainly as the result of an increase in recovered sulfur capacity. Sour natural gas treatment plants in the Ems/Weser zone of northern West Germany at Voigtei, Duste, and Grossenkneten increased production to about 350,000 tons of recovered sulfur per year.[12]

Iraq.—Production of Frasch sulfur at the Mishraq mine of Iraq National Minerals Co. was being expanded from its initial production of 250,000 tons per year to 1 million tons per year. This sulfur was being shipped by rail to the Iraqi port of Umm Qasr on the Persian Gulf near Basrah.[13] While the Mishraq operation is of potential importance as a source of Frasch sulfur supply, inadequate transportation facilities between the mine and the port have been a limiting factor, pending planned improvements to the railroad and port facilities and the purchase of additional liquid tank cars.

Japan.—Following a long-range trend, there was a further restructuring of the Japanese sulfur industry in 1973. Native sulfur ores, formerly a major source of supply, accounted for only an insignificant portion of the nation's sulfur output. Additionally, the pyrites industry was becoming of lesser importance as a source of supply, with a prospect that it would be largely phased out within the next decade. Counterbalancing the declines in the native sulfur ore and pyrites industries has been a very rapid growth in recovered sulfur output at petroleum refineries. Additionally, there has been a rapid growth in the production of sulfuric acid at smelters treating domestic and imported nonferrous sulfide ores and concentrates.

Contrary to general expectations, there was a moderate shortage of sulfur in all forms in 1973. However, it was anticipated that the planned expansion in desulfurization capacity at refineries and pollution control measures would result in an over-

[10] Oilweek (Canada). Gas Processing Plant Capacities 1974. V. 24, No. 49, Jan. 21, 1974, pp. 30–32.

supply situation in the near future. It was proposed to alleviate overproduction by promoting exports to Asiatic markets where the competitive power of Japan's product would be enhanced due to her advantageous position as regards transport costs.[14]

Mexico.—Conditions in the Frasch-based sulfur industry improved substantially over those in 1972, with increases in both production and exports. This industry had been adversely affected by the imposition of antidumping duties on the importation of Mexican sulfur into United States; historically, the U.S. market had been Mexico's major customer.

Mexico appeared to have successfully resolved this serious problem by a rather complete reconstruction of its export marketing patterns, with penetrations into the South American and Far East markets. The program was aimed at extending the concept of liquid sulfur transportation to South American markets and possibly to the Far East. Additionally, consideration was given to establishing a sulfur distribution center on the Pacific Coast of Mexico.[15]

Poland.—Poland continued to improve its position as one of the world's largest producers and exporters of elemental sulfur. A reorganization of the industry in the form of further decentralization became effective in late 1973. It was anticipated that decentralization would improve Poland's position in the production and marketing sectors of the industry. Poland's export capability was increased by the addition of a third liquid sulfur tank ship. Additionally, plans were being made for the construction of two additional liquid sulfur tankers with the expectation that they would be placed in operation by 1975.[16]

U.S.S.R.—The production of sulfur in all forms increased substantially over that of 1972. While pyrites was still a substantial source of sulfur production, the U.S.S.R. continued to emphasize the production of native sulfur. The principal native sulfur producing centers continued to be Rozdol and Yavorov (West Ukraine), Gaurdak and Shorsu (Central Asia), and the Volga group of the Kuybyshev sulfur complex. The Rozdol chemical complex was the country's major producer of native sulfur and, with the Gaurdak combine,

[1] In addition to countries listed, the Philippines produced less than 100 tons of sulfur annually in 1971 and 1972 from unspecified sources; output in 1973 was reportedly nil.

[2] Year beginning March 21 of year stated.

[3] Includes small quantity of byproduct sulfur recovered from sulfide ores as well as sulfur content of sulfur ores.

[4] Available sources do not divide Japanese 1973 sulfur output by type (ore and other elemental); because output from ore has been declining, the total undivided figure has been reported under other elemental.

[5] From petroleum refining.

[6] Includes in part sulfur content of H_2S converted directly into sulfuric acid.

[7] From processing of natural gas, petroleum, tar sands, and sulfide ores.

[8] From petroleum refining and smelting of sulfide ores.

[9] From petroleum refining and natural gas processing.

[10] From petroleum refineries only. Excludes an unreported quantity recovered from sulfide ores, which is included above (see footnote 4).

[11] From distillation of petroleum and lignite and from reduction of SO_2 gas.

[12] Less than ½ unit.

provided the bulk of the country's sulfur requirements. Output of sulfur at Gaurdak was expected to increase substantially during the next few years.

Increasing attention was also being given to the recovery of secondary sulfur. This included the production of recovered elemental sulfur at refineries and natural gas processing plants, and the production of sulfuric acid at nonferrous metal smelters.

TECHNOLOGY

The energy crisis combined with environmental goals to force a reappraisal of prospects for sulfur recovery from new sources. Most of the reviews and research published during the year were directed towards various scrubbing systems, designed to be added on to existing powerplants, or industrial plants, to reduce SO_2 emissions to levels called for in current regulations. Among these systems, alkaline scrubbing with lime or limestone was far in advance in respect to research performed and experimental installations operating. Nevertheless, it was still beset with severe problems of cost, reliability, and waste disposal; thus recovery systems in which the scrubbing medium is circulated and a useful sulfur product is obtained received increasing attention.

During the year some 26 pilot installations were operated to test lime or limestone scrubbing. Results were inconclusive. Few, if any, of the plants operated with the reliability needed in expensive full-scale units. Utilities companies showed some reluctance to commit large sums of money to scrubbing plants that might be obsolete before they were amortized. The Environmental Protection Agency (EPA), with support from environmentalist groups, nevertheless pushed ahead to attain 1977 environmental goals, modified only by temporary reprieves to meet fuels shortages. The Office of Management and Budget, on the other hand, reported that part of energy research funds would be used to examine the validity of present sulfur emission standards.[17]

Energy problems, which became more pressing late in the year with the Arab oil embargo, increased the likelihood that coal would be called upon to supply an increasing share of the fuel market to replace, in part, petroleum and natural gas. The increased attention to coal conversion emphasized the attractiveness of sulfur removal from fossil fuels at the time of conversion, rather than from the much larger volumes of stack gas; commercial processes are available to recover sulfur produced as hydrogen sulfide, the form in which most sulfur leaves the fuel conversion vessel.

The Office of Coal Research (OCR) of the U.S. Department of the Interior sponsored research into methods of removing sulfur from coal before and during combustion.[18]

The solvent-refined-coal (SRC) pilot plant being constructed for OCR at Fort Lewis, Wash., by the Pittsburgh and Midway Coal Mining Co. was almost complete by the end of 1973. Early tests of this process indicated that it would remove all the inorganic sulfur and 60% to 70% of the organic sulfur in the coal. Oklahoma State University was studying the removal of sulfur from coal-derived liquids in the SRC process. At the Colorado School of Mines, the solvent-refining technique was studied. Experiments underway centered around the conditions necessary to maximize the removal of sulfur.

Research on a clean coke process was carried out by the United States Steel Corp. under a continuing OCR contract. According to the process design, raw coal from the mine is split into two approximately equal portions; one portion is carbonized, whereby it is converted to low-sulfur char, and the other is processed in the hydrogenation section where it is converted to a liquid and a gas rich in light paraffins. Gases from the two sections are combined, and sulfur, among other products, is removed. The main products are metallurgical coke and chemicals.

Another successful year of char-oil-energy development (COED) pilot plant operations was completed during 1973 by the FMC Corp. under contract to OCR. The process is a pyrolysis of the coal feed at atmospheric pressure. In 1973 the plant feed consisted of two high-volatile D bituminous coals. The COED process yields synthetic crude and gas with a heating value of approximately 500 Btu per cubic foot. Sulfur can be removed from the gas by commercial processes. The Ralph M. Parsons Co., under separate contract to OCR, started a commercial design for a COED process complex.

Air Products and Chemicals, Inc., worked on a process to remove sulfur from producer gas in a fixed bed of lime or calcined dolomite. Work proceeded on phase I during the year involving the study of limestone to determine the type most suitable.

In work on an advanced coal gasification system for electric power generation, the Westinghouse Electric Corp., in a contract with OCR, used a lime sorbent in a recirculating bed devolatilizer and desulfurizer to convert the hydrogen sulfide formed into calcium sulfide, which was removed as the spent sorbent.

The Battelle Memorial Institute continued tests on a fuel gas scrubbing process to remove sulfur dioxide, using a molten mixture of lithium carbonate, sodium carbonate, potassium carbonate, and calcium carbonate as the working fluid.

OCR also requested during the year the reactivation of the Cresap, W.Va., facility for further testing of processes to produce low-sulfur fuel oil from Eastern high-sulfur coals. The Cresap pilot plant was originally sponsored under a contract with Consolidation Coal Co. from 1962 to 1969, being then known as Project Gasoline.

The Federal Bureau of Mines continued development of the citrate system for sulfur dioxide removal from stack gases.[19] A pilot plant to test the process was completed in December 1973 at the Bunker Hill Company lead smelter at Kellogg, Idaho. Preliminary test results were encouraging. The same process was tested in a pilot plant at Terre Haute, Ind., by a consortium of Arthur G. McKee & Co., Peabody Engineering Co., and Chas. Pfizer & Co.

The Bureau of Mines published a survey of the chemistry of sulfur dioxide in various processes tested to remove it from stack gases.[20]

A major symposium [21] was organized by the EPA to consider the state of the art of flue gas desulfurization. In the keynote address, an EPA official presented data indicating that elevated levels of SO_2 concentration lead to increased morbidity and mortality, and that suspended sulfates also were associated with heart and lung ailments.[22] Adverse health consequences were stated to be associated with SO_2 exposures in the range of 80 to 120 parts per million for 1 or more days.

An analysis was presented of costs of flue gas desulfurization in fossil fuel boiler plants.[23] It was concluded that desulfurization can be applied to 75% of existing fossil fuel utility capacity at an annualized cost of 1.5 to 3.0 mills per kilowatt-hour. Regenerative processes, which produce sulfur and recycle the scrubbing medium, are generally less costly than throwaway processes since waste disposal costs about $3 per ton of wet sludge.

Another limiting factor on the selection of throwaway processes for stack gas desulfurization would be the area needed to dispose of the resultant sludge; if the area is too large, regenerative processes will be mandatory. An estimate was made of this area. Assuming 3.5% sulfur in the coal and 50% solids in the sludge, lime scrubbing was found to require approximately 8,600 acre-feet for each 1,000 megawatts in the course of 20 years of operation; limestone scrubbing would require about 10,800 acre-feet per 1,000 megawatts in 20 years. It was estimated that 20,000 megawatts could be equipped with scrubbing systems by 1975, and perhaps 50,000 megawatts actually would be equipped by 1977.[24] This latter figure would require 3 to 4 square miles of disposal area per year, covered to an average depth of 10 feet. If the entire present U.S. coal generating capacity, about 200,000 megawatts at an average of 2% sulfur in the coal, were controlled in this way, it would require about 10 square miles per year of disposal area.

Additional papers presented discussed the status of various alkaline scrubbing processes in the United States and abroad, including pilot plant experience, and advanced concepts such as scrubbing with ammoniacal solutions, double alkali processes, molten salt scrubbing, and dry adsorption. In summing up, one of the session chairmen concluded that scrubbing technology was feasible in commercial-sized installations, but that certain problems remained to be solved. This conclusion supported that of the Sulfur Oxide Control Technology Assessment Panel (SOCTAP).

SOCTAP, a Federal interagency committee, released its final report.[25] It was concluded that sulfur dioxide removal from stack gases is technologically feasible in commercial-sized installations, and that a large fraction of the Nation's coal-fired steam-electric plants can ultimately be fitted with commercially available stack gas cleaning systems. Four processes were considered sufficiently developed to potentially desulfurize flue gas. These were wet lime/limestone scrubbing, magnesium oxide scrubbing, catalytic oxidation, and wet sodium-base scrubbing with regeneration. An additional process, the double alkali process, was considered potentially important.

A new pilot plant was completed by the Tennessee Valley Authority (TVA) at its generating plant at Colbert, Ala., to test the ammonium sulfate regeneration process in connection with ammonia-based scrubbing of sulfur oxides from stack gases. The ammonium sulfite formed is acidified with ammonium bisulfate, releasing SO_2; the ammonia and bisulfate are regenerated from the resultant sulfate with heat.[26]

The elemental sulfur pilot plant of American Smelting and Refining Co. and Phelps Dodge Corp. at El Paso resumed

operations after replacing the primary reactor. The plant had been closed down since early in 1972.[27] The process was designed to produce sulfur from smelter stack gases by direct reduction with natural gas. It is considered to be suitable for stack gases containing about 12% SO_2, such as those produced in flash smelting or other continuous smelting of base metal ores.

Sulfur recovery from base metal smelter emissions has been hampered by the intermittent nature of such operations. Attention during the year was focused on continuous smelting to alleviate this problem. The Mitsubishi, Worcra, and Noranda processes were basically continuous smelting with strong off gases.[28]

An experimental sodium-sulfur cell using a beta alumina electrolyte was described.[29] Characteristics of the anodic and cathodic reactants allow one to expect batteries with an energy density higher than 150 watt hours per kilogram, which makes them a promising energy source for urban electric vehicles. The average lifetime to date has been 90 ampere hours per square centimeter (A-hr/cm^2), with an upper limit of 150 A-hr/cm^2. It seems necessary to double this figure before a battery in the range of a few hundred watts can be constructed.

The Bureau of Mines developed a rapid quantitative analysis for pyrite in coal by X-ray diffraction with computerized data procession.[30] Noncrystalline sulfur is not detected. Pyrite in the usual range of 0.1% to 3% in coal can be detected quantitatively.

The TVA found that application of molten sulfur in producing sulfur-coated-urea (SCU) fertilizer substantially improved the coating process. Improvements included better coating efficiency and uniformity, less dust and mist formation, simplified coating drum design, and decreased requirement for preheating the urea. Crop yields continued to show promise for SCU, including more uniform plant growth, lower application costs, and higher yields under some conditions. On certain crops, such as forages and long-season horticultural crops, results of trials showed SCU superior to soluble nitrogen.[31]

A survey of users of sulfur dioxide and nitrogen oxides monitoring equipment revealed that in recent years high and variable levels of SO_2 in stack emissions have been successfully monitored by measurements of the strong ultraviolet light absorption of this compound. Measuring techniques commonly used for ambient monitoring had earlier been applied with only marginal success to stack monitoring.[32]

The present worldwide oversupply of sulfur, together with the projection that environmental controls would create an even greater oversupply position, was responsible for the expansion of a large number of research programs designed to develop new uses for sulfur of a magnitude that would alleviate this situation. These research projects were largely Government sponsored. Additionally, however, trade organizations, sulfur-producing companies, universities, and independent laboratories pursued programs designed not only to develop novel uses for sulfur, but to investigate the basic properties of sulfur as they might relate to new uses.

The Bureau of Mines continued its broadly based sulfur utilization program covering asphalt-sulfur paving materials, sulfur applications for land pollution abatement, characterization of construction materials containing sulfur, and new metallurgical applications for sulfuric acid. Under one segment of the Bureau's program, the Texas A & M Research Foundation reported on the beneficial use of sulfur in sulfur-asphalt pavements. This report, covering the first phase of a research project jointly funded by the Bureau of Mines and The Sulphur Institute, described familiarization and verification of existing technology, literature search and patent review, and preliminary design, construction, and quality control procedures.[33]

Talc, Soapstone, and Pyrophyllite

By J. Robert Wells [1]

Talc-group minerals were produced and consumed in 1973, both in the United States and worldwide, at an annual rate that was substantially greater, measured by both quantity and total value, than any previously recorded. The thriving tone of the industry was notable considering the negative influence of the mostly unjustified health-hazard uncertainties spilling over onto talc because of its acknowledged genetic and geological associations with some of the materials classified as asbestos. One such material is tremolite, which sometimes appears with a fibrous structure similar to that of the true asbestos minerals exemplified by chrysotile, and which may be found as a minor-to-major component in some commercial talc deposits.

The characteristic crystal form of the mineral talc is platy—foliated or tabular with poorly defined rhombic or hexagonal outlines—but talc, in certain deposits that also contain tremolite, may occur to some extent as a pseudomorphic replacement after that mineral. Mixtures of talc with 30% or more tremolite have been found to serve better in some specific applications than pure talc itself, with the result that the terms "fibrous talc" and "tremolitic talc" have become quite firmly implanted in the vocabulary of the industry and even appear without qualification in some mineralogical texts. Illustrative of the confusion that can follow from this imprecise terminology is the following statement taken from an item in a nationally circulated hobby-oriented magazine: "Tremolite, better known as talc, is a soft mineral and has a smooth feel when rubbed between the fingers. Ground, it is used for talcum powder." [2]

Legislation and Government Programs.—Defense materials inventories prepared by the General Services Administration showed that Government holdings as of December 31, 1973, included 1,170 short tons of talc (steatite, block or lump, purchased in compliance with a stockpile objective at $390.51 per ton) and 3,900 short tons of talc (steatite, ground, acquired in nonstockpile transactions at a cost of $59.26 per ton). During calendar 1973, 10 tons of the block, valued at $3,300, was sold from inventory, and arrangements were made for the disposal of 1,000 tons of the ground material, leaving 1,170 tons of block and 2,900 tons of ground talc listed as uncommitted excess at yearend.

The Office of Minerals Exploration, Geological Survey, offered to grant loans of up to 50% of approved exploration costs for eligible deposits of block steatite talc, but no loans for that purpose were made in 1973. The allowable depletion rates for talc, established by the Tax Reform Act of 1969 and unchanged through 1973, were 22% on production of block steatite talc of domestic origin and 14% on foreign production of the same material, which rate applied also to production of all other classes of talc from all sources.

Under terms of a regulatory ruling proposed by the Food and Drug Administration, U.S. Department of Health, Education, and Welfare, any talc to be approved for use in the manufacture and processing of drugs or in the packaging of foods would have to be tested by a proposed analytical method based on optical microscopy with polarized light (validation pending) and shown to be as nearly free of asbestos particles as is attainable. Quantitatively, talc for these applications that is not shown to be at least 99.9% free of amphibole types of asbestos fibers and at least 99.99% free of chrysotile asbestos fibers would be deemed adulterated in violation of section 501(a) of the Federal Food, Drug, and Cosmetic Act.[3]

Under the sponsorship of the U.S. Department of the Interior, the Bureau of Mines Division of Health, Metal, and Nonmetal Mine Health and Safety, held an open symposium on May 8, 1973, for the purpose of assembling information concerning hazards to workers' health posed by dusts generated in the production and processing of the different varieties of industrial talc. A stated objective of the conference, which was held in the auditorium of the Department of the Interior in Washington, D.C., was to determine whether exposure to these types of dust present health hazards similar to those from the mineralogically related substances known collectively as asbestos. The session was well attended and featured oral and visual presentations (followed by opportunities for questions, answers, and general discussion) by representatives of the sponsoring agency, the talc industry, and various health-oriented organizations. Publication of the symposium proceedings and attendance roster was postponed because of a Departmental reorganization, in which the functions of the Metal and Nonmetal Mine Health and Safety division were transferred to the Mining Enforcement and Safety Administration (MESA), also an agency of the Interior Department but separate from the Bureau of Mines.

DOMESTIC PRODUCTION

Mine production of crude talc and related minerals in the United States established new records in 1973 in both tonnage and total value, topping by 13% and 17%, respectively, the previous high marks reached in 1972.

Talc-group minerals were produced from a total of 51 mines distributed throughout 14 States. Talc or soapstone was mined at one or more locations in each of those States; domestic production of pyrophyllite was limited, as in 1972, to the output of just six mines, all in North Carolina. The six leaders among the talc-group producing States (Vermont, New York, Texas, Montana, California, and North Carolina, ranked in descending order by tonnage—New York, Montana, California, Vermont, Texas, and North Carolina, by value) jointly supplied 95% of the 1973 total domestic output. New York, the foremost producing State throughout most of the industry's history, remained in first place with regard to total value, but slipped in 1973 to second place in terms of tonnage.

The 10 largest domestic producers of talc-group minerals in 1973, listed alphabetically, were Cyprus Mines Corp., United Sierra Division, with mines in California, Montana, and Texas; Eastern Magnesia Talc Co. in Vermont; International Talc Co., Inc., in New York; Johns-Manville Corp. (successor to L. Grantham Corp.) in California; Pfizer Inc., Minerals, Pigments & Metals Division, in California and Montana; Piedmont Minerals Co., Inc., in North Carolina; Southern Clay Products, Inc., in Texas; R. T. Vanderbilt Co., Inc., in California and New York; Westex Talc Co. in Texas; and Windsor Minerals, Inc., in Vermont. Those firms supplied 85% of the 1973 tonnage (83% of the total value), and the combined outputs of about 20 smaller producers made up the remainder.

Talc minerals were ground for sale or industrial use in 1973 in approximately 35 mills operated by 29 companies in 11 States. Talc or soapstone mined in Nevada and

Washington was shipped to other States for grinding, and talc from outside sources was ground in Nebraska, where there was no mine production.

Noteworthy among 1973 events in the talc industry were major expansions, especially of ultrafine-grinding facilities, on the part of several important producers in the western United States.

[1] Data may not add to totals shown because of independent rounding.

CONSUMPTION AND USES

Apparent domestic consumption of crude and ground talc, soapstone, and pyrophyllite (total sales plus imports minus exports) passed an important milestone in 1973, the first 1-million-ton-per-year total under that heading in the history of the industry. Reported 1973 sales of ground material were 7% more in tonnage than in 1972, but the average unit value declined moderately, and the total value was 6% below that of 1972. Approximately 29% of the total quantity of talc-group minerals sold or used by domestic producers in 1973 was consumed in the manufacture of ceramics, 15% was used in paint, and another 15% was exported. An assessment of talc's future as an ingredient in high-quality paints and the special properties making the mineral virtually irreplaceable in that application were subjects dealt with in two industrial journal articles.[4]

The 1973 end-use distribution showed a 37% increase in talc utilization for papermaking, 7% of the total, compared with 5% in each of the 2 preceding years. It is no doubt significant in this regard that a number of talc processors in the western United States were pushing up their capacity to supply the ultrafine grades of material especially required by pulp and paper manufacturers for pitch control.

r Revised.
[1] Includes plastics, stucco, floor tile, foundry facings, rice polishing, crayons, art sculpture, and other uses.

STOCKS

According to estimates based on data reported by producers, the total quantity of crude, ground, and partly processed talc, soapstone, and pyrophyllite on hand in the United States (that is, mined but not yet sold or used) was approximately 157,000 tons on December 31, 1973, compared with 167,000 tons on that date in 1972.

PRICES

Engineering and Mining Journal, December 1973, quoted prices for domestic ground talc in carload lots, f.o.b. mine or mill, containers included, per short ton, as follows:

Vermont:	
98% through 325 mesh, bulk	$20.00
99.99% through 325 mesh, bags:	
Dry processed	58.00
Water beneficiated	86.00
New York:	
96% through 200 mesh	28.00
99.9% through 325 mesh	44.50
100% through 325 mesh, fluid energy ground	$80.00–90.00
California:	
Standard	37.00– 53.00
Fractionated	37.00– 71.00
Micronized	62.00–104.00
Cosmetic-steatite	44.00– 65.00
Georgia:	
98% through 200 mesh	14.00
99% through 325 mesh	25.00
100% through 325 mesh, fluid energy ground	75.00

American Paint Journal, December 1973, listed the following prices per ton for paint-grade talcs in carload lots:

California: 325 mesh, bags, mill:	
Fibrous, white, high oil absorption	$34.00–$37.00
Semifibrous, medium oil absorption	32.00– 73.95
Montana: Ultrafine grind, f.o.b. mill	70.00
New York: Fibrous and semifibrous, bags, mill:	
98% through 325 mesh	31.00
99.4% through 325 mesh	40.00
Trace retained on 325 mesh	80.00
Fine micron talcs (origin not specified)	68.00–111.50

The price range quoted in Chemical Marketing Reporter, December 31, 1973, for carload lots of imported Canadian talc, ground, in bags, was from $20 to $35 per ton, f.o.b. works.

The equivalents in dollars per short ton of price ranges for steatite talc, c.i.f. main European ports, quoted by Industrial Minerals (London), December 1973, were as follows:

Norwegian:	
Ground	$24.00–$29.00
Micronized	43.00– 79.00
French: Fine ground	39.00– 89.00
Italian: Cosmetic grade	66.00–103.00
Chinese	49.00– 65.00

FOREIGN TRADE

Exports.—The quantity of talc-group minerals exported from the United States in 1973 was 5% more than in 1972, and the total value was 14% higher, establishing new alltime highs in both respects. The largest share of the exported material was shipped to Mexico, followed in descending order by Canada, Belgium, Japan, Venezuela, and the United Kingdom. Shipments to those six destinations accounted for 90% of the 1973 total, and the remaining 10% was distributed among about 50 other countries.

Imports.—The tonnage of unmanufactured talc imported by the United States in 1973 was about one-fifth less than the corresponding figure for 1972, but the total value was only fractionally lower. Noteworthy among 1973 imports was an item in the Census Bureau's classification "Talc, steatite, and soapstone and articles of these, not specially provided for" that was listed as being valued at $150,000 and as having originated in the People's Republic of China.

Tariffs.—Schedules applicable throughout 1973 provided for import duties on the various classifications of talc as follows: Crude and not ground, 0.02 cent per pound; ground, washed, powdered, or pulverized, 6% ad valorem; cut or sawed, or in blanks, crayons, cubes, disks, or other forms, 0.2 cent per pound; and other, not specially provided for, 12% ad valorem.

WORLD REVIEW

Australia.—The Australian Department of Overseas Trade stated that a newly launched enterprise, that of Westside Mines N.L., at a site south of the Murchison River and near Meekatharra in Western Australia, is expected to develop into one of the world's foremost sources of white micaceous talc in grades especially suited for use by the cosmetic, paper, paint, and rubber industries. The Westside deposit's proved reserves of high-quality mineral were said to amount to more than 1 million tons, with at least double that quantity indicated as existing.

Canada.—Talc was produced in 1973 in two provinces—in Ontario by Canada Talc Industries, Ltd., from underground workings at Madoc; and in Quebec by Baker Talc, Ltd., from an underground mine at South Bolton and by Broughton Soapstone & Quarry Co., Ltd., from an open pit facilitiy near Broughton Station. Expectations for a second producer in Ontario received a setback when Canadian Johns-Manville Co., Ltd., terminated an agreement to assist Canadian Magnesite Mines, Ltd., in the installation of a flotation plant for the beneficiation of talc and magnesite ore from a property in the Timmins area. Both of the companies operating in Quebec, in addition to various grades of ground talc, also marketed soapstone in sawed form as metalworker's crayons or blocks for carving. Canada's production of pyrophyllite was confined to Newfoundland where Newfoundland Minerals, Ltd., operated an open pit mine to provide material for use in the manufacture of ceramic tile. The greater part of the talc and soapstone was consumed in Canada, but all the output of pyrophyllite was exported.

Finland.—The only producer of the mineral in Finland, Suomen Talkki Oy., announced that in 1972, in order to meet increased demand from the paper industry and despite intensified competition in filler application from British kaolin, it had been obliged to step up its output of high-quality floated talc by one-fourth.

France.—A detailed description was published of the operations of what is probably the world's largest talc mine, that of S.A. des Talcs de Luzenac in the foothills of the French Pyrénées. The Luzenac quarry, at an exposed position on the side of Mount Soularac at 6,000 feet above sea level, can be operated only 6 months of the year but even so supplies nearly half of the annual talc production of the entire European continent.[5]

Greece.—A magazine article surveyed Greece's situation with regard to a number of nonmetallic minerals including talc.[6] Talc deposits are found on the Greek mainland near Larissa in Thessaly and near Thessaloniki in Macedonia, as well as on the islands of Crete and Tinos. The country's most active talc mines at present are those on Tinos, but production there has been sharply curtailed in recent years because of the increasing preference of Greek tile manufacturers for talc imported from Italy.

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, Southern Rhodesia is believed to produce talc, but available information is inadequate to make estimates of output levels.

[2] Includes talc and wonderstone (pyrophyllite).

[3] Includes talc and pyrophyllite: in addition, pyrophyllite clay is produced as follows in short tons: 1971—354,160; 1972—343,180; 1973—355,096.

TECHNOLOGY

Research papers were published presenting information on properties that may be of assistance in delineating the genetic relationships of the mineral talc and hence possibly also in guiding future exploration in quest of commercial deposits. Scientists at Johns Hopkins University, in studying the stability field of talc at the earth's surface to define the conditions under which the mineral might be expected to form, concluded that the Gibbs free energy of the talc molecule, $Mg_3Si_4O_{10}(OH)_2$, must be at least 3 to 5 kilocalories per mole less negative than the previously accepted value. The new figure arrived at was —1,320 $\pm$ 2 kilocalories, a value said to be consistent with observed natural occurrences of talc.[7]

A British soil laboratory team determined the crystallographic properties of talc, the pure mineral, by a photographic X-ray diffraction procedure supplemented by least-squares mathematical analysis and

[7] Bricker, O. P., H. W. Nesbitt, and W. D. Gunter. The Stability of Talc. Am. Minerologist, v. 58, Nos. 1–2, January–February 1973, pp. 64–72.

reported that the true crystal form is triclinic and not monoclinic as is stated in many texts.[8]

The British investigators, confirming the conclusion drawn by a collaboration of workers in the United States several years ago,[9] reported that "The layers of the structure have almost monoclinic symmetry but the nearly hexagonal rings of oxygen atoms on the surfaces of the layers, formed by the bases of the silica tetrahedra, are not held in register by interlayer ions as they are in micas but are partly displaced so that the stack of layers forms a triclinic crystal."

Coincidentally, a lecture given at the annual meeting of the American Ceramic Society, Cincinnati, Ohio, April 30, 1973, included the following statement in regard to another of the talc-group minerals: "Until recently, pyrophyllite was regarded as a two-layer monoclinic structure, but in the course of studying the dehydroxylation reaction of this mineral it became necessary to reconsider the accepted structure. After a search for well-crystallized material, which is not easily obtained in the case of pyrophyllite, the structure was found to be a one-layer triclinic form."[10]

Exploration of a whole new technological frontier, in which synthesis of diamond has already been achieved and production of superconducting metallic hydrogen looms as a definite possibility for the near future, was the subject of a published essay.[11] Advances in this field of investigation, which involves subjecting materials simultaneously to temperatures measured in thousands of degrees and pressures in millions of pounds per square inch, demand the development of increasingly ingenious and sophisticated techniques for bringing forces of such unprecedented magnitudes to an effective focus. Several of the types of apparatus devised for these researches take advantage of the pressure transfer characteristics of pyrophyllite.

An article in an industrial journal compared the properties and mineralogical compositions of platy talcs originating in Montana and California with those of the so-called fibrous variety mined in the East (probably New York), explaining on that basis the results observed when substituting western mineral for eastern in established paint formulation practices.[12] It was concluded that utilization of a pure, platy talc to replace the more mineralogically heterogeneous type of material previously used can be accomplished without difficulty by observing two fundamental rules of paint compounding technology: (1) adjustment of paint PVC (pigments volume concentration) to compensate for differences in the absorptivity and void volume of the pigmentation, that is to say in the CPVC (critical pigment volume concentration), and (2) paying particular attention to the wetting/dispersing/stabilizing ingredients in the paint formula. It was further stated that, if these precautions are taken, no more than minor changes in paint properties, mostly arising from particle shape differences, need be anticipated. Appended to the article was a derivation of mathematical expressions for use in calculating numerical values for PVC and CPVC.

Toilet and pharmaceutical preparations, especially cosmetics ("talcum powder") constitute the end uses most familiarly associated with the mineral talc, although the tonnages currently consumed in this way account for no more than a minor fraction of each year's total. In value terms, the commercial significance of these applications is far from minor, however, because only substances of exceptional quality and outstanding purity and biological integrity, which are hence the highest priced, can meet the exacting specifications involved. An updated version was published of what has come to be accepted as the most authoritative treatise available on the technology of the compounding and testing of cosmetics. An extensive review of the new edition appeared in a scientific magazine.[13]

Success in studies aimed at elucidation of possible physiological consequences from absorption of talc into body tissues, whether by routes of ingestion, inhalation, or simple surface contact, hinges on an unequivocal means of identifying and measuring exceedingly minute quantities of the mineral profusely diluted with substances likely to interfere with and obscure the analysis. A British biological research organization developed a procedure for achieving a controlled partial dehydration of pure mineral talc and then replacing the expelled water, H_2O, with an equivalent quantity of tritium oxide, T_2O. It was thought that the presence of the radioactive hydrogen isotope "tag" would then provide an exceptionally sensitive tool for locating, identifying, and quantitatively estimating the tritiated talc after it had become dispersed within a living organism. Work was continued toward application of the new technique in the investigation of suspected cases of talc-induced pathology.[14]

Thorium

By Roman V. Sondermayer [1]

During 1973 primary thorium supplies from two domestic mines, located in Georgia and Florida, and imports, mostly from Malaysia, were more than adequate to meet demand. As in the past, there was no direct mine production of thorium. Monazite, the principal source of thorium, continued to be a byproduct of titanium mining and was recovered for its rare-earth content. Because of low thorium demand, thorium-containing residues from these operations were stored in holding areas for future use. However, during 1973 far lesser quantities of thorium-bearing materials were sent to holding areas than in the past. This change resulted from partial replacement of monazite by other materials as the major source of rare-earth oxides.

The weak market continued throughout 1973, but long-range potential for use of thorium was considered good. Energy shortages throughout the industrialized countries stimulated a search for new sources of energy. The existence of large resources of thorium in the United States and in the world encouraged research on the use of thorium as a nuclear fuel and on thorium-fueled reactors. Thorium programs sponsored by the Atomic Energy Commission (AEC) were under review, and more intensive research programs were expected. In contrast to higher demand for thorium as a nuclear fuel, only slight increases in demand were registered for other, nonenergy applications of thorium.

During 1973 thorium highlights were related to research and to industrial activities. Research started on application of the high-temperature, gas-cooled reactor (HTGR) as a source of industrial heat in production of hydrogen in coal gasification. A new process for utilizing U_{233} from domestic thorium in light-water-reactors (LWR) was announced. Seven HTGR's with a total capacity of 5,730 megawatts electrical (Mwe) were on order at the end of 1973. One HTGR, at the Fort St. Vrain, Colo., powerplant, with a capacity of 330 Mwe, was scheduled for commercial operation in 1974. In the last quarter, Gulf Oil Corp. and the Royal Dutch-Shell group entered into two 50–50 partnerships. The first, under the name General Atomic Co., will conduct operations in the United States. The second, under the name General Atomic International, will operate elsewhere. Shell companies initially contributed around $200 million to the partnership and further cash requirements will be provided equally by the partners. The partnership will be engaged primarily in developing, manufacturing, and marketing HTGR's.

One of the two processors of monazite for thorium stopped production at yearend.

DOMESTIC PRODUCTION

Mine Production.—Two mines, one in Georgia and the other in Florida, were the only producers of thorium in the country. At Humphreys Mining Co., with its operation near Folkston, Ga., output was slightly lower in 1973. The estimated ThO_2 content of monazite was 4%. Mining for titanium and zirconium was the principal activity at Folkston, and recovery of monazite was a byproduct operation. Suction dredges were used to mine the heavy beach sands. Most of the monazite was sold to W. R. Grace & Co., Chattanooga, Tenn. Ore reserves at the present mining site were expected to be exhausted by mid-1974. The company planned to continue operations by developing another heavy mineral sand deposit in Florida, a few miles south of the Folkston deposit. The heavy mineral sand concentrates from this new deposit will be proc-

[1] Physical scientist, Division of Nonferrous Metals—Mineral Supply.

essed at the existing plant near Folkston. Humphreys Mining Co. continued land rehabilitation of the area disturbed by mining. Mill waste was used as fill and, after grading, top soil was respread, and planted with grass.

Titanium Enterprises, jointly owned by American Cyanamid Co. and Union Camp Corp., was the second domestic monazite producer. At this operation, located near Green Cove Springs, Fla., the company mined a Pleistocene beach sand deposit mostly for ilmenite, rutile, and zircon. As in Georgia, monazite was a byproduct, and suction dredges were the principal mining equipment. During the latter part of the year, production of monazite was lower than mine capacity. Shortages of energy slowed the operation.

Refinery Production.—During 1973 the principal domestic firms processing monazite for thorium were W. R. Grace & Co., Davison Chemical Division, at Chattanooga, Tenn., and Lindsay Rare Earths, affiliated with Kerr-McGee Chemical Corp., West Chicago, Ill. The Lindsay plant stopped operations at yearend because of increased production costs.

A number of thorium-processing companies and dealers maintain stocks of various compounds and of the metal for nonenergy use and for nuclear fuels. Table 1 shows the principal companies.

Table 1.—Companies processing and fabricating thorium, in 1973

Company	Plant location	Operations and products
American Light Alloys, Inc	Little Falls, N.J	Magnesium-thorium alloy.

Wellman Dynamics Corp	Creston, Iowa	Magnesium-thorium alloy.
Westinghouse Electric Corp	Bloomfield, N.J	Processes compounds; produces metallic thorium.
Do	Columbia, S.C	Nuclear fuels.

CONSUMPTION AND USES

In 1973 the estimated apparent consumption of monazite and thorium compounds was about 240 tons of ThO_2 equivalent. This estimate was based on domestic mine production, imports, and changes in domestic stocks of monazite and thorium compounds. Actual industrial demand was substantially lower; the available monazite supply was processed essentially for its rare-earth content and most of the thorium-containing residues entered company holding areas. Nonenergy and energy uses were the two major areas of thorium consumption. Based on sales from Government stocks, and shipments from processors, U.S. industrial demand was estimated at about 130 tons of ThO_2 equivalent. Of the total, some 100 tons of ThO_2 were consumed in nonenergy sectors of the economy. Principal applications were in Welsbach incandescent gaslight mantles, as a hardener for magnesium-thorium alloys, in dispersion hardening, refractories, electronics, and chemical (catalytic) applications. About 30 tons of ThO_2 equivalent were used for production of nuclear fuels and nuclear research. Table 2 shows the status of HTGR development in the United States.

Philadelphia Electric Co. announced that two 1,160 Mwe HTGR's will be located in Fulton Township, Lancaster County, about 9 miles north of the Conowingo Dam and on the east side of the Susquehanna River. Each of the two reactors will be connected to two Westinghouse turbine generators.[2]

Gulf General Atomic (GGA) has chosen Bechtel Corp. of San Francisco, Calif., to design the plant for a 300-Mwe demonstration gas-cooled fast breeder reactor (GCBR). The cost for balance-of-plant design will be paid for with GGA and utility funds. The work will be coordinated by the Power Technology groups of Bechtel's Scientific Development Division. The GCBR is based on HTGR technology, and fuel and physics technology of the liquid metal fast breeder reactor.[3]

STOCKS

The Government stockpile, in the form of thorium nitrate, totaled 1,761 tons ThO_2 equivalent on January 1, 1974. During 1973 the thorium stockpile objective was reduced to zero, and all stockpiled thorium was available for disposal. However, only 28 tons of nitrate was sold from stockpile during the year.

Stocks held by industry were estimated in terms of ThO_2 equivalent, as follows: In monazite, 80 tons; in compounds, 82 tons; and in metal and alloys, 1 ton.

PRICES

During 1973 the price of monazite increased on the international market. The average declared value for imported monazite was $135 per ton compared with $99 in 1972.

Prices listed by the Davison Chemical Division, W. R. Grace & Co., Chattanooga, Tenn., were in the following ranges, per pound, depending on the quantity of purchase: Nitrate wire grade, 47% ThO_2, $2.45–$2.50; nitrate, mantle grade, 47% ThO_2, $2.50–$2.55; ThO_2, ceramic grade, 99.9% ThO_2, $6–$10; and ThO_2 refractory grade, 99.9% ThO_2, $7–$11.

Quotations in the American Metal Market on thorium metal in pellets remained steady at $15 per pound. The pure metal was $65 per pound.

FOREIGN TRADE

Imports of monazite, mainly for rare-earth content, increased above 1972 levels. Malaysia was the principal supplier. Imports of compounds declined, but imports of metal (scrap) increased. European countries and Canada were the main suppliers. Exports statistics for thorium compounds are combined with those for uranium in trade statistics. Although exact data are not available, thorium exports are believed to be minor.

WORLD REVIEW

Australia, India, Malaysia, Brazil, and the United States remained the principal thorium producers in the world. As in the United States, most thorium was a byproduct of rare-earth recovery from monazite. Because of the low demand for thorium, a sizable oversupply existed in world markets. Some of the producing countries regulated transactions in thorium metal and compounds because of their nuclear uses.

Australia.—A pilot plant for production of ilmenite and rutile, located 150 miles north of Perth and operated by Allied Eneabba Pty. Ltd., started operation in the spring of 1973. The new plant will also produce monazite, capacity for which was not disclosed.

Brazil.—The Commissão Nacional de Energia Nuclear (CNEN), a Brazilian Government agency, controlled the beach sand industry of Brazil. This industry remained the only producer of monazite in the country.

CNEN, through its Administração da Produção da Monazita (APM), operated workings at Itabapoana (Rio de Janiero) and Cumuruxatiba (Bahia). Monazita e Ilmenita do Brasil (MIBRA), a privately owned company, operated facilities for the production of monazite at Guarapari.

The mixed Government-private company, Cia. Brasileira de Tecnologia Nuclear (CBTN), took control of Orquima, a private company in the city of São Paulo. The new company, named Usina de Santo Amaro (USAM), was operating a pilot plant that separated rare-earth oxides and thorium from monazite. The aim was to develop an effective system for this separation and then market the rare earths and thorium independently. Formerly, USAM furnished only mixed concentrates.

Canada.—There was no official indication that thorium was produced in Canada during 1973. However, some thorium may have been produced because Denison Mines Ltd. reactivated its yttrium circuit at its Elliot Lake mill in Ontario. Production of yttrium requires removal of thorium during the process.

France.—An agreement was signed by GGA, the Commissariat à Énergie Atomique (CEA), and French industry to organize an HTGR nuclear-fuel manufacturing and marketing company. The new company, La Société de Combustible pour Reacteurs à Haute Température (CORHAT), will be jointly owned by GGA (30%) and a French organization, Cie. Industrielle de Combustibles Atomiques Frittes (70%). This agreement follows a previously signed agreement between GGA and CEA for exchange of HTGR technology.

Germany, West.—The Ministry of Science and Technology announced that reactor development funds, amounting to $80 million, will be used for the helium-turbine equipped 300-Mwe thorium high-temperature reactor (THTR) under construction at Schmehausen. Construction of this reactor was financed and supervised by Hochtemperatur-Reaktorbau GmbH (HRB), Cologne, West Germany. HRB belongs to the Swiss-controlled Brown, Boverie and Co. Mannheim (55%), and GGA (45%).

India.—Production of monazite decreased during fiscal years 1972 and 1973. The main reasons for the lower output were shortages of electric power and caustic soda, and leaner monazite content of beach sands. Production of thorium hydroxide (dry) was reported at 689 tons. Installed capacity for production of thorium hydroxide was 904 tons annually. Thorium-producing facilities of Indian Rare Earths Ltd. (IRE) were operating at about 76% of installed capacity. The Government of India bought all thorium hydroxide produced by IRE.

IRE continued to operate the thorium plant at Trombay as agent of the Government of India. Construction started on a solvent extraction pilot plant for production of thorium oxide and nitrate at Trombay.[4]

Beach sands of the coastlines of Kerala and Tamil Nadu remained India's most important commercial source of thorium in monazite. The largest concentrations occur at Chavara near Quilon in Kerala and at Manavalakurichi, a coastal village in the Kenyakumari District of Tamil Nadu. Large unmeasured tonnages of monazite also exist in sandstone beds inland from each of the black sand beach areas. Other beach sand areas exist around the southern tip of India and along the east coast of the country through Visakhapatnam to Palmiras Point, southwest of Calcutta. IRE continued as the

[4] Indian Rare Earths Ltd. 23rd Annual Report, 1972–73. Bombay, 1973, p. 23.

only mineral sand mining and processing firm in India. The company minerals division with offices at Quilon, Kerala, operated raw material plants at Manavalakurichi and at Chavara. Annual capacities for monazite at these two plants were reported at 4,898 and 645 tons, respectively. The average ThO_2 content of India monazite ranged from 8% to 10%.

India's nuclear planning remained oriented toward self-reliance. Having large resources of thorium, India decided to direct its future nuclear development toward thorium-fueled reactors. An experimental fast breeder reactor, located at Kalpakkam, near Madras, for which planning was underway, will be fitted with oxidal and radial thorium blankets. France has offered aid for construction of this reactor.

Japan.—The Public Utilities Bureau of the Ministry of International Trade and Industry proposed that the Electric Power Development Company (EPDC) should develop the HTGR in Japan. This would be the first reactor built by EPDC. The EPDC was established to develop hydroelectric power but later entered the field of thermal plants.

Japan pushed forward in expanding use of the HTGR. The Government and the iron and steel industry founded research on use of HTGR-generated process heat in production of steel.

The Japan Atomic Energy Research Institute completed a preliminary design for a multipurpose HTGR (power generation and process heat). Kawasaki Heavy Industries operated high-temperature piping in experimental production of iron and steel.

The Science and Technology Agency, established by the Government, released figures on quantities of nuclear fuel materials in Japan at the end of 1973. Stocks of thorium were reported at 565 tons in form of welding rods and lenses.

TECHNOLOGY

During 1973, energy, process heat, metallurgical applications, and isotopes were the principal subjects of research studies related to thorium. Except for some energy-oriented projects, most of the research was basic. Estimates indicated that two-thirds of the thorium research was on energy applications.

Nonenergy.—Most nonenergy research was related to thorium alloys. Metallurgical research was directed toward determining the effect of thorium and thorium compounds on the physical and chemical properties of alloys in different environments. One study indicated that ThO_2 dispersion in platinum and gold gives unique properties to these metals. Detailed results were announced on platinum only. Stress-rupture properties of platinum, better than those of the best platinum-rhodium alloys, were obtained when ThO_2 was dispersed. Addition of ThO_2 helped improve strength and durability of the platinum-thorium alloy at elevated temperatures. The platinum-thorium alloys with high corrosion resistance may have applications in the aerospace, electrical and electronic, chemical, and glassmaking industries.[6]

Another result of metallurgical research showed that ThO_2 strengthens oxygen-free-high-conductivity (OFHC) copper when 0.3% to 3% ThO_2 is alloyed with OFHC copper. The Cu–ThO_2 alloy retained excellent electrical and thermal conductivity. Application may include use in structural and current-carrying parts of microwave tubes, high-temperature conductors, and die-casing parts.[7]

A recent investigation was conducted to develop powder preparation and processing methods which could improve the optical perfection of sintered Y_2O_3 containing various quantities of ThO_2 and Nd_2O_3 in solid solution. The major part of the investigation was related to optical defects in the sintered material. A new process produced powders with a composition of 89% Y_2O_3, 10% ThO_2, and 1% Nd_2O_3 suitable for a sintering approach.[8]

Y_2O_3-ThO_2 ceramics find use as solid electrolytes. Y_2O_3-ThO_2 and zirconia are electrical insulators but, at elevated temperatures, they become electrical conductors. The high-temperature conductivity can be controlled by the amount of stabilizers (CaO and Y_2O_3) used in the formation. Characteristics of Y_2O_3-ThO_2 ceramics makes them suitable for new approaches to oxygen measurement, hydrogen production, and nuclear reactors. The Y_2O_3-ThO_2 ceramics are highly resistant to attack by molten sodium. Research was underway to use Y_2O_3-ThO_2 electrolytes for sodium-cooled nuclear reactors.[9]

Energy.—Energy research was directed mostly toward development of thorium fuels and their use in reactors. The AEC sponsored research and development in the nuclear field. In addition, GGA conducted research on applications of the HTGR gas-cooled breeder reactor (GCBR) and on a symbiotic relation in use of fuel between the GCBR and the HTGR.

Possibilities for the use of the HTGR as a source of process heat in various industrial fields were examined during 1973. For this use, the reactor remains basically identical to the HTGR used for power generation except for some modification required for generation of heat in the reactor and for application of that heat.

GGA and Stone & Webster Engineering (S&W), a subsidiary of Stone & Webster, Inc., started research on the use of nuclear power for converting coal into pipeline-with the HTGR. The S&W process treats coal as a basic hydrocarbon in which the hydrogen content is increased from approximately 5% in raw material to 25% in the methane product. The process quality gas and clean liquid fuels. The program integrated the S&W gasification process involved a stepwise hydrogenation of coal, first to liquid and then to synthetic gas by hydrogasification. The HTGR is included for power production of large quantities of hydrogen that are essential to the process. S&W will be the project manager of a 2-year test program that will cost approximately $650,000.

There are important advantages in the

[9] Sproule, T. Richard. Zirconia and Yttria-Thoria Ceramics Find New Uses As Solid Electrolytes. Mater. Eng., v. 19, No. 1, January 1974, p. 40.

use of a nuclear heat source in the process. The combined process produces about 30% more clean fuel per unit of coal fed through systems using coal for both a source of process heat and feedstock. In addition, HTGR-produced heat reduces the price sensitivity of synthetic gas to changes in the price of coal. Research was expected to take about 3 years. Construction of the commercial plant would take about 5 years after receiving all necessary approvals.

Research on production of hydrogen from water has been conducted by GGA with the HTGR heat source. A new multistep thermochemical process, using heat and chemicals, decomposed water into hydrogen and oxygen. The temperature range of 1,500° to 1,800° F, far lower than expected, is within the HTGR temperature range. Chemicals used in the process can be reprocessed, and only heat and water were consumed.[10]

The idea of a symbiotic relation between the GCBR and the HTGR was announced during 1973. Such a relation leads to an advantage in fuel cycle economics. The GCBR can supply fissile feed materials that are the best fuel for the HTGR. Uranium-233, bred in thorium blankets around the GCBR cores, could supplement the recycled supply of this material in the HTGR's fuel feed. One GCBR could supply fissile materials for three HTGR's.

Pacific Nuclear, Inc., in Richland, Wash., has announced development of a new process for utilizing U_{233}, (converted from Th_{232} in the HTGR) in existing LWR's. The new process prevents formation of undesirable U_{232} whose daughter products emit gamma radiation. This prevention is accomplished by a new core-loading pattern.[11]

Tin

By Keith L. Harris [1]

The Free World supply of tin trended from oversupply at the beginning of the year to undersupply at yearend with a shortfall of about 23,000 long tons.[2] Combined General Services Administration (GSA) shipments and International Tin Council (ITC) buffer stock sales of over 21,000 tons failed to alleviate the tight supply conditions. Prices rose to record levels on the world markets.

World mine production of tin in 1973 was 232,404 tons, down 3% from the 1972 level. U.S. consumption of primary and secondary tin increased 8% for the year, the first increase in U.S. consumption since 1968. The major uses for tin were in solder, 33%; tinplate, 28%; bronze and brass, 13%; chemicals including tin oxide, 6%; and babbitt, 5%. Most of the Nation's tin, in the form of slabs, bars, and ingots, came from Malaysia and Thailand. Less than 100 tons of tin, from mines in Alaska, Colorado, and New Mexico, was mined domestically during the year. About one-fifth of the tin used in the United States in 1973 was reclaimed from scrap at about 85 secondary smelters.

The only primary tin smelter-refinery operating in the United States in 1973 was the Texas City, Tex., facility of Gulf Chemical and Metallurgical Corp. (GCMC). The major feed to the smelter was tin concentrate from Bolivia's state-owned Corporación Minera de Bolivia (COMIBOL).

The Office of Preparedness (OP) lowered the tin stockpile objective from 232,000 tons to 40,500 tons during the year. GSA sold 19,262 tons of tin from the stockpile through commercial channels.

The average New York price for prompt delivery Straits (Malaysian) tin in 1973 was 227.558 cents per pound, a significant increase from the 1972 average of 177.469 cents per pound.

[1] Physical scientist, Division of Nonferrous Metals—Mineral Supply.
[2] Unless otherwise specified all units are long tons of contained tin.

The ITC invoked export controls on member producer nations from mid-January through September. At its September meetings, the ITC revised upwards the floor and ceiling prices of tin by 9% and 6%, respectively.

Legislation and Government Programs.—In April, the OP announced a reduction in the stockpile objective from 232,000 tons to 40,500 tons. A bill was submitted to Congress for authorization to dispose of the excess tin, but by yearend no action had been taken.

On June 7, GSA resumed commercial sales, suspended since July 1, 1968, of 18,253 tons of tin previously authorized for release. A disposal plan formulated by GSA, the Department of State, and the ITC proposed sales of 6,500 tons during the year, with 1,500 tons available through June and 5,000 tons available for the last half of the year. Demand for tin was so strong in July that the 5,000 tons allocated for the last half of the year was sold by July 11. In August, GSA discovered that an additional 32,000 tons could be released because the original authorization was not repealed in 1969 when Congress raised the objective to 232,000 tons. GSA resumed daily sales in September. A long-term sales program was announced December 5. Sales for the year total 19,262 tons, and shipments totaled 10,144 tons. At yearend, there was an excess of 190,512 tons on hand, of which 31,012 tons was approved for sale.

The Office of Minerals Exploration (OME), U.S. Geological Survey, continued its program of offering participatory loans for tin exploration up to 75% of approved costs.

DOMESTIC PRODUCTION

PRIMARY TIN

Mine Production.—Domestic production of tin in 1973 was less than 100 tons. Most of the year's output came from Colorado as a byproduct of molybdenum mining. Some tin concentrate was produced at dredging operations in Alaska and placer operations in New Mexico. Climax Molybdenum Co., a division of American Metal Climax Inc., announced it began preparation for open pit mining at its Climax mine in Colorado. This was in addition to a recently completed underground mining level. Climax recovered about 2 to 3 ounces of tin concentrate from each ton of ore processed. Getman Tin, Inc., began a small tin placer mining operation at Beaverhead, Catron County, N. Mex., in June. The Lost River Mining Corp. continued exploration at its property in the Lost River area of Alaska's Seward Peninsula. Financial arrangements were being negotiated for a $50 million facility to process 4,000 tons of ore per day from an open pit mine.

Smelter Production.—The only tin smelter in the United States is the Texas City, Tex., facility of GCMC. In 1973, it received 4,464 tons of tin-in-concentrate from Bolivia and 16 tons of tin-in-concentrate from the Republic of South Africa, which formed the base load, together with domestic tin concentrate and secondary tin-bearing materials. With the liquidation of the United Kingdom's Williams, Harvey & Co., Ltd. smelter, GCMC's major competitor for Bolivian concentrate, GCMC initiated plans to boost production from the present level of 4,500 tons per year to 8,000 tons per year by the end of 1974. Accordingly, GCMC and Bolivia negotiated a 10-year contract in which Bolivia guaranteed to deliver 6,000 tons of concentrate to GCMC in each of the first 3 years of the contract. Details of the remaining 7 years of the contract were not available. GCMC also had its GCMC brand of pig tin approved for delivery on the London Metal Exchange (LME).

SECONDARY TIN

The United States is the world's leader in the production of recycled, or secondary, tin. The United Kingdom, the Federal Republic of Germany, Austria, and Australia also produce secondary tin in significant quantities.

Of the tin recycled during 1973, 91% was an alloy constituent of bronzes, brasses, solders, and bearing and type metals. A small amount also remained in chemical compounds. Only 9% of the recycled tin, mostly from new tinplate scrap, found its way to market as metal. This latter volume provided only 3% of the total tin supplied to U.S. consumers in 1973, a proportion which does not vary appreciably from year to year.

Secondary tin furnishes about 25% of the total U.S. tin supply each year. In 1973 secondary tin produced in the United States increased 1% over the 1972 level to 20,477 tons.

Five companies in 11 States were engaged in the detinning business in 1973. Normally the raw materials used are tinplate scrap and spent chemicals or tinning solutions.

r Revised. XX Not applicable.
[1] Brass-mill stocks include home scrap, and purchased-scrap consumption is assumed equal to receipts; therefore, lines and total in brass-mill section do not balance.
[2] Omits "machine-shop scrap."

CONSUMPTION

The downward trend in tin consumption evident since 1968 was reversed in 1973. Total consumption of tin metal increased 8%, with primary and secondary tin consumption increasing 9% and 5%, respectively. The marked increase in tin used in solder, up 13% over the 1972 level, accounted for the majority of the overall rise. Although delegated to second place in relative importance of total tin consumption, tinplate continued as the most important primary tin consuming sector (37%). Consumption of tin for tinplate increased 1%, although the average amount of tin per short ton of tinplate continued to decline. An average of 9.7 pounds of tin was used per short ton of tinplate compared with 10.0 pounds in 1972. Most of the increased tinplate production was used in the manufacture of cans. Consumption increased in all sectors except bar tin and type metal. U.S. brass mills consumed 1,045 tons of primary tin, compared with 1,426 tons in 1972. Consumption of secondary tin, at 501 tons, was the same as in 1972.

[1] Includes secondary pig tin and tin acquired in chemicals.
[2] Includes pewter, britannia metal, and jewelers' metal.

STOCKS

Stocks of plant-held pig tin were 7% lower than in the corresponding period of 1972. Stocks dropped to a low of 5,050 tons in May, but resumption of commercial sales of pig tin by GSA were reflected by a rise in plant-held stocks to a high of 10,200 tons at the end of August. Drawdown of pig tin stocks continued for the remainder of the year. Tinplate mills held 4,405 tons of pig tin at yearend. Tin in process and tin in transit in the United States recorded increases from 1972 levels, but the increases were more than offset by declines in stocks held by jobbers-importers and tin afloat to the United States. Total tin stocks at yearend were 23,992 tons, 5% below the yearend 1972 level and the lowest since 1951.

r Revised.
[1] Tin content, including scrap.

PRICES

Prices of tin metal on world markets, in general, reflected conditions of supply, which ran the gamut from oversupply during the first 5 months of the year, through a tightening and balance of supply and demand during the next 5 months, to undersupply during the last 2 months. Factors making for market unpredictability included: ITC export controls and buffer stock sales; monetary problems of dollar devaluation and floating of the Malaysian dollar; U.S. tin stockpile sales; liquidation of the Williams, Harvey smelter; upward revision of the ITC buffer stock range and buffer stock restrictions; and the energy crisis.

Average prices for the year reached record highs on all markets. The average price for cash tin on the LME was £1960.44 per metric ton (218.04 cents per pound) compared with £1505.94 per metric ton (167.49 cents per pound) in 1972. The average Penang price for ex-works Straits tin was M$686.28 per picul[3] (213.55 cents per pound), compared with M$626.80 per picul (195.04 cents per pound) in 1972.

The Penang price for ex-works Straits tin began the year at M$625 per picul (194 cents per pound) and in general remained in the M$630 per picul range through May. The February devaluation of the dollar that moved U.S. and LME prices higher was not reflected in the Penang market. Tin supply tightened at the Penang market in June as Malaysia failed to meet its export quota for the quarter and prices rose. Malaysia floated its dollar in late June and prices dipped. After early July, the Penang price moved firmly into the upper sector of the buffer stock range. The buffer stock range was revised upward and export controls were dropped in September. The price remained firmly in the revised middle sector until late October when it moved into the upper sector. In November, the price penetrated the ITC ceiling price on its way to a record high in December. The move was caused by tight supply conditions aggravated by the buffer stock exit from the market and speculation. The price reached M$1,206 per picul (319 cents per pound) on December 10 but dropped off to end the year at M$815 per picul (254 cents per pound), substantially above the ITC ceiling of M$760 per picul (236 cents per pound).

FOREIGN TRADE

Although GSA sales of surplus stockpiled tin became a source of supply in the middle of the year, as reflected by a 13% drop in metal imports in 1973, the United States continued to rely upon foreign sources for the majority of its pig tin requirements. Of the 45,845 tons of tin metal imported into the United States, Malaysia furnished 62%; Thailand, 17%; and Australia and Indonesia, combined, 10%. The People's Republic of China was the fifth largest supplier of tin metal to the United States in 1973.

Imports of tin-in-concentrate destined for the Texas City, Tex., smelter totaled 4,480 tons in 1973. Bolivia furnished 4,464 tons and the Republic of South Africa, 16 tons.

Exports of metal from the United States trebled to 3,406 tons.

Small tonnages of secondary tin enter the United States as alloy constituents in recyclable solders or other alloys, or as tinplate or other scrap, dross, skimmings, and residues. These volumes find their way into consumption figures and account for the differences normally encountered between U.S. production and consumption of secondary tin. Tin that is a constituent alloy in imports and exports of babbitt, solder, type metal, and bronze is shown in the Minerals Yearbook chapters on "Copper" and "Lead." Ferrous scrap exports, including those of tinplate and terneplate scrap, are not classified separately.

[3] One Malaysian dollar (M$) = US$0.4149; one picul = 133.33 pounds.

WORLD REVIEW

INTERNATIONAL TIN AGREEMENT

The International Tin Council (ITC) operating under the Fourth International Tin Agreement (ITA), had an active year trying to control the tin situation. Large buffer stock holdings, a production surplus, and low tin prices forced the adoption of export controls on producer nations for the first quarter of the year. The possibility of unforeseen supply-demand problems developing because of GSA tin sales forced the retention of export controls through September 30. Inflation and an unstable monetary base forced an upward revision of the price range in late September. High demand, failure of some producing nations to meet export quotas, the closure of a major tin smelter, and the energy crisis caused a tight metal supply and led to a yearend shortfall of 23,000 tons between mine production and consumption. Prices rose above the ITC ceiling price to record highs, forcing curtailment of buffer stock operations, the only method available to the ITC for maintaining the ceiling price.

With the price of tin in the lower sector of the price range and over 12,000 tons of tin in the buffer stock, the ITC at its January meeting decided to impose export controls on member producing nations from January 19 to 31.

In March the ITC decided to retain export controls for the second quarter but cut the permissible tonnage 2.5% from the average 1972 export level and extended authorization for the buffer stock manager to operate in the middle sector.

A special session of the ITC met in July to consider revision of the floor and ceiling prices after floating of the Malaysian dollar. Since the value of the Malaysian dollar was only allowed to float upwards while the British pound floated freely, and the U.S. market was under the influence of GSA tin sales, the ITC decided not to revise price levels or the monetary base.

By the time of the ITC's mid-September session, the price of tin was firmly in the upper sector of the price range, GSA had sold its tin allocation for the year but had reentered the market because of the tight metal supply, and the buffer stock contained only 4,744 tons. Export control was dropped as of September 30, and authorization for the buffer stock manager to operate in the middle sector was withdrawn. Effective September 21, the price range was revised upward for the first time since October 21, 1970, after a compromise by the consuming and producing nations. The producing nations desired a 20% increase in the floor and ceiling price to compensate for inflation. The consuming nations felt a 5% increase was sufficient. The price range was revised as follows:

	Previous range		Revised range	
	M$/picul	U.S. equivalent, cents/pound	M$/picul	U.S. equivalent, cents/pound
Floor price	583	181	635	198
Lower sector	583–633	181–197	635–675	198–210
Middle sector	633–668	197–209	675–720	210–224
Upper sector	668–718	209–223	720–760	224–236
Ceiling price	718	223	760	236

In October, the ITC made known its position on U.S. stockpile sales. The ITC wished to be assured the following possibilities would not occur because of U.S. stockpile releases:

(a) Unacceptably low prices, leading to severe losses in the export earnings of producing countries and the closure of large sections of the mining industry, and consequent unemployment; whole sections of a country's or region's industry could be at risk.

(b) Breakdown of productive capacity or unwillingness to invest in new capacity, leading eventually to serious shortages of tin and excessively high prices; the larger the scale of the tin disposal program is, the more likely such shortages could eventually be.

(c) Serious prejudice to the objectives and work of the Council which has been carefully built up over the years; the buffer stock operations and export controls are currently operated in relation to commercial market conditions without extraneous supplies from non-commercial sources.[4]

By November 10 tin metal supply was so tight that even with combined GSA and buffer stock sales of over 15,000 tons, the price exceeded the ITC ceiling price. The buffer stock manager was released from the responsibility of supporting the ceiling price at the risk of exhausting the buffer stock. The price of tin rose to record highs in early December, and closed the year well above the ITC ceiling price.

During the year, the buffer stock levels continuously fell from 12,282 tons in January to 985 tons in December. The French Government contributed $3 million to the buffer stock fund. Ireland, Romania, and Turkey joined the Fourth ITA as consuming nations and the votes were adjusted as follows:

Austria	10	Italy	58
Belgium-Luxembourg	27	Japan	214
Bulgaria	11	Korea, Republic of	9
Canada	40	Netherlands	42
Czechoslovakia	30	Poland	35
Denmark	10	Romania	24
France	82	Spain	30
Germany, West	108	Turkey	14
Hungary	15	United Kingdom	121
India	34	U.S.S.R	64
Ireland	6	Yugoslavia	16
		Total	1,000

The producing nations' votes remained as established on October 1, 1972.

e Estimate. p Preliminary. r Revised.
[1] Data derived in part from the Statistical Bulletin of the International Tin Council, London, England.
[2] Includes tin content of alloys made directly from ores.
[3] Tin content of production from Metabol and Pero smelters plus exports by ENAF smelter.
[4] Estimate by International Tin Council.
[5] Estimate according to the 60th annual issue of Metal Statistics (Metallgesellschaft).
[6] Includes small production of tin from the smelter in Singapore.

Australia.—The Australian Government announced stricter controls on mining development and export prices of all minerals produced in an effort to ensure that Australian mineral wealth would benefit the nation and be sold at reasonable prices. The upward revaluation of the Australian dollar severely affected the Australian mining industry. Tin export controls reduced tin mine production by 13% and metal production by 2%.

Renison Ltd., Australia's largest tin producer, reported a slight drop in output because of a 3-month strike. Although the amount of ore treated was down 20% from that of 1972, the grade of ore rose from 1.30% to 1.49% and the recovery of tin-in-concentrate increased from 66% to 71% so the tonnage of tin-in-concentrate sold decreased only slightly to 3,809 tons compared with 3,845 tons in 1972. Renison announced an increase in tin ore reserves from 7,149,000 tons to 7,928,000 tons, with ore grade increasing from 1.30% to 1.34%. The installation of a heavy-media separation plant, to be completed in mid-1974, will increase mill throughput from 450,000 to 700,000 tons per year and enable treatment of lower grade ore.

The Aberfoyle group, consisting in part of Aberfoyle Ltd., Ardlethan Tin N.L., and Cleveland Tin N.L., reported disappointing earnings for its latest fiscal year because of fluctuating tin prices, increased operating costs, and the failure of the Storeys Creek mine.

Bolivia.—Of the 29,825 tons of tin-in-concentrate produced in 1973, COMIBOL contributed 20,515 tons, the medium miners 6,773 tons, and the small miners 2,537 tons.

Total tin exports were 27,950 tons, down 6% from the previous year's level. The Empresa Nacional de Fundiciones (ENAF), the national smelting company, increased its metallic tin exports from 6,158 tons in 1972 to 6,754 tons in 1973. ENAF sold 300 tons of electrolytic tin to Argentina, which ENAF felt may open the door to an expanded Argentine market for Bolivian tin metal.

ENAF obtained a loan from West Germany for plant equipment and machinery to expand the capacity of the Vinto smelter from 7,400 tons to 10,800 tons. The first stage was scheduled for completion by mid-1975 with final expansion to 19,700 to be completed by mid–1976.

Following the liquidation of the Williams, Harvey & Co., Ltd., smelter, which had been smelting the bulk of Bolivia's high-grade tin concentrate, the Bolivian Government contracted with Capper Pass & Son, Ltd., in the United Kingdom to take over smelting program. COMIBOL agreed to ship up to 6,000 tons of tin-in-concentrate per year for the next 3 years. Bolivia accepted a penalty readjustment in smelting fees as compensation for atmospheric contamination and another penalty for arsenic content. Overall, it is expected that smelting under the new contract will cost Bolivia about $1.3 million more each year than under the old contract. In addition, Bolivia can expect to collect only half of the $8.25 million debt owed by the Williams, Harvey smelter. Other smelters of Bolivian ore are located in the United States, Brazil, Mexico, Spain, and West Germany.

COMIBOL announced that its output of tin should reach 28,000 tons by 1980. Most of the increase is expected to come from more efficient recovery by extensive use of volatilization plants and new preconcentrating plants and techniques.

W. R. Grace & Co. sold its 75% interest in Estaños Aluviales, S. A. (ESTALSA), which operates a tin dredge and two washing plants, and its 57% interest in the International Mining Co. (IMCO), which operates an underground tin-tungsten mine. Tin production from these operations has been in the 2,000- to 2,300-ton range.

Brazil.—The Brazilian Industry and Trade Ministry concluded studies for the planning and development of Brazil's nonferrous metals industry. The Government will spend $16 million on a 2-year tin exploration and development program. Projected tin production of at least 7,500 tons per year by 1980 and projected consumption of 6,000 tons per year should allow Brazil to maintain its net export status.

In the Rondônia Area, Mineração Aracazeiro and Mineração Brasiliense (Mibrasa) blasted ore from bedded deposits. The deepest bed discovered so far, near Pôrto Velho, was 125 feet below the surface. W. R. Grace & Co. sold its 50% interest in Mibrasa to Brazilian interests. Tin production by Mibrasa has been about 750 tons per year.

Cia. Industrial Amazonense began operations at its new refinery in Manaus. The plant produces 78 tons of tin metal per month from Rondônian ores.

Canada.—Ecstall Mining Ltd., a subsidiary of Texas-gulf, Inc., installed a $5.5 million tin concentration circuit at the Kidd Creek mine near Timmins, Ontario. The new plant will recover fine cassiterite from tailings from the main plant. Bartles-Mozley wet gravity concentrator tables preconcentrate the byproduct tin to 0.7% tin. Further upgrading by tabling, flotation, and leaching produces a concentrate assaying 54% tin. Production of concentrate is expected to reach 700 tons per year.

Indonesia.—Even though operating under export controls for most of the year, Indonesia increased tin mine production 5% over the 1972 level to 22,135 tons, the highest level since 1960. Indonesia regained its position as the third largest tin producer, displacing Thailand. Increased output was attributed to the recent modernization by P.N. Timah of its bucket dredges and the introduction of new ore-dressing methods for improving cassiterite recovery. In accordance with Indonesia's new 5-year plan, tin mine output is targeted at 25,000 tons for 1974.

Two new seagoing bucket dredges, tentatively named *Bangka II* and *Bangka III*, were under consideration by P.N. Timah. Design will be similar to that of *Bangka I* to afford parts interchangeability, but the new dredges will be able to operate at a greater depth than the 130 foot-maximum of *Bangka I*. Firm financial arrangements have yet to be made.

P.T. Koba Tin, a joint venture owned 25% by the Indonesian Government and 75% by three Australian firms (Colonial Sugar Refining, Blue Metal Industries, and Ready Mixed Concrete, a subsidiary of Blue Metal) was the first overseas joint venture company to commence tin mining in Indonesia since independence in 1945. P.T. Koba Tin operated two gravel pumps and planned to install three more by early 1974. Production is expected to exceed 800 tons of tin concentrate in 1974.

P.T. Broken Hill Pty. Indonesia began rehabilitating the Kalapa Kampit lode mine on Bilitung. Production prior to its closure in 1942 reached 2,000 tons of tin-in-concentrate per year. After dewatering of a section of the mine, operations will resume at an initial rate of 100 tons of ore per day.

Malaysia.—Malaysia continued to lead the world in production, smelting, and exports of tin in 1973. A total of 71,119 tons of tin-in-concentrate was mined, the lowest level since 1966 and down 6% from the previous year's production because of export controls, heavy flooding during May in many mining areas, and low prices of tin during the first half of the year. At yearend there were 58 tin dredges, 873 gravel pump mines, and 43 opencast, underground, and other miscellaneous mines in operation, reflecting a 7% drop in total active mines through the year. The gravel pump mines bore the brunt of the decreased mining activity with a loss of 67 mines during the year.

Gravel pump operations, worked for the most part by the same families that own the mines, accounted for about 54% of the concentrate produced, while dredging by corporations furnished another 31%. Opencast mines brought in 5% of the ore produced, underground mines accounted for 3%, and the remaining 7% came from miscellaneous sources. The tin-mining labor force declined 9% to 41,744 workers at yearend.

Metal production, at 81,166 tons, was 9% below the 1972 level and the lowest since 1967. Exports of metal declined to 80,397 tons from 86,063 tons in 1972.

Perbadanan Nasional Berhad (Pernas), Malaysia's national mining corporation, was granted tin exploration rights to a concession of over 15,000 square miles offshore from Penang, Perak, and Selangor States. After an initial 3-year exploration period, Pernas can apply for a mining lease for 5% of the area. The remainder of the concession will revert to the Malaysian Government, but Pernas will retain first option on the areas surrendered.

Several new dredges started operations during the year. Conzinc Riotinto Malaysia Sdn. Berhad, a joint venture between Rio Tinto-Zinc (41.25%), Conzinc Riotinto of Australia Ltd. (13.75%), and Bethlehem Steel Corp. (45%), started dredging for tin at Labohan Dagong, Selangor. The 5,300-ton dredge built by IHC Holland can dig to a depth of 150 feet and has an annual throughput of 10 million cubic yards. The dredge has circular jigs and produces a low-grade concentrate prior to further upgrading onshore. Selangor Dredging Berhad's No. 2 dredge began operation late in 1973. The $4.7 million 24-cubic-foot bucket dredge is capable of annual throughput of 12 million cubic yards.

Other new dredges were in the planning stage. Selangor State Development Corp. contracted for the design of its first dredge. The $4.1 million dredge, scheduled to begin mining in 1976, will be operated by the corporation's subsidiary, Syarikat Timah Langat Sdn. Berhad, on a 2,000-acre area at Dengkil in Selangor's Kuala Langat forest reserve.

Berjuntai Tin Dredging Berhad, the largest private tin-mining company in the world, decided to proceed with the construction of its eighth bucket dredge. The new dredge will have 22-cubic-foot-capacity buckets, monthly throughput of 600,000 cubic yards, and a maximum dredging depth of 130 feet. Reserves sufficient for 11 years of operation have been allocated for the dredge. When No. 8 begins production, Berjuntai will close down its No. 1 dredge, which has been mining in Selangor for nearly 50 years. Berjuntai's tin concentrate production was down 366 tons to 4,551 tons for its fiscal year because of the lower grade ground worked by all but the No. 7 dredges. The two newer 20-cubic-foot bucket dredges, Nos. 6 and 7, produced 2,248 tons of concentrate, or about as much as the five older units combined. Output reached 2,467 tons, compared with 2,197 tons for the corresponding period in 1972.

Malayan Tin Dredging Ltd., and Southern Malayan Tin Dredging Ltd., had reduced outputs during the fiscal year 1973. Malayan Tin plans to divert the River Kinto so an additional 368 acres of land on its Kampong Gajah property will be available for dredging. The project is expected to be completed in 1979. The work will proceed in stages so the company's dredges can work systematically through the area.

Ayer Hitam Tin Dredging, Ltd., reported increased output of 3,469 tons in fiscal 1973, compared with 3,109 tons in

1972. Production during the fiscal year is expected to decrease because lower grade ground is being worked and the No. 2 dredge was temporarily shutdown.

Sungei Besi Mines Ltd., operating three opencast mines in southeastern Selangor, had a record production in fiscal year 1973 of 2,472 tons of concentrate assaying 74.3% tin. Stripping operations continued at the new 3/5 mine, with production scheduled to start in 1974.

Gopeng Consolidated Ltd., produced 2,686 tons of concentrate during the year, slightly less than in 1972. Gopeng purchased 2,167 acres of land, some of which is to be used for dumping tailings. This will ease the company's task in meeting Government water purification requirements prior to returning water to the normal river courses. Gopeng also concluded a lease-purchase agreement for 541 acres of mining land in the Batang Pedang district of Perak.

Pahang Consolidated Co., Ltd., whose mine at Sungei Lembing is the largest lode tin venture in Southeast Asia, produced 2,535 tons of concentrate, slightly less than during 1972. Pahang realized $3.5 million through the sale of its wholly owned subsidiary, The Kuala Reman Rubber Estates. Some of the funds will be used in sinking the Gakak shaft and installing a new heavy-media separation plant. Ore reserves are estimated at 11,500 tons of contained cassiterite.

Pacific Tin Consolidated Corp., the only U.S. company mining tin in Malaysia, showed decreases in total yardage treated and tin recovered in 1973. The No. 5 dredge was shutdown in February when its minable reserves were exhausted. Dredge No. 8, operating at Batang Berjuntai, dug 56% of the total yardage and produced 43% of the total tin recovered by all plants in 1973. Dredge No. 2 operated on leases along the Selangor River. Four gravel pump mines operated in the Ampang area, but one was closed down in September after allocated reserves were exhausted. Estimated tin ore reserves at yearend were about 8,000 tons.

A new regional tin center will be constructed in Ipoh by the Conference of Asian Nations on Geology. The center will conduct research on better methods of mining and treating tin ore.

Nigeria.—Production of tin in Nigeria declined for the fifth consecutive year to 5,736 tons, its lowest level since 1959. Over the past several years, spiraling production costs had lowered the profit margin of operators to a point where significant reinvestment and exploration programs had to be curtailed, forcing rapid depletion of minable ore bodies. In May, the Government changed the royalty levied on tin production from 17% to a sliding scale of 11% to 16% based on world price. The new rates were retroactive to April 1. The lower royalty should help encourage reinvestment in the hard-pressed tin industry.

Amalgamated Tin Mines of Nigeria Ltd., the largest tin producer in Nigeria, reported a 7% drop in tin concentrate production to 3,464 tons for the year ending in March, but had higher profits for the year because of improved tin prices. Production was adversely affected by heavy rains. Prospecting activities increased as the company sought extensions of alluvial deposits under the basalt.

Gold & Base Metal Mines of Nigeria Ltd., continued exploration at its Liruie project in Kano State. Five exploratory shafts were sunk to varying depths along a strike length of 4,550 feet. The lode ranges in width from 7 to 8 feet and contains an average of 0.8% tin and 3.42% zinc, calculated over a minimum mining width of 5 feet. Planned throughput was based on 900 tons per day.

South Africa, Republic of.—The two major South African producers, Rooiberg Minerals Development Co. Ltd. and Union Tin Mines Ltd., reported higher tin concentrate recoveries during their fiscal years, partially the result of successful operation of new flotation plants. Rooiberg's output increased 28% to 1,891 tons of tin-in-concentrate. Flotation recoveries by Union Tin increased to 551 tons compared with 205 tons in 1972, but gravity concentrate recoveries dropped to 147 tons from 376 tons in 1972. Total increase in tin concentrate output was about 20%.

Thailand.—Tin production decreased 7% to 20,232 tons in 1973 as heavy monsoon rains, the 3-month breakdown of the sea dredge *Temco II*, and the diesel oil shortage forced mine closures and production cutbacks. By yearend, about the same number of tin mines were in operation as at yearend 1972, because the number of gravel pump mines that closed was offset by an increased number of tin-tungsten operations. Of the 656 mines in operation, there were 25 dredges (17 inland, 8 offshore), 266 gravel pump mines, 8 hydraulic mines, 108 ground sluicing operations, 216 tin-tungsten mines, and 33 miscellaneous operations.

Southern Kinta Consolidated Ltd. modified its Takuapa near-shore suction dredge by increasing pumping capacity by 8,000 gallons per minute, enlarging suction dragheads, installing hydrocyclones for dewatering, and adding more swell compensators and longer suction pipes to enable operations to 60-foot depths where necessary. Southern Kinta's output increased 63% over the 1972 level to 856 tons of tin concentrate in 1973.

Tronoh Mines Ltd. reviewed designs of dredging equipment capable of round-the-clock operation throughout the monsoon season to determine whether tin deposits discovered on the west coast of Thailand could be economically exploited. Thai Tin & Tungsten Corp., a subsidiary of Pickands-Mather & Co., was acquired by Faber Merlin Ltd. Thai Tin and Pacific Tin Consolidated Corp. had been developing an underground tin-tungsten mine at Sichon in southern Thailand. Faber Merlin expects to bring the Sichon mine to the preproduction mill-testing stage by the end of 1974, with an initial mill throughput of 3,000 tons per month to yield 30 tons of tin and 4 tons of tungsten. Faber Merlin Thailand, 41.4% owned by Faber Merlin Ltd., purchased St. Piran Mining Ltd.'s Thai mining interests comprised of five dredges operated by Siamese Tin Syndicated Ltd. and Bangrin Tin Dredging Co., Ltd.

United Kingdom.—Consolidated Tin Smelters Ltd., announced the voluntary liquidation of the Williams, Harvey & Co., Ltd., smelter as the result of continuing monetary losses. Rundown operations at the smelter, located in Kirkby, continued until the end of December, but efforts to locate a new operator failed. The smelter was the larger of the two United Kingdom smelters, producing about 16,700 tons of primary metal in 1972. The smelter, built at a cost of $14.7 million 4 years ago, was never able to operate at a profit because of the high transportation costs and the difficulty of processing Bolivian concentrate, its main feed source. Capper Pass & Son Ltd., agreed to process the Bolivian concentrate previously sent to Williams, Harvey.

South Crofty, Ltd., a wholly owned subsidiary of St. Piran Mining Co. Ltd., purchased the Pendarves tin mine, which had been placed in receivership early in the year by Camborne Mines Ltd. Operations at the Pendarves mine will be integrated with those of South Crofty. The spare capacity of the South Crofty mill will be used to treat Pendarves ores. The South Crofty mine produced 1,529 tons of tin concentrate in 1973, down slightly from 1972 production.

Wheal Jane Ltd., a subsidiary of Consolidated Gold Fields, Ltd., produced 1,585 tons of tin-in-concentrate during 1973, 185 tons over its initial projected rate of 1,400 tons per year. Deepening and reequipping of the Clemow shaft was completed in January, allowing increased production even though ore grade was running lower than the anticipated 1.25% tin.

Cornwall Tin & Mining Corp. concluded financing arrangements which will enable it to bring its Mount Wellington property into production. The property, situated next to the Wheal Jane mine, has indicated reserves in excess of 5 million tons averaging 1.37% tin with associated copper and zinc.

TECHNOLOGY

Geochemical techniques for tin prospecting in British Columbia and the Yukon Territory in Canada were discussed.[5] The most practical analytical techniques were evaluated, including a spectrophotometric method and geochemical field kit. Suggestions were made for sampling soil horizons and rocks; a simple "heavy minerals collector" for stream sediment sampling was described; and arsenic, copper, fluorine, lead, molybdenum, tin, and zinc contents of various samples were analyzed by graphical and computer methods.

The metallogenetic basis of tin exploration in the Erzebirge mining district of

[5] Barakso, J. H., and J. A. Gower. Geochemical Prospecting for Tin. Western Miner, v. 45, No. 2, February 1973, pp. 37–44.

East Germany was described.[6] Factors and indicators critical in exploration for concealed endogenetic-epigenetic tin deposits were discussed. Leaching and redeposition in the formation of tin deposits were related, and a model concept was developed for the formation of endogenetic-epigenetic tin deposits.

The analytical system used to control the continuous flotation process at the Wheal Jane ore-processing plant allowed profitable mining of the previously uneconomic ore.[7] Mineralogical difficulties, such as a high concentration of sulfide minerals in the ore and finely disseminated cassiterite, that had stymied previous operators were overcome by frequent computerized X-ray spectrometer analysis of samples taken at all stages of the process. A description of the flotation methods used by Consolidated Gold Fields Group at its Wheal Jane mine as well as its three other lode tin mines was published.[8] A British patent was issued for a technique for gravity concentration of cassiterite from slimes.[9] Recoverey of particles in the 5- to 100-micrometer range was said to be possible.

The Australian Defence Standards Laboratories obtained favorable results in its study of antifouling systems of organotins in elastomer-toxicant combinations.[10] Compounds investigated were tri-n-butyltin oxide, tri-n-butyltin acetate, and tri-n-butyltin fluoride. Elastomers studied were natural rubber, nitrile rubber, and polychloroprene.

Tri-n-butyltin oxide combined with dieldrin, a chlorinated hydrocarbon, was very effective in protecting wood against termite attack.[11]

A new class of superconducting alloys consisting of 90% copper and one or two superconducting metals such as columbium and tin was developed.[12] The new class is ductile and pliable and can be fabricated into wires, strips, and tubes. Recent developments in the application of centrifugal casting of tin-containing alloys were reviewed.[13] Substitution of tin and tin alloys of lead and nickel for gold in the electronics industry became more widespread as the price of gold increased.[14] Tin alloyed with silver-antimony and lead-silver was being used by the automotive industry in special bonding preforms for new electronic ignition systems.[15]

The use of solder preforms in industry was on the increase.[16] In most cases, the preforms are tin-lead alloys of 60% tin and 40% lead or 45% tin and 55% lead. Once in place, the preforms can be joined by conventional heating methods to form perfect solder fillets. A discussion was presented of the influence of component materials on the quality of soldered joints with emphasis on tin and tin-lead coatings applied by hot-dipping or by electrodeposition.[17]

A study showed that pulse plating was a very effective technique for the electrodeposition of silver-tin alloys of fixed composition.[18] It is a particularly effective technique for the preparation of high-quality Ag_3Sn coatings with minimal amounts of elemental silver and tin.

By diffusing a tin coating into a ductile steel sheet, a tin-rich surface can be obtained that improves the corrosion properties of the steel without significantly altering other properties.[19]

A detailed study was made of the kinetics of the catalytic oxidation of carbon mon-

Titanium

By F. W. Wessel [1]

Production of all titanium commodities increased during 1973. Ore production benefited from a full year's operation by Titanium Enterprises in Clay County, Fla., and the opening of the American Smelting and Refining Company (Asarco) plant at Manchester, N.J. Pigment production increased because of plant expansions, principally that of E. I. du Pont de Nemours & Co. at New Johnsonville, Tenn. Industrial demand for titanium metal rose sharply during the last quarter.

Midyear indications of decreased housing starts had no apparent effect on the demand for pigment. Plastics industry demand was particularly strong, increasing about 35% over the previous year. The paper industry also is trending toward use of more pigment per unit weight of paper.

Worldwide criticism of waste-disposal practices at sulfate-process pigment plants prompted producers to adopt some type of pollution control. One European producer estimated a 15% increase in cost of product as a result. New sulfate-process capacity, accordingly, is being contemplated mainly in the less industrialized nations. Chloride-process plants, however, were being approached cautiously because of a limited world rutile supply.

Imports of natural rutile decreased about 15%, but imports of synthetic rutile increased appreciably. New or expanded facilities for ilmenite upgrading were under construction or on the drawing board in Australia, Canada, Japan, Taiwan, and the United States as the year ended. Ilmenite imports increased sharply during the year, but imports of Sorel slag and titanium pigment declined, in the latter case because of higher prices outside the United States.

Price increases in all sectors were prevalent and generally substantial. Ilmenite prices were up about 50%, rutile prices increased by 77%, and Sorel slag by more than 20%. Titanium sponge prices were about 8% higher at yearend. Only pigment prices, controlled by the Cost of Living Council, were slow to rise.

The political situation in Australia was such as to inhibit new mining investment;

international capital is apparently finding the situation there somewhat less congenial than formerly.

At yearend a commission formed by the European Community was studying titanium pigment operations and seeking a solution to its waste disposal problems.

Legislation and Government Programs.—About midyear the stockpile objectives for both rutile and titanium sponge were revised to zero. Disposal of 17,385 tons of rutile was authorized by Congress; of this quantity, 13,756 tons was sold by yearend for a total of $2.75 million. While deliveries of sponge under the 1972 contracts continued, small quantities of older sponge in inventory were released for sale.

Government exploration assistance for rutile, available through the Office of Minerals Exploration, U.S. Geological Survey, remained at 75% of the approved cost of exploration. The depletion allowance for ilmenite and rutile remained at 22% for domestic deposits and 14% for foreign deposits.

DOMESTIC PRODUCTION

Concentrates.—Production and shipments of titanium-mineral concentrate in 1973 increased 12.9% and 9.4%, respectively; the quantity of TiO_2 contained in the shipments increased 11.0%. The average grade of concentrate shipped was 57.4% TiO_2, a small increase over 1972 levels. The tonnage increases resulted from a full year's production at the new mine of Titanium Enterprises at Green Cove Springs, Clay County, Fla., and one-half year's production at the Asarco mine, Manchester township, Ocean County, N.J. Production continued at the mines of E. I. du Pont de Nemours & Co., Starke and Highland, Fla.; Humphreys Mining Co., Folkston, Ga.; SCM Corp., Glidden-Durkee Div., Lakehurst, N.J., and NL Industries, Inc., Tahawus, N.Y.

At Asarco's New Jersey property, construction was completed early in spring, and operations began in late June. The sand contains 4% heavy minerals; the concentrates contain 63% TiO_2. Some zircon and sillimanite are rejected. The sand reportedly contains no rutile. The dredge capacity is 1,200 tons per hour, but normal downtime, moving, etc., will limit daily production to an average of 20,000 tons. Operating capacity is estimated at 165,000 tons of product annually. The mine will probably operate for at least 20 years.

The Humphreys Mining Co. operation at Folkston, Ga., has probably had its last full year of operation at that locality. It is expected that the company will turn its attention to another sand deposit just within the Florida border and close enough to Folkston to permit trucking of the rough heavy-mineral concentrate to the dry plant there.

Ferroalloys.—Production of ferrotitanium increased to 1,156 tons in 1973, about 75% of the total representing the higher titanium-content alloys. Producers continued to be Shieldalloy Corp., Newfield, N.J., Union Carbide Co., Niagara Falls, N.Y., and Foote Mineral Company, Cambridge, Ohio. Scrap and ores were used as raw material.

Metal.—Production of titanium sponge was 50% higher than in 1972. Part of this increase was to fulfill General Services Administration contracts to procure the material for the Federal stockpile; shipments were made throughout the year by both producers. There was also a sharp increase in demand from industrial sources during the last 4 months of 1973. Producing companies were Titanium Metals Corp. of America (TMCA), Henderson, Nev., owned by NL Industries, Inc. and Allegheny Ludlum Steel Corp.; and RMI Co., Ashtabula, Ohio, owned by National Distillers & Chemical Corp. and United States Steel Corp.

Production of titanium ingot was 28,932 tons, a 43% increase over 1972 levels. As in 1972, the following nine companies produced ingot.

Company	*Plant location*
Crucible Steel Company of America.	Midland, Pa.
Howmet Corp	Whitehall, Mich.
Martin Marietta Aluminum, Inc	Torrance, Calif.
Oregon Metallurgical Corp	Albany, Oreg.
RMI Co	Niles, Ohio
Teledyne Titanium, Inc	Monroe, N.C.
Titanium Metals Corp. of America.	Henderson, Nev.
Titanium West, Inc	Reno, Nev.
TiTech International, Inc	Pomona, Calif.

Pigment.—Demand for all grades of titania pigment continued to be strong during 1973. Production increased 7.5% during the year, and shipments about 10.5%. Rutile-type pigment accounted for 72% of total production and was produced by all seven manufacturers. Anatase-type pigment was produced by five companies.

Strikes and mechanical difficulties are estimated to have cost the pigment industry more than 12,000 tons of production. At yearend, companies producing titania pigment, and their plant locations, were as follows: American Cyanamid Co., Savannah, Ga.; Kerr-McGee Chemical Corp., Hamilton, Miss.; E. I. du Pont de Nemours & Co., Antioch, Calif., Edge Moor, Del., and New Johnsonville, Tenn.; NL Industries, Inc., Sayreville, N.J., and St. Louis, Mo.; New Jersey Zinc Co. (a Gulf & Western Industries, Inc. unit), Gloucester, N.J., and Ashtabula, Ohio; SCM Corp., Glidden-Durkee Div., Baltimore, Md.; and Sherwin-Williams Chemical Co., Ashtabula, Ohio.

Du Pont's New Johnsonville plant capacity reached 228,000 tons per year by yearend. Work continued during the year at du Pont's Edge Moor plant, where chloride process capacity was replacing sulfate process units. The chloride-process plant will have 112,000 tons of annual capacity, and startup is scheduled for mid-1974. In April, du Pont's Pigments Department was considering construction of a 100,000-ton-per-year pigment plant on Colonel's Island, near Brunswick, Ga. Opposition from environmental groups was strong, however, concerning du Pont's plans for deep-well waste disposal. At last report the company was looking at alternate sites in the southeastern States.

Sherwin-Williams Co. and Rutile and Zircon Mines Ltd. (RZM), an Australian Company have concluded an agreement by which Sherwin-Williams will build a 50,000-ton-per-year plant to produce synthetic rutile on the basis of technology furnished by RZM. Completion is projected for late in 1974.

American Cyanamid Co. (Cyanamid) was notified early in January that its titania pigment plant in Savannah, Ga., was not in compliance with Georgia water-quality laws in its practice of discharging sulfate-process sludge into the Savannah River. At a cost of $80,000, Cyanamid obtained the right to use a process, developed by Ishihara Sangyo Kaisha, Ltd., for neutralizing acid wastes and thereby pro-

ducing usable gypsum. In May, the Georgia Ports Authority announced its intent to issue revenue bonds to finance construction of pollution abatement facilities based on the Ishihara process. Ground was broken on September 19, and the treatment complex will be operating by the end of 1974. Universal Gypsum Co. of Georgia, a subsidiary of Universal Chemical and Mineral, Inc., will operate the new plant, the cost of which is estimated at $20 million.

CONSUMPTION AND USES

Concentrates.—Consumption of ilmenite was 3% greater than in 1972. Consumption of Sorel slag was 7% greater. Consumption of rutile, including the synthetic, increased 14%.

Metal.—Consumption of sponge and ingot increased 54% and 30%, respectively. Shipments of mill products gained 15% over those of 1972. Beginning about September 1, an increase in demand for titanium became evident, originating primarily in the industrial sector. As a material of chemical engineering construction, the metal found increased use in petrochemical plants, chlor-alkali cells, and copper-leaching hardware. Scrap consumed for making ingot increased 29% above 1972 levels. There is some evidence that about 4 million pounds of ingot went into inventories, principally those of consumers, during the year.

Pigments.—Preliminary figures showed a 10.5% increase in shipments. The quantity in excess of the 7.5% increase in production was accounted for, as in 1972, by delivery of imports and of pigment withdrawn from stocks. The plastics industry, consuming pigment at an accelerated rate during 1972 and most of 1973, showed indications of stabilized demand late in the year; the industry was operating near capacity, and some feedstocks were becoming harder to obtain.

STOCKS

In 1973, stocks of rutile in the United States continued to decline; yearend inventories were 9% below those at yearend 1972. Slag inventories decreased by 22% but ilmenite in inventories increased by 10% during the year. Yearend stocks of titanium sponge were 1,941 tons, and of titanium scrap 4,447 tons, representing increases of 7% and 2%, respectively. Figures for titanium scrap refer to metal in the hands of ingot and mill shapes producers only. An appreciable but undetermined quantity of scrap was in the inventory of steel and ferroalloy plants. Industry stocks of titanium dioxide declined for the third successive year, from 54,982 tons on January 1 to 34,122 tons at yearend—a 38% decrease.

Table 7.—Stocks of titanium concentrates in the United States, December 31

1973	143,181	135,546

[e] Estimate. [r] Revised.

PRICES

Concentrates.—Published price quotations for ilmenite, $22 to $24 per long ton at the beginning of 1973, increased to $32 on August 17 and to $38 on December 21. These figures are nominal; almost all domestic production of ilmenite is captive. Australian ilmenite prices increased to A$11–A$12 f.o.b. Australian ports. Indian ilmenite remained unchanged at £3.95 f.o.b. Indian west coast ports, and Malaysian ilmenite continued to bring £9.35 to £11.32 per metric ton c.i.f. British ports.

Rutile, bulk, f.o.b. cars at Atlantic and Great Lake ports, was quoted at $175 per short ton until May 18, when the price went to $210. On December 14 the price increased to $310, a 77% increase during the year. Corresponding prices in Australia were A$115 to A$125 per long ton until May, when quotations went to A$125 to A$130. In July another small increase became effective; quotations were A$127 to A$132 f.i.d. (free in container depot, a new basing point). Additional increases were noted in October and December; the yearend price was A$147 to A$152. Rutile released from the Federal stockpile during the last half of 1973 brought prices of $170 per short ton in August and $226 in November.

Titanium slag (70% to 71% TiO_2), quoted at $50 per long ton f.o.b. plant at Sorel, Quebec, went to $53 in mid-August and $60 at the yearend.

Manufactured Titanium Dioxide.—Continued heavy demand for all grades of pigment and increasing raw material costs permitted no relaxation of upward price pressures. In lots of 20 tons minimum, prices at yearend were within the following ranges:

	Prices (cents per pound)
Anatase:	
Paper grade	24–24½
Other grades	27½–29½
Rutile:	
Standard grade	27½–28½
Premium grades	28½–30

Material shipped as slurry was generally ½ cent per pound cheaper.

Late in December, one pigment maker announced prices, effective January 1, 1974, to be 30½ cents per pound for premium-grade rutile and 29½ cents per pound for standard-grade rutile and the higher anatase grades.

During the first half of 1973, several major European producers increased prices for pigment. The Kronos group of West Germany raised its prices 8% in European markets and 12% in markets outside Europe in March. In May, British Titan, Ltd., increased its prices by £18 per ton (approximately 2 cents per pound).

Metal.—Domestic sponge began the year at $1.32 per pound. The price increased to $1.42 to $1.45 in May, and ended the year at that level, although at the end of the year a further increase seemed imminent. Sponge imported from Japan, priced at $1.20 to $1.25 at yearend 1972, went to $1.34 to $1.37 in May, to $1.28 to $1.33 in August, and finally ended the year in the $1.36 to $1.38 range.

FOREIGN TRADE

Titanium dioxide exports in 1973 amounted to 20,769 tons, double the 1972 figure. Of this total, Japan received 20%, other Far East countries 31%, Western Europe 17%, Latin America and the West Indies 16%, and Canada 11%. Exports of unwrought, waste, and scrap titanium were 18% higher than in 1972; 47% went to the United Kingdom, 20% to Italy, and 14% to Belgium. The average valuation was 43½ cents per pound compared with 31 cents in 1972. Exports of wrought titanium (ingots and mill shapes) were up 33% from 1972 levels. Canada imported 38% of the total, the United Kingdom 23%, and France, West Germany, and Italy a total of 25%.

As a result of changes in the titanium industry product mix over the past few years import statistics for titaniferous raw materials no longer give a clear, complete picture of foreign trade. Six different materials are being imported in significant quantities: Ilmenite, rutile, Sorel slag, synthetic rutile (beneficiated ilmenite), Sorelflux, and titaniferous iron ore. There are only three T.S.U.S.A. categories for titaniferous raw materials: 601.5120 Ilmenite and ilmenite sand, 601.5140 Titanium minerals n.e.s., and 603.6200 Titanium slag. In addition, some synthetic rutile is imported under category 603.7 (Other metal-bearing materials).

In 1973, imports as reported by the Bureau of the Census, Department of Commerce, were 216,350 tons of ilmenite and ilmenite sand, 311,153 tons of titanium minerals n.e.s., and 100,327 tons of titanium slag. However, the results of a Bureau of Mines canvass showed consumption of 281,791 tons of slag in 1973, of which only 22,373 tons came from inventory.

Since all slag and the great bulk of titaniferous iron ore was imported from Canada, and since Canada was the sole source of slag and of Sorelflux, the raw monthly data for imports from Canada were analyzed. The governing parameter was the declared valuation in U.S. dollars per short ton. Entries in the $5 to $25 range were reclassified as titaniferous iron ore, which included Sorelflux and material for aggregate. Entries in the $30 to $40 range were classified as ilmenite, and those in the $40 to $65 range were classified as Sorel slag. These classifications were for Canadian imports only; data for other imports were accepted on the basis of f.o.b. prices in the country of origin.

Synthetic rutile during 1973 bore a declared valuation of $65 to $110 per ton. Some entries in this price range were noted in both the 601.5120 and the 601.5140 listings. Valuations higher than $110 were identified as natural rutile. Entries in the three categories were reclassified accordingly:

Commodity	TSUSA Categories			
	601.5120	601.5140	603.6200	Total
	(short tons)			
Ilmenite	98,262	--	--	98,262
Titaniferous iron ore	83,513	--	--	83,513
Slag	83	136,838	100,327	237,248
Rutile (natural)	11,188	161,124	--	172,312
Rutile (synthetic)	23,305	13,190	--	36,495
Total	216,351	311,152	100,327	XX

XX Not applicable.

Of the 98,262 tons of ilmenite tabulated, 28,571 tons was reported from the Bahamas, a country which has no ilmenite production. Deducting this figure pending verification leaves a total ilmenite import of 69,691 tons.

Certain shipments from Japan, India, and Australia, totaling 37,515 tons, were entered under category 603.7000. These shipments met the declared-valuation criterion for synthetic rutile; however, addition of this quantity to the synthetic rutile tabulated above would result in an import volume far in excess of known world productive capacity. Therefore, pending verification, the data will not be used.

The data of table 9 are presented in accordance with the foregoing computations.

Imports of ilmenite from Australia doubled in 1973, the increase presumably coming from the new operations in Western Australia. Imports of Sorel slag from Canada amounted to 237,000 tons, a 20% decrease from the (revised) 1972 figure. Rutile from Australia was 20% less than in 1972, but substantial quantities of synthetic rutile from Japan and India brought the total imports to 209,000 tons, 5% less than the 1972 total. A total of 54,543 tons of off-grade titaniferous iron ore entered the port district of Galveston during the year, presumably intended for use in encasing seabed petroleum pipelines in heavy aggregate.

Imports of unwrought, waste, and scrap titanium increased 59% in 1973. Of the total, 5,172 tons was sponge coming from Japan (2,937 tons); U.S.S.R. (1,628 tons); and the United Kingdom (607 tons). The Japanese material had an average declared valuation of 92.5 cents per pound; the corresponding valuation of the Soviet sponge was 77 cents per pound. France and the United Kingdom were the principal sources of 512,547 pounds of titanium ferroalloys valued at $177,917.

Imports of pigment reached a total of 60,419 tons, 30% less than in 1972, but still about 7% of total U.S. consumption.

[1] Less than ½ unit.

Principal suppliers were West Germany and Canada, 23% each, and the United Kingdom and France, 14% each.

Imports of synthetic rutile from all three producing nations—Australia, India, and Japan—continued during the year. Shipments were reported from both current production and inventory.

WORLD REVIEW

Australia.—It was announced in August that Australia's Federal budget for 1973–74 for the first time contained no provision for tax concessions to private companies, including mining companies. In addition the Federal Government is restricting exports of minerals by setting minimum prices.

Restrictions inspired by environmental considerations were reported to have prevented mining of about one-fourth of the known mineral sand reserves on Australia's east coast, at an estimated cost of A$300 million in exports. NL Industries' $7.5 million beach sand project in Queensland was rejected by State authorities "for environmental reasons" although rehabilitation of the land following beach sand mining is usually successful.

Elsewhere on the east coast, production slowly advanced from the low fourth quarter of 1972. Totals for the year for New South Wales and Queensland were 351,000 tons of rutile and 38,900 tons of ilmenite.

A process by which ilmenite is upgraded to rutile grade, jointly owned by the Commonwealth Scientific and Industrial Research Organisation (CSIRO) and Murphyores Incorporated Pty. Ltd., was being tested jointly by Murphyores and Mitsubishi Chemical Industries, Ltd., in a pilot plant at Kurosaki, Japan. Planning began about midyear for a commercial-scale plant, using the process, to be built in Australia. Successful exploitation will permit expanded use of east coast ilmenites, which were in minimal demand for pigment production because of their chromium and vanadium content.

Mining activity along a 100-mile stretch of the Australian west coast continued at a high level during the year. Expansion of mineral sands production is proceeding from Jurien Bay to Geraldton, where proved and probable reserves exceed 130 million tons of heavy-sand products. Companies involved are Allied Eneabba Pty. Ltd., Ilmenite Pty. Ltd., A. V. Jennings Industries (Australia) Ltd., and Westcoast Rutile Pty. Ltd.

Allied Eneabba formally commissioned its 45,000-ton-per-year pilot plant on April 6. Operations at this scale apparently were successful, since in November it was announced that the company will begin construction of a 350,000-ton-per-year plant at a cost of about $12.4 million, to be fully operational by late 1975. Anticipated annual production at that time will be 200,000 tons of ilmenite and 50,000 tons of rutile. Leucoxene, zircon, monazite, and kyanite will also be produced in commercial quantities. During the pilot operation it became clear that dredging the deposit from a moving dredge pond was unsatisfactory; future mining will be conducted by dry methods. For the time being, exports will be made from the port of Geraldton, but it is possible that the company will build port facilities nearer the mining operation. A narrow-gage railway is also contemplated.

The litigation concerning 22 mineral claims in the Eneabba beach sands was decided in favor of Western Titanium N.L. A final appeal to the Privy Council in London is being considered. If the decision stands, Allied Eneabba's resources will be reduced to about 8 million tons of mineral concentrates, 0.75 million of which is rutile. However, Eneabba contemplates no change in its plans or the scale of operations.

A. V. Jennings Industries (Australia) Ltd., began processing its sands on a pilot scale in March. Construction of a $13 million full-scale plant is underway, to be operational in 1974 at the annual rate of 120,000 tons of ilmenite, 35,000 tons of leucoxene, 40,000 tons of rutile, and some zircon.

West Coast Rutile Ltd., a joint-venture company, one-third held by Mining Corp. of Australia Ltd. and two-thirds by Kamilaroi Mines, Ltd., completed a feasibility study on its 54 claims at Jurien Bay. Exploration indicates 3.2 million tons of heavy sands. A potential annual production scale was estimated at 150,000 tons of ilmenite, 19,000 tons of leucoxene, 25,000 tons of rutile, and some zircon and kyanite.

South of Perth, Westralian Sands, Ltd., established a new open pit mine in the Tutunup area, from which most of Westralian's production was coming at the yearend. Mining in the area between Yoganup and the Capel River ceased about midyear. Exploration further northward was undertaken in a joint venture with Tioxide Australia Pty. Westralian's production in the fiscal year ending June 30 exceeded 230,000 tons, 85% of it ilmenite.

Project Mining Corp. drilled nine claims at Hardy Inlet, near Augusta, and has an indicated reserve of 1 million tons of ilmenite. The company will initiate mining as soon as environmental clearance is obtained.

Western Titanium N.L. continued construction of its ilmenite upgrading plant at Capel, near Bunbury. The plant will produce a synthetic rutile of 94% TiO_2 grade and is expected onstream in April 1974. The company reports production of 43,553 tons of upgraded ilmenite between February 1, 1969, and June 30, 1973.

Brazil.—Cia. Vale do Rio Doce and two Japanese companies, Ishihara Sangyo Kaisha, Ltd., and C. Itoh, Ltd., signed an agreement to evaluate anatase resources in a carbonatite formation near Araxá, Minas Gerais. The Departamento Nacional de Produçáo Mineral (DNPM) evaluated reserves at 1,600 million tons of ore containing 10% TiO_2. The same two Japanese companies also signed an agreement with Cia. Brasileira de Tecnologia Nuclear to appraise the possibility of exploiting ilmenite beach sand resources in Espírito Santo to blend with the anatase as feed for a titania pigment plant. Earliest possible target date will be 1976.

Canada.—In December, Quebec Iron & Titanium Corp. announced plans to expand throughput of ilmenite ore at its Sorel, Quebec, plant to 2.2 million tons. The expansion will cost $8.8 million. An additional $2.6 million will be invested in pollution abatement at Sorel. Project completion is scheduled for mid-1975. Canadian pigment production was reported at 46,318 tons for the year.

India.—Recent estimates of ilmenite reserves and resources in India were placed at 356 million tons by the Geological Survey of India; by extension, reserves of rutile, monazite, and other associated minerals also are substantial. Indian Rare Earths, Ltd., a government corporation, is the sole beach sand mining entity. Annual capacity of the two company beneficiation plants, one at Manavalakurichi, Tamil Nadu, the other at Chavara, Kerala, totals 175,000 tons of ilmenite, 7,700 tons of rutile, and some zircon, monazite, garnet, and sillimanite. A 30% expansion at Chavara, underway during the year, will bring total ilmenite capacity to more than 200,000 tons.

The synthetic rutile facility of Dhrangadhra Chemical Works, Ltd., based on the Benilite process and obtaining its hydro-

Total	859,097	924,068	947,390

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, the U.S.S.R. also produces titanium concentrates, but available information is inadequate to make reliable estimates of output levels.

[2] Titaniferous slag production in Canada and Japan, reported under this heading in previous years, is reported separately in this edition. Ilmenite produced in Canada goes almost entirely into slag production; separate figures are not available.

[3] Includes leucoxene.

[4] Production of Comissão Nacional de Energia Nuclear only.

[5] Exports.

[6] Includes a mixed product containing ilmenite, leucoxene, and rutile.

[7] Contains 70% to 71% TiO_2.

chloric acid from a source adjacent to its location at Sahupuram, Tamil Nadu, was reported to have exported 38,000 tons of product to the United States up to March 31, 1973. The synthetic rutile contains 90%–92% TiO_2, 0.25% V_2O_5, and 0.2% Cr_2O_3.

Political difficulties have delayed the authorization to construct a titanium products complex at Chavara, issued originally to Ballarpur Paper and Strawboard Mills in 1968.

Italy.—The sulfate-process pigment plant of Montecatini Edison S.p.A. (Montedison) at Scarlino was the target of much criticism because of its practice of disposing of waste by dumping at sea. Quantities dumped ranged from 2,500 to 3,000 tons per day. Montedison sought temporary solutions by converting a portion of its effluent to ferrous oxide and reclaiming sulfuric acid, and also by disposing of its waste at depths below the normal habitat of most marine life. However, in September a local magistrate ordered seizure of the two ships used to move waste to the dumping grounds. As a long-range solution, Montedison was committed to adopt a process developed by New Jersey Zinc Co. to separate out ferrous sulfate and concentrate the remaining acid sufficiently for reuse. However, the recovery plant will probably be operative no earlier than mid-1976; meanwhile resumption of operations depends on further court action.

Montedison also contracted to build a 100,000-ton-per-year pigment plant in the U.S.S.R., payment to be received in the form of pigment produced at the plant.

Japan.—Ishihara Sangyo Kaisha, Ltd., reported that experience with its synthetic rutile product in making chloride-process titania pigment has been favorable. Kerr-McGee Chemical Corp. uses some of Ishihara's material in the feedstock to its pigment plant at Hamilton, Miss.

Following environmentally-induced shutdowns of pigment plants during 1972, supplies declined to less than domestic demand. As a result, Japan had no pigment available for export, and was offering to import from producing nations at prices somewhat in excess of those current in the United States. The shortfall of Japanese production was estimated at 11,000 tons for the year.

Japanese companies produced 7,173 tons of sponge and 4,690 tons of slag during 1973. The nominal capacity of Japan's three sponge producers—Osaka Titanium Co., Ltd., Toho Titanium Co., Ltd., and Nippon Soda Co.—is about 14,500 tons. The industry was reported to be in full-capacity production at yearend.

Malaysia.—Pacific Tin Consolidated Corp. was reported in September to be readying a plant to make an ilmenite concentrate as a byproduct of its tin recovery operations.

The Malaysian Titanium Corp. has contracted with Woodall-Duckham, Ltd., of the United Kingdom, for construction of an ilmenite upgrading facility, based on the Benilite process, at Ipoh, Perak. Capacity is stated to be 65,000 tons of product per year. The plant will cost $9 million, 35% of which will be supplied by an as-yet-unnamed company in the United States.

Mexico.—The 23,000-ton sulfate-process pigment plant of Pigmentos y Productos Quimicos, S.A. de C.V., at Altamira, Tamaulipas, was being replaced with a chloride-process plant of 35,000-ton capacity. A chlorine-caustic soda facility to supply the necessary chlorine was also approved for construction at the site. The cost of both plants is estimated at $8 million.

Norway.—Begun in 1972, current expansion of mining and beneficiating operations of Titania A/S, an NL Industries, Inc., subsidiary, at Hauge-i-Dalane will permit production of over 1 million tons of ilmenite flotation concentrate annually. The scale-up was essentially completed late in 1973. The ilmenite product contains about 45% titanium dioxide, 46.5% iron oxides, 0.16% vanadium pentoxide, and a maximum of 0.075% chromous oxide. The plant also produces annually 40,000 tons of magnetite at 65% iron and 10,000 tons of a sulfide concentrate containing over 4% nickel and over 2% copper.

Poland.—In May, the Polish Government placed contracts with Kronos Titan GmbH, Leverkusen, and Krupp Chemieanlagenbau, Essen, West Germany, for construction of a sulfate process pigment plant. The intended annual capacity will be 40,000 tons. The plant is to be built near Stettin, will cost $25 million, is expected onstream in mid-1976, and will use Norwegian ilmenite.

Sierra Leone.—Ownership of the 60% share of Sierra Rutile, Ltd., was transferred from Armco Steel Corp. to Bethlehem Steel Corp. during the year. Engineering studies, begun in 1972, continued during 1973, and in October Sierra Rutile began to staff key positions. A 100-ton-per-day pilot plant was under construction. Full-scale production at 20,000 tons of feed per day is expected by mid-1975; at this scale, 200 tons of rutile per day may be produced.

In September, the Bayer-Preussag Mining Co. resumed operations at the adjacent Bonthe and Moyamba mines, on a limited scale.

Spain.—Pigment from the 30,000-ton-per-year sulfate-process plant under construction at Huelva by a joint venture of Union Explosivos Rio Tinto (55%) and British Titan, Ltd. (45%), was expected to come on the market in 1975. The cost of the facility was estimated at $20 million. Some imports of ilmenite will be necessary at first. New plans called for expansion to 60,000 tons annually by 1976 and 100,000 tons by 1978. Meanwhile du Pont, which early in the year had been considering Spain as the site of a 100,000-ton-per-year plant, abandoned its interest about midyear.

Taiwan.—Woodall-Duckham, Ltd., undertook construction of a 30,000-ton-per-year synthetic rutile plant for Taiwan Alkali Co. at Kaohsiung. It will use the Benilite process, which is reputed to be pollution free. The sources of the feedstock and the grade of the product were not specified. Laporte Industries, Ltd., reportedly has signed a forward contract for delivery of 2,000–2,500 tons of the synthetic rutile.

U.S.S.R.—Reports indicated that a titaniferous slag containing 83% titanium dioxide is being made at Zaporozhe. The slag is chlorinated; the tetrachloride is purified and fed to Kroll-type reaction furnaces. New sponge-production facilities were said to be under construction during the year.

Yugoslavia.—A sulfate-process pigment plant of 27,000 tons annual capacity was opened June 30 at Celje. The plant, jointly owned by a Yugoslav and an East German corporation in a 51:49 ratio, was to export part of its production to East Germany. On July 7 production at the $31 million plant was halted by fire. Resumption of full production is expected early in 1974.

TECHNOLOGY

Mineral Deposits, Ltd., an Australian company mining rutile and zircon at Seven Mile Beach, New South Wales, installed Reichert cone concentrators as roughing units in its wet separation plant. A quite low operating cost is claimed. Total power consumption is quoted at 1.36 kilowatt-hours per ton of sand mined.[2]

Since silicates in certain proportions interfere with the effective chlorination of ilmenite in fluidized bed equipment, a mineral-dressing procedure has been devised by which the silicates may be separated on the basis of their selective wetting by an immiscible liquid and consequent spherical agglomeration.[3]

A method for using sulfate-process pigment plant effluent constructively, thereby solving a waste disposal problem, is being tried in Western Australia. Laporte Industries, Ltd., has contracted with Hancock & Wright for the latter to locate part of its manganese dioxide pilot plant at Laporte's Bunbury pigment facility. Treatment of lean manganese ore with the ferrous sulfate wastes permits subsequent extraction of high-grade manganese dioxide; ferric hydroxide becomes the waste product and is relatively less toxic and easier to dispose of than the sulfates.[4]

In spite of the inability of technical observers to find adverse effects in the oceanic dumping areas, pressure against discharging of sulfate-process waste at sea is increasing; the practice soon may no longer be permitted.[5] Three courses are open to the sulfate-process pigment producers: (1) Something useful may be made from the effluent; (2) the effluent

can be treated to separate something—most probably sulfuric acid—which can be recycled to the process; or (3) the effluent can be filtered and otherwise treated to make a solid having no pollution potential. Gypsum, copperas, iron powders and ferric oxide, and recycle sulfuric acid are most commonly mentioned as end products of effluent treatment.

Ishihara Sangyo Kaisha, Ltd., makes synthetic rutile by treating partially reduced ilmenite with sulfuric acid. The original plant reached its 27,000-ton capacity by the end of 1971, expanding to 40,000 tons by the end of 1973.[6] The product has been used experimentally as feed to chlorinators making titanium tetrachloride for conversion to titanium sponge. Toho Titanium Ltd., reported satisfactory results and intends using the material commercially.[7]

Basing its work on earlier studies by The Dow Chemical Co. and the U.S. Bureau of Mines, Dow and Howmet Corp. are jointly operating a pilot plant to produce, by fused-salt electrolysis, a titanium metal which will be competitive with Kroll-process sponge. The work is being done at Howmet's research center in Whitehall, Mich. Advantages claimed for the process include smaller capital investment, substantially lower energy needs, fewer pollution control problems, and a higher quality product. Some of the metal produced was converted to ingot, which has obtained some consumer acceptance.[8]

The Wyatt division of U.S. Industries Inc., developed and successfully used a technique by which large sections of titanium metal can be welded in the field. A shield over the welding area permits maintenance of a protective gas atmosphere.[9]

Airco, Inc., developed a method for converting light titanium 6/4 alloy scrap to a usable secondary alloy. The scrap, formerly wasted, now is cleaned and refined in a hearth-type furnace, where the aluminum and oxygen contents are decreased. The resultant metal has good strength and ductility. Initially Airco will produce a million pounds annually from home scrap. Probable applications will be in process industries hardware, where corrosion resistance at ambient or moderately elevated temperatures is desired.[10]

A new titanium alloy reportedly was developed by a defense contractor working with the U.S. Air Force. Called Ti17, it contains 5% aluminum, 4% each chromium and molybdenum, 2% each tin and zirconium, and small quantities of iron, manganese, and copper. It is said to be 25% stronger than titanium 6/4 and more resistant to crack growth.[11]

Made necessary by greatly increased mining of ilmenite in Western Australia, a method for determining the chromium content of ilmenite by atomic absorption spectrometry was developed. Sensitivity was in the area of 0.03% to 0.10% chromium.[12]

Tungsten

By Richard F. Stevens, Jr.[1]

Although domestic tungsten production, as measured by mine shipments, increased slightly in 1973, mine output decreased 7% to 7.6 million pounds. Most of this material was obtained from two domestic operations, one in California and one in Colorado, which were worked continuously throughout the year. Concentrate consumption rose 9% to 15.4 million pounds. Imports for consumption of tungsten concentrate almost doubled in 1973 and totaled 10.6 million pounds, the highest level in 16 years.

During 1973, the reported price of shipped tungsten concentrate, f.o.b. mines and custom mills, increased 5% and averaged $43 per short ton unit; the quoted European price averaged about $40 per short ton unit (about $44 per short ton unit with U.S. import tariff added).

No tungsten concentrate from Government stockpiles was sold until early in October 1973 when the General Services Administration (GSA) program was revised to a monthly sealed-bid basis. Under this program, almost 1.5 million pounds of tungsten in concentrate was awarded for domestic use (81%) and for export (19%).

Legislation and Government Programs.—On April 12, 1973, the Office of Emergency Preparedness (OEP) significantly reduced stockpile objectives and subobjectives for tungsten and tungsten-bearing materials as indicated by the following tabulation, in pounds of contained tungsten:

Material	Old objective	New objective
Tungsten ore and concentrate	55,655,500	4,234,000
Tungsten carbide powder	1,900,000	--
Tungsten metal powder, carbon reduced	547,000	--
Tungsten metal powder, hydrogen reduced	1,200,000	--

r Revised.
[1] Estimated tungsten content.
[2] Estimated number of persons at mines and mills, at yearend.

Also in April, "Omnibus" bills (H.R. 7153 and S. 1849) were submitted to the Congress to obtain authorization for disposal of these additional excess tungsten materials. This proposed legislation was reviewed by the American Mining Congress, a trade association of the domestic mining industry, in a detailed report.[2] Another bill (H.R. 1257) was reintroduced early in the year to temporarily suspend the tariff on tungsten concentrate and on other materials in chief value of tungsten (primarily synthetic scheelite). At yearend none of these bills had been acted upon by the Congress.

Under the President's Reorganization Plan No. 1 of 1973, issued January 26, 1973, the stockpile functions of OEP were scheduled for assumption by GSA at the beginning of the new Fiscal Year (July 1, 1973) and Executive Order 11725, issued June 29, 1973, created the Office of Preparedness (OP) within GSA to handle the former OEP stockpile operations.

Following the first half of 1973, GSA ceased offering excess tungsten concentrate for sale under a two-phase program that (1) offered tungsten as a "shelf-sale" item at $55 per short ton unit restricted to domestic consumption and (2) offered tungsten for export on a monthly sealed-bid basis. After reevaluating the tungsten market, GSA initiated monthly sealed-bid offerings in September at a rate not to exceed 6 million pounds of tungsten per year. Under this new program (ORES–199), approximately 80% of the sales was allocated for domestic use; the balance was for export. Almost 1.5 million pounds in concentrate was sold during 1973.

During the year, the price paid, excluding duty (ex-duty), for stockpiled tungsten concentrate for domestic use ranged from $40.65 to $48.32 per short ton unit. The price paid, ex-duty, for stockpiled concentrate for export ranged from $40.67 to $47.27 per short ton unit.

In addition, 51,000 pounds of contained tungsten in excess stockpiled concentrate was assigned for Government use in December.

Table 2.—U.S. Government tungsten stockpile materials inventories and objectives

(Thousand pounds, tungsten content)

DOMESTIC PRODUCTION

Domestic mine production fell 7% and totaled 7.6 million pounds of tungsten during the year, but mine shipments increased only slightly to less than 7.1 million pounds. Although 28 mines in eight Western States reported production and 25 mines reported concentrate shipments, only two mines operated continuously throughout 1973: The Pine Creek mine and mill of the Mining and Metals Division, Union Carbide Corp., located northwest of Bishop, Calif.; and the Climax mine and mill of Climax Molybdenum Co., a division of American Metal Climax, Inc. (AMAX), near Leadville, Colo. The major mineral value recovered at Pine Creek continued to be tungsten along with minor amounts of byproduct molybdenum, copper, silver, and gold. This material was processed on a "straight through" basis to produce ammonium paratungstate (APT), an intermediate processed form of tungsten suitable for ready conversion to tungsten metal powder.

[2] American Mining Congress. The Stockpile Problem. Washington, D.C., June 1973, 20 pp.

At Climax, the major mineral value recovered was molybdenum. Concentrates of tungsten, tin, and pyrite were recovered as coproducts and were largely dependent upon the rate of molybdenum producton.

In North Carolina, the Tungsten Queen mine and mill of Ranchers Exploration & Development Corp. near Townsville remained closed and on "standby" status throughout the year.

Table 3.—Tungsten concentrate shipped from mines in the United States

Year	Quantity			Reported value f.o.b. mine [1]		
	Short tons 60% WO_3 basis [2]	Short ton units WO_3 [3]	Tungsten content (thousand pounds)	Total (thousands)	Average per unit of WO_3	Average per pound of tungsten
1969	8,312	498,706	7,910	$18,770	$37.64	$2.37
1970	9,785	587,088	9,312	23,790	40.52	2.55

1972	7,401	444,145	7,045	18,104	40.77	2.56
1973	7,418	445,051	7,059	19,154	43.04	2.71

[1] Values apply to finished concentrate and are in some instances f.o.b. custom mill.
[2] A short ton of 60% tungsten trioxide (WO_3) contains 951.72 pounds of tungsten.
[3] A short ton unit equals 20 pounds of tungsten trioxide (WO_3) and contains 15.862 pounds of tungsten.

CONSUMPTION AND USES

The major domestic companies that were engaged in tungsten processing operations during 1973 are listed in table 5.

The application of tungsten in cutting and wear-resistant materials, primarily as tungsten carbide, increased and continued to represent the major form of tungsten product consumption. This use accounted for 56% of the total product consumption, which rose 35% to almost 18.0 million pounds of tungsten in 1973. Other major end-use categories during the year were as follows: Mill products (15%), specialty tool steels (11%), and welding and hardfacing materials (7%).

During 1973, the consumption distribution of intermediate tungsten products used to make end-use items was as follows: Tungsten carbide (including cemented, crushed, and cast), 43%; tungsten metal powder (including carbon- and hydrogen-reduced), 35%; and chemicals (including scheelite and scrap for direct addition to steel melts) and ferrotungsten, 11% each.

Two comprehensive reports based on information supplied by industry and Government specialists were published during the year.[3] These reports analyzed the tungsten industry and projected anticipated supply-demand relationships through 1987.

Micrograin tungsten carbide cutting tools were used in more high-temperature applications where conventional carbides chip and high-speed steels fail or soften. To eliminate voids, cemented tungsten carbides were produced by hot isostatic pressing.

A study to develop new less expensive, man-made cutting tools was continued by the General Electric Co. (GE) under funding sponsored by the Advance Research Projects Agency (ARPA), Washington, D.C. This study, conducted at GE's research laboratory in Schenectady, N.Y., was monitored by the Air Force Materials Laboratory (AFML) at Wright-Paterson AFB near Dayton, Ohio.

Several special review articles were published during the year that evaluated the application of tungsten metal in high-temperature nuclear applications, evaluated tungsten carbide cutting tools, and reviewed the current and future tungsten supply-demand situation.[4]

[2] At its Pine Creek mine and mill in California, UCC processes scheelite ore "straight through" to APT.
[3] Major consumers of tungsten concentrate and APT.

STOCKS

Stocks of tungsten concentrate held at domestic mines fell substantially at yearend and were 83% less than in 1972, whereas tungsten concentrate stocks held by consumers decreased 35% during the year. Industry stocks of intermediate tungsten products increased as indicated in tables 1, 4, and 6. Data on domestic stocks of tungsten concentrate held by dealers were not available.

W Withheld to avoid disclosing individual company confidential data, included in "Miscellaneous and unspecified."

[1] Includes melting base self-reducing tungsten.

[2] Includes both carbon-reduced and hydrogen-reduced tungsten metal powder.

[3] Includes tungsten chemicals natural and synthetic scheelite, tungsten scrap and other.

[4] Includes welding and hard-facing rods and materials and nonferrous alloys.

[5] Data may not add to totals shown because of individual rounding.

PRICES AND SPECIFICATIONS

During 1973 the average value of tungsten concentrate shipped from domestic mines as reported to the Bureau of Mines, increased 6% to $43.04 per short ton unit of WO_3. Although there were no Government stockpile sales during the first half of the year, the quoted domestic price (nominal) of tungsten concentrate during this period continued to be $55 per short ton unit, which reflected the GSA shelf price. Tungsten concentrate was purchased from GSA during the last quarter of 1973 at prices, ex-duty, ranging from $40.65 to $48.32 per short ton unit.

As quoted in the Metal Bulletin (London) and in Metals Week the European price of tungsten concentrate, shown in table 7, increased throughout the year from a low in January of £15.70 per metric ton unit (about $33.44 per short ton unit depending upon the prevailing rate of currency exchange) to a high of £22.20 per metric ton unit (about $49.03 per short ton unit) in November.

The price of metallurgical-grade APT, delivered to contract customers, was frozen at $50.50 per short ton unit during the year. A small amount of catalytic-grade APT and "Blue Oxide" was sold during 1973 at a frozen price of $53 per short ton unit. A conversion fee of about $11 per short ton unit was charged for "toll" processing tungsten concentrate to APT at a recovery of about 96%.

In January 1974, the price of metallurgical-grade APT was increased 24% to $62.50 per short ton unit. The price of catalytic-grade APT was increased to $65 per short ton unit in January, but the "toll" conversion fee remained unchanged.

The quoted price of carbon-reduced tungsten metal powder, as reported in

Metals Week, f.o.b. shipping point, was unchanged during the year at $4.50 per pound of contained tungsten in 1,000-pound lots. The price of hydrogen-reduced tungsten metal powder (99.99% purity), f.o.b. shipping point, as quoted in Metals Week, dropped to a range of $4.97 to $6.70 per pound of tungsten in 1973. Within this range, the price was primarily dependent upon the tungsten powder particle size (Fisher number).

The quoted price of low-molybdenum-containing ferrotungsten in lots of 5,000 pounds or more, ¼-inch lump, packed, f.o.b. destination, continental United States, 70% to 80% tungsten, remained unchanged at $4.60 per pound of tungsten during 1973. The quoted price of UCAR, the special high-purity ferrotungsten produced by Union Carbide Corp. at its Niagara Falls, N.Y., plant, 90% tungsten, was $3.98 per pound of contained tungsten during the year. The U.S. dealer price of ferrotungsten during 1973, as quoted in Metals Week, remained unchanged at $4.50 (nominal) per pound of tungsten.

Although not quoted, the price of scheelite concentrate (calcium tungstate) for direct addition to steel melts was believed to be comparable with data reported in table 7.

Table 7.—Monthly price quotations of tungsten concentrate in 1973

Month	Wolfram and scheelite London market, pounds sterling per metric ton unit of WO_3, 65% basis		Equivalent quotations, dollars per short ton unit of WO_3, 65% basis [1]		
	Low	High	Low	High	Average [2]

[2] Arithmetic average of weekly quotations. Equivalent 1973 average price $40.25; duty $3.97, equivalent price, duty paid, $44.22 per short ton unit.

FOREIGN TRADE

Exports.—All exports of tungsten concentrate in 1973, which decreased 5% compared with that of 1972, represented excess material purchased from GSA stockpiles. Exports of ferrotungsten fell 40%, but exports of APT rose by a factor of four during the year. Exports of mixed tungsten carbides, primarily to Japan (30%) and Canada (28%), decreased 31% during 1973.

Exports of unwrought tungsten metal and alloy in crude form, waste, and scrap increased 68% in 1973 to 672,773 pounds, gross weight, valued at $1,017,164, and were shipped primarily to West Germany (48%), the Netherlands (25%), Canada (15%), and Belgium-Luxembourg (9%). Tungsten and tungsten alloy powder exports fell 31% during the year to 356,954 pounds gross weight, value at $2,316,935. This material was exported primarily to Japan (30%), Canada (28%), West Germany (13%), Belgium-Luxembourg (8%), and Israel (7%).

Exports of tungsten and tungsten alloy wire almost doubled in 1973 to 224,750 pounds, gross weight, valued at $4,801,413. These exports were shipped primarily to West Germany (21%), Canada (17%), Japan (16%), Belgium-Luxembourg (10%), Brazil (9%), the United Kingdom (8%), and Mexico (7%). Wrought tungsten and tungsten alloy exports rose 75% during the year to 155,073 pounds, gross weight, valued at

$2,153,683. Most of these exports were shipped to Japan (37%), Canada (23%), West Germany (13%), and the United Kingdom (9%).

Imports.—Imports for consumption of tungsten concentrate increased 84% during the year and totaled almost 10.6 million pounds of contained tungsten, the highest import level since 1957. The major sources of concentrate imports in 1973 were Canada (30%), Bolivia (21%), Peru (10%), and Thailand (9%).

During the year, imports of tungsten carbide, primarily from West Germany (84%) and Sweden (14%), decreased 19% and totaled 208,561 pounds of contained tungsten valued at $1,497,415. Imports of waste and scrap containing over 50% tungsten decreased 25% and totaled 78,711 pounds of tungsten content valued at $255,199. This material was received primarily from West Germany (44%), the Netherlands (26%), and Japan (14%). Imports of unwrought tungsten (except alloys)

[1] Estimated tungsten content obtained by multiplying the gross weight by 0.78.

in lump, grain, and powder fell 61% to 55,601 pounds of contained tungsten valued at $298,561 and were received primarily from West Germany (47%), the United Kingdom (37%), Sweden (12%), and East Germany (3%).

In 1973, imports of unwrought tungsten, n.e.c., totaled 45,509 pounds, gross weight, valued at $160,101, and were received from West Germany (73%), and France (27%). Wrought tungsten imports tripled during the year and totaled 16,620 pounds, gross weight, valued at $762,156. This material was imported primarily from Japan (31%), Switzerland (23%), Austria (13%), Brazil (12%), the Netherlands (11%), and Sweden (7%).

Imports of tungsten material classified as "metal-bearing materials in chief value of tungsten" increased by a factor of almost three during 1973 and totaled 266,842 pounds of contained tungsten valued at $574,156. These imports were received primarily from Thailand (56%) and the Republic of Korea (42%). Most of the material imported under this classification was believed to be synthetic scheelite. In addition, 219,567 pounds of contained tungsten was imported, all from the Republic of Korea, as ammonium tungstate valued at $608,042. This material was upgraded at the new South Korean tungsten processing facility.

Calcium tungstate imports, almost all from West Germany, increased 35% in 1973 and totaled 36,814 pounds of contained tungsten, value at $389,527.

During the year the tariff rates on all forms of tungsten imports from non-Communist and Communist countries remained unchanged.

WORLD RESERVES AND RESOURCES

At yearend 1973, domestic reserves and resources of tungsten as reported by the U.S. Geological Survey and the Bureau of Mines totaled about 175 million pounds and 300 million pounds of tungsten, respectively.[5]

Estimated world reserves and resources of tungsten at yearend, totaled 2,750 million pounds and 3,060 million pounds of contained tungsten, respectively, as indicated in table 17.[6]

[1] Conversion factors: WO_3 to W multiply by 0.7931; 60% WO_3 to W multiply by 0.4758.

[2] In addition to the countries listed, Czechoslovakia reported tungsten production from tin-tungsten ores in previous years. It is not known if the production had continued to the present.

[3] Producer's shipments; actual production data is not officially reported, but available company figures indicate a substantial difference between actual output and shipments in some years.

[4] Data are the sum of production reported by COMIBOL and export credited to medium and small mines.

[5] Figures exceed those reported in official Brazilian sources; these sources do not include production by small mines, which in aggregate appear to be substantial.

[6] Production from Beardmore mine only, and are for the year ended September 30 of the year stated.

[7] Data are for South West Africa Co. Ltd. only, and are for the year ended June 30 of the year stated.

WORLD REVIEW

The Committee on Tungsten of the United Nations Conference on Trade and Development (UNCTAD) met in Geneva, Switzerland, late in the fall to discuss methods of stabilizing world prices, obtaining more detailed ore reserve data and evaluating statistical data on tungsten concentrate trade and product consumption. Membership in the Working Group, a subsidiary of the Committee on Tungsten, was further expanded to include Japan, the Netherlands, Thailand, the United Kingdom, and the U.S.S.R. Other members of the Working Group are Australia, Austria, Bolivia, Portugal, the Republic of Korea, Sweden, the United States, and West Germany. The Committee staff continued to canvass, tabulate, and report detailed statistics on tungsten production, consumption, and trade in the quarterly bulletin, "Tungsten Statistics."[7] Copies of these reports are $3 each and are available on a standing order basis from the United Nations Sales Section, Geneva, Switzerland, or New York.

A comprehensive evaluation of the present status of tungsten powder metallurgy in Canada, Italy, Japan, Romania, Spain, Sweden, the United Kingdom, the United States, the U.S.S.R., and West Germany was released during the year.[8]

Australia.—Aberfoyle Ltd. ceased tungsten production from the company's Storeys Creek facilities in Tasmania at mid-year 1973 and the operations were placed on

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition, the following countries may consume tungsten concentrate but specific data are not available: Denmark, Finland, Israel, Norway, Switzerland, and Yugoslavia.

[2] Production plus imports minus exports.

[3] Estimated by author of chapter.

[4] Data represents tungsten concentrate consumed to make ammonium paratungstate at new APT plant adjacent to Sangdong mine.

Primary source: UNCTAD Committee on Tungsten quarterly reports "Tungsten Statistics" and Annual Company Reports.

"standby" status.[9] Tungsten production from the adjacent tin-tungsten Aberfoyle mine was continued at a rate of 180 to 200 tons per day.

King Island Scheelite, Ltd., a subsidiary of Peko-Wallsend Ltd., continued to develop the Bold Head tungsten ore body in Tasmania.[10] Some development ore was available by late 1973, and full production is expected by mid-1975. When full-scale production is achieved, the Bold Head project is expected to have a capacity of about 200,000 tons per year of tungsten ore. King Island Scheelite has also announced plans to construct a plant to recover the molybdenum contained in the scheelite ores.

Canada.—During 1973, Canada Tungsten Mining Corp. Ltd. (CTMC), the country's major tungsten producer, at Tungsten, Northwest Territories, completed open pit mining operations and stockpiled a total of 103,670 tons of ore averaging 1.60% WO_3.[11]

At yearend, ore reserves amounted to 177,600 tons of scarn-type ore grading 1.62% WO_3 and 73,600 tons averaging 0.71% WO_3. This material could only be mined by using underground methods.

A total of 164,900 tons of ore containing an average of 1.22% WO_3 and 0.161% of copper (Cu) were processed during the year. Total production amounted to 161,430 stu WO_3 (almost 2.6 million pounds of contained tungsten). Overall mill recovery of WO_3 averaged 80.2% for the year. The concentrator operated a total of 90.1% of possible time and treated an average of 452 tons per day. Milling of the lower grade chert ore was discontinued in August when the higher grade skarn-type ore from the open pit became available. This resulted in a more efficient milling operation.

In addition to the scheelite concentrate, 197,861 pounds of byproduct copper concentrate was produced during 1973, a decrease of 12% compared with 1972 production.

At yearend CTMC estimated its chert ore reserves in place to total about 615,000 tons averaging 0.81% WO_3 (about 10 million pounds of contained tungsten). Stockpile balances at December 31, 1973, amounted to 34,460 tons of scarn ore grading 1.73% WO_3 for 59,507 short ton units (0.9 million pounds of contained tungsten) and 63,907 tons of chert ore grading 1.17% WO_3 for 74,528 short ton units (almost 1.2 million pounds of contained tungsten).

CTMC announced plans to commence underground mine production on a steady basis at Tungsten during 1974. The proven underground ore reserves totaled 4,242,000 tons at an average grade of 1.68% WO_3 for 7,106,000 short ton units (almost 113 million pounds of contained tungsten). This material should be sufficient for a 20-year supply at a milling rate of 500 to 600 tons per day.

The Vancouver Leach Plant of CTMC in North Vancouver, British Columbia, operated well during the year with overall recovery of 96.99%. There were no significant changes in the leach plant operation.

Mining at the Canex Tungsten Division of Placer Development Ltd. near Salmo, British Columbia, was completed in September 1973, and mill operations ceased.[12]

Underground production decreased as the ore reserves were depleted. Subsequently, the equipment and most of the buildings were sold at public auction. A termination allowance was provided by the company to assist employees put out of work by the closure.

AMAX Exploration Inc., a subsidiary of American Metal Climax Inc., identified a significant scheelite deposit of over 30 million tons of ore averaging 0.9% WO_3 in the MacMillan Pass district on the Yukon-Territories border northwest of Whitehorse. Further drilling and evaluation is required to fully outline the deposit.

China, People's Republic of.—The richest and most extensive tungsten deposits in the world are located in the south of China, along the Nan Ling Range. They extend from the southwest to the northeast, roughly parallel to the southwestern coast.[13]

A Japanese trade association indicated interest in obtaining Chinese tungsten concentrate if the material, which was re-

portedly far below Japanese standards, were upgraded. It is believed that the Chinese made subsequent efforts to upgrade the quality of their concentrate.

A sample analysis of Chinese tungsten concentrate being sold for export indicated the material to be mostly wolframite, with very little scheelite, containing about 65.6% WO_3. In addition, spectrographic analysis showed that the material contained 10% or more of iron, and 1% to 10% of aluminum, manganese, and silicon. Because of the lack of knowledge regarding the methods of processing concentrate, it is recognized that this material does not necessarily represent a true sampling of Chinese tungsten concentrate, but the analysis gives an indication of the type and grade of material available from China.

To promote trade with the People's Republic of China, several reports were prepared.[14] To keep abreast of the current activity in the People's Republic of China, a subscription to Translations From the Mainland China Press is available from the National Technical Information Service (NTIS) in Springfield, Va.

Reportedly, the status of powder metallurgy technology in the People's Republic of China is rapidly expanding, and the sintered carbide tools, which China exports to foreign countries, are suppose to be of high quality.[15]

Guatemala.—A medium sized coproduct mining operation, F. Y. Wellman Co., recovered tungsten and antimony (Sb) semiconcentrates, primarily for export, in the Department of Huehuetenango. Combined mine production (Sb plus WO_3) was about 165 short tons per month. In 1973 antimony production rose 63% while production of coproduct tungsten increased by a factor of almost 20. Most of this combined concentrate was shipped by rail through Mexico to the smelter of NL Industries, Inc., at Laredo, Tex., for further processing. At Laredo, a tungsten recovery circuit is scheduled to begin processing the imported tungsten semi-concentrate containing about 22% WO_3 in mid-1974 to a commercial grade concentrate (65% to 70% WO_3).

Japan.—The demand for tungsten in 1973 was extremely strong as Japanese consumption increased about 50% to 7.7 million pounds of tungsten. The Japanese tungsten utilization ratio was about as indicated in the following:

Industry	*Percent*	*Form*
Iron and Steel	40	Ferrotungsten.
Electronics (tungsten mill products).	30	Tungsten metal powder.
Tungsten carbide cutting tools.	29	Tungsten carbide.
Chemical	1	Ammonium paratungstate.

Because only about 1.9 million pounds of tungsten was recovered domestically, the remainder of demand comprised imports. In early December, the Japanese Tungsten and Molybdenum Association sent a mission to the People's Republic of China to negotiate purchase of 0.9 million pounds of tungsten for 1974 and to establish a long-term agreement that would give Japan an assured source of supply. In the near future, Japan reportedly plans to recover tungsten from tailings material.

The Uji ferroalloy works of the Awamura Metal Industry Co., in Osaka was the country's only ferrotungsten producer.[16] An electric furnace process is used. The three domestic producers of tungsten metal powder were Japan New Metals, Nakahara Construction, and Japan Heavy Metals. Their combined output was 2,020 tons, up nearly 40% from 1972.

Korea, Republic of.—The Korea Tungsten Mining Co. Ltd., (KTMC), which is owned 15.5% by the Government, continued to be the country's major tungsten producer during 1973 and accounted for 92.1% of the domestic supply.[17] As shown in the following tabulation, KTMC's Sangdong mine accounted for 90.6% of Korean production:

[1] About 6 mines.

Stocks of tungsten, primarily tungsten concentrate and chemicals, at yearend, fell 79% compared with those of 1972.

Mongolia.—The capacity of the tungsten mine and ore processing plant in Burentsogt, about 100 miles southeast of Ulan Bator, was doubled as a result of expansion and reconstruction conducted with technical and economic assistance from East German specialists. It appears possible that some of the Mongolian tungsten production, previously sent to the U.S.S.R. for further processing, will be exported to East Germany as repayment for technical assistance.

Portugal.—Beralt Tin and Wolfram Ltd. transferred all its holding in the Panasqueira, Barroca Grande, and Rio operations to Beralt Tin & Wolfram (Portugal) SARL, a Portuguese incorporated company, for an 80.55% equity interest in the new company.[18] Portuguese banking interests subscribed the equivalent of £1 million (about $2.5 million) for the remaining 19.45% interest. Production of tungsten at the Panasqueira mine increased as higher ore grade was recovered as a result of the recent development program carried out in the southern areas. The development program has been selective, and the resulting improvement in ore reserves will enable a satisfactory grade of tungsten to be mined during the next few years.

The tungsten-tin-copper ore concentration plant at Barroca Grande and the mill at Rio operated satisfactorily throughout the year with slightly improved recoveries.

The local labor supply continued to be unsatisfactory, and high periodic absenteeism created difficulties. Recruitment from the Cape Verde Island continued and the recruitment campaign for local employees was intensified.

Rhodesia, Southern.—During 1973, Rhodesian tungsten continued to be recovered from the Beardmore mine and mill, operated by the Messina (Transvaal) Development Co., Ltd., near Bikita.[19] An evaluation of Beardmore's stocks indicated that enough material was available to allow underground mining to continue through December. When this material has been mined the company plans to reprocess selected portions of the slime and sand dumps to produce about 100 tons of WO_3 (about 0.2 million pounds of tungsten) contained in concentrate by the end of the current financial year (June 30, 1974) when production is expected to cease.

In close association with the Tribal Trust Land Development Corp. plans for construction of an ion-exchange tungsten refinery to process tungsten from scheelite ore at a 95% recovery factor were reported.[20] The refinery, using considerable scheelite from tribal areas, is expected to be built at Ntabazinduna or in the Bulawayo industrial area about 200 miles southwest of Salisbury.

Sweden.—Tungsten concentrate was recovered by AB Statsgruvor at its Yxsjöberg mill in central Sweden. Full scale production has been under way since the beginning of November 1972 when scheelite-fluorspar ores were processed at an annual rate of 165,000 short tons of tungsten ore having an average grade of 0.3% WO_3.[21] During 1973 the mill's annual yield was reported to be about 440 tons of first-grade scheelite concentrate containing 73% WO_3 and about 110 tons of second-grade scheelite semiconcentrate containing 40% WO_3.

Thailand.—The recovery of tungsten concentrate from large deposits recently discovered at Khao Soon and Doi Mok in the southern peninsula area resulted in the substantial increase in tungsten production during the early 1970's. Mining methods used at these operations by thousands of peasants were extremely dangerous. Following the heavy rains in 1973, landslides caused the Doi Mok mine disaster, which involved several fatalities and closure of the mine. During 1973, Thai tungsten

[21] World Mining (International Edition). V. 26, No. 7, June 25, 1973, pp. 184–185.

production decreased 22% to 5.7 millon pounds of contained tungsten, 83% came from wolframite and 17% came from scheelite ores.

TECHNOLOGY

During the year, studies were continued by Bureau of Mines research scientists at the Salt Lake City Metallurgy Research Center to develop economic methods for recovering tungsten from the low-grade brine deposits of Searles Lake, Calif., which contain an estimated 135 million pounds tungsten. If recoverable, this could almost double the Nation's tungsten reserves. Bureau of Mines research engineers at Salt Lake City also evaluated methods for economically recovering tungsten and associated metals from oxide ores, machining wastes, and alloy scrap. Under this program, about 90% of the electrochemical machining sludges were recycled from the brine electrolyte.

Research metallurgical engineers at the Bureau of Mines Albany (Oregon) Metallurgy Research Center conducted two extensive evaluations of tungsten carbide coal cutters as part of studies on nonsparking steels and on ignition hazards due to frictional sparks.

A comprehensive bibliography of tungsten technology, published quarterly, is available from Climax Molybdenum Co., Greenwich, Conn.[22]

Studies conducted by Bureau of Mines metallurgists at the Boulder City (Nevada) Metallurgy Research Laboratory evaluated mixtures of sized tungsten carbide (WC) particles and solvent degreased Titanium—6% Aluminum—4% Vanadium alloys, which were compacted in a hydraulic press.[23]

A second annual report highlighting Bureau of Mines minerals research and reviewing molybdenum-tungsten research programs was published during the year.[24]

Studies of chemical vapor deposition (CVD) methods used in tungsten processing techniques were evaluated to determine the optimum conditions of temperature and pressure for hydrogen reduction of tungsten hexfluoride (WF_6).[25]

Although cladding tungsten with a palladium-gold gave only short-term protection against oxidation, the addition of tungsten to a Pd-33% Au alloy resulted in a stable coating for tungsten.[26]

A Soviet research study indicated that titanium coatings could be satisfactorily diffusion bonded to tungsten.[27]

Diffusion bonding and metallic spray coating by explosive bonding, results in a smooth tungsten coating with little oxide.[28] The adhesion strength of tungsten coatings prepared in this method is greater than that obtained by other, more conventional, spraying methods.

Tungsten-urania nuclear fuel elements developed for elevated temperature use in nuclear reactors were clad with coarse-grained tungsten to avoid loss of UO_2.[29]

Detailed studies of the electrochemical deposition of sodium tungsten bronzes were conducted during the year.[30]

Uranium

By Walter C. Woodmansee [1]

Following several years of slack demand and soft prices for uranium, the uranium and nuclear industries started an upward trend in 1973. This improved market was expected to gather momentum in 1974. The year 1973 was a good one in terms of new operable commercial power reactors and orders placed for reactor construction licenses. The Atomic Energy Commission (AEC) made progress in expediting the licensing procedure and planned to reduce the lead time required between the start of commercial nuclear reactor construction and operation from 8 to 9 years to 5 to 6 years.

Mine output was slightly reduced from that of 1972 in terms of U_3O_8 content of ore, but mill output continued an upward trend started in 1971. A number of small mines, mainly in Colorado, and two mills in Texas were closed during the year, but major, new mine-mill complexes were under construction in Wyoming and New Mexico.

Exploration for uranium continued strong, and a small net addition was made to domestic ore reserves, although the discovery rate (per foot drilled) was unfavorable. The Grand Junction, Colo., office of the AEC invited bids for mining leases on AEC-controlled lands, which contain substantial ore reserves. The Grand Junction office also announced the start of a multiyear national survey to evaluate low-grade potential uranium resources.

[5] Non-Communist only.
[6] At $8 per pound U_3O_8.
[7] In exploration, mining, and milling, at yearend.

Sources: U.S. Atomic Energy Commission and Federal Bureau of Mines.

Gas-centrifuge development for uranium enrichment progressed and will provide an alternative to gaseous diffusion enrichment technology. It was generally agreed that new enrichment capacity will be needed in the early 1980's, and the AEC initiated programs that offered AEC-developed enrichment technology to private industry for development of enrichment capability.

Development continued on private facilities to produce nuclear fuels, reprocess the burned fuels, and, in conjunction with the AEC, manage the radioactive waste products of this industry. Several sectors of the nuclear industry experienced shortages in supplies and equipment, engineers, and skilled labor.

In July, a basic contract was signed by the AEC, Tennessee Valley Authority (TVA), and private industry interests for the Nation's first demonstrator liquid metal fast breeder reactor (LMFBR) to be built in the TVA system, near Oak Ridge, Tenn.[2]

Exploration.—An industry survey conducted by the AEC's Grand Junction office indicated increased exploratory drilling footage and expenditures in 1973 and ambitious company plans for 1974–75.[3] A total of 84 companies reported total exploration expenditures of $49.5 million and land acquisition of 2.87 million acres for exploration. The number of exploration holes was sharply reduced from the 1972 total, but the average depth per hole was substantially higher. The average cost per foot drilled was $1.49. About one-half of this footage was drilled in Wyoming, 24% in New Mexico, 17% in Texas, and the remainder in 10 other States. Industry reported plans for drilling 29.1 million feet in 1974 ($72.5 million) and 33.7 million feet ($77.8 million) in 1975, a record rate. At yearend, companies held 6.9 million acres for uranium exploration.

The AEC's Grand Junction Office also announced plans for a National Uranium Resource Program. A preliminary overview program for potential resources, covering 62 projects in 42 areas, was started in March and was scheduled for completion in July 1975. A complete evaluation of domestic resource potential will continue until 1978.

Invitations to bid on 43 AEC-controlled tracts totaling 25,000 acres, mainly in the Uravan mineral belt of Colorado but also including acreage in Utah and New Mexico, were issued on October 1.[4] These lands contain uranium resources valued at $45 million to $50 million. At yearend, the AEC had issued 230 invitations for bids to interested parties and planned first-bid openings on April 1, 1974.

Table 2.—Surface drilling for uranium

Source: U.S. Atomic Energy Commission.

Shortages of drilling equipment and a tight skilled labor supply posed problems during the year. The larger, heavier drill rigs, needed for deeper drilling, were scarce because of demand for their use in coal and oil exploration.

A large new exploration project was announced for the Powder River Basin, Wyo. In a joint project, Denison Mines (U.S.), Ltd., will drill 510,000 feet on Nuclear Exploration and Development Co. (NEDCO) properties covering 64,000 acres during 1973–76. In addition, Pioneer Nuclear, Inc., will drill an 18,000-acre NEDCO property in the same area.[5]

Amax Uranium Corp., in an agreement with Weco Development Corp., will drill a 16,000-acre tract in the Ambrosia Lake area, McKinley County, N. Mex. Union Carbide Corp. will drill a 17,600-acre tract held jointly with New Mexico and Arizona Land Co., also in McKinley County. TVA concluded an agreement with United Nuclear Corp. (UNC) for a joint drilling program of UNC properties in Wyoming and New Mexico.

Resources.—The AEC reported a net increase of 4,000 tons U_3O_8 in reserves at a cutoff cost of $8 per pound U_3O_8. The yearend total of 277,000 tons, in 129 million tons of ore at 0.21% U_3O_8, resulted from newly established reserves of 24,000 tons and depletions of 14,000 tons mined and a 6,000-ton loss due to re-evaluation of exploration data. New Mexico held 49% of this $8 reserve and Wyoming, 35%. The remainder was in nine States, principally Colorado and Utah.[6]

DOMESTIC PRODUCTION

Mine.—Mine output was higher in 1973 in terms of gross weight of ore produced but was slightly lower in terms of U_3O_8 content in ore. The number of producing mines, sharply reduced because of the closing of a number of small operations mainly in Colorado, totaled 175 properties, including 122 underground mines (4,974 tons U_3O_8), 33 open pits (8,614 tons U_3O_8),

[6] U.S. Atomic Energy Commission, Grand Junction Office. U.S. Uranium Reserves at 277,000 Tons U_3O_8. News Release No. 654, Mar. 27, 1974. 5 pp.

and 20 miscellaneous operations (199 tons U_3O_8 from mine waters, heap and in-situ leaching, and raffinate). Wyoming was the leading producing State, with nearly 39% of total U_3O_8 output; New Mexico had 36% of the output. There was no production from South Dakota in 1973.[7]

New mines were under development, particularly in New Mexico and Wyoming. Kerr-McGee Corp. was sinking a concrete shaft, 1,850 feet deep and 14 feet in diameter, near Gallup, N. Mex. Production was scheduled for 1975. The ore will go to the company's mill in the Ambrosia district. A 600-foot shaft was being sunk at the L Bar Ranch property, 25 miles east of Grants and north of Laguna, N. Mex., by the Reserve Oil and Minerals Corp.-Sohio Petroleum Co. joint venture. Here, mining was expected to start in 1974.

Table 4.—Recoverable U_3O_8 mine production. by State[1]

(Thousand pounds U_3O_8 and thousand dollars)

[e] Estimate.
[1] Based on mill recovery factors and estimated average market price per pound U_3O_8. Does not include uranium recoverable in miscellaneous operations (leach, mine waters, and raffinate).
[2] Alaska, South Dakota, Texas, and Washington in 1971 and 1972; Alaska, Texas, and Washington in 1973; combined to avoid disclosing individual company confidential data.

In Wyoming, most new mining activity was in the Powder River Basin. Kerr-McGee Corp. was sinking a 950-foot shaft and also planned open pit development 25 miles northwest of Douglas, Converse County. Exxon Corp. started production in 1972 at its nearby Highland open pit and sank a 670-foot shaft which will serve two mines. Production started in September at the open pit of Teton Exploration Drilling Co., Inc., a subsidiary of United Nuclear Corp., near the Highland mine. Teton ore was shipped to the Exxon mill.

In the Crooks Gap district, 10 miles south of Jeffrey City, Wyo., Western Nuclear, Inc., started shaft-sinking for a 1,500-ton-per-day mine. The company reported recoverable reserves at 11.5 million pounds U_3O_8.

Numerous small mines were closed in Colorado during the year. Susquehanna Corp. closed its mines and disposed of its uranium interests in Falls City and Ray Point, Tex.

TVA secured interests in two significant mining ventures.[8] TVA leased all mining rights of Federal-American Partners in the Gas Hills district, Wyo., and acquired rights to the mill output after existing contracts are completed. TVA also purchased an interest, with options, in United Nuclear Corp.'s properties in Wyoming and New Mexico.

With uranium prices rising, the commercial recovery of byproduct uranium from wet process phosphoric acid (WPPA) fertilizer operations in central Florida approached economic viability. Uranium Recovery Corp. (URC) planned uranium recovery in 1975 from a modular unit adjoining a W. R. Grace & Co. fertilizer plant, 40 miles east of Tampa, and a central processing plant. which would treat the uranium-bearing solution following initial separation, near Mulberry, Fla. Capacity of the first plant would be 300,000 pounds U_3O_8 per year. In November, United Nuclear Corp. exercised an option to purchase an 85% interest in URC.[9] A number of companies were studying the recovery of uranium from WPPA operations. The phosphate rock in central Florida contains 0.01 to 0.02% U_3O_8, and approximately 1 pound U_3O_8 is recoverable per ton of P_2O_5. Larger WPPA operations could produce 1,500 to 2,000 tons of U_3O_8 per year. According to the AEC, this uranium would be

commercial at a U_3O_8 price of $10 to $15 per pound and as much as 70,000 tons U_3O_8 may be produced from Florida phosphates by the year 2000.

Mill.—Mill production increased slightly during 1973, although operable capacity was reduced by the closing of Susquehanna Corp.'s two mills in Texas. At yearend, capacity was 28,550 tons of ore daily and 18,000 tons U_3O_8 per year. Mill throughput averaged 18,400 tons per day, about 65% of the yearend capacity.[10] Rio Algom Mines, Ltd., was considering a mill expansion to 700 tons of ore per day and 1.7 million pounds U_3O_8 per year. Western Nuclear, Inc., planned to close its mill in Wyoming for expansion to 1,400 tons per day during 1974 and 1975. Exxon's mill in the Powder River Basin, Wyo., may also undergo expansion. New mills were planned by Kerr-McGee Corp. in the Powder River Basin and by Reserve Oil-Sohio Petroleum (1,000 to 1,200 tons per day) at its new mine near Laguna, N. Mex.

Nuclear Fuel Materials.—*Uranium Hexafluoride.*—U_3O_8 to UF_6 conversion capability was available at two plants—Allied Chemical Corp. at Metropolis, Ill. (14,000 tons uranium per year) and Kerr-McGee Corp. at Sequoyah, Okla. (5,000 tons uranium per year). The latter capacity will be doubled, although dates have not been announced.

Enriched Uranium.—During 1973 the AEC received revenues of $550.5 million for providing 3.56 million separative work units (SWU) to domestic customers and 12.93 million SWU to foreign customers. At yearend, the AEC had contracts for enrichment services with 32 domestic and 41 foreign customers.[11] A total of 10.3 million SWU were produced at the AEC's three gaseous-diffusion enrichment plants in fiscal 1973. This output was at about 60% of rated capacity. The planned Cascade Improvement Program (CIP) will add 5.8 million SWU capacity with no increase in power operating levels, and the Cascade Uprating Program (CUP) will add 4.7 million SWU capacity by increasing the total power level from the present 6,060 megawatts (MW) to 7,380 MW.[12] During the year, the AEC contracted for an average of 957 MW per year, and negotiations were underway for the remaining power needed for the full uprated capacity.

Projected CIP–CUP increases in addition to enriched uranium preproduced from the AEC U_3O_8 stockpile were expected to provide sufficient supplies until 1983.[13] Thereafter, new enrichment capacity, probably by private development, will be needed and, because of the long lead time from planning to operation, the commitment to a firm program by 1976 appeared urgent. Decisions would be necessary on contracts with private industry for enrichment plant, construction, the type and capacity of these plants, power sources, and financing in the billions of dollars. The AEC estimated that the capital cost for one 8.75-million-SWU diffusion plant, the minimum commercial size considered feasible, would be in excess of $1 billion. Other deterrents to private investment in enrichment were; competition from existing AEC facilities and subsidized foreign facilities, the future development of breeder reactors which would reduce demand for enrichment services, and a slow return on investment.[14]

Amendments to the AEC's Domestic Access Program, designed to encourage private domestic development of enrichment capacity, provide for availability of classified

AEC enrichment technology to approved private companies without the commitment of the participant to a research and development program.[15] The first permit was granted to Uranium Enrichment Associates (UEA), a joint venture of Bechtel Corp., Union Carbide Corp., and Westinghouse Electric Corp., which planned to evaluate diffusion and centrifuge technology and establish an enrichment plant. For the use of AEC-developed technology, the AEC would receive a 3% royalty on gross receipts during the first 17 years of commercial operation.[16]

The AEC studied the economics of diffusion and centrifuge technology. For electric power costs at 10 mills per kilowatt-hour and various amortization and other financial assumptions, enrichment services based on the centrifuge range from direct comparability with diffusion technology to cost levels nearly $20 per SWU lower.[17] Under the Centrifuge Development Program, the AEC was building a 25-SWU-per-year test facility at Oak Ridge, Tenn., and planned to spend $117 million through fiscal 1975. Access to classified data, under the Industrial Participation Program, was granted to seven companies in addition to the UEA joint venture.[18] General Electric Co. and Exxon Nuclear Corp. started a three-phase joint study on centrifuge enrichment.[19]

The AEC's new enrichment contracting policy, sent to the Joint Committee on Atomic Energy in January, became effective May 9. Contracting was suspended while AEC considered the reactions of domestic and foreign customers. The new fixed commitment contracting procedure replaced the old requirements-type contracts.[20] Late in the year, there was a flurry of new contracting activity involving 25 new domestic customers and 36 new foreign customers.

Fabrication.—The AEC reported the quantities of enriched UF_6 shipped to domestic and foreign nuclear fuel fabricators, in thousand SWU, as follows:[21]

Fiscal year	Domestic	Foreign
1972	1,266	356
1973	1,466	779

This does not include shipments for domestic test reactors and Navy programs.

The demonstration LMFBR fuel core was expected to have 43,000 fuel pins in 198 fuel assemblies, which had not been ordered at yearend.

The AEC estimated fabrication costs for mixed oxide (U–Pu) FBR fuels at $6,000 to $8,000 per kilogram of contained Pu during the next few years.

Table 7 lists the 14 companies engaged in commercial fabrication of UO_2, carbide, special, Pu, and U_{233} fuels at 21 plants.

Reprocessing.—Until December 31, 1977, AEC reprocessing facilities will be available for spent fuels from research and test reactors and other reactors for which these services are not available from industry at reasonable terms.

At yearend, three commercial reprocessing plants were under construction, one (Nuclear Fuel Services, Inc., at West Valley. N.Y.) was on standby, and one was planned (by General Atomic Co.) at an undetermined site. Full-scale operation at General Electric's Midwest Fuel Recovery Plant, Morris, Ill., where capacity is 330 short tons of uranium annually, was delayed until 1974. This facility has industry's first waste calciner for high-level materials. Nuclear Fuel Services' plant at West Valley, N.Y., was inactive; it was under modernization and expansion to 830 tons uranium per year and was scheduled for operation in 1977 or 1978. Allied Gulf Nuclear Services, Inc. (AGNS), continued construction on the largest domestic reprocessing plant, at Barnwell, S.C., where annual capacity will be 1,650 tons uranium. AGNS will receive spent fuels in 1974 and start processing in 1975. These companies were seeking contracts for future reprocessing work, but activity was light. Pending problems were short-term spent fuel storage capacity and limited shipping cask capacity. Estimated reprocessing cost was $40,000 per ton, excluding storage at site and canister shipping costs.[22]

Waste Management.—Three domestic commercial waste disposal companies and six burial sites were in operation. It was estimated that the volume of low-level wastes available for burial was 1.5 million cubic feet and will reach 2 million cubic feet in 1975, 4 million cubic feet in 1980, and 6 million cubic feet in 1985. AEC-generated solid wastes were accumulating at a decreasing rate because of a program to reduce the volume of wastes. During 1973, as estimated 1.3 million cubic feet of solid wastes were buried at AEC sites. The AEC estimated that approximately 3,899 cubic feet of significant radioactive wastes were generated annually at a 1,000-MW BWR and about 1,000 cubic feet at a 1,000-MW PWR. Shipments of high-level wastes to Federal repositories were expected to start about 1983, following a 10-year cooling and storage period at the reprocessing site. The AEC planned to build a Retrievable Surface Storage Facility for temporary high-level waste storage pending a final decision on permanent storage.[23] The objective was to improve the economics of waste management and lessen the necessity for surveillance and maintenance. A pilot plant holding 1,000 canisters will be built in a bedded salt formation. Battelle Pacific Northwest Laboratories, Richland, Wash., continued studies on disposal methods.[24] It was estimated that 80,000 waste canisters, measuring 1 by 10 feet, would be in storage by the year 2010.[25]

CONSUMPTION AND USES

According to the AEC, the use of U_3O_8 equivalent in domestic commercial reactors totaled 8,200 tons, a slight increase over that of 1972. Commercial reactor startup continued to be slowed by licensing delays, construction problems, technical failures, and growing shortages of supplies, equipment, and skilled labor. Efforts were made to shorten lead time from the present 8 to 10 years to 7 to 8 years in the short term and 5 to 6 years in the long term by reactor standardization and designated siting procedures.[26]

Although slippages were incurred in commercial reactor plans, new reactor orders and U_3O_8 buying activity were at record levels. A total of 38 nuclear units (42,670 MW) were ordered, compared with 35 units (38,000 MW) in 1972. At yearend, commercial reactor status was as follows:

Status	Number of plants	Capacity (megawatts)
Operable	42	25,024
Under construction	56	53,020
Under contract (reactors ordered)	101	109,735
Total	199	187,779

[26] Chemical and Engineering News. Quicker Startup of Nuclear Plants Sought. V. 51, No. 48, Nov. 26, 1973, pp. 7–8.

Fifteen additional units were planned at yearend, although reactors had not been ordered. During the year, 13 plants (10,341 MW) became operable, and the AEC issued construction licenses for 14 plants at 9 sites.

An AEC U_3O_8 market survey of 64 utility companies, 5 reactor manufacturers, and 20 U_3O_8 producers indicated increased U_3O_8 purchasing activity.[27] U_3O_8 delivery commitments increased substantially for the 1974–80 period; forward commitments of 120,000 tons U_3O_8 at yearend were 33,700 tons U_3O_8 higher than at the beginning of the year. The status, including foreign orders, was as follows, at yearend:

	U_3O_8 (tons)
Deliveries and forward commitments, Jan. 1	129,800
Deliveries and forward commitments, Dec. 31	175,600
Deliveries, through Dec. 31	55,600
Forward commitments, Dec. 31	120,000

The survey also revealed that buyers had contracted for only 68% of first core fuels and progressively less for the annual refueling needs.

Table 8.—Current and projected domestic commercial uranium delivery commitments

(Short tons U_3O_8)

Year	Commitments [1]	
	Annual	Cumulative
1973	12,100	[2] 55,600
1974	13,700	69,300
1975	15,500	84,800
1976	10,900	95,700
1977	11,600	107,300
1978	13,200	120,500
1979	12,100	132,600
1980	10,200	142,800

[1] In the post-1980 period through 1994, an additional 30,300 tons have been committed. In addition, 6,700 tons have been committed to foreign buyers, of which 5,500 tons were delivered prior to yearend 1973.
[2] Pre-1973 deliveries were 43,500 tons.

Source: U.S. Atomic Energy Commission.

Table 9.—Uranium fuel supply arrangements for domestic nuclear reactors [1]

(Percent of total nuclear generating capacity)

Source of Supply	First core	Reloads [2]														
		1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Primary producers	37	33	30	27	21	18	13	10	8	6	3	2	2	2	1	1
Reactor manufacturers	31	29	24	23	17	14	11	9	6	4	4	2	2	2	2	2
Total	68	62	54	50	38	32	24	19	14	10	7	4	4	4	3	3

[1] As of yearend 1973. Includes reactors operating, under construction, and scheduled totaling 188,000 megawatts. Does not include leases from AEC, which are small, comprising less than 0.5% for first cores and for refueling through seventh reload, when they are scheduled to terminate.
[2] Refueling estimated on annual basis.

Source: U.S. Atomic Energy Commission.

AEC estimates for projected U_3O_8 and enriched uranium demands were lower than those of the previous year, owing to the continuing slippages in commercial reactor schedules and to general energy conservation practices. Estimates for probable domestic nuclear capacity, in thousands MW, were as follows:

Year	1972	1973
1980	132	102
1985	280	250
1990	508	475
2000	1,200	1,090

Short-term U_3O_8 demand, during 1974–80, was correspondingly lower. Cumulative demand in 1980 was nearly 45,000 tons U_3O_8 below the earlier estimate. Projected demand for enrichment services was also affected by the reduced estimates for operable nuclear capacity, particularly in the short term.

Table 10.—Current and projected domestic U_3O_8 demand [1]

(Short tons)

Year	Low	High	Probable	
			Annual	Cumulative
1973	6,800	9,600	8,200	8,200
1974	9,700	12,300	11,600	19,800
1975	11,800	14,000	14,100	33,900
1976	12,700	15,900	15,200	49,100
1977	15,500	20,100	19,400	68,500
1978	20,500	26,200	23,900	92,400
1979	26,300	31,600	30,400	122,800
1980	30,300	35,500	37,900	160,700
1985	55,200	70,900	60,400	397,100
2000	119,200	202,700	156,900	2,186,900

tric Corp. and Tenneco Inc., was negotiating with suppliers and Government officials for a location site for offshore nuclear powerplant construction facilities. The company had selected a plant site near Jacksonville, Fla., and indicated that orders for six offshore reactor units would justify construction. Four units were ordered during the year—two to be located off the New Jersey coast and two off the Mississippi coast.[28] Each complete reactor unit would be barged to its operating site.

In November, the U.S. Maritime Commission received a proposal for construction of a 415,000-deadweight ton, nuclear-powered oil supertanker. The oil industry appeared interested; the proposed tanker could move an estimated 800,000 tons more crude oil per year than the slower conventional tankers of the same capacity.

Late in the year, plans were made to establish a World Nuclear Fuel Market (WNFM), an agency for the buying and selling of uranium and nuclear fuels, with headquarters at Atlanta, Ga. With international competition for uranium and nuclear fuels growing more intense, WNFM would set policies, resolve problems, and provide information on buyers and sellers to its members. Nuclear Assurance Corp. is the founder and coordinator.[29]

Nuclear Fuel Services, Inc., West Valley, N.Y., was granted a license for a cask, made of depleted uranium and of 50,000-pound capacity, for transporting spent fuel assemblies.[30]

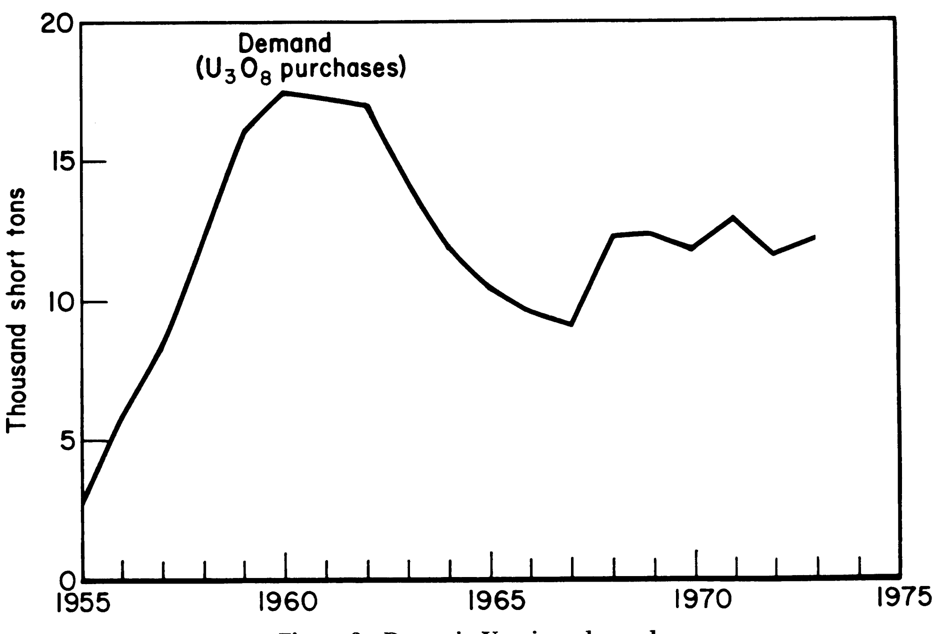

Figure 2.—Domestic Uranium demand.

STOCKS

The AEC reported private inventories at the beginning and end of the year, in tons U_3O_8, as follows:

	Jan. 1, 1973	Dec. 31, 1973
In ore at mills	271	113
In process at mills	468	328
In concentrate at mills	3,701	5,238
In concentrate held by utility companies and reactor manufacturers (includes UF_6)	14,400	19,900
Total	18,840	25,579

On the basis of delivery commitments and forecast demand, inventories were expected to increase to about 28,000 tons U_3O_8 in 1975–76 and decline thereafter.

PRICES

Following several years of depressed markets and soft prices for U_3O_8, the price strengthened during 1973. Whereas spot prices were on the order of $6 to $6.25 per pound U_3O_8 early in the year, they increased to about $7 per pound U_3O_8 at yearend and were expected to escalate further during 1974.

The AEC conducted a survey of prices paid by reactor manufacturers and utility companies, as of January 1, 1973, for existing contracts during 1967–72 and for delivery each year during 1973–80.[31] The price (1973 dollars) ranged from $7.10 per pound for delivery in 1973 to $7.80 for delivery in 1980. The AEC commented that these contracts represented only a small part of projected requirements to 1980, did not reflect higher prices in late 1973, and were not indicative of market prices prevailing throughout the year.

Although domestic and foreign sales contracts were negotiated, sales activity was slow during a period of low prices and an uncertain future. Competitive fixed-price bidding procedures appeared to have ended. Sellers were reluctant to conclude contracts, owing to questions arising on prices at time of future deliveries. Price adjustment clauses and currency shift safeguards were considered in long-term contracts.[32] Canada, Australia, the Republic of South Africa, and France, after several international meetings, established a policy of no price quotations for post-1980 delivery.

Higher prices, averaging about $7 per pound U_3O_8, were indicated in Canadian contracts for delivery to Spain in 1974–77 and to Japan in 1977–81. Reserve Oil and Uranium Co. announced a sale of 5 to 6 million pounds U_3O_8, valued at approximately $50 million, for delivery during 1977–81. In November, Kerr-McGee Corp. sold in excess of 12 million pounds U_3O_8 for more than $150 million for delivery during 1977–85.[33] Western Nuclear Inc. was seeking $12 per pound U_3O_8 for delivery in 1979–80, $14 for delivery in 1981–85, and $16 for delivery in 1986–90, all subject to escalation clauses.

Kerr-McGee Corp. offered UF_6 in specified quantities, also subject to escalation, at $35.95 per pound (equating to $12.10 per pound ($U_3O_8$) for delivery in 1977 and at $44.39 per pound (equating to $15.50 per pound U_3O_8) for delivery in 1982. A revised table of base charges for UF_6 and enriching services was announced by the AEC.[34] Effective August 14, 1973, AEC charges for enrichment services were increased from $32 per SWU to $38.50 per SWU, the third increase within 2½ years, for the old requirements-type contracts. The rate was reduced to $36 per SWU for the new, fixed commitment contracts covering 10 years and for short-term customers. The AEC re-

served the right to increase charges by at least 1% each 6 months after January 1, 1974.[35]

Urenco Ltd., the European company representing the United Kingdom-the Netherlands-West Germany enrichment project, announced terms and conditions for its enrichment services by gas centrifuge technology. Initial charges were the equivalent of $48 per SWU, subject to downpayment and price escalation, for minimum 10-year supply contracts.[36]

FOREIGN TRADE

Larger quantities of U_3O_8 concentrate and UF_6 entered the United States for enrichment services and re-export of the enriched product. The AEC had under consideration an amendment to the Uranium Enrichment Services Criteria, established pursuant to subsection 161(v) of The Atomic Energy Act of 1954, as amended.[37] The proposed amendment would remove the existing embargo on the use of foreign uranium in domestic reactors on a graduated basis, starting with 10% of the domestic supply permitted from foreign sources in 1977, 80% permitted in 1983, and no restrictions thereafter.

1 Includes thorium.
2 Includes carbon-14 and cobalt-60.
3 Includes plutonium, uranium-233, uranium-235, and enriched uranium.
4 Includes cobalt-60.

WORLD REVIEW

International maneuvering continued on a large scale in attempts to negotiate agreements for development of mine, mill, enrichment, and nuclear fuel facilities. New mines and mills were under development or planned in Australia, Canada, Niger, and the Territory of South-West Africa. Progress was made in gas centrifuge technology as an alternative to gaseous diffusion for uranium enrichment. The industrialized uranium-consuming nations conducted negotiations among themselves and with the uranium-producing nations for new enrichment capacity, which will be needed after 1980.

The tripartite project (West Germany, United Kingdom, and the Netherlands) for commercial development of centrifuge enrichment announced plans for two semicommercial-scale plants, each of 200,000 SWU, at Capenhurst (United Kingdom) and Almelo (the Netherlands).[38] The estimated initial cost for enrichment services was expected to be $48 per SWU, considerably higher than current costs. Urenco Ltd., the operating and marketing company, sponsored the Association for Centrifuge Enrichment (ACE), a multinational study group comprising 14 organizations in 11 countries.[39]

Demand for enriched uranium in Western Europe was 2.5 million SWU and was projected at 9 million SWU in 1980 and 21 million SWU in 1985. Urenco capacity was expected to be 2 million SWU in 1980 and 10 million SWU in 1985. Eurodif, an association sponsored by the French and based on gaseous diffusion enrichment, planned capacity of 10 million SWU in 1980.[40]

European Communities (EC) goals were directed toward reduction of dependence on the USAEC for enrichment services. The EC planned capacity of 3,000 to 4,000 SWU by 1981 as well as Urenco's 10 million SWU in 1985. A standing committee was established to develop a coordinated enrichment industry in Europe through market surveys and technical-economic analysis. The EC's Permanent Council wanted 70% of total requirements for enriched uranium produced within the EC by 1985, when full competitiveness with other producers was anticipated.[41] The status of power reactor development among the nine EC member countries, as of January 1. 1973, was as follows: Operable, 10,906 MW; under construction, 15,485 MW; and ordered or planned, 17,624 MW, for a total of 44,015 MW.[42] Projected EC capacity was 60,000 MW in 1980 and 133,000 MW in 1985. Because of possible future shortages of enriched uranium before sufficient capacity has been developed, the allocation from the United States was increased from 215,000 SWU to 583,000 SWU in August.

The International Atomic Energy Agency (IAEA) of the United Nations conducted power reactor surveys, sponsored feasibility studies, organized technical meetings, awarded training fellowships, and published a variety of international nuclear industry reports. A nuclear power market survey of developing nations during 1980–90 indicated the possibility of 164 nuclear plants (85,000 MW) in 10 countries as a low estimate and 412 plants (120,000 MW) in 53 countries as a high estimate.[43]

A study of the worldwide status of nuclear reactor development plans, made by the American Nuclear Society, indicated that 374 installations (262,754 MW) were in operation, under construction, and ordered, in 26 countries at midyear 1973.[44] About 47% of the total number of plants and 61% of the capacity were in the United States.

The NEA/IAEA Working Party projected non-Communist world nuclear capacity to 1985. Capacity involving 32 nations was expected to increase more than tenfold from 1973 to 1985. The United States, which had 56% of total capacity in 1973, would account for about one-half of total capacity in 1980 and 1985. The five leading nations (United States, Japan, West Germany,

United Kingdom, and France) would have about 80% of total capacity in those years.

Among the nine Communist nations of Eastern Europe, there would be 40,000 MW of nuclear capacity in 1980 and 160,000 MW in 1990. In these nations, nuclear power was expected to provide one-third of the electric power supply in the year 2000.

Australia.—Although there was no production of uranium during the year, a number of major new mines were under development, and new mills for production of uranium concentrate were planned. In the East Alligator River district, annual capacity of 5,000 tons U_3O_8 was anticipated from three operations by 1980. However, announced new Government policies concerning foreign participation in uranium ventures and uranium exports tended to reduce development activity. The Minister for Minerals and Energy announced plans to fulfill existing contract commitments but prohibited new export contracts, pending a new energy policy. Existing export contracts totaled 11,522 tons U_3O_8 for delivery during 1974–86 from three mines—Mary Kathleen Uranium Ltd., Ranger Uranium Mines (Pty.) Ltd., and Queensland Mines Ltd. At one point the Government considered supplying uranium for existing contracts from only the Mary Kathleen deposit in Queensland, which has been inactive since 1964 but maintained on a standby basis, and reserving production

Source: OECD Nuclear Energy Agency and International Atomic Energy Agency.

from Northern Territory mines until uranium prices firm up and a more favorable world market exists. Late in the year, the Government proposed development of the Ranger 1 mine in the Northern Territory to meet existing contracts.[45]

As a result of Government restrictions, Western Mining Corp. Ltd. (WMC) planned no further exploration and development at the Yeelirree deposit in Western Australia. Queensland Mines Ltd. suspended further development at Narbarlek, Northern Territory, because of concern with lease renewal in an aboriginal reserve. The purchase of a 10% interest in the Ranger 1 deposit by Ente Nazionale Idrocarburi (ENI) of Italy was subject to approval by the Government.[46]

Studies were underway for future uranium enrichment facilities in Australia. Research and development continued on the gas centrifuge. A preliminary feasibility study on a gaseous diffusion plant in Australia, using French technology, was made jointly with the Commissariat à l'Énergie Atomique (CEA). Possible sites, costs, resource requirements, and potential markets were considered. Australia joined the Association for Centrifuge Enrichment.

Canada.—Large uranium resources, a changing world energy market, growing world demand for uranium, and anticipated higher future prices, triggered new legislative policy proposals, limiting foreign ownership of uranium mines. One proposal limited ownership of Canadian enterprises to 10% by single foreign companies and 33⅓% by foreign company groups.

[1] In addition to the countries listed, Czechoslovakia, Finland, East Germany, West Germany, Hungary, India, Japan, People's Republic of China, and the U.S.S.R. are believed to have produced uranium oxide, but information is inadequate to make reliable estimates of output levels.

[2] Produced in part from imported material.

Mine and mill production varied only slightly from that of 1972. Three operations remained active, two in the Elliot Lake district, Ontario and the other at Eldorado, Saskatchewan. A total of 4,660 tons U_3O_8 concentrate was shipped during the year.[47]

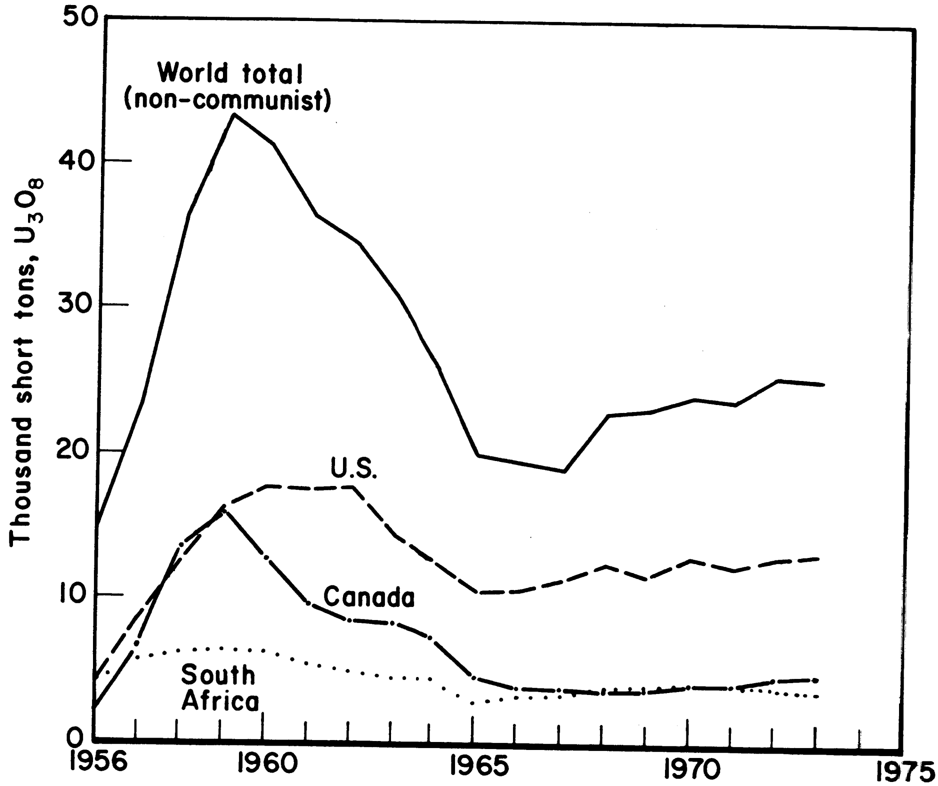

Figure 3.—World (non-Communist) production of uranium concentrate (U_3O_8).

Programs were in progress to increase production capacity. Denison Mines Ltd. was developing a new section of its mine and started mill expansion at Elliot Lake, where throughput capacity will be increased from 4,400 to 7,100 tons of ore per day and annual mill capacity to 10 million pounds U_3O_8.

Open pit mine development and mill construction was on schedule at Rabbit Lake, northern Saskatchewan, by Gulf Minerals Canada Ltd. (51% interest) and Uranerz Canada Ltd. (49% interest). Production was scheduled for 1975 at a rate of 4.5 million pounds U_3O_8 per year.[48]

A production rate of 14,000 tons U_3O_8 per year was planned for 1980. Canada expected to hold about 20% of the world market.[49] More than 78,000 tons U_3O_8 have been committed to domestic and foreign customers since 1966, and 13,000 tons U_3O_8 have been delivered, according to the Department of Energy, Mines and Resources. Long-term sales contracts for U_3O_8 were sought with utility companies.

The Canadian Government gave support to a proposal by Brinco Ltd., comprising RTZ Corp., Bethlehem Steel Corp., Japanese interests, and public shareholders, for a $1 billion enrichment plant, using U.S. gaseous diffusion technology. Brinco was seeking other partners in the venture.[50]

Late in the year, a $800 million contract was negotiated with Tokyo Electric Power Co., involving delivery of 40 million pounds U_3O_8 during 1984–93.[51] The contract was subject to final approval by the companies involved and the respective Governments.

France.—The CEA continued plans to gradually expand mine and mill production in metropolitan France. Eurodif, a multinational corporation comprising the CEA and Italy, Spain, Belgium, and Sweden announced plans to start construction of a $2.65 billion gaseous diffusion enrichment plant in 1974 at Pierrelatte. This plant was scheduled to provide enrichment services capacity of 5 million SWU in 1980 and 9 million SWU ultimately.[52] The CEA proposed French-Japanese and French-Australian establishment of enrichment facilities in the Pacific area, but no firm agreement was reached.

Péchiney-Ugine-Kuhlmann (PUK), in which Westinghouse holds a 35% interest, formed a nuclear fuel company, Eurofuel, which will provide complete fuel cores and replacement fuels for LWR's and mixed U-Pu fuels.

The 250-MW prototype fast breeder reactor (FBR) Phénix at Marcoule was tested early in the year, went critical in August, reached power production in October, and was operating at full power in the Électricité de France power grid at yearend. The CEA planned a 450-MW type and also a Super Phénix, a 1,200 MW FBR, possibly jointly with West German and Italian participation.[53]

Germany, West.—According to the Ministry of Science and Technology, Bonn, Steag A.G. negotiated with South African authorities concerning a cooperative agreement on uranium enrichment and proposed a study of the economic feasibility of the South African enrichment process.[54]

In October, Rheinisch-Westfaelisches Elektrizitaetswerk A.G. (RWE), West Germany's largest utility company, concluded an agreement with the U.S.S.R. in Moscow for 600,000 SWU of enrichment services during 1974–77. Other U.S.S.R.-West German contracts for enrichment services were expected.[55]

To achieve a goal of 18,000 MW of nuclear power capacity in 1980 and 40,000 MW in 1985, the Government planned to assist in reducing reactor construction time, support German companies in foreign exploration, increase enrichment service purchases, and spend about $2 billion on nuclear research and development during 1973–76. Emphasis would be placed on an accelerated reactor development program, stressing the FBR.

A $322 million initial contract was granted for the West German-the Netherlands-Belgium-Luxembourg, 300-MW prototype FBR, SNR–300, to be built at Kalkar. The installation was scheduled for completion in 1979.

India.—The atomic energy program was delayed by a general economic slowdown. Nuclear powerplant construction was 2 to 3 years behind earlier schedules.

[55] Engineering and Mining Journal. West German Companies Go the Soviet Way in Uranium Enrichment. V. 174, No. 12, December 1973, p. 23.

FBR research was conducted at Kalpakkam, near Madras, where an infrastructure has been developed for two existing CANDU-type plants. A 15 to 18 MW FBR of the French Rhapsodie type (but modified for electric power generation) was under construction with CEA technical assistance. Radiometallurgical, radiochemical, fuel processing, and fuel fabrication facilities were planned. Engineering designs for a 250- to 500-MW FBR were under study.

Japan.—The Japanese Government and industry were actively engaged in efforts to develop an assured, adequate supply of natural and enriched uranium. According to the annual report of the Japanese Atomic Energy Commission, nuclear power capacity would reach 32,000 MW in 1980 and 60,000 MW in 1985. Utility companies had made arrangements for delivery of 90,000 tons U_3O_8, considered adequate for most needs until 1985.

The Japanese budget for fiscal 1973 allotted $210 million for nuclear research and development, 15% more than fiscal 1972. Included was $107 million for nucleat power development, mainly the FBR.

The Enrichment Survey Committee (ESC), representing the power and nuclear equipment companies, projected uranium enrichment needs at 4 million SWU in 1980, 9 million SWU in 1985, and 15 million SWU in 1990. The ESC proposed Japanese participation in two or three enrichment plants of four to six such plants that would be needed in the non-Communist world during 1980–85. It also was engaged in a feasibility study with Uranium Enrichment Associates, which comprises Bechtel Corp., Union Carbide Corp., and Westinghouse Electric Corp., for the first private enrichment venture in the United States. The Japanese also discussed enrichment ventures with Canada, France, the U.S.S.R., Australia, and the Republic of South Africa.[56]

A U.S.-Japan agreement assures a 30-year supply for development of 60,000 MW of nuclear capacity. Industrial contracts were subject to negotiations between Japanese utility companies and the AEC. The Japanese planned to rely on U.S. enrichment services to 1980, participate in international enrichment ventures after 1980, and develop a commercial gas centrifuge operation in Japan by 1985.[57] Early in the year, Japanese utilities concluded an agreement with the AEC for 10 million SWU, valued at $320 million, with full delivery by 1981.[58] Nuclear powerplant construction experienced both material and labor shortages. At yearend, 14 plants were under construction and 7 plants were scheduled.

In breeder development, an experimental FBR was scheduled for 1974 and a prototype FBR in 1978.

The Science and Technology Agency decided to establish a semi-Government center responsible for radioactive waste management throughout Japan. The program would include waste storage on land, trial ocean disposal, research and development, and land or sea transport of wastes.

South Africa, Republic of.—The pilot enrichment plant of Uranium Enrichment Corp. of South Africa, Ltd., was scheduled for completion in 1974, and plans were made for a $825 million commercial operation of 2.4 million SWU per year.[59] The company reported that estimated capital investment in the commercial operation would be only 65% of that for a gaseous diffusion plant using U.S. technology because of a higher separation factor and the corresponding need for fewer enrichment stages. However, the South African process apparently requires greater energy consumption per SWU.

South-West Africa, Territory of.—RTZ Corp. concluded a partnership and uranium sales agreement with Total Compagnie Minière et Nucléaire concerning the Rossing mine, near Swakopmund.[60] Total acquired 10% of Rossing Uranium Ltd., the operating company, and will purchase a share of the uranium output after 1980. The open pit mine was scheduled for production in 1976 or 1977.

United Kingdom.—New USAEC contractual terms for enrichment services caused the tripartite nations (United Kingdom jointly with West Germany and the Netherlands) to revise plans for gas centrifuge

plant development. Scheduled planned pilot-plant capacity may be doubled, reaching 500,000 to 600,000 SWU per year by 1976, and commercial capacity was set at 2 million SWU in 1980 and 10 million SWU in 1985.

The National Nuclear Corp. (General Electric Co. 50%, Government 15%, other private 35%) was organized to assume responsibility for future nuclear powerplant design and construction. Controversy continued over whether to use nuclear plants of U.S. or U.K. design for the next stage of commercial development. The Central Electricity Generating Board announced preference for the LWR steam supply system of U.S. design and proposed ordering 18 reactors in two stages during 1974–83, 9 PWRs of U.S. design during 1974–79, and 9 HTGRs, also of U.S. design, thereafter.[61]

U.S.S.R.—Two contracts were concluded for providing 600,000 SWU of enrichment services for first cores at two 1,300-MW reactors in West Germany. The U.S.S.R. also negotiated with the Swedish Nuclear Fuel Supply Co. and the Swedish Oskarsham utility group for about 300,000 SWU, and options for more, for delivery in 1979–80.

The BN-350 FBR at Shevchenko was the first of commercial size to reach criticality, although it was operated at only partial power.[62]

The Communist nations' Council for Mutual Economic Assistance planned 40,000 MW of nuclear capacity by 1980 and 160,000 MW by 1990 in the Communist nations of Eastern Europe.

WORLD RESOURCES

The Organization for Economic Cooperation and Development reported an increase of 34% in reasonably assured resources at $10 per pound U_3O_8, compared to estimates made in 1970.[63] Total resources ($10-per-pound category), including estimated additional resources, also increased by approximately one-third. Major new reserves and resources in Australia, Niger, and the Territory of South-West Africa accounted for a large part of these expanded resources.

Table 17.—World resources of uranium[1]
(Thousand tons U_3O_8)

In Australia, exploration for uranium by national companies and multinational consortia continued at a fast pace, although reduced from the previous year because of announced Government policies. Discoveries were reported in the Northern Territory, South Australia, and Western Australia. Uranium reserves were expected to expand further as exploration and development drilling continued. According to the Australian Atomic Energy Commission (AAEC), reasonably assured resources recoverable at a maximum of $10 per pound U_3O_8 had increased to 140,000 tons at midyear.[64] The AAEC reported resources, as of June 30, 1973, as follows (in thousand tons U_3O_8):

	Less than $10 per pound U_3O_8	$10–$15 per pound U_3O_8
Reasonably assured	140	83
Estimated additional	48	43

In the East Alligator River district, Northern Territory, where a large part of Australia's total uranium resources have

been discovered in recent years, Peko-Wallsend Ltd. and Electrolytic Zinc Industries Ltd. continued evaluation of the Ranger group, 130 miles east of Darwin. In the Ranger 1 anomaly area, reserves were reported at 51,500 tons U_3O_8 (Jabiru ore body) and 31,000 tons U_3O_8 (Jacana ore body). Other localities in the Ranger area were under investigation. Queensland Mines Ltd. reevaluated earlier exploration data and continued exploration in the vicinity of the Nabarlek deposit, where reserves remained unchanged at 10,500 tons U_3O_8. Noranda Australia Ltd. continued development drilling at the Koongarra deposit and was participating in other exploration ventures. Pancontinental Mining Ltd., operator in a joint venture with Getty Oil Development Co. Ltd., was evaluating favorable anomalous areas. The Jabiluka 1 deposit was drilled out, and resources were reported at 3,850 tons U_3O_8. Jabiluka 2, 1,600 feet from Jabiluka 1, proved to be a substantial ore body, reported at 20,200 tons U_3O_8.

In South Australia the Petromin-Transoil-Exoil group (PTE) reported resources in the Beverly area, near Lake Frome, at 17,500 tons U_3O_8. Other companies were also active in this region.

In Western Australia, WMC completed development plans with auger, rotary, and diamond drilling in the Yeelirree area, where the mineralized area measured 28 by 2 miles along a buried stream channel. The ore is in horizontal beds, generally less than 25 feet below the surface. WMC announced reserves of 50,000 tons U_3O_8 in ore at 0.15% U_3O_8. including 26,000 tons U_3O_8 in high-grade ore at 0.36% U_3O_8.

Canadian uranium resources were higher than previously reported, particularly in the higher price categories. Estimated additional resources were nearly 70% higher than those reported for the NEA–IAEA Working Party in 1970.[65]

Exploration remained at a low ebb, owing to the continuing lack of market incentives and the Government attitude concerning restrictions on foreign ownership in the uranium industry. Minor exploration activities were underway in the Mont Laurier area of Quebec and in a few other areas. The main activity was in northern Sasketchewan, where Gulf Minerals conducted exploration in the Rabbit Lake area and planned drilling projects at several prospects. Other companies were also active in this region.[66]

As a result of continuing exploration and development drilling in Niger, the resource position at $10 per pound U_3O_8 improved substantially, particularly for resources moving into the more firmly established category. Reasonably assured resources at $10 per pound U_3O_8 reached 52,000 tons U_3O_8 and were expected to expand further. In addition to the producing Arlit mine and mill, the Government of Niger, the French CEA, and Japanese interests were engaged in a feasibility study of the Akouta deposit, where a substantial reserve has been established. The Niger Government, CEA, and Urangesellschaft m.b.H. of West Germany planned an exploration project at the Djado concession.

For the Republic of South Africa, NEA-ENEA reports of 263,000 tons U_3O_8 in resources at $10 per pound U_3O_8, a substantial increase over previous estimates, include resources in the Rossing deposit in the Territory of South-West Africa. Actual resources within the Republic, mainly in byproduct uranium from gold mines, have not changed significantly.

Exploration was underway by a number of major companies in the Beaufort West-Fraserburg area, 250 miles east-northeast of Cape Town. Extensive areas of low-grade mineralization (0.05% U_3O_8) in sandstones and conglomeratic sandstones were considered of significant potential. The Government planned an airborne survey of a 1,200-square-mile area.

TECHNOLOGY

A method for uranium identification by neutron activation and X-ray spectrometry was reportedly developed in Israel.[67] The neutron activation of a liquid or solid sample takes place in a reactor, and the X-ray spectrometry determines uranium and thorium content in geological materials with accuracy within a few percent. The

method was considered rapid, using the short half-lives of certain radioisotopes.

The distribution and zoning of uranium and other radioelements in porphyry copper deposits was analyzed by gamma-ray spectrometry. Uranium was found to be concentrated centrally or peripherally in different rock compositions of the porphyry copper deposits in Arizona and New Mexico.[68]

The presence of dissolved helium in ground water was used as a tool in exploration for uranium ore deposits. Helium flux was considered to be higher near these deposits; measurements near two known uranium deposits in Canada indicated a helium content up to 600 times normal for its solubility equilibrium with the atmosphere.[69] Another exploration technique involved the horizontal tracking of gaseous decay products, such as radon, in the atmosphere to source areas by correlation with wind conditions, after the radon had diffused to the surface from uranium deposits and became windborne.[70] In another technique using radon emanometric data, soil gas was extracted from drill holes, 2 to 4 inches in diameter and 3 feet deep, by a probe connected to a hand pump, and the radon content was measured in an alpha counting chamber.[71] This procedure was employed for roll front sandstone-type uranium deposits but may be used in exploration for other ores where uranium is an accessory mineral.

The AEC's Oak Ridge National Laboratory reported a new procedure for solvent extraction of uranium at WPPA operations. Tetravalent uranium is extracted with dioctyl phenyl phosphoric acid and is then stripped with product acid (54% H_3PO_4). The uranium is then oxidized to the hexavalent state with sodium chlorate. In a second stage, uranium is extracted with ethyl hexyl phosphoric acid (EHPA) and trioctyl phosphoric oxide (TOPO) and stripped with sodium carbonate. In an adaptation during WPPA processing, using HCL on the phosphate rock, the pregnant liquor is contacted with a mixture of dioctyl phosphate and dodecane, and the extractant is treated with water, the uranium entering the aqueous phase, which is separated for conventional processing.[72]

Research continued on health and safety in uranium mines. Filters, with vermiculite as the filtering material, were used in dust and radon control. Total dust, respiratory dust, and radon daughter collection efficiencies were analyzed statistically. The velocity of ventilation rather than the filter thickness affected radon daughter filtration. Other filter materials were more efficient, but vermiculite was lower in cost, easy to handle, resistant to moisture, and could withstand a large pressure drop.[73]

A method was proposed for removal of radon and other hazardous gases from a uranium ore body by drilling out the deposit, pumping ground water to establish permeability to gas within the formation, and then pumping the radon gas through the drill holes as the deposit is mined.[74]

A new thermoluminescent dosimeter (TLD) was considered superior to the photographic film-type badge worn by underground miners for recording radiation exposure. The TLD crystal, composed of lithium or calcium fluoride, calcium sulfate, or lithium borate, absorbs X-ray or gamma-ray energy, causing the capture of electrons by certain crystal impurities, which impart the thermoluminescent properties to the crystal. The TLD is re-usable, more accurate, more sensitive to small radiation dosages, and less affected by temperature and humidity than the film-type badge.[75]

Uranium was recovered from Elliot Lake ores, Ontario, Canada, by vapor-phase

[75] Chemical Week. Hot on the Trail of Radioactivity. V. 112, No. 26, June 27, 1973, p. 35.

chlorination.[76] Processing costs were considered comparable with those for conventional sulfuric acid leaching. With minus-12 mesh ore at 1,000° C, 340 pounds of chlorine were used per ton of ore, with 95% uranium recovery.

A strong acid leach of uranium afforded advantages over conventional dilute acid leaching for refractory ores. Costs were reduced because less ore grinding was necessary, less acid was consumed, and an agitated slurry leach was not required.[77]

In other ore-processing research, the leaching sulfuric acid was passed upward through the ore bed in a vat. The pregnant solution was removed from above for conventional processing, and the leached ore removed from the bottom of the vat. This procedure required less reagent use and minimized carryover of ore fines in the pregnant solution.[78]

Bureau of Mines research continued on extraction and elution of uranium from low grade ores and copper leach solutions. Solution flow in a compartmented continuous current ion-exchange column was regulated by an automatic control system. A test based on a solution upflow principle provided better uranium sorption efficiency from low-grade ores. A series of vertical sections in the column, separated by zones of reduced diameter, localized and increased the flow velocity and improved mixing in the higher sections. Uranium recovery from a bulk sample of Chattanooga shale, containing 0.006% U_3O_8, was more successful when agitation leaching followed an oxidation roast.

In a uranium heap-leaching operation, the leach solution was applied at the top of the heap for leaching to a desired depth.[79] The leached zone was then treated with water for several days or weeks, and the material slurried and moved to a settling basin, where the pregnant solution was recovered for processing. The same procedure may be followed on successive layers of the ore heap.

Uranium may also be recoverable from leach solutions, metallurgical processing solutions, or sea water by adsorption with titanated polyvinyl alcohol and desorption with an aqueous solution of sodium carbonate or ammonium carbonate.[80] Another process for recovery of uranium from sea water involved a belt with a layer of activated exfoliated vermiculite, which was moved through a solution, the vermiculite laminae absorbing uranium ions. The belt then moves through an elution station, where the ions are removed with a suitable reagent.[81]

A new method of gaseous diffusion uranium enrichment, called the shuttle method, was developed in Italy. In ordinary diffusion enrichment, the UF_6 goes through 1,700 to 2,000 diffusion stages. In the new procedure, the in-process material is subjected to repeated cycling through 100 to 200 stages. This required an elaborate system of in-process storage but lower capital investment in plant use and equipment.

Several gas-centrifuge enrichment models evolved from the AEC's Centrifuge Development Program. Four centrifuge prototypes were undergoing performance and reliability testing at Oak Ridge National Laboratory, Oak Ridge, Tenn. The aim was to develop manufacturing technology for component assembly and equipment fabrication. At the AEC laboratories at Livermore, Calif., and Los Alamos, N. Mex., enrichment by laser separation was under investigation. In theory, the isotopes (U_{235} and U_{238}) absorb light at slightly different energy levels. The separation process has proved successful in the laboratory, and commercial application was under study.[82]

Industrial applications of the high process heat of the gas-cooled reactor were under investigation in the United States and abroad. Gulf General Atomic Co. attempted the production of hydrogen by splitting H and O in ordinary water by a multistep thermochemical cycle using high-temperature, gas-cooled reactor (HTGR) heat in the range of 1,500° to 1,800° F.[83] Reactor

process heat also was considered for coal gasification, iron reduction, and as a coke substitute in the blast furnace.[84] Prototype nuclear steel plants, involving the gas-cooled reactor and a hot-gas direct reduction process, were under development in the United Kingdom, Japan and West Germany.[85] In Japan, a 6-year research program was underway on HTGR-generated nuclear heat utilization, which would reduce pollution and coking coal requirements and would save up to 12% in energy consumption.

AEC-sponsored research included studies on LMFBR fuels, materials, physics, components, and systems development.[86] Breeder fuels were tested for performance at rated power and operating conditions and for safety in abnormal situations. The objective was the development of high performance U–Pu carbide, nitride, and metal fuels with higher thermal efficiencies, higher fuel densities necessary for better breeding ratios, and reduced fuel fabrication costs and doubling time. The Fast Flux Test Facility at Hanford, Wash., which was re-scheduled for completion in 1977, will provide experience in LMFBR design, construction, operation, and maintenance and in fast flux irradiation of LMFBR fuels and materials.

Deformation studies on stoichiometric UO_2 crystals in fuels indicated that the presence of oxygen clusters in the fuel lowers yield stress and promotes cross-slip deformation.[87] Creep rates, studied at 1,300° C to 1,500° C and at 2,000 to 6,000 pounds per square inch, were found to be higher in mixed U–Pu carbide fuels than in U carbide fuels tested under similar conditions.[88] Grain size and porosity were factors in creep mechanism by grain-boundary sliding. Hot-hardness measurements indicated deformation by dislocation-impurity interactions. In fuels enriched to 1.82% U_{235}, tested in a reactor, the strain rate was proportional to the fission rate in a constant structural state, and radiation-induced creep was athermal at temperatures up to 500° C but may become temperature-dependent at higher temperatures.[89] Crack healing during grain growth was probably controlled by grain-boundary diffusion, if stress were small or compressive and diffusion not affected by fissioning.[90] This healing was of primary concern during initial reactor startup, when cracks may occur in oxide fuel pellets.

Nondestructive testing of LWR and FBR fuel materials by eddy current, penetrant, and ultrasonic methods was followed by radiographic fuel rod inspection and complementary techniques including gamma monitoring, fluoroscopy, and leak tests. The radioisotope Cf_{252} was used in neutron activitation analysis of pellet density, pellet enrichment, and fuel geometry.[91]

A new system of rapid refueling, on a semi-annual rather than annual basis, would permit savings during the refueling operation, due to a lower initial enrichment level needed and reduced downtime. For optimum performance, the fuel enrichment level tended to decrease as the number of refuelings increased.[92]

A newly developed cask for transporting spent fuel assemblies was licensed by the AEC in January. It consists of a lead gamma shield between two cylindrical steel shells, a compartmented neutron shield tank containing a borated antifreeze solution that serves as a neutron-shield, and multidirectional lightweight impact limiters. The vessel weighs 25 tons and will carry two BWR and one PWR fuel assemblies. It was designed for zero release of coolant solution in any hypothetical accident.[93] Another cask in service, the first accommodating the new, longer fuel assemblages, can carry 7 PWR or 18 BWR spent fuels by rail. It is cooled by natural convection and has an auxiliary forced-air circulation system.

In spent-fuels reprocessing, an electro-

lytic dissolver at the AEC's Chemical Processing Plant, National Reactor Testing Station, Idaho, enables faster, more economical processing of stainless-steel-clad fuels. An electric charge is applied to the metal cladding, which is immersed in nitric acid, causing the stainless steel, otherwise inert, to dissolve.

AEC capacity for high-level radioactive waste solidification was expected to be doubled with the 242–S Facility, which went into operation at Hanford, Wash., in November.[94] Waste solutions, steam-heated to 140° F to 165° F. are pumped to an evaporator-crystallizer facility, where the waste is boiled and the vapor collected and condensed at a rate of 40 gallons per minute. The remaining waste slurry is then pumped back to storage for settling of solids.

Two new processes for high-level waste treatment and solidification were also developed at Hanford. A pilot plant will provide engineering data on waste treatment by hot, concentrated sulfuric and nitric acid digestion. It was reported that each 100 kilograms of fuel produced 28 cubic feet of contaminated materials. In solidification, radioactive salt cake from underground storage tanks was converted to a hard insoluble rock-like material with basalt at 1,200° C and with iron oxide, silicon, and sand at 2,000° C.[95] The Japanese Atomic Energy Research Institute announced a method for high-level waste solidification by conversion to a glass, using sodium carbonate and other chemicals added to a zeolite.

Slightly radioactive oil generated at enrichment plants, formerly buried in drums, was fed to natural micro-organisms in soil at an Oak Ridge National Laboratory test area. The oil was consumed and dissipated as CO_2, and chemical contaminants were trapped in the soil. The process appeared effective, with no adverse environmental effects.[96]

Vanadium

By Harold A. Taylor, Jr.[1]

Domestic demand for vanadium reached an alltime high in 1973, slightly above the previous high of 1969. Overseas demand was also quite strong. Domestic production of vanadium pentoxide was somewhat lower than that in 1972, mostly the result of the Uravan-Rifle complex being partially shut down until May while the vanadium circuit was rebuilt. Exports of ferrovanadium were more than five times those of the previous year. Exports of vanadium ores and oxides also rose significantly above those of the previous year. The Government sold all of its ferrovanadium in the first half of the year.

Legislation and Government Programs.—On April 12, the Office of Preparedness decreased the vanadium pentoxide stock pile objective from 540 short tons of contained vanadium to zero, thereby eliminating the last remaining vanadium objective. Congressional authorization must be obtained before the remaining pentoxide can be sold.

The General Services Administration sold the 1,200 short tons (vanadium content) of ferrovanadium that remained in Government stockpiles. Of the 1,000 short tons sold to producers of ferrovanadium, 69% went to Shieldalloy Corp., 26% to Susquehanna-Western, Inc., and the balance to Gulf Chemical and Metallurgical Corp. Various metal traders bought the remaining 200 tons. No export restrictions were placed on this material.

As of December 31, 1973, the Government had an inventory of 1,231 short tons of vanadium, all in the national stockpile. Of this total, which includes material sold but not delivered, 399 tons was held as ferrovanadium and 832 tons was held as vanadium pentoxide.

r Revised.
[1] Recoverable vanadium contained in uranium and vanadium ores and concentrates received at mills, plus vanadium recovered from ferrophosphorus derived from domestic phosphate rock.

DOMESTIC PRODUCTION

The principal domestic source of vanadium in 1973 was the vanadium ore of Arkansas. The amount of vanadium recovered from Colorado Plateau uranium-vanadium ores declined, and the amount of vanadium recovered from ferrophosphorus did not change significantly. Some of the mills also processed vanadium-bearing oil residues, spent catalysts, vanadium-bearing residues from titanium dioxide production, and foreign vanadium-bearing slags.

The recovered vanadium pentoxide figures in tables 1 and 3 do not include vanadium recovered from imported vanadium-bearing slag. None of the figures include the vanadium recovered in any operation that produced ferrovanadium directly from slag or residue.

The Hot Springs, Ark., plant of Union Carbide Corp. produced all the vanadium recovered from Arkansas vanadium ore in 1973. The Uravan-Rifle mill complex of Union Carbide Corp. produced almost all the vanadium recovered from uranium-vanadium ores that year. The Soda Springs, Idaho, plant of Kerr-McGee Corp. and the Hot Springs, Ark., plant of Union Carbide Corp. produced all the vanadium recovered from byproduct ferrophosphorus. Other producers of vanadium from domestic ores and/or residues in 1973 included the Edgemont, S. Dak., mill of Susquehanna-Western, Inc.; the Wilmington, Del., plant of The Pyrites Co., Inc.; and the Moab, Utah, mill of Atlas Corp. Producing states include Arkansas 1971–73, Colorado 1971–73, Idaho 1971–73, New Mexico 1971–73, South Dakota 1972, and Utah 1971–73.

On October 1, the Atomic Energy Commission (AEC) began inviting bids for mining leases on 43 tracts of AEC-controlled land totaling about 25,000 acres. The land, mostly in the Uravan Mineral Belt of western Colorado, contains an estimated $45 to $50 million worth of uranium reserves and has good potential for further ore discovery. Included in the areas being offered were some lands mined under Government lease prior to 1962, when the leases were allowed to expire because of reduced procurement requirements for uranium. The leases, to be awarded on the basis of a competitive royalty bid, will have the royalty expressed as a percent of the value per dry ton of ore, this value to include both uranium and vanadium except for two tracts where the vanadium content of the ore is insignificant. AEC reserved 18 of the tracts for bidding by small business concerns and attached special terms to some of the other tracts. The opening of this new land to mining is expected to significantly prolong the life of the Colorado Plateau uranium-vanadium industry.

Earth Sciences Inc. awarded a $115,000 contract to the Ralph M. Parsons Co. for an economic feasibility study of a deposit of 15 to 25 million tons of material that is reported to average 0.76% vanadium. Earth Sciences controls the mineral rights to 3,000 acres of land in southeastern Idaho on which the deposit is located. Prior to awarding the contract, the company did some core drilling, some underground mine testing, and some hydrometallurgical testing on bulk samples mined underground.

The Pyrites Co., a subsidiary of Rio Tinto-Zinc Corp. Ltd., discontinued production at its vanadium operation at Wilmington, Del.

Table 2.—Mine production and recoverable vanadium of domestic origin produced in the United States

(Short tons of contained vanadium)

Year	Mine production [1]	Recoverable vanadium [2]
1969	5,737	5,577
1970	5,793	5,319
1971	5,547	5,252
1972	4,699	4,887
1973	4,117	4,377

[1] Measured by receipts of uranium and vanadium ores and concentrates at mills, vanadium content.

[2] Recoverable vanadium contained in uranium and vanadium ores and concentrates received at mills, plus vanadium recovered from ferrophosphorus derived from domestic phosphate rock.

Table 3.—Production of vanadium pentoxide in the United States [1]

(Short tons)

Year	Gross weight	V_2O_5 content
1969	12,120	10,542
1970	11,035	9,986
1971	10,492	9,448
1972	10,410	9,367
1973	8,226	8,683

[1] Includes vanadium pentoxide and metavanadate produced directly from all domestic sources, plus small byproduct quantities from imported chromium ores in 1971 and the preceding years.

CONSUMPTION AND USES

Domestic consumption of vanadium as reported for all types of material in table 4, or all end-use categories in table 5, rose about 22% in 1973. Increases occurred in all major end-use categories; the increase in consumption in the tool steel and nonferrous alloy categories was especially noteworthy. Consumption was at a fairly uniform high level from month to month during the year.

Westinghouse Electric Corp. received a $90 million contract for the nuclear reactor portion of the liquid-metal-cooled, fast-breeder reactor demonstration power-plant in Tennessee. Plans call for the plant to be operated by the Tennessee Valley Authority and to be on line by 1980. If vanadium metal is used as a structural material in this and other such reactors, a sizeable new market would be opened for vanadium.

The Vanadium International Technical Organization was launched during the year by most of the major producers of vanadium raw materials and ferrovanadium. It will sponsor research intended to lead to greater use of vanadium; its immediate objective is to develop vanadium-bearing high-yield steels for application under extreme conditions.

Table 4.—Consumption and consumer stocks of vanadium materials in the United States

(Short tons of contained vanadium)

Type of material	1972 Consumption	1972 Ending stocks	1973 Consumption	1973 Ending stocks
Ferrovanadium [1]	4,493	623	5,600	1,135
Oxide	189	56	199	49

Total	6,393

W Withheld to avoid disclosing individual company confidential data, included in "Miscellaneous and unspecified."
[1] Includes magnetic alloys.
[2] Includes pigments.

STOCKS

In addition to the consumers' stocks shown in table 4, producers' stocks of vanadium as fused oxide, precipitated oxide, metavanadate, metal, alloys, and chemicals totaled 2,815 short tons of contained vanadium at yearend 1973, compared with 3,540 tons (revised) at yearend 1972.

PRICES

Prices for vanadium pentoxide were unchanged in 1973. The price quoted by Metals Week for dealer export merchant technical-grade vanadium pentoxide continued to be $1.50 per pound of contained V_2O_5 for the entire year. The price for domestic 98% fused vanadium pentoxide (metallurgical markets) also remained $1.50 per pound of contained V_2O_5 in 1973. The price for technical-grade, air-dried vanadium pentoxide stayed at $2.21 per pound of contained V_2O_5, f.o.b. plant, for the entire year.

Kerr-McGee tried to increase its 98% fused vanadium pentoxide price on July 1 to $1.65 per pound of contained V_2O_5, a 10% increase from its previous price. The increase followed price increases by Highveld Steel and Vanadium Corp. of South Africa and reflected an improved market for vanadium. Although the Government's price freeze prevented the implementation of this price increase, it was indicative of the market at the time.

No changes occurred in the U.S. ferrovanadium prices either. The price for U.S. standard grade ferrovanadium remained at $4.19 per pound of contained vanadium f.o.b. shipping point for the entire year. The price for Carvan stayed at $3.66 per pound of contained vanadium in 1973. The price for Ferovan continued at $3.68 per pound of contained vanadium during the year.

Metal Bulletin's United Kingdom price for ferrovanadium containing 50% to 60% V rose over 12% from the beginning of the year to early April, after which it leveled off for the rest of the year.

FOREIGN TRADE

Exports of ferrovanadium were somewhat larger in the latter part of the year, with an especially large shipment leaving in July. Exports of vanadium ores and oxides were concentrated in the middle part of the year. The declared value for exports of ores, concentrates and technical-grade oxides averaged $1.40 per pound of contained vanadium pentoxide in 1973, compared with $1.21 in 1972. The declared value for exports of ferrovanadium averaged $3.08 per pound of alloy, compared with $2.34 in 1972.

Imports classified as vanadium ore and concentrate totaled 31,920 pounds of contained vanadium in 1973. Imports classified as vanadium carbide totaled 43,190 pounds (gross weight); almost all of it was from the Republic of South Africa. Imports classified as unwrought, waste and scrap vanadium metal, vanadium compounds, and organic vanadium salts totaled 80,203 pounds (gross weight). Imports of vanadium-bearing materials such as ashes and slags, which are classified as metal-bearing residues, were estimated to be about 5.2 million pounds of contained vanadium in 1973, compared with 2.8 million pounds in 1972. In both years, most of these materials originated in the Republic of South Africa and Chile.

WORLD REVIEW

In addition to the nations shown in table 8, several others produced relatively minor amounts of vanadium, usually from secondary, waste, or byproduct sources. Canada, Japan, and West Germany produced vanadium from several such sources. The world market for vanadium was quite strong in 1973, although a little weakening appeared towards the end of the year.

Australia.—The Ralph M. Parsons Co. completed an initial feasibility study for Ferrovanadium Corp. N.L. on the latter's ore deposit at Barrambie, Western Australia. The study recommended a concentrator at the mine site, a pipeline to move the concentrate 300 miles to Geraldton, and an electrometallurgical and chemical plant at Geraldton. Such an operation would cost $100 million and be able to produce over 3,000 short tons of vanadium as pentoxide, plus other products.

Under terms of an agreement with Ferrovanadium Corp. N.L., Pacminex Pty. Ltd., a subsidiary of CSR, Ltd., made a preliminary examination of the Barrambie project, after which it had the right to acquire 51% of the project. After examination, Pacminex withdrew from the project, explaining that the potential rewards to the company would not justify the expense and risk that would be incurred.

Canada.—The Mines Branch, Department of Energy, Mines and Resources, developed a pyrometallurgical process to recover vanadium and nickel from the fly ash that results from processing Athabasca tar sands. Recovery of these metals may be economically feasible when enough tar sand is being processed to recover over 200,000 barrels of synthetic crude per day; about 60,000 barrels per day is now being recovered.

Finland.—According to Finnish trade statistics, Finland exported 2,690 short tons of vanadium compounds[2] in 1972, of which 761 tons went to Sweden, 712 tons to West Germany, 482 tons to France, 331 tons to the U.S.S.R., and the balance to other European nations and Canada.

Germany, West.—According to official trade statistics, West Germany imported 33,664 short tons (gross weight) of vanadium-containing ashes, residues, and slag in 1973; 5,784 tons came from Hungary, 1,849 tons from France, 655 tons from Belgium-Luxembourg, 600 tons from Mozambique, 592 tons from the U.S.S.R., 255 tons from the Netherlands, 451 tons from other European, North American, and Israeli sources, and the balance from unspecified sources.

India.—Ferrovanadium production was 79 short tons in 1973, compared with 66 tons in 1972 and 52 tons in 1971. India exported 18,715 short tons (gross weight) of low-grade vanadium ore worth $950,900 in 1973, compared with 811 tons worth $61,470 in 1972 and 441 tons worth $24,930 in 1971.

The Geological Survey of India and the Orissa State Directorate of Mines are making a detailed investigation of the vanadiferous magnetite deposits of Orissa and Bihar, including field work. So far, they have proved enough ore to sustain Orissa State's proposed ferrovanadium plant for 10 years.[3] The Government of India has decided to include construction of this plant in its Fifth Plan (1974–79).

Dr. M. S. Patel of Bombay was attempting to complete arrangements for building a plant to recover 1,100 tons of vanadium per year as pentoxide from a titanomagnetite ore deposit in Bihar. Ore samples were being tested by a prospective collaborator in the United States.

South Africa, Republic of.—Production of vanadium-bearing slag by Highveld Steel and Vanadium Corp., Ltd., totaled 37,560 short tons (gross weight) in the fiscal year ending June 30, 1973, compared with 31,072 short tons in the previous fiscal year. This large increase reflects the solution of some long-standing problems in the iron plant and the resulting operation of the iron plant at its rated capacity. As a result of improving demand for vanadium pentoxide, the company operated its Vantra Division pentoxide plant at full capacity from the end of 1972 until October 1973, after which output was reduced in response to the reappearance of a weaker market. As a result of record production and sales, the company was able to declare the first dividend on its common stock.

Highveld Steel and Vanadium Corp., Ltd., announced plans to spend R14 million to

---

[2] Although the title of the export class is "vanadium compounds," the material is almost all vanadium pentoxide.

[3] Nanda, A. K. Our Resources of Vanadium Ore. J. of Mines, Metals, and Fuels (Calcutta), v. 21, No. 12, December 1973, pp. 373–376, 387.

expand vanadium-bearing slag and steel output by 25% at its Witbank plant. This would involve adding a sixth kiln, a fifth submerged arc iron melting furnace, a fourth continuous-casting machine, major modifications in the steel plant, and some expenditures at the Mapochs mine. The additional slag would be exported, as would most of the steel semimanufactures until such time as installation of a rolling mill becomes feasible.

Transvaal Alloys, Ltd., is mining a vanadium ore body near Uitvlugt, Transvaal, under a lease from Bushveld Development (Pty.) Ltd., and is expecting to remove 1.2 million tons of ore by the time the lease expires in February 1974. The company's vanadium pentoxide plant complex near Stoffberg is expected to be onstream in early 1974.

U.S.S.R.—The Kachkanar mining and beneficiation complex is reported to have reached its rated capacity of 36 million short tons of crude titanomagnetite ore per year, from which a concentrate containing about 18,000 tons of vanadium is produced. Rising demand for ferrotitanium has resulted in plans for expanding the capacity to 44 million tons of ore per year by the end of 1975.

Venezuela.—The Venezuelan Ministry of Mines and Hydrocarbons contracted with Gas Development Corp. for an evaluation of the possible development of the Orinoco heavy oils, and their associated vanadium and nickel values. Results of the study indicate that there are good prospects for producing 1 million barrels of oil per day, at which level an estimated 9,500 tons of byproduct vanadium per year could also be recovered. Total heavy oil in place is about 700 billion barrels, recovery of 2% to 10% of which could reasonably be expected. Because the metals contained in the heavy oil contaminate the catalysts used in processing the heavy oil into the final petroleum products, the metals must be removed first. Two types of processes seem most likely to be used for metal removal, one involves concentration of the metals in the asphaltene fraction and subsequent removal and the other involves deposition of the metals on a cheap material (probably a catalyst).[4]

TECHNOLOGY

A considerable volume of research on vanadium was conducted in 1973, most of it dealing with vanadium metal and alloys which could possibly be used as fuel-cladding materials in fast-breeder reactors, with the recovery of vanadium from petroleum, and with the vanadium released into the atmosphere by petroleum combustion and soil erosion. The research dealing with recovery of vanadium from petroleum received comprehensive coverage at a symposium on vanadium in petroleum held in Venezuela.

The Bureau of Mines made high-purity

(over 99.8%) vanadium metal by magnesium reduction of vanadium dichloride, obtaining yields of over 98%.[5]

Vanadium-chromium and vanadium-molybdenum alloys were found to have a lower oxygen solubility than vanadium metal when specimens of the metal and its alloys were exposed to an oxygen-containing coolant-type liquid sodium such as proposed for the fast-breeder reactor.[6]

Extensive adoption of the Flexicoking process could result in the recovery of large quantities of vanadium from crude residua in oil refineries, as requirements for low-polluting desulfurized demetallized petroleum products increase. The process combines fluid coking with coke gasification and concentrates 99% of the contained metals into a small purge stream while converting the residua into gas and lighter demetallized liquid amenable to further processing. Some of the purge stream product may be too low grade to make recovery worthwhile; this is evidenced by the purge stream product containing under 6% vanadium even when a high-metal Venezuelan feedstock was used. A semicommercial Flexicoking unit is now being built in Texas for startup in early 1974, and three commercial units are now being designed—two for Japan and one for the United States.[7]

Some other methods for recovering vanadium from petroleum were mentioned at the International Symposium on Vanadium and Other Metals in Petroleum, held August 19–22 in Maracaibo, Venezuela. One method involved extracting the vanadium directly from the petroleum with an aqueous solution of a strong complexing agent. Another possibility would involve removing the asphaltene fraction, which contains almost all of the vanadium, from the crude petroleum by electrodeposition. Vanadium could be recovered from petroleum by being adsorbed on bauxite in either a batch or a flow reactor. Vanadium could be obtained also, along with a synthetic natural gas and benzene, from a Venezuelan-type residuum by hydrogenation in a high-velocity fluidized bed.

The origin of vanadium-containing airborne particulates was determined at various locations. The atmospheric vanadium sampled in Puerto Rico was probably from the soil; the atmospheric vanadium sampled in the San Francisco Bay area appeared to be both from the soil, in the case of the larger particles, and from the combustion of petroleum, in the case of the smaller particles.[8] In Japan, vanadium concentration in the atmosphere was closely correlated to the amount of fuel oil burned and to the concentration of sulfur dioxide in the atmosphere.[9]

A variety of processes for separating vanadium-bearing solutions, sodium hexavanadate, ferrovanadium, or vanadium metal from various raw materials were patented in 1973. A vanadium-bearing solution can be recovered from a silica-containing titaniferous magnetic ore, such as that found in Tahawus, N.Y., by roasting a mixture of ore, a sodium salt, and cryolite at a temperature under 1,350° C for 30 minutes to 2 hours, and then leaching the mixture.[10]

Sodium hexavanadate can be recovered from the post-distillation residue which results from fractionating titanium tetrachloride from titanium ore or slag. Steps include uniformly contacting the residue with superheated steam in the presence of air, carbon dioxide, and carbon monoxide, treating it with aqueous sodium hydroxide, roasting it, extracting it with water, and filtering it to obtain a precipitate of sodium hexavanadate.[11]

A ferrovanadium-like alloying additive can be produced from fuel ash residue by leaching the residue, treating the leach solution

successively with finely divided carbon, ferric chloride, and ammonium chloride to precipitate a complex of vanadium and iron, and reducing the precipitate to get the additive.[12] Vanadium metal can be produced from vanadium ore or oxide by entraining the vanadium-bearing material in flowing methane or propane, introducing the flow axially into an electric arc heater and heating it sufficiently to get reduction to the metal, and letting the metal blow out of the exhaust port of the heating chamber.[13]

Vermiculite

By Frank B. Fulkerson [1]

In 1973 crude vermiculite production increased 8% to the record high of 365,000 short tons. The crude vermiculite, mined in Montana and South Carolina, was shipped to plants in 31 States for exfoliation. The quantity of exfoliated vermiculite sold and used by producers increased 19%. The exfoliated material was used mainly in the building industry for lightweight concrete aggregate, loose fill insulation, and other purposes.

DOMESTIC PRODUCTION

Crude Vermiculite.—Output increased from 337,000 short tons in 1972 to 365,000 short tons in 1973. The only producers of crude vermiculite were the Construction Products Division, W. R. Grace & Co., with mines near Libby, Mont., and Enoree, S.C., and Patterson Vermiculite Co., Lanford, S.C. W. R. Grace & Co. nearly completed construction on a new $7 million wet processing plant near Libby. The new plant will produce in excess of 1,000 tons per day of bulk vermiculite concentrate.

Exfoliated Vermiculite.—The tonnage of exfoliated vermiculite sold or used by producers increased from 247,000 in 1972 to 293,000 in 1973. Fifty-five plants in 31 States produced the lightweight product. The following five States supplied 41% of the national total: California, Florida, New Jersey, South Carolina, and Texas. W. R. Grace & Co., the leading producer of crude vermiculite, operated 27 exfoliating plants in 22 States. Patterson Vermiculite Co. consumed all its production of crude vermiculite at its Lanford, S.C., exfoliating plant. A quantity of crude vermiculite from the Republic of South Africa was exfoliated in the United States.

CONSUMPTION AND USES

By main categories, the use pattern for exfoliated vermiculite was as follows: Aggregates, 47%; insulation, 31%; agriculture, 17%; and miscellaneous, 5%. End uses in 1972 and 1973 are shown in thousand tons in the following tabulation:

[1] Industry economist, Division of Nonmetallic Minerals—Mineral Supply.

Use	1972	1973

Total	52	50
Miscellaneous	7	14
Grand total	247	293

[1] Includes vermiculite aggregate for products mixed on site as well as premixes for acoustic and fireproofing purposes, etc.

PRICES

The Engineering and Mining Journal quoted nominal yearend prices for crude vermiculite as follows: Per short ton, f.o.b. mines, Montana and South Carolina, $25 to $38; and c.i.f. Atlantic ports, Republic of South Africa ore, $55 to $70.

The average mine value of domestic crude vermiculite, screened and cleaned, was $25.93 per short ton, compared with $24.01 in 1972. The average value, f.o.b. producing plant, of exfoliated vermiculite, was $106.44 per short ton, compared with $100.31 in 1972. These values exclude container cost where applicable.

FOREIGN TRADE

Crude vermiculite was imported duty free into the United States. The Republic of South Africa was the only important source of vermiculite imports. A quantity of crude vermiculite was exported from the United States to Canada; however, tonnage figures were not published.

WORLD REVIEW

Canada.—All crude vermiculite exfoliated in Canada was imported from the United States and the Republic of South Africa, with the Libby, Mont. mine of W.R. Grace & Co. supplying most of the tonnage. Five companies exfoliated vermiculite at nine locations in 1972. The plants were in Vancouver, British Columbia (two plants); Edmonton, Alberta; Regina, Saskatchewan; Winnipeg and St. Boniface, Manitoba; St. Thomas, Ontario; and Montreal and Lachine, Quebec. Loose-fill insulation consumed 72% of production and insulating concrete and plaster most of the remainder.[2]

China, Peoples' Republic of.—Vermiculite was mined at 20 locations in Linshu County, Shantung Province. A plant was completed in the county to make heat-insulating bricks and slabs by bonding vermiculite with cement.

South Africa, Republic of.—Principal countries to which crude ore was exported in 1972 were the United Kingdom, 22%; the United States, 19%; Italy, 15%; West Germany, 10%; France, 10%; and Japan, 6%.

TECHNOLOGY

Canadian research showed that exfoliated vermiculite was effective in purifying the air in underground uranium mines by filtering out dust particles and radon daughters. Vermiculite was chosen as the filter medium because of its low cost, low density, and ability to stand high humidity.[3]

[3] Washington, R. A., W. Chi, and R. Regan. The Use of Vermiculite to Control Dust and Radon Daughters in Underground Uranium Mine Air. Can. Min. and Met. Bull., v. 66, No. 731, March 1973, pp. 152–155.

Zinc

By Albert D. McMahon,[1] John M. Hague,[2] and Herbert R. Babitzke [1]

In many ways 1973 was an outstanding year for zinc in the United States. Highs and lows for items of supply and demand were established, and unique situations developed. It was the best year on record for slab zinc consumption and the worst year for slab zinc production; it was the lowest and highest year for imports of concentrates and metal, respectively; the highest for stockpile releases and exports of concentrates and metal; and prices rose to record levels in both U.S. and world markets. The Government ceiling price control of zinc, administered by the Cost of Living Council, was on and off twice, and the shortage of zinc continued throughout the year. Of the 98 mines accounting for zinc mine production in the United States, the leading 25 mines produced 93% of the total. Missouri, with its byproduct zinc from lead mines in the fairly new southeast lead belt, became the leading zinc-producing State, while Tennessee and New York fell back owing to strikes and operating problems.

Smelter production of slab zinc declined 11% because of a decrease in zinc concentrate imports and the use of more domestic concentrates for American-process zinc oxide. This loss of raw material for the smelters was partially compensated by acquisitions of slab zinc from the national stockpile for remelting and direct shipment to consumers. Closure of the horizontal retort smelter at Amarillo, Tex., was delayed as the Texas Air Control Board rescinded a previous order and issued a variance permitting operations to continue until May 30, 1975. The State of Oklahoma in a similar action extended the variance for the horizontal zinc smelter at Bartlesville, Okla., until June 30, 1975, when it will be replaced by an electrolytic plant. Rehabilitation of the Sauget, Ill., electrolytic plant was completed, and erection of two new plants with a combined annual capacity of 340,000 tons of slab zinc was being considered.

Demand continued to rise through most of the year at a rate of almost 8%. However, because of a slowdown in the last 2 months, the year ended with only a 6% increase over that of 1972.

The major sources of zinc concentrate imports continued to supply less zinc for domestic smelters, but imports of metal increased 13%. Exports of concentrate and metal increased to take advantage of higher prices in the world market. The lead and zinc flexible-tariff bill and the bill to suspend the duty on imports of zinc concentrates were reintroduced in Congress. Both bills were in the House Ways and Means Committee at yearend.

Under the Administration's plan to reduce objectives for most stockpiled materials, that for zinc was lowered from 560,000 to 202,700 tons, creating an additional surplus of 357,300 tons. New legislation authorizing disposal of this quantity was signed by the President on December 28, 1973.

Phase 3 of the President's economic stabilization program effective January 11, 1973, abolished the Price Commission and established voluntary controls subject to the Cost of Living Council regulations. Prices advanced from a range of 18–18.52 cents per pound to 20.25–21 cents, where they were frozen June 13 by Presidential order. The ceiling prices prevailed until December 6, 1973, when the Cost of Living Council abolished Government price control on zinc. The domestic price advanced immediately to a range of 28–32 cents per pound.

Legislation and Government Programs.—The General Services Administration (GSA)

[1] Physical scientist, Division of Nonferrous Metals—Mineral Supply.
[2] Mining engineer, Division of Nonferrous Metals—Mineral Supply.

sold 266,315 short tons of zinc from the stockpile during 1973. Government agencies received 117 tons, which was transferred under authorization of Public Law 89–9, leaving a balance of 21,980 short tons. Commercial sales totaled 266,198 tons as authorized by Public Law 92–283 of April 26, 1972. Of the latter amount, 62,477 tons was sold under the set-aside program, and 204,923 tons was sold to the seven participating primary zinc producers under terms of their long-term contracts. At yearend there remained under Public Law 92–283 approximately 30,085 tons of zinc to be released through primary domestic producers and 25,000 tons in the set-aside program. Based on inventory, actual movement of zinc from the stockpile in 1973 was 272,574 tons. This amount includes the drawdown of some of the zinc that was transferred to the Treasury Department in 1970.

By June 30, 1973, all the zinc that was provided for the initial 75,000-ton set-aside program was sold; therefore, on July 1, 1973, the set-aside program was revised upwards to allow releases of 25,000 tons of zinc per quarter as long as zinc remained in the authorization and at the same time allowing the primary producers to draw more zinc. In the revised program, 5,000 tons of Special High Grade zinc was provided, and consumers were limited to purchases of 120 tons of Special High Grade per quarter or 480 tons of High Grade, Intermediate, or Prime Western. On every quarterly allocation the consumers ordered more zinc than what was made available; consequently, the orders were reduced in proportion to what was available.

In April, the stockpile objective for zinc was reduced from 560,000 tons to 202,700 tons, which created a surplus of 357,300 tons. New legislation, Public Law 93–212, authorizing disposal of this quantity was signed by the President on December 28, 1973. This bill provided that 150,000 tons of zinc be sold direct to the consumers, 75,000 tons during the second quarter of 1974 and 25,000 tons each following quarter for the balance. The remaining 207,300 tons was for the participating primary zinc producers.

The President's economic stabilization program entered phase 3 on January 11, 1973, which removed the mandatory price ceiling on zinc and allowed limited price increases, but on June 13, 1973, phase 4 was established by Presidential order which froze the price of zinc once again. This status remained until December 6, 1973, when the Cost of Living Council was abolished and zinc pricing was decontrolled.

The lead and zinc flexible-tariff bill and the bill to suspend the duty on imports of zinc concentrates were reintroduced in Congress in March 1973. Each incorporated a significant change from the previous bills. The new flexible-tariff bill permitted a larger quantity of zinc metal to enter the United States before the high duties became effective, and the duty suspension bill on zinc concentrates was for 2 years. At yearend, both bills were in the House Ways and Means Committee. Another bill, also in the House Ways and Means Committee, proposed suspension of the duty on imports of zinc metal.

The International Lead and Zinc Study Group held its 17th session in Geneva from November 7–12, 1973, to review developments leading to the current situation and the outlook for these metals. Representatives from 28 of the 30 member countries attended. Representatives of several intergovernmental organizations were also present. The strong growth in zinc consumption featured in 1972 continued through most of 1973, but a slowdown in the rate of growth was forecast for 1974. The 1973 forecasts for mine and metal production were adjusted to increases of 3% and 5%, respectively, over 1972 production; zinc metal consumption, rising strongly in most countries, was expected to register an increase of 10%, following one of 11% in 1972. Producers' stocks were drawn down to very low levels, and a large statistical deficit developed. This situation was expected to continue into 1974. The various price rulings throughout the world created a complex basis for zinc sales. In the United States domestic production was subject to Government price control, substantially under world markets at 20.25 to 21 cents per pound, but imported metal was sold in the United States at much higher levels. The European producer price increased in stages to 31.54 cents per pound, while the London Metal Exchange quotation increased dramatically to over 95 cents per pound. The Statistical Committee set up an ad hoc working party to review the importance of secondary materials as a source for lead and zinc. Other topics discussed at the meeting included new mine and smelter projects, consumption trends, trade liberalization, and long-term projections.

DOMESTIC PRODUCTION

MINE PRODUCTION

Mines in the United States produced 478,850 tons of recoverable zinc, 532 tons more than in 1972 and the first increase since 1969. Production was reported in 18 States. Seven States recorded increases over that of 1972, and 11 States registered decreases. Missouri with its byproduct zinc recovery from lead ores led the Nation in zinc production with 33% more than in 1972. New York moved up into second place with a 34% increase, and Tennessee dropped to third with a decline of 37%. Colorado, Idaho, and New Jersey followed in order, repeating the 1972 pattern. The States east of the Mississippi River accounted for 52% of the U.S. 1973 mine production.

Sources of zinc production for 1973 are shown in table 5 according to the principal metal or combination of metals extracted. The percentage distribution is as follows: Zinc ore, 57%; zinc-lead ore, 19%; lead ores, 18%; copper-zinc and copper-lead-zinc ores, 5%; all other sources, 1%.

The 25 leading mines listed in table 6 accounted for 93% of the domestic recoverable mine production. The five leading mines produced 43%, and the first 10 mined 63%.

Missouri attained first place among the zinc-producing States with a 33% increase over 1972. Byproduct zinc production from St. Joe Minerals Corp.'s four operating lead mines in the New Lead Belt in southeast Missouri (Fletcher, Viburnum, Indian Creek, and Brushy Creek) increased in 1973, and more is expected in 1974. The mills at Fletcher and Brushy Creek are among the most modern in the industry and incorporate computer-controlled processes allowing the entire plant to be operated by only a few employees.[3] The Missouri mine-mill-smelter complex, owned jointly by American Metal Climax, Inc. (AMAX) and Homestake Mining Co., benefited from higher production, favorable ore grade, and higher prices. About 1.6 million tons of ore were mined and milled in 1973, an increase of 10% over 1972. Production of zinc concentrate was up 42% to 116,500 tons.[4] The Magmont mine at Bixby, Mo., operated by Cominco American Incorporated, a joint venture of Cominco, Ltd. and Dresser Industries, Inc., produced 934,000 tons of ore averaging 8.3% combined lead and zinc compared with 1,034,000 tons of 7.9% ore in 1972. Except for a 1-month strike in June, a high level of production was maintained throughout the year.[5]

Byproduct zinc output by the Ozark Lead Co. was lower in 1973 because of a 2-month strike which ended on April 30 with agreement on a 3-year labor contract. A shortage of skilled underground maintenance personnel also adversely affected production. In 1973, Ozark Lead Co. was awarded the national Sentinels of Safety trophy for outstanding underground mine safety performance. This award is sponsored by the Bureau of Mines and the American Mining Congress. Ozark was honored for the second consecutive year—the first time a U.S. mine has achieved that distinction since 1928.[6]

Mine production in New York, all from the Balmat-Edwards mining complex of St. Joe Minerals Corp., increased 34% in 1973, and higher production is expected in 1974. St. Joe has concentrated on exploration and continued the modernization and underground development programs at the Balmat-Edwards mines. Two mills treat 5,000 tons of ore per day and produce a 55% zinc concentrate. The Balmat mill has over 85% of that capacity and is one of the most automated mills in the world.[7]

Tennessee dropped to third place after ranking first among the mine-producing States for 15 years. The decline of 37% was due principally to the closure of three mines for 8 months by a strike. Occidental Mineral Corp. (Oxymin), a subsidiary of Occidental Petroleum Corp., increased its leaseholdings in the vicinity of Carthage, Tenn., to a total of 1,300 acres. Further exploration and development are being discussed with several mining companies.[8]

The New Jersey Zinc Co.'s newest mine, in Elmwood, Tenn., is scheduled to begin initial production in the spring of 1974.[9]

The Jefferson City mine of New Jersey Zinc Co. and the Zinc Mine Works of United States Steel Corp. in east Tennessee operated throughout the year. American Smelting and Refining Company (ASARCO) started construction on a new concentrator at the Young mine in December. It will be more modern and 20% larger than the Mascot mill.[10]

Operational problems continued at the industrial chemicals plant at Cities Service Co., at Copperhill, Tenn., which had been revamped and expanded. Zinc concentrate sales increased 71% in 1973 to 18,100 tons.[11]

Production in New Jersey, Pennsylvania, and Virginia by New Jersey Zinc Co. declined for the third straight year to 68,567 tons, 6.4% below that of 1972. This company is continuing an active exploration program for additional minerals with emphasis on zinc-bearing ores. Significant progress was made in deepening the shaft at the Friedensville, Pa., mine.[12]

In Colorado, mine output decreased in 1973 to 58,339 tons, a decline of 8.6% below that of 1972. The New Jersey Zinc Co. Eagle mine produced the largest tonnage of zinc, although slightly less than in 1972. The Resurrection mine, a joint venture shared equally by Resurrection Mining Co. (a 100% owned subsidiary of Newmont Mining Corp.) and ASARCO, continued operation without interruption during the year. The mine produced only about 75% of its rated capacity of 700 tons of ore per

day, due largely to a manpower shortage. However, because of an increase in ore grade, higher metal prices, and carefully controlled costs, the mine, operated by ASARCO, had a profitable year. The average grade of ore milled in 1973 was 8.95% zinc, 3.96% lead, 2.8 ounces of silver, and 0.07 ounce of gold per ton, compared with 7.6% zinc, 3.9% lead, 2.4 ounces of silver, and 0.07 ounce of gold per ton in 1972. Ore reserves as of January 1, 1974, were estimated at 2,619,000 tons averaging 9.71% zinc, 4.98% lead, 2.53 ounces of silver, and 0.067 ounce of gold per ton, compared with 2,609,500 tons averaging 9.92% zinc, 5.16% lead, 2.53 ounces of silver, and 0.068 ounce of gold per ton at yearend 1972. The Newmont Mining Corp. Idarado mine was the third largest producer in Colorado, and the Sunnyside mine of Standard Metals Corp. ranked fourth. Idarado's 1973 tonnage milled was only slightly below that of 1972. Additional income from higher metal prices in 1973 was offset by higher operating costs and by increased development expenses required to open more stopes and add to broken ore reserves. In 1973, the mill treated 378,150 tons of ore averaging 3.44% zinc, 2.55% lead, 0.56% copper, 1.39 ounces of silver, and 0.052 ounce of gold per ton. This compares with 386,500 tons milled in 1972 averaging 3.74% zinc, 2.74% lead, 0.72% copper, 1.74 ounces of silver, and 0.063 ounce of gold per ton. Ore reserves at the end of 1973 were 3,241,000 tons averaging 4.61% zinc, 3.36% lead, 0.77% copper, 1.77 ounces of silver, and 0.02 ounce of gold per ton, compared with 2,865,000 tons in 1972 containing averages of 4.80% zinc, 3.31% lead, 0.74% copper, 1.75 ounces of silver, and 0.03 ounce of gold per ton.[13]

Mine production of zinc in Maine increased to 19,640 tons as the Blue Hill mine completed its first full year of operation. The ore body is a difficult one to mine, and at yearend the designed production of 1,000 tons per day had not been attained over a 7-day-per-week basis. Milling throughout the year was restricted to 5 days per week owing to the inability to develop enough ore faces in the mine for a greater production rate. During 1973, 230,200 tons of ore averaging 10.69% zinc and 0.63% copper was milled to produce 885 tons of copper and 23,030 tons of zinc in separate concentrates. Minable ore reserves, including an allowance for dilution and based on past mining experience, on December 31, 1973, were estimated to be 742,000 tons grading 5.68% zinc and 1.7% copper.[14]

Mine production of zinc in Idaho for 1973 increased 19% to 46,107 tons. Ore production at the Bunker Hill mine increased about 17%, reflecting greater production of zinc ores from the upper levels of the mine which have been under development for the last 2 years. Zinc metal content of ore increased 25%, while lead and silver remained unchanged from 1972. Ore reserves were nearly the same as in 1972 with the development of new reserves to replace those mined during the year. The intensified mine exploration program, which began in 1973, is on schedule and will continue for 4 more years. Gross production from the Star mine equaled that of 1972, although zinc production was off by 8%. Higher metal prices more than offset rising operating costs, and the mine experienced its first profitable year since 1967. In 1973 production from company owned and controlled mines amounted to 38,000 tons of zinc, 31,000 tons of lead, and 2.6 million ounces of silver.[15] The Star-Morning mine, 30% owned by Hecla Mining Co. and 70% owned by the Bunker Hill Co., produced 265,781 tons of ore in 1973 assaying 6.68% zinc, 5.18% lead, and 2.79 ounces of silver per ton compared with 263,595 tons in 1972 containing 7.36% zinc, 5.33% lead, and 2.87 ounces of silver per ton.[16] During 1973 an independent contractor operating the Day Mines, Inc., Monitor mine produced 20,674 tons of ore averaging 7.90% zinc, 2.71% lead, and 0.86 ounce of silver per ton from the Gray Rock section. Ore reserves were increased to provide adequate ore for an additional 3 years of production at the current rate.[17]

Mine production of zinc in Utah declined 23%. Zinc, lead, and silver production at the Kennecott Copper Corp. Tintic Division (Utah) decreased in 1973 owing to a critical shortage of skilled miners and mechanics. Also, adverse underground mining conditions inhibited development work and production.[18]

Zinc mine production in Arizona for 1973 was 17% lower than in 1972. The Bruce mine near Bagdad, Ariz., is operated by the Cyprus Bruce Copper and Zinc Co., a wholly owned division of Cyprus Mines Corp. In 1973, mine output of ore was 93,000 tons with an average grade of 12.7% zinc and 3.68% copper. Concentrates produced contained 3,000 tons of copper and 9,500 tons of zinc. Record earnings were achieved owing to good metallurgical results, acceptable production costs, and high average prices received for copper, 60.8 cents per pound, and zinc, 26.4 cents per pound. Exploration did not add much to known reserves, but surface and underground drilling will continue in 1974. Known ore reserves of 467,000 tons with an average grade of 12.4% zinc and 3.72% copper will sustain the operation for about 5 years.[19]

In 1973, mine output of zinc in New Mexico declined 3% from that in 1972. At the ASARCO Ground Hog mine, the zinc content of ore produced was 13,500 tons, compared with 14,000 tons in 1972.[20] UV Industries, Inc., anticipates some zinc production from the reopening of the Hanover mine in New Mexico. Byproduct zinc will be recovered from the copper ore processed at the Continental Mill No. 1 at Bayard, N. Mex. A 2-year program will define the extent of the copper, iron, and zinc reserves.[21]

In Washington, 1973 mine production dropped slightly to 6,378 tons. Pend Oreille Mines & Metals Co. mined and milled 212,289 tons of ore and produced 10,834 tons of zinc concentrate. Development of the Yellowhead Area is underway with several headings being driven from the Yellowhead Exploration Decline. Several areas of low- to high-grade lead-zinc ore have been intercepted, but continuity of mineralization is still a problem that precludes making an accurate estimate of minable ore reserves.[22]

The Callahan Mining Corp. has resumed work at its zinc-lead property near Colville, Wash., under an agreement reached in the last quarter of 1973 granting United States Borax & Chemical Corp. and the British Newfoundland Exploration Ltd. the right to earn jointly up to 51% interest in the property through work expenditures. The program, which will include geologic work and drilling during 1974, is designed to test potential for increasing ore reserves indicated by prior surface drilling and underground test work.[23]

Wisconsin mine production of zinc increased 26% in 1973. In Illinois and Kentucky production decreased 54% and 85%, respectively.

SMELTER AND REFINERY PRODUCTION

U.S. slab zinc production at smelters and electrolytic plants was 628,785 short tons in 1973, a decrease of 11% from that of 1972. The decline may be attributed to the closure of the horizontal retort smelter at Blackwell, Okla., the inability of the AMAX plant at Sauget, Ill. to come on full stream during the year, a decrease in imports of zinc concentrates, and the use of more domestic concentrates for American process zinc oxide.

Drawdown of producers' stocks was minor for the year. Ending stocks at producer plants were 20,291 tons. In addition to the slab zinc production, producers purchased 154,327 tons of GSA stockpile zinc during the year; 44,994 tons was shipped directly to customers, and 109,333 tons was remelted for upgrading.

Smelter and refinery capacities were increased 28,000 tons during the year to 749,500 tons. This increased capacity may be attributed to the startup of the AMAX Zinc Co., Inc., at Sauget, Ill., and the expansion of St. Joe Minerals Corp. at Monaca, Pa.

Refined zinc production at primary smelters and electrolytic refineries was derived from the following: Domestic ore, 58%; foreign ore, 28%; and scrap, 14%. Slab zinc produced from domestic and foreign ore decreased 9% and 24%, respectively, from that of 1972, but that produced from scrap increased 19%.

Primary slab zinc produced at electrolytic plants was 19% less than that in 1972 and was 33% of the total slab zinc produced. Smelter production (distilled) was down 11% and made up 53% of the total. Redistilled slab zinc from secondary zinc materials by primary smelters increased 2% and contributed 10% of the total, and redistilled production at secondary plants

more than doubled over that of 1972 and was 4% of the total. Production of all grades of zinc declined except for a 9% increase for Prime Western. Distribution of the total grades was as follows: Special High, 40%; High, 4%; Intermediate, 6%; Brass Special, 10%; and Prime Western, 40%.

ASARCO is considering the construction of an electrolytic zinc refinery on 1,400 acres of land on the Ohio River, near Stephensport, Ky. If undertaken, the plant would be completed by 1976 and would produce about 180,000 tons of zinc per year and significant byproduct sulfuric acid and cadmium. ASARCO's reasons for choosing the Stephensport area were the availability of rail and river barge transportation at the plant site, and its closeness to both ASARCO Tennessee zinc mines and the principal Midwestern markets for refined zinc and sulfuric acid.[24] The cost for construction of the plant was revised upward to $150 million, up $50 million from a previous estimate.[25]

During 1973, ASARCO installed an electric melting furnace at its electrolytic zinc plant in Corpus Christi, Tex., to provide a cleaner and more efficient operation than was possible with the two gas-fired reverberatory furnaces which it replaced. The $3.7 million program to convert from in-plant generation of electric power to purchased power continued and is expected to be completed in 1974. Regarding the Amarillo, Tex., plant, a variance was granted in July by the Texas Air Control Board to allow the plant to operate until May 30, 1975. The operation will be phased out at that time, or shortly thereafter, as the expenditures necessary to meet the applicable air quality standards are not justified at this horizontal retort zinc smelter.[26]

The Sauget, Ill., electrolytic zinc plant, purchased by AMAX in 1972, underwent extensive rehabilitation with initial production commencing in May 1973. A total of 25,000 tons of refined zinc was produced for the year, and an output of 70,000 tons is expected in 1974. Full capacity of 84,000 tons of zinc should be reached by 1975, and an annual production of 1.35 million pounds of cadmium and 150,000 tons of sulfuric acid is also expected. Completion of preleach facilities late in 1974 will permit the processing of high-magnesium-bearing zinc concentrates. At full production, the Sauget plant will represent about 12% of total U.S. zinc smelter capacity.

By the end of 1973, the planned phase-out of the AMAX Blackwell, Okla., horizontal retort furnaces was completed, although sintering operations were to continue through the first part of 1974. Production in 1973 totaled 39,000 tons of zinc. The change in basic product grade, from Prime Western zinc produced at Blackwell to Special High Grade produced at Sauget, will provide AMAX with additional capability to supply zinc to the die-casting and to other premium markets.[27]

St. Joe Minerals Corp., the Nation's largest zinc smelter, which provides about one-third of the domestic zinc, produced 231,085 tons of zinc (zinc equivalent) in 1973, slightly less than that of 1972 and under its 245,000-ton capacity. An expansion program has begun at the smelter that will increase the annual capacity by 40,000 tons in 1976. During the year the zinc smelter phased out its production of Special High Grade zinc alloys in order to concentrate its productive capacity on the fast-growing zinc oxide field and on a full line of zinc metal for the galvanizing industry.

Zinc oxide has become an increasingly important product for St. Joe Minerals Corp., now the second largest producer in the United States. Production in 1973 was 62,000 tons and it is expected to go over 70,000 tons in 1974. An expansion program is underway with an investment of approximately $5 million to increase the zinc oxide facilities to 85,000 tons. The full amount of this capacity should be on line in late 1974.

In 1973 capital expenditures for environmental improvement at the Monaca, Pa., smelter totaled $5.2 million. An additional $6 million will be spent in 1974 in the continuing program to keep the zinc smelter in full compliance with Federal and State air and water environmental regulations.[28]

The New Jersey Zinc Co. reported an increase of 28% to $130.5 million in net sales for fiscal 1973. Zinc metal production was 103,000 tons, up 6% over that of fiscal

[28] Pages 3 and 18 of work cited in footnote 3.

1972, while pigment production was 177,000 tons, an increase of 20%. The strong demand for zinc metal and oxides, combined with reduced U.S. production capacity, contributed to a maximum level of operations.[29]

The New Jersey Zinc Co. announced that it is considering building an electrolytic zinc refinery and a zinc oxide plant near Clarksville, Tenn., and modernizing its Palmerton, Pa., zinc plant. If undertaken, the Clarksville refinery would begin production in 1977, and by 1979 the plant should have an annual capacity of 160,000 tons. The new plant would use zinc concentrates produced at company mines in Tennessee and Virginia. The modernization program at Palmerton includes improved mix houses, modifications of the roasting and acid plant, mechanization of bagroom oxide handling, revisions of materials handling systems, and new dust-control facilities. The modernization program will also increase production capacity for French process and American process zinc oxide.[30]

The Bunker Hill Co., a division of Gulf Resources & Chemical Corp., of Kellogg, Idaho, produced 98,300 tons of zinc in 1973, down from 101,700 tons in 1972. The annual capacity of the zinc plant is approximately 104,000 tons. The drop in production was caused by a work stoppage and by domestic price controls which made it difficult to compete successfully in world ore markets for quality concentrates. Total net sales in 1973 were $102.4 million, compared with $91.9 million in 1972.

The Bunker Hill Co. continued work with the Bureau of Mines on construction of a plant adjacent to the smelter for large-scale testing of the Bureau's citrate process for sulfur dioxide removal from stack gas. The plant was completed, and startup trials have been initiated. The company has budgeted $2.5 million to maintain compliance with regulations under the Environmental Protection Act. Historically Bunker Hill Co. has expended a grand total of $22 million on pollution control and related facilities.[31]

National Zinc Co., Inc., at Bartlesville, Okla., was under attack by the Oklahoma Air Pollution Board, but was granted a 1-year variance to secure financing for an $18 million plant addition to eliminate pollution.[32] The Federal deadline to comply with the pollution law or close down is July 1, 1975. The State of Oklahoma extended its variance until June 30, 1975.[33]

The company announced later that it will build a 50,000-ton-per-year electrolytic plant at Bartlesville to replace the 66-year-old horizontal retort smelter. The scheduled completion date was set for May 31, 1975.[34]

In the latter part of 1973, Engelhard Minerals & Chemicals Corp. contracted to purchase for $4 million the assets of National Zinc Co., Inc. Title to the properties at Bartlesville, Okla., was taken on February 11, 1974. The plan to erect an electrolytic zinc plant at the old site will hold firm. The new installation, estimated to cost approximately $30 million, should be onstream in early 1976, and the company hopes to continue operation of the retort furnaces until they are replaced by the new electrolytic process, but this will be subject to extension of the existing variances issued by pollution control authorities.[35]

Secondary Zinc Smelters.—Zinc recovered from zinc-bearing scrap was 387,539 tons in 1973, nearly the same as in 1972. Semimanufactured forms of zinc- and copper-base alloys accounted for 98% of the new and old scrap. New scrap, chiefly zinc- and copper-base alloys from manufacturers and drosses from galvanizing and die casting pots, accounted for 76% of all the scrap processed. Recovery of new scrap decreased, while old scrap increased to replace that which was not recovered in new scrap. The zinc was recovered in alloys, 53%, principally brass and bronze; in metal, 32%; and in chemical products, 15%.

Slag-Fuming Plants.—Slag-fuming plants process hot and cold lead blast furnace slags and residues which contain from 11% to 23% recoverable zinc to produce zinc oxide fume. The oxide is either sent to zinc smelters or electrolytic refineries for recovery of zinc, or sold to the consumers as zinc oxide. During the year three plants were operating: ASARCO at El Paso, Tex.,

and East Helena, Mont., and The Bunker Hill Co. at Kellogg, Idaho.

Byproduct Sulfuric Acid.—In 1973, there were nine plants with facilities for roasting zinc sulfide concentrates. Seven plants were equipped with sulfuric-acid-producing facilities, one of which operated solely for producing calcine for subsequent processing to zinc oxide or zinc metal. Two horizontal retort smelters did not have sulfuric-acid-producing facilities, one of these shut down its zinc smelter in November, but continued to operate the roaster. In 1973, production of byproduct sulfuric acid from the zinc plants and three lead smelters was 966,128 tons, compared with 859,103 tons produced in 1972.

Zinc Dust.—Production of zinc dust decreased 5% from that of 1972 to 56,154 tons in 1973. Zinc dust from distilled scrap accounted for 36,202 tons, 64% of the total zinc dust produced.

CONSUMPTION AND USES

Consumption of slab zinc in the United States in 1973 was 1,503,938 tons, an increase of 6% over that of 1972. The zinc content of the ore and concentrate used directly in galvanizing or to make pigments and salts was 129,651 tons (118,305 in 1972), and the zinc content of secondary materials to make alloys, zinc dust, and compounds totaled 298,336 tons (307,369 in 1972). Total consumption of zinc for all classes was 1,931,925 tons, an increase of 5% over that of 1972.

Slab zinc consumption was reported by 650 users in 1973. Of the total slab zinc consumed, zinc-base alloys accounted for 610,606 tons (41%); galvanizing, 563,837 tons (37%); brass products, 197,650 tons (13%); rolled zinc, 40,763 tons (3%); zinc oxide, 61,734 tons (4%); and other uses, 29,348 tons (2%). Most of the use categories showed gains over last year. The largest gain was in galvanizing, with an increase of 45,633 tons over that of 1972, followed by die casting alloys with a gain of 31,793 tons over 1972. A net gain of 85,589 tons was realized over last year. While gains were recorded for most of the use categories, losses were noted in slush and sand casting alloys, rolled zinc, and other uses.

Distribution of slab zinc consumed by grade in 1973 was as follows: Special High Grade, 739,447 tons (49%); High Grade, 167,466 (11%); Intermediate, 37,384 tons (3%); Brass Special, 132,148 tons (9%); Prime Western, 426,559 tons (28%); and Remelt, 934 tons (less than 0.1%). Compared with 1972, except for the small decline in Remelt, consumption of all grades of slab zinc increased. The largest increase was in Special High Grade with a gain of 41,866 tons.

Slab zinc consumed by rolling mills was 40,763 tons in 1973, a decrease of 10% from that of 1972. Production of rolled zinc products decreased 5% to 41,301 tons. Strip and foil accounted for 74%, and 20% was used for photoengraving plates. Exports were nearly unchanged from those of last year at 2,480 tons, while imports were cut in half from those of 1972. Nearly 30,000 tons of zinc was rolled from scrap in 1973; therefore, a total of 70,202 tons of rolled zinc was produced during the year, compared with 85,237 tons in 1972.

The leading slab-zinc-consuming States in 1973 were Ohio with 215,106 tons (14%); Pennsylvania, 201,168 tons (13%); Illinois, 195,382 tons (13%); Michigan, 163,602 tons (11%); Indiana, 149,651 tons (10%); and New York, 121,664 tons (8%). These leading six States accounted for almost 70% of the slab zinc consumed. Ohio ranked the highest for galvanizing with 108,241 tons, and Michigan was first in die casting with 140,465 tons.

ZINC PIGMENTS AND SALTS

Production.—Published data for zinc pigments and compounds include zinc oxide and zinc sulfate. Information for leaded zinc oxide, lithopone, and zinc chloride was withheld in 1971–73 to keep individual company data confidential.

Production of zinc oxide in 1973, 252,500 tons, increased 7% over 1972 production, and shipments were approximately equal to production. Zinc sulfate production, 43,900 tons, showed an increase, but the dry basis (100% $ZnSO_4$) was a smaller proportion of the gross weight than in former years.

The source of domestic zinc oxide production was 53% from ore and concentrate (American process), 32% from slab zinc (French process), and 15% from secondary material. Zinc sulfate production came 56%

from secondary material and 44% from ore or intermediate products. Lead-free zinc oxide was produced at 12 plants in the United States, and leaded zinc oxide was produced at only 1 plant. At least eight plants produced zinc sulfate, and five produced zinc chloride.

Production of zinc oxide by The New Jersey Zinc Co. and St. Joe Minerals Corp. were described under Smelter and Refinery Production. A third producer using ores or concentrates as a major source material was ASARCO with plants at Columbus, Ohio, and Hillsboro, Ill. Other major zinc oxide producers, such as the Eagle-Picher Industries, Inc., Hillsboro, Ill., plant and the Sherwin-Williams Coffeyville. Kans., plant, used calcines, fume, and secondary materials as raw materials.

Consumption and Uses.—The apparent consumption of zinc oxide increased by 5% from about 259,000 tons in 1972 to 273,000 tons in 1973. Analysis of domestic shipments by industry usage showed the rubber industry as consuming 51% of U.S. shipments, and reported destinations of imported oxide indicated a still higher percentage of imports going to rubber manufacturers. The second-ranking use was photocopying with a 7% annual increase, and third ranking was chemicals with a 15% annual increase. Use of zinc oxide in paints decreased slightly, probably owing to fewer housing starts in 1973. The use of zinc oxide in agriculture may have been partly concealed in "other" or "chemical" destinations. Agriculture is the chief use for zinc sulfate, with lesser amounts going for rayon, flotation reagents, and chemicals. The use of leaded zinc oxide in rubber and paints increased substantially during 1973, regaining the volume of several years ago. Zinc chloride usage declined slightly but continued to be a significant part of zinc compound consumption; incomplete industry returns precluded analysis of shipments by industry.

Prices.—Zinc oxide and compound prices tended to follow increases in the price of zinc metal, but the changes were often announced several days after the metal price change. At the beginning of 1973 prices ranged from 15.75 cents per pound for activation-grade zinc oxide through 18.75 cents for French process to 22 cents for U.S.P. grade. On January 29 price increases were initiated that averaged about 2 cents for each grade. On or about April 1 several companies posted further increases of 1 to 2 cents per pound. By June other suppliers had come up to a scale that ranged from 19 cents for activation grade through 22 cents for French process to 24 cents for U.S.P. grade. Prices remained steady during the period June 13 to December 6, when zinc prices were controlled by the Cost of Living Council. During the second week in December, after release from price control, three companies raised prices about 9 cents per pound so that at yearend most quotations ranged from 30.5 cents for American process lead-free pigment grade through 31.5 cents for French process to 33.5 cents for U.S.P. grade. Leaded zinc oxide was quoted at 17 cents per pound in January 1973 and had risen to 30.25 cents by January 1974. The price of zinc sulfate in June 1973 was reported as $13 per 100 pounds, granular monohydrate industrial, 36% zinc, bags in car-load lots. By yearend this price had become $18.50 per 100 pounds.

Foreign Trade.—Exports of zinc oxide increased by 24% during 1973 to a record 7,600 tons, and lithopone exports decreased by 29% to less than 1,000 tons. Imports of almost all classes of zinc compounds increased in 1973 to a total of 36,500 tons, a 40% gain. As in 1972, zinc oxide was the major component of imports of zinc compounds, with a 42% gain to 27,500 tons. The net imports of zinc oxide, 19,850 tons, thus became about 7% of U.S. supply. Mexico, Canada, and France were major sources, and other European Community countries contributed small tonnages.

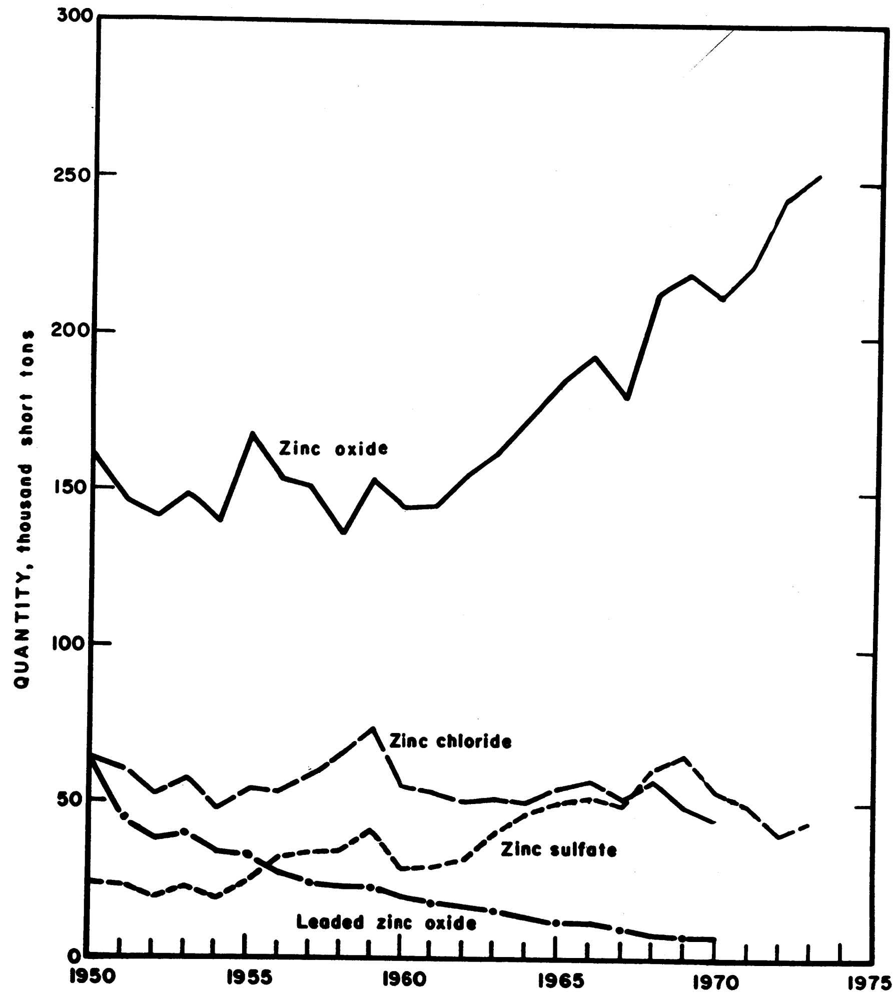

Figure 5.—Trends in shipments of zinc pigments.

STOCKS

Producer Stocks.—According to the monthly data reported by producers to the Zinc Institute, Inc., stocks at the beginning of the year were 31,775 tons. By midyear they declined to 22,168 tons, but at yearend they increased to 29,233 tons, just 2,542 tons short of what stocks were at the beginning of the year. The GSA stockpile gave considerable relief; 167,447 tons of zinc passed through the producers either as remelt or direct shipment.

Consumer Stocks.—Slab zinc inventories at consumer plants, which were 124,956 tons at the beginning of the year, declined 9% to 114,317 tons at yearend. Prime Western zinc stocks accounted for the largest decrease, 23% or 11,516 tons less than that at yearend 1972.

Government Stockpile.—During 1973, the GSA stockpile inventory was reduced from 949,583 tons to 677,583 tons. This indicates that 272,574 tons of slab zinc went into domestic supply from the Government stockpile.

PRICES

The year began with a three-tier price structure for domestic Prime Western zinc, 18.0, 18.5, and 18.52 cents per pound. Phase 3 of the President's economic stabilization program, effective January 11, 1973, removed the mandatory price ceiling on zinc, and by February 1, the price of Prime Western zinc was increased to 19.0, 19.25, and 19.5 cents per pound. On March 9, another round of price increases began, and by March 28, all the producers but one had increased their price of Prime Western zinc to 20.25 cents per pound. One company, National Zinc Co., Inc., increased its price to 20.5 cents per pound, and on April 19, this same company increased its price to 21 cents per pound while the other producers kept their price at 20.25 cents per pound. During all of this period, the price of Special High Grade zinc was 1 cent per pound higher than that of Prime Western zinc. On June 13, 1973, by Presidential order, the price of zinc was frozen to the last round of increases. Phase 4 of price controls became effective August 12, 1973, when the base price for zinc was set at the price during the last fiscal quarter prior to January 11, 1973, (18 cents per pound). Cost increases were passed through on a dollar-for-dollar basis without the maintenance of profit margins allowed under phases 2 and 3. The Cost of Living Council required a 30-day notice from producers with $100 million sales or more for any price increases. The ceiling prices prevailed until the Cost of Living Council abolished the control on zinc on December 6, 1973. One company immediately raised its price of Prime Western zinc to 32 cents per pound, and others quoted prices between 28 and 30 cents per pound where they remained to yearend.

The foreign producer price (mostly Canada, Peru, and Australia) was always at least 1 cent per pound higher than the U.S. producer price. Coming into the year, imported zinc (Prime Western equivalent) was 19.5 and 20 cents per pound. This price remained in effect until March 8, when the price became 21 cents per pound, but one company representing the Australian producers increased the price of zinc to 22.5 cents per pound on March 29 and to 23.5 cents per pound on May 29. Effective June 12, imported zinc (Prime Western equivalent) ranged from 22.3 to 23.5 cents per pound; however, one Canadian firm passed on the 0.7-cent-per-pound tariff to its U.S. customers. A second Canadian company followed suit on June 30, and a third company raised its price but absorbed the tariff. Effective August 1, 1973, imported zinc (Prime Western equivalent) ranged from 24.3 to 27.5 cents per pound. The high price of 27.5 cents per pound was set on July 26 by an Australian firm. On September 20, the spread increased to 24.3 to 31.0 cents per pound, but on October 1 the range narrowed to 27.3 to 31.0 cents per pound. The high side of the price range increased on November 27 to 36.5 cents per pound, and the final increase for the year on December 21, 1973, occurred on the low end of the range with a price of 31.0 cents per pound.

The European producer price for Good Ordinary Brand (GOB) zinc (Prime Western equivalent) was £173 per metric ton (18.5 cents per pound U.S. equivalent) at the first of the year. During the year the European producer price increased five times, as follows: February 28, £190 per metric ton; June 14, £205 per metric ton; July 16, £220 per metric ton; September 24, £250 per metric ton; and on November 27, £300 per metric ton. The last conversion to U.S. equivalent was 31.5 cents per pound and was the price that prevailed to the end of the year.

The London Metal Exchange (LME) price for zinc started the year at a lower level than the U.S. producer price and the European producer price. The monthly average price for zinc in January was 17.5 cents per pound, but during the year the price fluctuated upward until it reached a record high on December 4, 1973, of 99 cents per pound. The price then declined to 63 cents per pound at yearend.

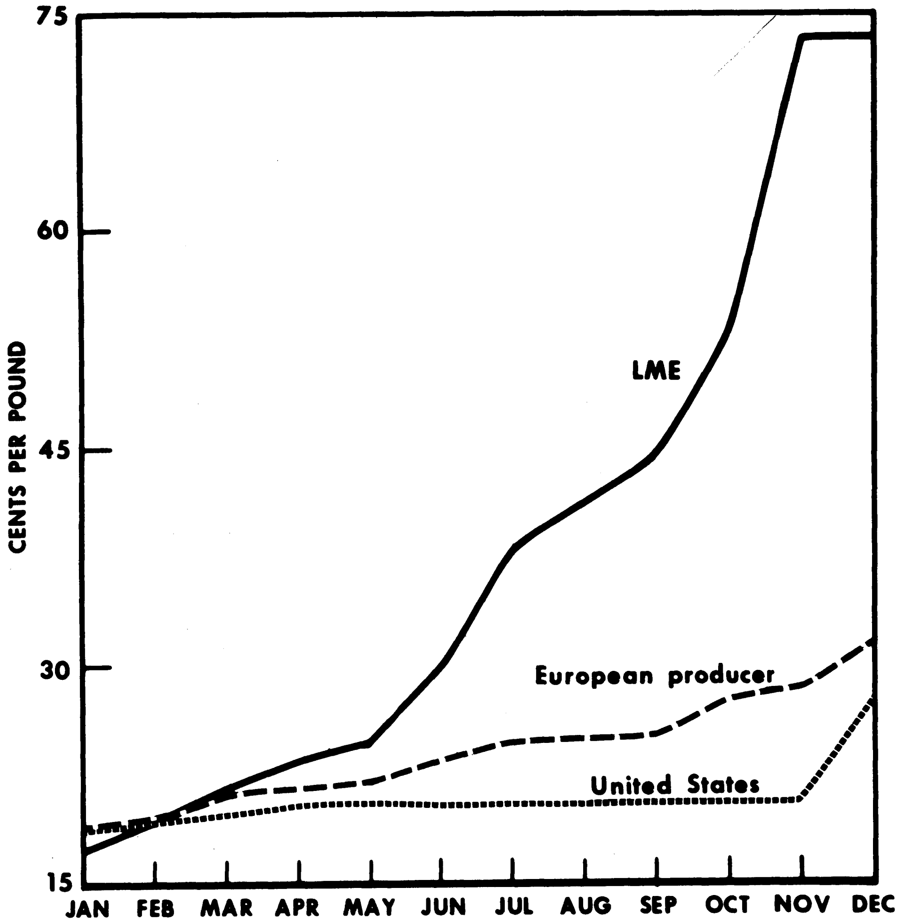

Figure 6.—Average monthly prices in 1973 for U.S. Prime Western zinc and equivalent foreign grade.

FOREIGN TRADE

Exports of slab zinc increased more than three-fold from 4,324 tons to 14,566 tons in 1973, of which 15% went to Brazil, 15% to Japan, 12% to Venezuela, and 11% to Colombia. Exports of rolled zinc products, sheets, plates, strips, etc., increased 3% over those of 1972; Canada received nearly half, 1,201 tons.

General imports of zinc in ore declined 22% to 199,053 tons in 1973, the lowest since 1940. Canada supplied 62%, or 124,261 tons, and receipts from Mexico accounted for 17%, or 33,878 tons. General imports of metal increased 13% to 588,725 tons. Canada with 344,697 tons, supplied 59%. The other large suppliers were Australia, Belgium-Luxembourg, Japan, and Zaire.

Imports of ore for consumption declined 12% to 153,898 tons in 1973. Since the imports of ores for consumption had been significantly less than general imports of ore for the last 2 years, this suggested that a buildup of ores was taking place at the bonded warehouses. Metal imports for consumption increased 14% over those of 1972 to 587,429 tons in 1973, and were only slightly less than general imports. This was the second year in a row in which imports of metal exceeded the quantity of zinc in imported ores and concentrates.

No change took place in the tariff rates in 1973. The duties on unmanufactured zinc and zinc-containing materials were as follows: Slab zinc, 0.7 cent per pound; zinc ores, concentrates, and fume, 0.67 cent per pound (on zinc content less specified allowable deductions for processing losses); zinc scrap, including skimmings and drosses, 0.75 cent per pound; and zinc dust, 0.3 cent per pound. The duty rate for unwrought alloys of zinc, which includes diecasting alloys, was 19% ad valorem.

The bill to suspend the U.S. tariff on zinc concentrates (H.R. 6191) passed the House on May 7, 1974, after which it was submitted to the Senate Finance Committee.

WORLD REVIEW

World mine production of zinc in 1973 gained about 3% over that of 1972, continuing the slow but steady growth rate apparent in recent years. Zinc metal production also increased, with gains in Europe and Canada more than making up for the loss of production in the United States. The consumption of zinc in the developing countries continued to grow at a faster rate (12%) than the world average (7%) and helped to maintain a worldwide shortage, driving up prices and spurring the use of substitute materials where available. The generally tight supply situation increased interest in secondary materials and concern for gathering information about their availability and use. Byproducts and scrap were used in greater amounts for production of both zinc metal and zinc compounds.

Argentina.—Compañía Minera Aguilar, a subsidiary of St. Joe Minerals Corp., sustained a 2-week strike in November which was settled after the national government intervened and negotiated a 20% wage increase. Production of zinc concentrates in 1973 was 9% less than in 1972 and was estimated to contain about 43,700 tons of zinc. Two zinc smelters affiliated with Aguilar but not affected by the strike produced about 40,900 tons of zinc in 1973.[36]

Australia.—Mine production of zinc in Australia declined 6% in 1973 to 526,400 short tons of zinc in concentrates. Exports to the United States included 7,281 tons of zinc in concentrates and 42,077 tons of slab zinc, 10% of Australian zinc production.

The decrease in national mine production was due in part to the failure of a stope wall in the New Broken Hill Consolidated Mines at about the No. 17 level during the first week in October. The temporary closure of haulage on the No. 15 level caused a shortfall in production at this most productive Australian zinc mine during the last quarter. Zinc Corp., North Broken Hill, Mount Isa Mines, West Coast Mines, and Cobar mines contributed a normal or slightly reduced zinc production during 1973. Broken Hill South, Ltd., recovered about 8,000 tons of zinc from dumps, partially replacing the loss of production from the closed Broken Hill South mine.

Published ore reserves and announced plans for expansion predicted greater zinc production from Australia in the future. Mount Isa Mines (MIM) was developing the Hilton mine, about 12 miles north of Mount Isa, and was increasing capacity at the Mount Isa concentrator. Both mines have large reserves of zinc-lead-silver ores, 36 million tons at Hilton and 56 million tons at Mount Isa.[37] MIM also holds large reserves or resources of zinc-lead ores in the McArthur River area, Northern Territory, estimated to contain 200 million tons assaying 9% zinc.[38] E–Z Industries, Ltd., planned to expand zinc capacity at its mines in Tasmania and its smelter at Risdon to a yearly production of 242,000 tons of zinc.

Smelter production in 1973 was 328,000 short tons of zinc: Risdon (E–Z Industries) 213,000, Cockle Creek (Conzinc Rio Tinto of Australia) 65,000, and Port Pirie (BHAS Proprietary, Ltd.) 50,000.

Belgium.—Zinc production increased 9% during 1973 to a total of 309,800 tons. Exports to the United States were about 39,400 tons of slab zinc. Metallurgie Hoboken-Overpelt was constructing a new elec-

[36] Lead and Zinc Statistics, Monthly Bulletin of the International Lead and Zinc Study Group. V. 14, No. 6, June 1974, pp. 16–17.

[37] M.I.M. Holdings Ltd. Annual Report for the Year Ending June 30, 1973. P. 7.

[38] Mount Isa Mines. Metals Sourcebook. No. 21, Oct. 29, 1973, p. 2.

trolytic zinc refinery at Overpelt scheduled for commissioning in mid-1974; the older zinc retorts were shut down progressively so that zinc production decreased in 1973 from the 1972 output. Société de Prayon, S.A. sustained its first full year of production at its new electrolytic plant at Ehein. Société des Mines et Fonderies de Zinc de la Viellie Montagne, with four plants in Belgium, produced a total of 281,000 tons of ingot zinc, 5% more than in 1972, but plants in France participated in this production.

Brazil.—The two electrolytic zinc plants in Brazil produced 24,600 tons of zinc in 1973, achieving a 43% increase from production in 1972. Both plants are supplied by the silicate and oxide ores from Vazante, Minas Gerais. The Companhia Minera de Metais, one of the two producers, has announced plans to increase production to about 29,000 tons annually by 1977, using a new process developed by Metais and a German firm, Lurgi Chemie und Huettentechnik.

Canada.—Mine production of zinc increased again in 1973 to 1.49 million short tons of zinc content in concentrates. Zinc smelter production increased to 587,000 tons in 1973, a 12% increase from the 525,000 tons in 1972. Canada thus retained by a wide margin its position as the world's largest zinc-mining country and passed the United States to become the third largest zinc-refining country. A substantial part of this production came to the United States. Of a total of 874,900 short tons of zinc in concentrates exported from Canada, 124,300 tons was imported into the United States; of 463,000 tons of metal exported, 345,000 tons came to the United States as general imports. Consumption of zinc in Canada was estimated as 140,000 tons, a 9% increase from 1972 consumption.

In the Northwest Territories, Pine Point Mines Ltd., with Cominco, Ltd., acting as operator, was the major zinc producer mining 3,896,000 tons of ore averaging 6.0% zinc and 2.9% lead. Concentrates from this operation were sold to Canadian refineries, chiefly Cominco, 62%. The remainder was exported with Europe receiving 20%, Japan, 10%, India, 5%, and South America and United States, collectively, 3%.[39] Cominco continued exploration of silver-zinc deposits near Bathurst Inlet and at the Polaris lead-zinc deposit on Little Cornwallis Island. Several thousand tons of high-grade ore (35% to 40% lead-zinc) was shipped from the Polaris mine for metallurgical testing. Texasgulf, Inc., has formed a joint venture with Mineral Resources International Ltd. to study and possibly develop a zinc-lead property on the north shore of Baffin Island. All three of these Arctic deposits will be hampered in their development by a short shipping season, and the logistics of their operations will require careful cost studies; but the high grade of the deposits insures their eventual exploitation.

The major zinc mine in Yukon Territory, Anvil Mining Corp. Ltd. at Faro, took 2,899,000 tons of ore from its open pit operation and produced concentrates containing 118,000 tons of zinc, 112,000 tons of lead, and 2,578,000 ounces of silver.[40] The Anvil concentrator capacity was increased from 8,000 to 10,000 tons daily during 1973. Anvil and other companies announced exploration programs in the Yukon Territory for 1974; Anvil planned a regional geochemical survey covering large areas of favorable carbonate rocks, and Barrier Reef Resources Ltd. arranged to have its new discovery 125 miles northeast of Mayo drilled by two coventurers in 1974.

British Columbia zinc production increased about 13% in 1973 with the Sullivan mine of Cominco, Ltd., as the major producer. Cominco resumed mining at the H.B. mine near Salmo; its output will replace the concentrates formerly drawn from the Bluebell mine, shut down in 1972. Other mines producing zinc in the province were the Bradina at Houston (suspended operations August 1973), the Silmonac at Sandon, the Reeves MacDonald at Remac, the Highland Bell at Beaverdell, and Western Mines at Buttle Lake. Reeves MacDonald Mines Ltd. announced that mining and milling at its properties would be discontinued on October 1, 1973; exploration has been unsuccessful in locating new reserves but would continue on adjoining properties. Exploration in the Province appeared to fall off during 1973, but Texasgulf continued its drilling program at the Robb Lake lead-zinc prospect and reported encouraging results.[41] Several railway extensions were planned to extend service to

[41] Texasgulf. 3rd Quarter Report. Sept. 30, 1973, p. 6.

northern British Columbia and to make a link in southwest British Columbia bypassing the Fraser River Canyon; mineral traffic and the development of new mining areas were primary reasons for the proposed construction. The Cominco smelter at Trail produced 248,000 tons of zinc in 1973; operations were hampered in December by an electrical failure and fire in the roaster control room, but by yearend zinc output had returned to normal.

In Manitoba, Hudson Bay Mining & Smelting Co. Ltd. achieved an 8% increase in zinc production in 1973 to 82,882 tons, and began development work on the new Centennial mine. Nine operating mines in the Flin Flon area produced continuously during the year. Ore reserves in the Flin Flon district at yearend were 18,000,600 tons containing 3.1% copper, 2.9% zinc, 0.03 ounce of gold, and 0.5 ounce of silver per ton.[42] Sherritt Gordon Mines, Limited, continued to operate the Fox Lake copper-zinc mine and in May began production from the new copper-zinc Ruttan mine. Production of zinc in concentrates at the two mines was 7,060 tons at Fox Lake and 17,130 tons at Ruttan, making Sherritt Gordon a major zinc producer, in addition to its substantial copper production. Concentrates went to Hudson Bay at Flin Flon, to Mitsubishi Metal Corp. in Japan, and to a zinc plant in the United States.[43] Freeport Canadian Exploration Co., in a joint venture with Beth-Canada Mining Co., discovered a copper-zinc deposit near Reed Lake, Manitoba; a preliminary estimate of the tonnage and grade was given at 1 million tons with about 2% copper and 4% zinc. The two companies are subsidiaries of Freeport Minerals Co. and Bethlehem Steel Corp., respectively.

The largest zinc producer in Ontario was Ecstall Mining Ltd., a subsidiary of Texasgulf, Inc., with a production of about 295,000 tons of zinc in concentrates from the Kidd Creek mine and 107,100 tons of zinc metal from the nearby zinc plant at Hoyle. Annual capacity of the refinery was to be increased from 120,000 to 150,000 tons per year. Production from the open pit mine will be gradually replaced by underground mining within a few years. During 1973, the Canadian Development Corporation, a Crown Corp., acquired a large share of the stock of Texasgulf, Inc., through a public tender offer.

Other zinc mines active in Ontario were Mattagami Lake Mines Ltd., Mattabi mine averaging over 3,000 tons per day grading 11.36% zinc, 1.10% copper, 1.06% lead, and 5.30 ounces of silver per ton and Noranda Mines Limited, Geco mine producing 4,880 tons per day grading 4.53% zinc, 1.70% copper, and 1.63 ounces of silver per ton.[44] The construction of a 1,200 ton-per-day concentrator and mine was started in the Sturgeon Lake area by Sturgeon Lake Mines Ltd. and Falconbridge Nickel Mines Ltd. At Parham in southeastern Ontario the Long Lake mine, a small mine by modern standards, began operation in March, producing about 7,000 tons of crude ore per month with a 10-man crew running the mine and heavy media plant. The upgraded ore, 4,600 tons per month, is trucked to St. Joe Minerals Corp. at Balmat, N.Y. Lynx Canada Exploration Ltd. and Canadian Reynolds Metals Co. Ltd. share ownership of the mine.

Hudson Bay Mining & Smelting Co. Ltd. began construction of a new zinc oxide plant near Brampton, Ontario. The planned initial capacity was 60 tons, increasing ultimately to 100 tons per day; as production reached capacity, an older plant in Montreal operated by a subsidiary of Hudson Bay, Zochem Ltd., would be gradually closed down.

Mattagami Lake Mines, Ltd., continued to be a major zinc producer in Quebec, milling 1,387,000 tons of ore averaging 7.48% zinc, 0.57% copper and 0.84 ounce of silver per ton. The Orchan Mines mill treated 270,100 tons averaging 7.39% zinc and 0.97% copper from the Orchan mine and 180,130 tons averaging 3.33% zinc and 1.45% copper from the Garon Lake mine. Kerr Addison Mines continued to operate the Normetal Mine and the Joutel Mine, producing 12,500 tons and 13,100 tons of zinc in concentrates, respectively. The Lake Dufault division of Falconbridge Copper Ltd. produced 18,795 tons of zinc in concentrates as a coproduct of copper production from ore that averaged 3.65% copper and 4.41% zinc. Manitou Barvue Mines Ltd. reopened the Louvem silver-zinc mine and operated its mill at a rate of 20,000 tons per month through 1973.

The Sullivan Mining Group Ltd. closed

[42] Hudson Bay Mining & Smelting Co. Ltd. 1973 Annual Report. P. 13.

[44] Noranda Mines Limited. 1973 Annual Report. Pp. 10–15.

the Weldon mine in June 1973 but continued operations at the Cupra and D'Estrie divisions, both producing zinc concentrates from copper-zinc ores. Development of the Clinton Copper Mines property was started with joint control by Dome Mines, Ltd.; reserves contain minor amounts of zinc. Total production of the Sullivan Group for fiscal year 1972–73 was 9,115 tons of zinc.

Canadian Electrolytic Zinc Ltd., owned by Mattagami Lake Mines, Noranda, Orchan Mines, and Kerr-Addison, announced that its electrolytic zinc plant is to be expanded from the present capacity of 400 tons to 620 tons per day by 1975. The expansion will cost $30 million to $45 million and will increase yearly production capacity from 145,000 to 225,000 tons.

In New Brunswick, the Brunswick Mining & Smelting Corp. Ltd. continued to operate the No. 6 and No. 12 mines and the concentrator treated 3,288,000 tons of ore averaging 9.8% combined lead and zinc.[45] The conversion of the zinc-lead Imperial-type smelter at Belledune to a lead smelter was completed early in 1973 and zinc concentrates are now shipped overseas. During 1973, Amax Base Metal Group, operating the Heath Steele Mines, produced 1,078,000 tons of ore yielding 78,000 tons of zinc concentrate. An expansion program started in 1972 proceeded toward an eventual increase in mine-mill production of about one-third when completed in 1975.[46] The Sullivan Mining Group, Ltd., announced plans to resume its Nigadoo River Mines operations in the Bathurst district, subject to negotiating satisfactory smelter contracts.

Nova Scotia was the scene of exploration at a potential zinc-lead property in the Gays River district. The mining division of Imperial Oil Ltd. was drilling on the property of Cuvier Mines with three drill rigs testing zinc-lead mineralization in dolomitized limestone over a wide area. A large tonnage of ore was reported to average 2.75% lead and 3.39% zinc.

A deposit with a similar Appalachian-type environment at Daniel's Harbor in Newfoundland was the subject of a feasibility study by Newfoundland Zinc Mines, Ltd., a subsidiary of Teck Corp., with American Metal Climax, Inc. as a coventurer. A high-grade portion of the ore body was reported to contain 4,400,000 tons averaging 8.8% zinc.

The Buchans mine in Newfoundland, 50% controlled and managed by ASARCO, suffered from a 6-month strike during 1973 but managed to produce 11,500 tons of zinc in concentrates, less than half normal production.[47]

Canadian zinc smelter production in 1973 and announced plans for future capacity are summarized as follows:

Company	Production in 1973 (short tons)	Planned capacity 1974–75 (tons per year)
Canadian Electrolytic Zinc Ltd., Valleyfield, Quebec	148,800	225,000
Cominco, Ltd., Trail, British Columbia	248,000	305,000
Hudson Bay, Mining & Smelting Co., Ltd., Flin Flon, Manitoba	82,900	80,000
Ecstall Mining Ltd., Timmins, Ontario	107,100	150,000

Finland.—The electrolytic plant at Kokkola produced 89,200 short tons of zinc metal in 1973. The mines at Vihanti, Pyhasalmi and Metsamonttu produced concentrates containing 41,150, 18,348 and 3,899 tons of zinc respectively. The Keretti and Vuonos mines produced 713 and 477 tons, zinc content, as byproduct concentrates from copper ores.

France.—Production of slab zinc in France in 1973 was 284,184 tons, slightly less than in 1972.[48] Zinc consumption was estimated to be 320,000 tons with the difference made up from net imports and producers' stocks.

Germany, West.—Production of zinc in West Germany increased in 1973 to 435,433 short tons and includes secondary making maximum use of producing capacities. Five German lead-zinc mines contributed about one-third of the total zinc output. One of the five, the Randsbeck mine, was scheduled for shutdown on January 31, 1974. Consumption of zinc was 511,000 tons, with 37% going into galvanizing.

Honduras.—The El Mochito mine produced during 1973 21,681 tons of zinc and 272 tons of cadmium in zinc concentrates as well as substantial amounts of gold, silver, and lead in lead concentrates.[49] A joint venture between Rosario Resources Corp.

[45] Page 12 of work cited in footnote 44.
[46] Page 18 of work cited in footnote 4.
[47] Page 20 of work cited in footnote 10.
[48] Zinc Institute, Inc. 1973 Annual Review. P. 16.
[49] Rosario Resources Corp. 1973 Annual Report. P. 6.

and ASARCO was formed to drive an exploratory tunnel beneath the old Rosario mine.

India.—Although lead and zinc prospects are known throughout India and Government statistics claim large ore reserves, Indian zinc smelter production in 1973 was only one-third of its rated capacity and accounted for only 16% of its consumption with the balance made up from imports. Hindustan Zinc, Ltd., produced 2,200 tons and has a capacity for 19,800 tons per year, and Cominco Binani Zinc Ltd. produced 11,800 tons but has a capacity for 22,000 tons per year. Hindustan's Debari smelter was shut down for much of the year because of a breakdown of the melting furnace, and at Cominco Binani labor disputes put the plant out of action for 3 months. Hindustan Zinc announced plans to increase mine capacity in the Zawar area and to expand smelter capacity to 45,000 tons by 1978–79.

Ireland.—Tara Exploration and Development Co. Ltd. started to develop its potentially large mine at Navan, County Meath, in July 1973, with an inclined entry and a 1,000-foot vertical shaft. Commercial production of ores was scheduled to begin in late 1975. The development program proceeded despite a setback by an adverse judicial decision concerning ownership of the northern part of the proposed state mining lease containing about 10 million tons of ore. The balance of the ore body, now under development, was said to contain about 67 million tons grading 10.9% zinc and 2.6% lead. Near the end of 1973, an agreement was negotiated with Noranda Mines Limited under which Noranda would arrange a $6 million line of credit in return for warrants to purchase 100,000 shares of Tara and other considerations subject to Tara obtaining an acceptable state mining lease. As a result of this association, Tara, together with its controlling parent, Northgate Exploration Ltd., and Noranda, began a joint study as to the feasibility of constructing an electrolytic zinc reduction plant in Ireland.[50]

Two other major lead-zinc mines in Ireland continued production in 1973. The Tynagh mine of Irish Base Metals Ltd. in County Galway produced 16,500 short tons of zinc, 1,300 tons of copper, and 45,000 tons of lead in concentrates. The mine at Silvermines, County Tipperary, 75% owned by Mogul of Ireland Ltd., treated 917,400 tons of ore to produce concentrates containing 59,500 tons of zinc and 17,600 tons of lead.[51]

The Irish Government announced in September 1973 that the 20-year tax holiday on profits of base metal mines was to end. A new tax system, beginning April 1, 1974, will allow prospecting and depreciation deductions with special provisions for companies already in production and relief for marginal mines.

Italy.—Production of slab zinc in Italy reportedly increased from 171,800 tons in 1972 to 209,500 tons in 1973. This reflected the operation during 1973 of the new Imperial Smelting furnace by Ammi Sarda, S.p.a., at Porto Vesme, Sardinia. Italy is still a net importer of zinc, importing about 53,000 tons of metal in 1973.

Japan.—Japan once again achieved world record production with a total of 929,000 tons of zinc metal. Mine production supplied about 291,000 tons of zinc in concentrates. Consumption of zinc increased 14% to 834,800 tons in 1973, and demand for remelted zinc metal increased by 20% to 59,300 tons, making total slab zinc consumption about 894,100 tons.[52] Akita Zinc Co. Ltd. reported that the program to double capacity at its Iljima plant to 14,000 tons per month was expected to be completed in the summer of 1974 with full production at the end of the year. At the end of 1973, Mitsui Mining & Smelting Co. Ltd. was increasing the capacity of its Hikoshima refinery from 5,500 to 7,700 tons per month. However, all Japanese zinc producers predicted setbacks in scheduled zinc production in 1974 owing to power restrictions caused by the energy shortage.

Mexico.—Production of zinc from mines in 1973 continued at a rate about the same as in 1972, slightly over 299,000 short tons. Smelter output of primary metal was below that of 1972, 74,000 tons versus 87,500 tons. Exports of zinc concentrates and metal from Mexico to the United States decreased sharply in 1973 from exports in 1972. U.S. general imports of zinc from Mexico were about 33,900 tons of zinc in concentrates and 1,900 tons as slab zinc, compared with 57,300 tons of zinc in con-

[50] Tara Exploration and Development Co. Ltd. 1973 Annual Report. P. 5.

[52] Metals Week. Japan's Consumption of Zinc Increased. V. 45, No. 24, June 17, 1974, p. 6.

centrates and 8,400 tons of slab zinc in 1972.

Industrias Peñoles, S.A., inaugurated its new electrolytic zinc refinery at Torreón on October 30, 1973. The new plant was expected to produce 115,000 tons of zinc annually as well as 200,000 tons of sulfuric acid and 935 tons of cadmium. The feed to the plant will be mainly Mexican concentrates, thus cutting Mexican exports of zinc concentrates from about 300,000 tons (gross) to 100,000 tons per year and gaining about $58 million per year in foreign exchange.

Two feasibility studies concerning construction of zinc refineries in Mexico were undertaken during 1973, one conducted by Asarco Mexicana, S.A. and Dowa Mining Co. of Japan and the other by Zincamex, S.A. and Mitsui. The Asarco Mexicana-Dowa study indicated that the proposed smelter would require imports of zinc ores or concentrates from outside Mexico, and thereafter negotiations made little progress.

Netherlands.—Construction of the new electrolytic zinc plant at Budel was substantially completed in 1973, and full production was expected for the third quarter of 1974.[53] The older retort smelter was being gradually phased out. Production of primary zinc in the Netherlands in 1973 was about 33,600 short tons.

Nicaragua.—Neptune Mining Co., owned 51.8% by ASARCO and 36% by Rosario Resources, produced over 12,000 tons of zinc and 138 tons of cadmium in zinc concentrates from the Vesubio mine. Rosario acquired the Rosita copper mine and the Siuna gold mine and announced plans to do exploration work in adjacent areas for base metals as well as gold and silver.

Peru.—The Cerro de Pasco Corp. properties in Peru were expropriated by the Peruvian government effective January 1, 1974, after talks, carried on during the second half of 1973, concerning a partial takeover, were unsuccessful. However, operations were still under Cerro control throughout 1973 and resulted in a high level of zinc output. Refined zinc produced by the Cerro smelter was 73,959 short tons, and zinc concentrates and calcines produced for export amounted to 115,728 tons of zinc content.[54] Compañia Minerales Santander, Inc., a subsidiary of St. Joe Minerals Corp., produced 69,725 tons of zinc concentrates in 1973, slightly less than in 1972. The total production of Peruvian ores and concentrates for export contained 379,300 tons of zinc, which when added to metal, powder, and sulfate production gives a total zinc output of 456,000 tons. Of this, only about 13,000 tons of zinc in concentrates and 19,000 tons of zinc as metal came to the United States.

Poland.—Production of zinc in Poland was estimated to be 259,000 short tons in 1973, making Poland the largest source of zinc in Europe outside Soviet Russia. Metal production approached the target of the 1971–75 5-year plan, 260,000 tons per year. Poland could be self-sufficient in zinc concentrate production, but has been importing about 30,000 to 40,000 tons per year of concentrates from nonsocialist countries. Poland has traditionally sold zinc on the international market and in 1973 exported about 38,000 tons to Western countries in addition to about 56,000 tons to Communist countries, mainly Soviet Russia.

Spain.—The Cartagena plant of Española del Zinc planned a new electrozinc refinery that would increase capacity from 33,000 to 82,000 tons per year by the middle of 1975. Asturiana del Zinc S.A. prepared to increase capacity from 88,000 tons to 132,000 tons per year with a new roasting plant using the Lurgi-Vieille Montagne process; the new installations were scheduled for completion late in 1974. Spanish mines produced 193,000 tons of concentrates in 1973 containing 104,000 tons of zinc, and metal production from two plants was 117,900 tons of zinc.

Sweden, Norway, and Denmark.—Production of slab zinc in Norway was 88,700 short tons in 1973; mine production of zinc in Sweden was 126,400 tons and in Norway was 21,300 tons. The Black Angel mine in Greenland (Denmark) began production late in the year and reported a production of 50,800 tons with a planned annual production of 94,000 tons of zinc. Cominco, Ltd., was a 61.5% owner of Vestgron Mines Ltd. which operated the Black Angel mine through a Danish subsidiary, Greenex, A/S. The deposit was reported to contain 4,100,000 tons of 20% combined lead and zinc and 1 ounce of silver per ton.

[54] Cerro Corp. 1973 Annual Report. P. 17.

Yugoslavia.—Zinc metal production in Yugoslavia in 1973 was 60,820 short tons, an increase of 13% over that of 1972. Three plants were the major contributors, the electrolytic plant of Trepča at Zvecán, the electrolytic plant at Sabac-Zorka, and the new imperial furnace smelter at Zletovo (Titov Veles) which started production in the summer of 1973. The annual capacity of the Titov Veles smelter should eventually become 72,000 tons of zinc and 39,000 tons of lead, all destined for export. Two new lead and zinc concentrators at Kriva Feja and Leposavci in Serbia were completed in 1973. Concentrates will go to the Trepča smelter. The Trepča Enterprise was renovating or developing several mines in Serbia and one in Montenegro in a program to increase lead and zinc mine production. Yugoslavian mine production of zinc was estimated as 110,000 tons of zinc in concentrates in 1973.

TECHNOLOGY

Research at the Bureau of Mines Rolla Metallurgy Research Center was conducted to develop a workable means for separating and recovering zinc and lead from flue dusts, slags, and other metallurgical processing wastes. The project included construction and operation of a continuous system for the recovery of zinc and lead from electric furnace steelmaking dusts. An evaluation of other zinc-bearing waste such as lead blast furnace slag will also be made. Another project at Rolla was to develop low-cost hydrometallurgical processes for recovering zinc and elemental sulfur from sphalerite concentrate with minimum evolution of sulfur oxides, hydrogen sulfide, or other pollutants. A project on reduction of zinc sulfide with iron was underway at the Albany Metallurgy Research Center. The objective was to determine the practicability of winning zinc from sulfide concentrates by direct reduction with iron, thereby bypassing sulfurous gas formation. The Reno Metallurgy Research Center was conducting a research project to develop an aqueous chlorine or anodic oxidation leaching process for extracting metal values from lead-zinc sulfide concentrates, and to develop techniques for recovering metal values from leaching solution in a marketable form.

Results of several research investigations or studies were published by the Bureau of Mines and Geological Survey.[55]

Gulf & Western Industries, Inc., and Occidental Petroleum Corp. were engaged in a $10 million joint venture to perfect a practical zinc chloride rechargeable battery system that would power urban and recreational vehicles.[56]

The International Lead-Zinc Research Organization (ILZRO) sponsored numerous projects in 1973 to develop fundamental data on particular applications of zinc or zinc-containing materials. Progress reports of these projects are released annually by means of the ILZRO Research Digest.

Work during the year involved an ILZRO Prototype House which illustrates a variety of zinc applications, improvement of die-casting processes, galvanizing, alloy development, and plating.[57]

A comprehensive coverage of zinc-related investigations and an extensive review of current world literature on the uses of zinc and its products are contained in monthly issues of the 1973 Zinc Abstracts published by the Zinc Institute. Inc., 292 Madison Avenue, New York, N.Y. 10017, and provided free of charge.

r Revised.

Table 15.—Zinc recovered from scrap processed in the United States, by kind of scrap and form of recovery

(Short tons)

Kind of scrap	1972	1973	Form of recovery	1972	1973
New scrap:			As metal:		
Zinc-base	145,620	137,671	By distillation:		
Copper-base	158,834	152,190	Slab zinc [1]	r 73,718	87,466
Aluminum-base	3,649	4,035	Zinc dust	40,123	36,202
Magnesium-base	281	306	By remelting	6,674	1,737
Total	308,384	294,202	Total	r 120,515	125,405
Old scrap:			In zinc-base alloys	16,480	16,362
Zinc-base	42,998	50,301	In brass and bronze	r 192,647	180,674
Copper-base	32,456	38,494	In aluminum-base alloys	7,638	7,961
Aluminum-base	3,854	4,436	In magnesium-base alloys	434	546
Magnesium-base	69	106	In chemical products:		
Total	79,377	93,337	Zinc oxide (lead-free)	25,897	29,289
			Zinc sulfate	11,076	9,444
Grand total	387,761	387,539	Zinc chloride	11,126	16,639
			Miscellaneous	1,948	1,219
			Total	r 267,246	262,134
			Grand total	387,761	387,539

r Revised.
[1] Includes zinc content of redistilled slab made from remelt die-cast slab.

Table 16.—Zinc dust produced in the United States

Year	Quantity (short tons)	Value	
		Total (thousands)	Average per pound
1969	55,055	$21,361	$0.194
1970	51,136	20,045	.196
1971	50,259	19,691	.196
1972	59,358	24,669	.208
1973	56,154	29,279	.261

Table 17.—Consumption of zinc in the United States

(Short tons)

	1969	1970	1971	1972	1973
Slab zinc	1,385,380	1,186,951	1,254,059	1,418,349	1,503,938
Ores (recoverable zinc content) [1]	126,712	124,781	119,254	118,305	129,651
Secondary (recoverable zinc content) [2]	302,075	259,864	277,381	r 307,369	298,336
Total	1,814,167	1,571,596	1,650,694	r 1,844,023	1,931,925

r Revised.
[1] Includes ore used directly in galvanizing.
[2] Excludes redistilled slab and remelt zinc.

Table 18.—Slab zinc consumption in the United States, by industry use

(Short tons)

Industry and product	1969	1970	1971	1972	1973
Galvanizing:					
Sheet and strip	268,682	253,155	255,335	294,205	321,927
Wire and wire rope	32,348	30,857	29,895	30,769	34,315
Tubes and pipe	65,898	64,479	65,122	64,549	68,048
Fittings (for tube and pipe)	11,418	9,498	10,240	11,106	11,969
Tanks and containers	5,561	3,924	2,759	3,645	2,941
Structural shapes	19,454	18,761	18,589	20,302	21,714
Fasteners	5,536	5,318	5,159	4,310	4,782
Pole-line hardware	9,409	9,938	8,358	8,437	8,193
Fencing, wire, cloth, and netting	17,984	18,114	20,232	21,995	25,418
Other and unspecified uses	57,091	60,205	59,063	58,886	64,530
Total	493,381	474,249	474,752	518,204	563,837
Brass products:					
Sheet, strip, and plate	90,777	61,672	78,929	105,405	109,582
Rod and wire	56,989	41,459	46,514	63,143	63,164
Tube	10,928	9,086	9,399	8,886	10,858
Castings and billets	5,958	4,606	4,479	6,840	6,000
Copper-base ingots	13,642	9,946	10,440	7,137	6,895
Other copper-base products	1,175	978	725	736	1,151
Total	179,469	127,747	150,486	192,147	197,650
Zinc-base alloy:					
Diecasting alloys	565,839	453,490	504,823	566,932	598,725
Dies and rod alloy	504	87	270	56	111
Slush and sand-casting alloy	10,048	10,059	11,018	12,773	11,770
Total	576,391	463,636	516,111	579,761	610,606
Rolled zinc	48,650	41,065	38,852	45,216	40,763
Zinc oxide	41,447	43,829	40,043	51,992	61,734
Other uses:					
Light-metal alloys	7,562	3,985	4,575	6,300	7,466
Other [1]	38,480	32,440	29,240	24,729	21,882
Total	46,042	36,425	33,815	31,029	29,348
Grand total	1,385,380	1,186,951	1,254,059	1,418,349	1,503,938

[1] Includes zinc used in making zinc dust, wet batteries, desilverizing lead, bronze powder, alloys, chemicals, castings, and miscellaneous uses not elsewhere mentioned.

Table 19.—Slab zinc consumption in the United States in 1973, by grade and industry use

(Short tons)

Industry	Special high grade	High grade	Inter-mediate	Brass special	Prime [1] western	Remelt	Total
Galvanizing	40,242	31,745	16,235	125,083	350,054	478	563,837
Brass and bronze	43,745	113,421	86	6,795	33,568	35	197,650
Zinc-base alloy	595,867	13,739	14	269	388	329	610,606
Rolled zinc	16,553	479	20,462	--	3,269	--	40,763

e Estimate. p Preliminary. r Revised. NA Not available.

1 In addition to the countries listed, North Vietnam also produces zinc, but available information is inadequate to make reliable estimates of output levels.

2 Zinc content of concentrates.

3 Sum of production by COMIBOL and exports by medium and small mines.

4 All data for 1971 are for fiscal year ending June 30, 1971; data for 1972 and 1973 are a summation of company figures for calendar year 1972 and 1973 for Tsumeb Corp. Ltd. and for fiscal year ending June 30, 1972, and June 30, 1973, for Rosh Pinah mine and Berg Aukas mine. Output of Tsumeb Corp. Ltd. for period July 1, 1971, through December 31, 1971 (which is not otherwise covered in this table), was 3,161 short tons.

5 Year beginning March 21 of year stated.

6 Contained in zinc concentrates. Additional quantities of zinc may be contained as a byproduct in lead concentrates produced, but information is inadequate to make reliable estimates of such production, if any.

7 Revised to zero.

[1] In addition to the countries listed, North Vietnam also produces zinc, but available information is inadequate to make reliable estimates of output levels.

[2] Includes production from reclaimed scrap.

Zirconium and Hafnium

By Sarkis G. Ampian [1]

Zircon production and sales by domestic mining companies were over 20% higher in 1973 than in 1972. Zircon exports increased 67% from 17,360 tons in 1972 to 28,921 tons in 1973 while imports increased 45% from 67,537 tons in 1972 to 98,023 tons in 1973. Exports of zirconium oxide rose in 1973 while zirconium metal, and zirconium alloy exports declined. Production of zirconium-bearing compounds for chemicals and refractories also increased. Zircon consumption by foundries increased slightly from 92,000 tons in 1972 to 92,500 tons in 1973.

The 1973 worldwide zircon supply-demand picture was characterized by a diminishing supply coupled with an unprecedented demand. Domestically, zircon reflected the worldwide situation and also was in tight supply because of an increased demand, mainly in manufacturing specialized refractories and abrasives. This increased domestic zircon demand was sufficient to offset the increased supply brought about by the return of zircon imports to normalcy and advances in domestic production.

Legislation and Government Programs.—The Statistical Supplement to the Stockpile Report to Congress, December 31, 1973, showed no objectives for zirconium and hafnium materials. Stocks of 15,998 tons of Brazilian baddeleyite and 1 ton of zirconium metal powder were in excess. The U.S. Atomic Energy Commission (AEC) had an inventory as of June 30, 1973, of approximately 1 ton of zirconium crystal bar and scrap; 937 tons of zirconium sponge; 84 tons of Zircaloy ingot and shapes; 2 tons of hafnium scrap; 47 tons of hafnium oxide; one-half ton of hafnium sponge and shapes; and 39 tons of hafnium crystal bar.

[1] Physical scientist, Division of Nonmetallic Minerals—Mineral Supply.

[e] Estimate. W Withheld to avoid disclosing individual company confidential data.
[1] Includes baddeleyite: 1969—383 tons; 1970—355 tons; 1971—871 tons; 1972—385 tons; 1973—1,019 tons.
[2] Excludes foundries.
[3] Excludes oxide produced by zirconium metal producers.

DOMESTIC PRODUCTION

E. I. du Pont de Nemours & Co. and Titanium Enterprises, Inc., were the only major producers of zircon mineral concentrate in the United States. Zircon was recovered from mineral sands at the dredging and milling facilities owned by du Pont at Starke, Fla.; by Humphreys Mining Co. for du Pont, near Folkston, Ga.;

and Titanium Enterprises at Green Cove Springs, Fla. Production data were withheld from publication to avoid disclosing individual company confidential data. The combined zircon capacity of these three plants is estimated to be 135,000 tons per year.

Statistical data on production of zirconium sponge, ingot, and scrap and on hafnium sponge and oxide are also withheld to avoid disclosure of company confidential data. However, it was estimated that the total domestic sponge metal capacity was increased 50% in 1973 to approximately 7 million pounds per year to accommodate the demand for publicly announced ordnance purchases. The U.S. consumption of zirconium metal during the year was an estimated 6 million pounds, with 1.5 million pounds consumed in other free economies.[2]

Approximately 5,000 tons of alloys containing from 3% to 70% zirconium was produced in 1973.

Three firms produced 49,000 tons of milled (ground) zircon, an increase of 9% from the reported 1972 production. Six companies, excluding those that produce metal, produced 14,300 tons of zirconium oxide. Oxide production in 1973 increased nearly 12% over that reported in 1972.

Hafnium crystal bar, produced by several firms, amounted to 41 tons, compared with 40 tons in 1972.

Teledyne Wah Chang Albany Corp	Albany, Oreg	Oxide, sponge, crystal bars, ingot.

CONSUMPTION AND USES

Zircon consumption in the United States in 1973 was estimated at 175,000 tons. Consumption of zircon concentrate and milled zircon was 92,500 tons for foundries, 27,000 tons for refractories, 22,000 tons for zirconium oxide, 3,500 tons for zirconium alloys (excluding zirconium-base alloys), and 30,000 tons for all other uses. Foundries consumed approximately one-half of the domestic zircon production, with the remaining half consumed by refractory, abrasive, ceramic, metal, and other industries. Domestic zircon was also marketed in proprietary mixtures for use as weighting agents, zircon TiO_2 blends for welding rod manufacture, and zircon-refractory heavy mineral (kyanite, sillimanite, and staurolite) sand blends, for foundry sand and sandblasting applications. The zircon-bearing foundry sand was reportedly designed to provide consistent high-quality performance at low cost for critical casting applications.

Imported Republic of South Africa baddeleyite ore in 1973 was used principally in the manufacture of alumina-zirconia abrasives and also in ceramic colors, refractories, and for other uses.

Preliminary Bureau of the Census figures for 1973 showed that shipments of zircon and zirconia brick and shapes, composed mostly of these materials, totaled 2.3 million brick, expressed in terms of equivalent 9-inch brick, valued at $8.8 million. In 1972, final figures for shipments were 2.0 million brick valued at $8.3 million.[3]

Dealers and other firms reported shipments of milled zircon and concentrate in 1973 to the following markets: Foundry use, 46,000 tons; refractory and chemical use, 57,000 tons; chemical, metal, alloying, compounds, and other uses, 4,300 tons.

Zirconium metal was used in nuclear reactors, in chemical plants for corrosion-resistant material, in refractory alloys, and in photography for flashbulbs. AMAX and Wah Chang enlarged flat product mill capacities in 1973. AMAX began rolling zirconium metal in its Cleveland refractory metals mill: the mill was acquired from the General Electric Co. (G.E.). Wah Chang was planning to install Fansteel's Schloemann mill, recently acquired, at its Albany Oreg., plant.

Zirconium compounds, natural and manufactured, were used in refractories, glazes, enamels, welding rods, chemicals, and sandblasting. Zirconium chemicals were finding increasing applications in the paint, textile, and pharmaceutical industries. Ionarc/TAFA streamlined its pilot commercial-scale ZrO_2 plant. This new plant has a projected capacity of 1 million pounds per year of its unique plasma-produced zirconia. This highly reactive zirconia, readily soluble in sulfuric acid, was reported to be particularly suited for zirconia-based colors, chemicals, and polishes. Magnesium Elektron, Inc. (MEI), purchased the Tizon Chemical Corp. facility in Flemington, N. J. MEI planned to add zirconium chemicals to its line of magnesium-zirconium casting alloys. Tizon will continue furnishing its proprietary polishing mixtures containing zirconium chemicals.

Hafnium metal, alloys, and compounds continued to have few uses. The metal was used for nuclear reactor control rods, in special refractory alloys, and in photographic flashcubes. The nonnuclear hafnium metal uses were reportedly increasing.

Zirconium:		
Oxide[1]	1,300	648
Sponge	471	520
Ingot	W	342
Scrap	722	840
Alloys	285	1,190
Refractories	9,585	9,395
Hafnium:		
Sponge	25	28
Crystal bar	6	10

W Withheld to avoid disclosing individual company confidential data.
[1] Excludes oxide held by zirconium metal producers.

PRICES

Published prices for domestic and foreign zircon rose $5 and $30, respectively, from those of 1972. The prices of zirconium oxides and chemicals, zirconium hydride, zirconium metal powder and sponge, and hafnium metal products were relatively unchanged. The baddeleyite price was furnished by Ronson Metals Corp.

Table 6.—Published prices of zirconium and hafnium materials in 1973

Specification of material	Price
Zircon:	
Domestic, f.o.b. Starke, Fla. (Folkston, Ga.), bags, per short ton [1]	\$59.50 -\$60.50
Domestic, 75% minimum quantity zircon and aluminum silicates, Starke, Fla. (Folkston, Ga.), bags, per short ton	40.00
Imported sand, containing 65% ZrO_2, c.i.f. Atlantic ports, bags, per long ton [2]	95.00 -100.00
Domestic, granular, 30-ton lots, from works, bags per pound [3]	.0475
Domestic, milled, 15-ton lots, from works, bags, per pound [3]	.050
Baddeleyite imported concentrate: [4]	
98% to 99% ZrO_2, minus 100-mesh, c.i.f. Atlantic ports, per pound	.16 - .20
99 + %, minus 325-mesh, c.i.f. Atlantic ports, ton lots, per pound	.48 - .63
Zirconium oxide: [3]	
Powder, commercial-reactor grade, drums, from work, per pound [3]	6.50 - 8.00
Chemically pure white ground, barrels or bags, works, per pound [3]	1.50
Electric fused, lump, bags, works, per pound	.505- .530
Milled, bags, 5-ton lots, from works, per pound [3]	.64
Glass-polishing grade, 100-pound bags, 85% to 90% ZrO_2, works, per pound [3]	.71
Opacifier grade, 100-pound bags, 85% to 90% ZrO_2, per pound [3]	.42
Stabilized oxide, 100-pound bags, 91% ZrO_2, milled, per pound [3]	.80 - 1.10
Zirconium oxychloride: Crystal, cartons, 5-ton lots from works, per pound	.515
Zirconium acetate solution: [3]	
13% ZrO_2, drums, carload lots, from works, per pound	.22
22% ZrO_2, same basis	.38
Zirconium hydride: [3] Electronic grade, powder, drums, from works, per pound	14.50 - 16.00
Zirconium:	
Powder, per pound [5]	10.00
Sponge, per pound [2]	5.50 - 7.00
Sheets, strip, bars, per pound [2]	8.00 - 17.00
Hafnium: [5]	
Sponge, per pound	75.00
Bar and plate, rolled, per pound	120.00
Nitrided	34.25

FOREIGN TRADE

Exports of zirconium ore and concentrate and zirconium oxide rose in 1973 compared with 1972 figures. Exports of all forms of zirconium metal and alloys, in general, were lower in 1973 than in 1972.

Zirconium ore and concentrate, exported to 13 countries in 1973, increased from 34,-719,653 pounds valued at \$940,347 in 1972 to 57,842,328 pounds valued at \$2,288,128. The quantity exported increased 67% over that shipped in 1972, but the value rose 43%. Both the 1973 quantity and value were alltime highs. The average value of the zirconium ore and concentrate exported in 1973, \$79.12 per ton, represented an increase from the 1972 value of \$54.17. This increase was attributed to larger amounts of higher cost granular and milled zircon shipped. The increase in the amount of higher cost zircon shipped also indicates a return to the normal zircon exporting pattern. Exports in 1972 consisted of a larger than normal percentage of lower cost zircon sand. The major recipients of the exported zirconium ore and concentrate were Japan, 39%; the Netherlands, 30%; Mexico 12%; Brazil, 11%; and Canada, 7%.

Exports of zirconium oxide increased from 1,304,352 pounds valued at \$931,867 in 1972 to 2,055,000 pounds valued at \$1,402,-167 in 1973. Export quantity and value increased 58% and 50%, respectively, in 1973. These zirconium oxide shipments were made to 21 countries. The five major recipients in 1973 were Japan, 32%; West Germany, 17%; Mexico, 15%; Canada, 13%; and Brazil, 7%.

Total exports of other classes of zirconium decreased nearly 23%, from 1,314,219 pounds in 1972 to 1,016,437 pounds in 1973. The value of this material rose 8% in 1973 to \$12,424,733 from the 1972 value of \$11,508,858. Of the three categories listed, only zirconium and zirconium alloy foil and leaf increased in both value and quantity in 1973. The zirconium and zirconium alloys, wrought class decreased 14% in the pounds exported but increased 21% in value, and exports of zirconium and zirconium alloys, unwrought, and waste and scrap decreased 54% in quantity and declined 51% in value.

Imports for consumption of zirconium ores in 1973 rose to 98,023 short tons, a 45% increase compared with the 67,537 short tons in 1972. The 1973 figure represents an alltime high tonnage of ore imported. Zirconium ore imports from the Republic of South Africa were chiefly baddeleyite (ZrO_2). The remaining zirconium ore imports were believed to be Australian zircon.

The average value of imported zircon at foreign ports increased 11% in 1973 to $51.76 per short ton, compared with $46.79 in 1972. The Republic of South Africa baddeleyite value in 1973 of $386.65 per short ton decreased slightly from the 1972 value of $387.01. The tonnage imported rose 165% in 1973.

Imports for consumption of zirconium and hafnium in 1973 increased both in quantity and value in all categories: Zirconium, wrought; zirconium, waste and scrap and unwrought; zirconium alloys, unwrought; zirconium compounds, n.e.c.; zirconium oxide; and hafnium, unwrought and waste and scrap. Wrought hafnium imports resumed in 1973.

WORLD REVIEW

Australia.—Allied Eneabba Pty. Ltd., a joint venture of E. I. du Pont de Nemours & Co. and Allied Minerals N.L. on the latter's rutile prospect in Western Australia, revealed details of its future plans. Du Pont reportedly will provide both technical and financial assistance in constructing a pilot plant designed to produce 7,000 tons per year (tpy) of rutile, 15,000 tpy of zircon, and 28,000 tpy of ilmenite.[4]

Construction of a full-scale plant capable of producing 50,000 tpy of rutile, 200,000 tpy of ilmenite, 100,000 tpy of zircon, and unspecified quantities of monazite, leucoxene, and kyanite, was scheduled for completion in 1974. Du Pont has contracted to purchase 200,000 tons of ilmenite annually over a 15-year period.[5] It was estimated that the Allied Eneabba mineral field contains, in million tons, 14.0 of ilmenite, 6.3 of zircon, 2.2 of rutile, and 0.2 of monazite.[6]

Westralian Sands Ltd., a Western Australia mineral sands producer, announced setting up of a new open pit operation and a mill in the Yoganup Extended area, South of Capel, to meet increased demand. The mill includes a mobile concentrator and screening plant. Westralian Sands planned to begin mining at its Tutunup area properties upon cessation of its current mining operation between Yoganup and the Capel River. Exploration from Boyanup (between Capel and Bunbury) northwards has been undertaken in a joint venture with British Titan Products' subsidiary, Tioxide Australia Pty. Ltd., to develop the area if warranted, by a new subsidiary. Westralian Sands has also been exploring for heavy mineral sands north of Perth in association with Lennard Oil NL.[7]

e Estimate. p Preliminary. r Revised. W Withheld to avoid disclosing individual company confidential data.
[1] Figure for 1971 includes 4,594 short tons of zircon and 362 short tons of baddeleyite; similar breakdown for 1972 and 1973 not available.
[2] Output of Indian Rare Earths Ltd. for year beginning April 1 of year stated.
[3] Official South African production figures are not reported; data presented are total recorded imports of zirconium ores and concentrates reported by the United States, Japan, and West Germany. As such, listed figures may be only a part of total output.

The Government of Western Australia was investigating the possibility of coordinated export facility at the Geraldton depot for the four new and existing mineral sand producers. Presently, Allied Eneabba was the first major producer to go onstream with a projected annual capacity of 350,000 tpy. A second producer, A. V. Jennings Industries (Australia) Ltd., was scheduled to begin production in 1974 with an initial capacity of 240,000 tpy of heavy minerals. The third party, Ilmenite Pty. Ltd., was planning to prove and test its reserves southwest of Eneabba by the end of 1974, prior to finalizing development plans. The fourth company, Westcoast Rutile Pty. Ltd. has located two deposits in the Jurien Bay area and hopes to complete a feasibility study for their development in the latter part of 1974.

This expansion in heavy mineral sand production is taking place along a 100-mile stretch of coast between Geraldton and Jurien Bay. This stretch of coast has proved and probable heavy mineral reserves exceeding 140 million tons.[8]

Mining Corp. of Australia (MCA), a company organized by Kamilaroi Mines Ltd. and Westcoast Rutile for exploiting their Jurien Bay properties, has revised its heavy mineral reserve estimates. The reserves now are 2 million tons of proved ore; 470,000 tons of probable reserves; and 600,000 tons of possible reserves. MCA also stated that the grade of ore is 8% to 9% heavy mineral at a cut-off grade of 3%.[9]

Canada.—Chase Brass Division of Kennecott Copper Corp. and Noranda Metals Corp. announced plans to construct two tubular production plants near Ottawa, capable of producing zirconium fuel cladding. These plants will use zirconium alloys supplied by both AMAX and Teledyne Wah Chang.[10]

France.—The diversified St. Gobain-Pont-à-Mousson group was expected to gain control of Sté. Générale des Produits Réfractaires S.A. (SGPR), one of France's major manufacturers, by acquiring Péchiney-Ugine-Kuhlmann's holdings. SGPR produces a wide range of clay and nonclay refractories. St. Gobain also increased its shareholdings in l'Electro-Réfractaire (fused cast refractories), in 1972, by purchasing shares held by Corning Glass, Co. U.S.A., and formed a partnership with the Italian company, Montedison, Refradige S.p.A., to produce fused cast refractories in Italy.[11]

India.—The capacity of the Chavara dry plant, operated by the Indian Rare Earths Ltd., near Quilon, was being expanded to yield over 200,000 tpy of ilmenite with proportionate increases in the output of zircon.[12] The other company plant at Manavalakurichi, Kerala State, underwent an expansion to 40,000 tpy a few years ago. The two principal destinations for Indian heavy minerals were Japan and Czechoslovakia.[13]

The Industrial and Investment Corp. of Mahrashtra was examining the State's beach sand deposits for feasibility of producing beneficiated titanium products and associated heavy minerals.[14]

Sierra Leone.—Heavy mineral sand operations at the Bonthe and Moyamba mines, relinquished by Sherbro Mining Ltd. 2 years ago, were reopened by a subsidiary of two West German companies, the Bayer-Preussag Mining Co. Details regarding rutile and zircon production were unannounced.[15]

South Africa, Republic of.—A pilot plant to recover titaniferous and zircon-bearing heavy minerals from the dune area sands north of Richards Bay, Natal, has been put onstream by the Industrial Development Corp. of South Africa, in association with King Resources S.A. Pty. Ltd. The pilot plant was to provide sufficient information to decide if full-scale exploitation is possible.[16] The Phosphate Development Corp. Ltd. (FOSKOR) was undergoing expansion to enable an eventual twofold increase in the production capacity for its unique baddeleyite concentrates. The baddeleyite concentrates, pure and ultrapure were favorably received by the abrasive and ceramic industries. Palabora Mining Co. Ltd. (PMC), mining a contiguous deposit in the Palabora igneous complex, was also undergoing an expansion. A market survey conducted earlier by PMC indicated a strong demand for its stockpiled baddeleyite. The baddeleyite concentrates are coproducts from copper, phosphate, and iron operations.

Tanzania.—The Tanzania State Mining Corporation reported coastal deposits containing zircon, ilmenite, rutile, and other heavy minerals.

TECHNOLOGY

The Office of Coal Research (OCR), U.S. Department of the Interior, completed negotiations with the U.S.S.R. for joint research on the magnetohydrodynamic (MHD)[17] method of generating electricity.[18] In further MHD research the OCR also let a contract to G.E., Philadelphia, Pa.,[19] and announced a cooperative effort with the U.S. Air Force.[20]

The joint U.S.-U.S.S.R. MHD research will capitalize on the experience gained from the minimally operating 25-megawatt MHD pilot plant in Moscow. An exchange of scientific MHD data should prove mutually beneficial in achieving the rapid commercialization of MHD generating systems. The contract with GE was awarded to improve high-temperature operations required by advanced systems for generating electricity from coal. G.E. was to provide for the experimental work at its Space Sciences Laboratory, Valley Forge, Pa. The work involves construction and operation of a pilot heat exchanger to determine its effectiveness towards increasing the temperatures for coal gas fired, closed cycle MHD systems. The U.S. Air Force and OCR cooperative effort was to be done at the Air Force's Arnold Engineering Development Center, Tullahoma, Tenn., and was to demonstrate the higher efficiency of a coal-based MHD generator compared with conventional steam-generating plants. The Air Force was providing both the research facilities and the MHD generator. This effort, started at yearend, was to be done by ARO, Inc., a civilian operating contractor for the Arnold Center.

[17] MHD involves generating electricity without rotating parts associated with the less efficient conventional steam turbine generating systems. Coal-fired MHD systems are fired at high temperatures and pressures and the resulting gases are forced through a duct at high velocities. The gases move through a magnetic field surrounding the duct, resulting in the generation of an electric current. The ultra-high-temperature MHD systems are more efficient than lower temperature MHD systems and use stabilized zirconia electrodes and insulator materials in the ducts.

Bureau of Mines research efforts were directed towards zirconium electrowinning technology and developing advanced molybdenum-zirconium alloys. The zirconium electrowinning research goals were twofold. The initial goal was to lower the cost of producing electrowon zirconium by a Bureau-developed process and the second goal was to operate a 1,000-ampere cell for meaningful upscaling evaluations. The Bureau of Mines electrolytic process uniquely produces a high-purity metal remarkably low in interstitial contaminants. The advanced molybdenum-zirconium alloy research consists of three integrated phases: 1. Castability of alloys; 2. Stable oxide coatings; and 3. Casting oxidation resistance metal protective coatings. The compositions included in this research were TZM (Mo-0.5Ti-0.08Zr—0.015C) and binary molybdenum alloys containing various levels of zirconium and hafnium.

Bureau of Mines research in the K_2HfF_6-K_2ZrF_6—1.25 weight-percent HF systems revealed even though hafnium enrichment can be obtained in recrystallized liquors, the existence of hydrates coupled with the slopes of their connecting solubility curves precludes the suitability of this system in separating high-purity K_2HfK_6 from K_2HfF_6-K_2ZrF_6 mixtures.[21]

The history, geology, mining, and processing methods, along with shipping and quality control particulars, of the Allied Eneabba western Australian deposit, were related to present and future mining operations.[22] A detailed discussion of the Richert cone concentrator, a high-capacity, low-cost gravity pinch sluice-type, developed by Mineral Deposits Ltd. of Southport, Queensland, Australia, was published.[23] The detailed discussion includes not only flowsheets for several Australian heavy sand operations but also flowsheets for recovering cassiterite, baddeleyite, and magnetite from sand and nonsand ores.

The solid-liquid interfacial parameters of the zircon-sodium oleate (soap) system were experimentally determined by absorption measurements, zeta-potential, and infrared studies and correlated with parallel flotation experiments on high-purity zircon. The studies, mutually supporting, showed that the adsorption of sodium oleate on zircon is due mostly to a van der Waals-type attraction between the hydrocarbon chains of the fatty acid soap.[24] The completion of this theoretical study, directly applicable to soap-floating zircon from beach and other sands, was reported.[25] This work, devoted to determining the effects of pH on the flotation recovery of zircon from different sodium oleate concentrations, discovered the antagonistic role of hydroxyl ions with increasing pH. Recoveries of 100% zircon were experienced between the pH range of 6 to 9 at sodium oleate concentrations of 6.58 times 10^{-4} mole per liter. Zircon recoveries at other concentrations and pH were markedly lower.

Semicrystalline glazes, containing zirconia to improve opacity and acid resistance, compatible with low expansion cordierite white bodies were developed.[26] These glazes, reportedly attractive with a satin finish, consist of low expansion crystals dispersed in a vitreous or glassy matrix; they are suitable for application to the popular new dinnerware and cookware. Instability of reheated plasma-sprayed zircon coatings were attributed to the destabilization of the resulting dense cubic zirconia to the less dense monoclinic variety. The cubic zirconia crystallites, dispersed in a glassy silica matrix, on heating, undergoes a polymorphic transformation which results in a destructive pore contraction and/or shrinkage phenomenon.[27]

An article evaluated the considerations in selecting coreless induction furnace refractories. Vibrated monolithic silica linings, although dry, are preferable for these furnaces; circumstances are stressed in which brick or composite linings, such as zircon, zirconia, alumina, and magnesia, would be the better choice. Physiochemical and eco-

nomic considerations are also weighed.[28] The occurrences of known Canadian mineral deposits suitable for clay and nonclay refractories production, irrespective of economics, were highlighted. The majority of the reported zircon occurrences were in Ontario.[29]

The lanthanum modified lead zirconate-lead titanate (PLZT) polycrystalline bodies, aside from their usefulness as electrooptic (electric switching and/or memory application) materials, when suitably hot-pressed have especially useful light optical transparency at near theoretical densities. However, the development of commercially acceptable light transparent PLZT bodies have been hampered because of reduced light transparency or opaqueness due to deviations from their theoretical density. These deviations were traced to the presence of pores or voids which contributed to opaqueness by a light-scattering mechanism. Methods to both calculate the expected transparency and relate it to deviations from theoretical density were advanced. This calculating technique should hasten the development of commercial PLZT bodies.[30] Mechanisms and systems, including improvements in atmospheric sintering processes were used successfully in fabricating transparent PLZT plates over 8.4 centimeters in diameter. A combined cold- and hot-pressing scheme, limiting the rate of lead oxide volatilization, proved to be the most reliable process for atmospherically sintering these large transparent PLZT ceramics.[31]

In another related PLZT work, contributing to a better understanding of these ceramics, the low-temperature phase relations were determined as a function of lanthanum content and temperature. Dielectric and piezoelectric measurements and X-ray data were used to locate and identify the critical phase transitions.[32] Laser-induced Raman spectra of pure powder and multidomain single crystals of lead zirconate, a component used in PLZT body synthesis, was added to the literature. These spectra, previously unavailable, should lead to more efficient PLZT synthesis.[33]

The fracture toughness of a partially stabilized ZrO_2 (PSZ) in the system CaO-ZrO_2 was studied to determine the mechanisms of crack propagation.[34] PSZ ceramics in the system CaO-ZrO_2 are superior to conventionally prepared fully stabilized zirconia in thermal-shock properties. Solid solutions of ZrO_2 and Y_2O_3, prepared by decomposing coprecipitates, were adversely affected by atmospheric CO_2. The atmospheric CO_2 reportedly forms a carbonate complex during preparation which is only partially driven-off during sintering.[35] The remaining CO_2 stabilizes an amorphous phase which encourages crystal nucleation and growth during sintering for oxygen potential probes.

Phase transformation of monoclinic ZrO_2 single crystals, prepared by flux and hydrothermal methods, were studied primarily by DTA. A histogram plot of the transformation temperatures determined from heating and cooling experiments from approximately 60 single crystals revealed two distinct temperature ranges. The transformation temperatures on heating were in the range 1,160° to 1,190° ± 3° C and on cooling, 1,070° to 1,100° ± 3° C.[36] A new binary conducting phase, $Ce_2Zr_3O_{10}$, was discovered in the system CeO_2-ZrO_2.[37] Cerium zirconates are prime candidates as MHD electrodes because of their resistance to alkali attack at elevated temperatures in air.

The pseudobinary Ti-ZrO_2 system was investigated by metallographic, X-ray diffraction, electron probe, and melting-point techniques. This investigation revealed a

similarity to the $Zr-ZO_2$ system and also presented the phase relations in the $Ti-ZrO_2$ section between 600° and 2,000° C.[38] Phase relations were also proposed for the HfO_2-rich portion of the system $Hf-HfO_2$.[39] Phases in the $Ti-ZrO_2$ and $Hf-HfO_2$ systems are potentially valuable as refractory cermets. Zirania, a new family of zirconium oxide titanium ceramics, was recently developed by United Technology Research, Inc., Hauppauge, N.Y. Zirania, developed for the U.S. Air Force, reportedly can withstand repeated intensive shock at temperatures to 4,000° F without melting or cracking.[40] Zirania may be the answer for a high-temperature substrate to support the platinum or palladium catalysts in automobile catalytic convertors.

The AMAX Zr–Hf Newsletter listed approximately 900 reference abstracts devoted to zirconium and hafnium technology in 1973. Many of these articles were devoted to the use of zirconium and hafnium as metal alone, in alloys and as alloying elements, not only in nuclear applications but also in refractory and oxidation- and corrosion-resistance technology.

AMAX Specialty Metals and Titanium Metals Corp., in a joint effort, succeeded in producing high-purity electrolytic zirconium in a prototype production-size cell. Tests were currently underway on converted wrought shapes for comparison with Kroll-process zirconium.[41]

The major domestic and foreign nuclear fuel fabricators and zirconium metal suppliers participated in a Symposium on Zirconium in Nuclear Application sponsored by the American Society for Testing and Materials, Portland, Oreg., August 21 to 24, 1973. The participants reviewed zircaloy testing methods and procedures and concluded that zircaloy continued to be superior to any other material for the cladding of nuclear fuel in the water-moderated nuclear reactors.

CONTENTS

ARSENIC [1]

Domestic Production.—Arsenic trioxide was produced in the United States solely as a byproduct of base-metal ores, primarily copper ore, and only at the Tacoma, Wash., plant of the American Smelting and Refining Company. Production figures cannot be published but output was only slightly below that in 1972. Shipments exceeded production and yearend stocks were substantially below yearend 1972 inventories.

Consumption and Uses.—Apparent consumption of arsenic, essentially all as white arsenic (As_2O_3), increased 29% over that in 1972. Calcium and lead arsenate were the major end products; minor quantities of arsenic were used in sodium arsenate and other chemical compounds. About 3% of the arsenic consumed was used as metal for alloying with lead and copper. Small quantities of high-purity arsenic were used in the manufacture of gallium and indium arsenides for semiconductors.

Arsenic was used primarily for its toxic qualities in the agricultural industry for insecticides, selective plant killers, defoliants, and for parasitic control in chicken feed. Under the cattle fever tick eradication program, 240,000 cattle were dipped in a 0.22% arsenious oxide solution prior to entry into the United States.

Wood preservation continued as an important use for arsenical compounds. Consumption of chromated copper arsenate (CCA compounds) has grown from 1,165 tons in 1967 to 4,874 tons in 1972. Chromated copper arsenate solutions were used to treat more than 35% of the lumber and timbers treated in 1972. The use of fluor chrome arsenate phenol (Wolman salts and osmosalts) has dropped from 2,671 tons in 1967 to 957 tons in 1972. Until 1969, Wolman salts was the principal wood preservative.

Prices.—The price of refined white arsenic, 99.5%, at New York docks, in barrels, small lots, has been unchanged at 6¼ to 6¾ cents per pound since July 6, 1968. This quotation held through March 8, 1973; thereafter, quotations were listed as nominal. Refined white arsenic in bulk carload lots at Laredo, Tex., was $120 per ton, and crude white arsenic was quoted at $94 per ton at Tacoma, Wash. Lead arsenate in 50-pound bags was quoted at 26 to 29 cents per pound throughout 1973.

Arsenic metal was quoted in London at £690 per metric ton (75.1 cents per pound) until January 18 when it rose to £800 per metric ton (87.1 cents per pound). On June 21 the price was quoted at a range of £800 to £1,000 per metric ton (87.1 to 108.9 cents per pound) where it remained through yearend.

Foreign Trade.—No exports of arsenic metal or white arsenic were reported.

Imports of white arsenic decreased for the third successive year. Receipts were

[1] Prepared by Gertrude N. Greenspoon, mineral specialist.

16% below those in 1972 and the lowest since 1958. Mexico was the chief supplier with 49% of the total imports, followed by Sweden with 36% and France with 11%.

Sweden supplied 590 tons of the 643 tons of arsenic metal imported in 1973. The United Kingdom and Belgium-Luxembourg furnished 20 tons each. The remainder came from Canada, West Germany, Japan, and the Netherlands.

Tariff.—Arsenic oxide (white arsenic) enters the United States duty free. A 1.2-cent-per-pound duty was applicable to arsenic metal.

World Review.—*Philippines.*—Shipments of high arsenic-bearing copper concentrate by Lepanto Consolidated Mining Co. to the Tacoma, Wash., smelter were reduced from 7,000 to 4,500 tons per month because of antipollution curbs placed on the

[1] Including calculated trioxide equivalent for output reported as elemental arsenic and arsenic compounds other than trioxide.

[2] In addition to the countries listed, Argentina, Austria, Belgium, the People's Republic of China, Czechoslovakia, East Germany, Finland, Hungary, Southern Rhodesia, the United Kingdom, and Yugoslavia have produced arsenic and/or arsenic compounds in previous years, but information is inadequate to ascertain whether such output has continued, and if so at what levels.

[3] Output of Tsumeb Corp. Ltd. only.

[4] Production for year ended June 30, 1971. Output during July 1, 1971, to December 31, 1971, was 2,988 short tons.

smelter. The company was attempting to find an alternate smelter to avoid a 35% production cutback.

Sweden.—Arsenic production rose 2% in 1973. The low output in 1972 resulted from lower arsenic content of the ores and to changes in the refining plant. Production of arsenic metal rose as an additional unit went into operation. The current capacity of 1,500 tons annually for the metal plant can be increased if market conditions warrant expansion.

CESIUM AND RUBIDIUM [2]

Domestic Production.—There was no domestic production of cesium or rubidium ores in 1973. All domestically produced cesium and rubidium compounds were processed from imported pollucite or *ALKARB* (a residue from the processing of lithium ores).

Total production of cesium chemical compounds declined slightly in 1973, whereas the output of rubidium chemical compounds tripled. Cesium and rubidium compounds were produced by Kawecki Berylco Industries, Inc., Revere, Pa.; Kerr-McGee Corp., Trona, Calif.; and Rocky Mountain Research, Inc., Golden, Colo. There was no reported production of cesium or rubidium metal during the year; however, small quantities of cesium and rubidium metals were shipped from stocks.

Consumption and Uses.—Data, relating to the consumption and use pattern of cesium and rubidium metals and compounds, were not available. However, major uses were thought to be in research and development of new power-generating systems, biological sciences, and other technical areas. Cesium and rubidium found commercial application in the manufacture of pharmaceuticals, ultracentrifuge separation of organic compounds, ionic propellant engines for space-flight applications, and electronic apparatus such as scintillation counters, photomultiplier tubes, and photoelectric cells. Cesium, rubidium, and their compounds can be substituted for each other in some end uses.

Any potential for a large-scale increase in the demand for cesium and rubidium continued to be contingent on the commercial development of magnetohydrodynamic (MHD) electric power generators and thermionic converters. The Office of Coal Research, U.S. Department of the Interior, continued to fund MHD research.

Prices.—During the year, the American Metal Market quoted a nominal price for pollucite, containing about 20% Cs, in minimum lots of 10 tons delivered to an entry point, at $300 per short ton. The Metal Bulletin also quoted the nominal price for pollucite concentrates, containing minimum 24% Cs_2O, f.o.b. source, at $11.08 per metric ton unit (22.046 pounds of Cs_2O). The American Metal Market quotation on cesium metal, 99+% purity, remained unchanged at $100 to $375 per pound. The quotation on rubidium metal, 99.5+% purity, also remained unchanged at $300 per pound.

Table 4.—Prices of selected cesium and rubidium compounds

Item	Base price per pound [1] Technical grade	High-purity grade
Cesium bromide	$28	$65
Cesium carbonate	29	67
Cesium chloride	30	68
Cesium fluoride	35	75
Cesium hydroxide	35	75
Rubidium carbonate	45	75
Rubidium chloride	46	76
Rubidium fluoride	51	83
Rubidium hydroxide	51	83

[1] Excludes packaging cost, 50- to 100-pound quantities, f.o.b. Revere, Pa.

Source: Kawecki Berylco Industries, Inc.

Foreign Trade.—Only small quantities of pollucite were imported from Canada during the year, but data on the quantity and value of imports of cesium and rubidium ores were not available. Imports of cesium compounds declined greatly from 12,048 pounds, valued at $330,691 in 1972 to 3,159 pounds, valued at $111,631 in 1973. No rubidium metal was imported during 1973. No other data were available on imports or exports of cesium and rubidium products.

World Review.—During 1973, the Tantalum Mining Corp. of Canada, Ltd., produced about 300 tons of pollucite. Of this

[2] Prepared by Benjamin Petkof, physical scientist.

quantity, 250 tons was shipped to the U.S.S.R.

Although Southern Rhodesia has not officially reported pollucite production since its independence in 1966, the Bikita Minerals Ltd. Mining Lease No. 1, near Glen Cova in the Victoria District was listed as an operating mine as of January 1, 1973, and presumably remained in operation throughout the year.

No information was available on the 1973 status of the mining properties in the Karibib area of the Territory of South West Africa, which were in operation through 1967, the last year for which official data were published.

GERMANIUM[3]

Domestic production and consumption of germanium in 1973 was little changed from that of the last 3 years with the use of germanium in optics increasing to where it nearly equals that used in semiconductors.

Legislation and Government Programs.—On June 26, 1973, the Tariff Commission received advice from the Treasury Department that germanium point contact diodes from Japan were being or were likely to be sold at less than fair market value within the meaning of the Antidumping Act of 1921. Accordingly, the Commission instituted an investigation. A public hearing was held August 10, 1973, and on the basis of evidence supplied to the Commission, it concluded that a domestic industry was not being injured by reasons of importation of germanium point contact diodes from Japan at less than fair market value.

Domestic Production.—Production of germanium from domestic sources was estimated at 27,000 pounds in 1973, with an additional 10,000 pounds recovered from germanium-containing zinc concentrates imported from other countries. No new residues were recovered from the treatment of ores from the Kansas-Missouri-Oklahoma zinc-bearing region, most of the germanium was obtained from such smelter residues that had been stockpiled. Primary production is supplemented by recycled waste or new scrap, which returns from 65% to 80% of that metal used in semiconductors.

All the primary germanium was produced by Eagle-Picher Industries, Inc., from stockpiled zinc smelter residues at its Quapaw, Okla. plant. Eagle-Picher also reprocessed new scrap. Other producers of secondary germanium were GTE Sylvania, Inc., Towanda, Pa.; Kawecki Berylco Industries, Revere, Pa.; and Atomergic Chemetals Co., Long Island, N.Y.

Consumption and Uses.—Apart from germanium's specialized uses in the realm of transistors and solid state physics, germanium has important applications in metallurgy, chemotherapy, polymer chemistry, and optical instrumentation. Since germanium-containing glass has a high refractive index, it finds use in wide-angle camera lenses and microscope objectives. Other uses are for making special glasses for spectroscopes and infrared devices, in high-temperature technology as a stabilizer for zirconium against phase changes, and in the fabrication of fuel elements in atomic reactors. Semiconductors and optics account for approximately 90% of the domestic use of germanium.

There is currently a great deal of interest in organogermanium compounds as polymers and therapeutic agents. Certain of these compounds have been found to have marked antimicrobial activity combined with low mammalian toxicity. Of greater interest is the possible use of germanium compounds for treating carcinoma and leukemia.[4]

[3] Prepared by Herbert R. Babitzke, physical scientist.

Medicines containing carboxyethylgermanium sesquioxide have been developed for domestic animals. The organic germanium medicines are effective in curing and preventing various animal diseases caused by viruses, bacteria, and protozoans.[5]

A new medicinal toothpaste containing GeO_2 was highly effective for control of periodontopathia. Gingivostomatitis was cured 4 months after application of the prepared toothpaste.[6]

Research and development is continuing in the use of platinum-germanium catalysts. Gasoline is reformed with hydrogen over a bimetallic catalyst with continuous halogen additions. The catalyst is platinum metal and a germanium compound on a porous carrier.[7]

Superconductors continued to receive researchers' attention. Investigations have revealed that niobium-germanium films remain superconducting up to 22.3° K. The high critical temperature of the films was attributed to the formation of a more nearly perfect stoichiometric Nb_3Ge compound that had not been attained before.[8]

New diamondlike semiconductor materials have been developed that show promise for infrared, nonlinear optical and electroluminescent applications. One of the ternary materials, $ZnGeP_2$, has the potential to emit light at the proper wavelength, which makes it important to the field of optical communications.[9]

The Bureau of Mines has employed handheld scanners in investigations to detect abnormal surface temperatures on dumps of flood-generated trash near Wilkes-Barre, Pa.[10], and in coal mines to detect failure in roof and ribs of an underground opening.[11] The scanner, which was originally developed for military use as a night vision device, has a lens configuration consisting of two germanium components and one silicon component. The operator views a thermal image of the target area in which the contrast in the image is proportional to the magnitude of the temperature differences on the target. In a normal operation mode, hot areas are bright in the image.

Table 6.—U.S. imports for consumption of germanium, by country

Country	Quantity (pounds)	Value
Unwrought and waste and scrap:		
Belgium-Luxembourg	1,995	$674,351
Czechoslovakia	110	5,750
Denmark	160	10,002
Germany, West	4,206	226,603
U.S.S.R.	7,696	449,532
United Kingdom	538	32,509
Total	14,705	1,398,747

Prices.—The prices of domestic zone refined (intrinsic) germanium and domestic germanium dioxide remained at $293 and $167.50 per kilogram, respectively, through 1973. These prices have been in effect since June 8, 1970. The selling price of imported germanium metal and germanium dioxide was increased by about 13% to reflect the devaluation of the dollar. The increases, effective February 14, 1973, brought the price of germanium metal to $260 per kilogram from $229 and germanium dioxide to $136 per kilogram from $120.

Foreign Trade.—U.S. imports of germanium metal (unwrought and waste and scrap) was 14,705 pounds valued at $1,398,747 in 1973, nearly a threefold increase in quantity and a twofold increase in value over 1972 imports. The U.S.S.R. supplied 52% of the germanium imports, West Germany supplied 29%, and Belgium-Luxembourg supplied 14%.

World Review.—World production of primary germanium was estimated at 165,000 pounds in 1973.

INDIUM [12]

Domestic Production.—The only domestic production of primary indium metal reported during the year was by the American Smelting and Refining Company (Asarco) at its Denver, Colo., and Perth Amboy, N.J., plants. Other companies processed or refined imported material and domestic stocks to produce high-purity metal components, alloys, and compounds. Domestic production of indium is a small fraction of U.S. consumption.

Uses.—The pattern of indium usage was estimated to be divided among several industries: 25% in solders and low-melting-point alloys, 20% in forming junctions with semiconductors and other electronic components, 20% in bearing alloys to increase hardness and resist corrosion, 10% in lamps and other optical devices, 12% in silver alloys used in atomic reactor control rods, 13% for research and other uses.

Stocks.—Producer stocks are estimated to have decreased considerably from those held several years ago.

Prices.—Indium pricing is based on the standard-grade metal (99.97% pure): higher purity grades (99.999% plus) are available at a premium. In 1972 and earlier years, sticks in lots of less than 100 ounces and ingots of 100 ounces were quoted at prices above the base price, but since December 1972, the only producer quotation published in Metals Week has been for ingots in lots of 10,000 ounces or more. Throughout the year, to December 10, 1973, this quotation was $1.75 per ounce. Asarco raised the price to $2 per ounce on December 10, after the Cost of Living Council had released most nonferrous metals from price controls.

During 1973, indium of Soviet origin was apparently withdrawn from the European market, and prices that had been considerably below the U.S. producer price began to approach this price as a tighter supply situation developed.

Foreign Trade.—Imports of indium continued to increase, rising 29% over 1972 imports to 811,527 troy ounces. The main sources of imports were Canada (41%), U. S. S. R. (14%), Belgium-Luxembourg (13%), and the United Kingdom (12%).

The duty effective in 1973 on unwrought and waste and scrap indium was 5% ad valorem and on wrought indium was 9% ad valorem for most favored nations. Duties on waste and scrap were suspended until June 30, 1975. The statutory duty for the Soviet Union was 25% ad valorem on unwrought indium and 45% ad valorem on wrought metal.

Table 7.—U.S. imports for consumption of indium, by country

Country	Quantity (troy ounces)	Value
Unwrought and waste and scrap:		
Belgium-Luxembourg	104,796	$54,164
Canada	333,231	377,240
Germany, West	3,084	4,406
Japan	6,412	7,301
Netherlands	59,572	75,012
Peru	87,089	145,064
Switzerland	58	1,322
U.S.S.R.	115,164	110,650
United Kingdom	95,691	198,658
Total	805,097	973,817
Wrought:		
Netherlands	6,410	9,171
Switzerland	12	1,905
United Kingdom	8	1,109
Total	6,430	12,185

Technology.—Researchers in England investigated the photoluminescence of indium phosphide in light-emitting diodes and results were published in a trilogy of papers.[13] The use of indium-111 in radionuclides to diagnose and possibly to treat tumors was described.[14] The thermodynamic properties of indium in low-melting alloy systems was investigated at United States and Indian universities.[15]

RADIUM [16]

A downtrend in the use of radium continued during 1973. Radium was used primarily in therapeutic treatment of cancer. In medical and industrial applications, radium was more frequently replaced by cheaper and less hazardous radioisotopes.

Domestic Production.—There was no production of radium in the United States during the year. The small domestic demand was met by imports or withdrawals from dealers' stocks. Radium Chemical Co., Inc., New York, was the main dealer in the United States.

Consumption and Uses.—Radium, in small quantities expressed in milligrams, was used in treatment of cancer and in luminous compounds, static eliminators, and neutron sources. Based on manufacturers' sales data, about 1,300 to 1,600 curies of radium have been sold in the United States through 1973. Approximately 330 to 360 curies, contained in 50,000 to 60,000 sources, were in use in medical applications during 1973. Nonmedical uses accounted for 250 curies, and the rest was involved in luminous compounds and other uses.[17]

Several curies are added annually to the total radium in use in the United States. The aftereffects of gamma radiation in medical applications and the price of radium have lead to substitution by other radioisotopes. This trend was also apparent in other uses of radium.

Prices.—Radium prices, per milligram, were quoted by Radium Chemical Co., as follows: Less than 100 milligrams, $24; 200 to 499 milligrams, $20; 500 milligrams to 4.99 grams, $18; over 5 grams, $17.

Foreign Trade.—Data on trade in radium was not published; in most cases, the radium data was included with that for other items in trade statistics. Belgium remained the principal source of radium imported into the United States.

World Review.—Information on radium in world markets was not readily available. The Belgian company, Union Minière S.A., was the largest radium producer and supplier in the noncommunist world. In addition, small quantities of radium were apparently produced in Canada and the United Kingdom. Czechoslovakia, with its long tradition in uranium mining, and the U.S.S.R. probably also produced some radium. Throughout the world, uses of radium were similar to those in the United States.

Technology.—The Federal Bureau of Mines, Salt Lake Metallurgy Research Center, Salt Lake City, Utah, completed a study to develop techniques for recovering radium from uranium ores, tailings, and processing solutions to eliminate this radioactive contaminant.

The U.S. Atomic Energy Commission sponsored a research program studying the distribution of radium and 13 other metallic elements. This distribution was quantitatively compared by distributing a radiotracer of the element of interest between an aqueous phase and an organic phase. From the ratio of activity in the organic phase to activity in the aqueous phase, distribution coefficients were calculated as function of pH.[18]

SCANDIUM [19]

Research activities led to a few new industrial applications for scandium, although only small quantities of scandium were involved. The small domestic supply of scandium was provided by one producer of the metal and oxide, which were derived from imported raw materials. Supply was adequate to meet demand.

Domestic Production.—There was no scandium mine production in the United States during 1973. The small output of scandium metal, measured in a few tens of pounds and derived from imported raw materials, was at approximately the same level as in 1972. Research Chemicals, a division of Nucor Corp., Phoenix, Ariz., remained the only domestic producer.

---

[16] Prepared by Roman V. Sondermayer, physical scientist.

[17] Data on uses are estimates based on partial sales reports.

[18] Jackson, W. M., and G. I. Gleason. Distribution Studies of Radium and Other Metallic Elements Between Thenoyltrifluoracetone in Methyl Isobutyl Ketone and Aqueous Solution. Anal. Chem., v. 45, No. 12, October 1973, pp. 2125–2129.

[19] Prepared by Roman V. Sondermayer, physical scientist.

Consumption and Uses.—Scandium was used in research and in a few industrial applications. Research was aimed at better understanding the properties and behavior of scandium in different environments. Researchers studied scandium radioisotopes and investigated alloying, electrical, and chemical properties of the metal, compounds, and products.

The main industrial applications of scandium were in high-intensity lamps for lighting outdoor events to be televised in color and in radioactive tracers for controlling flow of underground fluids in petroleum production. Small quantities of scandium were also consumed in magnesium alloys and in the electronics and chemical industries.

Prices.—The price of scandium oxide, 99.9% Sc_2O_3, as quoted by Research Chemicals, remained unchanged from that of 1972 at $2.80 per gram in lots of 100 to 453 grams; the price of scandium metal in ingots and distilled grades was $8 and $15 per gram, respectively; whereas that of powder and chips remained unchanged at $10.35 per gram. Prices for scandium sheet foil were $17.85 to $105 per square inch for 51- to 100-square-inch lots, ranging from 0.001 to 0.1 inch in thickness. For most items, larger quantities were available at lower prices.

Foreign Trade.—Official U.S. foreign trade statistics did not report trade in scandium as such but included scandium with other minerals and metals. However, based on available information, Australia and the Communist countries, probably the U.S.S.R., were the principal suppliers of scandium-bearing raw materials.

World Review.—Information on scandium-related activities in foreign countries was not readily available. The industrialized nations were involved in scandium research and used small quantities of scandium in industrial applications.

Technology.—A magnetically controlled switch, which can modulate light, was developed in Bell Laboratories. The switch consists of a thin film of single-crystal yttrium-gallium-scandium iron garnet, a small electric circuit, and two prisms that guide the light beam into and out of the garnet. Electric current creates a magnetic field, which causes the light beam to change its polarization and direction. Development of the new light switch permits use of laser beams instead of wire conductors, coaxial cables, and microwaves in future communication systems.[20]

Because of good hydrogen absorption properties of scandium, a new scandium detector was developed for use with a gas chromatograph. The device can operate at temperatures up to 325° F. The new detector has successfully analyzed residues of pesticides in samples of vegetable crops at the 0.1-part-per-million level.[21]

Scientists of the Australian Atomic Energy Commission at Lucas Heights, New South Wales, developed an instrument that employs gamma radiation from radioactive scandium oxide tracers to measure the density of wood and locate termite colonies. Termites were fed with the radioactive tracer, which was later excreted and used to build nest walls. A portable Geiger counter would locate these nests by indicating areas of anomalous radioactivity.[22]

SELENIUM[23]

Domestic production of selenium from primary materials was 627,000 pounds in 1973, a 15% decrease from 1972 production. Shipments by domestic producers decreased 10% with the difference supplied by stocks, which were reduced 55,000 pounds to 106,000 pounds at yearend. World production decreased 9% to 2,458,000 pounds. Congress authorized disposal of selenium held in the national stockpile on August 11, 1971, and during 1971 and 1972 a total of 16,090 pounds of metal was sold or traded. During 1973 a total of 329,790 pounds of selenium was sold or exchanged for strategic commodities needed for the national stockpile. At the end of 1973, the national stockpile contained 128,894 pounds of uncommitted selenium.

Table 8.—Salient selenium statistics

(Thousand pounds of contained selenium)

	1969	1970	1971	1972	1973
United States:					
Production	1,247	1,005	657	[1] 739	[1] 627
Shipments to consumers	1,429	1,056	663	[1] 761	[1] 682
Imports for consumption	546	454	395	430	553
Stocks, Dec. 31, producers	240	189	182	161	106
Producers average price per pound commercial and high-purity grades	\$7–\$8.50	\$9–\$10.50	\$9–\$11.50	\$9–\$11.50	\$9.25–\$12.36
World: Production	2,834	2,883	2,506	2,687	2,458

[1] In addition, an estimated 30,000 pounds of selenium was refined from secondary sources.

Domestic Production.—Primary selenium was produced at four plants operated by the following major electrolytic copper refiners: American Metal Climax, Inc., Carteret, N.J.; American Smelting and Refining Company, Baltimore, Md.; The Anaconda Company, Perth Amboy, N.J.; and Kennecott Copper Corp., Garfield, Utah. Crude materials containing primary selenium were transferred to these plants from copper refineries operated by Inspiration Consolidated Copper Co., Magma Copper Co., and Phelps Dodge Corp. An estimated 30,000 pounds of selenium was recovered by domestic secondary refineries from purchased electronic scrap. Considerable selenium home scrap was reused by manufacturers after outside reprocessing under toll contracts. Some domestic selenium-containing material was shipped to foreign plants for refining. High-purity selenium and various selenium compounds were produced by primary and other processors from commercial-grade metal.

In September the American Smelting and Refining Company began constructing a 420,000-ton-per-year electrolytic copper refinery near Amarillo, Tex., that will eventually replace a plant of 312,000-ton capacity at Baltimore, Md. The new, larger plant will recover byproducts, including selenium, and its completion will increase domestic selenium production capacity.

Consumption and Uses.—Apparent selenium supply and consumption, consisting of producer shipments, net imports, and stockpile releases, increased about 34% over that in 1972. Selenium demand, as indicated by dealer prices, increased moderately during the first 10 months of the year and increased sharply in November and December. Most of the increased use occurred in electronic applications. Major uses were electronic components, 45%; ceramics and glass, 34%; chemicals, 13%; and other, 8%.

Consumption of selenium in xerography increased during 1973, and this use now consumes over one-fourth of the primary metal shipped. More efficient use of selenium in xerographic copying machines and reclaiming of home scrap have kept the consumption of primary selenium in xerography from increasing as fast as the use of xerographic copying machines. However, new applications in this field promise a larger future demand. Selenium consumption for rectifiers, photoelectric cells, and other electronic applications increased, although more slowly than industrial production of these items owing to more efficient use of selenium. These uses consumed about one-fifth of the selenium marketed. Use of selenium in glass manufacturing increased because of increased glass production.

Small proportions of selenium compounds are added to glass melts to neutralize the green coloration caused by iron. Larger proportions are used to produce gray and bronze tinted window glass that reduces glare and heat transmission and to produce red- and amber-colored glass for signals and decorative uses. Demand for selenium in pigments and steel alloys increased significantly. Other chemical, pharmaceutical, and miscellaneous uses increased slightly over those in 1972.

Prices.—The producers' price remained at \$9 per pound for commercial-grade selenium and \$11.50 per pound for high-purity metal from the start of 1973 until April 2 when one producer increased the price of each metal grade by \$1 per pound. Other producers did not change their price, and the split quotation continued until June and was then frozen by the Cost of Living Council. Selenium prices were decontrolled on December 10, and domestic producers increased their prices to \$11 and \$12 per pound for commercial grade and $14 per pound for high-purity grade and continued these quotations to the end of the year.

Domestic dealer prices of commercial-grade selenium were about $8.40 per pound at the start of 1973. The average price received at Government stockpile sales was $8.50 per pound on February 14; $9.10 per pound on June 25; $9.68 per pound on August 27; and $12.88 per pound on November 15. At the end of December, dealer selenium prices were $17 to $17.50 per pound for commercial-grade metal.

Canadian producers priced commercial-grade selenium at $9 per pound from January to late March, at $10 per pound from late March to late October, and at $11 per pound for the remainder of the year. European dealer prices for the commercial grade increased from $9 to $10 per pound during the first half of the year, increased further to $11.50 per pound in late September, and to $17.50 per pound in late October, with this price continuing the remainder of the year.

In August principal European metal dealers formed the Minor Metals Traders Association, open to dealers in minor metals including selenium. The association plans to set up standard sales contracts for minor metals and possibly establish a minor metal trading ring and arbitration panel.

Foreign Trade.—Selenium exports increased about 20% from those of 1972; the largest shipments were made to West Germany, the Netherlands, and the United Kingdom.

Selenium imports for consumption increased 29%, and the value of imports increased 32%. Canada continued to be the main supplier.

Total	43	556

[1] Less than ½ unit.

World Review.—World refinery production is shown in table 10. Japan was the leading selenium producer, U.S. was second, and Canada was third. These three countries accounted for 82% of world production (excluding the U.S.S.R.).

Zambia.—Sludges and slimes from electrolytic copper refineries are treated outside Zambia for recovery of selenium and other byproducts. In 1973, plans were made to build a plant in Zambia to recover the byproducts. The plant will be located near the Ndola Copper Refinery and is expected to be operational in 1976.

Technology.—The Selenium-Tellurium Development Association, Inc., continued sponsorship of research programs designed to increase selenium utilization.

On April 27, 1973, the Food and Drug Administration (FDA) proposed that animal feed regulations should be amended to allow the addition of selenium as a nutrient in the feed of chickens, turkeys, and swine. The FDA set the minimum dietary requirement for available selenium in feed at 0.1 part per million (ppm) for swine and for chickens up to 16 weeks in age, and at 0.2 part per million for turkeys. A dietary intake of less than these amounts may result in a variety of debilitating, or even fatal, afflictions such as exudative diathesis, and degeneration of organs and musculature. The selenium content of corn grown in the Midwestern States varies from 0.01 to 2.03 parts per million selenium with the median being 0.05 part per million. Thus the addition of selenium is desirable to feed grown in most States. Studies made for the FDA established that the addition of the recommended quantities of selenium to animal and poultry feed would not cause a significant increase in the selenium content of animal tissue consumed by humans. The present human dietary intake of selenium in the United States was shown to be adequate for good nutrition and safely below the toxic level for selenium ingestion.[24]

e Estimate. p Preliminary. r Revised.

[1] Insofar as possible, data relate to refinery output of elemental selenium only; thus countries that produce selenium in copper ores and concentrates, blister copper, and/or refinery residues but do not recover elemental selenium have been excluded to avoid double counting.

[2] In addition to the countries listed, West Germany and the U.S.S.R. are known to produce refined selenium, and Zaire and Zambia may produce refined selenium, but available information is inadequate to make reliable estimates of output levels.

[3] Exports.

[4] Recoverable selenium content of blister copper treated at domestic refineries plus refined selenium from domestic raw materials, but excludes other unspecified materials that provide a portion of total refined selenium output. Corresponding figures for previous years in thousand pounds are 1971—719; 1972—655.

Increasing fuel and energy costs resulting from the petroleum shortage stimulated interest in greater use of selenium-tinted window glass to reduce heat-transfer rates. Increasing interest was also shown in direct conversion of sunlight to electricity with photogalvanic cells. A new analytical method was developed at North Carolina State University to rapidly determine small quantities of mercury and selenium in coal and other materials. A new low-energy photodetector is used to improve the neutron activation method. Instrumental errors of less than 0.1 part per million are indicated.[25]

TELLURIUM [26]

Domestic tellurium production of 241,000 pounds in 1973 was 6% below that of 1972. Domestic shipments of 287,000 pounds were the highest on record and were 6% above those of 1972. Producer stocks were drawn down 46,000 pounds to 56,000 pounds, the lowest inventory since before World War II. Imports decreased to a normal 71,000 pounds from the unusually high 1972 receipts.

Domestic Production.—Production of tellurium was reported by the following major electrolytic copper or lead refiners: American Metal Climax, Inc., Carteret, N.J.; American Smelting and Refining Company, Baltimore, Md.; The Anaconda Company, Perth Amboy, N.J.; and United States Smelting Lead Refinery, Inc., East Chicago, Ind., a division of UV Industries, Inc. Electrolytic refinery sludges containing primary tellurium were also produced at refineries operated by Inspiration Consoli-

dated Copper Co., Kennecott Copper Corp., Magma Copper Co., and Phelps Dodge Corp. High-purity tellurium, tellurium master alloys, and tellurium compounds were produced by primary and intermediate processors from commercial-grade metal and tellurium dioxide.

Production of tellurium was terminated at the United States Smelting Lead Refinery, Inc., during the year because of the exhaustion of unrefined tellurium inventories accumulated during a previous operating period when large quantities of primary lead containing tellurium were refined. Two copper refinery expansions were begun or announced that will result in the future recovery of larger quantities of tellurium-containing electrolytic-copper-refining sludge. Plans were also announced for future byproduct tellurium production from gold telluride deposits in which development has been resumed following the rapid increase in the price of gold.

Consumption and Uses.—Apparent consumption, as indicated by shipments plus imports for consumption, was 358,000 pounds, a reduction of 14% from that in 1972. However, actual consumption probably increased during 1973 with dealer and fabricator inventories being drawn down as were producer inventories. About 65% of tellurium consumed in 1973 was used as a free-machining agent in carbon and stainless steel and as a chilling agent in cast iron. In 1973 carbon steel production increased 20%, stainless steel 22%, and iron and steel castings 12%. Tellurium consumption in iron and steel products showed a similar increase. About 17% of the tellurium consumed was used in free-machining copper. Consumption of copper ingots and ingot bars increased about 3% with about the same increase being made in tellurium usage. Rubber manufacturing consumed about 10% of all tellurium used, chemicals about 6%, and electronic and other uses 2%. Small increases in tellurium consumption were made in these industries.

Prices.—The producer price for commercial-grade powder and slab remained at $6 per pound from 1962 until December 10, 1973, when, following decontrol of tellurium prices by the Cost of Living Council, producers increased their price to $7 per pound and continued this quotation to the end of the year. Merchant prices remained close to producer prices throughout the year. Prices for high-purity grades of tellurium ranged from $10 to $32 per pound.

Foreign Trade.—Imports in 1973 totaled 71,000 pounds, compared with an unusually high import of 146,000 pounds in 1972. The average import during the past 5 years has been 85,000 pounds. Canada and Peru continued to supply nearly all of the U.S. imports.

World Review.—The United States continued to lead the world in tellurium output; Japan was second, and Canada was third.

THALLIUM [27]

Thallium is a highly toxic metallic element that is limited in its use and size of market.

Domestic Production.—Thallium is recovered as a byproduct from flue dust and residue produced in the smelting of base metals, principally zinc. American Smelting and Refining Company Globe Plant at Denver, Colo., was the only domestic producer of thallium and thallium compounds. Production and shipments were nearly the same as those for 1972. Domestic and world identified resources of thallium from zinc, lead, and iron sulfides were 266 tons and 1,390 tons, respectively. Additional U.S. and world resources contained in coal ash are 119,000 and 715,000 tons, respectively.[28]

Uses.—Estimates of world consumption of thallium approximates 30,000 pounds annually. U.S. requirements are about one-fifth of the world requirements.

The current uses of thallium are primarily in electronics and metallurgical processing; minor applications are in glass, agriculture, medicine, and explosives. Some thallium compounds are extremely photosensitive, especially to light of low intensity. This unique property of specific compounds promises new and interesting applications. Uses and demand are limited by the need for comprehensive research into its complete physical and chemical properties and into its potential uses. The highly toxic nature of thallium salts is a deterrent, and substitutes are available for some of its present applications.

Storage batteries with silver thallium iodide solid electrolyte were under investigation in Japan. Mixed crystals of AgI-TlI were prepared. Results after testing indicated very small changes in voltage and current after 8 hours of discharging.[29]

Thallium sulfate, a highly toxic pesticide, is still turning up in the marketplace after 7 years of warning of its dangers. The Environmental Protection Agency requested all retail outlets to surrender all supplies. Continued sale subjects the dealer to civil and criminal penalties.[30]

Prices.—The price of thallium in 25-pound lots has been $7.50 per pound since December 1957.

Foreign Trade.—U.S. imports for consumption in 1973 were 541 pounds of unwrought and waste and scrap thallium valued at $1,730. The amount was only about one-third of that imported in 1972. Thallium compounds imported were 258 pounds valued at $4,030.

GREENSAND [1]

Greensand (glauconite) continued in 1973 to be produced only by the Inversand Co., Clayton, N.J., a subsidiary of Hungerford and Terry, Inc. Production and sales data are withheld to avoid disclosure of company confidential data. Production in 1973 was approximately at the same rate as in 1972.

Most of the product was treated and used by the parent company in its line of water conditioning equipment. Crude greensand was also used as a soil conditioner in agriculture.

A cooperative agreement continued between the Federal Bureau of Mines and the Geological Survey of the State of Delaware to develop new uses for greensand. Possible use in treating industrially polluted water was being considered, and various water samples were analyzed to determine the basic chemistry involved.

IODINE [2]

Consumption of crude iodine did not change appreciably from 1972, and there was a continued supply surplus for most of 1973. Industry stocks were still high in late 1973, although lower than a year ago. Domestic output, which represented a small part of overall supply, decreased considerably as compared with 1972, whereas imports showed no great change.

Crude iodine production in non-Communist countries dropped by possibly 400,000 pounds or 2%, almost all accounted for by Japan. Output by Chile, the world's second ranking iodine producer, was close to the 1972 level. Japan increased the price of its iodine from $1.86 per pound to $2.06, and was virtually the sole supplier of iodine to the United States for the second straight year. Chile cut the price of its iodine from $2.27 to $2.06 per pound in the hope of meeting Japanese competition. Domestic iodine was still quoted at $2.27, and there seemed to be some difficulty in selling at this price. The price of Japanese iodine went up abroad, directly as a result of the upward evaluation of the yen which subsequently declined slightly by yearend.

Legislation and Government Programs.—On December 31, 1973, the Government strategic stockpile contained 2,955,842 pounds of crude iodine and the supplemental stockpile 5,055,972 pounds for a total of 8,011,814 pounds. The stockpile objective for iodine, established by the Office of Preparedness, was reduced from 7.4 million pounds to nothing in early 1973. However, there were no disposals of iodine from the Government stockpile in 1973, because of the lack of Congressional approval.

Total	[1] 30	5,258	100	[1] 32	5,770	100

W Withheld to avoid disclosing individual company confidential data; included with "Other inorganic compounds."
[1] Nonadditive total because some plants produce more than one product.

Domestic Production.—The Dow Chemical Co., the only domestic producer, recovered crude iodine from well brines at Midland, Mich., as a coproduct with bromine, calcium and magnesium compounds, and potash. The process employed has been used since the start of operations in 1964. Compared with 1972, ouput decreased by approximately 20%.

Consumption and Uses.—Based upon a Bureau of Mines canvass, approximately 5.77 million pounds of crude iodine was consumed by 32 firms in 13 States. Leading iodine-consuming States in 1973, in descending order of magnitude, were Missouri, New York, Pennsylvania, and New Jersey which together accounted for more than four-fifths of the total crude iodine consumption.

The above information is indicative of the consumption pattern, but is not necessarily completely comprehensive. Iodine and iodides used as catalysts and "dissipative" uses in general, particularly in making synthetic rubber, are not well covered. Imports alone have been consistently higher than reported consumption, with net differences as follows, in thousand pounds: 1970, 981; 1971, 2,473; 1972, 949; and 1973, 348. A more exact estimate of apparent consumption cannot be published, as U.S. production figures for crude iodine cannot be revealed.

Iodine consumed in making immediate downstream products, such as resublimed iodine, potassium iodide, sodium iodide, and organic iodine-containing compounds, have not shown any radical changes in recent years. As for ultimate downstream uses, the major categories for 1973 were roughly as follows, in order of descending importance as consumers of iodine: Catalysts (in rubber), food supplements, stabilizers (in nylon), inks and colorants, pharmaceuticals, sanitary uses, and photographic uses. Iodine was also consumed in making high-purity metals, motor fuels, iodized salt, photographic chemicals, smog inhibitors, swimming pool sanitizers, and lubricants.

Prices.—The price of Japanese iodine went up to $2.06 per pound around mid-February 1973. U.S. iodine was quoted at $2.27 all year, whereas Chilean iodine was brought down from the U.S. price to the Japanese level in mid-1973. As usual, prices had little to do with supply and demand, since an oversupply situation was accompanied by high prices. Quoted prices for iodine and iodine compounds at yearend 1973 were as follows:

	Per pound
Crude iodine, drums	$2.06–$2.27
Resublimed iodine, U.S.P., drums, f.o.b. works	3.97– 4.00
Calcium iodate, drums, delivered	2.50– 2.80
Calcium iodide, 35-pound drums, f.o.b. works	5.98
Potassium iodide, U.S.P., crystals, drums, 1,000-pound lots, delivered	2.60– 3.15
Sodium iodide, U.S.P., crystals, 300-pound drums, freight equalized	3.50– 3.91

Source: Chemical Marketing Reporter.

Foreign Trade.—Crude iodine imported into the United States in 1973 declined by 1.4% in quantity as compared with 1972, but total value increased 3.0%. The average value (f.o.b. originating country) of imported crude iodine rose from $1.64 per pound in 1972 to $1.71 in 1973, reflecting primarily changes in Japanese prices and discounts during actual transactions. About 6.1 million pounds of crude iodine was im-

Table 2.—U.S. imports for consumption of crude iodine, by country

(Thousand pounds and thousand dollars)

Country	1971		1972		1973	
	Quantity	Value	Quantity	Value	Quantity	Value
Chile	2,950	5,679	--	--	88	160
Japan	4,325	5,831	6,207	10,184	6,030	10,324
Total	7,275	11,510	6,207	10,184	6,118	10,484

ported, almost all from Japan. In an oversupply situation, high-priced Chilean iodine was hardly attractive in the U.S. market. Imports of resublimed iodine were nominal as compared with imports of crude iodine.

World Review.—*Chile.*—Production of crude iodine in 1973 as a byproduct of nitrates probably was less than 2,500 short tons. Output was on the low side for Chile, but even the upper limit would not be much greater, since iodine extraction is primarily controlled by nitrate production. The change in Chile's Government, marketing difficulties, and operating problems were factors holding back production.

Chile's three iodine plants, namely, Valdivia, Victoria, and Elena, were all owned by Sociedad Química y Minera de Chile S.A. (SOQUIM). The two latter plants were run at full capacity during most of the year. However, Valdivia, the most modern and largest plant, had not yet totally recovered from a major fire in late 1971 and may not be able to produce as much as previously without basic repairs requiring large additional investment.

Chile priced itself out of the U.S. market during all of 1972 and most of 1973, shipping almost completely to European and Latin American countries and the People's Republic of China. Lowering iodine price from $2.27 per pound to $2.06 did not result in immediate better sales, although small shipments started to arrive in the United States near yearend.

China, People's Republic of.—An estimate of China's iodine output is not possible, although the quantity is known to be small. Some iodine reportedly has been produced at the Haifang seawater salt processing plant in Amoy, Fukien Province, and the Peihai chemical plant of the Pingkuei Mining Administration in Kwangsi Province. Recently recovery of iodine and bromine from complex salts was started at the Yuncheng salt basin in southern Shansi Province at the "Chin Chien-cheng Chemical Industry Base."[3] China is short of iodine, making up the deficiency mainly through imports from Chile with whom trade agreements specify shipments of approximately 660,000 pounds annually. Exports from Japan to China were only 8,800 pounds in 1972 and 29,000 pounds during 1973.

Indonesia.—Abundant supplies of brackish water in many localities of Indonesia represent a significant potential source of iodine. Japanese and European firms both have been interested in these possibilities. In the fall of 1973, Ise Chemical Industries, Ltd., of Japan announced that it had applied to the Indonesian Government for approval to establish a joint venture with Mitsui & Co. and Indonesian interests.[4] Ownership would be 55% for the Japanese during the first 10 years and changing to 55% for the Indonesians thereafter. Specific locations were not mentioned, but development would take 3 or 4 years and eventual annual output may reach 1 million pounds of iodine.

Japan.—Japan continued to be the world's foremost iodine producer during 1973. Its output of 8,038 short tons of crude iodine, a decline of about 2.5% from the 8,240 tons produced in 1972, was still more than three times that of Chile, the only other major non-Communist nations producer. Over four-fifths of the Japanese production was exported, mainly to the United States which took about 3,015 short tons in 1973. Japan's other iodine markets included European Community countries, India, Switzerland, the U.S.S.R., and Canada.

Natural gas brines are the source of Japan's iodine which is recovered along with

[3] Ta-kung-pao (Peking). May 28, 1972, p. 1.
[4] Japan Chemical Week (Tokyo). Ise Chemical Eyes Joint Iodine Venture in Indonesia. V. 14, No. 699. Sept. 20, 1973, pp. 1, 5.

natural gas. Eighteen plants owned by five manufacturing groups provide the entire output. Except for one in Niigata in northwest Honshu, all iodine plants are located around Kujikurihama in Chiba Peninsula east of Tokyo. Only about one-third of the plants have been built in the last few years, and the older ones are having some operating problems.

Although Japan's crude iodine capacity was about 9,000 short tons per year at yearend 1973, possibly a third of this may not be operable in the near future because of ground subsidence difficulties related to withdrawal of brines and not pumping solutions back. Ise Chemical Industries, Ltd. (Ise Chemical), was the leading firm, with roughly half of the country's capacity and most of the best plants. In addition to its own seven plants, Ise Chemical runs a plant for Teikoku Oil Co. Ltd (Teiseki) and another one for United Resources (Godo). Godo, with two plants, had about one-fifth of Japan's capacity. Nippon Tennen (Nitten) with three plants and Kantoh Tennen (Kanten) with four plants each had just over one-tenth of the total capacity. Two sister companies, Nippon Chemical Industries and Nippon Halogen, have one plant each. At least three other firms, Teiseki, Tokyo Gas Co., and Fuji Boring Co., have been extracting natural gas in the Chiba City area, and they have agreed to abandon their wells by 1976.

The pattern of Japanese iodine production started to undergo basic changes in 1973. Japan's Environment Agency, the Ministry of International Trade and Industry, and Chiba Prefectural authorities initiated a series of stringent measures to protect the highly-populated area of Chiba from further ground subsidence and tidal wave flooding brought about in part by withdrawal of brines.[5] New wells will be prohibited except in special cases, existing wells will be abandoned if shown to be causing subsidence, water will be recycled if possible, water discharge will be controlled, and drilling will be coordinated. The net result means that Japan's iodine production capacity will decrease in the next few years, and an upturn will not take place until the second half of the 1970's. Ise Chemical's facilities in Chiba will suffer the least, and more new iodine operations will be developed by Teiseki and Ise in northeastern Honshu.

U.S.S.R.—Iodine apparently is produced at the Neftechlinski field, the Slavyansko-Troitskoe area near the Black Sea, and at a plant in the Baku area. Soviet iodine output may have tripled between 1966 and 1971, to 3.3 million pounds in the latter year.[6] Unknown, but probably not too large, quantities of iodine are presumably imported from Chile. Soviet iodine imports from Japan were about 250,000 pounds in 1972 and 330,000 pounds from January to October 1973.

LITHIUM [7]

Domestic output of lithium minerals and lithium carbonate from brines increased substantially over that of 1972, and was the largest ever reported. Imports for consumption of lithium minerals were 5 times the quantity imported in 1972.

Legislation and Government Programs.—The General Services Administration (GSA) sold 950 short tons of lithium hydroxide monohydrate during 1973. At yearend 5,540 short tons of lithium hydroxide monohydrate were held by GSA under the Federal Property Act.

Domestic Production.—Foote Mineral Co. mined and milled spodumene from pegmatites at Kings Mountain, N.C., and also recovered lithium carbonate from brines at Silver Peak, Nev. Lithium Corp. of America, a subsidiary of Gulf Resources and Chemical Corp., mined and milled spodumene near Bessemer City, N.C.; Kerr-McGee Corp. recovered lithium carbonate from brines at Trona, Calif.

Lithium Corp. of America completed an expansion of their mine and plant at Bessemer City, N.C., early in the year.

Processors of lithium raw materials to lithium primary products were Foote Mineral Co., Sunbright, Va., and Silver Peak, Nev., Kerr-McGee Corp., Trona, Calif., and Lithium Corp. of America, at Bessemer

[7] Prepared by Donald C. Wininger, physical scientist.

City, N.C. Production data were not available for publication.

Consumption and Uses.—Domestically produced lithium minerals were processed into numerous lithium chemicals for a wide variety of applications. Major uses were in primary aluminum production, ceramics, greases, air conditioning, alloying, welding and brazing, swimming pool sanitation, and organic synthesis.

Although consumption of most lithium compounds increased during the year, sales of lithium carbonate to the aluminum industry continued to show the most significant increase. A special grade of high-purity lithium carbonate is being used in the production of photochromic optical glass. This is a specialized but growing market.[8]

Prices.—Domestic prices of lithium minerals are usually determined by direct negotiation between buyer and seller and are seldom published. However, Ceramic Industry, in January 1973, listed prices for spodumene supplied to the ceramic industry ranging from $77 to $89.50 per ton, unchanged from the previous year.

Prices for the major lithium compounds at yearend were quoted in the Chemical Marketing Reporter as follows:

	Per pound
Lithium metal, 1,000-pound lots or more delivered	$8.18
Lithium bromide, anhydrous, drums, ton lots, delivered	1.70
Lithium carbonate, powder, carlots, truck loads, delivered	.555
Lithium chloride, anhydrous, carlots, truck loads, delivered	.94
Lithium fluoride, carlots, truck loads, delivered	1.63
Lithium hydride, carlots, truck loads, delivered	8.05
Lithium hydroxide, monohydrate, carlots, truck loads, delivered, in drums	.63
Lithium nitrate, technical 100-pound lots, in drums	1.25–1.55
Lithium stearate, 50-pound cartons, carlots, works, freight allowed	.61–.64
Lithium sulfate, 100-pound lots, in drums	1.20–1.30

Foreign Trade.—Exports of lithium hydroxide declined from 1,097,175 pounds valued at $595,232 in 1972 to 1,043,459 pounds valued at $604,730 in 1973. Quantitative data on exports of lithium minerals and lithium metal, alloys, and other compounds were not available. Domestic imports of lithium minerals were 5 times the 1972 level. Brazil supplied 87% of all the imports. Imports of lithium compounds were 22,298 pounds valued at $82,312, principally from France (83%) and the United Kingdom (14%) with small amounts from Canada and West Germany.

World Review.—*Canada.*—In Manitoba the Chemalloy Minerals subsidiary, Tantalum Mining Corp., began production of lithium concentrates from a 150-ton-per-day pilot mill at its Bernic Lake mine site in early May.[9] If the results of this work are favorable, the plant will be expanded to between 350 and 450 tons per day.

Technology.—Lithium battery development work continued at a high level during the year. A number of articles in the Journal of the Electrochemical Society during the year reported on the results of various phases of the research.

Table 3.—U.S. imports for consumption of lithium ore, by country of origin and U.S. customs district

Country and customs district	1972 Quantity (short tons)	1972 Value (thousands)	1973 Quantity (short tons)	1973 Value (thousands)
Baltimore district:				
Australia	1,215	$33	--	--
Brazil	--	--	5,303	$334
South Africa, Republic of	--	--	565	47
Pembeina: Canada	--	--	205	51
Total	1,215	33	6,073	432

GTE Laboratories Inc. announced the development of an experimental lithium battery which is said to produce 8 times more energy than a conventional flashlight cell and has a life of more than 2 years. "Initial applications may be in flashlights, portable radios, calculators, cameras, hearing aids, wrist watches and other portable battery powered products."[10]

e Estimate. p Preliminary. r Revised. W Withheld to avoid disclosing individual company confidential data.

[1] In addition to the countries listed, others (notably the U.S.S.R.) may produce lithium minerals, but available information is inadequate to make reliable estimates of output levels.

[2] U.S. imports from listed producing country.

[3] Output has not been reported since 1964, but presumably has continued. Figures given are simply the 1964 output level rounded to the nearest thousand tons, and are presented only to indicate order of magnitude of previous production, there being no assurance that the output level has not varied (see also footnote 4). In 1964, total reported production was distributed as follows by mineral, in short tons: Eucryptite—806; lepidolite—22,943; petalite—36,449; spodumene—6,965.

[4] Output has not been reported since 1966, but presumably has continued, inasmuch as a number of countries record imports from "South Africa." Estimates given represent total reported imports from South Africa by the United States and the European Community less the reported output of the Republic of South Africa. These quantities, however, may include significant amounts originating in Southern Rhodesia (see footnote 3) rather than in the Territory of South-West Africa. In 1966, total reported production was distributed as follows, by mineral, in short tons: Amblygonite—30; lepidolite—365; petalite—1,344.

MEERSCHAUM [11]

No imports of crude meerschaum were reported in 1973. The United States does not produce meerschaum and is dependent upon foreign sources. Historically, over a 53-year period, 1920–72, the United States has imported approximately 722,400 pounds of crude meerschaum, valued at approximately $1.46 per pound. Primary domestic use of the meerschaum has been in smoking articles, such as pipes and cigarrette holders.

Meerschaum from Turkey has accounted for about 80% of the total 722,400 pounds exported to the United States. Other sources have been Austria, Belgium and Luxembourg, France, Italy, India, Iran, Japan, Kenya, Somali Republic, and the Republic of South Africa.

QUARTZ CRYSTAL [12]

ELECTRONIC-GRADE

Total raw natural and manufactured crystal consumption increased 32% over that of 1972. Consumption of manufactured quartz exceeded that of natural quartz, but consumption of both categories increased. Domestic manufactured quartz production increased significantly. Imports of natural quartz and exports of natural and manufactured quartz also increased. Production of finished crystals showed a small increase.

Legislation and Government Programs.—During 1973 the Government reduced the stockpile objective from 320,000 pounds to 209,000 pounds of electronic-grade quartz crystal. The GSA continued to sell excess stockpiled quartz crystal. The Defense Materials Inventory declined from 4.34 million pounds of stockpile-grade and 352,960 pounds of nonstockpile-grade material at the end of 1972 to 4.05 million pounds of stockpile-grade material and 175,096 pounds of nonstockpile-grade material at the end of 1973.

Domestic Production.—There was no reported domestic production of natural electronic-grade quartz crystal during 1973. At yearend six companies reported production of manufactured quartz for use by the quartz crystal cutting industry. These companies were P.R. Hoffman Co., Carlisle, Pa.; Motorola, Inc., Chicago, Ill.; Quality Crystals, Inc., Cortland, Ohio; Sawyer Research Products, Inc., Eastlake, Ohio;

[11] Prepared by Arthur C. Meisinger, industry economist.

[12] Prepared by Benjamin Petkof, physical scientist.

Thermodynamics Corp., Shawnee Mission, Kans.; and Western Electric Co., Inc., North Andover, Mass. The firms producing manufactured quartz remained unchanged from the previous year. Manufactured quartz production increased 30% from the quantity reported in 1972 to 207,541 pounds.

As of May 1, 1973, all the outstanding shares of Sawyer Research Products, Inc. were purchased by Brush Wellman, Inc., of Cleveland, Ohio. Brush Wellman, Inc., announced an expansion of Sawyer's facilities to meet the increasing demand for quartz crystal.

Table 5.—Salient electronic- and optical-grade quartz crystal statistics

(Thousand pounds and thousand dollars unless otherwise noted)

	1971	1972	1973
Production of manufactured quartz	110	160	208
Imports of electronic- and optical-grade natural quartz crystal			
Quantity	35	65	104
Value	76	78	92
Exports of electronic- and optical-grade quartz crystal			
Quantity	174	149	287
Value	1,626	1,228	3,283
Natural:			
Quantity	113	90	205
Value	833	587	1,933
Manufactured:			
Quantity	61	59	82
Value	793	641	1,350
Consumption of raw electronic-grade quartz crystal	133	189	249
Natural	62	87	99
Manufactured	71	102	150
Production piezoelectric units, number ... thousands	20,924	25,555	27,006

Consumption and Uses.—Total raw quartz crystal consumption increased from 189,078 pounds in 1972 to 248,929 pounds in 1973. Consumption of natural quartz increased 14% from 87,157 pounds in 1972 to 99,395 in 1973. Manufactured quartz consumption increased 47% from 101,921 pounds to 149,534 pounds in 1973. The consumption of manufactured quartz exceeded that of natural quartz for the third consecutive year. The number of finished crystal units fabricated from raw quartz (natural and manufactured) consumed during the year reached 27 million units. The 1973 consumption data reported in table 5 are based on reports received from 32 crystal cutters in 13 States. Finished piezoelectric units were produced by 28 of the cutters, the remainder produced only semifinished blanks. Of these, two consumed natural quartz only, 19 cut manufactured quartz only, and 11 cut both natural and manufactured quartz. Thirteen consumers in four States accounted for 86% of the raw quartz crystal consumption. Pennsylvania was the leading quartz-consuming State with 42% of the total, followed by Illinois, Kansas, and Massachusetts.

Piezoelectric units were manufactured by 36 producers in 16 States. Nine of these producers worked from partially processed quartz crystal blanks and consumed no raw quartz (natural or manufactured). Fourteen plants in four States, Kansas, Illinois, Pennsylvania, and Massachusetts, supplied three-fourths of the total output of finished crystal units. Oscillator plates comprised 82% of production. The remainder included filter plates, telephone resonator plates, and other miscellaneous items.

Stocks.—At yearend, stocks of raw quartz crystals held by consumers totaled 114,205 pounds. Of this total 90,886 was natural material and 23,319 was manufactured quartz.

Foreign Trade.—U.S. exports of natural quartz crystal increased 128% from 90,246 pounds in 1972 to 205,420 pounds in 1973. Exports of manufactured quartz increased 40% from 58,914 pounds in 1972 to 82,241 pounds in 1973. The average price of natural quartz crystal exported was $9.43 per pound; that of manufactured quartz was $16.46 per pound.

Imports of electronic- and optical-grade natural quartz crystal, valued at more than $0.50 per pound, increased in both quantity and value in 1973 to 103,569 pounds and $92,258, respectively. This was an increase of 59% in quantity and 18% in value from the previous year's totals. The average value of imports was $0.89 per pound, a decline of 26% from the previous year's average value of $1.20 per pound. Brazil supplied 90% of the total imports of electronic-grade natural quartz. The remainder was supplied by the United Kingdom, France, West Germany, Japan, Malagasy Republic, and the Republic of South Africa.

A total of 961,205 pounds of lasca, valued at $271,332 was imported in 1973, an increase of 40% in quantity and 7% in value from 1972 data. The average value of imported material was $0.28 per pound. Lasca was used to manufacture fused quartz and as a nutrient material in the production of manufactured quartz crystal. Brazil provided 96% of total lasca imports, and the remainder was received from Japan.

World Review.—*Brazil.*—The Nation was the dominant world producer of natural quartz crystal. Exports of quartz crystal for electronic use totaled 783,000 pounds valued at $429,000 in 1973. In addition, 2 million pounds of lasca, valued at $1.4 million was exported.

Technology.—A device, using a coated piezoelectric crystal (quartz), has been developed for the detection and measurement of sulfur dioxide. The response of the device was observed as a function of sample size, weight of substrate application to the crystal, sulfur dioxide concentration, and sample volume. The instrument is rugged, portable, low cost and amenable to automation.[13]

Single crystals of ferroelectric lithium tantalate were grown as an alternate material for quartz crystal in the manufacture of piezoelectric resonator and filter devices. The lithium tantalate crystals were grown by the Czochralski crystal pulling technique.[14]

A paper was presented describing the hydrothermal synthesis of quartz and the manufacturing facility of a major producer. The advantages of manmade quartz, industry facts, the recent industry developments were discussed.[15]

STAUROLITE [16]

Staurolite is a complex hydrated ferrous-aluminosilicate mineral, some properties of which may differ from one specimen to another, implying some variability of composition. The mineral most commonly occurs as opaque reddish-brown to black crystals with a specific gravity ranging from 3.65 to 3.77 and between quartz and topaz in hardness (7 to 8 on Moh's scale). Aside from a small rock-shop trade in cruciform-twinned crystals from some deposits ("fairy crosses") that are sold as curiosities or amulets, staurolite is produced commercially in the United States only in the form of a magnetic fraction from heavy-mineral concentrates recovered by E. I. du Pont de Nemours & Co. from a deposit of ice age beach sand in Clay County, Fla.

Formerly the staurolite fraction so obtained was used mostly in portland cement mixtures, but more recently this product (with minor admixtures of several other minerals) is being marketed by Du Pont under two trade names, "Starblast" for use as a sandblast abrasive, and "Biasil" for mixing with bentonite and other substances to serve as a foundry sand in some specialized molding applications. Increasing industrial demand for these products can be inferred from the observation that the ratio of staurolite shipments to staurolite production, which had averaged around 1:2 in the 1965 to 1969 period, has been well over 1:1 in every year since, pointing to a substantial movement of previously stockpiled material. Quantitative data are not released for publication, but the 1973 production of staurolite was 60% greater than that of 1972, while shipments increased 22% in tonnage and 37% in total value.

STRONTIUM [17]

Domestic consumption of strontium on a strontium carbonate basis was estimated at 33,000 short tons in 1973, representing a 5% increase over the previous year. Although imports of strontium minerals declined for the second year, imports of strontium chemicals, primarily from Canada, increased ninefold compared with 1972.

Legislation and Government Programs.—The Government sold 8,010 short tons of stockpile-grade celestite during 1973. Government stockpiles contained 4,052 tons of stockpile-grade and 14,408 tons of nonstockpile-grade celestite at yearend.

Domestic Production.—Strontium minerals have not been produced commercially in the United States since 1959. However, a number of firms produced various strontium compounds from imported celestite.

Consumption and Uses.—Domestic consumption of celestite in the manufacture of various strontium chemicals declined from the 1971 high. Quantitative information concerning consumption is incomplete, however, one leading company reported a slight increase in 1973 over 1972. Sales of domestically produced strontium carbonate to manufacturers of glass for color television picture tubes declined considerably from 1972. The trend of celestite consumption in the manufacture of chemicals for pyrotechnics was not clear.

Miscellaneous applications for strontium compounds included ferrites, greases, ceramics, plastics, toothpaste, pharmaceuticals, paint, electronic components, welding fluxes, and high-purity zinc. Small quantities of imported strontium metal were used primarily by research companies.

Table 6.—Major producers of strontium compounds, 1973

Company	Location	Compounds
Atomergic Chemetals Co	Carle Place, N.Y	Various compounds.
J. T. Baker Chemical Co	Phillipsburg, N.J	Do.
Barium & Chemicals, Inc	Steubenville, Ohio	Do.
Chemical Products Corp	Cartersville, Ga	Carbonate.
E. I. du Pont de Nemours & Co., Inc	Grasselli, N.J	Nitrate.
FMC Corp	Modesto, Calif	Carbonate, hydrate, nitrate.
Hercules, Inc	Glens Falls, N.Y	Chromate.
King Laboratories Inc	Syracuse, N.Y	Metal alloys.
Mallinckrodt Chemical Works	St. Louis, Mo	Various compounds.
Mineral Pigments Corp	Beltsville, Md	Chromate, molybdate.
NL Industries, Inc., Tam Div	South Amboy, N.J	Titanates.

Prices.—At yearend, prices quoted in The Chemical Marketing Reporter were as follows: Strontium carbonate—technical, bags, carlots, works, at 13 to 21 cents per pound; strontium nitrate—bags, carlots, works, at $15 per 100 pounds, unchanged from the previous year. Prices for strontium minerals are usually determined by direct negotiation between buyer and seller and are seldom published. The average value of imported strontium minerals at foreign ports was $24.63 per short ton.

Foreign Trade.—Imports of strontium minerals totaled 27,040 tons, a 12% decline from 1972. The material was imported from Mexico, Spain, and Guatemala. Imports of strontium compounds increased 9 times over those of 1972 with most of the material coming from Canada (94%). In addition to the items listed in table 8, 4,189 pounds of organic strontium salts valued at $4,229 from the United Kingdom and 50 pounds of strontium metal valued at $375 from Canada were imported during 1973. Quantitative data on U.S. exports of strontium compounds were not available.

Table 7.—U.S. imports for consumption of strontium minerals,[1] by country

Country	1972 Quantity (short tons)	1972 Value (thousands)	1973 Quantity (short tons)	1973 Value (thousands)

e Estimate. p Preliminary. r Revised.
[1] In addition to the countries listed, West Germany, Poland, and the U.S.S.R. produce strontium minerals, but available information is inadequate to make reliable estimates of output levels.
[2] Year beginning March 21 of that stated.

World Review.—*Canada.*—Kaiser Strontium Products Ltd. marketed strontium chemicals worldwide from its plant at Point Edward, Cape Breton Island, Nova Scotia. Technical problems, however, continued to delay commercial-scale production of glass-grade strontium carbonate.

Technology.—A report of experimental work was published on the purification of strontium metal by reactive distillation.[18]

A paper was published presenting the results of studies on the characterization and sintering behavior of barium and strontium ferrites.[19]

[18] Kaldis, E., J. Muheim, J. Evers, and A. Weiss. Purification of Strontium by Reactive Distillation. J. Less-Common Metals, v. 31, No. 1, April 1973, pp. 169–173.
[19] Reed, James S., and Richard M. Fulrath. Characterization and Sintering Behavior of Ba and Sr Ferrites. J. Am. Ceram. Soc., v. 56, No. 4, April 1973, pp. 207–211.

A process for the purification of celestite, to obtain a glass- or ceramic-grade strontium carbonate analyzing about 99% pure was patented.[20]

WOLLASTONITE [21]

Wollastonite, which is a metasilicate of calcium that theoretically consists of 48.3% lime combined with 51.7% silica and varies in structure from massive to tabular to fibrous, occurs chiefly as a contact mineral along certain igneous rock-limestone interfaces and often in association with some variety of garnet. Wollastonite from selected deposits has found increasing use as an ingredient in ceramic mixes for glazes and enamels and especially for floor and wall tile; in the building industry for the production of mineral wool and cold-setting insulation foams, as a pigment and extender for paints, and to enhance the cross-rupture strength of cement-asbestos siding, shingles, and drainpipe; as a filling and felting agent for plastics, rubber, and asphalt products; in agriculture as a fertilizer and soil conditioner; in some glass-making formulations; and in a wide variety of other applications still being developed.

Wollastonite was produced in the United States in 1973 from one underground mine operated by Interpace Corp. at Willsboro, Essex County, N.Y.; output tonnage was 25% greater than in 1972, and the corresponding total value was 28% higher, new alltime highs for both figures. Notably, the 1973 tonnage also surpassed that of 1966, the record year hitherto, by 12%.

Wollastonite has been mined in California intermittently since 1933, but no commercial production has been reported in that State since 1969. A new firm, Western American Minerals Co., was organized in early 1973 with the announced aim of mining and processing wollastonite from a deposit near Hunter Mountain in California's Inyo County. Adverse weather, specifically an unprecedented heavy snowfall on access roads, was blamed for delaying the start of operations beyond the target date.

Chemical Marketing Reporter quoted wollastonite prices in bags, carlots, works, at $43.80 per ton for paint grade, fine, and $33.00 per ton for paint grade, medium, unchanged (both quotations) December 1971 through December 1973. The average unit value reported for production, all grades, advanced twice, however, in that same period. American Paint Journal, December 31, 1973, reported the following prices for wollastonite, paint grade: Extra gliders, bolted, $35.00 to $50.50 per ton; medium, carlots, f.o.b. plant, $29.00 per ton. Ceramic Industry Magazine, January 1974, listed wollastonite prices in the range from $22.50 to $37.00 per ton. It is to be understood, however, that actual sales of wollastonite were arranged as usual at negotiated prices not publicly disclosed.

A report was issued that presented reported or estimated figures for wollastonite production in Kenya, India, Finland, Mexico, and the United States in the years 1967 through 1971.[22]
