There were no imports of magnesium in 1940, and exports declined 59 percent compared with those estimated for 1939. The nominal quoted price for the metal at New York remained unchanged at 27 cents a pound throughout the year.

World production of magnesium in 1940 is believed to have increased about 29 percent. Although most of the metal was used in the construction of military airplanes, a substantial quantity also was employed in the manufacture of incendiary bombs, flares, and other munitions.

PRODUCTION

Primary magnesium.—Production of primary magnesium in the United States totaled 12,521,726 pounds in 1940 compared with 6,700,122 and 6,433,390 pounds in 1939 and 1938, respectively. The Dow Chemical Co.—the only domestic producer—recovered all the metal from brine containing 3.2 percent $MgCl_2$ (0.8 percent magnesium), pumped from underground wells near Midland, Mich. Here the bromine and the sodium and calcium salts first are removed by evaporation, filtration, and fractional crystallization; chlorine is added during the process. The purified magnesium chloride solution remaining is concentrated further by crystallization, and the $MgCl_2 \cdot 6H_2O$ thus formed is partly dried. Molten magnesium chloride with some added sodium chloride then is electrolyzed in rectangular cast-steel cells. Production at Midland was doubled in February 1940, when capacity was increased to 13,000,000 pounds a year. In April 1941 capacity again was enlarged, this time to 15,500,000 pounds.

A new plant at Freeport, Tex., with an unlimited supply of raw materials began to produce in January 1941 and probably will attain its originally rated annual capacity of 13,000,000 pounds in May 1941. With the expansion program under way this plant should reach a production rate of 19,000,000 pounds in September 1941 and 37,000,000 pounds early in 1942, giving Dow a total magnesium-producing capacity of 52,500,000 pounds. The last 18,000,000-pound addition is being constructed for Dow operation at a cost of about $8,000,000 by the Defense Plant Corporation, a Reconstruction Finance Corporation subsidiary. At Freeport, magnesium is recovered from sea water containing 0.48 percent $MgCl_2$ (0.12 percent magnesium). Milk of lime, obtained by adding water to calcined oyster shells, precipitates magnesium hydroxide (milk of magnesia) from sea water. The magnesium hydroxide is thickened, filtered, and treated with hydrochloric acid to produce magnesium chloride, which is made nearly anhydrous and electrolyzed by the same method employed at Midland. In addition to magnesium, Dow produces caustic soda, ethylene dibromide, and ethylene glycol at Freeport.

In February 1941 the Reconstruction Finance Corporation approved a loan of $9,250,000 to the chemical engineering division of the Todd-California Shipbuilding Corporation for the construction of magnesium producing and fabricating facilities at Permanente (near San Jose), Calif., the cost of which will total about $11,500,000. The company was immediately advanced $3,500,000, and erection of an 8,000,000-pound production unit was begun in March 1941 which the company expects will be in operation beginning August 1941. Capacity ultimately will be increased to 24,000,000 pounds or more a year. Magnesite and brucite occurring near Luning, Nev., will be calcined and the magnesium oxide treated by the relatively new Hansgirg direct electrothermal reduction process. The company also plans to employ magnesium oxide recovered from sea water by the Westvaco Chlorine Products Corporation near Newark, Calif. Reduction with carbon will take place in an electric arc furnace at about 2,000° C. The resultant metal vapor will be chilled suddenly and condensed at about 200° C. in natural gas instead of hydrogen which was formerly used in Austria where the process was developed.

Early in 1941, several other well-established chemical, metallurgical, and mining companies were considering domestic production of magnesium, using various raw materials [1] and processes.[2]

On January 30, 1941, the United States, through the Department of Justice, indicted the Aluminum Co. of America, American Magnesium Corporation, Magnesium Development Corporation, Dow Chemical Co., I. G. Farbenindustrie A. G., and the General Aniline & Film Co. for violating the antitrust laws and hampering the defense program. It charged the first four American firms with retarding and stifling production by pooling patents, maintaining high prices, limiting consumers to one domestic source of supply, and making unlawful agreements pertaining to foreign sales and output in the United States. The case probably will be tried in the fall of 1941 in the District Court of the United States for the Southern District of New York. In answer to the charges, the American Magnesium Corporation stated that patents have not restricted the domestic fabrication of magnesium metal into armaments for national defense or industrial purposes. The firm also stated that its affiliate, the Magnesium Development Corporation, formed in 1931 by the I. G. Farbenindustrie A. G. and the Aluminum Co. of America as a magnesium patent-holding company, does not restrict its licenses to any responsible and competent concern. The Dow Chemical Co. reports that its magnesium production process does not depend on foreign patents but admits that it has procured licensing rights on some fabricating methods that it has made available to industry without royalty.[3]

Secondary magnesium.—Substantial quantities of new and old magnesium scrap (chiefly the former) were consumed during 1940. The new scrap essentially is primary metal circulating in the consuming industry and has already been recorded as primary metal. Old scrap consumed in 1940 totaled 557,000 pounds, which is equivalent to 507,000 pounds of magnesium if one assumes that it consisted chiefly of alloy averaging 91 percent magnesium. Only one concern operates a secondary magnesium remelting plant exclusively on scrap. Most scrap is utilized by foundries manufacturing magnesium alloy sand castings from primary metal as well as scrap.

CONSUMPTION

In 1939 and 1940, after years of research and education, the aircraft, textile, portable tool and equipment, automotive, and other industries became more firmly convinced of the advantages of the light weight and high strength, machinability, and chemical and physical characteristics of magnesium-alloy products and consequently increased consumption of these alloys. In 1940, the huge Army, Navy, and

[2] Pannell, Ernest V., How Europe Produces Its Magnesium: Chem. and Met. Eng., vol. 48, No. 1, January 1941, pp. 78-81.
[3] Grant, L. B., Magnesium: Metals and Alloys, vol. 12, No. 6, December 1940, pp. 762-763.

British aircraft-construction program was set in motion, and demand soon overtook the supply of metal. Late in the fall of 1940 the aircraft industry was demanding virtually all of the magnesium produced, which discouraged the other newly developed commercial uses. Sales projects involving months of negotiation, designing, discussions, and testing had to be shelved, which adversely affected manufacturers of textiles, shoes, carpets, rubber goods, foundry equipment, optical apparatus, business machines, motor trucks, photoengravers' etching plates,[4] and other commodities.[5] Airplane makers meanwhile specified magnesium products for such new applications as oil tanks, baggage floors, landing-wheel dust covers, wheel fairings, conduit fittings, ventilating ducts, partitions, seat and instrument panels, carburetor bodies, and other parts, which involved the production of more sand and die castings, extrusions, and sheet.

Apparent domestic consumption of primary magnesium in 1940 increased 73 percent over the previous peak reached in 1939.

Production, sales, imports, exports, and apparent consumption of primary magnesium, in the United States 1938–40, in pounds

Year	Production	Sales	Imports	Exports	Apparent consumption[1]
1938	6,433,390	4,819,617	[2] 60	[3] 2,100,000	2,719,700
1939	6,700,122	10,650,121	[2] 76	[3] 4,200,000	6,450,200
1940	12,521,726	12,823,633	----------	[4] 1,668,765	11,154,868

[1] Does not consider fluctuations in consumers' stocks and metal derived from scrap. Withdrawals from producers' stocks totaled 3,949,999 pounds in 1939 and 301,907 pounds in 1940; additions to producers' stocks totaled 1,613,773 pounds in 1938.
[2] Includes alloys and scrap (magnesium content).
[3] Estimated.
[4] Of the 1,718,444 pounds of metal exported, 49,679 pounds consisted of magnesium alloy.

In addition to the 11,154,868 pounds of primary magnesium ingot and stick delivered by the producer to domestic industry in 1940, consumers withdrew 68,632 pounds of metal from stocks, making a total of 11,223,500 pounds of primary metal actually entering domestic consumption during the year. Of this, approximately 7,363,000 pounds were used directly in making magnesium-rich alloys or in sweetening such alloys in remelting operations in fabricating plants; 3,215,000 pounds were used directly in aluminum-rich alloys; 357,000 pounds in wire, ribbon, powder, shavings, and sawdust; and 288,500 pounds for other purposes.

Magnesium-rich alloys are used chiefly in the manufacture of structural products, such as castings, extruded shapes, and sheet. Some alloy, largely scrap, is used in making aluminum and other alloys, chemicals, and as a scavenger and deoxidizer. Wire, ribbon, powder, shavings, and sawdust are intermediate products, which eventually are consumed in the pyrotechnic, chemical, metallurgical, and other industries. Because of the complexity of intercompany sales of alloy ingot, scrap, and intermediate products, it is difficult to show statistically the flow of primary magnesium into the final products of manufacture. Moreover, in the process of manufacture primary metal merges with old scrap returning from use. In 1940, 507,000 pounds of magnesium contained in old scrap were consumed

[4] Wood, Robert T., Magnesium Alloys for Photoengraving: Metals and Alloys, vol. 11, No. 2, February 1940, pp. 33–41.
[5] Mathes, John C., Magnesium Alloys in Industry: Metals and Alloys, vol. 13, No. 1, January 1941, pp. 23–29.

by industry, making a total of 11,730,500 pounds of primary and secondary metal entering consumption during the year, of which actual returns received from 157 consumers accounted for 11,531,000 pounds. This metal was used as follows:

Actual consumption of primary and secondary magnesium in 1940, by uses, in pounds

Use	Quantity	Use	Quantity
Structural products [1]	7,363,200	Pyrotechnics	43,500
Aluminum alloys	3,556,500	Chemicals	70,200
Zinc alloys	68,000	Other	50,400
Other alloys	17,600		
Scavenger and deoxidizer	361,600	Total	11,531,000

[1] Castings, sheet, extruded shapes, forgings, etc.

From 7,363,200 pounds of magnesium used in the manufacture of structural products, 5,383,670 pounds emerged in finished items. As magnesium oxidizes readily at temperatures above the melting point, the remaining 1,979,530 pounds (or 27 percent) of the metal consumed by this industry were lost or burned in the manufacturing process while molten. The gross weight of finished structural products was 5,916,120 pounds, of which 5,475,530 pounds were sold or used.

Structural magnesium alloy and nonstructural magnesium products manufactured and sold in 1940 rose 125 percent over those in 1939. Sales of structural products increased 132 percent and of nonstructural products 50 percent. Of the structural products sold or used, sand and permanent mold castings (chiefly the former) comprised 73 percent, die castings 13 percent, extruded products 7 percent, sheet 6 percent, and forgings and other structural products 1 percent. The value of sand and permanent-mold castings in 1940 averaged $1.85 a pound; die castings, $0.93 a pound; and all castings, $1.71 a pound (compared with $1.31 in 1939). The increase in values is attributed to the greater production of more complicated aircraft parts.

Magnesium products (other than ingot and stick magnesium [1]) manufactured in the United States and sold or used by the companies manufacturing the products, 1938–40

Product	1938		1939		1940	
	Pounds	Value	Pounds	Value	Pounds	Value
Structural products:						
Castings:						
Sand and permanent mold	1,067,310	$1,392,882	1,321,080	$2,030,175	3,973,757	$7,345,050
Die			525,372	385,770	699,212	653,289
Sheet	124,930	79,764	180,896	116,287	322,664	246,476
Structural shapes, rods, tubing (extrusions)	80,206	49,972	308,443	185,746	410,912	349,123
Forgings	5,924	6,541	17,065	26,925	25,938	34,602

[1] 435,483 pounds of stick manufactured and sold or used in 1940.

The number of fabricators of magnesium products increased from 22 in 1939 to 30 in 1940. In addition to the manufacturers mentioned in Minerals Yearbook, 1939 (pp. 708–709) and 1940 (p. 721), the following companies produced magnesium products in 1940: Aluminum Industries, Inc., 2438 Beekman Street, Cincinnati, Ohio; Carnes Artificial Limb Co., 904 East 12th Street, Kansas City, Mo.; General Electric Co., Schenectady, N. Y.; Hines Flask Co., 1324 Hird Avenue, Cleveland, Ohio; Lestershire Spool & Mfg. Co., Johnson City, N. Y.; Los Angeles Die Casting Co., 240–246 Crocker Street, Los Angeles, Calif.; Permold Co., 6700 Grant Avenue, Cleveland, Ohio; Port Huron Brass Foundry Co., Port Huron, Mich.; and Superior Bearing Bronze Co., 42–43 10th Street, Long Island City, N. Y.

The American Magnesium Corporation, which has been in the magnesium business since 1917 and is the largest producer of magnesium products, began tripling its fabricating capacity in the fall of 1940. At that time most of its plants were operating on a three-shift-a-day, full-capacity basis. Plants are situated at Cleveland, Ohio (sand, die, and permanent mold castings, forgings, powder, wire, ribbon, etc.); Buffalo, N. Y. (capacity for 225,000 pounds of sand castings monthly); Los Angeles, Calif. (sand castings); Garwood, N. J. (capacity for 30,000 pounds of die castings monthly); New Kensington, Pa. (extrusions and capacity for 10,000 pounds of sheet monthly); Edgewater, N. J. (pressings); and Bridgeport, Conn. (sand castings). Operations were first started at the Buffalo foundry in July 1940, at the New Kensington sheet mill in March 1940, and at Garwood in August 1940, but operations at Bridgeport will not begin until about September 1941. On February 6, 1941, the Aluminum Co. of America purchased the other half interest in the American Magnesium Corporation that had been owned by the General Aniline & Film Corporation and announced further expansion in the operations, which have already been increased to 20 times the normal peacetime demands experienced by the company in 1938. A sit-down, slow-up strike threatened company operations in Cleveland for a short time in April 1941. The Dow Chemical Co. also expanded fabricating facilities in 1940; it completed a $500,000 sheet-rolling mill at Midland, Mich., and early in 1941 began to construct a $1,000,000 addition to the new castings foundry at Bay City, Mich. In the spring of 1941 the Ford Motor Co. completed a new sand-casting foundry of 110,000 pounds monthly capacity to manufacture parts for Pratt & Whitney aircraft engines.[6] The use of magnesium in Ford automobiles and tractors was discontinued for the duration of the magnesium shortage. Other established companies that greatly extended their magnesium-fabricating facilities include the Wright Aeronautical Corporation, Fairlawn, N. J.; Eclipse Aviation Division of the Bendix Aviation Corporation,[7] Bendix, N. J.; Bohn Aluminum & Brass Corporation, Detroit, Mich., and its subsidiary, Magnesium Fabricators, Adrian, Mich.; Wellman Bronze & Aluminum Co., Cleveland, Ohio; Springfield Bronze & Aluminum Co., Springfield, Mass.; Harvill Aircraft Die-Casting Corporation, Los Angeles, Calif.; and Doehler Die Casting Co., Batavia, N. Y.

Aircraft manufacturers took 75 percent of the magnesium-alloy products made in the United States during 1940. Producers of air-

[6] Iron Age, Ford Describes New Magnesium Foundry: Vol. 147, No. 2, January 9, 1941, p. 75.
[7] Ward, Robert E., Manufacturing Nonferrous Sand Castings for Aircraft: Foundry, Vol. 69, No. 5, May 1941, pp. 81–83, 175–176.

plane engines (and propellers) purchased 64 percent of the products made for this industry, airplane-wheel manufacturers 19 percent, and airframe makers 17 percent. Magnesium alloys crowded aluminum alloys to a small extent in the structural aircraft field because of their excellent strength-weight ratio, easy machinability, and welding properties. The wider use of magnesium-alloy castings in engines and of various structural products in secondary airframe structures gradually was extended to more important parts of the landing-gear and control systems.[8] The service record and weight saving of magnesium-alloy wheels of large land planes have been so satisfactory that over 75 percent of the commercial and military planes now under construction are so equipped. The very low weight of American aircraft engines per horsepower is attributed to the use of magnesium-alloy products. Work is proceeding on a fuselage using plastics molded over magnesium-alloy reinforcements, and full-size wing panels of the metal are being tested. It is evident that the demand for magnesium not only has been spurred onward by the 518-percent increase in military-airplane output (from a monthly average of 178 in 1939 to about 1,100 in March 1941) but also by the greater quantity of magnesium-alloy products used per plane.

The automotive industry was the second largest consumer of magnesium-alloy products in 1940, taking 10 percent of the total sales. Products sold or used in the portable machine, equipment, and tool industries comprised 6 percent, textile industry 3 percent, foundry equipment industry 2 percent, stationary machinery industry 1 percent, and all other industries 3 percent.

Stocks of the cruder forms of magnesium on hand at producers' and consumers' plants on December 31, 1940, totaled 620,242 pounds of pure magnesium (ingot, stick, powder, etc.) and 1,746,011 pounds of original and secondary magnesium alloy (ingot and scrap), with a total magnesium content of 2,209,100 pounds, compared with 924,791 pounds of pure magnesium and 1,334,170 pounds of alloy, with a total magnesium content of 2,138,900 pounds, on December 31, 1939. The increase in structural magnesium alloy product fabricating capacity and the subsequent enlargement of working stocks is attributable to the 31-percent advance in stocks of magnesium alloy.

NATIONAL DEFENSE AND PRIORITIES

Magnesium, formerly listed as a critical material by the Army and Navy Munitions Board, was the second metal upon which formal mandatory priorities were invoked. Although there are abundant domestic supplies of magnesium-bearing raw materials, extraction of the metal therefrom is difficult and involves intricate processes. Before the present emergency, Army and Navy authorities considered magnesium important from a military standpoint chiefly in its pyrotechnic application in tracer bullets, flares, star shells, etc. Today, however, the metal has assumed unprecedented importance in the national defense program because of its use in airplanes and engines and for incendiary bombs.

In the summer of 1940 there was a slight shortage in the supply of magnesium; but during the fall months, as aircraft-production in-

[8] Mathes, John C., Magnesium Alloys in the Aircraft Industry: Jour. Soc. Automotive Eng. (Trans.), vol. 48, No. 2, February 1941, pp. 76-80.
Woldman, Norman E., Magnesium in Aircraft: Metals and Alloys, vol. 12, No. 4, October 1940, pp. 430-435.

creased and more metal was specified per plane, the shortage became more critical. Although a number of domestic concerns became interested in production of the metal late in 1940 the only assured expansion is that of the Dow Chemical Co. and the Todd-California Shipbuilding Corporation, previously mentioned.

On February 12, 1941, E. R. Stettinius, Jr., Director of the Priorities Division of the Office of Production Management, requested producers of magnesium and magnesium products to allocate all metal to defense needs. The Dow Chemical Co. then asked that orders for metal be accompanied by a certification that the material was to be used to meet current defense requirements. On March 3, 1941, the Priorities Division removed magnesium from a preferential allocation status and placed it under mandatory priorities, subject to the controls imposed February 24, 1941, on producers of aluminum and machine tools. Magnesium producers and fabricators subsequently were required to submit monthly a complete booking of orders for the ensuing month. The Division obtains from the Scheduling Unit, Wright Field, Dayton, Ohio, monthly data on the requirements of the military aircraft program and then allots the Unit the larger portion of the metal output for distribution to manufacturers of airplane parts. The Division allocates the remaining magnesium to other uses—for pyrotechnics in ordnance, as an alloying constituent in aluminum and zinc, for British export, and for important civilian requirements. On March 26, 1941, the Priorities Division made available 200 short tons of magnesium for export to Great Britain and stipulated that British defense orders receive the same priority treatment as United States defense orders.

It appears that unless domestic production of magnesium is sharply increased, virtually all of the metal will continue to be consumed by defense industries whose 1941 requirements are expected to be much greater than the supply.

PRICES

The nominal New York price for 99.8-percent ingot magnesium, carlots, remained unchanged at 27 cents a pound throughout 1940. Quotations for less than carlots, 100 pounds or more, were 29 cents a pound. Extruded sticks, carlots, were quoted at 34 cents a pound; for less than carlots of 100 pounds or more, 36 cents a pound. Alloy ingot normally is quoted at 3 cents a pound more than pure magnesium ingot. London magnesium ingot quotations remained at 1s. 6d. to 1s. 7d. a pound during the year.

FOREIGN TRADE

Official export statistics on magnesium were not separately reported prior to September 1939. It is estimated, however, that exports totaled approximately 4,200,000 pounds in 1939 and 2,100,000 pounds in 1938. Export data compiled by the Bureau of Foreign and Domestic Commerce show that during the period from September to December 1939, inclusive, the United States shipped 979,936 pounds of magnesium valued at $274,382, of which 642,431 pounds were sent to France and 147,605 to the United Kingdom. In 1940 exports totaled 1,718,444 pounds valued at $582,961, of which 546,437 pounds were shipped to the United Kingdom, 478,472 to France, 244,772 to Mexico, 213,195 to Sweden, 147,062 to Canada, and 49,846 to Italy. During the first quarter of 1941 the United States shipped 299,785 pounds of metal valued at $112,110, of which 180,870 pounds were sent to the United Kingdom, 95,897 to Canada, and 20,000 to Mexico. On July 5, 1940, magnesium was placed under export control. No magnesium has been imported since 1939, when 66 pounds of metal and scrap valued at $24 and 10 pounds of alloy valued at $25 were received from Germany.

TECHNOLOGIC DEVELOPMENTS

Numerous United States patents were granted in 1940 on the production of magnesium, and other new and undisclosed production methods were under investigation by various organizations. Of the two basic processes, the electrolytic chloride continues to be the method most widely used in the production of metal, although direct electrothermic oxide reduction is receiving increasing attention.

According to Pidgeon and Phillips, anhydrous magnesium chloride can be satisfactorily produced by passing chlorine through a porous, granular mixture of MgO and C at temperatures between 800° and 1,000° C.[9] Reducing agents recommended in the thermal processes include calcium carbide, aluminum, carbon, and ferrosilicon. The Blackwell-Turner (British) direct thermal recovery process employs a high-frequency induction furnace with a ferrosilicon or calcium carbide reducing agent, wherein the resultant magnesium vapor is condensed on a cooling dome that covers the furnace.[10]

The Metallurgical Division of the Bureau of Mines completed its laboratory-size magnesium pilot plant at Pullman, Wash., in March 1941. Magnesia is to be reduced here with carbon by the direct electrothermal process and a spray of oil employed to shock-cool the resultant metal vapor.[11]

Technologic improvements were made in 1940 on the fabrication of magnesium-alloy products;[12] on new alloy compositions, especially those of high strength and improved chemical stability; on surface treatments;[13] on basic design factors relative to structural airplane subassemblies; in the art of permanent molding; and in the technique of spot and arc welding,[14] riveting, and general assembly practices.[15] The Guerin stamping process, using rubber as the forming medium and heated steel dies, is employed to fabricate airplane parts from sheet made of magnesium alloyed with 1.2 percent manganese. Tests indicate that substantial savings in weight and costs are effected by using magnesium-alloy sheet in monocoque airplane construction.[16]

The incendiary bombs used in the European War weigh about 2 pounds and consist of a case or shell of magnesium alloy filled with a thermite mixture of granulated aluminum, iron oxide, and sometimes a little magnesium powder. The impact detonator ignites the thermite, which burns at 3,000° C. and in turn ignites the magnesium shell casing, which burns at 1,300° C.;[17] both flames are practically impossible to extinguish, yet they burn so quietly that a serious fire may be started before measures are taken to control it. A large bomber can carry 1,000 to 2,000 of these light bombs.

WORLD PRODUCTION

Although official data are lacking, there is no doubt that world production and consumption of magnesium metal rose to new high points in 1940. The meager information available indicates the following general trend in world production of magnesium in recent years.

Estimated world production of magnesium, 1937–40, by countries, in metric tons

Country	1937	1938	1939	1940
France	1,500	1,800	2,500	2,000
Germany	12,080	14,100	16,500	19,000
Italy	66	102	300	500
Japan	1,200	1,500	2,000	4,000
Switzerland	230	300	700	700

Canada.—Experiments by the National Research Laboratories indicate that brucite granules are the most suitable domestic raw material for the production of magnesium by the electrolysis of fused chloride but that dolomite probably is better when a ferrosilicon reducing agent is used in a distillation method.[18]

Germany.—In spite of stocks being accumulated in 1938 and 1939, German production of magnesium is estimated to have increased to a total between 16,000 and 19,000 metric tons in 1940. A decree dated December 9, 1940, prolonged State control on the establishment and expansion of magnesium plants until the end of 1945. The pilot plant at Radenthein, Kaernten, Austria, which used the Hansgirg direct electrothermal reduction process and magnesite as raw material, had a hydrogen explosion in August 1939, and the works were abandoned temporarily for lack of construction steel.

Italy.—Early in 1940 the Società Anonima Italiana per il Magnesio e le Leghe di Magnesio started producing magnesium at Bolzano, and by early fall output reached 1 ton of metal daily.

United Kingdom.—Magnesium Elektron, Ltd., and Magnesium Metal & Alloys, Ltd., produce most of the British output of metal. Domestic dolomite and sea water have replaced imported magnesite as the chief raw materials. Distribution and fabrication of magnesium are controlled by the Minister of Aircraft Production.

ANTIMONY AND CADMIUM

By T. H. Miller and T. P. Wootton [1]

SUMMARY OUTLINE

ANTIMONY

The antimony industry was unusually stable from late in 1939 throughout 1940, in spite of numerous events of importance to world trade in the metal. The German conquest of western Europe in the early months of the year further dislocated international trade; Japanese occupation of eastern China prevented shipments via normal trade routes, and for the fifth consecutive year Chinese exports declined. The curtailment of Chinese shipments was largely offset by marked increases in production from Bolivia and Mexico. World production is estimated to have been 10 to 12 percent above that of 1939. or about 35,000 metric tons.

The New York price for American brands was maintained at 14.00 cents a pound compared with an average price of 12.36 cents in 1939 and 12.35 cents in 1938. The price for Chinese metal was stable at 16.50 cents, duty paid, compared with 14.44 cents in 1939 and 14.59 cents in 1938.

Domestic production of ore and concentrate declined sharply, but metal contained rose about one-fourth. The antimony content of antimonial lead produced from all classes of domestic ores increased 106 percent over the 1939 figure and was the largest recorded since 1929. The total production from all raw materials—scrap and domestic and foreign ores—increased nearly 45 percent and was the largest since 1930. Primary metal available for consumption increased 55 percent but did not quite equal the record set in 1937. Stocks of metallic antimony, as reported to the Bureau of Mines by six producers, increased from 734 tons at the end of 1939 to 1,024 on December 31, 1940.

The Laredo and Los Angeles smelters again reported substantial increases in production; and, for the first time, the new Kellogg plant

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

of Bunker Hill & Sullivan Mining & Concentrating Co. reported production and the Texas smelter reported metal recovered from domestic ores. The new Bunker Hill plant operates on tetrahedrite from silver ore of the Coeur d'Alene district, Idaho. Antimony and bismuth are recovered as byproducts.

A new book [2] gives a brief résumé of the metallurgy of 24 metals, including antimony and cadmium.

Figure 1 shows trends in world production from 1910 to 1938 and United States imports and prices from 1910 to 1940.

National defense.—The general national defense aspects of antimony were discussed in detail in Minerals Yearbook, 1939. The metal is still classified as a strategic raw material by the Army and Navy Munitions Board. The United States Department of the Interior continued its investigation of deposits and issued reports on antimony ore in Inyo County, Calif., and Valley County, Idaho.

Presidential Proclamation No. 2413 of July 2, 1940, effective July 5, 1940, listed various articles and materials to be exported only when authorized by license provisions contained in the proclamation. Mineral commodities covered by the proclamation included antimony ores, concentrates, metal, alloys in crude and semifabricated form, and antimony compounds.

The Strategic Materials Act (Public, No. 117—76th Congress, 1939) and a subsequent act (Public, No. 664—76th Congress, June 25, 1940) authorized the Reconstruction Finance Corporation to acquire stocks of strategic and critical materials for use in the national defense program. On June 28, 1940, the Metals Reserve Co. was created for this purpose. Purchases of metallic antimony were included in the program, and at the end of April 1941 the company had received 6,796 tons of Chinese and 250 tons of domestic antimony. There remained on order 2,750 tons of domestic metal and an undisclosed amount of Chinese material, included, with wolframite and tin, in the recent $90,000,000 loan to China. Domestic antimony was purchased from the Texas Mining & Smelting Co., produced at Laredo, Tex., from ore mined in Mexico. Deliveries are to be made at the rate of 250 tons a month until the 3,000-ton contract is completed.

DOMESTIC PRODUCTION

MINE OUTPUT

Antimony produced in the United States from domestic ores is derived from antimony, lead, and gold mines. Byproduct antimonial drosses obtained in lead refining are used in the manufacture of antimonial lead, other alloys, and chemical compounds, such as oxides and sulfides. The 1940 production of antimonial lead at primary lead refineries from domestic ores contained 1,915 tons of antimony—an increase from 929 tons in 1939.

Domestic ores and concentrates produced in 1940 contained 494 tons of recoverable antimony (25 percent greater than in 1939), although the output of ore and concentrates declined from 3,174 to 1,124 tons. Thirty-nine producers shipped ore containing 1 ton or more of antimony from 5 States and Alaska as follows: 2 each in Arizona and Montana, 11 in California, 3 in Idaho, 20 in Nevada, and 1 in Alaska, where Morris P. Kirk & Son, Inc., continued to be the only producer. The Yellow Pine district, Valley County, Idaho, and the Kantishna district, Alaska, were the outstanding producing areas.

Alaska.—The Stampede mine in the Kantishna district, owned by Morris P. Kirk & Son, Inc., ran at full capacity throughout the summer months and produced about 40 percent more ore than in 1939. The ore was treated in a small mill erected in 1939, and the concentrates were shipped to the company plant in Los Angeles, Calif. The ore and concentrates are hauled by tractor-drawn sleds during the winter months to the railroad at Lignite, from where it is reshipped to the States by rail and water. Antimony minerals have long been known to occur on Stampede Creek, but no systematic attempt at commercial exploitation was made until 1936, when Kirk began operations. The ore occurs as a lode in schist and is found principally in a large lens of nearly pure stibnite containing only minor amounts of gold or silver. The mine is developed by a vertical shaft, an adit, and surface trenches. Ore formerly was beneficiated by hand-sorting until it contained 50 to 55 percent antimony.

Arizona.—A small amount of ore containing about 23 percent antimony was produced from the Tip-Top and Walker districts, Yavapai County. The Tip-Top deposit was discovered during the year, and the ore is reported to contain some gold and silver.

California.—Most of California's production came from Kern County, but two small shipments were also made from Inyo and San Bernardino Counties. The Inyo County deposits were described in a report [3] issued in connection with the strategic minerals investigations being conducted jointly by the Bureau of Mines and the Geological Survey, United States Department of the Interior. The author's abstract is quoted in full:

> The antimony deposits of the Wildrose Canyon area, Inyo County, Calif., are in chlorite schist and amphibolite of probable pre-Cambrian age. All but two of the large deposits lie within a small area of close folds, striking about north-northeast, near Antimony Ridge on the south side of the canyon and were deposited in zones of fracture and shearing along the limbs and crests of the anticlines. Fracturing favorable to the reception of the ores is commonest in the amphibolite—a tough rock competent to hold open spaces.
>
> The antimony minerals of the deposits are stibnite and several oxides. The chief gangue mineral is quartz, which encloses fragments of country rock; gypsum is rather common, and fluorite is rather abundant in one deposit. It is believed that the stibnite and associated primary minerals were deposited at low temperature and shallow depth in Tertiary or Quaternary time. They are probably not directly related in origin to the dikes of aplite and pegmatite, the only igneous rocks exposed in the region, though like these dikes, they may have come from a magmatic source.
>
> The reserves are estimated to be about 50,000 tons of ore, containing 1½ to 5 percent of antimony. They may be somewhat greater, but they can hardly be much greater unless the ore goes deeper than now appears probable. A price for antimony of 20 to 30 cents a pound would be required to assure a profit on the mining of most of this ore.

Idaho.—As in the past, most of Idaho's production came from the Yellow Pine district, Valley County. Production of the Bradley Mining Co. was negligible, but the United Mercury Mines Co. produced ore containing more than 100 tons of metallic antimony. The Bureau of Mines and the Geological Survey continued their investigations under the Strategic Materials Act, and a formal report [4] was issued late in the year. White's abstract is quoted herewith:

> The area described in this report lies in the northeastern part of the Yellow Pine district, Valley County, in central Idaho. It has produced much gold and little else in the past, but it has a special interest at present because it contains what is probably the largest reserve of antimony in the United States.
>
> The ores, as ores of antimony, are in general of low grade. Stibnite, the only antimony mineral present, occurs partly in veins and veinlets and partly disseminated throughout wide shear zones in quartz-monzonite of the Idaho batholith. The main shear zone, which strikes northeastward, may be an offshoot of

[3] White, Donald E., Antimony Deposits of the Wildrose Canyon Area, Inyo County, Calif.: Geol. Survey Bull. 922-K, 1940, pp. 307-325.

[4] White, Donald E., Antimony Deposits of a Part of the Yellow Pine District, Valley County, Idaho: Geol. Survey Bull. 922-I, 1940, pp. 247-279.

the north-striking Monday fault. Both the shear zone and the fault are in quartz-monzonite and are probably related to the nearby contact of the monzonite with a huge roof pendant of metamorphosed sedimentary rocks.

Two periods of mineralization are represented in the area, the first by pyrite, arsenopyrite, and gold; the second by antimony and silver. The two periods are believed to have been genetically related and to have occurred in Tertiary time. Mineralization in even the earlier period is thought to have taken place at relatively shallow depth. The temperature was high during the early stages but decreased considerably while the ore minerals were being introduced.

The principal mine of the area is the Yellow Pine mine. The Meadow Creek mine also contains possible reserves. The main workings of the Yellow Pine mine are two quarries, one on each side of the East Fork of the South Fork of the Salmon River. The ore in the eastern quarry will be referred to as the East ore body, that in the western quarry as the West ore body, though the two may be continuous under the stream. The mine is owned by the Bradley Mining Co. That company is mining at present only in the East ore body, which is rich enough in gold to be profitably worked but contains only a negligible amount of antimony. The West ore body contains a much higher proportion of antimony, as well as some gold and silver, but it was not being mined in late 1939 because the net value of the ore at the current price of antimony was considerably less than that of the ore in the East body.

Some mining may soon be done in the West body because of a temporary emergency. The recovery of gold from ore of the East body is unsatisfactory, and to increase the percentage of recovery a cyanide plant will probably be built. It may then be deemed expedient to suspend mining in the East body until the cyanide plant is put in operation and to keep the miners busy meanwhile in the West quarry. But long-continued mining of the West ore body will not be worth the owners' while unless the ore can be made to yield at least as high a profit as that of the East ore body.

This condition might be brought about through a rise in the contract price paid by the smelter for antimony; the price of 3.75 cents a pound paid in 1939 for the antimony contained in the concentrates would have to be raised to about 7 cents. The West ore body might also be made profitable by building a plant for electrolytic separation of antimony. Such a project is not likely to be attempted unless an open-market price of 12 cents a pound could be assured for several years. Under either of the two conditions stated the largest possible production would probably be between 1,200 and 1,600 tons of antimony. Greater production might follow a price high enough to warrant expansion of the plants at mine and mill. It is not easy to predict how high a price would be necessary to encourage greater production, but it might be about 10 cents a pound for antimony containedi n concentrates, or the equivalent price of 15 cents a pound for metallic antimony. Assured stability of price, however, be it said again, would be essential.

The easily minable reserves in the West ore body are estimated to be at least 193,000 tons of ore, containing 7,620 tons of recoverable antimony. About 2,625,000 tons more, estimated to contain 18,350 tons of recoverable antimony, may lie between the creek level and a depth 200 feet lower; but this estimate is more doubtful than the preceding, especially with respect to grade. It appears likely that a large additional tonnage may lie in ground either outside or beneath that now known to be productive that could be explored at low cost. The amount of antimony ultimately mined must of course depend on the prices obtainable for it.

Montana.—Two operators shipped ore containing an estimated total of 23 tons of antimony from the Burns district, Sanders County. This is the first recorded production of antimony from Montana deposits since the last war, when several carloads were shipped from this same area.

Nevada.—Several shipments of ore containing a total of 157 tons of metal were reported from Elko, Lander, Nye, Pershing, and White Pine Counties in 1940. Extensive prospecting and sampling were carried on in several other districts and in some old mines.

Oregon.—Some prospecting was done on deposits in Baker and Jackson Counties, but no production was recorded.

SMELTER OUTPUT

In 1940, primary antimony for shipment to others was produced from foreign and domestic ores at three plants in the United States: Bunker Hill & Sullivan Mining & Concentrating Co., Kellogg, Idaho; Menardi Metals Co., El Segundo, near Los Angeles, Calif.; and Texas Mining & Smelting Co., Laredo, Tex. In addition, metallic antimony was produced by the American Smelting & Refining Co. but was converted into other products such as antimonial lead and was not sold as metallic antimony.

A new unit costing approximately one-half million dollars was added to the Bunker Hill smelter at Kellogg to produce metallic antimony by the Lee-Muir process from the tetrahedrite ores of the Coeur d'Alene district. A test run was made at the plant March 1, 1940, and operations were begun soon thereafter.

At the Menardi plant,[5] the concentrates are slowly calcined at a closely regulated temperature with a limited amount of air. The mercury passes out of the furnace with the gases, and the antimony remains behind in the sinter; 1,000 pounds of sinter are mixed with 200 pounds of cast-iron borings, 175 pounds of silica, 100 pounds of mill scale, and 150 pounds of soda ash and charged to a 5- by 16-foot reverberatory furnace. Metal, matte, and slag are drawn together into 400-pound pots and allowed to cool. The resulting button of metal is easily separated from the matte and slag. About 1.5 percent of the antimony is lost in the slag and about 3.5 percent in the matte. Iron and arsenic are removed from the crude metal as it goes through a sweating furnace, four small reverberatories, and a tilting starring furnace. Oxides recovered from the flues, baghouse, and spray tower are reduced with charcoal and crude oil and the resulting pigs refined in the furnaces mentioned above. Pigs average 42 to 43 pounds each and are sold in three grades: C Brand, 99.0 percent antimony; M Brand, 99.5 percent; and M Special, 99.8 percent. All grades have the "stars" characteristic of the trade.

Imports of antimony ore in 1940 amounted to 37,966 tons containing 15,733 tons of antimony. Of this total, 9 smelters received 32,354 tons of ore containing 13,071 tons of antimony or 83 percent of the total antimony. Receipts exceeded consumption at these plants, and stocks of antimony ore increased 30 percent. In addition, 9 firms that treat chiefly scrap lead reported imports of 2,176 tons of antimony ore containing 1,055 tons of antimony. Data for the 18 firms are summarized in the table below.

Consumption and stocks of foreign antimony ore by 18 companies during 1940, in short tons

	Foreign antimony ore			Foreign antimony ore	
	Gross weight	Antimony content		Gross weight	Antimony content
Stocks on Dec. 31, 1939	7,775	3,388	Consumed during 1940	31,982	13,421
Received during 1940	34,530	14,126	Stocks on Dec. 31, 1940	10,323	4,093

[5] Menardi, H. B., Reduction of Livingstonite Concentrate: Am. Inst. Min. and Met. Eng. Tech. Pub. 1042, February 1939, 8 pp.

Production of antimonial lead at primary lead refineries is shown in the accompanying table. The figures cover only part of the total antimonial lead production, as large quantities are produced at plants that operate exclusively on scrap, and some hard lead is made by mixing antimony and soft lead.

Antimonial lead produced at primary lead refineries, 1936–40, in short tons

Year	Production	Antimony content				
		From domestic ores	From foreign ores [1]	From scrap	Total	
					Quantity	Percent
1936	23, 230	1, 434	37	691	2, 162	9. 3
1937	27, 524	1, 636	90	853	2, 579	9. 4
1938	24, 123	1, 871	209	729	2, 809	11. 6
1939	21, 995	929	179	923	2, 031	9. 2
1940	29, 762	1, 915	162	867	2, 944	9. 9

[1] Includes lead ores, antimony ores, and metallic antimony.

SECONDARY PRODUCTION

A large part of the total antimony available for consumption each year in the United States is recovered in the treatment of secondary nonferrous metals. The production of antimony from secondary metals in 1940 totaled 11,421 tons—a 16-percent increase from the 9,810 tons produced in 1939. Primary antimony available for consumption in the United States in 1940 totaled 17,955 tons. Total antimony available was thus 29,376 tons, including 61 percent primary and 39 percent secondary; similar percentages for 1939 were 54 and 46, respectively.

Most of the secondary antimony is recovered from old scrap returning from worn-out and obsolescent equipment. In 1940, old scrap yielded 11,176 tons of antimony and new scrap 245 tons. Lead-base alloys, chiefly antimonial lead, supplied 97 percent of the total secondary antimony recovered in 1940; most of the remainder came from tin-base scrap. Discarded storage batteries are the largest single source of secondary antimony. In 1940, plants treating secondary metals reported the consumption at 165,387 tons of battery lead plates yielding 5,954 tons of recoverable antimony or 52 percent of the total secondary antimony produced. Babbitt of all types, including Mixed Common, No. 1, and Genuine, yielded 2,387 tons of antimony, and 1,968 tons came from type metals and drosses. The remainder of the secondary antimony in 1940 came from hard lead (yielding 837 tons of antimony), cable lead (241 tons), No. 1 pewter (19 tons), and lead sludge (15 tons).

Most of the plants treating scrap metals containing antimony also consume other antimony materials, such as antimony ore or metallic antimony. These materials are used to adjust or "sweeten" the antimony content of the products. Refined metallic antimony is rarely produced from scrap metals, as most of the output is in the form of lead-base and tin-base alloys. Much of the production is in the form of antimonial lead returned directly to the storage-battery trade. Antimony oxide, sodium antimonate, and other compounds are also produced from scrap metals.

DOMESTIC CONSUMPTION

Precise data on the consumption of primary antimony in the United States are not available owing to lack of information on dealer and consumer stocks and on the quantity of domestic antimony recovered in alloys other than antimonial lead and in compounds; however, an approximate idea of the trend of consumption can be obtained from the following table, which shows the annual supply available for consumption.

Primary antimony available for consumption in the United States, 1936–40, in short tons [1]

	1936	1937	1938	1939	1940
Domestic antimony recovered in antimonial lead	1,434	1,636	1,871	929	1,915
Imports for consumption (antimony content):					
Antimony ore	10,545	13,818	8,322	9,448	15,733
Needle or liquated [2]	830	540	63	160	79
Compounds [3]	975	909	336	138	4
Type metal, etc	309	410	355	121	191
Regulus	1,171	1,043	821	1,045	209
Total available	15,264	18,356	11,768	11,841	18,131
Exports under draw-back	224	224	211	232	176
Available for consumption	15,040	18,132	11,557	11,609	17,955

[1] Excludes domestic antimony recovered as miscellaneous alloys, oxides, and other compounds.
[2] Content estimated at 70 percent.
[3] Content estimated at 80 percent.

Primary antimony available for consumption in 1940 increased 55 percent over the figure for 1939, both imports of ore and domestic production having increased markedly. According to the American Bureau of Metal Statistics, 115,600 tons of antimonial lead were used in manufacturing storage batteries during the year compared with 106,500 tons in 1939 and 92,000 in 1938. This battery metal contains 4 to 12 percent antimony, largely from scrap, although a substantial quantity of new metal is added to "sweeten" the alloy.

An important use of antimony is in white-base antifriction bearing metals. Shipments of this material produced for sale and for plant consumption in 1940, according to the Bureau of the Census, totaled 12,822 tons compared with 11,785 tons in 1939 and 8,259 in 1938. These figures are taken from reports submitted by 39 manufacturers in 1938 and 1939 and 38 manufacturers in 1940, who represent approximately 84 percent of the total industry.

The use of antimony in making chemicals continued to grow in 1940, as the production of oxides and other compounds increased 33 percent to 10,211 short tons containing approximately 8,223 tons of metal. Figures on the production of compounds in the 4 preceding years, with the estimated antimony content in parentheses, are as follows: 1939, 7,668 tons (6,188); 1938, 4,393 tons (3,539); 1937, 6,992 tons (5,667); and 1936, 4,852 tons (3,940). Nearly all of this material was made from foreign ores. Oxide is the most important compound. It is used extensively in paints and sanitary enamelware. Hansen [6] has commented interestingly on the substitution of zircon for antimony in certain enamels:

[6] Hansen, J. E., New Porcelain Enamels Use No Antimony, Have High Quality: Steel, vol. 108, No. 1, January 6, 1941, p. 249.

* * * New zircon-type enamels containing no antimony develop high reflectance values and assure us of high-quality white enamels in the event that supplies of antimony compounds are restricted. Such restrictions might possibly be invoked since antimony is listed as a strategic material by the War Department. These new zircon-type enamels are being used by a large number of enameling plants.

The following companies reported production of oxide and other salts in 1940:

American Smelting & Refining Co	120 Broadway, New York, N. Y.
Harshaw Chemical Co	Elyria, Ohio.
John D. Lewis, Inc	Mansfield, Mass.
McGean Chemical Co	Cleveland, Ohio.
Menardi Metals Co	Los Angeles, Calif.
Metal & Thermit Corporation	120 Broadway, New York, N. Y.
Texas Mining & Smelting Co	Laredo, Tex.

In a recent paper,[7] Bissell stated that plated stamped-steel or antimonial lead die castings containing 8 to 13 percent antimony will appear on practically all 1942 model automobiles. He stated further:

Antimonial lead die castings cost about 25 percent more per part than zinc-alloy die castings. The former costs about 25 percent less per pound but has a specific weight more than 50 percent higher. Although its tensile strength is only about one-third that of zinc alloy, engineers who plan to use it as a substitute material contend that its strength is adequate for the unstressed decorative parts for which it is to be used. An important advantage of their use is that the antimonial lead die castings can be made from the same dies used previously for zinc. On the other hand, antimonial lead die castings must be made with care in buildings which are separated from plants in which zinc alloys are being cast; otherwise the lead may get into the zinc and spoil it. Antimonial lead also is difficult to polish. Radiator ornaments, trim strips on fenders, lamp bodies, and other ornamental strips are also slated to be made of antimonial lead die castings on some cars when zinc is not longer obtainable. Furthermore, antimonial lead die castings can be made with steel reinforcements in them in parts where additional strength is required.

According to Bissell, in case of a shortage of antimony for these antimonial lead die castings, they can be replaced by parts of plated stamped steel or by plastics. He also points out that before such substitutions become necessary the zinc situation may be relieved to such an extent that the zinc-alloy die castings as originally designed can be used.

The substitution of calcium for antimony in certain products has been proposed.[8] Metallurgists claim that an alloy containing 0.1 percent calcium can be substituted satisfactorily for the storage-battery grids now made of an alloy containing 10 percent antimony. The Bell Telephone Co.'s technical staff states that an alloy containing 0.04 percent calcium is more satisfactory for cable sheathing than the present material, which contains about 1 percent antimony.

FOREIGN TRADE

The following tables show imports and exports of antimony and antimony products.

[7] Bissell, Thomas A., Designing for Alternate Materials: Soc. Automotive Eng. Preprint (mimeographed), June 1941, 20 pp.

[1] Imports credited to Argentina originate largely in Bolivia.

Estimated antimony content in type metal, antimonial lead, and other alloys imported for consumption in the United States, 1936–40, in short tons[1]

Year	Type metal and antimonial lead	Other alloys[2]	Total	Year	Type metal and antimonial lead	Other alloys[2]	Total
1936	[3] 56	253	309	1939	59	62	121
1937	[3] 17	393	410	1940	191		191
1938	[3] 59	296	355				

[1] For details of gross weight and values, see imports shown in Lead chapter of this volume.
[2] Chiefly in special antimony-lead alloys containing high percentage of antimony.
[3] Type metal only.

Foreign antimony (regulus or metal) exported from the United States, 1936–40

Year	Short tons	Value	Year	Short tons	Value
1936	392	$56,308	1939	58	$16,736
1937	437	86,991	1940	276	75,440
1938	711	96,836			

As in other recent years, imports of antimony ore in 1940 came principally from Mexico and Bolivia. Imports from Bolivia more than doubled in 1940, and receipts from Mexico were the highest on record, except for 1937, when 34,736 short tons were imported.

In addition to the exports of foreign metal reported in the last table above, 176 tons were exported in finished products under the draw-back provisions of the tariff law; draw-back exports were 232 tons in 1939 and 211 in 1938. Stocks of antimony in bonded warehouses on December 31, 1940, totaled 3,417 tons compared with 685 at the end of 1939—an increase of 400 percent. This increase is due largely to stocks being acquired by the Metals Reserve Co.

PRICES

On September 25, 1939, domestic brands of metallic antimony were quoted at 14.00 cents a pound in New York. This price remained unchanged during the remainder of 1939 and throughout all of 1940 and was still quoted in June 1941. Similarly, the price of Chinese metal, duty paid, at New York was quoted at 16.50 cents a pound on October 27, 1939, and this price also had not been changed by June 1941. These prices compare with an average of 12.36 cents for American brands and 14.44 cents for Chinese brands in 1939. Very little Chinese metal was available in 1940.

Average monthly quoted prices of antimony, prompt delivery at New York, 1936–40, in cents per pound

Month	Chinese brands (duty paid)[1]					American brands[2]

[2] Metal Statistics, 1941, p. 537.
[3] No average, owing to lack of offerings during greater part of month.

The price of English regulus (minimum of 99 percent antimony) was £87½ a long ton from November 1, 1939, through January 1940. On February 1 the price rose to £92½, and on May 1 it reached £98. There was a slight increase to £98–99 during July and August, but on September 1 it was reduced to £90, where it remained the balance of the year. On December 31, the quotation was further reduced to £85. Foreign regulus (spot deliveries from warehouse, duty paid) was quoted at £87½ during January but rose to £95 February 1. A further increase to £98 was effective May 1, and it fluctuated near that figure throughout August. On September 1 the price dropped to £91, thence to £90, where it remained the remainder of the year.

Quotations for antimony ore on January 4, 1940, according to Engineering and Mining Journal Metal and Mineral Markets, were as follows: "Per (short-ton) unit of antimony contained, 50 to 55 percent, $1.50 @ $1.60; 58 to 60 percent, $1.60 @ $1.70; 60 to 65 percent, $1.80 @ $1.90. London, 60 to 65 percent, 10s. 6d. per long-ton unit." By mid-March, quotations had risen to $1.70 @ $1.75 for the lower-grade ore, $1.75 @ $1.85 for intermediate-grade, and $2.00 @ $2.20 for higher-grade at New York and 12s. 6d. for higher-grade in London. During the remainder of the year, prices generally declined, and on December 12 quotations were $1.25 @ $1.35 for 50- to 55-percent ore, $1.40 @ $1.50 for 58- to 60-percent, and $1.50 @ $1.60 for 60- to 65-percent in New York and 9s. 3d. for the higher-grade ore in London.

WORLD PRODUCTION

Data on world production in 1939 and 1940 are very incomplete, since the nations at war will not release their figures. However, data from countries that supplied 89 percent of the total recorded world production in 1938 indicate a decline of about 1 percent in 1939. Similarly, statistics from countries that produced 77 percent of the total in 1938 indicate a 12-percent increase over that year in total world production during 1940. Production from Bolivia and Mexico increased and again exceeded that of China. Bolivia produced (exported) approximately 30 percent, China 15 percent, and Mexico 31 percent of the world total during 1940. The United States produced about 1 percent.

World production of antimony, 1936–40, by countries, in metric tons [1]

REVIEW BY COUNTRIES

Argentina.—The most recent available information on the antimony industry in Argentina appears in the July 1940 issue of Foreign Minerals Quarterly, published by the Bureau of Mines. The section on antimony is quoted in full:

The output of antimony ore in 1937 was 18 tons, in 1938, 383 tons, and in 1939, 210 tons. Most of this production comes from the Pabellon mine at 14,500 feet altitude in the Cerro Granadas, in the Department of Rinconada, Province of Jujuy.

The deposit at Pabellon is a vein crosscutting the schist country rock and developed by adits over a length of 300 feet, with an easterly strike and 25° dip to the north. Both stibnite and antimonite occur irregularly scattered in this argillaceous quartz vein, and the ore reserves are said to be small. Only the richer portions of the vein are mined, and the ore is hand-sorted, crushed, and concentrated by primitive methods to a 68-percent sulfide product and a 54-percent oxide product.

Another antimony mine in this Province is the Cerro Lina, which is just south of the 23° parallel at 12,500 feet altitude in the Department of Susques. The deposit is a north-south vertical vein from a few inches to several feet in width, containing auriferous stibnite in a gangue of quartz, limonite, and some pyrite and oxidized copper ore. In 1939, 40 tons of product with 48 percent antimony and 13 grams gold were made.

In the Province of La Rioja is a small antimony mine, the Santa Isbel, situated in the valley of Cebila 20 miles from the town of Chumbicha. Here four parallel veins from 5 to 15 inches wide, with vertical dips, traverse the metamorphic schists and have been prospected by adits and open cuts over a length of 1,200 feet. Both sulfide and oxide of antimony occur with some pyrite in irregular concentrations along these veins. The output in 1938 was 43 tons and in 1939, 4 tons.

The National Lead Co. produces a small tonnage of byproduct antimony from the imported Bolivian lead ores at its smelter at Puerto Vilelas. It also imports about 100 tons of antimony ore from Bolivia for the manufacture of antimonial lead.

Bolivia.—A comprehensive review of the Bolivian antimony industry was reprinted in Minerals Yearbook, 1940, from Foreign Minerals Quarterly (vol. 2, No. 4, October 1939, pp. 39–45). Two additional timely papers [9] appeared during the year.

Canada.—The electrolytic antimony plant of the Consolidated Mining & Smelting Co., Ltd., ran throughout the year at a daily rate of about 5 tons of metal. Costs are reported to have been reduced appreciably, and continued successful operation is expected. The metal is extracted from flue dusts recovered at the company refinery at Trail, British Columbia. According to press reports, a car of antimony ore was shipped to Montreal from the Stuart Lake property of Pioneer Gold Mines of B. C., Ltd.

In June 1940 a crew was employed by Reed Realities, Ltd., to sample an old antimony mine at South Ham, Wolfe County, Quebec. This deposit was discovered in 1863. The ore consists of stibnite, kermesite, valentinite, and native antimony in a series of slates and schists. The antimony content is said to average about 5 percent.

China.—The Chinese apparently still control their main producing areas, but Japanese control of normal trade routes continues to interrupt the flow of metal to consumer countries.

Germany.—No figures are available on German trade in antimony, but it is presumed that the Reich is amply supplied from Czechoslovak and Yugoslav production and possibly from Belgian stocks.

Indochina.—Only 9 metric tons were reported produced in 1940. The Cao-Bang area, however, is said to have deposits containing 250,000 tons of marketable ore.

Italy.—An antimony smelter at Su Suergiu near Villasalto, Cagliari, Sardinia, has produced as much as 900 tons of metal annually in recent years. According to press reports, Italian imports of metal declined sharply in 1939. No figures for 1940 are available.

Mexico.—Mexican antimony is derived from three sources: Antimony ores from several localities, as metal and as alloys from lead ores smelted at Monterrey, and from the mercury-antimony ores of the Huitzuco district, Guerrero. Most of the straight ores are exported to the Texas Mining & Smelting Co. plant at Laredo, Tex., and concentrates from the Huitzuco district are shipped to the Menardi plant near Los Angeles, Calif., where both mercury and antimony are recovered.

---

[9] Reagan, P. H., Bolivia for Strategic Minerals: Eng. and Min. Jour., vol. 141, No. 10, October 1940, pp. 57–58. Wright, Charles Will, South America as a Source of Strategic Minerals: Min. and Met., vol. 21, June 1940, pp. 283–287.

The Huitzuco deposits have been described by Vaupell, from whose paper [10] the following notes have been abstracted. The deposits are in north-central Guerrero, a State on the Pacific Ocean southwest of the Federal District of Mexico. Discovery was recorded in 1873, and for many years mercury was the only metal sought. At the surface the ore occupies extinct mud geysers, but in depth it is found in breccia, veins, and as replacements in limestone. The deposits have been developed to a total vertical depth of about 850 feet. The antimony occurs as the sulfide, stibnite, and in the rare mercury-antimony mineral, livingstonite. The stibnite increases in depth. The ore is treated in a 175-ton flotation plant, and the concentrates are shipped by rail to the United States. A recent shipment of concentrates contained 7.73 percent mercury, 26.40 percent antimony, and 29.68 percent sulfur. Mining and milling operations are carried on by Explotadora de Mercurio de Huitzuco, S. A.

According to a press report, late in 1940 an antimony sulfide deposit was being developed in the vicinity of Nogales, Sonora. Another report, earlier in the year, was to the effect that a 15,000-ton body of sulfide ore, containing appreciable quantities of antimony and arsenic had been discovered at a property near Guadalcazar, San Luis Potosi.

Peru.—Production increased 8 percent over that in 1939. In January the Bureau of Mines issued a report[11]—Mineral Resources, Production and Trade of Peru—from which the following notes on antimony have been extracted.

Antimony is produced at a large number of small mines in the Departments of Puno, Huanuco, and Lima. The deposits consist of ore shoots, or concentrations of stibnite, in quartz viens traversing belts of slate and schist, but usually of no great tonnage. In general, the mines are worked by primitive methods and without mechanical equipment. Because of the spotty nature of the occurrences, the annual output varies considerably.

For 20 years (from 1915 to 1935) production varied from none to 500 tons, averaging 100 tons. This production increased to 1,907 tons in 1936 and to 2,560 tons in 1937 but dropped to 1,445 tons in 1938. In 1939 the estimated output is about the same as in 1938.

Besides the stibnite concentrate, since 1935 from 10 to 20 tons of antimony bars, with 78 percent antimony and 15 percent lead, and several hundred tons of antimonial lead with 5 to 6 percent antimony have been produced each year at the La Oroya smelter.

Among the outstanding prospects in the Department of Puno is that of La Suerte, 60 miles north of Juliaca. Here ore pockets containing from 100 to 200 tons of stibnite occur in a quartz vein and from these a monthly output of about 30 tons of concentrate is made. About 3 miles east of La Suerte another antimony prospect is now being developed.

In the Department of Huanuco near the town of Obas three quartz veins from 1 to 3 feet wide, with ore shoots of stibnite, occur in a phyllite and greenstone schist. These have been developed by several adits, and the present monthly output is about 15 tons. As the only means of transport to this property is by mule, transport costs are naturally high.

In the Department of Lima, Province of Canta, and 3 miles from the town of Carac, is the Santa Rosa antimony mine at 14,000 feet altitude. Here a quartz vein a foot wide has been developed by three adits 100 to 150 feet long. The ore mined averages 4 percent, and present production is about 10 tons a month. A large reserve of ore averaging 1.5 to 2 percent is said to occur in other quartz veins at this mine, but mining costs are too high at present to permit exploitation.

BIBLIOGRAPHY

In addition to the papers cited in footnotes to the text, the following selected list of references is presented for the information of those interested.

AREND, A. G. Reclaiming Antimony from Waste; an Economic Use for Speiss. Chem. Age—Met. Section, vol. 44, No. 1127, February 1, 1941, pp. 77–78.

Speiss is obtained in the smelting of nickel, copper, and tin ores and residues. The antimony content of a typical speiss ranges between 10 and 15 percent. This can be recovered by fusing with pyrite, crushing to 16-mesh, fusing with sodium sulfate and coal, dissolving in boiling water, and depositing the metal electrolytically, using lead anodes and sheet-iron cathodes in iron tanks.

CAPPS, STEPHEN R. Geology of the Alaska Railroad Region. Geol. Survey Bull. 907, 1940, 201 pp.

The region described extends from Seward on the Gulf of Alaska 450 miles north to Fairbanks and the Yukon Basin and covers a strip approximately 70 miles wide on each side of the Government owned and operated Alaska Railroad. Important mineral deposits, particularly gold and coal, occur in the region, and reserves are known to be large. Mineral production during the last 40 years has amounted to about $150,000,000. During this same period, the Geological Survey and the technical press have issued more than 100 written reports and maps on the region, and Bulletin 907 was issued to bring that information together under one cover and in condensed form. Three geologic maps on a scale of approximately 4 miles to the inch accompany the report.

ERICKSON, STEPHEN E., AND ANDERSON, ARVID E. Recovery of Antimony and Tin Compounds from their Ores. U. S. Patent 2,230,972, February 4, 1941.

This invention relates to a process for recovering compounds of antimony and tin from their ores, and more particularly from refractory ores that are not amenable to the ordinary metallurgical methods. Oxide ores containing a metal included in the group consisting of antimony and tin are mixed with soda ash and sulfur and subjected to an anhydrous reducing roast at a high temperature, the soluble polysulfides are leached out with water, and the metal values are recovered by precipitation.

McKEOWN, M. R. Gold-antimony Deposits of Nullagine. Chem. Eng. and Min. Rev., vol. 32, No. 376, January 10, 1940, pp. 143–144.

These lodes, in the Pilbarra district, Western Australia, have been worked desultorily since about 1905. Stibnite and gold occur in a gangue of quartz and partly decomposed country rock. The ore is reported to be very uniform throughout the district. Tests indicate that 85 percent of the antimony and 95 percent of the gold is recoverable by flotation of the stibnite, followed by cyanidation. Some cervantite is present in the oxidized zone.

SEGURA, DAVID. Metallurgy of the Huitzuco Mercury Ores. Am. Inst. Min. and Met. Eng. Tech. Pub. 896, February 1938, 7 pp.

This paper presents the findings of the preliminary tests, which resulted in the construction of a flotation plant at the mine and a reduction plant for the recovery of antimony and mercury at Los Angeles, Calif.

SCHIRRMEISTER, KURT. Manufacture of Antimony Trioxide Pigments. U. S. Patent 2,200,478, May 14, 1940.

This patent covers the preparation of antimony trioxide by the reaction of antimony trifluoride with alkaline reacting compounds instead of by the usual sublimation of the metal or its compounds. The product is claimed to be at least equal to the sublimed oxide, especially with reference to its covering power, whiteness, and the ease with which it is ground with oil.

SOUTH AFRICAN MINING AND ENGINEERING JOURNAL. Antimony Mining in South Africa, vol. 51, No. 2457, pt. 1, March 2, 1940, pp. 9 and 11.

A résumé of the history of antimony mining on the Murchison range from the first World War to the present. Production figures are given, and the prospects for revival of the industry are discussed.

CADMIUM

In 1940, the cadmium industry established new records for the production of both metallic cadmium and cadmium compounds.

Domestic production of the metal increased more than 34 percent, and the production of cadmium compounds increased 24 percent over 1939. Apparent consumption was 23 percent greater than in 1939, in spite of the fact that producers' exports exceeded imports by 100,285 pounds in 1940. Sales of metallic cadmium increased 20 percent and exceeded production by nearly 5 percent. Stocks of metallic cadmium at producers' plants decreased from an estimated 656,000 pounds at the end of 1939 to 330,000 pounds on December 31, 1940. Further declines in producers' stocks were reported early in 1941, and stocks of metallic cadmium held by producers on June 1 were estimated at 200,000 pounds. Data on stocks at consumers' plants are not available, but surveys developing this information are being made.

Demand for cadmium for electroplating increased markedly in 1940 despite rising metal prices, and producers could not meet requirements completely. Much of the demand for cadmium-plated goods was indirectly the result of the national defense program, and considerable cadmium is used directly in filling military orders. These requirements are expected to increase during 1941. Cadmium for military requirements includes cadmium-plated bolts and nuts for aircraft assembly, cadmium-plated wire cloth, and cadmium-plated shoe nails. Increased demand also was reported for cadmium bearings and other alloys and for pigments.

World production data for 1939 are incomplete, and censorship restrictions applied in 1940 prohibited publication of such fragmentary data as were available.

Imports of cadmium dust from Mexico increased slightly in 1940, but imports of metallic cadmium dropped to only 27,491 pounds, all of which came from Belgium before the German invasion. Exports of metallic cadmium by producers totaled 127,776 pounds in 1940; in addition, considerable metallic cadmium was exported by jobbers and brokers. Cadmium was placed on the list of materials under export-license control by Proclamation No. 2463 of March 4, 1941.

Except for the first few days of January 1940, the price of metallic cadmium in commercial sticks, f. o. b. New York, was 80 cents a pound the entire year. Patented shapes continued to hold a premium of 5 cents a pound. During the last few months of the year, however, these quotations were considered nominal, as sales were reported at much higher prices.

Cadmium produced, sold by producers, imported, and consumed in the United States, 1936–40, in pounds

Year	Produced			Metallic cadmium sold by producers	Metallic cadmium imported	Apparent consumption
	Metallic cadmium	Cadmium compounds (estimated Cd content)	Total cadmium			
1936	3,633,495	626,800	4,260,000	3,626,669	576,139	4,836,000
1937	[1] 4,265,973	828,000	[1] 5,094,000	[1] 4,059,764	828,535	[1] 5,923,000
1938	[1] 4,077,961	431,000	[1] 4,509,000	[1 2] 2,525,666	22,582	[1] 4,073,000
1939	[1] 4,411,530	679,000	[1] 5,091,000	[1] 5,190,273	309,874	[1] 5,401,000
1940	5,921,488	845,000	6,766,000	[3] 6,206,627	27,491	6,666,000

[1] Revised figures.
[2] Of this quantity, 458,283 pounds were exported.
[3] Of this quantity, 127,776 pounds were exported.

DOMESTIC PRODUCTION

Cadmium derived from both domestic and foreign raw materials is included in the data in the foregoing table. Figures on the production from each source are not available. Cadmium flue dust imported from Mexico in 1940 yielded 945 tons of metallic cadmium compared with 852 tons in 1939 and 838 in 1938.

In the United States, cadmium is derived chiefly from zinc ores, and normally its production is therefore directly related to the production of zinc. Zinc smelters operated substantially at capacity during 1940, and consequently the output of cadmium increased to a new record. Large quantities of foreign zinc concentrates are now being treated at domestic smelters, however, which may materially change the cadmium production. The Herculaneum (Mo.) plant of the St. Joseph Lead Co. again entered the list of producers of metallic cadmium, and the Sherwin-Williams Co. began producing the metal at its plant at Coffeyville, Kans.

Two domestic cadmium plants are briefly described in Bray's[12] new book on nonferrous metallurgy, and the following notes have been taken from his work.

The Midvale (Utah) plant of the United States Smelting, Refining & Mining Co. treats dust from the lead smelter containing about 22 percent cadmium, 11 percent lead, and 48 percent arsenic. The material is roasted, mixed with sulfuric acid and water, and heated in a reverberatory furnace to convert all of the base metals to sulfates and remove most of the arsenic. The sulfates are then leached about 20 minutes in an agitator, and the zinc, iron, lead, and copper are precipitated by neutralization with lime and filtered out of the solution. The filtrate contains about 12 percent cadmium and is electrolyzed in small tanks between aluminum cathodes and Duriron anodes with a current density of 5 to 8 amperes per square foot at 3 volts. The metal is melted in iron pots under caustic soda cover and cast into the required shapes for the market.

The plant of the American Zinc, Lead, & Smelting Co. at East St. Louis, Ill., is designed to treat 200 tons a day of zinc concentrates, containing approximately 0.4 percent cadmium. The flow sheet accompanying Bray's article shows the flow of materials through the zinc-cadmium distillation plant, from the raw concentrate to the finished zinc, cadmium, and sulfuric acid. The feed is treated in gas fired roasters, and the cadmium is caught in the Cottrell and flue dusts, which are then mixed with the calcines, residues, zinc chloride liquor, and fuel and sent to Dwight-Lloyd sintering machines. The fume from these machines, containing the cadmium, is recovered in another Cottrell precipitator. This dust is leached with sulfuric acid and sodium chlorate; the zinc and cadmium go into solution as the lead is precipitated as the sulfate. The solution is then transferred to another tank, and 90 to 95 percent of the cadmium is precipitated as a sponge by the slow addition of zinc dust. The sponge is then filtered, washed, and dried, mixed with lime and a reducing agent, and distilled in a horizontal batch retort. The retorts yield metallic cadmium, blue powder, and a residue containing 1.5 to 6.0 percent cadmium, 7.0 to 30.0 percent zinc, and 1.5 to 8.0 percent lead. This residue and the zinc chloride-sulfite liquor are returned to the circuit to form part of the Dwight-Lloyd sintering-machine charge.

[12] Bray, John L., Nonferrous Production Metallurgy: John Wiley & Sons, New York, 1941, 430 pp.

The following companies produced cadmium or cadmium compounds in 1940:

	Location of plan
American Smelting & Refining Co	Denver, Colo.
American Steel & Wire Co	Donora, Pa.
American Zinc Co. of Illinois	Fairmont City, Ill.
Anaconda Copper Mining Co	Great Falls, Mont.
Chemical & Pigment Co., Inc	Baltimore, Md.
E. I. du Pont de Nemours & Co	Cleveland, Ohio.
Eagle-Picher Mining & Smelting Co	Henryetta, Okla.
Harshaw Chemical Co	Elyria, Ohio.
New Jersey Zinc Co	Palmerton, Pa.
St. Joseph Lead Co	Josephtown, Pa., and Herculaneum, Mo.
Sherwin-Williams Co	Chicago, Ill., and Coffeyville, Kans.
Sullivan Mining Co	Kellogg, Idaho.
U. S. Smelting, Refining & Mining Co	Midvale, Utah.

DOMESTIC CONSUMPTION

Exact data regarding the consumption of metallic cadmium by uses are not available, but estimates based upon information furnished by producers indicate that the 6,206,627 pounds of metallic cadmium shipped to consumers in 1940 were divided about as follows: 3,736,000 pounds for electroplating, 1,145,000 pounds for cadmium bearings, 272,000 pounds for alloys other than bearings, 705,000 pounds for pigments and chemicals, and the remainder (348,627 pounds) for other purposes and export. Similar estimates for 1939 and earlier years are not available. The demand for cadmium as a corrosion-resisting plating on iron has increased rapidly in recent years and is strong even in years of high cadmium prices. The consumption of cadmium in automobile bearings has varied widely from year to year. Cadmium is also used as an alloy in copper wire; in rolled plates for locomotive fire boxes, castings in electrical apparatus, fusible alloys in fire-extinguishing devices, pigments, solders, stereotype plates, accumulator cells, and glass manufacture; as a deoxidizer in alloys of aluminum, silver, and nickel; and in domestic silverware.

Russell [13] has described the effects of cadmium salts on the body as follows:

> The salts of cadmium, particularly the sulfate, carbonate, and oxide, may cause irritation of the respiratory tract, and gastrointestinal disturbances. Fatal cases of poisoning by cadmium fumes have been reported. The symptoms of cadmium poisoning include weakness, shortness of breath, vomiting, headache, dryness of the throat, and bronchitis. It has been found that the safe limit of cadmium vapors in the air is 0.1 milligram per cubic meter. Electroplating tanks in which cadmium is used should be equipped with efficient local exhaust ventilation to prevent the escape of cadmium fumes.
>
> The use of chemically impure electrodes, or other materials in electroplating, may cause poisoning by the impurities present, such as arsenic, lead and mercury.

A brief discussion of cadmium recently appeared.[14] Markwith lists the industries and occupations wherein cadmium poisoning may be contracted, with particular reference to Ohio.

An interesting paper on the occurrence of cadmium and certain other minor elements in sphalerite recently appeared.[15] The author states, "The data used consist of new spectrographic analyses of minor

[13] Russell, J. P., Health Hazards in Electroplating: Metal Finishing, vol. 38, No. 6, June 1940, p. 324.
[14] Markwith, R. H., Cadmium and Its Compounds: Ohio Dept. of Health, 1940, 7 pp.; mimeographed; contains bibliography.
[15] Stoiber, Richard E., Minor Elements in Sphalerite: Econ. Geology, vol. 35, No. 4, June–July 1940 pp. 501–519.

elements in 75 sphalerite samples from many varied localities." Fifty-three of the specimens analyzed originated in the United States. According to a table accompanying the article, cadmium was found in all the specimens, consituted 0.1 percent or more in 73, and exceeded 1 percent in 9.

According to Johnston,[16] the length of runs between grinds on multislide presses can be increased as much as 300 percent by cadmium-plating the material being formed. The plating apparently acts as a lubricant.

Recent patents on cadmium include the following:

Blackwell, H. A., and Turner, W. L., Process for the Reduction of Zinc, Cadmium, and Mercury: U. S. Patent 2,229,716, January 28, 1941.

Groombridge, W. H., and Dee, T. P., Process of Preparing a Cadmium Metaphosphate Catalyst: U. S. Patent 2,206,226, July 2, 1940.

O'Brien, James J., Production of Cadmium Colors: U. S. Patent 2,220,116, November 5, 1940. Method of Making Cadmium Sulfide Pigments: U. S. Patent 2,220,117, November 5, 1940. Process of making Cadmium Red Pigments: U. S. Patent 2,226,573, December 31, 1940. Preparation of Cadmium Pigments: U. S. Patent 2,237,311, April 8, 1941.

FOREIGN TRADE

In normal years, considerable metallic cadmium is imported from Canada and various European countries, including Belgium, Netherlands, Italy, Norway, Poland, and Germany. Imports from European countries were disrupted in 1940, and only 27,491 pounds were received, all of which came from Belgium before the German invasion. Imports in 1939 were 309,874 pounds, of which 197,454 pounds came from Belgium. Exports of cadmium as metal vary between wide limits. Producers of metallic cadmium reported direct exports of 458,283 pounds of metal in 1938, none in 1939, and 127,776 pounds in 1940. In addition, considerable cadmium is exported by jobbers, dealers, and brokers who purchase metal from domestic producers. These exports are not reported to the Bureau of Mines. There is a limited import and export trade in cadmium compounds, but the quantities involved are believed to be relatively unimportant. Exports of cadmium with benefit of draw-back totaled 13,996 pounds in 1940 compared with 52,149 pounds in 1939 and 36,081 in 1938; most of this metal was in bearings. The United States also imports crude materials containing cadmium for refining. Cadmium recovered from flue dust imported from Mexico in 1940 totaled 1,890,000 pounds compared with 1,704,000 pounds in 1939. Production of cadmium from imported flue dust and other residues will increase sharply in 1941 owing to receipts of material from Africa that formerly went to Belgium and Germany.

PRICES

The average of producers' and platers' quotations in 1940, as reported by Engineering and Mining Journal Metal and Mineral Markets, was 82.3 cents a pound compared with 64.1 cents in 1939, 98.0 cents in 1938, $1.223 in 1937, 97.8 cents in 1936, 70.5 cents in 1935, and 55 cents in 1933 and 1934. The average price, based solely upon quotations by producers for ordinary commercial shapes, quan-

[16] Johnston, J. G., Stamp-forming Runs Increased 300 Percent by Cadmium-plating the Material: Steel, vol. 108, No. 1, January 6, 1941, p. 243.

tity business, in 1940 was 79.9 cents a pound compared with 59.2 cents in 1939, when Metal and Mineral Markets established this basis. The average value, based upon sales as reported to the Bureau of Mines by producers, was 70 cents in 1940 compared with 54 cents in 1939, 75 cents in 1938, $1.14 in 1937, 80 cents in 1936, and 50 cents in 1935.

At the beginning of 1940, patented shapes were quoted at 85 cents a pound to platers, and the quotation for commercial sticks in wholesale quantities was 75 cents; but, effective January 8, the price of sticks was raised to 80 cents. There were no further changes in the quotations of either commodity during the year, but sales were reported at prices far above the published quotation during the last quarter.

The London market opened at 5s. 6d. a pound and remained there until early May, when quotations dropped to 5s. on Empire metal and 4s. 10d. on outside offerings. Quotations were within 2d. of this last figure the balance of the year.

WORLD PRODUCTION

Data on the world output of cadmium are very incomplete because the belligerent nations have restricted the publication of production figures. The following table gives the salient statistics on world production, insofar as they are available.

World production of cadmium, 1936–40, by countries, in kilograms

[Compiled by L. P. Lounsbery]

Country	1936	1937	1938	1939	1940
Australia (Tasmania)	251,826	210,608	199,326	175,150	(1)
Belgium	203,997	271,000	182,000	[2] 530,800	(1)
Canada	356,484	338,018	317,122	426,234	(1)
France	84,000	99,000	116,000	(1)	(1)

Metallic cadmium	1,648,117	1,935,603	1,849,722	2,001,026	2,685,928
	3,600,000	4,300,000	4,100,000	(1)	(1)

[1] Data not available.
[2] Exports.
[3] Mexican Government reports total cadmium content of material produced in Mexico as follows: 1936, 535,017 kilos; 1937, 619,792 kilos; 1938, 762,398 kilos; 1939, 816,584 kilos; 1940, 815,734 kilos. This material is exported for treatment elsewhere; therefore, to avoid duplication of figures, the data are not included in this table.
[4] Cadmium content of quantity exported. Represents in part shipments from stocks on hand.
[5] Estimated cadmium content.

REVIEW BY COUNTRIES

Canada.—Most of the cadmium produced in Canada comes from the plants of the Consolidated Mining & Smelting Co. at Trail, British Columbia, and the Hudson Bay Mining Co., at Flin Flon, Manitoba. These plants have an annual capacity of 500 and 180 tons, respectively. No figures on 1940 production have been released, but the plants operated continuously throughout the year, undoubtedly at a greatly increased rate.

Germany.—Certain restrictions were placed on the use of cadmium in 1939, but after the plants in Upper Silesia and Norway were acquired the situation was eased somewhat. The metal has largely replaced nickel as a rust-preventing plating metal. The price for rods (sticks) and anodes (shapes) remained about the same, that is, 4.50 and 5.0 reichsmarks per kilo, respectively.

Mexico.—No metallic cadmium is produced in Mexico, but a large part of the United States supply comes from Mexican ores. Most of it is recovered in flue dust at smelters in Monterrey and Rosita. The material is shipped to the Globe plant of the American Smelting & Refining Co., Denver, Colo., for treatment. During the period 1936–40, domestic metal produced from dust imported from Mexico averaged 1,530,000 pounds a year or nearly 30 percent of the average apparent domestic consumption in those years.

South-West Africa.—Otavi Minen und Eisenbahn Gesellschaft is the sole producer of cadmium in the territory. The metal is contained in flue dust, which is a byproduct from the smelting of the copper-lead-zinc ores of the Tsumeb mine and contains approximately 38 percent cadmium. Before the European conflict, the flue dust was shipped to Belgium and Germany, but no exports were made to these countries in 1940.

PLATINUM AND ALLIED METALS

By H. W. DAVIS

SUMMARY OUTLINE

There was an active demand for platinum metals in the United States during 1940. Stimulated by defense activities, there were noteworthy increases in sales to the electrical and chemical industries. Although sales to the jewelry trade were considerably higher than in 1939, they represented a smaller proportion of the total. Recoveries of new and secondary platinum metals in the United States gained 14 and 5 percent, respectively, in 1940. Production of placer platinum metals increased 12 percent. Imports of platinum metals declined 36 percent from 1939, which, however, was a record year. On the other hand, exports of unmanufactured platinum metals were 19 percent greater than in 1939. Despite the increased demand for platinum metals in 1940, prices remained relatively stable for all metals except iridium, which toward the year end sold at more than $275 an ounce. The greatly increased price of iridium was attributed to cessation of supplies from the U. S. S. R., accelerated consumption, and speculation.

Salient statistics of platinum and allied metals in the United States, 1939–40, in troy ounces

[1] Subject to revision.
[2] In 1940 includes 8,427 ounces (8,205 in 1939) of new platinum from domestic sources, comprising 3,957 ounces (2,919 in 1939) derived from crude placer platinum, none (16 ounces in 1939) from ore, and 4,470 ounces (5,270 in 1939) obtained from domestic gold and copper ores as a byproduct of refining.
[3] Beginning with 1940, figures include stocks held in the United States by importers of platinum-group metals from the United Kingdom.

Although the United States leads the world by a wide margin in consumption of platinum metals, before 1935 it had supplied but a very small proportion of the world output. During the 10 years 1925–34, annual production averaged only 8,300 ounces—1,000 ounces of placer platinum, 600 ounces from palladium-bearing copper ore, and 6,700 ounces as byproduct of gold and other metals. Since 1935, however, largely in consequence of large-scale mining in Alaska, the production of platinum metals in the United States has increased phenomenally, attaining a maximum of 48,269 ounces in 1938—40,932 ounces of placer platinum, 7,247 ounces recovered from gold and copper refining, and 90 ounces obtained from platinum-bearing ore. During the 5 years 1935–39 it averaged 28,300 ounces—20,600 ounces of placer platinum, 7,600 ounces recovered from gold and copper refining, and 100 ounces obtained from platinum-bearing ore. In 1940 production was about 44,300 ounces. Thus, the United States has attained the rank of fourth largest producer of platinum metals.

In addition, the United States is an important refining center and occupies a prominent position in the international platinum trade. During 1940, for example, 47,339 ounces of new platinum metals and 66,430 ounces of secondary platinum metals were recovered by domestic refiners, 195,645 ounces of unmanufactured platinum metals were imported for consumption, and 55,027 ounces of platinum and allied metals (ingots, sheets, wire, alloys, and scrap) and a considerable quantity of placer platinum were exported.

Despite the much larger output of domestic placer platinum, most of the new platinum metals recovered by refiners in the United States in 1940, as in previous years, were derived from crude platinum from foreign sources, notably Colombia, as most of the Alaska platinum was refined abroad. The major part of the refined new platinum metals now consumed in the United States emanates from the United Kingdom; the metals are recovered there chiefly as byproducts in refining nickel-copper matte from the Sudbury district of Ontario and, to a smaller extent, from matte from the Rustenburg district of the Union of South Africa and from placer platinum originating in the Goodnews district (Alaska).

CRUDE PLATINUM

Production.—Mine returns for 1940 indicate a production of 35,000 ounces of crude platinum (containing 28,860 ounces of platinum-group metals valued at $1,092,000) in Alaska,[1] 1,400 ounces in California, 31 ounces in Montana, and 69 ounces in Oregon—a total of 36,500 ounces. Comparable figures for 1939 are 31,300 ounces of crude platinum (containing 27,230 ounces of platinum-group metals valued at $997,000) in Alaska, 1,140 ounces in California, and 20 ounces in Oregon—a total of 32,460 ounces. Production in Alaska came mainly from placer deposits in the Goodnews district of southwestern Alaska; most of it was mined by a large modern dredge and by well-mechanized draglines. In California most of the output of platinum was a byproduct of dredges working the gold placers in Amador, Merced, Placer, Sacramento, Shasta, Siskiyou, Stanislaus, Tehama, and Trinity Counties. The production in Montana was a byproduct of a dredge working the gold placer in Lewis and Clark County. The principal production in Oregon came from the ocean beach near Cape Blanco, Curry County.

Many gold and copper ores in the United States contain small quantities of platinum metals. In 1940, 7,774 ounces of platinum metals were recovered as a byproduct of refining gold and copper ores compared with 8,634 ounces in 1939.

[1] Figures and other information for Alaska from Federal Geological Survey.

The Goodnews (Alaska) platinum deposits have been described recently by Mertie.[2] The report describes the geography, general geology, and economic geology of the platinum deposits and is illustrated with topographic and geologic maps. It includes 28 commercial analyses of platinum metals of Fox Gulch and Platinum Creek, 8 of Squirrel Creek, 47 of Lower Platinum Creek and Salmon River, and 1 of Clara Creek. The average commercial analysis of platinum metals of the streams follows:

Average commercial analysis of platinum metals of the Goodnews district, Alaska, in percent

	Fox Gulch and Platinum Creek	Squirrel Creek	Lower Platinum Creek and Salmon River	Clara Creek
Platinum	62.10	68.69	73.48	73.29
Iridium	20.34	13.19	9.77	5.90
Osmium	3.93	3.25	1.93	.69
Ruthenium	.33	.25	.15	.13
Rhodium	1.49	1.38	1.05	.42
Palladium	.23	.27	.31	.56
Gold	.32	.41	2.10	1.01
Impurities	11.26	12.56	11.21	18.00

Purchases.—Platinum refiners in the United States reported purchases of domestic crude platinum from the following sources in 1940: Alaska, 4,293 ounces; California, 1,563 ounces; Montana, 31 ounces; and Oregon, 119 ounces—a total of 6,006 ounces (4,479 ounces in 1939). Domestic refiners also reported purchases of 34,374 ounces (35,135 ounces in 1939) of foreign crude platinum or osmiridium in 1940—2 ounces from Canada, 33,320 ounces from Colombia, and 1,052 ounces from the Union of South Africa.

Prices.—Buyers reported purchases at $21.92 to $37.67 an ounce for domestic crude platinum and $26.92 to $51.03 an ounce for foreign crude platinum or osmiridium in 1940.

REFINED PLATINUM METALS

New metals recovered.—Reports from refiners of crude platinum, gold bullion, nickel, and copper indicate that 47,339 ounces of platinum metals were recovered in the United States from these sources in 1940, a 14-percent increase over 1939. It is estimated that 12,704 ounces of the total output in 1940 were derived from domestic sources.

New platinum metals recovered by refiners in the United States in 1940, by sources, in troy ounces

[1] Revised figures.

Prices.—Except for iridium, there were no appreciable changes in the quoted prices [3] of platinum metals in 1940. Platinum opened the year at $40 an ounce but declined to $38 on April 15 and to $36 on September 5. Palladium remained steady at $24 an ounce, as did rhodium at $125 and ruthenium at $35 to $40. Iridium, however, opened the year at $125 an ounce and advanced on January 11 to $175, but on April 25 it declined to $150 and on September 12 to $125, where it remained until October 27. Effective October 28, the quoted price was raised to $140, and increases on November 11, 26, and 29 and December 11 brought it to $275. Some sellers were reported to have asked higher prices. The advance in price was attributed to heavier demand from the aircraft industry, greatly reduced imports, and speculative influences. Because of the advance in the price of iridium a study of military requirements and available supplies was conducted by the Office of Production Management, which found according to a press notice of January 15, 1941, "There is no justification whatever for the great advance in the price of iridium, culminating in a jump during November and December from $148 to $300 or more per ounce" and "* * * that contrary to prevalent rumor there is no real shortage of iridium." On February 6, 1941, the quoted price was lowered to $175 an ounce.

Consumption and uses.—Platinum and its allied metals (palladium, iridium, rhodium, ruthenium, and osmium) are characterized by high melting point, whiteness, and resistance to oxidation at high temperatures and to attack by destructive chemical compounds. As pure metals, combined, clad, or alloyed with other metals, the platinum metals are employed in jewelry and dentistry, in the chemical and electrical industries, and for numerous miscellaneous purposes.

A material gain in world output of platinum metals, owing chiefly to improvements in metallurgical processes for refining copper-nickel ores, has made available large quantities of platinum, palladium,

[3] Engineering and Mining Journal, Metal and Mineral Markets: Vol. 11, 1940.

iridium, rhodium, ruthenium, and osmium. In 1938—the latest year for which fairly complete figures are available—world production of platinum metals was about 540,000 ounces, of which about 57 percent was recovered as byproducts in the refining of nickel, copper, and gold ores, whereas in 1929 world production was about 231,000 ounces, of which about 17 percent was so obtained. With increased supplies, relative stability in the price of platinum and palladium has been reached at levels that permit their use for plant equipment and other industrial purposes. Despite the rapid advance in output of the platinum metals during the past decade, research has found new uses for them, and developmental activities are opening up larger and more diversified markets in which they are becoming accepted.

The most widely used metal of the group is platinum, which constituted 122,978 ounces (59.4 percent) of the total platinum metals reported sold to consumers in the United States in 1940. The largest single buyer of platinum is the jewelry industry, where, alloyed with iridium or ruthenium, it is employed as a setting for diamonds and other precious stones in rings and other forms of jewelry. About 42 percent (51,296 ounces) of the total sales of platinum went to the jewelry trade in 1940.

Second in magnitude as a consumer of platinum in 1940 was the chemical industry, which took 25 percent (31,174 ounces) of the total domestic sales. Platinum is used in this industry as a catalyst to produce sulfuric acid and for ammonia oxidation to produce nitric acid and nitric oxide, lining processing and reaction vessels, hydrogenation of organic compounds, rayon spinnerets, nozzles for the production of glass fiber, glass insulators for the bases of electric-light bulbs, tubing, valves, siphons, and safety disks for handling corrosive liquids and gases, anodes for the production of "per" salts, gas-analysis cells, crucibles, and laboratory equipment.

The electrical industry, which usually ranks fourth as a consumer of platinum, advanced to third place in 1940, taking 14 percent (17,548 ounces). Platinum is used in this industry for thermocouples, temperature measuring and recording instruments, precision resistance thermometers, high-temperature furnace windings, spark-plug electrodes, magneto contacts, electrical contacts, relays, thermostats, automobile voltage regulators and direction indicators, and switches for potentiometric recorders.

The dental industry dropped from third to fourth position as a consumer of platinum in 1940, taking 8 percent (9,859 ounces). Platinum, either pure or alloyed, is used in tooth pins, bridges, and bracings for artificial teeth, as matrices on porcelain inlays, and in orthodontic appliances.

Next to platinum, palladium is the most extensively used metal of the platinum group; it is about half as common as platinum but less costly. It comprised 69,319 ounces (33.5 percent) of the total platinum metals sold to domestic consumers in 1940. Palladium, pure or alloyed, is adapted to many of the uses of platinum and during the past 2 decades has been employed in increasing quantities by the dental, electrical, and jewelry industries. The conservation of gold by many countries has stimulated the demand for the platinum metals, particularly palladium, and the substitution of palladium for gold alloys for dental restoration, pen points, and articles of jewelry has made substantial progress. Palladium in telephone relays and other types of electrical contacts found an improved market in the electrical field; in consequence, the electrical industry was the chief consumer in 1940, taking 47 percent (32,528 ounces). There was an increased demand for palladium in dentistry, which took 38 percent (26,346 ounces) of the total. The jewelry industry is the next largest consumer of palladium, and small quantities are used in the manufacture of chemical ware.

The consumption of the other platinum metals—iridium, rhodium, osmium, and ruthenium—is comparatively small and comprised only 7.1 percent of the total for the group in 1940. Iridium is used chiefly as a hardening addition to platinum, rendering it suitable for laboratory vessels, surgical tools, hypodermic needles, thermoelements, and jewelry. Its compounds are employed as fixing agents, porcelain pigment, and (in the form of black) as a catalyst. There was a noteworthy increase in the demand for iridium in magneto contacts for airplanes in 1940. Rhodium is alloyed with platinum for high-melting-point thermocouple wire, furnace windings, and laboratory ware for certain special applications, and for use as a catalyst to produce sulfuric acid and for ammonia oxidation to produce nitric acid and nitric oxide. Rhodium plating is employed as a finish for glassware and silverware and in surfacing reflectors for searchlights and projectors. Platinum-rhodium spinnerets continue to replace the older platinum-gold spinnerets in the production of rayon, because of their superior resistance to the various corrosive agents used. Osmium, in association with other metals, provides pen points that will resist wear and corrosion by ink. These alloys also replace jewels as bearings in fine instruments. The oxide is used as a biological stain for fats and for fingerprint work. Ruthenium also is utilized as a hardener for platinum metals, and one of its salts serves as a biological stain. Because of the increased demand for iridium in the aircraft industry, ruthenium was effectively employed as a hardener of platinum in jewelry.

The following table shows reported sales of platinum metals to consumers in the United States in 1940; such sales totaled 206,890 ounces. The figures include sales of platinum metals recovered from crude platinum, gold bullion, copper and nickel bullion and matte, electrolytic muds, and scrap materials and sweeps; sales of imported platinum metals handled by domestic refiners; and sales in the United States by importers of platinum-group metals from the United Kingdom. Before 1940 the figures excluded sales in the United States by importers of platinum-group metals from the United Kingdom; therefore, the statistics for 1940 are not comparable with those for earlier years.

Platinum metals sold in the United States in 1940, by domestic consuming industries, in troy ounces [1]

Industry	Platinum	Palladium	Iridium, osmium, rhodium, and ruthenium	Total
Chemical	31,174	1,624		
Electrical	17,548	32,528		
Dental	9,859	26,346	14,593	206,890
Jewelry	51,296	7,624		
Miscellaneous and undistributed	13,101	1,197		
	122,978	69,319	14,593	206,890

[1] Figures include sales in the United States by importers of platinum-group metals from the United Kingdom.

Stocks.—On December 31, 1940, 269,914 ounces of platinum metals were in the hands of refiners and importers of platinum-group metals from the United Kingdom. Before 1940, the stocks of platinum metals held in the United States by importers of platinum-group metals from the United Kingdom were not included in the statistics; therefore, the figures for 1940 are not comparable with those for earlier years.

Stocks of platinum metals held by refiners in the United States, December 31, 1936–40, in troy ounces [1]

Year	Platinum	Palladium	Iridium	Osmium, rhodium, and ruthenium	Total
1936	56,886	29,853	[2] 8,198	[2] 8,980	103,917

[2] Revised figures.

FOREIGN TRADE [4]

Imports.—Imports of platinum metals into the United States during 1940 dropped to 195,645 ounces from 306,627 in 1939; the latter figure, however, was an all-time high. Although the imports of all metals of the platinum group except osmium declined, the most noteworthy decrease was that of iridium; receipts amounted to only 237 ounces (all from the United Kingdom) compared with 6,363 ounces in 1939, of which 4,284 ounces came from the U. S. S. R., 1,665 ounces from the United Kingdom, 318 ounces from Norway, and 96 ounces from France. During the 5 years 1935–39, imports averaged 4,354 ounces, of which 45.6 percent came from the United Kingdom, 43.0 percent from the U. S. S. R., 10.9 percent from Norway, and 0.5 percent from other sources. Imports of osmiridium dropped to 1,857 ounces in 1940 from 2,204 ounces in 1939 and from an average of 3,380 ounces during the 5 years 1935–39. Imports of refined platinum decreased substantially in 1940 compared with 1939, but those of unrefined platinum increased considerably, chiefly because of the receipt of concentrates from Canada.

The principal sources of imported platinum metals in 1940 were the United Kingdom (122,957 ounces), Canada (35,659 ounces), and Colombia (34,011 ounces).

Platinum metals imported for consumption in the United States, 1936–40

Exports.—Exports of unmanufactured platinum metals increased to 55,027 ounces in 1940 from 46,329 ounces in 1939. Noteworthy were the exports to the United Kingdom, which advanced to 22,622 ounces (2,859 in 1939). There were also conspicuous increases in the exports to Argentina, Brazil, and Japan. On the other hand, exports to Germany ceased (11,401 ounces in 1939), and those to France declined to 3,877 ounces (13,709 in 1939).

Platinum and allied metals exported from the United States, 1936–40

Year	Unmanufactured		Manufactures of, except jewelry

WORLD PRODUCTION

Figures on world production of platinum metals by countries are fairly complete for 1936, 1937, and 1938, and data are available for most of the chief producing countries for 1939; however, because of government restrictions on the publication of statistics for many countries, few figures for 1940 are available.

World production of platinum and allied metals, 1936–40, in troy ounces

[1] Data not available. [2] Recovered from nickel-copper mattes. [3] Year ended June 30 of year stated.
[4] Produced from platinum ores. [5] Produced from treatment of gold ores on the Rand.
[6] Estimated production. [7] Subject to revision.
[8] New platinum metals recovered in gold and copper refining of domestic materials.
[9] Exclusive of Ethiopia and Japan.
[10] Exclusive of New South Wales, Belgian Congo, Ethiopia, Italy, and Japan.

Canada.—Figures on recovery of platinum metals from the nickel-copper ores of the Sudbury district, Ontario, in 1940 are not available, but in 1939, 148,877 ounces of platinum and 135,402 ounces of other platinum-group metals were recovered. Concentrates assaying 50 to 60 percent platinum metals from the Port Colborne refinery, those assaying 80 to 90 percent platinum metals from the Copper Cliff refinery, and residues averaging about 4 percent platinum metals from the Clydach (South Wales) refinery are normally shipped to the International Nickel Co. precious metals refinery at Acton, England, for the recovery of platinum, palladium, iridium, rhodium, and ruthenium. In 1940, however, some concentrates were refined in the United States. Platinum and palladium are recovered in the form of sponge of an average purity of 99.93 and 99.94 percent, respectively, and rhodium, ruthenium, and iridium in the form of meal of an average purity of 99.7 percent each. The platinum metals contained in the ore of the Falconbridge Nickel Mines, Ltd., were, before the German occupation of Norway on April 9, 1940, recovered at the precious metals separating plant at Kristiansand. Osmium is not present in the Sudbury nickel ore in sufficient quantity to make its recovery commercially important.

Colombia.—The South American Gold & Platinum Co. produced 24,294 ounces of crude platinum metals in 1940 (27,975 in 1939) and 58,462 ounces of gold (59,416 in 1939). The figures of other operators are not available.

Union of South Africa.—According to the Department of Mines and Industries, the estimated content of platinum metals produced in the Union of South Africa was about 43,600 ounces during the 7 months January–July 1940. Figures for the entire year are not available. In the year 1939 production was 66,342 ounces.

Sales of platinum metals from South Africa were 28,483 ounces valued at £228,504 (£8.02 an ounce) during the first 7 months of 1940 compared with 47,912 ounces valued at £302,370 (£6.31 an ounce) in the entire year 1939. The average composition of the product sold in 1939 was platinum 66.27 percent, palladium 25.71 percent, iridium 0.42 percent, osmium and osmiridium 0.22 percent, rhodium 0.64 percent, ruthenium 2.20 percent, and gold 4.54 percent.

Sales of osmiridium were 3,369 ounces valued at £40,779 (£12.10 an ounce) during the first 7 months of 1940 compared with 6,076 ounces valued at £36,456 (£6 an ounce) in the entire year 1939. The average composition of the product sold in 1939 was osmium 28.64 percent, iridium 25.72 percent, ruthenium 13.52 percent, platinum 10.37 percent, gold 3.88 percent, rhodium 0.40 percent, and undetermined 17.47 percent.

The platinum deposits of the Union of South Africa have been described briefly in a recent report of the Department of Mines.[5]

MINOR METALS

By Paul M. Tyler

SUMMARY OUTLINE

Although none of the various minor metals regularly reviewed in this chapter was included in the Army and Navy strategic- or critical-materials lists, many of them were carefully studied by various Government agencies. Several items normally are imported; nevertheless, it has been possible to undertake domestic production of virtually all those that hitherto came from continental Europe. Owing to the small tonnages involved, shipping space was available for necessary imports of ores from South America; in fact, the only real problem was the bidding for bottoms by importers of Indian ilmenite, which tended to aggravate the difficulty and cost of getting cargo space for manganese ore and certain other needed imports from British India and other Far Eastern sources. Virtually the only other item in this group that involves movement of more than a few hundred tons of material overseas is mixed zircon-rutile concentrate, which comes from Australia.

By virtue of the military order of July 2, 1940, the export from the United States of various materials was permitted only under license, and other items were added from time to time. Effective April 15, 1941, or earlier, the minor metals and their (specified) ores, salts, and compounds subject to export control (Schedule 1) included beryllium, radium, titanium, and uranium. Ferrocolumbium was also included.

The story of the year, as regards wide popular appeal, was the premature announcement that atomic energy had been harnessed so that it could be employed for performing useful work. According to one rumor, Hitler had set 200 scientists to working out practical details, so that this new power could be employed to speed up airplanes and other instruments of the blitzkrieg. The real achievement in this field was isolation of the isotope of uranium, U235, whose fission does afford the hope of commercially tapping this boundless new reservoir of potential energy. On the other hand, it was found that less than 1 percent of this isotope is present in ordinary uranium and that methods of separating it are highly inefficient. Through the shroud of mystery that hides from the layman the advances on this uttermost frontier of modern science, nothing definite has yet penetrated that justifies definite prediction as to commercial implications.

Exploring the same general sector of atomic research, Dr. Pecher, at the University of California, produced radioactive yttrium by transmutation of strontium under bombardment of 16-million-volt deuterons from a cylotron. According to Jeffries:[1]

> * * * The yttrium produced by transmutation of strontium is strongly radioactive, with a life of about 100 days. This life is long compared with, say, radioactive sodium but it is short compared with radium. Radioactive yttrium may be used to radiograph steel and metal parts. The amount so far produced experimentally is equivalent to about 25 milligrams of radium. At present, however, production of yttrium by this process is more expensive than radium for similar doses of gamma radiation. It seems probable that the ultimate cost of producing gamma radiation from yttrium may be much lower than from radium. What these experiments suggest, however, is that other radioactive materials may come from the cylotron and other atom-smashing hoppers.

IMPORTS

Imports of specified rare metals and alloys during the last 3 years are summarized in the accompanying table.

Imports of minor metals for consumption in the United States, 1938–40 [1]

Commodity	1938		1939		1940	
	Quantity	Value	Quantity	Value	Quantity	Value

BARIUM

Barium metal is now made in the United States, chiefly to supply the small requirements for radio, vacuum, and thermionic tubes where it is used as "getter," along with lithium, potassium, and calcium. In common with other rare metals, it is now supplied by Kemet Laboratories (Cleveland, Ohio) clad in iron or other common metal. An interesting use of Kemet Iron Clad barium wire is to form a high-temperature lubricating film on special steel balls for rotating anodes in highly evacuated small X-ray tubes.[2] At high temperatures the barium diffuses through the iron, volatilizes, and condenses, in part, on the surfaces of the balls. Oil could not be used for this work, both because of the high temperature and because of its volatility, and the reduction in friction and improved life of rotating parts resulting from the barium coating are quite remarkable.

BERYLLIUM

Beryllium production is still an infant industry, but in 1940 it grew lustily. Most of the metal is now produced as a 4-percent master alloy with copper, in which form it is sold at $15 per pound of contained beryllium, whereas beryllium metal of domestic manufacture costs approximately $45 a pound compared with $100 formerly charged for German-produced metal of less purity. Wrought beryllium alloys—which are made by remelting the master alloy and which are ready for fabrication—now range from 0.1 to 2.25 percent in beryllium content. Best-known and longest on the market is a binary alloy containing 2 to 2.25 percent beryllium. The base price for strip and other merchant forms of this alloy is 96 cents per pound when copper is 10 cents (98 cents at 12-cent copper). By adding a little cobalt (0.25 percent, for example), which seems to stabilize the properties and improve uniformity as well as to facilitate precipitation hardening, the Be content can be reduced to 1.8 percent without loss of properties obtainable by heat treatment.[3] Another alloy on the market contains approximately 0.5 percent beryllium and 2.6 percent cobalt, and there is also one with only about 0.1 percent beryllium and 0.3 percent chromium, the remainder being copper in both instances. These two alloys are primarily electrical alloys (conductivity, approximately 50 and 70 percent that of copper, respectively) with excellent strength and hardness. The 2.6-percent cobalt alloy, however, is reported also to have an unusually high endurance limit at temperatures around 500° F.

In its annealed, soft condition, the 2-percent beryllium-copper alloy shows a tensile strength of about 66,000 pounds per square inch, with 50-percent elongation in 2 inches. According to the leading producer, cold-rolled and heat-treated strip will show over 190,000 pounds per square inch tensile strength with about 3 percent elongation. The heat-treatable nature of beryllium alloys results from precipitation hardening. When a beryllium-copper alloy is cooled (quenched) rapidly from 800° C., the copper becomes supersaturated with beryllium and is in a soft, unstable state. During aging or reheating in the range 250° to 300° C., a stable condition is reached

[3] Stott, L. L., Beryllium and Beryllium Copper: Metal Progress, vol. 38, No. 4, October 1940, pp. 539–540.

through precipitation of the excess in the form of a submicroscopic dispersion of the gamma phase. Extended reheating in the precipitation range of temperature will cause apparent coalescence and growth in size of grain, with consequent resoftening.

A fair amount of beryllium oxide is sold—chiefly as a superrefractory but also for other purposes—but beryllium is used mainly in alloys, almost entirely in beryllium copper. Beryllium nickel, however, also has possibilities, aluminum alloys with beryllium additions are being investigated, and the metal itself has recently been made experimentally in the United States. Sawyer and Kjellgren[4] have reported tests on 99.5-percent pure beryllium metal with impurities divided between aluminum, iron, magnesium, carbon, and silicon. The high velocity of sound in beryllium was remarkable, as it conducted sound waves 2-1/2 times as rapidly as steel. The polished metal also exhibited fairly good reflectivity for white light (52 to 55 percent); although this was not as good as that of polished aluminum (80 percent), the surface seemed to be permanent, and this factor, combined with its low density of 1.84, its high elastic modulus, and fair electrical (and thermal) conductivity, suggests its use for instrument mirrors, both oscillating and stationary. A chill-cast bar was rather weak, very brittle (ultimate tensile strength, 20,990 pounds per square inch without any measurable elongation), and hard (114 Brinell at 1,500-kg. load).

Beralite, a beryllium-aluminum alloy sponsored by E. B. Wilford and H. S. Cooper, was being investigated in 1940 for possible use in aircraft construction. It is claimed that this alloy is lighter than aluminum, as strong as good steel, and comparatively noncorrosive.

Great strength combined with good electrical heat conductivity and resistance to wear had led to the use of beryllium copper in many industries, but the property now being emphasized as outstanding is the stability of the spring properties of alloys under steady loads. When properly heat-treated, beryllium copper exhibits a remarkably small amount of elastic drift or hysteresis compared to steel or other bronzes, according to the manufacturer. This characteristic is bringing increased use of the material for calibrated springs in instruments of all kinds where accuracy of spring properties is vital, as well as in the electrical field wherever maintenance of constant contact pressures is desired.

The following comments on uses are abstracted from Mineral Trade Notes:[5]

> At the moment the rapidly expanding demand for beryllium comes from a diversity of minor uses—in little gadgets of various kinds. By far the largest outlet is for springs and similar small parts in business machines. Next in importance is the construction of control instruments, but the new aircraft program promises to make this the most important field, even though no additional uses are found for these alloys.
>
> Characteristic of certain valuable properties of beryllium alloys is their use in Bourdon springs in pressure gages, notably those for oxygen, which have to resist corrosion as well as retain indefinitely their resistance to fatigue. Most metals—and, more particularly, heat-treated alloys—after long repeated stress tend to "creep" or lengthen, just as a rubber band when overstretched does not quite return to its original length. Part of the reputedly phenomenal fatigue resistance of beryllium alloys is due to their high tensile strength and elastic limit, but their

[4] Sawyer, C. B., and Kjellgren, B., Beryllium and Some of Its Aluminum Alloys: Metals and Alloys, vol. 11, No. 6, June 1940, pp. 163–167.
[5] Tyler, Paul M., Beryllium: Bureau of Mines Mineral Trade Notes, vol. 11, No. 5, November 20, 1940, pp. 5–8.

stability of spring performance seems to be due in part also to a peculiar inherent property of the alloys after precipitation hardening. It has been suggested that the very low "elastic drift" or hysteresis results from the circumstance that stresses are relieved by heating to about the same temperature as that required for precipitation hardening. They are also claimed to exhibit remarkable resistance to wear and change in volume when subjected to rubbing loads under heavy pressure. Beryllium-copper alloys have been used for nonmagnetic ball bearings under certain circumstances, for fuse springs in shells, and in the automobile industry for solderless connectors and spring terminals, with a resultant speeding up of the assembly of distributors and sundry electrical equipment.

A specialized outlet for beryllium copper is in low-sparking or "safety" tools. Various nonferrous alloys have been used for hammers and cold chisels where a spark from a steel tool might cause serious explosion, as in repairing a gas tank. But most of these alloys lacked the hardness, strength, and toughness of beryllium copper, which, therefore, has been adopted by several leading chemical and oil companies. The range of safety tools for use where dangerous gases or liquids are present extends from wire brushes to axes, pitchforks, pliers, wrenches, and wrecking bars, in addition to the better-known hammers and chisels. No type of tool will eliminate spark hazard but beryllium-copper tools greatly reduce it.

Beryllium has recently been proposed in England as an ingredient of a new textile fiber of the rayon family. The other principal raw material is seaweed. The spinning solution for the new filaments, as reported in The Chemical Age (January 11, 1941, p. 39), is sodium alginate, which can be spun by the usual rayon machinery, comprising a gear pump, a "candle" filter, a multiple-orifice jet, and a final silk-fabric filter. The sodium alginate solution is readily obtained from seaweed, of which very large quantities are available. The quality of the yarn, however, is determined by the composition of the coagulating bath. A simple calcium chloride solution, preferably slightly acidified, can be employed, but a calcium alginate yarn dissolves in warm soap and soda solutions, such as might be used for laundering fabrics. A certain amount of washability may be obtained by treating such yarns with aluminum or chromium acetate, but the yarn with best all-round characteristics so far made from seaweed is hardened in a coagulating bath of beryllium acetate. Upon the basis of present prices for beryllium ore the manufacture of beryllium-alginate rayon appears commercially feasible, according to the report in The Chemical Age.

The present high cost of beryllium is not due to the cost of raw materials or to lack of efficient processes for recovering the metal from beryl, which is apparently the only commercial ore. Even under present conditions, the metal probably could be sold with good profit at $5 a pound, provided the volume of sales was large enough to carry the heavy expense of laboratory and market research and general overhead. Such items can bog down any infant enterprise, and they have proved to be extraordinarily serious in the beryllium industry. Undoubtedly the demand for beryllium would increase even more rapidly if the price could be reduced still further, particularly the price to the ultimate consumer. Even now the instrument maker or fabricator must pay almost as much for his beryllium alloys as he did 5 years ago, when the beryllium content of the master alloy cost exactly twice as much as it does today.

Apart from price, another deterrent to more rapid expansion in the utilization of beryllium has been doubt among consumers as to the adequacy of beryllium-ore supplies. Actually, the offerings of beryl have greatly exceeded demand, and now both leading American beryllium companies are confident that as the industry grows ore supplies will grow proportionately. Although several substantial deposits have been reported that are alleged to contain enough beryl to permit being worked for beryl alone without depending on joint products (feldspar, gem materials, or other minerals) to carry the expense of mining, it is generally conceded that supplies must be drawn from various States and perhaps from South America and other foreign countries as well. Statistics of domestic production or consumption of beryllium cannot be published, but information available to the Bureau bof mines indicates that domestic production of beryl has ranged in recent years from less than 100 to a maximum of not more than 200 tons a year, whereas imports have been increasing. From 50 to 100 tons annually of beryl are ground and used in certain kinds of pottery or ceramic wares. As a good deal of the apparent supply has gone to build up socks, domestic consumption in making beryllium oxide and alloys has never exceeded about 300 tons. With beryl worth only $30 to $50 a ton, the total apparent consumption is obviously a small item in our national economy; yet it should be noted that a single ton of beryl worth, say, $50 delivered at the furnace will yield enough beryllium to make at least 3,000 pounds of beryllium alloy, and the present trend may increase this to an average of 5,000 or even 8,000 pounds, thus multiplying the value of the mine product at least 100-fold.

Imports of beryl in 1940 rose to a new record—805 short tons valued at $23,865—of which 422 tons were from Argentina, 377 from Brazil, and 6 from Union of South Africa.

CALCIUM

Metallic calcium, produced before the European War almost exclusively abroad, chiefly in France, is now made in the United States, the leading consumer. It is employed more and more for grain-refining alloy steels and in small amounts in some magnesium products. Various uses, as summarized by Mantell,[6] include: (a) Deoxidizer and alloy agent for copper, lead, and other nonferrous metals; (b) preparation of high-temperature, high-resistance nickel-chrome and nickel-chrome-iron alloys; and (c) as a reducing agent, in form of hydride, in the manufacture of rare metals, such as titanium, uranium, vanadium, and zirconium.

COLUMBIUM AND TANTALUM

Both columbium and tantalum are used indirectly in the manufacture of munitions and to a minor extent directly. Total imports of tantalum ores in 1940 jumped to 490,460 pounds compared with only 56,561 in 1939, the previous high record. Owing to collapse of markets in Europe, tantalum ores from Belgian Congo and other African sources, as well as from Brazil, came to the United States during the latter part of 1940. Such ores substantially augmented available supplies of tantalum, but the fact that they contained more columbium than those from Australia is indicated by a decline in the average value of the imports to less than 53 cents a pound from $1.47 in the preceding year. Imports of columbium ore, including rather small quantities from other countries than Nigeria, which hitherto has furnished virtually all the imports into the United States, advanced

[6] Mantell, C. L., New Uses of the Minor Metals: Metal Progress, vol. 38, No. 4, October 1940, pp. 527–528.

to 595,220 pounds, more than five times the quantity imported in 1939 but substantially less than the annual imports during the preceding 4 years. Early in 1941, the Fansteel Metallurgical Corporation, pioneer domestic producer of tantalum metal, was expanding its North Chicago (Ill.) plant at an estimated cost of $150,000. Vascoloy-Ramet Corporation, Jersey City, N. J., a subsidiary, was also expanding manufacturing facilities, according to press reports.

Small additions of ferrocolumbium make stainless steel more weldable, inhibiting intergranular corrosion ("weld decay"). A new development in the General Electric Co. laboratories in 1940, possibly highly significant, involves preparation of a new precipitation hardening alloy containing 3 percent columbium (balance iron). This alloy—which is not a steel, as it contains no carbon but contains the intermetallic compound, Fe_3Cb_2—reveals exceptionally good rupture strength at 1,100° F. As it exhibits remarkably low creep at high temperatures, it may be possible with this alloy to boost the temperatures at which steel turbines are operated without recourse to the expensive steels hitherto considered necessary.[7] Possible applications of tantalum are indicated in connection with nitriding steels,[8] but additions of tantalum tend to render steel unfit for use in guns or even in structural work. Although the demand for ferrotantalum has declined, owing to substitution of much cheaper ferrocolumbium, certain tantalum alloys are not unimportant—notably tantalum-tungsten and tantalum-nickel, which are employed in fountain pens and radio tubes, respectively. Ultrahard cemented carbides of tantalum are being used increasingly—alone or in combination with carbides of tungsten or titanium—in wire-drawing dies, steel cutting tools, and wear-resistant parts of machines. The metal has a variety of commercial applications, of which perhaps the most important with regard to quantity requirements is in the manufacture of corrosion-resistant apparatus and equipment in chemical plants and laboratories. Newly developed is a bayonet-type heater comprising 19 tantalum-protected steel tubes, which can be filled with live steam and plunged into hydrochloric acid. Tantalum is also used in various types of heat interchangers, pump and valve parts, nozzles, and spinnerets for rayon and other synthetic fibers and threads, temperature-control apparatus, and sundry vessels and parts exposed to chlorine and other corrosive agents. Copper or steel pipes can be lined or covered with a thin layer of tantalum. Tantalum is still used in certain types of current rectifiers, although demand from this source has declined. Another use, associated more directly with the national defense program, is for portable radio transmitters; owing to its remarkable gas-absorptive properties, it is one of the best metals for radio-transmitting tubes or valves.

Sintered tantalum for electrolytic condensers can now be made with a coarse, porous structure, whose many microscopic surfaces are covered with films of tantalum oxide, which gives the material its condenser qualities and which is re-formed by reaction with the electrolyte if ruptured by electric overload. An important use of such

[7] Parker, E. R., The Development of Alloys for Use at Temperatures Above One Thousand Degrees Fahr.: Am. Soc. Metals (paper presented at 22d annual convention, Cleveland, Ohio, October 21-25, 1940).
[8] Genders, R., and Harrison, R., Tantalum-Iron Alloys and Tantalum Steels: Jour. Iron and Steel Inst., 1936, No. II, p. 173P.

condensers is for lightning and surge arresters in railway-signal circuits, especially for the protection of signal lamps. Several thousand are in use; so far, not one has been reported damaged by lightning.[9]

Really high-grade tantalite was in good demand and was quoted in Engineering and Mining Journal Metal and Mineral Markets during 1940 up to $2.50 a pound of contained Ta_2O_5, basis 60-percent concentrate. Domestic ores, however, are mixtures of columbite and tantalite—as are almost all ores except the tantalite produced near Wodgina, Australia, and the columbite produced in Nigeria—and the following remarks by Groves [10] deserve careful attention by all prospective miners and mineral merchants:

> * * * The materials most sought after are columbite with a small content of tantalum and tantalite with a small columbium content. Whereas the former fetches prices in the neighborhood of £70 a ton, the latter runs up to about £600 a ton. It is, however, a great mistake to suppose that ore with roughly equal amounts of columbic and tantalic oxides should be worth something approximately midway between the two prices. The fact is that, although prior to the outbreak of hostilities Germany bought considerable quantities of such ore, at the present time there is little or no market for it. What the prospector really wants to find then is tantalite with not more than a few percent of columbic oxide, similar to the best Australian tantalite which carries 70 percent or more of Ta_2O_5 and only a few percent of Cb_2O_5. If he finds such ore, the next step is to ascertain whether it is free from cassiterite or wolframite; if it is, then he is lucky and a representative sample should be sent for assay. Until the results of the assay are available, however, it is impossible to assess the value of the material with any certainty. If cassiterite or wolframite occur mixed with the tantalite, provided the tantalum content of the tantalite is high, it should be possible to arrange for a mineral separation or to sell at a penalized price.

Tantalum metal was quoted in the United States throughout the year at $160.60 (base) a kilogram for C. P. rod and $143 for sheet, subject to discounts on volume business. Corresponding figures for columbium metal were $560 a kilogram for rod and $500 for sheet. Ferrocolumbium, 50 to 55 percent, was quoted at $2.25 to $2.35 a pound of columbium contained (f. o. b. producer's plant). Groves (work cited) describes British Empire conditions as follows:

> Tantalum metal, now quoted as nominal, was sold for some time before the war at £18 per pound (as compared with platinum at £10 an ounce). The average value of the Australian production of tantalite in 1936 was £A.630 and in 1937 £A.886. The total Australian output in these 2 years was 31,000 and 36,800 pounds respectively. Tantalite from elsewhere, i. e., tantalite containing an appreciable amount of columbium, is generally quoted at 55s. to 60s. a unit, i. e., in the neighborhood of £150 a ton. The best columbite fetches only about half this price.

Small amounts of tantalum scrap occasionally reach the market, chiefly in the form of discarded rayon spinnerets. The scrap recovery value of tantalum used in chemical equipment is relatively low, and it costs over 100 times as much as stainless steel, yet it has proved the most economical construction material to transfer heat efficiently in various processing operations where corrosion conditions are severe. No production of tantalum-bearing ores was reported for the United States in 1940.

---

INDIUM

Reduction in price of electrolytic indium (99.99+ percent) from $30 to $15 and later to $12.50 a troy ounce tended in 1940 to increase demand for the metal in platings and diffused platings on cadmium and other alloy bearings for airplane and other high-duty internal-combustion engines. Indium is also used in small quantities as an alloy constituent of jewelry and dental alloys, to improve the tarnish resistance of silverware, as a glass colorant, in the electrical contact field, and in low-melting alloys.

In dental castings 0.5 percent indium is said to improve corrosion resistance, melting range, hardness, and strength. A large optical company has used it for small pins in hinges of spectacle frames to resist corrosion.

In wearing parts of engines and machines, indium affords desired corrosion resistance without impairing fatigue resistance and other good properties of cadmium alloy bearings. For such service, the procedure (patented) is to plate indium onto the base metal and then to cause it to diffuse or alloy in the surface by means of a low-temperature treatment which (on steel-backed pieces) takes 2 hours at 340° F. Modern engines need bearings having great strength and wear resistance—such as cadmium alloys, lead alloys, copper-lead, and copper-nickel alloys—all of which corrode more easily than certain older mixtures in the presence of lubricants containing organic acids from animal- or vegetable-oil additions or oxidation of petroleum oils.

Indium is a very soft, heavy (specific gravity, 7.28), silvery, easily melted (melting point, 155° C.) metal that boils at red heat. According to Dyer,[11] as recently as 1924 it took several months to round up a total of 1 gram of the metal at a cost considerably higher than that of platinum—$10 a gram. A little research showed that it was a stabilizer for certain nonferrous metals, and when sizable quantities of indium-bearing ores were found in Mohave County, Ariz., the deposit was explored by shaft and drifts. This property, which is owned by the Indium Corporation of America (Home Office: 805 Watson Place, Utica, N. Y.), is reported to be able to supply large quantities of the metal. However, the potentially large production of indium from metallurgical residues more than suffices for current needs.

RADIUM AND URANIUM

The agreement between the Union Minière du Haut Katanga of Belgium and Eldorado Gold Mines, Ltd., of Canada, dividing world markets for radium in a 60:40 ratio, is said to have remained in force during 1940. World events, however, virtually eliminated the continent of Europe as a market for radium, and stocks sent to the United States for safekeeping are reported to be more than adequate to meet any anticipated requirements during the next several years. Normal sales for medical purposes in the United States are estimated at less than 25 grams a year. Luminous paints, which are used on instrument dials for airplane and other military equipment, do not require very large quantities, because a little radium goes a long way. One gram, for example, will furnish all the luminous paint needed for several thousand planes. Metal radiography seems to be growing more important and may be used extensively for the examination of castings,

[11] Dyer, J. R., Jr., Indium—Properties and Uses: Iron Age, vol. 146, No. 25, December 19, 1940, p. 35.

forgings, and other metal parts for munitions, but inasmuch as the radium for these purposes can be used repeatedly and can be transported readily from place to place, 5-or 10-gram lots at a few strategic locations could take care of national defense requirements.

Owing to a sharp decline in world demand for radium and uranium the Canadian producer stopped all operations at Great Bear Lake in June 1940. Early reports implied that the shut-down might be brief—only long enough for refinery and sales development to catch up with recent increases in ore output—but later advices indicated that the mine might remain closed at least 2 or 3 years. It is stated that the mine is in excellent condition and that ore reserves are ample to keep the concentrator (100-ton daily capacity) in operation for a long time. During the winter of 1939–40 flotation equipment for cleaning pitchblende was flown in by plane, and other additions and changes were made to increase the efficiency of the mill. Refining capacity at Port Hope, Ontario, was expanded before the end of 1939 to 8 grams of radium and 40 tons of uranium compounds a month. It was rumored that stocks of ore and material in process at Port Hope were ample to keep the refinery busy for 3 years or more. Moreover, it was announced [12] that uranium concentrates from the United States had been received for treatment upon a custom basis.

Although the radium refinery at Oolen, near Antwerp, fell into German hands upon the surrender of Belgium the mines in Belgian Congo did not come under Hitler's control, and the colonial government decided to permit shipments of copper and other metals and mineral products to Great Britain and the United States. Imports into the United States of uranium compounds dropped to 240,199 pounds valued at $388,355 in 1940 compared with a maximum of 1,439,324 pounds with a value of $1,197,786 in 1939, whereas imports of "uranium ore," normally negligible (5 pounds valued at $10 in 1939) jumped to 2,400,198 pounds valued at $2,110,927 in 1940; all came from Belgian Congo.

The price of radium advanced slightly to $30 a milligram early in 1940, then remained unchanged throughout the remainder of the year. Imports aggregated only 30.311 grams valued at $24,700 a gram in 1940 compared with 78.631 grams valued at $24,800 in 1939 and 38.75 grams valued at $20,300 in 1938.

About 85 percent of the world radium output is employed for medical purposes, 10 percent in luminous material, and 5 percent for miscellaneous uses, including the inspection of metal castings and forgings for inner flaws.

Polonium and ionium.—These materials may be extracted from Canadian radium ores. Ionium, which is about 40 times as abundant in these ores as radium, has long been used meagerly in scientific work, notably at meteorological stations, and may have possibilities in luminous paints, although it is not recovered by the Port Hope refinery process. Recently polonium has found actual commercial employment in a spark-plug alloy. Said to be worth $2,000,000 an ounce, minute traces are nevertheless used by Firestone Tire & Rubber Co. in spark-plug electrodes to ionize the air gap and speed the passage of a hot spark under all temperature conditions.

[12] Mining Journal (London), vol. 210, No. 5482, September 14, 1940, p. 566.

Uranium.—When uranium 235 is hit by a neutron that enters into its nucleus the atomic weight becomes 236, which is an exploding atom that splits easily. Merely by adding water, energy can be released, and when all this water is converted into steam the process stops unless more water is supplied, making the energy-liberating process automatic and self-regulating. Uranium 238 seemingly disintegrates only according to the well-known, leisurely schedule that ends up with lead after intermediate transformations into radium or actinium. When hit by a neutron that enters its nucleus its atomic weight may be increased to 239, but this is a relatively stable, nonexploding atom. Only about 0.1 percent of ordinary uranium is U–235, and production of this isotope on a commercial scale is problematical. However, fully a half-dozen laboratories are working on uranium as a source of power.

As a corollary to this research, there has been some quiet inquiry into sources of uranium. Assuming that 1 pound does yield as much power as 5 million pounds of coal or 3 million gallons of gasoline, we do not need very much uranium to supply even the enormous power requirements of the United States where 400,000,000 to 500,000,000 tons of coal burned annually furnish only 47 percent of the total energy consumed, the remainder being generated by oil (32 percent), natural gas (11 percent), and water power (10 percent).

The leading domestic producer of uranium ores today is the United States Vanadium Corporation at Uravan, Colo., where a new plant costing about $100,000 was built in 1940 to recover uranium from tailings from the vanadium plant. The total capacity is 50 tons a day, but details of anticipated uranium recoveries have not been published. Some of the concentrates, however, have been shipped to Port Hope, Ontario, as well as to Pittsburgh, Pa., for refining.

It is interesting now to revive the theory that because naturally disintegrating uranium and its derivatives constantly emit heat and are so universally distributed in the earth's crust, they must have profoundly modified the earth's rate of cooling in the past and must still play an important part in maintaining terrestrial heat. Almost all rocks, especially acid igneous rocks, are radioactive and so are the waters of the ocean and inland seas. Water from deep-seated springs and wells usually has marked radioactivity, so much so that the curative properties of waters at certain spas were attributed to this cause. Even the atmosphere is charged with radioactive substances that are carried down by rain or snow. In compact and unweathered rocks there is a nearly constant ratio of radium to uranium, provided they are old enough for equilibrium to have been reached. This ratio is 3.3×10^{-7}:1, which is another way of saying that very old rocks are likely to contain 3,300,000 times as much uranium as radium. The uranium content of younger granites actually may be more than their radioactivity would indicate. On the other hand, it does not follow that uranium is distributed as widely in nature as are radioactive substances because such materials may include fugitive emanations, mesothorium, and other products that may not even be in the uranium family.

Although at least 100 minerals contain uranium, the only important uranium ores have been uraninite or pitchblende and carnotite. Pitchblende occurs massive in metalliferous veins, notably at Joachimsthal, Bohemia, and also at Johanngeorgenstadt, Saxony; more recently, it has been found in Belgian Congo and Canada. Carnotite has been noted chiefly as a canary-yellow impregnation in sandstone in western Colorado and eastern Utah. Many pegmatites contain crystals of uraninite or pitchblende and occasionally other uranium-bearing minerals, usually in such small proportions as to preclude their commercial consideration, except perhaps as a minor byproduct of feldspar or mica mining. Apart from pegmatite specimens (from North Carolina, Connecticut, the Black Hills of South Dakota, and the even more diversified mineral galaxy at Barringer Hill, Tex.—mostly sold to mineral collectors) and carnotite, virtually the only domestic production of uranium mineral has been in Colorado, mainly in Gilpin County, where pitchblende has been found associated with pyrite and zinc and lead sulfides. Autunite, which has been reported in South Dakota and Utah and recently in the Ruby Mountains, Nev., may have somewhat more commercial significance as a source of uranium than of radium, as its radium content is less than the usual ratio for uranium minerals.

According to Clarke,[13] Maj. C. E. Dutton has suggested that radio-activity in limited tracts 1 to 3 and not over 4 miles below the surface of the earth may develop enough heat to fuse the rocks and cause periodic eruptions; at least one investigator who agrees with this theory has reported an astonishingly high figure for the radium content of fresh lavas from Vesuvius.

All but the most basic rocks contain at least 1 part of radium per trillion, and acid rocks contain more than 3 parts per trillion. This may indicate as much as 1 part in 100,000 or 0.001 percent of uranium in the average rock.

SELENIUM AND TELLURIUM

Consumption of selenium in glassmaking, by far the leading use, increased in 1940, and several of the numerous minor applications expanded.

Both selenium and tellurium are employed to improve the machinability of copper and copper alloys and to a very small extent as modifying agents in corrosion-resistant steels. Additions of selenium have been made successfully to 18/8 steels whose work-hardening properties tend to develop extreme surface hardness as soon as they are cast or otherwise worked, the improvement being similar to that obtained by additions of sulfur and without the deleterious effect of sulfur on corrosion resistance and mechanical strength. Fansteel Metallurgical Corporation (North Chicago, Ill.) has announced a new line of industrial rectifiers employing selenium plates. Suggested applications include supply of current for magnetic clutches, solenoid valves, alarm signal and communication systems, and isolated direct-current motors. The International Telephone Development Co. (New York, N. Y.) is also reported to be using selenium rectifiers.

Small but steadily growing quantities of tellurium are used to toughen rubber and lead. Tellurium lead has been in service long enough now to confirm by practical tests the claims as to its extraordinary resistance to corrosion, wear, and mechanical break-down, which are all the more remarkable in view of the fact that it differs in composition from ordinary good chemical lead only by an addition

[13] Clarke, F. W., The Data of Geochemistry, 4th ed.: Geol. Survey Bull. 695, 1920, p. 310.

of less than 0.1 percent tellurium. Small additions of tellurium, in this instance about 0.5 percent, are employed in two new free-machining forgeable alloys of copper recently developed and patented by the Chase Brass & Copper Co. Another new development [14] is to improve the quality and lengthen the useful life of chilled-iron car wheels; this is accomplished by introducing very small quantities of graphite and tellurium in correct proportion and balance into each ladle as the metal is poured. A newly patented "daylight lamp" employs tellurium vapor in a tube to fill in certain wave lengths to produce a continuous spectrum.

Prices of selenium (black, powdered, 99.5 percent) and of tellurium remained at $1.75. Barium selenite ($BaSeO_3$) was quoted in Glass Industry at $1.40 to $1.60 a pound with "commercial (25 percent Se)" at $0.85 a pound, and sodium selenite (Na_2SeO_3) at $1.50 to $1.65 a pound.

Production, sales, and imports of selenium and production and sales of tellurium in the United States, 1936–40

Year	Selenium				Tellurium	
	Production (pounds)	Sales [1] (pounds)	Imports		Production (pounds)	Sales [1] (pounds)
			Pounds	Value		
1936	352,480	226,402	122,806	$215,835	57,956	25,453
1937	435,821	282,598	92,523	161,382	51,409	23,365
1938	225,674	166,494	101,034	163,598	11,076	26,944
1939	227,131	345,726	124,830	193,168	25,234	63,431
1940	328,731	368,709	134,429	198,163	85,622	88,996

[1] Bureau of Mines not at liberty to publish value.

TITANIUM

The feature of the titanium industry in 1940 was the phenomenal rise in ocean freight on imported ilmenite. The bulk of the ilmenite consumed in the United States for making pigments and much of that for alloys and miscellaneous uses is imported from British India. A much larger proportion of the domestic consumption of rutile—chiefly for welding-rod coatings and ceramics—is produced in the United States, and substantial quantities of processed rutile of domestic as well as of foreign origin are exported from this country.

Although the price of ilmenite f. o. b. Travancore actually declined further during 1940 (average invoice value of imports a long ton: $3.75 in 1940, $4.40 in 1939, and $5.05 in 1938), quotations delivered c. i. f. U. S. Atlantic ports advanced during the summer to $18 to $20 a gross ton. Owing to the higher ocean freight and marine insurance, this quotation continued nominal throughout the remainder of the year; it compares with $10 to $12 during 1939 and earlier years. Actually, the freight rates, which normally average around $4 a long ton, had advanced by the end of the year to more than $20 a ton; and in March 1941, owing to the competitive bidding of imports of manganese, cargo rates as high as $28 a long ton were bid for shipments of ilmenite to the United States Atlantic seaboard.

[14] Drake, C. C., The Importance of Tellurium in Manufacturing: Mines Mag., vol. 30, No. 9, October 1940, pp. 498–500, 516.

After a study of the geological origin of the nelsonite dikes of Amherst County, Va., which have furnished most of the domestic output of both rutile and ilmenite to date, Moore [15] concluded that thorough exploration should reveal large domestic reserves heretofore little suspected. Higher prices for ilmenite naturally stimulated interest in domestic sources, and it was rumored that certain large consumers examined various properties and even did some active prospecting in the Carolinas, California, and elsewhere; but no definite information as to new mining developments has been furnished the Bureau of Mines, except regarding New York, where the National Lead Co. was reported [16] to be negotiating to acquire the old MacIntyre iron mine, Tahawus, N. Y. The ore body is a titanium-bearing magnetite, and the property has been inoperative for about 30 years.

Imports of ilmenite declined late in the year, whereas consumption probably increased, as it was encouraged not only by the acceleration of general industrial activity but also by the necessity for conserving zinc and perhaps lead, thus speeding further substitution of titanium pigments for competitive materials. Consideration has been given to the wider use of ferrotitanium in steelmaking as a means of conserving ferromanganese. Mention may be made also of Grainal alloys—complex deoxidizers that contain aluminum, titanium, and a hardening agent such as vanadium, the titanium functioning to protect and intensify the hardening effect of the vanadium so that less of this more expensive element can be used. As the aluminum and titanium develop fine-grained metal by deoxidization, metal so treated develops a desirable combination of strength and ductility, as well as strength and hardness when quenched and drawn. This treatment is applied chiefly to forging steels containing about 0.4 percent carbon and 1.8 percent manganese.

Malaya, which produced virtually no ilmenite until 1935, has since furnished 5,000 to 10,000 long tons a year, the output rising to 11,098 tons in 1939. This material is derived by magnetic separation from "amang", the refuse from washing crude tin concentrates. Stocks of amang in heaps, surveyed before September 1939, aggregated 358,700 tons; but it is not known how many years' accumulation this stock represents or how much ilmenite could be recovered annually from current tin-mining operations.[17] In accordance with the tin restriction agreement, no export is permitted if the amang contains as much as 0.5 percent tinstone.

Ferrocarbon-titanium continued to sell at $142.50 a short ton f. o. b. producer's plant. Notwithstanding the rapid advances in delivered cost of ilmenite raw material, titanium pigments remained virtually stationary in price. Titanium dioxide (carloads) dropped from 13¼ to 13 cents a pound but on December 31, 1940, was advanced to 13½ cents. Calcium-base pigment was quoted through much of the year at 5 to 6½ cents a pound, according to quality, and barium- or magnesium-base pigment at 5¼ to 6¼ cents, but the minimum prices on these items were advanced fractionally at the end of the year to 5¼ and 5½ cents, respectively. In 1921, titanium dioxide sold for 40 cents a pound and the composite barium-base product for 12 cents.

[17] Imperial Institute, The Mineral Resources of Malaya: Bull., vol. 38, No. 1, January–March 1940, pp. 76–77, 82.

Domestic production of rutile in Virginia and Arkansas undoubtedly attained an all-time record in 1940, although figures cannot be published. As reported in the official statistics, imports of rutile declined from 442 short tons valued at $23,170 in 1939 to only 156 tons valued at $14,849 in 1940, but probably several times this quantity of rutile is imported from Australia in the form of mixed concentrates classified as "zirconium ores," and doubtless the total supply of rutile from foreign sources increased over 1939.

Engineering and Mining Journal quotations for rutile remained unchanged throughout the year at 10 cents a pound (nominal) for 94-percent concentrate, and advanced from $60 to $75 a short ton for 88- to 90-percent concentrates, c.i.f. New York, reflecting increased freight rates as well as confirming a substantial increase in the foreign market values as indicated by the import statistics.

Production of metallic titanium involves special precautions owing to its avidity for both oxygen and nitrogen. The process of W. Kroll (Niagara Falls, N. Y.) described at the Electrochemical Society meeting at Ottawa, Ontario, October 2 to 5, 1940,[18] begins with $TiCl_4$, which is reduced with pure magnesium in a molybdenum-lined crucible in the presence of pure argon at about 1,000° C. The powdered metal, which does not alloy with magnesium, is separated from the magnesium salts by leaching and acid treatment. It is compressed into bars and melted in a special vacuum apparatus. The absence of all gases that might react with the metal is of especial importance. After melting, the titanium is easily rolled hot. A strip 1 mm. thick can be bent cold without fracture.

The high opacity and hiding power of titanium pigments are utilized not alone in paint and decorative coatings but to an increasing extent in paper, rubber, cosmetics, rayon, and other products. In papermaking they can be dispersed in starch, glue, and casein size, and their ready retention in paper pulps permits their addition as beater fillers—improving opacity, color, and brightness with a minimum of loading.[19]

For compounding white and colored rubber the dioxide and calcium-base pigments can be employed because of their fine particle size, high opacity, and chemical inertness. Titanium-barium pigments are used for similar reasons in leather manufacture, for drumming wet skins for white or light-color leathers.

By dispersing some of the titanium pigment in the viscous solution before spinning and thus incorporating it into rayon filaments, the luster of the rayon can be readily controlled without clogging spinnerets or weakening the material.

As it causes no irritation and is nontoxic, titanium dioxide finds increasing use in the cosmetic field, as whitener in face powders, skin lotions, etc. Additions of 1 percent TiO_2 notably improve the appearance of white soap.

In respect to uses, Wartman [20] says:

> By far the greater proportion of titanium consumed is in the form of purified titanium dioxide or mixtures thereof with other substances, such as zinc oxide, barium or calcium sulfate, etc., for use as white or yellow pigments in paints, enamels, rubber, plastics and like materials. On a basis of area covered per dollar of cost titanium dioxide is one of the cheapest white pigments. It possesses

[19] Canadian Chemical and Process Industries, Work cited in footnote 18, p. 508.
[20] Wartman, F. S., Titanium: Paper presented at dedication of Bureau of Mines Experiment Station, Salt Lake City, Utah, 1940.

also the advantages of being nontoxic and immune to discoloration by exposure to sulfur-bearing gases.

Ilmenite is the raw material from which white pigment is usually made. One process involves digestion of the concentrate with fuming sulfuric acid, filtration and clarification of the solution of iron and titanium sulfates, reduction of iron to the ferrous condition, and precipitation of titanic dioxide by hydrolysis.

Rutile as such is used to the extent of two or three thousand tons per year for coating welding rods for the electric arc. The fluxing power of titanium oxide gives a slag of the right viscosity and its electrical properties aid in producing a steady arc. Titanium compounds are also used in minor amounts as mordants in dyeing, as catalysts in various chemical reactions, for coloring and increasing the acid resistance of ceramic glazes, and for smoke screens in warfare.

The amount of titanium used pure or in metallic alloys is estimated to represent only a few percent of the total amount consumed. Most of the titanium used in the metallic state is in the form of alloys such as ferrotitanium, ferrocarbontitanium, cuprotitanium, etc. These alloys are added to molten metal as scavengers just before casting. . . .

Ferrocarbontitanium is the cheapest of the ferro-alloys and the one most used as a deoxidizer in steel and grey cast iron. In amounts up to a few pounds per ton, it is added just before casting. . . .

For carbon control purposes, the more expensive ferrotitanium is used.

There are at least three commercial processes for the production of this material. One is a modification of the thermite process. The thermite process cannot be used to produce pure titanium because the heat of reaction is not great enough, but it can be used to reduce a mixture of one part TiO_2 with several parts Fe_2O_3 to give ferrotitanium which may contain 22-42 percent Ti, and 3-8 percent Al with very little carbon. The reduction may also be carried out by dropping the oxides to be reduced onto a bath of molten aluminum. The third method depends on the fact that at the high temperature of the electric furnace, and in the presence of molten iron, an excess of silicon will reduce titanium dioxide to metal, although at lower temperatures metallic titanium will decompose silica. By this process a low-carbon, aluminum-free alloy for use in grey cast iron is obtained. . . .

The use of titanium in sintered hard alloys for machine tools is a recent development. The carbide, nitride, and silicide may be so used. The latter two are among the hardest synthetic compounds known to man. . . .

Titanium carbide is reported to be harder than tungsten carbide but not so good a conductor of heat. For this reason the use of titanium carbide in the tool is desirable if maximum hardness is essential, but otherwise is detrimental since the lower heat conductivity adversely affects the life of the tool.

It will have been noted that thus far no mention has been made of uses for pure titanium and alloys of which titanium forms a major part. The reason is simply that there is no real field of application for either type of material at present. Titanium in alloying with other metals, tends to form compounds insoluble in the solid state or if it forms solutions, the tendency is toward those which are stable only in the liquid state. Such conditions favor the formation of brittle alloys of little structural use. Pure titanium is so difficult to prepare at present that it is of no commercial use, although with physical properties similar to those of wrought iron and only sixty percent as heavy per unit volume, it would be an interesting structural material if it could be prepared cheaply. . . .

ZIRCONIUM

Improved demand for zircon was reported by Zircon Rutile, Ltd., which recently completed plant extensions increasing capacity about 70 percent for treating beach sands near Byron Bay on the north coast of New South Wales, Australia. Imports into the United States of "zirconium ore" jumped in 1940 to 16,845 short tons, about one-half of which was mixed zircon-rutile concentrate from Australia.

Zircon is used to a steadily growing extent in refractories, specialized porcelains, and heat-resisting glass. It is also the usual raw material for the manufacture of zirconium compounds, of which opacifiers are probably most important, supplanting antimony and to some extent tin oxide in vitreous enamels and ceramic glazes. The use of zircon enamels is growing; they are nonpoisonous and the same opacity is obtained with 2 percent zirconium as with 6 percent antimony oxide, it is claimed.

Metallic zirconium is employed as powder or ductile metal in photoflash bulbs, radio-transmitter tubes, ammunition primers, spot welding electrodes, and a variety of other applications. According to information furnished by the Foote Mineral Co. (1609 Summer St., Philadelphia, Pa.), this metal has a unique combination of high corrosion resistance and ability to absorb large volumes of certain gases. Below 100° C., the metal is immune to attack by some of the most corrosive agents known. At 500° to 860° C. it can absorb great quantities of hydrogen and at higher temperatures oxygen, nitrogen, carbon monoxide, carbon dioxide, and other gases. Zirconium, accordingly, is particularly well suited as a "getter" in vacuum tubes and chemical processes to improve and maintain high vacuum. In steelmaking, zirconium acts as a scavenger and deoxidizer, removing nitrogen and oxygen as well as nonmetallic inclusions. In the range 0.08 to 0.10 percent zirconium the improvement in grain is marked, and above 0.15 percent the zirconium combines with sulfur to produce a better surface on high-sulfur steels. Cast nickel-silicon bronze and other nonferrous alloys may benefit by additions of zirconium.

An interesting property of zirconium and of titanium metal is that, when drawn across glass or a glazed ceramic surface, they leave a brilliant, silvery, adherent streak. This affords a means of decorating high-grade glassware and pottery without the present necessity of using platinum compounds, followed by a special firing operation.

Engineering and Mining Journal quotations at the end of 1940 were: Zircon ore, 55 percent ZrO_2, f. o. b. Atlantic seaboard, carloads, $70 a short ton. Zirconium metal, commercially pure, powdered, $7 a pound. Zirconium alloys, 12 to 15 percent Zr, 39 to 43 percent Si, $102.50 to $107.50 a gross ton; 35 to 40 percent Zr, 42 to 52 percent Si, 14 and 16 cents a pound. These quotations are the same as those in 1939 except for zircon ore and the lower-grade alloy (ferrosilicon zirconium). The former remained at $55 a ton until the fourth quarter of the year, when it began to advance by $5 steps to $70 a ton in early December. The alloy was advanced from $97.50 to $102.50, where it had remained for a long time, to $102.50 to $107.50 in July.

PART III. NONMETALS

BITUMINOUS COAL[1]

SUMMARY OUTLINE

The bituminous-coal industry in 1940 responded to the increased industrial activity growing out of the defense program; production was much greater than in 1939 and reasonably steady throughout the year.

An outstanding event of the year was the establishment of minimum prices for bituminous coal, f. o. b. mine, effective October 1, 1940, by the Bituminous Coal Division, United States Department of the Interior, operating under the Bituminous Coal Act of 1937. The Coal Act, due to expire April 26, 1941, was granted a 2-year extension by the Congress.

Production.—The output of soft coal in 1940 was 453,245,000 net tons—a 15-percent increase over 1939 (see tables 2 and 3). The coal industry made substantial gains, in common with general business activity throughout the year, and the total output for the year was 46 percent above the record low of 1932, although 15 percent below the 534,989,000 tons of 1929 (see figs. 1, 2, 4, and 5).

Imports and exports.—Exports of bituminous coal rose from 11,590,478 net tons in 1939 to 16,465,928 in 1940—a 42-percent increase. At the same time imports, which are relatively insignificant, rose only 5 percent from 355,115 tons in 1939 to 371,571 in 1940. As in the past, virtually all these imports and more than 80 percent of the exports represented trade with Canada (see fig. 10).

Consumption.—After allowances have been made for foreign trade and changes in consumers' stocks, the total consumption of bituminous coal in 1940 totaled 430,723,643 tons—an increase of 52,745,006 net tons over 1939. Each of the more important classes of consumers shared the increase, which ranged from 109 percent for

[1] The collection of statistics on the bituminous-coal industry which previously was conducted by the Bureau of Mines is now performed by the Bituminous Coal Division, U. S. Department of the Interior, H. A. Gray Director.

Material in this chapter was prepared in the Division's Economics Branch under the supervision of G. A. Lamb, chief. They were completed under the immediate direction of W. H. Young, in collaboration with R. L. Anderson and M. E. McMillan.

Final figures for 1939 are being compiled under a joint agreement between the Bureau of the Census and the Bituminous Coal Division, and these figures will be released later. Final figures for 1940 are being compiled by the Bituminous Coal Division. and these figures will be released later. Data for 1938 are final.

beehive coke ovens to 7 percent for railroads. Bunker consumption declined slightly (see fig. 3 and table 4).

Changes in stocks.—The reserve supply of coal in the hands of industrial consumers and retail coal yards rose from a total of 44,571,000 net tons at the beginning of the year to 50,998,000 tons at the close. Between the same periods stocks on the upper Lake docks declined 591,996 tons, and unbilled coal in cars at the mines or classification yards fell 234,800 tons (see fig. 1 and tables 1 and 5).

Distribution.—Shipments of bituminous coal during 1940 rose substantially above the 1939 level in each of the primary channels of distribution. Table 6 shows trends in distribution of bituminous coal for 1923, 1929, and 1936–40. Changes in the monthly volume of the more important movements are shown in figure 4.

Freight rates.—The average revenue per ton of bituminous coal

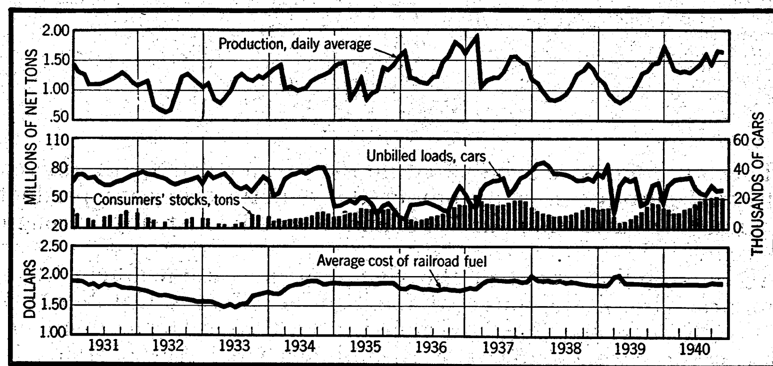

FIGURE 1.—Trends of production, stocks, and prices of bituminous coal, 1931–40.

originated, often called the average railroad freight charge, was $2.23 in 1939 compared with $2.22 in 1940.

Mechanization.—Data available early in 1941[2] indicate continuation of the sharp advance in the mechanical loading of bituminous coal in 1940.

Sales of mechanical loading equipment for use in bituminous-coal mines, in terms of total capacity, increased 11.6 percent in 1940 over 1939. Reports from 32 manufacturers show sales of 233 mobile loaders for 1940 as against 292 in 1939 and 344 in the peak year 1936. Sales of conveyors at bituminous and anthracite mines totaled 1,762 in 1940 compared with 1,311 in 1939 and 994 in 1936. Trends from 1900 to 1939 are shown in figure 9.

Mechanical cleaning.—Sales of mechanical cleaning equipment in 1940 (see Coal Age, February 1941, p. 59) indicate a substantial gain over earlier years in mechanically cleaned coal. The total capacity of cleaning plants sold in 1940 is estimated at 12,000 net tons of cleaned coal an hour.

Trend of employment.—Estimates on the average number of men employed at bituminous-coal mines in 1940 indicate a slight rise over the 1939 figure of 422,000 which is based upon returns to the Bureau of the Census. Indexes compiled by the Bureau of Labor Statistics upon the basis of a sample that includes more than half the workers

[2] Coal Age, February 1941, p. 59, and Mining Congress Journal, February 1941, p. 23.

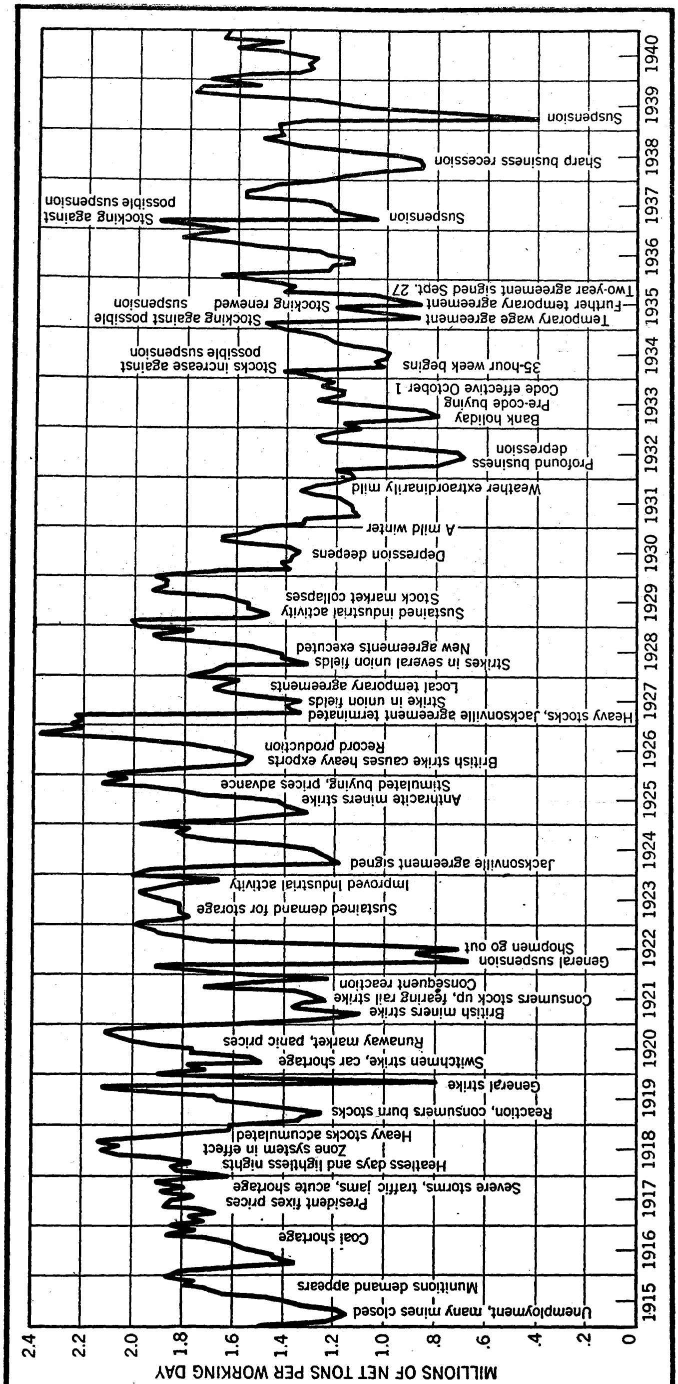

FIGURE 2.—Average production of bituminous coal per working day in each month, 1915–40.

in the industry show an increase of almost 2 percent in employment for 1940 over 1939 if normal operations during the April–May suspension are assumed in 1939. Reports from mining departments of several States indicate no substantial change for the same period. These data suggest an estimate of 431,000 employees for 1940. In comparison with 1929 (when the average number of men employed at bituminous-coal mines totaled 502,993) the 1940 figure represents a decrease of 72,000 (see fig. 9).

Statistics for employment of bituminous-coal workers cannot be interpreted satisfactorily without considering the intermittent operation that characterizes most coal mines. In 1939, for instance, it is

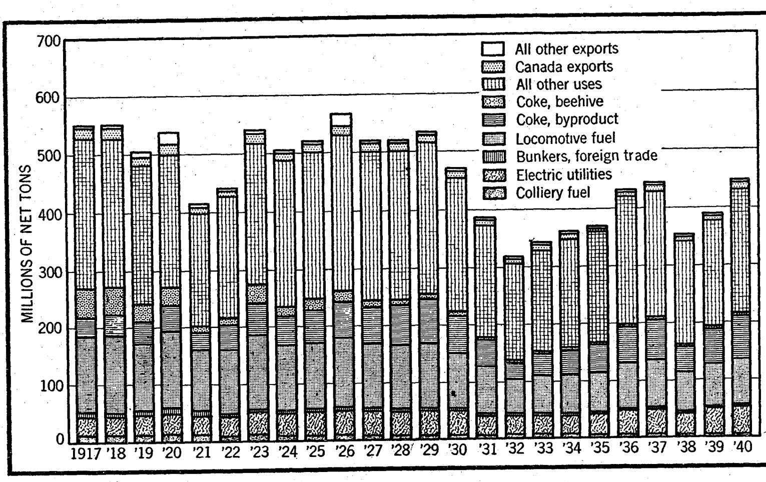

FIGURE 3.—Tonnage of bituminous coal absorbed by the principal branches of consumption, 1917–40.

estimated that the bituminous mines were operated an average of 179 days out of the 261 possible under the 5-day week of the union-wage agreement. Consequently, a substantial proportion of the manpower on the rolls of the industry was idle throughout the year, the number depending on the market and the season.

Trend of capacity.—The potential full-time output of active mines in the bituminous-coal industry increased 2 percent between 1938 and 1939. The coal industry reached its peak capacity in 1923 when (upon the basis of 308 operating days) the potential output was 970,000,000 tons. Subsequent liquidations forced the closing or abandonment of thousands of mines and reduced the indicated capacity to 622,000,000 tons in 1934. The potential output upon a 308-day basis was 676,000,000 tons in 1939. Under the 5-day week, full-time operation is limited to approximately 261 days. The potential capacity of operating mines upon a 261-day basis was 573,000,000 tons in 1939 compared with the total actual production of 393,065,000 tons.

Trend of fuel efficiency.—Since the World War period improvements in fuel engineering have contributed to a continuing decline in the market for coal for industrial uses. Although the effect of such improvements is cumulative from year to year the rate of decline is smaller in recent years, as the remaining margin of possible increase in fuel efficiency becomes progressively less.

The class I steam railroads had the same average coal consumption for coal-fired locomotives in 1940 as in 1939—115 pounds per 1,000 gross ton-miles of freight service (see fig. 6 and table 8). For all railroad freight service, including oil-burning and electric locomotives, the average consumption of energy, converted to coal equivalent, was reduced from 113 pounds per 1,000 gross ton-miles in 1939 to 112 pounds in 1940. During the same period, public-utility power plants lowered their average consumption of fuel from 1.39 pounds to 1.37 per kilowatt-hour. In the iron and steel industry the average consumption of coke in iron blast furnaces was increased from 1,778 pounds in 1939 to 1,781 in 1940 per net ton of pig iron produced, representing a drop from 2,547 to 2,541 pounds of coking coal per net

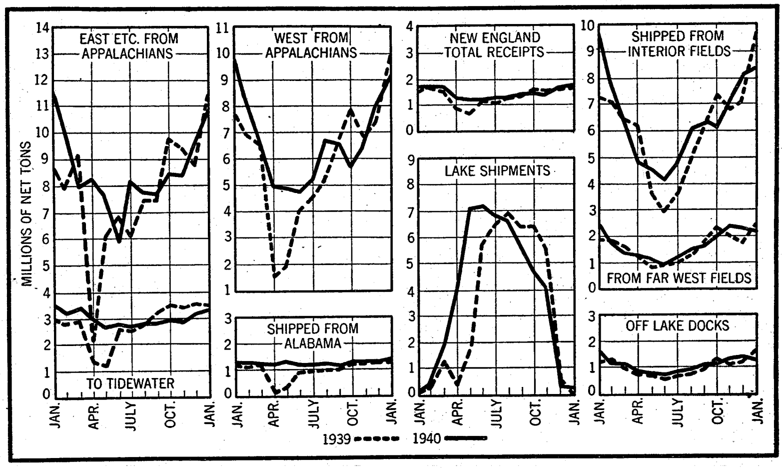

FIGURE 4.—Monthly movement of bituminous coal in the major channels of distribution, 1939–40.

ton (2,853 and 2,846 pounds per gross ton) of pig iron for 1939 and 1940, respectively.

Improvements in combustion practice among domestic consumers and small industrial and commercial establishments also are effecting decreases in the aggregate volume of fuel consumption. Furthermore, increasing economy in combustion methods is being supplemented by improvements in space-heating methods and by progress in building construction and insulation.

Competition of oil and gas.—In the competitive struggle between coal and oil in 1940 coal appeared to hold its own or gain slightly on oil. The consumption of coal by railroads in 1940 increased 7.0 percent over 1939, while the consumption of oil by railroads increased 7.1 percent during the same period. The consumption of coal by steamships in 1940 decreased 3.4 percent from 1939, while the consumption of oil by steamships declined 5.4 percent for the same period. Electric public utilities consumed 15.5 percent more coal in 1940 than in 1939 while consuming 3.7 percent less oil and 4.2 percent less gas during the same period. However, the kilowatt-hours produced by water power at electric public-utility power plants increased 8.5 percent in 1940 over 1939.

In domestic heating, comparable figures are available for mechanical firing equipment only. Estimates of sales of new equipment reflect a marked increase in the use of automatic coal-burning equipment. Sales of domestic stokers (under 61 pounds an hour capacity) using bituminous coal rose from 78,332 in 1939 to 123,167 in 1940—a 57-percent increase—whereas sales of oil burners for domestic use rose from 165,711 to 197,755, a 19-percent increase. This does not entirely represent the relative positions of the two competing fuels in new plants because the oil-burner sales cover virtually all installations in which oil is used, while sales of mechanical stokers do not consider new installations of hand-fired equipment.

TABLE 1.—*Salient statistics of the bituminous-coal industry in the United States, 1939–40*

[All tonnage figures represent net tons]

	1939	1940	Change in 1940 (percent)
Production	[1] 393,065,000	[1] 453,245,000	+15.3
Exports to Canada and Mexico [2]	9,975,919	13,537,342	+35.7
Exports overseas and all other [2]	1,614,559	2,928,586	+81.4
Imports [2]	355,115	371,571	+4.6
Consumption in the United States (calculated)[3]	[1] 377,978,637	[1] 430,723,643	+14.0
Stocks at end of year:			
Industrial consumers and retail yards	44,571,000	50,998,000	+14.4
Stocks on upper Lake docks	7,590,254	6,998,258	−7.8
Unbilled loads, at mines or in classification yards [4]	1,533,100	1,298,300	−15.3
Price indicators (average per net ton):			
Average cost of railroad fuel purchased, f. o. b. mines [5]	$1.91	$1.88	−1.6
Average cost of coking coal at merchant byproduct ovens [6]	$4.57	$4.40	−3.7
Average cost of bunker coal to vessels in foreign trade [7]	$4.83	[1] $4.81	−0.4
Average value of exports to all countries (at port)[8]	$3.69	[1] $3.69	
Average retail price—38 cities [9]	$8.52	[1] $8.60	+0.9
Average railroad freight charge per net ton [10]	$2.23	$2.22	−0.4
Underground loading machinery sold to bituminous mines: [11]			
Mobile loading machines (number)	292	233	−20.2
Scrapers (number)	18	36	+100.0
Conveyors, including those with duckbills (units)	1,095	1,573	+43.7
Pit-car loaders (units)	2	3	+50.0
Average number of men employed at mines operating [12]	[1] 422,000	[1] 431,000	+2.1
Fuel-efficiency indicators:			
Pounds of coal per kw.-hr. at electric power plants [13]	1.39	[1] 1.37	−1.4
Pounds per 1,000 gross ton-miles—railroads [14]	113	[1] 112	−0.9

[1] Subject to revision.
[2] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.
[3] Production plus imports minus exports plus or minus net changes in consumers' stocks.
[4] Association of American Railroads.
[5] Interstate Commerce Commission. Excludes freight charges.
[6] As reported by coke operators to the Bureau of Mines.
[7] Computed from records of the Bureau of Foreign and Domestic Commerce.
[8] Computed from records of the Bureau of Foreign and Domestic Commerce. The figure represents the average value at the point of export of shipments to all foreign countries, including Canada.
[9] Bureau of Labor Statistics.
[10] Average receipts per net ton of revenue bituminous coal originated, as reported by the Interstate Commerce Commission.
[11] Young, W. H., Anderson, R. L., Lamb, G. A., and Shore, F. M., Mechanization Sales: Coal Age, February 1941, pp. 59–61; and Mining Cong. Jour., February 1941, pp. 23–25.
[12] The estimate for 1939 is based upon incomplete returns to the Bureau of the Census. The figure for 1940 is estimated from various sources, including the employment index of the Bureau of Labor Statistics and State mine inspectors' reports.
[13] Federal Power Commission.
[14] Interstate Commerce Commission; includes coal equivalent of fuel oil consumed.

The bituminous figures shown in table 3 are preliminary estimates based upon railroad carloadings and river shipments of coal and beehive coke, supplemented by direct reports from a number of mining companies, local coal operators' associations and detailed monthly production statistics compiled by the State Mine Departments of Colorado, Illinois, Pennsylvania, Washington, and West Virginia. In making the estimates, allowance is made for commercial truck shipments, local sales, and colliery fuel and for small trucking mines producing over 1,000 tons a year. Where a mine is on the border between two States, the production is accredited to the State from which the coal is extracted rather than that in which the tipple is situated.

The estimates given are based upon the latest information available and differ in some instances from the current figures previously published in the Weekly Coal Reports.

TABLE 2.—*Preliminary estimates of production of bituminous coal in the United States, by weeks, 1939–40* [1]

1939				1940			
Week ended—	Production (net tons)	Number of working days	Average production per working day (net tons)	Week ended—	Production (net tons)	Number of working days	Average production per working day (net tons)

[1] North Carolina included with Georgia.
[2] Includes operations on the N. & W., C. & O., Virginian, K. & M., and B. C. & G., and on the B. & O. in Kanawha, Mason, and Clay Counties. Excludes output of a mine whose tipple is in McDowell County, W. Va., but whose coal comes chiefly from Tazewell County, Va., and therefore is credited to Virginia.
[3] Rest of State, including the Panhandle district, and Grant, Mineral, and Tucker Counties.
[4] Less than 500 tons.
[5] Includes the output of lignite for historical comparison and statistical convenience.
[6] U. S. Bureau of Mines. Includes colliery fuel, dredge and washery coal, and shipments by truck from authorized operations. Does not include an unknown amount of bootleg product.
[7] Oklahoma included with Arkansas.
[8] Missouri included with Kansas.
[9] South Dakota included with North Dakota.

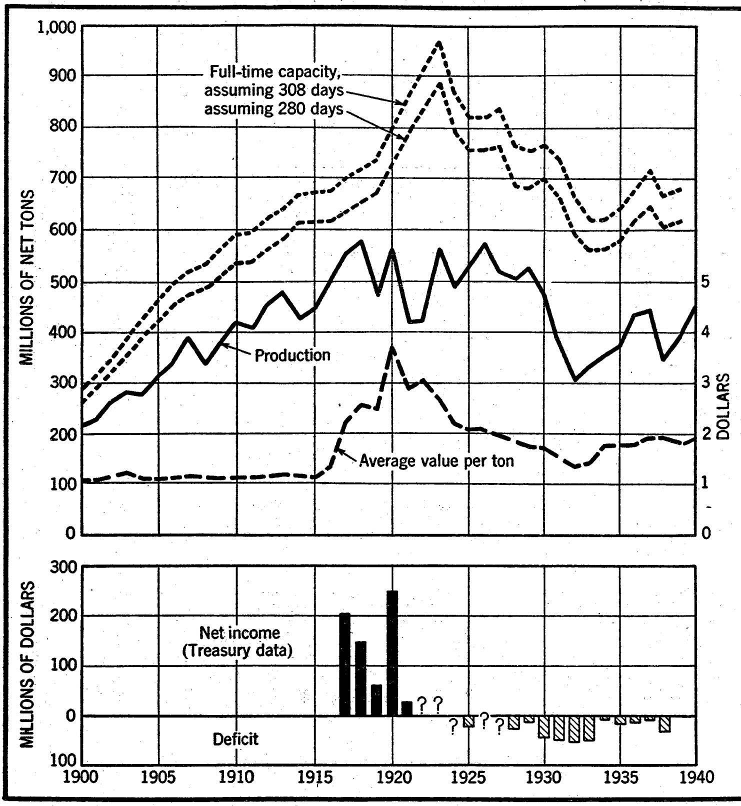

FIGURE 5.—Trends of bituminous-coal production, realization, mine capacity, and net income or deficit in the United States, 1900–1940.

TABLE 4.—*Changes in the United States consumption of bituminous coal by such classes of consumers as report currently and by all other consumers, 1929 and 1934–40, in thousands of net tons* [1]

[Information on several other classes of consumers is available for certain years. The items shown in this table are selected because they are available in strictly comparable form for each year]

Year	Consumed in the United States								Exported [2]		Total of consumption and exports [8]
	Colliery fuel	Electric power utilities [3]	Bunkers, foreign trade [2]	Locomotive fuel, class I roads [4]	Coke [5] Beehive ovens	Coke [5] By-product ovens	All other uses [6]	Total consumption [7]	To Canada and Mexico	To other countries (seaborne)	
1929	4,663	44,937	4,287	113,894	10,028	76,759	264,987	519,555	14,727	2,702	536,984

1939 [9]	2,810	46,223	1,477	73,833	2,298	61,216	190,122	377,979	9,976	1,614	389,569
1940 [9]	3,241	53,398	1,426	78,966	4,803	76,583	212,307	430,724	13,537	2,929	447,190

[1] Comparable data for other earlier years in Minerals Yearbook, 1937, p. 799.
[2] Bureau of Foreign and Domestic Commerce.
[3] Geological Survey and Federal Power Commission. Represents all coal consumed by public utility power plants in power generation, including a small amount of anthracite.
[4] Interstate Commerce Commission. Represents bituminous coal consumed as locomotive fuel by class I steam railways, excluding switching and terminal companies. During more recent years, data are available on the consumption of coal by all classes of railroads and all uses, that is, total railway consumption, which was 80,454,720 net tons in 1940.
[5] Bureau of Mines.
[6] Obtained by subtracting the known items from the calculated total consumption. Includes general manufacturing, domestic, and many miscellaneous uses.
[7] Production plus imports minus exports, plus or minus changes in consumers' stocks.
[8] Includes imports.
[9] Subject to revision.

TABLE 5.—*Stocks of bituminuos coal in hands of commercial consumers and of anthracite and bituminous coal in retail dealers' yards in the United States, 1939–40*

Date	Total stock of bituminous coal estimated (net tons)	Days' supply at current rate of consumption on date of stock taking									
		Byproduct coke plants	Steel plants	Other industrials	Coal-gas plants	Electric utilities	Retail yards, bituminous	Railroads	Cement mills	Total bituminous	Retail yards, anthracite

[1] The figures for west Kentucky cover in recent years a much smaller percentage of the field's production than do those for Illinois and Indiana and may not be fully comparable with earlier years.
[2] Excluding commercial sales by truck and wagon, except from upper Lake docks. Figures for 1939 are subject to revision.
[3] Percentage of total national shipments from all mines, all destinations.
[4] Less than 0.1 percent.
[5] Data not available.

TABLE 7.—*Indicators of effect of fuel economy on consumption of coal in the United States per unit of performance since the World War of 1914–18*

	Pounds	Reduction from base period (percent)
Steam railroads:		
Pounds per 1,000 gross ton-miles freight service:		
Average, 1919–20	170	----------
Average, 1939	113	33.5
Average, 1940	112	34.1
Pounds per passenger-train car-mile:		
Average, 1919–20	18.5	----------
Average, 1939	14.8	20.0
Average, 1940	15.0	18.9
Electric public utility power plants:		
Pounds per kilowatt-hour, 1919	3.2	----------
Pounds per kilowatt-hour, 1939	1.4	56.2
Pounds per kilowatt-hour, 1940	1.4	56.2
Iron and steel—pounds coking coal per gross ton of pig: [1]		
1918	3,577	----------
1939	2,853	20.2
1940	2,846	20.4
Coke manufacture: Savings of heat values through recovery of gas, tar, light oils, and breeze by extension of byproduct in place of beehive coking, 1913–40, expressed as percent of coal used for all coke in 1940 [2]	----------	20.2

[1] Includes only savings through higher yields of merchantable coke per ton of coal charged and lower consumption of coke per ton of iron. Excludes economies through recovery of byproducts, which are treated in next item.
[2] These byproducts are used in part for boiler fuel, in part for metallurgical purposes, in part for domestic heating and cooking, and to a small extent for automotive fuel.

SOURCES OF DATA AND ACKNOWLEDGMENTS

Bituminous-coal production statistics for 1939 and 1940 are preliminary estimates based upon (1) weekly or monthly reports of railroad carloadings of coal and beehive coke by all the important carriers, (2) shipments by river as reported by the United States Army Engineers, (3) direct reports from a number of mining companies, (4) monthly production statements compiled by various local operators' associations, including the following: Central Pennsylvania Coal Producers Association, Hazard Coal Operators Association, Kanawha Coal Operators Association, North Dakota Board of Railroad Commissioners, Utah Coal Operators Association, Virginia Operators Association, Winding Gulf Operators Association, and Operators Association of the Williamson Field. Especial acknowledgment for detailed monthly production reports is made to Thomas Allen, Colorado inspector of coal mines; James McSherry, director, Illinois Department of Mines and Minerals; Jonas Waffle, managing director, Coal Trade Association of Indiana; Richard Maize, secretary, Pennsylvania Department of Mines; N. P. Rhinehart, chief, West Virginia Department of Mines; and J. E. Bergin, chief inspector, Washington Department of Mines.

In the estimates for 1939 and 1940 allowance has been made for commercial truck shipments, local sales and colliery fuel, and small trucking or wagon mines producing over 1,000 tons a year. Production of mines on the border between two States has been credited to the State from which the coal is extracted rather than that in which the tipple is situated. If the coal is mined from lands in both States the tonnage has been apportioned accordingly.

The data in this report on the output of bituminous coal in 1938 (tables 13 to 37) are based upon detailed annual reports of production and mine operation courteously furnished by the producers and present data not available when the last preceding volume in this series was published. As in previous years, all but a small percentage of the output was covered by the reports submitted. For the remaining output not directly reported, consisting chiefly of small mines, it has been possible to obtain data of reasonable accuracy from the records

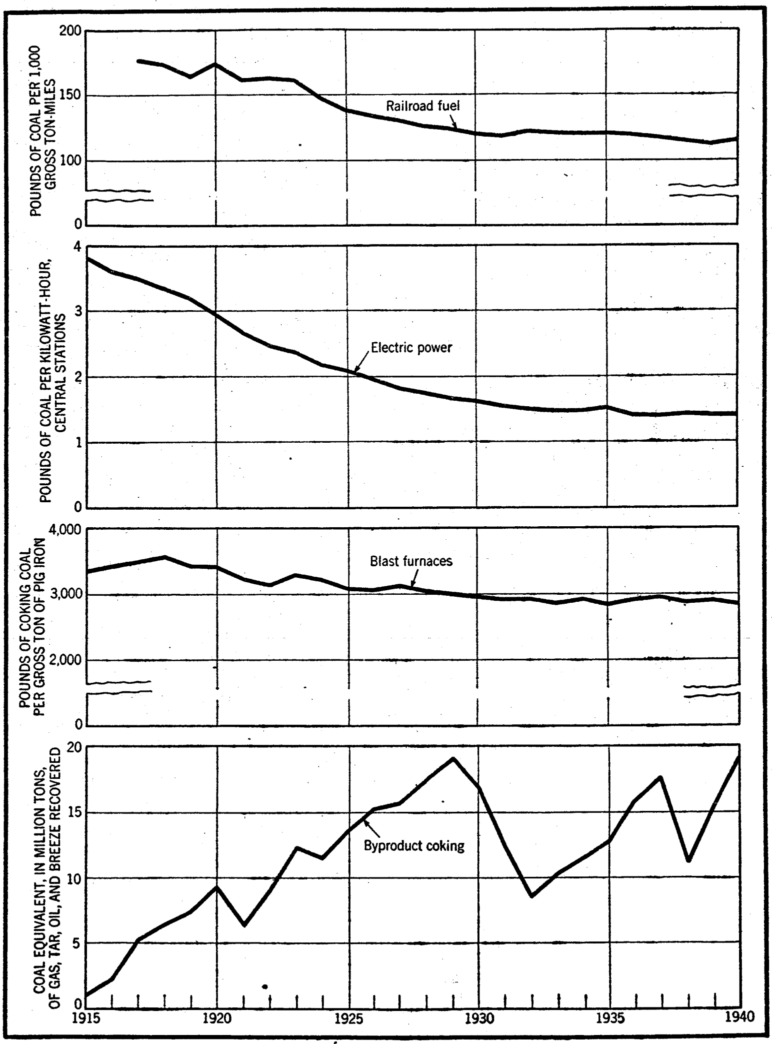

FIGURE 6.—Trends of fuel efficiency in the United States, 1915–40.

of the State mine departments, which have statutory authority to require such reports, or in a few instances from railroad carloadings.

Acknowledgment is made to the many individuals and agencies, both public and private, who have cooperated generously in making the survey possible. Special acknowledgment is made to officials of central cleaning plants and manufacturers of mechanical loading and cleaning equipment.

RELATIVE RATE OF GROWTH OF COAL, OIL, AND WATER POWER, 1889–1940

According to preliminary data, the total supply of available energy in the form of coal, oil, and natural gas, and water power in 1940 was 27,095 trillion B. t. u.—a 10.3-percent increase over 1939 (see fig. 7). The figures are expressed in British thermal units because some common denominator is necessary for such unlike quantities as tons of coal, barrels of oil, and cubic feet of gas. Table 8 summarizes the equivalent of each of the fuels in trillions of British thermal units. Water power is represented by the equivalent fuel required to perform the same work. The table covers the years since 1933. Details for 1889 to 1932 are given in Minerals Yearbook, 1937, page 807.

In converting water power to its fuel equivalent, two alternative assumptions have been made. The first, as in previous issues of these tables, assumes a *constant* fuel equivalent of 4.02 pounds of coal for each kilowatt-hour of water power produced throughout the entire period from 1889 to 1940. This factor was selected because it represents, in round numbers, the average efficiency of all central stations generating steam-electric power in 1913, the midpoint of the period under review. The usefulness of the *constant* factor lies in showing the rate at which water power is being developed. It permits direct comparison between the relative increase in kilowatt-hours of water power and the corresponding increase (or decrease) in tons of coal, barrels of oil, or cubic feet of gas produced. On the other hand, the constant factor makes no allowance for the fact that coal and other fuels produced today are used more efficiently than formerly.

To throw light on the influence of improving fuel efficiency, a second computation of the energy equivalent of water power has therefore been made. This assumes a *prevailing* fuel equivalent, diminishing year by year, which represents the average performance of all fuel-burning central electric stations for the year in question. This average has declined from about 7.05 pounds of coal per kilowatt-hour in 1899 to 1.37 pounds in 1940. (The *prevailing* factor is thus much above the *constant* factor in 1899 and much below it in 1940.) The *prevailing* fuel equivalent indicates more nearly the quantity of fuel that would have been needed in any one year to generate the same power in a steam-electric station. It should be noted, however, that the ultimate uses to which the water power generated is put often displace fuel burned much less efficiently than in central stations and that in any instance no other important branch of fuel consumption has made advances in fuel efficiency approaching that of the central stations.

As these tables attempt to determine the total energy from all fuels and from water power, the ideal factor for converting water power into fuel equivalent would be the average efficiency of all forms of fuel consumption in each year. No basis for determining such an all-embracing average exists at present, but enough is known to make certain that it would show much less reduction from 1899 to 1940 than did the central stations. For the present, a just comparison of the changing contributions of water power and of fuel to the national energy supply would lie somewhere between the results shown by the *constant* equivalent and the *prevailing central-station* equivalent in these tables.

As in earlier issues of these tables, the figures for oil and natural gas represent the entire production of crude petroleum and of gas. Most of this production does not come into direct competition with coal. Much of the supply of both oil and gas is used in regions of the country, such as California and portions of the Southwest, where coal is available only at unusually high cost because of heavy transport charges. Nearly half of the natural gas is used in the field for drilling or operating oil and gas wells and pipe lines or for the manufacture of carbon black. More than half the oil is used in the form of gasoline, kerosene, and lubricants, for which purposes coal cannot well compete, except at very much higher levels of oil prices. Even these refined

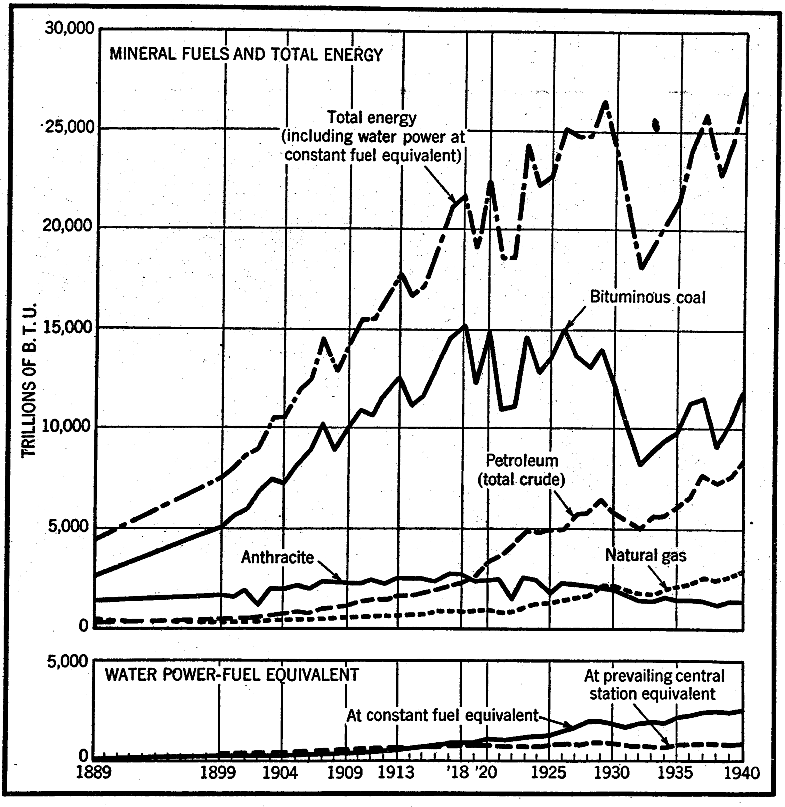

FIGURE 7.—Annual supply of energy from mineral fuels and water power in the United States, 1889–1940.

products, however, involve a certain measure of indirect competition with coal, for the energy market of the country is becoming more fluid and competitive, and a demand that cannot be met by one source of supply tends to fall back on the others.

The subject of interfuel competition is exceedingly complex, and an elaborate analysis and the accumulation of data not now available would be required to determine even approximately how much of any one fuel actually has been displaced either by other fuels or by water power. The present tables do not permit determination of such displacement; their purpose is rather to measure the long-time trends in the total demand for energy.

The figures for anthracite represent the output from established operations only and do not include bootleg or stolen coal, the amount of which is not accurately known. The bootleg tonnage has been estimated by the Commonwealth of Pennsylvania Anthracite Coal Industry Commission at the rate of 2,400,000 tons a year during 1936 and 1937, which is equivalent to 5 percent of the output of the legitimate operations. (Trade estimates place the figure as high as 3,000,000 to 3,500,000 tons.) The Pennsylvania Department of Mines estimates the bootleg tonnage at 2,500,000 tons in 1938 and 3,500,000 in 1939. The Anthracite Institute estimates the bootleg tonnage at approximately 4,000,000 tons in 1940. If this additional item of 3,500,000 tons were included, the total energy from anthracite in 1939 would be 1,496 trillion B. t. u. and the total energy from all sources 24,669 trillion B. t. u. If the additional item of 4,000,000

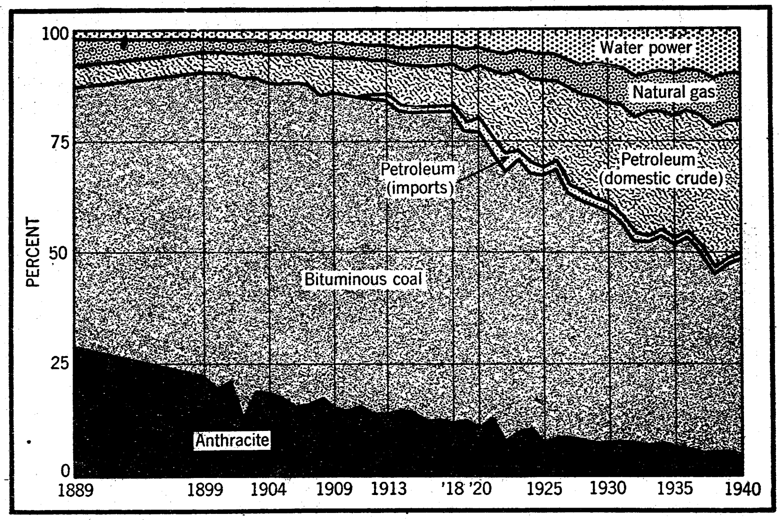

FIGURE 8.—Percentage of total B. t. u. equivalent contributed by the several sources of energy, counting water power at constant fuel equivalent, 1889–1940. If water power is counted at the prevailing fuel equivalent of central stations in each year, its proportion is 3.2 percent in 1899 and 3.5 percent in 1940, and the proportions of the other sources of energy are affected accordingly.

tons were included, the total energy from anthracite in 1940 would be 1,470 trillion B. t. u. and the total energy from all sources 27,204 trillion B. t. u.

Table 9 compares the relative increase in the several sources of energy by means of index numbers in which production for 1918 is represented by 100. Production of anthracite in 1940 was 49 percent below 1918 (45 percent if bootleg coal is included) and of bituminous coal 22 percent below 1918. Production of domestic petroleum increased 280 percent and natural gas 270 percent over 1918.

There was an increase of 213 percent in the amount of water power developed (represented by the constant fuel equivalent).

Table 10 gives the percentage composition of the total energy supply on the alternative assumptions of water power at constant and at prevailing central-station equivalents in fuel (see fig. 8). On the assumption of constant equivalent, the proportion contributed by water power has increased from 1.8 percent in 1899 to 9.7

in 1940. On the assumption of prevailing central-station equivalent, it has remained substantially unchanged between 3 and 4 percent. As already noted, the truth lies somewhere between the two assumptions. Upon either basis, water power furnishes a relatively small fraction of the total energy budget of the Nation, although, of course, a much larger fraction of the electric power produced by public utilities.

TABLE 8.—*Annual supply of energy from mineral fuels and water power in the United States, 1933–40,*[1] *in trillions of B. t. u.*[2]

Year	Pennsylvania anthracite	Bituminous coal	Total coal	Petroleum (total crude, including that refined)		Natural gas (total production)	Total petroleum and natural gas	Total mineral fuels	Water power (fuel equivalent)		Grand total energy	
				Domestic production	Imports				At constant fuel equivalent[3]	At prevailing central station equivalent[4]	Water power at constant fuel equivalent	Water power at prevailing central station equivalent
1933	1,348	8,741	10,089	5,434	191	1,672	7,297	17,386	1,931	711	19,317	18,097
1934	1,555	9,415	10,970	5,448	213	1,904	7,565	18,535	1,896	698	20,431	19,233
1935	1,419	9,756	11,175	5,980	193	2,060	8,233	19,408	2,207	806	21,615	20,214
1936	[5]1,485	11,504	12,989	6,598	194	2,330	9,122	22,111	2,256	812	24,367	22,923
1937	[5]1,410	11,673	13,083	7,675	165	2,588	10,428	23,511	2,446	871	25,957	24,382
1938	[5]1,255	9,132	10,387	7,286	158	2,468	9,912	20,299	2,466	866	22,765	21,165
1939[6]	[5]1,400	10,298	11,698	7,590	199	2,663	10,452	22,150	2,423	838	24,573	22,988
1940[6]	[5]1,361	11,875	13,236	8,111	256	2,872	11,239	24,475	2,620	893	27,095	25,368

[1] Comparable data for earlier years in Minerals Yearbook, 1937, p. 807.
[2] The unit heat values employed are: Anthracite, 13,600 B. t. u. per pound; bituminous coal, 13,100 B. t. u. per pound; petroleum, 6,000,000 B. t. u. per barrel; natural gas, 1,075 B. t. u. per cubic foot. Water power includes installations owned by manufacturing plants and mines, as well as Government and privately owned public utilities. The fuel equivalent of water power is calculated from the kilowatt-hours of power produced wherever available, as is true of all public utility plants since 1919. Otherwise the fuel equivalent is calculated from the reported horsepower of installed water wheels, assuming a capacity factor of 20 percent for manufacturers and mines and of 40 percent for public utilities.
[3] Assuming 4.02 pounds per kilowatt-hour, which is the average of central electric station practice in 1913, the midpoint of the period for which data are available.
[4] Assuming the average central-station practice for each of the years for which data are available, which declined from about 7.05 pounds per kilowatt-hour in 1899 to 1.39 pounds in 1939.
[5] Does not include an unknown amount of bootleg or stolen coal. If this were included, the energy for anthracite would be approximately 1,550 trillion B. t. u. in 1936; 1,476 in 1937; 1,323 in 1938; 1,496 in 1939; and 1,470 in 1940, and the total energy would be increased accordingly.
[6] Subject to revision.

TABLE 9.—*Index numbers for relative rate of growth of coal, oil, and water power in the United States*[1]

[The figures are expressed as a percentage of the 1918 rate]

Year	Pennsylvania anthracite	Bituminous coal	Total coal	Petroleum (total crude)		Natural gas (total production)	Total petroleum and natural gas	Total mineral fuels	Water power (at constant fuel equivalent)	Grand total	
				Domestic production	Imports					With water power at constant fuel equivalent	With water power at prevailing central station equivalent
1933	50	57	56	252	90	205	229	82	231	87	83
1934	58	62	61	255	94	246	241	88	227	94	89
1935	53	64	63	280	85	266	262	92	264	99	93
1936	55	76	73	309	86	301	291	105	270	112	106
1937	[2]52	77	73	359	73	334	332	112	292	119	112

[1] Comparable data for earlier years in Minerals Yearbook, 1937, p. 810.
[2] If bootleg coal were included the proportion from anthracite would be 5.7 percent in 1937, 5.8 in 1938, 6.1 in 1939 and 5.4 in 1940 at *constant* and 6.0 in 1937, 6.2 in 1938, 6.5 in 1939 and 5.8 in 1940 at *prevailing* water power equivalents.
[3] Subject to revision.

TREND OF AVERAGE VALUE PER TON, F. O. B. MINES, 1929–39

Before the Bituminous Coal Act of 1937 was passed the most valuable single index of the trend of prices at the mines was the "average value per ton, f. o. b. mines," as given in the familiar annual coal reports of the Bureau of Mines, United States Department of the Interior. This series was referred to in Bureau of Mines reports as representing "bituminous coal" and covered all coal other than Pennsylvania anthracite produced in the United States. It represented the bituminous-coal industry as the term ordinarily was used in the trade and included the lignite of the Dakotas, Texas, and Montana, as well as any small tonnages of hard coal produced outside of Pennsylvania.

With the passage of the Coal Act the Bureau of Mines relinquished the collection of statistics relating to bituminous coal, effective June 30, 1937, but continued to compile data regarding lignite. Effective on the same date, the Coal Commission became responsible for the compilation of data on bituminous coal, although it did not attempt to collect data regarding lignite, which was specifically exempted by the act. The records of the Commission (now the Bituminous Coal

Division, United States Department of the Interior) relate to all coal other than lignite and Pennsylvania anthracite.

To permit comparison of the old and new series, therefore, the lignites must be separated from the bituminous coals, though for the convenience of the student the combined average for the two is continued in a form as nearly comparable as possible to the old series (see table 11).

A more important change in the two series relates to the treatment of selling expenses. The old Bureau of Mines series of "value at the mines" excluded the selling cost. The reporting operator was asked to state the "amount received at the mines f. o. b. cars less the selling expense." No details were asked regarding the items included in the value, and no systematic effort was made to follow up the exclusion of selling expenses. It was realized at the time that some producers might find it impractical to exclude selling costs and that some part of the selling expenses of the industry might be included in the results. Nevertheless, the reports were checked for consistency from year to year, the questions were retained in the same form without change, and the results are believed to have been comparable from one year to the next. The new series of the Coal Commission represents the total or gross realization on all coal produced and specifically includes the selling cost.

The two sets of data may not be precisely comparable with respect to coal produced but not sold on the commercial market. In the Bureau of Mines series the reporting operator was instructed that the "value of coal not sold but used by producer, also mine fuel and coal made into coke, should be estimated at average prices that might have been received." The instructions of the Coal Commission regarding such items were in effect similar, though given in greater detail.

A comparison of the two series is possible for 1936. In that year the average value a ton upon the old (Bureau of Mines) basis amounted to \$1.761 per ton for bituminous coal, excluding lignite. The average gross realization, as determined from information collected by the Coal Commission, was \$1.831 per ton. The difference amounts to \$0.07 per ton—an amount somewhat less than the average selling expenditure computed per ton of all coal produced, as reported to the Coal Commission. The comparison confirms previous indications that the great majority of operators reporting in earlier years had followed instructions and omitted selling expenses in computing the average value but that some of them had included the selling expense. The change in method of reporting should be kept in mind in comparing the two sets of data. As the reports to the Commission were submitted on a detailed accounting return and made under oath they are to be accepted. The returns of earlier years, upon a voluntary basis and not in all instances uniform as to treatment of selling costs, seem to have been thoroughly comparable from one year to the next and afford the best available index to the rise and fall of the mine prices received by operators down to 1936.

TABLE 11.—*Trend of average value in the United States of bituminous coal and lignite per ton, f. o. b. mines, 1929–39*

Year	Bituminous[1] coal (subject to regulation under 1937 Act)	Lignite[2]	Total
Average value per ton less selling expense (Bureau of Mines series):			
1929	$1.782	$1.548	$1.781
1930	1.702	1.556	1.701
1931	1.542	1.410	1.541
1932	1.313	1.313	1.313
1933	1.337	1.188	1.336
1934	1.751	1.387	1.749
1935	1.772	1.120	1.767
1936	1.761	1.061	1.756
Average gross realization, including selling expense (Coal Commission series):			
1936	1.831	[3] 1.061	1.826
1937	1.946	[3] 1.080	1.939
1938	1.955	[3] 1.071	1.947
1939	[4] 1.854	[3] 1.135	1.853

[1] Includes all coal produced other than Pennsylvania anthracite and the lignite included in the second column.
[2] North Dakota, South Dakota, and the lignite counties of Montana and Texas.
[3] Figures of the Bureau of Mines, excluding selling expense as before. Data on sales realization were not collected from lignite mines by the Coal Commission, now Bituminous Coal Division.
[4] Estimated from incomplete returns to Bureau of the Census. Producers were asked by that Bureau to exclude selling expenses in reporting value, but a number of them included such expenses.

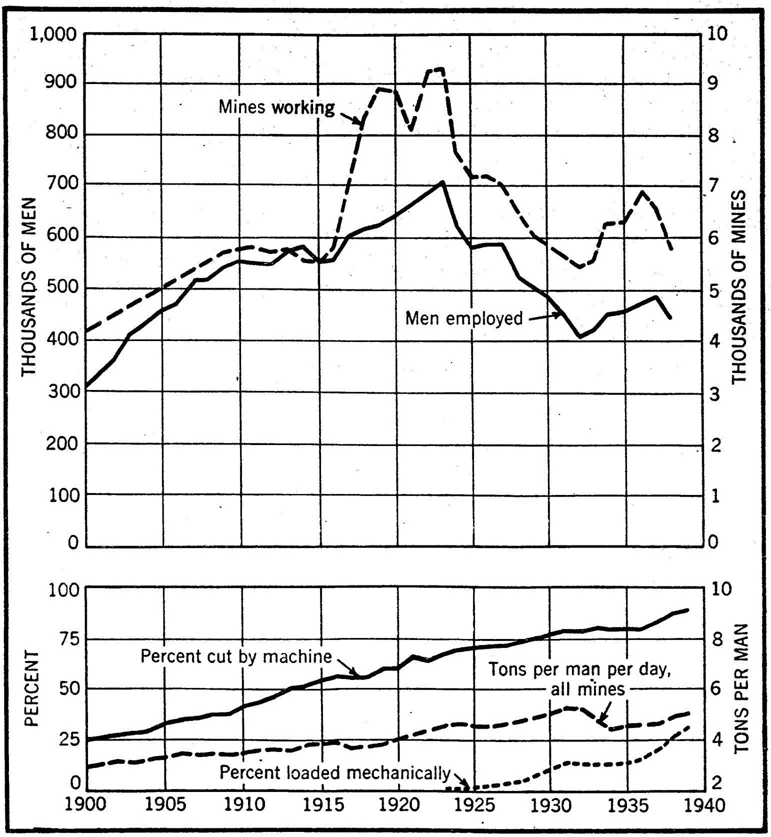

FIGURE 9.—Trends of employment, mechanization, and output per man at bituminous-coal mines, 1900–1939.

FINAL BITUMINOUS STATISTICS FOR 1938

SUMMARY BY DISTRICTS

TABLE 12.—*Number of mines, production, men employed, days operated, man-days of labor, and output per man per day in the United States in 1938, by price areas and districts*

[Districts as defined in the Bituminous Coal Act of 1937. Exclusive of product of wagon mines producing less than 1,000 tons]

Minimum price area and producing district	Number of active mines	Net tons					Number of employees				Average number of days mines operated	Man-days of labor	Average tons per man per day
		Loaded at mines for shipment by rail or water	Shipped by truck or wagon	Coal used by employees or taken by locomotives at tipple or other uses at mines	Used for power and heat or made into coke at mines [1]	Total production	Underground	Surface		Total			
								In strip pits	All others				
PRICE AREA 1													
District 1. Eastern Pennsylvania [2]	744	29, 604, 131	1, 631, 903	1, 488, 199	[1] 524, 277	33, 248, 510	46, 928	57	6, 403	53, 388	161	8, 570, 409	3. 88

PRICE AREA 8													
District 21. North-South Dakota	180	1,492,522	437,474	160,415	7,746	2,098,157	685	367	368	1,420	173	246,258	8.52
PRICE AREA 9													
District 22. Montana	78	2,524,145	• 191,291	13,000	3,614	2,732,050	1,126	40	359	1,525	174	265,784	10.28
PRICE AREA 10													
District 23. Washington [7]	54	1,149,909	384,562	13,896	19,934	1,568,301	1,993	--------	603	2,596	163	423,764	3.70
Alaska	6	151,656	------------	231	2,795	154,682	100	--------	44	144	204	29,413	5.26
Total, Price Area 10	60	1,301,565	384,562	14,127	22,729	1,722,983	2,093	--------	647	2,740	165	453,177	3.80
Grand total, areas listed above [8]	5,777	312,238,996	25,592,058	6,860,817	[1] 3,852,893	348,544,764	370,004	7,877	63,452	441,333	162	71,325,374	4.89

[1] Includes coal made into beehive coke at mines in the following districts in 1938: District 1, 160,266; District 2, 604,987; District 3, 7,020; District 7, 36,709; District 8, 441,055; District 13, 10,000; District 17, 84,172; District 20, 15,667—a grand total of 1,359,876 tons in 1938.

[2] Includes Maryland, and Grant, Mineral, and Tucker Counties, W. Va.

[3] According to the act, the Minimum Price Area 1 includes that part of Southeastern District 13 comprising Van Buren, Warren, and McMinn Counties, Tenn. Production in these counties is negligible and has been included here in Price Area 3.

[4] Includes Colfax County, N. Mex.

[5] Includes Arizona and California, but excludes Colfax County, N. Mex.

[6] Includes Idaho.

[7] Includes Oregon.

[8] For purposes of historical comparison and statistical convenience, the figures include the output of lignite and of anthracite and semianthracite outside of Pennsylvania. Note that no district organization has been created for District 21, North and South Dakota, the output of which is usually classified in the coal trade as lignite.

STRIPPING OPERATIONS

TABLE 13.—*Stripping operations of all types in bituminous-coal fields of the United States, in 1938, by States and counties*

[Returns for mines that recover coal both by stripping and by underground operations do not permit separating men engaged in stripping from those engaged in other work. For this reason the figures of men employed represent all persons working at these mines, including those underground. The total tons produced by both methods at these same mines are also shown]

State and county	Number of strip pits	Number of power shovels			Coal produced (net tons)		Number of employees				Average number of days mines operated	Percent of county or State total mined by stripping	Man-days of labor	Average tons per man per day
		Steam	Electric	All others	Mined by stripping	Total at same mines	Underground	Surface		Total				
								In strip pits	All others

TABLE 13.—*Stripping operations of all types in bituminous-coal fields of the United States, in 1938, by States and counties*—Continued

[Returns for mines that recover coal both by stripping and by underground operations do not permit separating men engaged in stripping from those engaged in other work. For this reason the figures of men employed represent all persons working at these mines, including those underground. The total tons produced by both methods at these same mines are also shown]

State and county	Number of strip pits	Number of power shovels			Coal produced (net tons)		Number of employees				Average number of days mines operated	Percent of county or State total mined by stripping	Man-days of labor	Average tons per man per day

[2] Probably includes some "permissible" machines not so specified by the operators.

POWER DRILLING IN UNDERGROUND BITUMINOUS-COAL MINES

Although power drills have been in use in bituminous-coal mines for over 50 years, it is only within the last 15 years that the number in use has shown a marked increase. Portable electric power drills were introduced in 1917. Power drills are now in use or have been on trial in nearly every coal-producing county in the United States.

Table 17 shows the coal produced in underground mines in working places where shot holes were power-drilled during 1936 and 1938. The total quantity produced by power drills increased from 111,950,000 net tons in 1936 to 122,581,133 in 1938 (9.5 percent). In 1936 the following States led in underground tonnage from working places where shot holes were power-drilled: Illinois, 24.2 percent; Pennsylvania, 19.0 percent; West Virginia, 17.5 percent; Kentucky, 11.2 percent; and Indiana, 7.2 percent. In 1938 they were: West Virginia, 21.7 percent; Illinois, 19.8 percent; Pennsylvania, 17.1 percent; Kentucky, 14.1 percent; and Indiana, 4.9 percent. The tonnage produced by pneumatic drills decreased from 10.6 percent of the total in 1936 to 9.1 percent in 1938, while the tonnage from electric drills increased from 89.4 percent to 90.9 in the same period.

TABLE 17.—*Coal produced in underground bituminous mines in the United States in working places where shot holes were power-drilled, 1936 and 1938,[1] in net tons*

[1] Data for 1937 not available.
[2] Included under "Undistributed."
[3] Compiled by Bureau of Mines.

The States showing the highest percentage of deep-mined production power-drilled in 1938 were Wyoming, Montana, Utah, Indiana, Illinois, and Washington.

The following summary gives the number of electric and pneumatic drills in use in coal and rock in 1938:

TABLE 18.—*Electric and pneumatic drills in use in coal and rock in the United States in 1938*

Use	Drills		
	Electric	Pneumatic	Total
Coal	3,616	303	3,919
Coal and rock	1,043	311	1,354
Rock	412	851	1,263
Total United States	5,071	1,465	6,536

Table 19 shows the technologic improvement of the coal industry in regard to power drilling, machine cutting, and mechanical loading, by States, in 1936 and 1938. The national deep-mined output of bituminous coal power-drilled increased from 27.2 percent in 1936 to 38.5 in 1938; machine cutting from 84.8 to 87.5; and loading by mechanical devices from 16.3 to 26.7.

TABLE 19.—*Percent of output of deep-mined bituminous coal power-drilled, cut by machines, and mechanically loaded in each State, 1936 and 1938* [1]

State	Power-drilled		Cut by machines		Mechanically loaded [2]	
	1936	1938	1936	1938	1936	1938
Alabama	23.0	37.7	72.8	73.5	14.3	18.3
Tennessee			70.0	75.7	5.7	12.2

Undistributed	17.6	8.7	20.6	11.3	8.4	15.1
Total United States	27.2	38.5	84.8	87.5	16.3	26.7

[1] Data for 1937 not available.
[2] Includes mobile loaders, scrapers, duckbills, other self-loading conveyors, pit-car loaders, and hand loaded conveyors.
[3] Included under "Undistributed."
[4] Includes lignite.

During 1938, 1,061 mines employed power drills; in 350 of these mines they were used in drilling coal only, in 415 they were used in both coal and rock, and in 296 they were used in drilling rock only.

Table 20 gives the total bituminous deep-mined production at mines using power drills in 1938, by States. At mines using power drills in coal only, 18.4 percent (58,488,723 tons) of the Nation's deep-mined output was produced. In the mines where power drills were used in coal and rock, 34.6 percent (109,985,045 tons) of the total underground production was accomplished, whereas the mines using power drills in rock only produced 17.2 percent (54,922,320 tons), accounting for 70.2 percent of the national deep-mined output from mines employing power drills.

TABLE 20.—*Total production of deep-mined bituminous coal at mines using power drills in the United States, in 1938*

[The figures indicate, for example, that in Colorado 33.5 percent of all the deep-mined production of the State came from mines using one or more power drills in coal only, 22.1 percent from mines using power drills in coal and rock, 18.0 percent from mines using power drills in rock only, a total of 73.6 percent for the State]

State	Total production				Percent of deep mined production for area

MECHANICAL LOADING

Mechanical loading of coal in the United States continued to advance in 1938, when 95,244,505 tons were loaded, compared with 94,183,837 in 1937. Mechanical loading in the bituminous mines increased from 83,500,000 tons in 1937 to 85,092,836 in 1938, while that in the Pennsylvania anthracite region declined from 10,683,837 tons in 1937 to 10,151,669 in 1938. Although the total tonnage mechanically loaded in bituminous mines in 1938 represented only a small increase over the estimated figure for 1937 (1.9 percent), the proportion of deep-mined coal loaded mechanically increased from 20.2 percent of the total production in 1937 to 26.7 percent in 1938.

Illinois continued to lead in tonnage in the bituminous fields; West Virginia, Pennsylvania, Indiana, Wyoming, Ohio, and Kentucky followed in the order named. Although Arkansas and Utah do not show large increases in tonnage, there were high percentage gains in 1938 over 1937.

Table 21 shows the tonnage loaded mechanically by States, 1935–38.

TABLE 21.—*Coal loaded mechanically underground in the United States, 1935–38, by States, in net tons*

State	1935	1936	1937 (estimated) [1]	1938
Bituminous:				
Alabama	1,303,653	1,741,452	2,100,000	2,017,045
Arkansas	292,064	522,411	550,000	692,462

Undistributed	518,524	754,824	760,689	895,729
Total bituminous	47,177,224	66,976,872	83,500,000	85,092,836
Pennsylvania anthracite [3]	9,279,057	10,827,946	10,683,837	10,151,669
Total United States	56,456,281	77,804,818	94,183,837	95,244,505

[1] For sources of estimates, see Minerals Yearbook, 1939 (p. 798).
[2] Included under "Undistributed."
[3] Minerals Yearbook, 1939 (p. 857).

Sales of mechanical loading equipment in 1940.—Sales of equipment for the mechanical loading of coal showed an increase in 1940 over 1939 for all items except mobile loaders. Sales of mobile loaders totaled 233 units in 1940 compared with 292 in 1939—a decrease of 20.2 percent. Total sales of scraper loading units amounted to 39 in 1940 compared with 26 in 1939—an increase of 50 percent. Conveyor sales, which included hand-loaded face conveyors and those equipped with duck-bills or other self-loading heads, were 1,762 units in 1940 compared with 1,311 in 1939—a 34.4-percent increase. Sales for each year, 1933–40, are shown in table 22.

TABLE 22.—*Units of mechanized loading equipment sold to bituminous and anthracite mines in the United States, as reported by manufacturers, 1933–40* [1]

Type of equipment	1933	1934	1935	1936	1937	1938	1939	1940	Percent increase or decrease, 1940 over 1939
Mobile loaders	41	55	115	344	292	241	292	233	−20.2
Scrapers [2]	65	34	22	28	29	10	26	39	+50.0
Conveyors [3]	396	610	681	994	1,095	990	1,311	1,762	+34.4
Pit-car loaders	18	26	28	11	32	139	2	3	+50.0

[1] The figures for 1933–36 included reports from 28 manufacturers. In 1937, 1 manufacturer indicated that he was no longer producing this type of equipment and accordingly was dropped from the active list; however, at the same time another manufacturer was added to the list, and the number of reporting firms remained at 28. In 1938, 1 manufacturer of material-handling machinery began the production of underground loading equipment; and in 1939, 2 new manufacturers entered the field, increasing the total number reporting to 31. Figures for 1940 include reports from 32 manufacturers.
[2] Reported as scrapers or scraper haulers and hoists.
[3] Includes hand-loaded conveyors and those equipped with duckbills and other self-loading heads. As sales of both loading heads and shaker conveyors are counted, the figures involve a certain measure of overlap, which cannot be determined accurately. It should also be noted that a small number of conveyors sold in recent years, particularly in 1936–38, were for use in conjunction with mobile loading machines.

TABLE 23.—*Sales of mechanized loading equipment in the United States, 1939–40, compared with total number of machines in active use in preceding years*

Type of equipment	Number of machines in active use [1]								Number of machines sold [2]	
	1930	1931	1932	1933	1934	1935	1936	1938	1939	1940
Bituminous mines:										
Mobile loading machines	545	583	548	523	534	657	980	1,405	292	233
Scrapers	150	146	128	93	119	78	106	117	18	36
Pit-car loaders	2,876	3,428	3,112	2,453	2,288	2,098	1,851	1,392	2	3
Conveyors equipped with duckbills and other self-loading heads	140	165	159	132	157	179	234	346	[4] 1,095	[4] 1,573
Hand-loaded conveyors—number of units	(3)	(3)	(3)	525	574	670	936	1,526		
Anthracite mines (Pennsylvania):										
Mobile loading machines	384	5	11	18	14	1	504	(5)	------	------
Scrapers		457	479	455	517	507		545	8	3
Pit-car loaders		28	24	19	25	22			------	------
Conveyors equipped with duckbills and other self-loading heads	421	1	17	12	13	30	1,790	[5] 1,831	[4] 216	[4] 189
Hand-loaded conveyors—number of units		547	818	940	1,338	1,563				

[1] As reported by mine operators. Data for 1937 not available for bituminous mines. Minerals Yearbook, 1939 (p. 857) shows 539 scrapers and 1,855 conveyors and pit-car loaders, including a few mobile loaders in the anthracite mines for 1937.
[2] As reported by manufacturers.
[3] Number of units not reported in these years.
[4] Reported as face conveyors (hand-loaded), "shaker drives," and "duckbills." The figures of numbers sold in 1939 and 1940 are not exactly comparable with the number in use in 1938, because of uncertainties in defining what constitutes a conveyor and because of certain overlaps in the reporting of duckbill loading heads and shaker conveyors.
[5] Mobile loading machines included with conveyors and pit-car loaders.

TABLE 24.—*Comparison of mobile loaders, scrapers, and conveyors in actual use in coal mines in the United States in 1938 with sales reported, 1939–40, by States and regions*

State and region	Mobile loaders			Scrapers			Conveyors [1]

[1] Includes hand-loaded conveyors and conveyors equipped with duckbills or other self-loading heads.
[2] Includes Arkansas, Colorado, Iowa, Montana, New Mexico, North Dakota, Oklahoma, Utah, Washington, and Wyoming.
[3] Mobile loaders and pit-car loaders included with conveyors.

The number of units of mechanized loading equipment sold in 1939 and 1940 compared with the total number of machines in active use in preceding years is shown in table 23. The reports of sales of conveyor equipment are not strictly comparable with reports of the number of units actually in use.

Table 24 shows the comparison, by regions and classes of equipment, of loading machinery in active use in 1938 with the sales reported in 1939–40.

Detailed statistics of mechanical loading in biiuminous mines in 1938, by types of equipment.—In 1938, 85,092,836 net tons of bituminous coal were loaded mechanically. Table 25 shows the tonnage loaded by the various classes of equipment. Similar data for 1937 are not available. The comparative change in the tonnage loaded by principal types of machines in 1936 and 1938 is shown in table 26. The net increase in 1938 over 1936 was 18,115,964 tons (27 percent).

The following classes of equipment showed increases in tonnage loaded in 1938 over 1936: Hand-loaded conveyors, 49.1 percent; mobile loading machines, 41.1; and duckbills and other self-loading conveyors, 31.1. The other two classes (scraper loaders and pit-car loaders) decreased in tonnage loaded in 1938 compared with 1936.

TABLE 25.—*Bituminous coal loaded mechanically underground in the United States in 1938 by types of machine*

Type of machine	Net tons	Percent
Loaded by machine:		
Mobile loading machines	57,824,252	91.7
Scraper loaders	1,030,468	1.6
Conveyors equipped with duckbills and other self-loading devices	4,248,434	6.7
Total loaded by machine	63,103,154	100.0
Handled by conveyors:		
Conveyors equipped with duckbills and other self-loading devices	4,248,434	16.2
Pit-car loaders	5,652,562	21.5
Hand-loaded conveyors	16,337,120	62.3
Total handled by conveyors	26,238,116	100.0
Recapitulation, less duplications:		
Mobile loading machines	57,824,252	68.0
Scraper loaders	1,030,468	1.2
Conveyors equipped with duckbills and other self-loading devices	4,248,434	5.0
Pit-car loaders	5,652,562	6.6
Hand-loaded conveyors	16,337,120	19.2
Grand total loaded mechanically	85,092,836	100.0

TABLE 26.—*Comparative change in tonnage of bituminous coal loaded by principal types of machines in the United States, 1936 and 1938* [1]

Type of machine	1936 (net tons)	1938 (net tons)	Increase or decrease, 1938	
			Net tons	Percent
Mobile loading machines	40,969,625	57,824,252	+16,854,627	+41.1
Scraper loaders	1,272,466	1,030,468	−241,998	−19.0
Duckbills and other self-loading conveyors	3,240,411	4,248,434	+1,008,023	+31.1
Total loaded by machines	45,482,502	63,103,154	+17,620,652	+38.7
Pit-car loaders	10,538,331	5,652,562	−4,885,769	−46.4
Other hand-loaded conveyors	10,956,039	16,337,120	+5,381,081	+49.1
Grand total	66,976,872	85,092,836	+18,115,964	+27.0

[1] Data for principal types of machines not available for 1937. The total tons loaded mechanically for that year as estimated from sales of new equipment, State mine inspectors' reports, and other sources was 83,500,000 net tons.

TABLE 27.—*Mechanical loading underground in bituminous-cool mines in the United States, in 1938 by States*

[Table includes all soft-coal mines that produced any part of their tonnage with the aid of mechanical loading devices in 1938. The mines have been grouped into 3 classes. First includes those mines in which all of the tonnage mechanically loaded was obtained with machines that substantially eliminate hand shoveling—mobile loaders, scrapers, and duckbill-equipped conveyors. It should be noted, however, that some of these mines make use of conveyors in conjunction with mobile loaders to perform the initial phase of transportation. Second class includes those mines in which all the tonnage loaded mechanically was obtained with hand-loaded conveyors or pit-car loaders. Third class includes mines that load with both types of machines]

State	Number of mines				Number of machines					Production mechanically loaded (net tons)			Total production of mechanized mines (net tons)			
	Using loading machines only [1]	Using conveyors only [2]	Using both loading machines and conveyors	Total	Mobile loading machines	Scrapers	Conveyors equipped with duckbills and other self-loading devices	Pit-car loaders	Installations of hand-loaded conveyors [3]	Loaded by machines [1]	Handled by conveyors [2]	Total	Mines using loading machines only [1]	Mines using conveyors only [2]	Mines using both loading machines and conveyors	Total

[1] Includes mobile loading machines, scrapers, and conveyors equipped with duckbills and other self-loading heads. Some mines in this class also use conveyors in conjunction with mobile loaders to perform initial phase of transportation.
[2] Includes hand-loaded conveyors and pit-car loaders.
[3] Number of mines in which hand-loaded conveyors (other than pit-car loaders) were used.
[4] Included under "Undistributed."

[1] Includes mobile loaders, scrapers, and duckbills. Data for 1937 not available.
[2] Includes hand-loaded conveyors and pit-car loaders. Data for 1937 not available.
[3] Principally by scrapers.
[4] Included under "Undistributed."
[5] Entirely by mobile loaders.
[6] Principally by pit-car loaders.
[7] Principally by mobile loaders.
[8] Entirely by pit-car loaders.
[9] Virtually all by mobile loaders.
[10] Entirely by conveyors.
[11] Entirely by scrapers.
[12] Principally by conveyors.
[13] Included in total; tons loaded and percentage by types not given because State groups are not comparable in 1936 and 1938.

Mechanical loading by States.—Illinois continued to lead all other States during 1938, with 23,363,426 tons of mechanically loaded coal. It was followed by West Virginia, with 20,530,906 tons; Pennsylvania, with 12,090,021; Indiana, with 5,905,834; and Wyoming, with 4,740,527. These five States accounted for 78.3 percent of the total output of mechanically loaded bituminous coal in the United States in 1938. Details of the number of mines and machines, tonnages mechanically loaded, and total production of mechanized mines, by States, are given in table 27.

In terms of tonnage increase of mechanically loaded coal in 1938 over 1936, West Virginia led with 11,817,971 net tons, which was more than half of the total increase of all States. Other States, in order of tonnage increase, were Pennsylvania, 3,056,166 tons; Kentucky, 2,593,941; Ohio, 1,814,396; and Virginia, 1,067,574. Illinois, Indiana, and Wyoming had less tonnage mechanically loaded in 1938 than in 1936. Details are shown in table 28. In comparing 1938 with 1936, it should be remembered that the total United States production decreased from 439,087,903 tons in 1936 to 348,544,764 in 1938, 20.6 percent.

Percentage of deep-mined output mechanically loaded.—The degree of mechanization can best be measured by comparing the percentage of coal mechanically loaded underground to the total output of all underground mines. In the United States this percentage has increased from 12.0 percent in 1933 to 26.7 in 1938. Individual States range from 94.2 percent in Wyoming to 8.6 in Kentucky during 1938.

TABLE 29.—*Percent of underground bituminous coal in the United States loaded mechanically in each State, 1926 and 1928–38*

State	1926	1928	1929	1930	1931	1932	1933	1934	1935	1936	1937	1938

[1] Included under "Undistributed."
[2] Texas included with Montana.
[3] North Carolina only.
[4] Not calculated because figures are not comparable from year to year.

Table 30 shows the contribution of each State to the total coal loaded mechanically in underground bituminous mines. The five most important States in regard to coal loaded mechanically were the same in 1928 as in 1938, but West Virginia and Wyoming exchanged their order of importance; West Virginia went from fifth place in 1928 to second in 1938 and Wyoming from second place in 1928 to fifth in 1938.

The percentages in 1938 were Illinois, 27.5; West Virginia, 24.1; Pennsylvania, 14.2; Indiana, 6.9; and Wyoming, 5.6.

[3] North Carolina only.
[4] Texas included with Montana.

MECHANICAL CLEANING

Although the total bituminous coal cleaned decreased from 65,000,000 net tons in 1937 to 63,454,588 in 1938, the percentage of the total output cleaned increased from 14.6 percent of the total in 1937 to 18.2 in 1938. In the following tables, the 1938 data are compared with 1936, as detailed statistics for 1937 are not available.

In 1938 the total quantity of bituminous coal mechanically cleaned increased 2,359,612 tons (3.9 percent) over 1936. The tonnage cleaned at the mines increased from 53,386,477 tons in 1936 to 57,998,341 in 1938, an 8.6-percent increase. The quantity of coal cleaned at central washeries operated by consumer steel companies in Colorado and Pennsylvania was 5,456,247 tons in 1938—a 29.2-percent decrease from 1936.

Table 32 shows data on bituminous coal mechanically cleaned by wet and pneumatic methods in 1936 and 1938.

TABLE 32.—*Bituminous coal mechanically cleaned by wet and pneumatic methods in the United States, 1936 and 1938,*[1] *in net tons of clean coal*

Method	1936	1938	Increase or decrease, 1938	
			Net tons	Percent
By wet methods:				
At the mines	42,795,529	47,730,138	+4,934,609	+11.5
At central washeries operated by consumers	7,708,499	5,456,247	−2,252,252	−29.2
Total wet methods	50,504,028	53,186,385	+2,682,357	+5.3
By pneumatic methods	10,590,948	10,268,203	−322,745	−3.0
Grand total	61,094,976	63,454,588	+2,359,612	+3.9

[1] The total tonnage of coal mechanically cleaned as estimated for 1937 was 65,000,000 tons, of which 7,866,360 tons were mechanically cleaned at central washeries operated by consumers.

Mechanical cleaning, by types of equipment.—The total tonnage of coal cleaned by wet washing methods reached 53,186,385 net tons in 1938—an increase of 2,682,357 tons (5.3 percent) over 1936. The quantity of coal cleaned by pneumatic methods was 10,268,203 tons in 1938—a decrease of 322,745 tons (3.0 percent) from 1936. Jigs and jigs in combination with concentrating tables were the only types that showed tonnage and percentage gains over 1936. Data on jigs in combination with upward-current classifiers were not shown separately in 1936. The tonnage cleaned by concentrating tables and launders and upward-current classifiers was less in 1938 than in 1936. The total tonnage cleaned by wet methods increased 5.3 percent in 1938 over 1936, while the coal cleaned by pneumatic methods decreased 3.0 percent in the same period.

During 1938, 301 wet washing and 73 pneumatic cleaning installations were in operation. Thirty-four tipples used both wet and dry methods in 1938 compared with 31 in 1936. In addition to the 31 plants using both wet and dry methods during 1936, two plants used two wet systems and one plant used three wet systems of equipment, thus accounting for four more duplications, or a total of 35 duplications in 1936. Deducting these duplications gives a net total of 307 plants that cleaned coal by mechanical methods in 1936 compared with 340 in 1938.

Details of coal cleaned in 1936 and 1938, by classes of equipment, are shown in table 33.

TABLE 33.—*Bituminous coal cleaned in the United States, 1936 and 1938,[1] by types of equipment in actual operation*

[Coal cleaned and plants operated by consumers at central washeries in Colorado and Pennsylvania are included]

Type of equipment	Plants in operation		Net tons of clean coal		Increase or decrease 1938 over 1936		Percent cleaned by each type	
	1936	1938	1936	1938	Net tons	Percent	1936	1938
Wet methods:								
Jigs	154	161	23,417,266	27,614,663	+4,197,397	+17.9	38.3	43.5
Concentrating tables	8	8	1,843,167	983,911	−859,256	−46.6	3.0	1.6
Jigs in combination with concentrating tables	16	19	2,612,666	2,790,930	+178,264	+6.8	4.3	4.4
Jigs in combination with launders and upward-current classifiers	(2)	8	(2)	2,026,699	+2,026,699	(2)	(2)	3.2
Launders and upward-current classifiers	98	105	22,630,929	19,770,182	−2,860,747	−12.6	37.1	31.1
Total wet methods	276	301	50,504,028	53,186,385	+2,682,357	+5.3	82.7	83.8
Pneumatic methods	66	73	10,590,948	10,268,203	−322,745	−3.0	17.3	16.2
Total, United States	[3] 342	[3] 374	61,094,976	63,454,588	+2,359,612	+3.9	100.0	100.0

[1] Data for 1937 not available by classes of equipment. See table 32, footnote 1, for estimate of total coal mechanically cleaned in 1937.
[2] This classification was not shown in 1936.
[3] Number of plants using both wet and pneumatic types was 31 in 1936 and 34 in 1938.

Mines served by cleaning plants, exclusive of those that ship to washeries operated by steel companies, produced a total of 108,237,541 tons (31.1 percent of the total bituminous output) in 1938. In this same group of mines, 57,998,341 tons were mechanically cleaned; therefore, 53.6 percent of the coal produced at mines with cleaning plants in 1938 was cleaned at the mine. This compares with 46.3 percent in 1936 and 45.3 in 1935. The remainder of the output (46.4 percent) presumably represents the larger sizes, which commonly are picked by hand.

TABLE 34.—*Total production of bituminous coal at mines in the United States equipped with cleaning plants, 1936 and 1938,[1] in net tons*

[Does not include any estimate for mines that may ship to consumer-operated plants]

Methods	1936	1938	Increase or decrease, 1938

United States production of bituminous coal	439,087,903	348,544,764	−90,543,139	−20.6
Percent produced at mines with cleaning plants	26.3	31.1		

[1] Data for 1937 not available.
[2] This classification was not shown in 1936.
[3] Mines using both wet and pneumatic methods.

Table 34 shows the total production of coal at mines with cleaning plants, by methods of preparation, in 1936 and 1938.

Coal cleaning, by States.—The following States led in volume of total coal mechanically cleaned in the United States in 1938: Pennsylvania, 26.9 percent; West Virginia, 25.0; Illinois, 16.0; and Alabama, 14.3. These four States accounted for 82.2 percent of the total mechanically cleaned coal in 1938.

The States that showed outstanding gains in percentage of their total output mechanically cleaned were as follows: Kansas, Illinois, Missouri, Washington, and Indiana.

Table 35 gives detailed data, by States, on coal mechanically cleaned in 1936 and 1938. The nine States that cleaned more than 10 percent of their total output in 1938 are as follows: Alabama, 82.0 percent; Washington, 76.4; Kansas, 39.7; Missouri, 37.5; Illinois, 24.2; Pennsylvania, 21.9; Indiana, 17.4; West Virginia, 17.0; and Ohio, 11.4.

TABLE 35.—*Bituminous coal mechanically cleaned by wet and pneumatic methods in the United States, 1936 and 1938,*[1] *by States*

[Coal cleaned at central washeries operated by consumers in Colorado and Pennsylvania is included]

State	Clean coal (net tons)		Increase or decrease, 1938		Percent of State output mechanically cleaned	
	1936	1938	Net tons	Percent	1936	1938
Alabama	9,922,514	9,072,987	−849,527	−8.6	81.1	82.0
Colorado	713,678	458,876	−254,802	−35.7	10.5	8.1

[4] Arkansas, Maryland, Montana, and New Mexico in 1936; Arkansas, Maryland, Michigan, Montana, New Mexico, Texas, and Utah in 1938.

Methods of mining at mines served by cleaning plants.—Mechanical loading both in underground mines and strip pits appears to be closely related to mechanical cleaning. Table 36 shows the mining methods at mines that have cleaning plants. Production of coal from strip mines in 1938 was 30,406,855 tons; 15,213,564 tons (50.0 percent) were from strip mines having mechanical cleaning tipples. This compares with 38.9 percent in 1936. There were 85,092,836 tons of underground coal loaded mechanically in 1938, of which 37,195,439 tons (43.7 percent) passed through tipples equipped with mechanical cleaning devices compared with 35.0 percent in 1936. Hand-loaded underground coal production in 1938 totaled 233,045,073 tons, of which 24.0 percent passed through tipples equipped with cleaning plants. This percentage in 1936 was 23.5.

TABLE 36.—*Method of mining used at mines in the United States served by cleaning plants, 1934–36 and 1938* [1]

[1] Data for 1937 not available.

Relation between raw coal, clean coal, and refuse.—For every 100 tons of raw coal cleaned at the mines during 1938, 88.6 tons of clean merchantable coal, on an average, were obtained, and 11.4 tons of refuse were discarded. Table 37 shows the tonnage, by States, of total production of mines with cleaning plants and the results of the cleaning operations. Many operators could not furnish exact figures on the raw coal or refuse, and in such instances estimates were made from all available information at hand.

TABLE 37.—*Relation between total production, raw coal, and refuse resulting from cleaning operations in the United States in 1938, by States, in net tons*

STATISTICS OF LIGNITE IN 1939 [3]

PRODUCTION OF LIGNITE

The Bureau of Mines prepares final statistics of the lignite industry from an annual canvass, by mail, of operators of lignite properties included in the areas mapped as "lignite" in Geological Survey Profes-

[3] Compiled by J. A. Corgan and A. Coleman, Coal Economics Division, Bureau of Mines.

sional Paper 100–A, The Coal Fields of the United States. Subbituminous coal is not included. The data on individual operations furnished by the producers are voluntary and confidential, as is customary in the statistical surveys of the Bureau of Mines.

The production of lignite in 1939 totaled 3,042,537 net tons, exclusive of many small mines producing less than 1,000 tons. Output in 1939 showed a slight increase over the 2,997,921 tons produced in 1938. The average value per ton was $1.13 in 1939 compared with $1.07 in 1938. The total employees in 1939 numbered 2,096 against 2,019 in 1938, while the average output per man per day for the same periods was 7.61 and 8.06 tons, respectively. The average number of days worked by the industry was 179 in 1939 compared with 184 in 1938. The length of the workday in most of the mines was 8 hours. Some mines showed a 7-hour day on their reports to the Bureau and a few a 9-hour day, while many of the small mines did not reply to this question. No labor disturbances were reported.

As for many years in the past, North Dakota was the chief producer of lignite in 1939, followed in order by Texas, South Dakota, and Montana. The North Dakota output comprised 70 percent of the total production, that of Texas 27, and the outputs of South Dakota and Montana, taken together, 3.

According to the Federal Power Commission, 1,538,174 tons of lignite were used in 1939 for generating electric energy in the United

TABLE 38.—*Summary of production, value, men employed, days operated, man-days of labor, and output per man per day at lignite mines in the United States in 1939, by States*

	North Dakota	South Dakota	Montana [1]	Texas	Total

Average tons per man per day: 1939	8.57	5.82	3.52	6.30	7.61
1938	8.62	5.65	3.55	7.64	8.06

[1] Includes output of Custer, Dawson, McCone, Prairie, Richland, Roosevelt, Sheridan, Valley, and Wibaux Counties.
[2] Some shipments are included in commercial sales.
[3] A small amount of coal used at the mines is included in other sales to local trade.
[4] Based upon the "reported" number of man-shifts where the operator keeps a record thereof, otherwise upon the "calculated" number of man-shifts obtained by multiplying the average number of men employed underground and on the surface at each mine by the number of days worked by the mine and tipple, respectively. Using the "calculated" man-shifts throughout as developed before 1932, the average output per man per day was 8.59 in 1938 and 8.10 in 1939.

States. This tonnage is equivalent to 51 percent of the total production of the industry. The consumption in the West North Central Division was 468,512 tons. The West South Central and Mountain Divisions consumed 686,954 and 382,708 tons, respectively.

TEXAS

County	Total production (net tons	Value: Total (thousand dollars)	Value: Average per ton	Total number of employees	Man-days of labor [1]	Average number of days mine operated	Average tons per man per day [1]
Bastrop and Milam	86,475	$66	$.76	116	17,446	150	4.96
Henderson, Titus, and Wood	727,547	809	1.11	443	111,674	252	6.51
Total: 1939	814,022	875	1.07	559	129,120	231	6.30
1938	846,219	679	.80	506	110,768	219	7.64

[1] Based upon (1) the "reported" number of man-shifts where the operator keeps a record thereof; otherwise upon (2) the "calculated" number of man-shifts obtained by multiplying the average number of men underground and on the surface of each mine by the number of days worked by the mine and tipple respectively. Using throughout the "calculated" man-shifts as developed before 1932 (namely, the product of the total number of men employed at each mine times the tipple days) the average output per man per day was 3.52 in 1939 in Montana, 9.55 in North Dakota, 5.10 in South Dakota, and 6.31 in Texas.

[2] The output is obtained chiefly from strip pits, in which the production per man per day is large.

Detailed statistics of production in 1939 are presented in the following tables. Data on the industry in 1940 were not available in time for insertion in this chapter but will be published later as a supplement to the Weekly Anthracite-Beehive Coke Report and may be obtained upon request from the Coal Economics Division of the Bureau of Mines.

NUMBER AND SIZE OF LIGNITE MINES

For 1939 the Bureau of Mines received reports from 206 lignite mines (exclusive of many mines producing less than 1,000 tons a year). This is comparable with 212 mines reporting for 1938. Five mines produced 200,000 to 500,000 tons each, and the output of these mines amounted to 58 percent of the total production. Four mines reported an output of 50,000 to 200,000 tons each and accounted for 17 percent of the total tonnage; 20 mines in the 10,000- to 50,000-ton class reported 13 percent of the total production; and 177 mines producing less than 10,000 tons each accounted for 12 percent of the total output of the industry.

LENGTH OF WORKING DAY IN LIGNITE MINES

Reports from operators in the lignite fields in 1939 show that 141 mines, or 68 percent of the total mines reporting, were working an 8-hour day. The men employed at these mines numbered 1,512—72 percent of the total men employed at the lignite mines.

The following table summarizes the replies of mine operators to the question, "Number of hours operated per shift."

TABLE 40.—*Number of lignite mines in the United States having established working shift of certain length and number of men employed therein in 1939, by States*

State	7 hours		8 hours		9 hours		Not reporting and all others [1]		Total	
	Mines	Men	Mines	Men	Mines	Men	Mines	Men	Mines	Men

North Dakota	12	229	115	868	3	114	29	180	159	1,391
South Dakota			7	40			6	13	13	53
Texas			[2] 8	[2] 559	(3)	(3)			8	559
Total United States	15	239	141	1,512	6	125	44	220	206	2,096

[1] Includes mines where day was more than 9 or less than 7 hours or was irregular, or where it was changed during the year; also mines (1) where operator has included time when the men were entering or leaving the mine, (2) where operator has reported time of men in certain occupations where workday is longer than for other employees, as in stripping overburden, or (3) where work is staggered and 2 crews of men overlap. Many smaller mines failed to answer question.

[2] Includes data of 9-hour shift.

[3] Included in 8-hour shift.

LIGNITE LOADED FOR SHIPMENT BY INDIVIDUAL RAILROADS

TABLE 41.—*Lignite loaded for shipment by individual railroads in the United States in 1939, as reported by operators, in net tons*

Railroads	State	Quantity
Chicago, Milwaukee, St. Paul & Pacific	North Dakota South Dakota	51,428
Great Northern	Montana North Dakota	344,326
International-Great Northern	Texas	797,531
Missouri-Kansas-Texas	do	
Rockdale, Sandow & Southern	do	
St. Louis Southwestern of Texas	do	
Texas Short Line	do	
Minneapolis, St. Paul & Sault Ste. Marie	North Dakota	556,050
Northern Pacific	do	611,982
		2,361,317

METHODS OF RECOVERY

TABLE 42.—*Lignite mined in the United States in 1939, by methods and by States*

State	Mined by hand	Shot off the solid	Cut by machines [1]	From strip pits	Not specified	Total
Montana	[2] [3] 82,925	[2] 736,222	(3)	[2] 35,342	7,301	47,768
North Dakota	104,012	119,997	520,371	1,367,162	19,710	2,131,252
South Dakota	1,892			44,945	2,658	49,495
Texas	(2)	(2)		(2)		814,022
Total United States	[3] 188,829	856,219	[3] 520,371	1,447,449	29,669	3,042,537

[1] A total of 22 machines was used—14 "permissible" and 8 of other types.
[2] Montana includes Texas.
[3] Small amount of machine-cut coal is included in "Mined by hand."

STRIPPING OPERATIONS

The production of lignite from strip pits in 1939 amounted to 1,447,449 tons—48 percent of the total output of the industry. Most of the stripping was done in North Dakota, which produced 1,367,162 tons by that method. This represented 94 percent of all the strip-pit production and 45 percent of the total tonnage produced by the lignite industry. The tonnage from stripping operations in Montana, Texas, and South Dakota was only 80,287 tons. The number of employees working in the strip pits was 445, with an average output of 12 tons per man per day, and the average number of days worked was 195.

Detailed statistics for stripping operations in the lignite industry are shown in table 43.

TABLE 43.—*Summary of stripping operations that produced lignite in 1939, by States*

State	Number of strip pits[1]	Number of shovels, dragline excavators, and coal-loading machines[2]	Coal mined by stripping (net tons)	Total value at mines (thousand dollars)	Average value per ton	Number of employees: In strip pits	Number of employees: All others	Number of employees: Total	Average number of days mines operated	Man-days of labor[3]	Average tons per man per day[3]
Montana[4]	6	2	35,342	$25	$0.71	[5] 26	(5)	26	95	2,478	14.26
North Dakota	55	32	1,367,162	1,501	1.10	395	143	538	199	107,116	12.76
South Dakota	4	1	44,945	61	1.36	24	7	31	211	6,553	6.86
Texas	(4)	(4)	(4)	(4)	(4)	(4)	(4)	(4)	(4)	(4)	(4)
Total	65	35	1,447,449	1,587	1.10	445	150	595	195	116,147	12.46

[1] Includes some pits in which the stripping is done by hand.
[2] In some cases the same equipment was used for stripping or excavating and for loading the coal; this duplication has been eliminated. In some cases coal was excavated by machine and loaded by hand.
[3] Based upon (1) the "reported" number of man-shifts where the operator keeps an accurate record thereof; otherwise upon (2) the "calculated" number of man-shifts obtained by multiplying the number of men employed at the tipple, in loading coal, etc., and in stripping overburden by the number of days worked in each department, insofar as separately reported by the operator.
[4] Texas included with Montana.
[5] "All others" are included in "In strip pits."

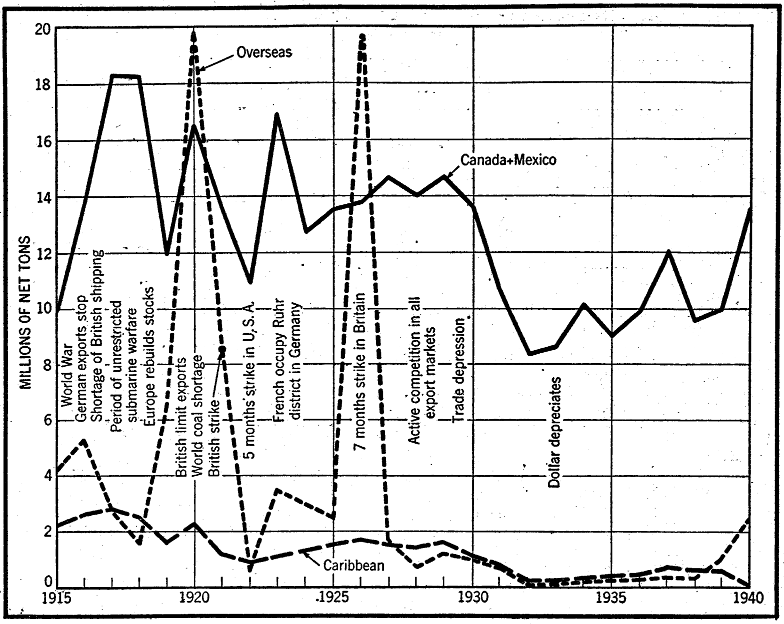

FIGURE 10.—Exports of bituminous coal to Canada and Mexico, the Caribbean, and "overseas" destinations, 1915–40.

Shipments to Alaska, Hawaii, Midway Islands, Puerto Rico, and Virgin Islands.—In addition to export trade proper, the United States supplies a small tonnage of anthracite and bituminous coal to Alaska, Hawaii, the Midway Islands, Puerto Rico, and the Virgin Islands. Shipments of bituminous coal to each of these possessions in 1940 were as follows: Alaska, 14,794 net tons; Hawaii, 1,631; Midway Islands, 106; Puerto Rico, 11,106; and Virgin Islands, 55,579. Comparative shipments for 1939 were: Alaska, 17,587; Hawaii, 1,540; Midway Islands, 81; Puerto Rico, 14,709; and Virgin Islands, 69,751.

WORLD PRODUCTION

Bituminous and anthracite (by subtraction)	1,229,000	1,296,000	1,205,000	(2)	(2)

[1] Coal is also mined in Argentina, Iran, and Italian East Africa. Production figures for these countries are not available, but estimates are included in the totals.
[2] Data not yet available.
[3] Estimate included in total.
[4] Production less than 1,000 tons.
[5] Production of most important coal mines.

PENNSYLVANIA ANTHRACITE

By F. M. Shore, J. R. Bradley, J. A. Corgan, and A. V. Coleman

SUMMARY OUTLINE

The total production of Pennsylvania anthracite in 1940 was 51,484,640 net tons—a decrease of only 2,737 tons compared with 51,487,377 tons produced in 1939. It should be remembered that these figures include dredge coal, which in many instances is taken from the rivers and creeks some distance from the anthracite regions. In 1940, dredge operations produced 942,944 tons and in 1939, 703,860 tons. Exclusive of dredge coal, the production in 1940 was 50,541,696 tons and is comparable with 50,783,517 tons in 1939.

Despite the slight decrease in anthracite production, several important developments in 1940 are believed to have benefited the industry. Of these, the most important was the voluntary anthracite production control or allocation plan, which was approved by the Governor of Pennsylvania in January and, with the cooperation of the operators and the United Mine Workers of America, doubtless has helped to bring production in closer alinement with current demand.

Moreover, a committee of operators and miners has been working on the problem of "bootleg" or illicit coal, with the hope of formulating a workable plan for its solution. Early in 1941 a plan to end "bootleg" mining was approved by the Anthracite Emergency Committee and adopted by operators representing more than 90 percent of the total anthracite production.

Finally, the price situation in the industry was more stable, and the producers realized higher prices at the mine for the output in 1940 than in 1939.

Research was continued within the industry, and, as provided in the Miller bill passed by the Pennsylvania General Assembly in 1939, the program of research in the Pennsylvania State College School of Mineral Industries is well under way; much valuable information already has been obtained. The program calls for special consideration of the use of anthracite in generating water gas and its utilization as an activated carbon.

There were no major labor disturbances in the anthracite industry during 1940. The wage agreement between the anthracite mine operators and the United Mine Workers of America, which was effected in May 1939, expired April 30, 1941. After a 1-day suspension, a new contract was arranged between the operators and the United Mine Workers of America. The agreement became effective May 1, 1941, and expires April 30, 1943. The miners were given a compensation payment to cover vacation expenses and also received a graduated percentage increase over the old scale.

Freight rates affecting the movement of anthracite were not changed greatly in 1940. The so-called motor-compelled rates, which were inaugurated originally to compete with the trucking of anthracite, were to expire December 20, 1940, but were extended until June 21, 1941, and were again extended to December 20, 1941. A group of large anthracite producers and the Commonwealth of Pennsylvania together petitioned the anthracite-originating railroads that rates on steam sizes be reduced to destinations to which reductions already have been made on domestic sizes and that the area to which reductions apply be made more extensive. The anthracite carriers refused both the reduction in rates and the extension of the area; then early in 1941 the anthracite producers filed freight-rate conplaints with both the Interstate Commerce Commission and the Pennsylvania Utilities Commission.

Definition of Pennsylvania anthracite industry.—Based upon differences in composition and characteristics of the product, trade practice and historical usage recognize two major divisions in the coal industry of the United States—bituminous coal and Pennsylvania anthracite. Anthracite and semianthracite also are mined in parts of Virginia, Arkansas, Colorado, and in New Mexico. Locally these coals represent distinct and important industries, but the tonnages involved are small and for statistical convenience usually are grouped with the totals of the bituminous-coal industry.

The Pennsylvania anthracite industry, as here defined, includes all nonbituminous fields of that State. Trade usage commonly includes the output of the Bernice Basin in Sullivan County with Pennsylvania anthracite, although the coal of this basin is classified officially as semianthracite.

Anthracite program.—Since about 1924 the general trend of production in the Pennsylvania anthracite industry has been downward, due chiefly to the increasing competition of other fuels. The declining output has resulted in keen competition for the anthracite markets within the industry itself.

TABLE 1.—*Statistical trends of Pennsylvania anthracite industry, 1936–40*

	1936	1937	1938	1939	1940
Production:					
Loaded at mines for shipment:					
Breakers ____ net tons __	46,256,132	44,016,915	39,010,935	[1] 43,660,662	[1] 43,800,127

13 Bureau of Labor Statistics.

For several years there has been much discussion of the unsatisfactory situation, and several plans have been under consideration which (it was thought) might bring some measure of relief to the economic ills of the industry. The present voluntary production-control program is the result of conferences between Pennsylvania State officials, representatives of the United Mine Workers of America, and committees of old-line and independent mine operators. It is reported that the voluntary agreement, when submitted to the Governor, was agreed to by producers whose output comprised about 98 percent of the total anthracite production.

The program is supervised and controlled by the Anthracite Emergency Committee, composed of nine members appointed by the Governor. The operators, the United Mine Workers of America, and the public are represented by three members each. The program is administered by an executive committee of three.

A producers' advisory board of 14 members advises and makes recommendations to the executive committee on production requirements, considering stocks, unsold anthracite in cars at mines, and other factors that affect the consumption of anthracite.

Each cooperating producer is to be assigned a certain percentage of the total tonnage allocated for the week. The percentage positions were determined by careful study of the production history of each mine by committees of operators and miners.

A provision is included for amendment by cooperating producers. It is said that elimination of overproduction is the aim of the program and that it does not attempt to regulate marketing or to control prices.

Illicit coal.—One of the most difficult problems with which the industry has had to contend in recent years is the illicit or "bootleg" coal industry. The illicit coal trade first started during the depression years, when unemployed miners dug coal from land owned by the anthracite operating companies to heat their own homes; but it soon grew beyond this phase, and before long trucks were hauling the coal to cities some distance from the anthracite fields, where it was sold in competition with the legitimate product. According to a survey by the Anthracite Emergency Committee, as of March 15, 1941, 10,031 men and boys were working in 2,862 "bootleg" openings. In addition to these workers, 1,697 men and boys were working in 340 breakers and washeries preparing the product for the market. The survey revealed that free-lance miners produced 535,556 tons of anthracite in January 1941. According to the Anthracite Institute, the illicit production for 1940 was more than 4,000,000 net tons.

To find some solution to this problem, a plan was adopted in amendment form to the anthracite emergency program early in 1941 and was agreed to by the State, the operators cooperating under the program, and the United Mine Workers of America. Among other things, the plan provides that the committee will make an immediate survey of all "bootleg" operations; and any cooperating producer may make a lawful arrangement to purchase the output of a "bootleg" hole or holes, in addition to his quota of production under the emergency program, which will not be affected thereby. Moreover, cooperating producers may employ "bootleggers" formerly engaged in illegal mining, and such producers will receive a supplemental allocation equal to 3¼ net tons per man per day of commercial output for each man so employed.

The legitimate operators are reported as hopeful that successful operation of the plan will solve this social and industrial problem.

Distribution.—According to the Pennsylvania State Department of Mines, Pennsylvania anthracite mine shipments to destinations within the United States totaled 44,982,363 net tons in 1940, exclusive of illicit or "bootleg" coal. Of this tonnage, the total truck shipments were 6,192,067 tons, or about 14 percent. This is comparable to a movement of 4,824,537 tons (11 percent) in highway-borne traffic in 1939.

For many years most of the anthracite shipped by rail has been destined to New England, New York, New Jersey, and Pennsylvania, and in 1940 these States received 36,492,328 tons or 94 percent of the total rail shipments within the United States. Three States—Pennsylvania, New York, and New Jersey—received 6,025,310 tons (97 percent) of the total tonnage moved from the mines by truck in 1940.

According to the Commonwealth of Massachusetts, Division on the Necessaries of Life, total receipts of Pennsylvania anthracite in New England in 1940 were 4,802,000 net tons compared with 11,679,000 tons in 1917. Until recent years, tidewater receipts of anthracite in New England comprised a large percentage of the total shipments to these States. For example, in 1917 tidewater receipts amounted to 4,421,000 tons (38 percent) of the total receipts. By 1940, the tonnage had declined to 763,000 tons (16 percent of the total). Table 3 gives details of the anthracite movement into New England.

Loadings at Lake Erie ports dropped from 531,335 net tons in 1939 to 430,192 in 1940—a 19-percent decrease. Receipts at Duluth-Superior fell 32 percent and those on the Upper Lake Docks 15 percent in 1940 compared with 1939.

TABLE 3.—*Receipts of anthracite in New England, 1917, 1920, 1923, and 1927–40, in thousands of net tons*

Year	Receipts by tide [1]						Receipts by rail [1]	Imports [2]	Total receipts of Pennsylvania anthracite [3]

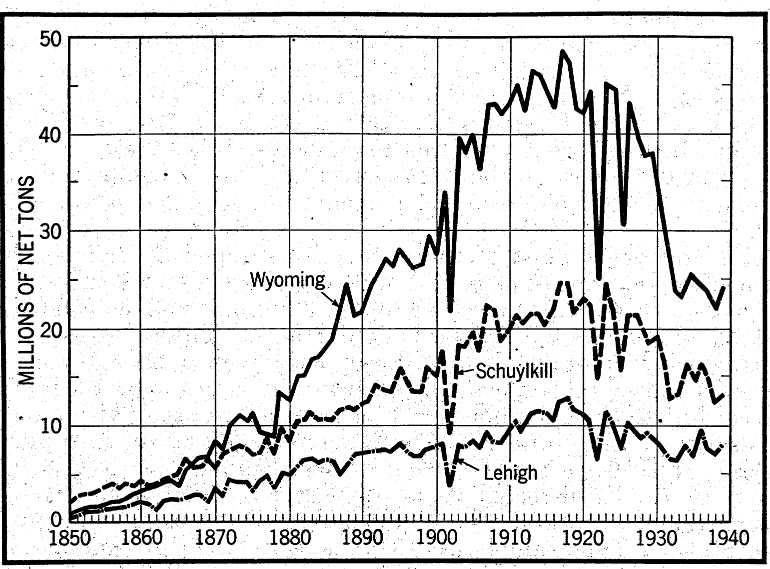

FIGURE 1.—Anthracite shipped from the Lehigh, Schuylkill, and Wyoming regions, 1850–1939.

Competitive fuels in the United States and in principal markets.—The New England States, New York, New Jersey, Delaware, Maryland, Pennsylvania, and the District of Columbia are important, highly competitive markets for domestic fuels. Excluding bituminous coal and liquefied gases (as well as wood fuel for which no data are available), these States in 1939 used solid fuels and heating and range oils equivalent to about 74,774,000 net tons of bituminous coal or 72,025,000 tons of anthracite, largely for heating homes, apartment houses, and public buildings. Based upon reports of the Pennsylvania Department of Mines, rail and truck shipments of Pennsylvania anthracite in 1940 to points within the United States totaled 44,982,363 tons, of which 97 percent went to the States mentioned above. Shipments in 1940 (other than of illicit or "bootleg" coal, the inclusion of which would increase the total by perhaps 10 percent) were slightly higher than in 1939. The consumption of heating and range oils in 1939 in terms of coal was about 27,000,000 tons. Such data as are available indicate that the consumption of oils in 1940 exceeded that in 1939 and set a new high record. The only other fuel of importance in the States mentioned (and again excluding bituminous coal) is coke, use of which for domestic purposes amounted to 4,128,000 tons in 1940, including 76,000 tons imported, some possibly for metallurgical uses. Details are shown in table 4.

For the United States as a whole, the supplies of fuels commonly used for domestic purposes in 1940 show increases over 1939, the outstanding gains being recorded for heating oils for domestic and commercial uses, the sales of which increased from 136,232,000 barrels in 1939 to an estimated 162,000,000 barrels in 1940. Range-oil sales increased from 37,061,000 to 48,600,000 barrels, and liquefied petroleum gases from 2,084,000 to 3,191,000 barrels. Details regarding other fuels used for domestic heating will be found in table 5.

[1] A considerable part of Buckwheat No. 1 and smaller steam sizes is used by industries, railroads, and public utilities.
[2] Production plus imports less exports.
[3] Partly estimated.
[4] Data not available.
[5] Subject to revision.
[6] An estimated one-half is used for domestic purposes.
[7] Exact data not available; estimated between 55 and 77 million tons a year, including lignite and anthracite and semianthracite outside of Pennsylvania, which is shown separately.
[8] Range oil is a light distillate used for house heating, hot-water heating, and cooking.
[9] Revised figures.
[10] Includes all grades of fuel oil used for heating buildings.
[11] Includes gas used for heating offices, hotels, apartments, schools, hospitals, and stores and other large buildings, as well as houses.
[12] American Gas Association.

Transportation of anthracite to principal markets.—Data compiled from reports issued by the Pennsylvania State Department of Mines indicate that of the total anthracite mine shipments by rail and truck to destinations in the United States, 86 percent moved by rail and 14 percent by truck in 1940; of the rail shipments, 62 percent was domestic and 38 percent steam sizes. In 1939, 89 percent of the total shipments was carried by the railroads and 11 percent by truck.

It is interesting to note (table 7) that in 1940, 2,911,316 tons or 47 percent of the total tonnage trucked were sold to local trade within the anthracite region and that 1,433,939 tons or 23.2 percent of the total trucked coal were sold within Pennsyvlania but outside the anthracite region. New York and New Jersey received 27.2 percent of the total truck shipments. Taken as a whole, these three States—Pennsylvania, New York, and New Jersey—received 97 percent of the coal shipped by truck. It is also of interest to note that the largest percentage of the trucked coal is transported to market during January, February, March, October, November, and December.

[1] Compiled from reports of Pennsylvania Department of Mines.

In view of the rise from 3,177,656 tons in 1936 to 6,192,067 in 1940, it is apparent that the trucking of coal is increasing and that the railroads, therefore, are not transporting as high a percentage of shipments as they formerly did.

The distribution of rail shipments of anthracite, by States of destination, for 1938–40 is shown in table 6 and truck movement of Pennsylvania anthracite by months, in 1940, by States of destination, in table 7.

Consumption.—Considering changes in producers' stocks and making allowances for foreign trade, the total consumption of anthracite in 1940 was 49,000,000 net tons compared with 49,700,000 in 1939. The consumption for 1940 is not exactly comparable with that for 1939, because the producers' stock figure for 1940 was as of December 28 and the stock for 1939 was as of December 31. Class I railroads and electric power utilities consumed 3,804,209 net tons of anthracite in 1940; in 1939, this group consumed 3,925,649 tons. Illicit coal is not included in the figures of either year.

According to the Census of Manufactures, 1939, the consumption of anthracite, as well as of other solid fuels, in manufacturing establishments declined in 1939 compared with 1937. The consumption of anthracite decreased from 6,562,000 net tons in 1937 to 5,016,000 in 1939.

Consumption by principal industry groups in 1937 and 1939, respectively, was as follows: Paper and allied products, 1,280,000 and 1,039,000 net tons; food and kindred groups, 1,021,000 and 738,000 net tons; nonferrous metals and their products, 966,000 and 598,000 net tons; textile-mill products and other fiber manufactures, 681,000 and 507,000 net tons; chemicals and allied products, 605,000 and 641,000 net tons; iron and steel and their products, except machinery, 486,000 and 511,000 net tons; and stone, clay, and glass products, 449,000 and 239,000 net tons.

Changes in stocks.—On December 31, 1940, stocks of anthracite held by railroads (class I), electric power utilities, and other industrial consumers totaled 1,589,427 net tons. On the corresponding date in 1939, stocks held by the same group of consumers amounted to 1,390,010 tons.

The stocks of anthracite on the upper Lake docks on December 31, 1940, were 217,970 net tons—a slight decrease from the 295,084 tons on this date in 1939.

Producers' stocks amounted to 939,227 net tons on December 28, 1940. On December 31, 1939, stocks in producers' yards were 993,848 net tons.

Stocks held by 176 selected retail dealers totaled 358,422 net tons in January, reached a low point of 197,618 tons in March and a high of 432,587 tons in November, and were 429,382 tons or slightly above the 1939 figure in December.

Trend of employment.—The peak year for employment in the Pennsylvania anthracite industry was 1914, when 179,679 men were employed. In 1926 the figure had fallen to 165,386 and declined steadily until 1939, when 93,138 men were on the pay rolls. In 1940 the number employed had fallen to 91,313.

The decrease in the number of men employed in the anthracite industry is due to several developments, principally the decline in production, the increased mechanization of the mines, and the extended mining in strip pits. The first has caused a natural decline in the men employed, and the latter two have resulted in a higher output per man per day, reducing the labor required for a given tonnage.

Trend of prices.—According to trade-journal quotations, the circular prices, f. o. b. mine, quoted by leading anthracite-producing companies, effective January 1940, were as follows: For Broken, Egg, Stove, and Chestnut sizes, $6.25 a net ton; for Pea, $4.75 a ton. To stimulate spring fill-up and summer business the prices were decreased 50 cents a ton in April and then gradually increased until September, when they equaled those at the beginning of the year. Buckwheat. Rice, and Barley sizes were firm throughout the year at $3.50, $2.75, and $2.00 a net ton, respectively. Comparable quotations were not published by the trade journals for each month in 1939. However, trade reports indicate that in 1939 the price structure was unstable throughout the year and that the price situation was more favorable to the industry in 1940.

According to the Bureau of Labor Statistics, United States Department of Labor, the retail prices for Stove size on December 15, 1939, in Boston, New York City, and Washington, D. C., were $13.00, $10.69, and $12.65, respectively. On the same date in 1940, comparable prices were $13.75, $11.72, and $12.95. At the same periods, the prices for Buckwheat No. 1 in these three cities were $9.75, $7.59, and $9.55 in 1939 compared with $10.00, $8.38, and $9.60 in 1940. The prices are for a net ton of 2,000 pounds in Boston and New York and a gross ton of 2,240 pounds in Washington, D. C. The New York prices also include a 2-percent sales tax.

Sales realization.—The average sales realization on breaker shipments in 1940 was $4.27 a net ton compared with $3.85 in 1939—an 11-percent increase. However, the realization was low in 1939 because of the chaotic price situation in that year. The average sales realization was $4.16 a net ton in 1938 and $5.63 in 1929.

The value at the mines of all anthracite production in 1939 was $187,175,000, while in 1940 (with prices more favorable to the producers) it reached $205,490,000—a 9.8 percent increase.

Imports and exports.—Imports of anthracite decreased from 298,153 net tons in 1939 to 135,436 in 1940—a 55-percent reduction. The United Kingdom and Canada supplied all of the imported coal in 1940, 98 percent coming from the former. Imports from Canada doubtless represent reexports of coal. Exports, on the other hand, increased approximately 3 percent in 1940 compared with 1939, as the tonnage rose from 2,590,000 tons to 2,667,632. Canada received about 98 percent of the total exports in 1940 (see tables 33–35).

Mechanical stokers and oil burners.—According to the Bureau of the Census, United States Department of Commerce, factory sales of mechanical stokers for burning anthracite have shown little change in the last 3 years. Sales of class 1 stokers (capacity under 61 pounds of coal an hour) were 12,651, 11,776, and 11,917 units, respectively in 1938, 1939, and 1940. Sales of class 2 stokers (capacity 61 to 100 pounds of coal an hour) were 970 units in 1940. Data on class 2 stokers for 1938–39 are not available.

Shipments of oil burners in 1940 (for purposes other than ranges, stoves, water heaters, and space heaters) within the United States increased from 210,120 burners in 1939 to 260,991 in 1940.

Research and technologic developments.—The fourth annual anthracite conference of Lehigh University was held at Bethlehem, Pa., May 8–9, 1941. A paper presented by Carl A. Fraser, Albany, on Practical Merchandising of Anthracite from the Dealer Viewpoint, stressed the needs of the ultimate consumer, service, budget selling, and automatic heating equipment. In Market Opportunities for Anthracite, J. D. Jillson, Anthracite Industries, Inc., discussed competitive fuels in the primary anthracite markets, including Canada, with special reference to the influence of war-time economy on the demand for anthracite. J. F. K. Brown, Hudson Coal Co., in a paper Observations on the Use of Anthracite in Foundry Cupolas, added to the information presented on this subject in his paper read at the 1940 conference. Other papers included:

Future Research in the Anthracite Industry, by Frank C. Wright, Jr., vice president, The Philadelphia & Reading Coal & Iron Co.

Anthracite Fuel Beds in Water-gas Generators, by C. C. Wright, associate professor of fuel technology, and L. L. Newman, assistant professor of fuel technology, Pennsylvania State College.

Advanced Developments in the Control of the Combustion of Anthracite, by Allen J. Johnson, director, Anthracite Industries Laboratory.

Preparation of Activated Carbon from Pennsylvania Anthracite, by Eric Sinkinson, associate professor of fuel technology, Lehigh University, Bethlehem, Pa.

Practical Pointers in Domestic Stoker Installations, by Joseph K. Goundie, Fritch Coal Co., Bethlehem, Pa.

Nonfuel applications of anthracite and anthracite refuse, including the use of anthracite ashes for soil improvement, the production of mineral wool from anthracite culm and ashes, and the production of lightweight aggregate from anthracite ashes for use in various concrete products, among other subjects, were discussed in the paper, Anthracite Research at Mellon Institute, by H. J. Rose.

According to the Anthracite Institute, anthrafilt expanded into new markets and is now a widely used filtering material in municipal and industrial water plants. Oil refineries and the paper-mill industry are employing it more extensively, and the War Department has found it of value in water softening and filtering problems.

Anthracite Institute.—The Anthracite Institute carried on its usual functions and information services. It opposed actively the reduction of freight rates on oil commodities, the extension of natural-gas pipe lines into eastern markets, and hydroelectric projects in competition with anthracite. The institute, with other interested parties, successfully opposed railroads that had filed reduced rates for crude petroleum from the St. Louis-Chicago area to the eastern seaboard.

SOURCES AND ACKNOWLEDGMENTS

Final statistics of the Pennsylvania anthracite-mining industry are prepared from an annual canvass, by mail, of all known anthracite operations, including over 400 mines, large and small, that are active producers. About 95 percent of the tonnage is reported direct, and the remaining 5 percent is collected by personal visits or from reliable collateral evidence. The data on individual operations furnished by the producers are voluntary and confidental, as is customary in the statistical services of the Bureau of Mines.

In assembling available detailed information, free use has been made of the pertinent figures prepared by the Anthracite Institute, the Anthracite Emergency Committee, the American Association of Railroads, and the Pennsylvania Department of Mines; to all of these, thanks are extended for their cordial and continued cooperation. Thanks are also due especially to the producers for reporting so promptly and, in general, so fully upon their 1940 operations.

PRODUCTION

The production of Pennsylvania anthracite in 1940 was 51,484,640 net tons—a slight decrease compared with the output of 51,487,377 tons in 1939. These figures include a small tonnage of semianthracite produced in Sullivan County (50,844 tons in 1940) and also the output of dredge coal (which amounted to 942,944 tons in 1940 and 703,860 tons in 1939), but they do not consider the production of "bootleg" or illicit coal, which has been increasing since its beginning during the depression years and has been estimated as amounting to at least 4,000,000 tons in 1940.

The peak year in production was reached in 1917, when the output was 99,611,811 net tons. Since 1924 the general trend has been downward, and in 1940 the output was a little more than one-half of that in 1917.

Weeks and months.—Tables 8 and 9 summarize the statistics of weekly and monthly production of anthracite. Statistics of current output are estimated from records of car loadings and from tonnage reports from trade sources. The weekly and monthly figures in tables 8 and 9 have been adjusted to the annual total ascertained by direct canvass of the operators.

TABLE 8.—*Estimated weekly production of Pennsylvania anthracite in 1940, in net tons*

Week ended—	Production	Week ended—	Production

[1] Production is estimated from weekly carloadings as reported by the Association of American Railroads and includes mine fuel, coal sold locally, and dredge coal. Does not include an unknown amount of "bootleg" production. Monthly statistics from 1905 to 1925 will be found in Mineral Resources, 1925, pt. II, pp. 427–428, and from 1925 to 1930 in Mineral Resources, 1930, pt. II, p. 741.

Small mines and intercompany sales.—All known legitimate operations are included in the statistics. In recent years, conditions have favored the development of numerous small mines operating on lease or subcontract and producing run-of-mine coal, which is sold to larger companies for preparation at a breaker. At the same time, there has developed an increasing transfer of coal from one operation to another, and some of the companies have built central breakers to which coal from numerous mines is shipped by rail or truck for preparation. These tendencies have increased the complexity of the task of collecting and compiling statistics of the industry, but great care has been exercised to avoid double counting of tonnages produced by one operator and prepared for market by another, and the figures herein represent the net quantity of merchantable coal plus the fuel used by the collieries themselves. The employees of operators producing run-of-mine only have been included in the employment statistics, as they have received wages from the industry and have contributed to the final product.

Regions, fields, and counties.—The anthracite fields are divided into three trade regions— Lehigh, Schuylkill, and Wyoming. This classification is generally used by the trade, and it is also followed in the district organization of the United Mine Workers of America, in which District 1 corresponds to the Wyoming region, District 7 to the Lehigh region, and District 9 to the Schuylkill region. Geologically the anthracite area is classified by fields—the Northern, Eastern Middle, Western Middle, and Southern. This classification is used in technical operating studies because it follows more closely the geologic conditions that largely influence the methods and cost of mining. The Northern field is the same as the Wyoming region. The Lehigh field and that part of the Southern field lying east of Tamaqua (known as the Panther Creek Valley) make up the Lehigh region. The Schuylkill region comprises that part of the Southern field lying west of Tamaqua and the Western Middle field. For historical comparison, the tonnage of the small Bernice Basin is often included with the statistics of the Northern field, although the coal is classified officially as semianthracite. The total area of the four fields is about 484 square miles—the Northern covers 176 square miles, the Eastern Middle 33, the Western Middle 94, and the Southern 181.

Change, 1940 ... percent	+0.4	+11.0	−0.9	−3.5	−6.5	−5.3	(4)	+9.8

1 Value given is value at which coal left possession of producing company and does not include margins of separately incorporated sales companies.
2 Small quantity of washery coal included with breaker.
3 For purposes of historical comparison and statistical convenience, the mines of Sullivan County are grouped with the Pennsylvania anthracite region, although the product is classified as semianthracite according to the American Society for Testing Materials Tentative Standard.
4 Less than 0.1 percent.

Based upon minable reserves, the Southern field is first, followed by the Western Middle, Northern, and Eastern Middle.

Tables 10–12 present production data by regions, fields, and counties.

TABLE 11.—*Pennsylvania anthracite produced, by fields, 1936–40, in net tons*

[The figures of breaker product include a certain quantity of culm-bank coal, which amounted to 763,648 tons in 1940. Data for 1913–25 will be found in Mineral Resources, 1925, pt. II, p. 517, and for 1919–30 in Mineral Resources 1930, pt. II, p. 747]

[1] Value given for shipments is value at which coal left possession of producing company; does not include margins of separately incorporated sales companies.

[2] Counties producing dredge coal only.

Culm-bank coal.—The culm banks in the anthracite region have been a source of coal for many years. In the early days of anthracite mining, the smaller sizes of anthracite, especially Pea and smaller, were not used as they are today, and these sizes and larger pieces of refuse containing much good coal were piled in large banks throughout the region. In recent years, with the increased demand for the smaller sizes and more efficient preparation methods, the product of these banks is run through the washery or breaker, and a prepared coal is obtained.

In 1939, this source supplied 2,583,814 net tons of coal. Prepared coal from culm banks in 1940 amounted to 2,783,038 tons. Tables 13 and 14 give a detailed break-down of culm-bank product by regions and fields.

Dredge coal.—Dredging anthracite from the stream beds is an important industry to many operators along the banks of the rivers and creeks that drain the region. From 1915 to 1940, inclusive, 16,946,557 net tons of anthracite, with a reported value of $16,455,313, have been produced in this manner. The industry reached a peak in 1925, when 1,015,708 net tons of anthracite with a value of $929,292 were taken from the river and creek bottoms. In 1940, this source supplied 942,944 net tons of anthracite valued at $1,096,926.

TABLE 13.—*Pennsylvania anthracite produced in 1940, classified as fresh-mined, culm-bank, and river coal and as breaker, washery, and dredge product, by regions, in net tons*

[1] Includes a small amount of washery coal.

Reconciliation of fresh-mined, culm-bank, and breaker product.—Anthracite is now produced from three sources—from mines, from old culm banks, and from the rivers that drain the anthracite region. As all three sources contribute to the country's supply, it is important to consider them all to ascertain the total production. No difficulty is experienced in separating the figures of production by dredges, as this is a distinct industry. It is difficult, however, to differentiate sharply between fresh-mined and culm-bank coal that can be maintained throughout the statistics of the industry.

As the best solution of this problem, the individual breaker, washery, or dredge is taken as the unit in compiling the statistics, and the producing companies are asked to supply separate statements for each. These are totaled to form the primary tables of this report to show the total quantity of breaker product, washery product, and dredge product, with related figures of value and number of employees.

The figures for breaker and washery product, however, are not exactly equivalent to the fresh-mined and culm-back coal because of the practice, sometimes adopted, of putting culm-bank coal through a breaker, either directly from the bank or after preliminary treatment in a washery. The tonnage of culm-bank coal prepared at the breakers is broken down by fields and shown in table 15.

TABLE 14.—*Pennsylvania anthracite produced in 1940, classified as fresh-mined, culm-bank, and river coal and as breaker, washery, and dredge product, by fields, in net tons*

[1] No culm-bank coal is put through breakers in Sullivan County.
[2] Includes some washery coal.

Interregional variation in sizes.—Geologic conditions affect the percentages of domestic and steam sizes produced and consequently the value of the product as a whole. In the Wyoming and Lehigh regions, the percentage yield of the higher-priced domestic sizes is relatively high; in the Schuylkill region, it is less because of the crushing of the coal by faulting and folding of the beds. In 1940, the breaker output of the Wyoming region comprised 70.4 percent domestic sizes and 29.6 percent steam sizes; the Lehigh region—63.8 percent domestic and 36.2 percent steam sizes; the Schuylkill region—58.5 percent domestic and 41.5 percent steam sizes. Table 16 shows shipments of anthracite by regions and sizes. Table 17 shows by regions the percentages of various sizes in relation to total breaker product.

Anthracite sizing specifications.—Table 18 gives the new sizing specifications for the anthracite industry, adopted by the Anthracite Emergency Committee January 8, 1941, which became effective April 1, 1941. These specifications replace those adopted by the Anthracite Institute in 1931. The test mesh is round.

TABLE 18.—*Standard anthracite sizing specifications approved and adopted by the Anthracite Emergency Committee*

	Test mesh, inches	Percent				
		Oversize maximum	Undersize		Maximum impurities	
			Maximum	Minimum	Slate [1]	Bone
Broken	Through 4 3/8				1 1/2	2
	Over 3 1/4		15	7 1/2		
Egg	Through 3 1/4	5			1 1/2	2
	Over 2 7/16		15	7 1/2		
Stove	Through 2 7/16	7 1/2			2	3
	Over 1 5/8		12 1/2	7 1/2		
Nut	Through 1 5/8	7 1/2			3	4
	Over 13/16		10	5		
Pea	Through 13/16	10			4	5
	Over 9/16		15	7 1/2		
Buck	Through 9/16	10			Ash, 12	
	Over 5/16		15	7 1/2		
Rice	Through 5/16	10			Ash, 13	
	Over 3/16		15	7 1/2		
Barley	Through 3/16	10				
	Over 3/32		20	10		

[1] When slate content on Broken to Pea, inclusive, is less than the above standards, bone content may be correspondingly increased, but slate content specified above shall not be exceeded in any event and the total maximum impurities shall not exceed those above specified.

AVERAGE SALES REALIZATION

The valuation figures in this study represent value at the breaker or washery reported by the operating companies. The company is requested to "estimate value of the product not sold" and to "exclude selling expenses" in making its report.

From this it will be seen that when a producing concern sells its output to a separately organized sales company, the value reported will exclude the margin of the sales company and may therefore be somewhat less than the circular price at which the coal is placed on the general market. This fact should be borne in mind in considering the variations in value among different regions, shown in the tables, for the same sizes of coal.

The average sales realization per net ton on breaker shipments was $4.27 in 1940 compared with $3.85 in 1939—an 11-percent increase (see table 19).

If local sales, colliery fuel, and washery and dredge coal are included, the average value per net ton of the total 1940 production was $3.99 compared with $3.64 in 1939 (see table 20).

TABLE 19.—*Average sales realization per net ton on Pennsylvania anthracite shipments from breakers, 1938–40, by regions and sizes*

[Value does not include margins of separately incorporated sales companies]

Size	Lehigh region			Schuylkill region			Wyoming region

Wyoming	3.95	4.10	1.08	3.79	4.43	4.25	1.06	4.23
Total, excluding Sullivan County	3.75	3.81	1.24	3.64	4.14	3.71	1.26	3.99
Sullivan County	2.41	2.84	1.04	2.62	2.41	2.51	1.10	2.40
Grand total	3.75	3.81	1.24	3.64	4.14	3.71	1.26	3.99

[1] Value given for shipments is value at which coal left possession of producing company and does not include margins of separately incorporated sales companies.

LABOR STATISTICS

The average number of men employed in the Pennsylvania anthracite industry in 1940 was 91,313—a decrease of 1,825 from the 93,138 employees in 1939 (see tables 21 and 22). The number employed is based upon reports direct from the operators and includes the workers from strip and dredge operations.

Although there were no major labor distrubances in either 1940 or 1939, the number of man-days lost because of strikes amounted to 241,688 and 176,432, and the average days lost per man employed in the industry was 2.6 and 1.9 in these years, respectively (see table 23).

According to the Bureau of Labor Statistics, average weekly earnings ranged from a low of $21.48 in October to a high of $33.46 in January and averaged $24.95 compared with $25.52 in 1939. The index of employment (1929 average=100) fluctuated between 49.4 percent in October and 52.2 percent in March and for the year as a whole averaged 0.2 percent above 1939. The index of pay rolls reached a low of 32.3 in October and a high of 52.5 in January and averaged 2.5 percent below 1939.

EQUIPMENT AND METHODS OF MINING

Mechanical loading.—The percentage of total deep-mined production of anthracite loaded mechanically continued to increase. In 1940, the 12,326,000 tons so loaded comprised 29.7 percent of the total underground output compared with 27.7 percent (11,773,883 tons) in 1939 and 26.6 percent (10,151,669 tons) in 1938 (see tables 24–26). The total tonnage loaded mechanically underground increased 5 percent from 1939 to 1940; hand-loading declined 5 percent.

Mechanical loading has increased more rapidly in the Northern field than in the other three anthracite-producing districts. The reason for this is that the coal measures in the Northern field are flatter than those in the Lehigh and Schuylkill regions. In 1940, the tonnage loaded mechanically in the Northern field was nearly four times that so loaded in the Western Middle, Eastern Middle, and Southern fields combined.

TABLE 24.—*Relative growth of mechanical loading, hand loading, and stripping in Pennsylvania anthracite mines, 1936–40*

[Mechanical loading includes coal handled on pit-car loaders and hand-loaded face conveyors]

Year	Net tons			Index numbers: 1927=100

FOREIGN TRADE [1]

Anthracite imported into the United States in 1940 declined to 135,436 net tons, which was less than one-half the quantity imported in 1939 (tables 31 and 32). Pennsylvania anthracite exported from the United States increased slightly over 1939, and practically all of the exports were sent to Canada (tables 33 and 34).

Canadian market.—Coal and lignite production in Canada in 1940 totaled 17,551,000 net tons (12-percent increase over 1939); it was about the same as output in 1927, 1928, and 1929 and nearly 2,500,000 tons greater than in the war year 1918. Coal available for consumption in Canada (production, plus imports, minus exports) totaled nearly 35,000,000 tons and closely approached the record of 1918; about half was imported, mainly from the United States, whereas in 1918 Canada imported about 21,000,000 tons of coal from the United States. Imports of bituminous coal from the United States in 1940 increased 36 percent over 1939. The quantity of anthracite imported was almost identical with the 1939 tonnage, and Pennsylvania anthracite retained its relative position in the market at about 60 percent of the total; Great Britain supplied the remainder. That country typically produces about 6,000,000 long tons of anthracite annually, of which two-thirds is exported; Canada and the United States together take roughly 1,000,000 tons, and practically all of the remainder is exported to Europe. With the loss of the European market, for the time being at least, British exporters may be expected to endeavor to increase their exports to Canada. British anthracite has always entered the Canadian market duty free; however, the duty on bituminous coal from Great Britain was removed late in 1940.

Details of the coal and coke industry and foreign trade of Canada in 1939 and 1940 are shown in table 35.

TABLE 35.—*Coal and coke industry and foreign trade of Canada, 1939–40* [1]

[3] Anthracite output of Japan is said to average about 225,000 tons a year. Production figures are not available.

COKE AND BYPRODUCTS

By F. M. Shore, M. M. Otero, and M. F. Cooke

SUMMARY OUTLINE

More coke was produced during 1940 than in any year since 1929. The production from byproduct ovens—54,014,309 net tons (see table 1)—was the highest on record, and coke from beehive ovens totaled 3,057,825 tons.

Compared with the output of 42,882,313 tons in 1939 (see table 2), byproduct-coke production increased 26 percent. Production from beehive ovens increased 112 percent over 1939, as the large demand for metallurgical coke stimulated activity within the industry and led to the rehabilitation of ovens that had been out of service for many years. Of the total production in 1940, byproduct ovens contributed 95 percent and beehive ovens 5 percent. The 29-percent increase in the output of all coke compares favorably with the 33-percent rise in the production of pig iron but is substantially greater than the improvement in industry generally, which was only 13 percent, according to the Federal Reserve Board index of the physical volume of industrial production.

The survey of employment and accidents in coke-oven plants in 1940 revealed that, in the byproduct-coke industry, 17,469 men were employed and worked a total of 50,350,927 man-hours, compared with 14,852 men working 42,196,654 man-hours during 1939; in the beehive industry 2,493 men were employed during 1940, contributing 3,272,729 man-hours of work. This compares with 1,757 men working 1,540,540 man-hours during 1939.

The total value of coke, breeze, and tar produced and of other byproducts sold in 1940 was $442,282,951—an increase of $87,170,042 (25 percent) over 1939.

Coke used in blast furnaces (used by producers, sold to financially affiliated corporations, or sold to other companies) totaled 42,483,624 tons (nearly 75 percent of the total coke production) and exceeded the figure for 1939 by 10,985,067 tons. Coke used for other purposes (in foundries, for manufacturing water gas, and for other industrial

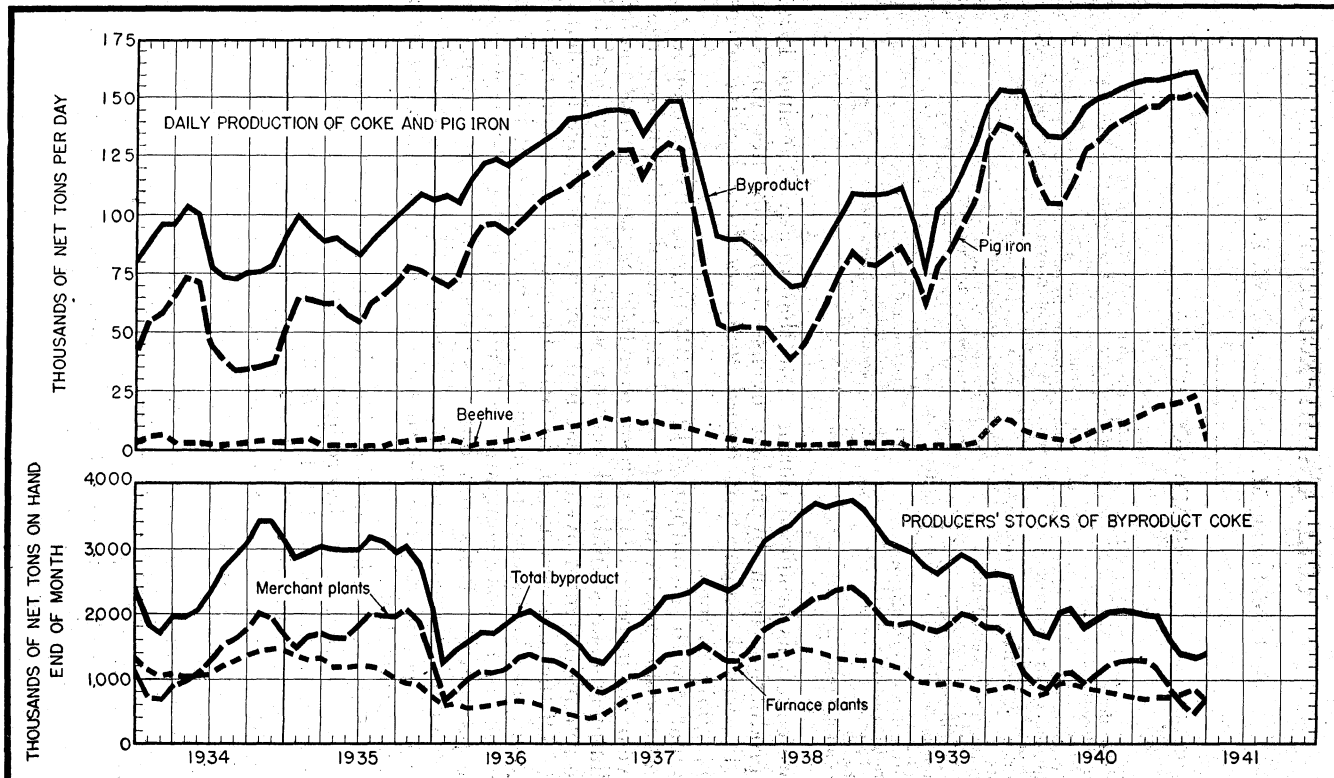

Figure 1.—Average daily production of beehive and byproduct coke and pig iron; and producers' stocks of byproduct coke, 1934–41, by months.

uses), totaled 7,130,073 tons compared with 6,186,827 tons in 1939. Coke sold for domestic use was reported at 8,231,013 tons in 1940 compared with 7,638,141 in 1939.

The average receipts per ton of coke sold by the producers in 1940 were as follows: Furnace coke, $4.40, an increase of 4 cents over 1939; foundry coke, $8.28, which was 53 cents higher than in 1939; coke used in the manufacture of water gas, $5.99, which exceeded the price in 1939 by 12 cents; other industrial coke, $5.42, which dropped 52 cents below the cost in 1939; and domestic coke, $6.00, an increase of 86 cents.

The production of screenings or breeze was 4,165,453 tons in 1940 and exceeded that in 1939 by 759,536 tons; the average receipts from sales dropped from $2.42 a ton to $2.24.

Producers' stocks of coke at the end of 1940 totaled 1,956,442 tons—a reduction of 645,657 tons from the quantity on hand at the end of 1939. Stocks of furnace coke decreased 72,132 tons; foundry coke, 39,987 tons; and domestic coke, 533,538 tons.

Coke exported in 1940 amounted to 804,095 tons—an increase of 214,170 tons (36 percent) over 1939. Imports of coke were 112,550 tons—21 percent less than in 1939.

Consumption of coke during 1940 is calculated at 57,026,246 tons—an increase of 12,073,164 tons over 1939.

Accompanying the increased activity of the byproduct industry in 1940, production of the four principal byproducts of the coking process was substantially augmented. The value realized through their sale (including tar used by the producer) during the year was $153,416,975. The output of gas increased 158,618,519 M cubic feet (23 percent); tar, 118,880,301 gallons (21 percent); ammonium sulfate or equivalent, 310,612,823 pounds (23 percent); and crude light oil, 44,250,468 gallons (26 percent). The role of byproducts is becoming increasingly important for national defense requirements.

TABLE 1.—*Salient statistics of the coke industry in 1940*

	Byproduct	Beehive	Total

Ovens:					
Beehive, in existence, end of year	62,349	12,194	10,816	10,934	15,150
Byproduct, in existence, end of year	11,156	12,718	12,724	[4] 12,732	12,734
Byproduct under construction, end of year	629	259	146	----------	492
Cost of coal charged, byproduct ovens, average per ton	$4.76	$3.74	$3.92	$3.75	$3.68
Prices of coke:					
Average spot price of Connellsville furnace coke, f. o. b. ovens	$5.33	$4.29	$3.86	$4.09	$4.42
Average realization on byproduct coke sold:					
Furnace coke (merchant sales)	$6.74	$4.34	$4.41	$4.38	$4.55
Foundry coke	$10.54	$8.47	$8.39	$8.15	$8.67
Other industrial (including water gas)	$9.06	$6.08	$5.68	$5.64	$5.86
Domestic	$9.05	$6.53	$6.17	$5.90	$6.03
Yield of byproducts per ton of coal charged:					
Tar gallons	8.1	8.67	9.27	9.06	8.79
Ammonium sulfate or equivalent pounds	21.2	21.84	23.36	22.33	22.00
Light oil gallons	2.7	2.86	2.99	2.99	2.93
Surplus gas sold or used M cubic feet	5.9	6.66	7.14	7.08	6.84
Average gross receipts for byproducts, per ton of coke produced:					
Tar sold and used	$0.51	$0.588	$0.654	$0.622	$0.571
Ammonia and its compounds	$0.84	$0.326	$0.380	$0.341	$0.364
Light oil and its derivatives (including naphthalene)	$0.51	$0.443	$0.423	$0.414	$0.421
Surplus gas sold or used	$1.37	$1.483	$1.907	$1.676	$1.507
Total byproducts, including breeze	$3.48	$3.068	$3.647	$3.315	$3.117

[1] Furnace and foundry coke only.
[2] Before 1934, the figures represented general imports; beginning with 1934, they represent imports for consumption only.
[3] Included in "Other industrial (including water gas)."
[4] Revised figure.

SCOPE OF REPORT

This report contains final statistics of the production of both byproduct and beehive coke (tables 3 to 48), coke breeze (table 28), coke byproducts (tables 49 to 56), and city-gas company statistics (table 57) for 1940. In addition to the customary annual report, there are included a survey of the coke-producing capacity of the United States; a table showing the precentage of low-, medium-, and high-volatile coals used in each State for making coke; and a summary of the distribution of coke shipments, by uses.

Those industries in the United States engaged in the production of coke include the byproduct and beehive coke ovens, petroleum and tar refineries, and coal-gas retorts. There is also a fuel obtained from low-temperature carbonization, which has been established commercially in recent years.

In 1940, 1,526,600 tons of petroleum coke and 90,906 tons of coal-tar pitch coke were produced compared with 1,666,400 and 90,124 tons, respectively, in 1939. The quantity of coke produced in the manufacture of coal-gas in retorts is relatively small and the figure is not now available.

Only coke from byproduct and beehive ovens is suitable for blast furnaces and foundries, which consume the bulk of all coke produced. Therefore, as the coke trade is concerned only with these two types of coke, the statistics of this report are confined thereto.

COKE AND COKE BREEZE

MONTHLY AND WEEKLY PRODUCTION

TABLE 3.—*Byproduct, beehive, and total coke produced in the United States, 1937–40 by months, and average per day, in net tons*

Month	1937		1938		1939		1940

GROWTH OF THE INDUSTRY

The record of developments in the coke industry follows the pattern of growth in the iron and steel industry, because the principal use of beehive and byproduct coke is for metallurgical fuel. As activity in the iron and steel industry is a primary indicator of general industrial development, the growth of the coke industry affords a fairly accurate picture of the industrial growth of the country. Table 7 shows the course of developments in the coke industry from 1880 (the earliest record) to 1940, inclusive.

From 1880, when coke production in the United States was 3,338,300 net tons, until 1919, when it was 44,180,557 tons, beehive plants dominated the coke industry. The first byproduct ovens in this country were 12 Semet-Solvay ovens constructed in 1893 for use in connection with the chemical works of the Solvay Process Co. at Syracuse, N. Y. Compared with the wasteful beehive method, the advantages and economies realized by the use of coal-carbonizing equipment (designed for the recovery of valuable byproducts), were responsible for the steady growth of the byproduct method as an efficient means of producing coke.

The growth of the byproduct industry was at first slow. However, from 1900 to 1907—a period of rapid industrial expansion, particularly in the iron and steel industry—the number of byproduct ovens, as well as the number of beehive ovens, increased rapidly to meet the demand for coke during that period. At the close of 1910, 4,078 byproduct ovens had been built, and the number of beehive ovens in existence had reached a maximum of 100,362. Beehive plants produced 83 percent of the total coke production that year. Since 1910. however, the number of beehive ovens reported in existence has steadily declined at a rate that has varied with the demand for coke; meanwhile, byproduct ovens steadily increased in number. Not until 1939 did the number of beehive ovens reported increase over the preceding year, and during 1940 over 4,000 additional beehive ovens were added to the existing ovens, as the iron and steel industry made increasing demands for coke.

Coke production from byproduct ovens exceeded that from beehive ovens for the first time in 1919, as the 5 year period ended that year (during which 4,111 ovens were built) represented the era of greatest construction activity in the history of the byproduct industry, owing largely to war-time demands for coke from the steel industry and for such byproducts as ammonia, benzol, and toluol from war industries. At the end of 1921, when national production dropped to 25 million tons, that portion supplied by byproduct plants amounted to 78 percent—a 22-percent increase during the 2 years. The sudden increased demand for coke in 1922 and 1923 slowed the rate of decline of beehive ovens during this period, and byproduct ovens produced only 66 percent of the 57-million ton output for 1923. By 1929, however, byproduct ovens in existence totaled 12,649 and supplied 89.2 percent of the record coke production attained during that year. Beehive ovens in 1929 made some recovery, producing 2 million tons more than the preceding year; but in the following year, with slackening demand for coke, they produced only 6 percent of the national output. During the depression years, there was little change in the productive facilities of the byproduct-coke industry, and in the ensuing years up to 1940 but slight variation was noted in the number of ovens reported in existence. Only 83 more byproduct ovens were in existence at the end of 1939 than at the end of 1929. Beehive ovens, however, being less efficient, declined from 30,082 in 1929 to 10,934 at the end of 1939, and their annual output followed the same trend. Many new byproduct ovens were under construction during 1940 and ordered for completion during 1941; and altogether, 565 new and replacement ovens were scheduled to begin operation during 1941. The list of beehive ovens reported in existence increased by 4,216 in 1940, and there are indications that the number may be increased further during 1941.

The economic significance of the growth of the coke industry is broadly indicated by the value of its products. Thus, from the earliest record, when the total value at the plant of the products of the industry was only $6,631,267, this figure had grown to $581,594,972 in 1920 but was $442,282,951 in 1940. With the advent of byproduct ovens, byproducts of the coking process constituted an important and growing addition to the total value of the industry, reaching the maximum of $192,231,520 in 1929 and amounting to $168,450,541 in 1940.

TABLE 7.—*Statistical summary illustrating growth of coke industry in the United States, 1880–1940*

Year	Production (million net tons)			Percent of total production from byproduct ovens	Number of ovens in existence		Number of byproduct ovens under construction at end of year	Coal charged (million net tons)	Yield of coke from coal (percent)	Average value of coke per ton at plant	Total value at plant (million dollars)			
	Byproduct	Beehive	Total		Byproduct	Beehive					Beehive coke	Byproduct coke	All byproducts[1]	Total coke and byproducts

[1] Value for tar up to and including 1917 represented that of tar "obtained and sold," which did not always include value of tar used by producer. Beginning with 1918, tar used by producer is specifically included. Value of breeze produced at byproduct plants is included for those years for which it was reported, namely, 1916, 1917, and 1919–40. For other byproducts, only value of those sold is included. Value of breeze produced at beehive plants is not included, as it has usually been much less than a million dollars.

[2] No accurate data on value of the byproducts available.

[3] Revised figure.

PRODUCTION BY FURNACE AND NONFURNACE PLANTS

The terms "furnace" and "merchant" plants originated in the Connellsville beehive-coke trade, although in this report the distinction is applied to byproduct-coke plants only. Furnace plants are those affiliated with the iron and steel industry, with an output that does not ordinarily enter the open market. Merchant plants include some that are affiliated with local iron furnaces but produce more coke than the furnaces can consume and therefore depend on foundry, domestic, or other markets. The term also includes producers of coke who sell their entire output on the competitive market; the plants affiliated with alkali works; low-temperature carbonization plants; and, in addition, a number of plants that, although not public utilities, were constructed primarily to supply city gas and which sell their coke for domestic, industrial, and metallurgical use.

TABLE 8.—*Number and production of byproduct-coke plants connected with iron furnaces and of other byproduct plants in the United States, 1913, 1918, and 1938–40*

Year	Number of active plants		Coke produced (net tons)		Percent of production	
	Furnace plants	Other plants	Furnace plants	Other plants	Furnace plants	Other plants
1913	20	16	9,277,832	3,436,868	73.0	27.0
1918	36	24	19,220,342	6,777,238	73.9	26.1
1938	44	40	20,668,878	10,989,525	65.3	34.7
1939	45	39	31,811,807	11,070,506	74.2	25.8
1940	45	40	41,465,177	12,549,132	76.8	23.2

December	76,700	31,400	117,300	34,400	122,200	36,000
Average	56,600	30,100	87,200	30,300	113,300	34,300

In 1940, 45 furnace plants produced 41,465,177 tons, (77 percent of all byproduct coke); and 40 "other", or merchant, plants produced 12,549,132 tons (23 percent). The proportion of coke from furnace plants has remained fairly constant, except in years of depression or exceptional activity in the iron and steel industry. In 1932, furnace plants furnished only 54 percent and in 1938 only 65 percent of the total byproduct coke.

PRODUCTION BY STATES AND DISTRICTS

All 20 States in which the byproduct-coke industry operates shared the increased output in 1940. Illinois led with the highest percentage of increase—60 percent—followed by Colorado, with an advance of 37 percent; Pennsylvania, 35 percent; Indiana, 31 percent; Ohio, 29 percent; and Alabama, 23 percent. Increases in the other States ranged from 19 percent in Tennessee and West Virginia to 1 percent in New Jersey.

Pennsylvania retained its lead in the tonnage produced and in 1940 contributed 28 percent of all byproduct coke and 83 percent of all beehive coke produced in the United States. Not only is Pennsylvania the principal coke-producing State, but it also leads in the shipment of coking coal to ovens in other States.

[1] Includes plants at Hamilton, Ironton, Lorain, Painesville, Portsmouth, Toledo, and Warren.

NUMBER AND TYPE OF OVENS

In the byproduct industry at the end of 1940, the number of ovens in existence totaled 12,734, only 3 were added to the record of existing capacity, and only 1 was abandoned during the year. However, in view of the growing demand from the iron and steel industry, 492 ovens were under construction or reconstruction at the end of the year. In addition, there were 73 ovens which, though not under actual construction on December 31, 1940, will come into operation during 1941. The ovens to be completed in 1941 will add about 3,000,000 tons to the present annual capacity of the byproduct-coke industry.

In the face of an impending heavy demand for furnace coke, the beehive-coke industry restored to the list of existing ovens many whose use had long been abandoned and began a program of repairing and rebuilding old ovens that apparently continues. Nearly 5,000 ovens were restored to the "in existence" list during the year 1940. Of the total 15,150 beehive ovens reported as in existence at the end of

1940, 1,350 were under construction or reconstruction at that time. During January, an average of 5,000 beehive ovens was active, but the number gradually declined to 2,634 in May. From then on, the average number of active ovens increased steadily, reaching a peak of 8,895 in December; evidence pointed toward further expansion in 1941.

[2] Includes 46 Curran-Knowles, 27 Parker-Russell, 60 Improved Equipment Co., 8 Piette, and 3 Disco ovens in 1940.

CAPACITY OF BYPRODUCT PLANTS

The fundamental basis upon which the maximum capacity (see table 17) of a byproduct plant is established is the minimum coking time at which the ovens in that plant can be operated to produce coke of characteristics suitable for the use for which it is intended. This theoretical capacity is seldom attained in practice for reasons that may be due to operating, economic, or labor conditions. For many years the Bureau of Mines has been obtaining annually from the operators of byproduct-coke plants data showing the daily coke-producing capacity of the ovens in existence at the end of the calendar year. The operators are requested to state daily capacity in the terms of the total quantity of coke, of grades they aim to produce that can be obtained with all conditions favorable and all ovens active.

The potential maximum daily capacity of the 89 byproduct-coke plants in existence December 31, 1940, both active and idle, was 170,467 tons. The daily capacity of the 43 merchant plants was 41,926 tons and that of the 46 furnace plants 128,541 tons.

It should be noted that the estimated maximum daily capacity is not necessarily a true guide for calculating annual capacity, as in the latter allowance may be included for possible interruptions to full running time in the course of a normal year. The estimated maximum capacity of byproduct ovens on December 31, 1940, was obtained through a special survey of the industry, the results of which are shown in succeeding pages.

During 1940 the byproduct-coke industry was busily engaged in gearing its productive facilities to higher limits to meet the steadily growing demand from the steel industry for metallurgical coke. To supplement existing facilities, construction of new ovens and rehabilitation of old ones were under way at the end of the year.

[1] Capacity of all ovens in existence, whether active or idle, based upon maximum daily capacity times days in month.

COKE-PRODUCING CAPACITY OF THE UNITED STATES

The potential annual coke-producing capacity of the byproduct and beehive ovens, active and idle, in existence on December 31, 1940, as reported by the operators, was 69,035,730 net tons, according to a special survey made by the Bureau of Mines, United States Department of the Interior, at the request of the Advisory Commission to the Council of National Defense, now part of the Office of Production Management.[1] Of this capacity, 59,394,070 tons represented that of byproduct ovens and 9,641,660 tons that of beehive ovens. In reporting these capacities to the Bureau of Mines, the operators were asked to give the capacity of ovens in existence on December 31, 1940, and that which would be added during 1941 through the building of new ovens or the reconstruction of old ones; they were also asked to state the estimated maximum annual coke capacity of their ovens "of grades you aim to produce, that can be obtained with all conditions favorable and all ovens active." Of the total capacity reported, the part that is considered potential represents only ovens in need of repairs, rebuilding, or replacement. This category comprises a relatively small percentage of the byproduct ovens but a much larger percentage of the beehive ovens. Additional beehive ovens are being reconditioned from time to time, progressively converting potential into active capacity. For comparison, it is noted that during December 1940 byproduct ovens produced at the rate of 57,576,195 tons and beehive ovens at the rate of 5,758,476 tons a year. In March 1941 byproduct coke was produced at the rate of 58,862,820 net tons a year and beehive coke at the rate of 7,004,653 net tons a year.

Byproduct ovens in existence at the end of 1940 totaled 12,734, of which 12,175 were active. To the estimated maximum annual capacity of ovens in existence December 31, 1940 (amounting to 59,394,070 tons), 492 new and replacement ovens in course of construction at the end of 1940 and ordered for completion during 1941, plus 73 ovens whose construction was begun after December 31, 1940, will add 2,994,563 tons—a total of 62,388,633 tons of potential annual capacity of ovens in existence at the end of 1941. In addition, operators reported that they contemplated building additional capacity amounting to 847,700 tons. Of course, plans for this additional tonnage may not be consummated. Of the 89 byproduct plants in existence at the end of 1940, 4 containing 164 ovens with an estimated capacity of 298,200 tons were idle. The 85 active plants contained 12,570 ovens with an estimated maximum annual capacity of 59,095,-

[1] Special acknowledgment is due Carl D. Ulmer, then of the Koppers Co., for his valuable assistance in making the capacity survey.

870 tons. Not all of the ovens at active plants were in operation at the end of 1940; but it is probably safe to assume, for the idle ovens at these plants, that if repairs are needed they will be reconditioned and placed in operation should the demand for coke continue to grow. In fact, one of the 4 plants that were idle on December 31, 1940, has already been reconditioned. Press reports indicate also that contracts have been made for building 2 new plants in the Pittsburgh area and additional capacity in the Philadelphia area that would add about 877,000 net tons of coke per year to existing capacity, but it was not expected that these plants would be completed during 1941.

Of the capacity represented by byproduct ovens in existence at the end of 1940, Pennsylvania had 28 percent, followed in order by Ohio with 15 percent, Indiana, 12 percent, and New York and Alabama with 9 percent each.

In addition to the byproduct ovens needing repairs or reconditioning on December 31, 1940, a number of operators reported that auxiliary equipment would need to be repaired, replaced, or enlarged to obtain the estimated potential maximum output reported. Reports indicating the need of new auxiliary equipment or the repair of old equipment came from plants having a total annual capacity of 2,276,938 tons. Repairs that "might" be needed represented 664,425 additional tons of capacity. These figures represent the capacity of plants that doubtless include ovens whose capacity was not limited by the needs reported. It should be kept in mind that the reported needs do not necessarily mean that the ovens to which they relate were not capable of producing coke. On the contrary, much of this capacity probably was being operated but perhaps at a somewhat reduced rate.

Reports as to the year of first operation of byproduct coke ovens when new or after rebuilding or major repairs throw an interesting light upon the durability of this type of equipment. For example, 556 of the existing byproduct ovens first operated prior to 1910, and 5,334 ovens first operated prior to 1920. Almost half of the existing ovens are 20 years old or more upon the basis stated.

Beehive ovens reported in existence on December 31, 1940, totaled 15,150 with an estimated maximum potential annual capacity of 9,641,660 tons. This number is an increase of 4,216 ovens over those reported in existence at the end of 1939 and represents chiefly restoration to the record by the operators of existing ovens, many of which previously had been considered and reported as abandoned. Of the ovens in existence, 9,148 were reported as active at the end of 1940. New and replacement beehive ovens in course of construction December 31, 1940, and ordered for completion during 1941 numbered 1,350 and would add 43,320 tons of capacity to that reported for ovens in existence at the end of 1940, making an estimated annual capacity of 9,684,980 net tons available at the end of 1941. Of the total capacity of beehive ovens in existence at the end of 1940, 79 percent was represented by ovens in Pennsylvania; Virginia was next with 7 percent.

The estimated potential annual capacity of 9,684,980 net tons of beehive coke at the end of 1941 is based upon reports covering plants known to be in existence December 31, 1940. The canvass of plants begun in January 1941 was continued into April. This capacity figure must necessarily be subject to periodic revision in the event of an increasing demand for coke that would induce the building of new ovens or the restoration and rehabilitation of old ones.

The operators of beehive plants representing an annual capacity of 2,663,000 tons indicated that, to obtain the maximum coke-producing capacity reported, it would be necessary to replace, repair, or rebuild 4,439 ovens. It is to be noted further that the repair, replacement, or enlargement of auxiliary equipment was also reported as essential for maximum capacity operation of some of the existing ovens.

Official and trade press reports indicate that, until recently, at least, rehabilitation of old ovens was still in progress in the beehive industry and that the number of active ovens was increasing. Whether this trend will continue depends on future demand. For the beehive industry, therefore, the statistical picture is subject to short-time change in line with changes in the demand for coke.

Byproduct-coke output, which surpassed that of beehive coke for the first time in 1919, has gradually relegated operation of beehive ovens to the status of a standby industry to take up the excess load during periods of large demand. Thus, since the loss of its primary importance as a source of metallurgical fuel, the output of the beehive ovens has fluctuated widely with variations in the activity of the heavy industries. It is worth noting, however, that although beehive ovens waste valuable byproducts in the production of coke, they afford a relatively rapid means for speedy expansion in coke capacity when needed to meet sudden abnormal demand. Old beehive ovens can be repaired or rebuilt or new ovens constructed in less time than would be required to build byproduct ovens.

QUANTITY AND COST OF COAL CHARGED

In 1940, byproduct and beehive coke ovens together consumed 81,385,800 tons of coal—18 percent of the total estimated production of bituminous coal for the year—compared with 16 percent in 1939. Of this quantity, byproduct ovens consumed 76,582,800 tons of coal and beehive ovens 4,803,000 tons. Table 20 gives a further indication of the increased activity of the beehive industry in supplementing byproduct production in supplying a rising demand for metallurgical coke by the quantity of coal it has consumed monthly over the 3-year period. The consumption of coal by beehive ovens reached a maximum of 773,600 tons in December 1940, and indications in early 1941 pointed toward even greater requirements.

The average cost of coal for byproduct ovens in 1940 was $3.68 a ton as compared with $3.75 in 1939. Coal used for producing beehive coke averaged $1.99 a ton, which was the same as in 1939.

The cost of coal charged into byproduct ovens in 1940 ranged from $2.39 in West Virginia to $5.16 in Minnesota, where it includes freight charges from distant mines. The average cost of coal for beehive ovens is much less than that for byproduct ovens, as the former usually are built at or near the producing mines and therefore benefit from the saving in transportation charges. On the basis of average costs of coal for beehive ovens by States, Virginia was low with $1.78 a ton, while the average cost in the Western States—Colorado, Utah, and Washington combined—was high with $3.61 a ton.

PREPARATION AND SOURCE OF COAL

In Colorado and Tennessee all of the coal used for coking in 1940 was washed. Most of that used in Alabama and more than a third of that used in Pennsylvania was washed prior to charging into the ovens. Other States that employed washed coal for part of their requirements were Illinois, Michigan, New Jersey, New York, Ohio, and West Virginia. This practice usually occurs where the ash or sulfur content of the available coal is high. High ash content of coal charged into coke ovens results in an even higher ash content of the coke produced. Both pneumatic cleaning and wet washing of coal are employed to prepare it for use in coke ovens, in accordance with local conditions throughout the areas concerned with the problem. Sometimes the washing is done by coal producers at the mines and sometimes by coke operators at the plants. In 1940, 19,667,262 tons (26 percent) of the coal consumed in byproduct ovens were washed; the percentage was unchanged from that in 1939. In beehive ovens 680,925 tons (14 percent) of the coal consumed (21 percent in 1939) were washed before charging.

Pennsylvania led in the production of coal used in byproduct coke plants, and West Virginia was a close second. Together these States supplied 77 percent of the coal used in byproduct ovens in 1940. Next in order of importance were Kentucky, with 11 percent; Alabama with 9 percent; and Virginia, with 2 percent. The remainder was obtained from Colorado, Georgia, Illinois, New Mexico, Ohio, Tennessee, and Utah; each supplied less than 1 million tons.

TABLE 24.—*Coal purchased for manufacture of byproduct coke in the United States in 1940, by fields of origin, in net tons*

[Based upon detailed reports from each coke plant. Difference between these totals and those shown in tables 1, 11, 20, 21, etc., is due to change in stock, loss of weight in handling, and the fact that these sometimes represent purchases during year rather than actual consumption]

State and district where coal was produced	Total purchased	States where coal was consumed—in order of importance
Alabama	6,716,803	Alabama.
Colorado:		
Canon, Crested Butte, and Walsen	126,890	Colorado.
Trinidad	719,543	Do.
Georgia	14,423	Tennessee.
Illinois: Southern	214,845	Illinois.
Kentucky, Eastern:		
Elkhorn (including Hazard)	2,067,341	Indiana, Ohio, New York, Illinois, New Jersey, Michigan, Minensota, and Wisconsin.
Harlan	4,254,922	Indiana, Illinois, Ohio, Minnesota, Michigan, New York, and Wisconsin.
Kenova-Thacker	1.709,299	Michigan, Ohio, Wisconsin, and West Virginia.
Miscellaneous	181,716	Indiana and Missouri.
New Mexico	4,413	Colorado.
Ohio	972	Ohio.
Pennsylvania:		
Central Pennsylvania:		
Medium-volatile	574,035	New York and Pennsylvania.
Low-volatile	1,738,156	Pennsylvania, New York, and Maryland.
Connellsville	17,868,048	Pennsylvania, Ohio, West Virginia, New York, Illinois, Minnesota, Indiana, and Michigan.
Freeport	1,982,018	Ohio, West Virginia, Michigan, New York, and Pennsylvania.
Pittsburgh	9,627,541	Pennsylvania, New York, Ohio, Michigan, Illinois, and Wisconsin.
Somerset	662,302	Pennsylvania and West Virginia.
Westmoreland	915,380	Pennsylvania, New York, Minnesota, Ohio, Wisconsin, and Maryland.
Miscellaneous	32,905	Pennsylvania.
Tennessee	116,138	Tennessee.
Utah	369,145	Utah.
Virginia: Southwestern [1]	671,527	Michigan, New York, New Jersey, Ohio, and Illinois.
West Virginia: [1]		
Coal and Coke	85,044	Pennsylvania.
Kanawha-Logan	8,529,353	Massachusetts, Ohio, Indiana, New Jersey, Illinois, New York, Kentucky, West Virginia, Michigan, Wisconsin, Pennsylvania, Connecticut, Rhode Island, Missouri, and Minnesota.
New River:		
High-volatile	486,874	New York, Massachusetts, and Connecticut.
Low-volatile (including Winding Gulf).	2,245,900	Massachusetts, New York, New Jersey, Michigan, Missouri, Rhode Island, Pennsylvania, Illinois, West Virginia, Connecticut, Kentucky, Maryland, Minnesota, and Ohio.
Northern	3,666,260	Maryland, Pennsylvania, Ohio, Michigan, and West Virginia.
Pocahontas (including Tug River)	11,578,864	Indiana, Ohio, Illinois, New York, Michigan, Maryland, Wisconsin, Pennsylvania, Minnesota, Kentucky, Connecticut, Alabama, Massachusetts, Tennessee, and West Virginia.
Webster-Gauley	182,586	Pennsylvania and New York.
	77,343,243	

[1] Coal from extension of the Pocahontas field in Virginia is included under Pocahontas district, West Virginia.

TABLE 25.—*Coal purchased for manufacture of byproduct coke in the United States in 1940, by States where produced and where consumed and by merchant and furnace plants, in net tons*

As an important adjunct of coal-preparation operations, the practice of mixing various types of coking coals before charging into the ovens is employed to a large extent in the byproduct-coke industry. This practice has several aims and takes into account factors important to the byproduct-plant operators concerned. Primarily it is designed to produce, economically, coke of satisfactory quality for the use for which it is intended. Some coals that have characteristics favorable for producing high-quality coke expand when coked; therefore their use alone would cause difficulty in discharging the coke and possibly some destructive effect on most byproduct-oven walls. However, these can be utilized by mixing them with other coking coals that neutralize this expansion upon coking, thereby eliminating this harmful effect. From an economic standpoint, mixing permits the usage of coals which have good coking properties but may have objectionable chemical analysis with reference to the limits of content of the several undesirable constituents, such as ash, sulfur, and phosphorus, and which for that reason could not be used as a 100-percent charge into the ovens to produce coke to conform with specifications upon this basis. Further, the mixing of coking coals provides a means of controlling the quality and strength of the coke and the yield of byproducts and permits flexible operation of byproduct plants with reference to the supply of coking coals.

A classification of all coal purchased for coking in byproduct ovens in 1940, as reported by the operators, indicated that 49,385,976 tons (64 percent) contained over 32 percent volatile matter; 16,395,484 tons (21 percent), 14 to 22 percent volatile matter; and 11,561,783 tons (15 percent), 23 to 31 percent volatile matter.

During 1940, 64 of the 85 byproduct plants that were active purchased coals of different volatile content. Both low-and high-volatile coals were purchased by 49 plants; low-, medium-, and high-volatile coals were purchased by 12 plants; and low- and medium-volatile coals were purchased by 3 plants. Of the 21 plants that did not purchase coals of different volatile-content classification, 15 purchased high-volatile coal and 6 medium-volatile coal. Table 26 shows the purchases, by States, of the coals used in the manufacture of byproduct coke, classified as to volatile content.

TABLE 26.—*Coal purchased for manufacture of byproduct coke in the United States in 1940, by States where consumed, and by volatile content, in net tons* [1]

[1] Yield computed by dividing production of breeze by the coal charged at the plants actually recovering.
[2] Included under "Undistributed."
[3] As reported: quantity produced but not used was undoubtedly greater. See Mineral Resources of the United States, 1922, part 2, pp. 726–727

CONSUMPTION OF COKE

Allowing for imports, exports, and changes in producers' stocks, the indicated consumption of coke in 1940 was 57,026,246 tons. Of this quantity, 41,839,039 tons (73 percent) were—according to figures compiled by the American Iron and Steel Institute—consumed by blast furnaces in the manufacture of pig iron and ferro-alloys. The remainder (27 percent) was used in foundries, in smelting the nonferrous metals, in the manufacture of water gas, in miscellaneous other industrial uses, and in domestic heating.

The improvement in the efficiency of fuel utilization in blast-furnace operation during recent years is shown by the fact that the quantity of coking coal required per net ton of pig iron and ferro-alloys has dropped from 3,247.5 pounds in 1913 to 2,540.9 in 1940. In terms of coke, 1,781.2 pounds were required per ton of pig iron and ferro-alloys in 1940 compared with 2,172.6 in 1913.

TABLE 29.—*Coke consumed in manufacture of pig iron and for other purposes in the United States, 1913, 1918, and 1937–40, in net tons*

Year	Total production of coke	Imports	Exports	Net changes in stocks	Indicated United States consumption [1]	Consumed by iron furnaces [2]		Remainder consumed in other ways

1940	57,072,134	112,550	804,095	−645,657	57,026,246	41,839,039	73.4	15,187,207	26.6

[1] Production plus imports minus exports, plus or minus the decrease or increase, respectively, of the net changes in stocks.
[2] From Report of American Iron and Steel Institute. Figures include coke consumed in the manufacture of ferro-alloys.
[3] Data not available.

TABLE 30.—*Coke and coking coal consumed per net ton of pig iron made in the United States, 1913, 1918, and 1937–40*

Year	Coke per net ton of pig iron and ferro-alloys [1] (pounds)	Yield of coke from coal (percent)	Coking coal per net ton of pig iron and ferro-alloys calculated (pounds)	Year	Coke per net ton of pig iron and ferro-alloys [1] (pounds)	Yield of coke from coal (percent)	Coking coal per net ton of pig iron and ferro alloys calculated (pounds)
1913	2,172.6	66.9	3,247.5	1938	1,801.0	69.7	2,583.9
1918	2,120.7	66.4	3,193.8	1939	1,778.0	69.8	2,547.3
1937	1,830.6	70.3	2,604.0	1940	1,781.2	70.1	2,540.9

[1] From report of American Iron and Steel Institute; the consumption per ton of pig iron only, excluding the furnaces making ferro-alloys, was 2,172.6 in 1913, 2,120.7 in 1918, 1,806.7 in 1937, 1,774.6 in 1938, 1,760.0 in 1939, and 1,756.9 in 1940.

FURNACE, FOUNDRY, DOMESTIC, AND OTHER COKE

The terms "furnace coke" and "foundry coke," as used in the trade, refer to the size and grade of the coke, as well as to the use for which it may be intended. Byproduct furnace coke is usually run-of-oven coke from which the breeze and all small coke have been removed. Byproduct foundry coke is usually a blocky coke larger than furnace coke, from which all sizes under 2½ to 3 inches are screened out. Coke smaller than furnace and foundry (excluding breeze) is often called domestic coke. It may result from the screening of furnace or foundry coke or, where the demand for domestic coke is greater, may be obtained by crushing the larger product. Other sizes and grades may be prepared for special purposes. Thus, not all furnace coke finds its way to blast furnaces or all foundry coke to foundries proper, for either grade may be purchased by other classes of consumers.

Coke is burned as a domestic fuel chiefly under two regional conditions—in areas where there is a surplus production of metallurgical coke, or when the manufacture and distribution of large quantities of city gas as a primary objective result in the yield of correspondingly large quantities of coke that also must find a market. The consumption of coke for domestic heating tends to be localized in regions near centers of production. A majority of the coking plants are equipped to screen and size coke for domestic use.

In 1940, byproduct coke sold for furnace use, including all coke sold to financially affiliated corporations, totaled 5,134,395 tons—26 percent more than 1939. The sales for other uses and their increase over 1939 are as follows: Foundry use, 1,858,664 tons (25 percent); domestic use, 8,131,947 tons (8 percent); and other industrial, including that used in the manufacture of water gas, 1,754,917 tons (16 percent).

Beehive coke sold for furnace use in 1940 totaled 1,799,292 tons—an increase of 175 percent over 1939. The percentages of increase for other uses are as follows: Foundry use, 16 percent; domestic use, 12 percent; and other industrial use, 7 percent.

[1] Sales of furnace coke plus total quantity reported "used by producer." Includes coke consumed for other than blast-furnace use.
[2] Includes coke sold for manufacture of water gas.
[3] These figures represent quantity distributed in year without taking into account changes in producers' stocks and therefore differ slightly from published totals of production. In 1915 and 1916, moreover, they do not include quantity exported.
[4] Separate figures for by-product and beehive not available.
[5] "Other industrial" and "domestic" were not reported separately before 1923.
[6] Figures do not include exports and hence are not strictly comparable with other years.

STOCKS OF COKE AND COKING COAL

As a general rule, stocks of coke held by producers decline when pig-iron and coke production increases. At the end of 1940, 1,913,134 tons of byproduct coke were on hand, 26 percent below the stocks at the beginning of the year. During the same period, stocks of furnace coke declined 12 percent; of foundry coke, 72 percent; and of domestic and other coke, 29 percent. Beehive plants carry small stocks of coke; at the end of 1940, only 43,308 tons were in reserve.

TABLE 37.—*Stocks of bituminous coal at byproduct-coke plants in the United States at end of each month, 1937–40, in net tons*

Month	1937	1938	1939	1940
January	8,030,871	6,469,457	7,373,871	6,613,253
February	8,687,389	5,822,943	7,372,654	5,978,167
March	9,638,317	5,231,300	7,221,632	5,373,567
April	8,543,774	4,934,840	4,434,124	5,217,870
May	8,187,883	4,867,332	2,598,470	5,995,170
June	7,770,256	4,999,856	3,548,326	6,506,396
July	7,432,741	5,364,442	4,534,922	7,448,266
August	7,455,932	5,539,623	5,631,984	7,831,640
September	7,760,533	5,951,617	6,220,015	8,860,832
October	8,066,938	6,459,096	7,250,436	9,711,983
November	8,114,094	7,172,900	8,114,807	10,091,259
December	7,273,403	7,462,163	7,992,848	10,184,443

Stocks of bituminous coal used by the byproduct ovens closely follow the trend of monthly coke production. In 1940 the highest reserves were on hand at the end of December, when 10,184,443 tons were reported. The lowest supply of coal was at the end of April, when 5,217,870 tons were in reserve. The largest quantity of byproduct coke was produced in December and the lowest in April.

VALUE AND PRICE

In previous years, reference has been made in the Coke chapters to the various accounting methods used by coke operators affiliated with iron and steel plants, by which the coke sometimes is charged to the furnace department at cost and sometimes includes a percentage of profit at the current market price. On the open market, however, price cutting, long-term contracts, and other factors materially affect the prices at which coke-plant operators actually dispose of coke. According to sales data furnished by the operators, average receipts for byproduct coke sold rose as follows: Furnace coke, 35 cents; foundry, 52 cents; domestic, 13 cents; and other industrial, 22 cents. Receipts for beehive coke in 1940 differed from those in 1939 as follows: Furnace coke, 3 cents less; foundry coke, 35 cents more; domestic coke, 36 cents more; and other industrial coke, only 1 cent less.

TABLE 38.—*Average receipts per net ton for coke sold in the United States in 1940 by States*

State	Byproduct				Beehive

[1] Includes coke sold to affiliated corporations for all other purposes and merchant sales.
[2] Included under "Undistributed."

According to trade-journal quotations published during 1940, the cost of byproduct foundry coke increased in all of the markets listed except New England, which showed no change. The increases ranged from an addition of 38 cents at Birmingham to 75 cents at Cleveland and Indianapolis. Connellsville prices for beehive coke, which were usually the basis for the entire industry, rose 33 cents for both furnace and foundry coke.

SHIPMENTS BY RAIL AND WATER

TABLE 41.—*Beehive coke loaded for shipment on originating railroads and waterways in the United States in 1940, by routes, as reported by coke producers*

Route	State	Net tons: By States	Net tons: Total	Percent of total
Railroads:				
Baltimore & Ohio	Pennsylvania	512,634	540,876	18.3
	West Virginia	28,242		
Chesapeake & Ohio	West Virginia	28,622	28,622	1.0
Denver & Rio Grande Western	Colorado	66,745	75,181	2.5
	Utah	8,436		
Interstate	Virginia	176,109	176,109	6.0
Ligonier Valley	Pennsylvania	42,000	42,000	1.4
Nashville, Chattanooga & St. Louis	Tennessee	4,431	4,431	.2
Monongahela	Pennsylvania	786,227	786,227	26.6
New York Central	West Virginia	177,697	177,697	6.0
Norfolk and Western	Virginia	24,640	24,640	.8
Pennsylvania	Pennsylvania	1,024,008	1,024,008	34.7
Pittsburgh & Lake Erie	do	68,080	68,080	2.3
Total railroad shipments		2,947,871	2,947,871	99.8
Waterway: Ohio River	Pennsylvania	4,290	4,290	.2
Grand total		2,952,161	2,952,161	100.0

DISTRIBUTION OF BYPRODUCT AND BEEHIVE COKE IN 1940

Consumption of coke in the United States during 1940 increased 23 percent over 1936—the year covered by the latest previous distribution survey made by the Bureau of Mines. Pennsylvania, the leading coke-producing State, likewise led in tonnage consumed, with 27 percent of the total United States consumption. Ohio, New York, and Indiana were next in the order named, using, respectively, 17, 10, and 9 percent of the total; Alabama and Illinois followed, each using 8 percent.

Increased activity in the steel industry raised the tonnage of coke consumed by that industry to a point approaching record proportions at the end of 1940. In 1936, 46,668,547 tons of coke were used for all purposes, while in 1940, 57,170,633 tons were consumed. Of these totals, 31,062,616 and 42,401,997 tons supplied furnace demands in 1936 and 1940, respectively, the difference amounting virtually to the increase in total consumption during the period. Use of domestic coke decreased 1,674,058 tons compared with 1936, while coke going into the manufacture of water gas increased 685,065 tons.

Furnace coke was consumed in 23 States during 1940. However, 82 percent of the total tonnage was used by 5 States—Pennsylvania, Ohio, Indiana, Alabama, and Illinois. Coke for foundry use was shipped into all States but 2 during 1940. Coke was used for manufacturing producer gas in 12 States and for producing water gas in 31. Other industrial needs indicated widespread usage generally throughout the country; only 4 States received no shipments of coke under this classification. Domestic coke was consumed in all but 5 States during 1940. New York, Michigan, and Massachusetts were the principal consumers, and together accounted for 44 percent of the total used for this purpose.

Pennsylvania and Ohio used more than 80 percent of their production in blast furnaces. Indiana used 65 percent and Illinois 60 percent of their respective outputs for that purpose. Maryland used all of its production within the State and supplemented this by shipments from nearby States. Alabama shipped coke to 30 other States and West Virginia to 24 other States and the District of Columbia.

Table 42.—*Summary of byproduct and beehive coke and breeze consumed in each State in 1940, in net tons*

[Based upon reports from all United States producers showing destination of coke used by producer or sold in 1940. Does not include imported coke, which totaled 112,550 net tons in 1940]

Consuming State	Coke							Coke breeze
	Furnace use	Foundry use	Making producer gas	Making water gas	Other industrial use	Domestic use	Total

Figures showing the distribution, by States of destination, of coke shipped by producers in 1940 are shown in the following tables. Additional data and discussion relating to the geographic distribution of coke in 1940, by principal uses, will be published in Distribution of Byproduct and Beehive Coke in 1940, which may be obtained on request from the Coal Economics Division, Bureau of Mines.

TABLE 43.—*Distribution of coke shipped or used by producer in 1940*

PRODUCED IN ALABAMA

EXPORTS AND IMPORTS [2]

Exports of coke from the United States in 1940 totaled 804,095 net tons valued at $5,024,992—an increase of 214,170 tons (36 percent) over 1939. Canada, the principal country to which coke was exported, received 722,740 tons (90 percent of all exports), the bulk going via Buffalo and Michigan. Other than Canada, the export market for American coke is relatively small, although Mexico and Cuba each purchased nearly 20,000 tons, and 10,291 tons of coke were shipped to Sweden in 1940—large increases over their respective tonnages in 1939.

[2] Figures on exports and imports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

Coke imports form a very small part of the requirements of the country and under normal conditions are important in certain regions only. In 1940, 112,550 tons were received in the United States, supplied entirely by Canada and the United Kingdom.

WORLD PRODUCTION

The continuation through 1940 of the European War, which involved more than half of the countries listed in the following world table, was chiefly responsible for the dearth of data on 1940 production. Coke production in Canada established a new record during 1940, which exceeded by 345,534 metric tons the previous peak production, attained in 1929. Decreases are noted in the output of coke by Indochina and in the coke exports of China. Production of coke in the Straits Settlements, which in the previous years covered by the table showed little change, indicated a sharper increase during 1940, exceeding each of the 1937, 1938, 1939 figures by more than 1,300 metric tons.

TABLE 48.—*Coke produced in principal countries of the world, 1929 and 1937–40, in metric tons* [1] [2]

[1] Gas-house coke is not included.
[2] In addition to countries listed above, coke is produced in Chosen and Japan, but data of production are not available.
[3] Data not available.
[4] Excluding Sudetenland since October.
[5] In Great Britain the production of gas-house coke (including breeze), not included above, is especially important and was as follows: 1937, 13,151,057 tons; 1938, 13,049,139 tons.
[6] Figures for 1929 represent "hard" and "soft" coke made at collieries only (73,616 tons of "hard" coke and 769,888 tons of "soft" coke). Data for other years shown represent total "hard" coke manufactured. In addition, the following quantities of "soft" coke were made at collieries: 1937, 850,581 tons; 1938, 921,479 tons; 1939, data not available.
[7] Exclusive of Mexico and Spain.

COKE-OVEN BYPRODUCTS

The recovery of the valuable byproducts formed during the coking process represents, to coke-plant operators, a source of additional revenue and a means of reducing to a minimum the cost of conversion of coal to coke. To the national economy, it represents an important asset in the recovered products, essential to the public welfare, that would be lost with use of the earlier methods and equipment designed for the recovery of coke only. For example, the value at the plant of the byproducts recovered in 1940, which would have been wasted if the coke had been made in beehive ovens, is estimated at more than $200,000,000. Of these byproducts recovered, gas, tar, and light oils had a calorific value equivalent to 19,036,000 net tons of coal. Modern byproduct coke ovens therefore are a definite contribution to progress in the conservation of our mineral resources. Conditions of demand for all the byproducts of the coking process, however, are not always favorable, and the quantity produced is also affected by the demand for coke. The total number of byproducts, identified as chemical compounds, that might be obtained by distilling coal in byproduct ovens has never been actually determined. A conservative estimate of the number of definite compounds present in tar alone is 200, but only a few have been separated in the pure state. The statistics in the following tables are confined to the major products of byproduct coke ovens, which fall into five general groups. They are (1) gas, the most valuable byproduct, followed by (2) light oil and its derivatives, (3) ammonia, (4) tar, and (5) miscellaneous products.

Although the quantity of coke produced by byproduct ovens in 1940 established a new record, the output of the major byproducts (with the exception of light oil) fell slightly short of the previous record attained in 1929.

The total sales value of all byproducts sold in 1940 (excluding the value of tar used by the producers and the value of coke breeze produced) was $145,081,877—56 percent of the value of the byproduct coke produced. It is noteworthy that, of this sales value, $4,257,088 is represented by tar derivatives reported from 11 byproduct plants. There is some indication of a trend toward more extensive incorporation into byproduct recovery plants of tar-distillation units to produce the several derivatives in the pure or crude state.

In addition to providing the fuel requirements of the byproduct ovens from which it is evolved, coke-oven gas supplies various other fuel needs. During 1940, 523,640,555 M cubic feet (63 percent of the 833,761,720 M cubic feet of gas produced) were used or sold for industrial purposes and for distribution through city gas mains. Its average sales value as reported by operators was $0.155 per M cubic feet—a decrease of $0.011 per M cubic feet under the 1939 figure of $0.166. In this connection it is noted that, of the volume of surplus gas placed on the market by the increased production of byproduct coke, 12,555,062 M cubic feet were wasted compared with 8,567,855 M cubic feet in 1939.

National defense requirements place important emphasis on the byproducts of the coking process, particularly on toluol (a derivative of light oil) and on ammonia. Toluol is a principal ingredient of trinitrotoluene (one of the more important explosives), and ammonia is an important raw material for producing nitric acid and also is used in the manufacture of explosives. The production of 26,406,407 gallons of byproduct toluol in 1940 was the highest on record, exceeding that for 1939 by approximately 7 million gallons, while the output of ammonia (NH_3 equivalent of all forms) totaled 416,054,299 pounds. In the absence of heavy demand by the industries manufacturing explosives, the major portion of byproduct toluol production must seek other outlets on the market, chiefly as a motor-fuel ingredient or as a commercial solvent. In this event, it is seldom of nitration quality, and its value is diminished considerably. In 1939, the average value of toluol was $0.194 a gallon; in 1940 this had advanced to $0.242 a gallon. As usual, the bulk of the ammonia recovered in 1940 went into the production of ammonium sulfate. The demand of the fertilizer industry is chiefly responsible for the conversion of the ammonia to the sulfate. The average value of sulfate production in 1940 was $0.012 a pound—an increase of $0.001 of $0.011 a pound over the 1939 figure.

Value of all byproducts sold			[6] 145.081,877	

[1] Includes products of tar distillation conducted by coke-oven operators under same corporate name, except, however, phenol and other tar acids produced at Clairton, Pa.
[2] Includes gas wasted and gas used for heating ovens.
[3] Refined on premises to make the derived products shown: 207,272,848 gallons.
[4] Total gallons of derived products.
[5] Ammonia thiocyanate, asphalt paint, cyanogen, sodium carbolate, sodium prussiate, spent soda solution, sulfur, vented vapors, and a small amount of miscellaneous products.
[6] Exclusive of value of breeze production, which was $8,472,114 in 1940.

Due to the increasing importance of tar acids, used largely for making plastics, some byproduct coke plants which do not have facilities for the complete processing of crude tar have installed equipment for "topping" the tar to recover these acids. "Topping" is designed primarily to strip from the tar its constituents comprising the light oil and tar acid oil fractions, and in some cases, even higher fractions. The process represents a means of conserving these materials where full refining equipment is not available at the byproduct plant, or

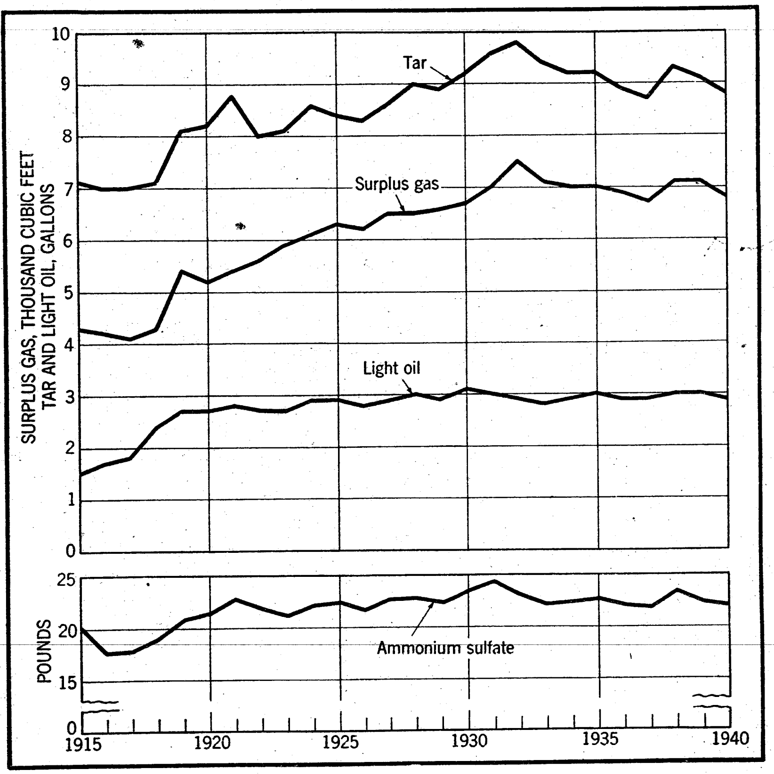

FIGURE 2.—Average yield of principal byproducts per net ton of coal carbonized in byproduct coke ovens, 1915–40. Figures for light oil represent average at plants recovering light oil.

when the crude tar cannot be sold to tar refineries. The "topped" tar is available for further refining or for use as fuel. Information regarding the quantity of tar "topped" at byproduct coke plants was collected by the Bureau of Mines for the first time in 1940. Returns from producers indicate that 94,890,278 gallons of tar were "topped" during 1940.

Statistics covering the production and sales of coke-oven byproducts during 1940 are shown in tables 49 through 56. Figure 2 supplies information on yield per ton of coal carbonized.

TABLE 50.—*Coal equivalent of byproducts of byproduct coking in the United States, 1913, 1914, 1918, and 1939–40*

1940	72,522,476	1,248,051	1.7	2.3

BYPRODUCT COKE OVENS OWNED BY CITY-GAS COMPANIES (PUBLIC UTILITY PLANTS)

Adaptation of byproduct coke ovens to the needs of city-gas manufacture has led a number of gas companies to install batteries of byproduct ovens to supplement or even replace their coal or water-gas plants. Although more emphasis is placed upon the production of gas of proper analysis than upon the grade of coke obtained, from the point of view of supply and demand for coke and byproducts these installations belong to the byproduct-coke industry and are therefore included in the statistics furnished by the Bureau of Mines.

During 1940, 16 byproduct plants owned by city-gas companies were active and contributed 3,356,403 tons of coke (6 percent of the total production of the byproduct industry)—an increase of 197,274 tons over 1939, when 17 plants were active.

The following table presents salient statistics for 1939 and 1940 of the city-gas byproduct-coke plants in relation to the industry as a whole.

TABLE 57.—*Production of coke, breeze, gas, and byproducts in the United States at byproduct-coke plants owned by city-gas companies (public utilities) and at all other byproduct-coke plants, 1939–40*

FUEL BRIQUETS AND PACKAGED FUEL[1]

By G. S. Goodman

SUMMARY OUTLINE

Fuel briquets produced in the United States in 1940 amounted to 1,050,870 net tons—an increase of 17.8 percent over 1939; production of packaged fuel (treated separately in this report) amounted to 284,513 tons—an increase of 32.0 percent over 1939. The combined output totaled 1,335,383 tons, valued at $8,830,874.

Records on the production of fuel briquets have been collected since 1907; that in 1940 was the third highest in the history of briquetting and was exceeded only in 1929 and 1936. Data on packaged fuel, obtained by the Bureau of Mines since 1935 (graphically illustrated for the first time in these reviews in fig. 2), show that a new high record was made in 1940, as the output rose to more than 11 times that in 1935.

The widespread trend toward the packaging of merchandise has also invaded the bulk-briquet market to some extent, according to returns received in response to a special item on the Bureau of Mines questionnaire for 1940. The advantages of cleanliness and of buying packaged fuels in less than ton lots appeal to small householders; however, the packaging of bulk briquets is a merchandising feature only—the briquets are not fired in the package—whereas in packaged fuel the entire package usually is placed in the stove or furnace. Eleven fuel-briquet operators reported that about 47,000 tons were boxed or bagged at the plant, including 45,000 tons distributed by the operators in paper bags containing 25 to 50 pounds each and in burlap bags of 100 pounds each; the remainder—2,000 tons—was packaged in cartons holding 40 pounds. Several operators reported that retailers are doing some packaging.

Technologic developments.—Production has increased materially and research continued, although industrial conditions have not especially

[1] Directories of fuel-briquetting and packaged-fuel plants operating in 1940 and names of manufacturers of equipment will be furnished on request by the Coal Economics Division, Bureau of Mines, Washington, D. C.
Data on employment and the principal expenses in the manufacture of fuel briquets may be obtained from the Bureau of the Census, which collects and publishes such data in alternate years.
Briquets made from charcoal, wood wastes, and fruit pits are not included in the Bureau of Mines review.

favored the construction of new plants. The 1940 review of the industry revealed five plants under construction in 1940—two in Illinois using Illinois coals, one in North Dakota using carbonized lignite, one in Michigan using bituminous coal, and one in Rhode Island using Pennsylvania anthracite; it is understood that several of these have begun to operate commercially.

Commercial briquetting of Texas lignite (without charring) was reported in 1940; however, the tonnage involved is small. No information is available regarding the details of the process. The plentiful supplies of natural gas and oil in this area are likely to present difficulties in developing a market for briquets.

Research in briquetting Illinois coals is nearing the demonstration stage at the Illinois Geological Survey.

Under appropriation from the 1939 General Assembly of Illinois a commercial-scale briquetting press designed by Dr. R. J. Piersol [2] and built by the J. P. Devine Manufacturing Co., Inc., of Mt. Vernon, Ill., is now installed in the recently completed Applied Research Laboratory of the Illinois Geological Survey at Urbana, Ill. This press system weighs about 34 tons, costs less than $50,000, and at 60 r. p. m. has a capacity of 500 tons per 24-hour day. Demonstrations on the briquetting of various Illinois coals will be made during 1941.

Dr. Piersol discovered recently as a result of laboratory investigations that coals in central and northern Illinois may be briquetted by his process without preheating or predrying; such briquets have about four times the crushing strength of those made with binder. He also found that deduster dust and sludges from many Illinois coals contain a concentration of fusain high enough to produce smokeless briquets by his process commercially without partial devolatilization.

The use of briquets in orchard heating and the economic phases of such frost protection are discussed in considerable detail by Floyd D. Young [3] in a recent report.

Smoke tests [4] of packaged fuel made from high-volatile bituminous screenings from various sources indicated considerable reduction in smoke. However, it is reported that the increased price of high-volatile screenings has retarded the development of this type of packaged fuel.

FUEL BRIQUETS

The salient statistics of the fuel-briquetting industry from 1936 to 1940 are summarized in the following table. Similar data for earlier years are to be found in annual issues of Mineral Resources (part II), which include chapters on briquetting, beginning with 1907, and Minerals Yearbook.

Production.—The output of fuel briquets in 1940 totaled 1,050,870 net tons valued at $6,438,952 (see fig. 1) and represents an increase of 17.8 percent in tonnage and 11 percent in value over 1939.

Briquets were produced in 17 States, and 13 of these showed increases over 1939. The bulk of the output continues to be concentrated in Wisconsin; but the Eastern States made the greatest gain, and West Virginia almost doubled its 1939 production. Wis-

[2] Production plus imports minus exports.

consin and Pennsylvania also reported considerable gains. Other States producing over 20,000 tons, in relative order of importance, were Oregon, Missouri, North Dakota, Minnesota, and Washington.

The sharp increase in 1940 probably is due to the heavier demand occasioned by the unusually severe winter in the North Central States in 1940.

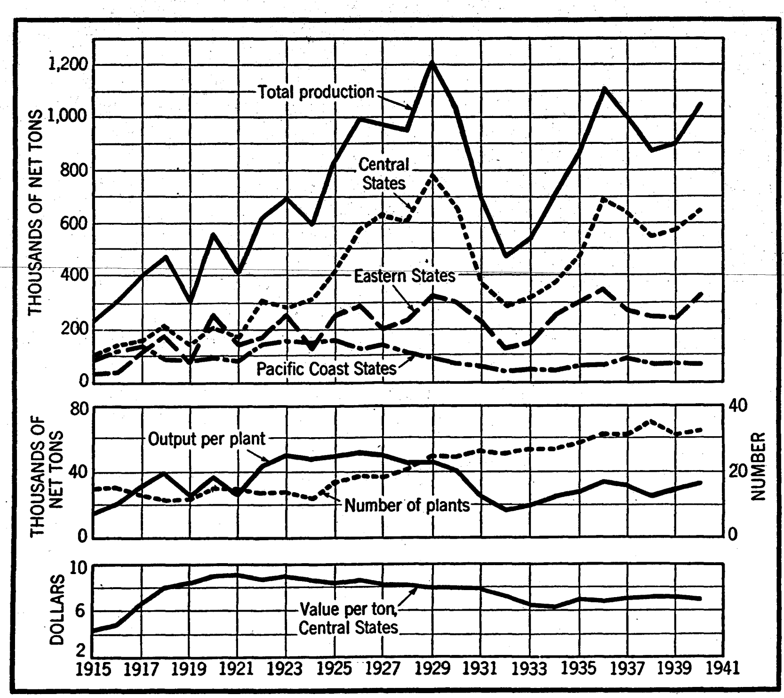

FIGURE 1.—Production of fuel briquets, number of plants in operation, and average value per ton, f. o. b. plant (Central States), 1915–40.

Production of fuel briquets in the United States, 1939–40

	1939			1940

June	61,531	71,273	57,814				
July	37,283	42,184	76,148		871,260	892,213	1,050,870

January and December were the months in 1940 when production was highest. The peak output in January reflects the fuel demand caused by the unusually severe weather in that month in the North Central States, where departures from normal reached a low of −15.2°. According to the Weather Bureau,[5] this was the coldest January of record in large areas.

Eighteen plants operated every month in the year—7 between 8 and 11 months and 7 between 4 and 6 months.

Value.—The sales realizations on briquets in the scattered producing centers in a given year vary considerably. An average value per ton for the entire industry therefore has doubtful significance because of the different conditions under which briquets are manufactured in various parts of the country. The most important factors that influence the value per ton realized at any plant probably are the cost of raw materials and the price of competing fuels; hence, the general trend of fuel-briquet prices [6] from year to year is indicated best in this review by the average values in the Eastern, Central, and Pacific Coast States, shown in the foregoing table of salient statistics.

[5] Reed, W. W., The Weather of 1940 in the United States: U. S. Dept. of Agriculture Monthly Weather Rev., vol. 68, No. 2, February 1941, p. 49.

[6] Retail fuel-briquet prices for certain cities are issued by the Retail Price Division, Bureau of Labor Statistics, Department of Labor, Washington, D. C., in its monthly releases, Retail Fuel Prices by Cities.

These figures are not the prices paid by the consumers. Some plants are distant from the markets they serve, and transportation charges and the margin of the wholesaler or retailer, sometimes both, must be added to the value at the plant.

The total value of fuel briquets manufactured in 1940 was $6,438,952 f. o. b. plant—an increase of $637,286 or 11 percent compared with 1939.

In the eastern part of the country the average value of $3.95 a ton is relatively low because virtually the entire output comes from plants in the low-volatile bituminous fields of West Virginia and in the anthracite region of Pennsylvania, where the freight charges are not so important an item in the cost of raw fuel. In the Central States most of the raw fuel (bituminous low-volatile and Pennsylvania anthracite) comes from the Lake docks, and the average value of $6.95 a ton discloses the extent to which freight charges affect value. In the Pacific Coast States, where carbon residue from the manufacture of oil gas forms the greater part of the raw fuel used, the average value dropped from $8.96 in 1939 to $8.84 in 1940.

Number of plants.—Thirty-two plants reported commercial production in 1940; all but one of these (that in Texas, which reported for the first time) were also active in 1939. One plant at the Lake docks changed hands in 1940. Ten plants were idle in 1940; all of these were also idle in 1939, and three of them (in Rhode Island, Pennsylvania, and North Dakota) went out of business in 1940. Five plants under construction in 1940 expect to begin operations in 1941 (two in Illinois, one in Michigan, one in North Dakota, and one in Rhode Island).

Size of plants.—The following table classifies the plants operating in 1939–40 according to actual production as well as actual capacity; however, a better indication of the size of the plants is gained from their capacity, even though the latter is affected by seasonal variations in output.

The total annual capacity of the 32 plants active in 1940, as reported by the operators, is 3,082,400 net tons—almost three times the 1940 production of 1,050,870 tons. It is interesting to note that although the figure for 1940 represented a 17.8 percent advance over 1939, these plants drew on only one-third of their potential annual capacity.

The average output of the individual plants increased 14 percent—from 29,000 tons in 1939 to 33,000 in 1940. Eighteen plants operating every month in 1940 produced 954,571 tons—91 percent of the total.

Classification of briquetting plants in the United States, 1939–40, by size of output and annual capacity

Output (net tons)	Plants		Annual capacity (net tons)	Plants	
	1939	1940		1939	1940
Less than 2,000	6	5	Less than 5,000	2	2
2,000 and less than 5,000	2	5	5,000 and less than 10,000	3	2
5,000 and less than 10,000	6	3	10,000 and less than 25,000	6	7
10,000 and less than 25,000	8	8	25,000 and less than 100,000	13	13
25,000 and less than 100,000	6	6	100,000 and less than 200,000	2	4
100,000 and over	3	5	200,000 and less than 400,000	3	2
			400,000 and over	2	2
	31	32		31	32

Raw fuels.—The briquetting process is now applied to a wide variety of raw fuels ranging from Texas lignite (without charring) and North Dakota lignite (after carbonization at low temperature) to Pennsylvania anthracite and includes petroleum coke and the residual carbons from oil-gas manufacture and natural-gas pyrolysis. The number of plants, by type of fuel used, is shown below.

Classification of fuel-briquetting plants in the United States in 1940, by kinds of raw fuel used

Kind of raw fuel used:	*Plants*
Anthracite and semianthracite fines exclusively	5
Mixture of Pennsylvania anthracite and bituminous	6
Bituminous:	
Low-volatile	13
High-volatile	1
Lignite	1
Semicoke (lignite char)	1
Residual carbon from pyrolysis of natural gas	1
Residual carbon from manufacture of oil gas	2
Petroleum coke	5
	[1] 35

[1] 4 plants made two kinds of briquets, hence the sum of these items exceeds the total number of plants.

The use of bituminous coals in the manufacture of briquets, now representing virtually two-thirds of the raw fuels used, continues to increase each year, while the use of Pennsylvania anthracite has decreased since 1934 from about one-third to less than one-fourth of the total raw fuels used. As shown in the following table, however, the greatly increased production of briquets in 1940 over 1939 represents increases in the tonnage of both bituminous and anthracite raw fuels used.

Operations of one of the country's largest briquetting companies, using bituminous coal at its plant at the mine and also at its second plant at the Lake docks, are described pictorially in the modern manner in The Coal Dealer.[7] The successful briquetting of North Dakota lignite is discussed in considerable detail by R. Dawson Hall [8] in Coal Age and by W. B. Pratt [9] in the Mining Congress Journal.

Raw fuels used in making fuel briquets in the United States, 1939–40

	Net tons		Percent of total	
	1939	1940	1939	1940
Anthracite and semianthracite culm and fine sizes	196,758	222,618	23.5	22.2
Bituminous and subbituminous slack [1]	503,431	636,312	60.2	63.4
Residual carbons from oil-gas manufacture and natural-gas pyrolysis; petroleum coke; and semicoke (lignite char)	136,213	144,167	16.3	14.4
	836,402	1,003,097	100.0	100.0

[1] Includes small tonnage of Texas lignite used without charring.

[9] Pratt, W. B., Lignite Progresses—Future Promising: Min. Cong. Jour., vol. 26, No. 9, 1940, pp. 30–32.

Eight operators reported washing their raw fuel (totaling 230,937 tons) before its manufacture into briquets.

Two kinds of briquets were made by a large Wisconsin operator—one a mixture of Pennsylvania anthracite and low-volatile bituminous coal and the other low-volatile bituminous exclusively. Two kinds (petroleum coke and semianthracite) were also reported by two Nebraska operators; and an operator in Missouri made two kinds from the hard coals of Arkansas.

The success of a briquetting plant depends largely on its location with relation to the source of the raw-fuel supply and to the consuming market for the finished product, freight rates, cost of raw fuel, and prices of competing fuels to the consumer. In 1940, as indicated in the following table, plants at the mines, particularly those in West Virginia and Pennsylvania, reported the largest increase in production over 1939.

Production of fuel briquets in 1939–40, with reference to sources of raw fuels used

Location of plant	Net tons		Change in 1940
	1939	1940	Percent
At or near Lake Superior or Lake Michigan coal docks	443,215	511,336	+15.4
At coal mines	323,141	414,490	+28.3
At or near petroleum refineries and oil- and natural-gas plants	113,413	111,667	−1.5
At other locations [1]	12,444	13,377	+7.5
	892,213	1,050,870	+17.8

[1] Fall River, Mass., and Omaha, Nebr.

Binders and recarbonization.—Asphaltic pitch continues to be the preferred binder in the briquetting of coal and petroleum coke. Two plants briquetting the carbon residue from the manufacture of oil gas and one plant using low-volatile bituminous coal employed no binder. The percentage of binder by weight ranged from slightly less than 5 to more than 9 percent; the majority of plants used 5 to 7 percent.

No recarbonization of the briquets after leaving the presses, to drive off smoke caused by the binder, was reported by any operator in 1940.

Classification of briquetting plants in the United States in 1940, by type and percentage of binder used

Type of binder	Plants	Ratio of binder to raw fuel (by weight)	Plants
Asphaltic pitch	24	Less than 5 percent	2
Mixed pitches	3	5 and less than 7 percent	16
Asphalt and starch	1	7 and less than 9 percent	8
Starch	1	9 percent and over	3
No binder	[1] 3	No binder	[1] 3
	32		32

[1] 2 plants use residual carbon from manufacture of oil gas, and 1 uses bituminous coal as raw fuel.

Weight and shape.—Pillow-shaped briquets predominate in the United States. Of the total production in 1940, 26 of the 32 active plants produced 766,347 tons (73 percent) of pillow-shaped briquets; 3 plants 267,348 tons (25 percent) of cylindrical type; and 3 plants 17,175 tons (less than 2 percent) of cube-shaped briquets.

According to reports received, only one plant made briquets in more than one shape in 1940—an operator in Wisconsin who produced a square pillow type of Pennsylvania anthracite and bituminous low-volatile and a modified pillow type of bituminous low-volatile exclusively.

In 1940 all but 1.7 percent of the total briquets made weighed less than 5 ounces each.

Two plants made two sizes—one in Nebraska a 20-ounce petroleum coke cube and a 24-ounce semianthracite cube; the other in Wisconsin (the plant referred to above) a Pennsylvania anthracite and bituminous low-volatile pillow briquet (2 by 2 by 1¼ inches) and a bituminous low-volatile modified-pillow briquet (2 by 1½ by 1¼ inches).

Prevailing weight of briquets produced in the United States in 1940

Weight (ounces)	Plants	Production		Weight (ounces)	Plants	Production	
		Net tons	Percent of total			Net tons	Percent of total
Less than 2	4	58,984	5.6	6 and under 10			
2 and under 3	15	598,482	57.0	10 and under 16			
3 and under 4	5	308,224	29.3	16 and under 25	3	17,175	1.6
4 and under 5 5 and under 6	4 1	68,005	6.5		32	1,050,870	100.0

Distribution.—The distribution of briquets as indicated by reports from the manufacturers is penetrating new markets and increased 17 percent over 1939. In 1940 briquets were shipped into 41 States, the District of Columbia, and Alaska and exported [10] to Canada, Sweden, Bolivia, Brazil, and other countries.

Shipments into Wisconsin (and within the State) again led in 1940, with Minnesota, Michigan, North Dakota, and South Dakota following in order of importance. Notable increases over 1939 occurred in Indiana, Michigan, Minnesota, Missouri, and Ohio.

It is not possible to show the shipments from each producing State because in many States there are only one or two producers and the results of individual companies would be revealed. For a graphic presentation of the centers of production with corresponding States of destination, see Minerals Yearbook 1937 (p. 965, fig. 65).

Information on tonnages shipped by rail and truck was requested for the first time on the 1938 questionnaire and published in Minerals Yearbook 1939 (p. 918). Similar data for 1939 and 1940, shown below, indicate slight increases in tonnages moving by truck in the Central States. Generally speaking, rail movement represents shipments to destination at considerable distances, and truck shipments represent local and nearby consumption.

Virtually all tonnages move by rail from the Eastern States, three-fourths by rail from the Central States, and about one-third from the Pacific Coast States.

[10] See table of exports for quantities exported by countries.

Shipments of fuel briquets of domestic manufacture by States of destination, 1939–40, in net tons

[1] Includes local deliveries.

Imports and exports.[11]—Before 1922 the quantity of fuel briquets imported into the United States was negligible. The anthracite shortages of 1922–23 and 1925–26, however, created a demand for the European product (mostly from Germany, Belgium, and France, mainly for consumption in the anthracite-consuming States), which in 1926 reached a record of 123,593 net tons.

Imports continued at a comparatively high level in the following years; in 1932 they amounted to 80,288 tons but thereafter dropped markedly and since the beginning of the war in September 1939 have ceased. The last shipment (1,344 net tons), from Belgium to Massachusetts, arrived in February 1939.

Records of imports of briquets since 1919, the first year of record, are included in the Mineral Resources and Minerals Yearbooks.[12]

Exports of briquets were reported separately for the first time by the Bureau of Foreign and Domestic Commerce in 1937, when they totaled 25,350 tons. In 1939 the exports dropped to 12,576 tons but in 1940 rose to 23,285 tons.

Nearly all exports usually are destined for Canada, but in 1940, 3,118 tons were shipped to Sweden. The only other shipments to

World production.—Official data on the production of fuel briquets in other countries in 1939 and 1940 have been meager, owing to the war. Such revisions as are possible will be made in forthcoming issues of this series.

World figures for 1938, though still incomplete, indicate a peak output of about 65 million metric tons, including about 51 million produced by Germany, about 7.5 million by France, 1.7 million by Belgium, 1.3 million by the Netherlands, and about 1 million by the United States.

The United States proportion of the world production of fuel briquets rose from less than 0.50 percent in 1913 to nearly 1.5 percent in 1938.

World production of fuel briquets, 1936–40, by countries, in metric tons [1]

[1] In addition to the countries listed, briquets are produced in Canada, New Caledonia, and Spain; data on output are not available.
[2] Data not available.
[3] Data for year ended Mar. 31 of year stated.
[4] Incomplete figures.
[5] From domestic coal only.
[6] Includes packaged fuel as follows: 1936, 60,261 tons; 1937, 132,482 tons; 1938, 146,012 tons; 1939, 195,504 tons; 1940, 258,105 tons.
[7] Totals incomplete, representing sum of figures given in table only.

PACKAGED FUEL [13]

Packaged fuel differs from fuel briquets in that the former is a more or less friable product wrapped to withstand weathering and breakage in shipment. Packaged fuel, designed primarily for local or nearby consumption, consists of 3- to 4-inch cubes (usually six to a package, weighing about 10 pounds), wrapped tightly in heavy paper and sealed with gummed tape. It is made from various types of high-quality coal or coke screenings, usually mixed with a neutral binder.

The manufacture and merchandising methods employed by a number of the larger successful operators are discussed in the trade journals.[14]

The National Association of Packaged Fuel Manufacturers, which met several times during 1940, has divided the field into 10 districts, with a view toward closer contacts and increased service for its membership.[15]

[13] Directories of operations and manufacturers of equipment may be obtained free from the Coal Economics Division, Bureau of Mines, Washington, D. C.

National Association of Packaged Fuel Manufacturers, Sales-merchandising Bulletin: Vol. 2, No. 7, December 24, 1940, p. 2.

The industry continues to grow and reached a new high output of 284,513 net tons produced in 1940 valued at the plant at $2,391,922. Although comparatively few operators have achieved conspicuous success,[16] a large number of retailers, as evidenced by the results of inquiry since 1935, have found it a profitable side line if not their principal business activity.

The manufacture of packaged fuel, which began with the idea of utilizing the degradation resulting from handling the coarser sizes at retail yards, has grown so rapidly that shipped-in slack from the mines and Lake docks now represents 80 percent of the raw fuel used.

Of the total production in 1940, 246,006 tons were reported by 72 operators as machine-wrapped and 36,501 tons by 34 operators as hand-wrapped; 2,006 tons were sold unwrapped.

Two kinds of packaged fuel were made by six operators; four made bituminous low-volatile and petroleum-coke cubes, one bituminous high-volatile and petroleum coke, and one Arkansas semianthracite and petroleum-coke cubes.

Packaged-fuel sales in 1940 amounted to 281,905 tons, of which all but 6,900 tons were sold for local or nearby consumption; seven operators reported 4,529 tons were shipped by rail. The balance of the tonnage was either called for or delivered by truck.

Processes.—No new processes or types of machinery were reported in 1940. The Eberling process,[17] introduced about 6 years ago (for briquetting slack or screenings with a starch binder and wrapping the cubes by machine or hand) was used by 86 manufacturers in 1940. This type of briquet is adapted primarily for local consumption. The processes used by the other plants are described briefly in the following paragraphs.

The Johnson Coal Cubing Co.[18] of Detroit, Mich., the largest operator since 1932, has used a process and equipment of its own design to produce cubes bearing the trade-mark "Koal Pak," eight to a package, wrapped in heavy paper; in 1939 it began to make pillow-shaped fuel briquets in bulk, known as "Black Knight Fire Quets."

In the Glenn Smith process,[19] used in the manufacture of both bulk briquets and packaged fuel, the heated mixture of raw fuel and liquid binder is molded under very high pressure. The resulting cubes are cooled on a conveyor that feeds them to the wrapping machine, which automatically wraps and labels the packages. Packaged-fuel manufacturers using this process in 1940 sold a small part of their product unwrapped.

The Leemon process,[20] introduced commercially in 1939, was used by 14 plants in 1940. Equipped with a mixture of slack and volatile binder, the machine produces 3- to 4-inch cubes, which are wrapped 6 to a package, averaging 190 to 200 packages to the net ton.

The salient statistics of the packaged-fuel industry from 1935 to 1940 are summarized in the following table; 1935 is the first year for which these data were collected by the Bureau of Mines.

Salient statistics of the packaged-fuel industry in the United States, 1935–40

[Data regarding fuel briquets are given separately in beginning of this chapter]

Year	Production (thousands of net tons)			Value of production (thousands of dollars)	Plants in operation	Average output per plant (thousands of net tons)	Average value per net ton, f. o. b. plant	
	Eastern and Pacific Coast States	Central States	Total				Eastern and Pacific Coast States	Central States
1935	(1)	25	25	(2)	25	1	(2)	(2)
1936	6	60	66	505	48	1	$8.84	$7.49
1937	10	136	146	1,287	64	2	9.62	8.76
1938	9	152	161	1,405	76	2	9.92	8.66
1939	9	207	216	1,867	103	2	9.69	8.62
1940	8	277	285	2,392	106	3	10.12	8.36

[1] Less than 1.000 net tons; no packaged-fuel plants in Pacific Coast States in 1935.
[2] Data not available.

Production and value.—The 106 active plants, all but 7 of which are in the Central States, produced 284,513 net tons valued at $2,391,922 in 1940 (see fig. 2). The production indicated a 32-percent increase

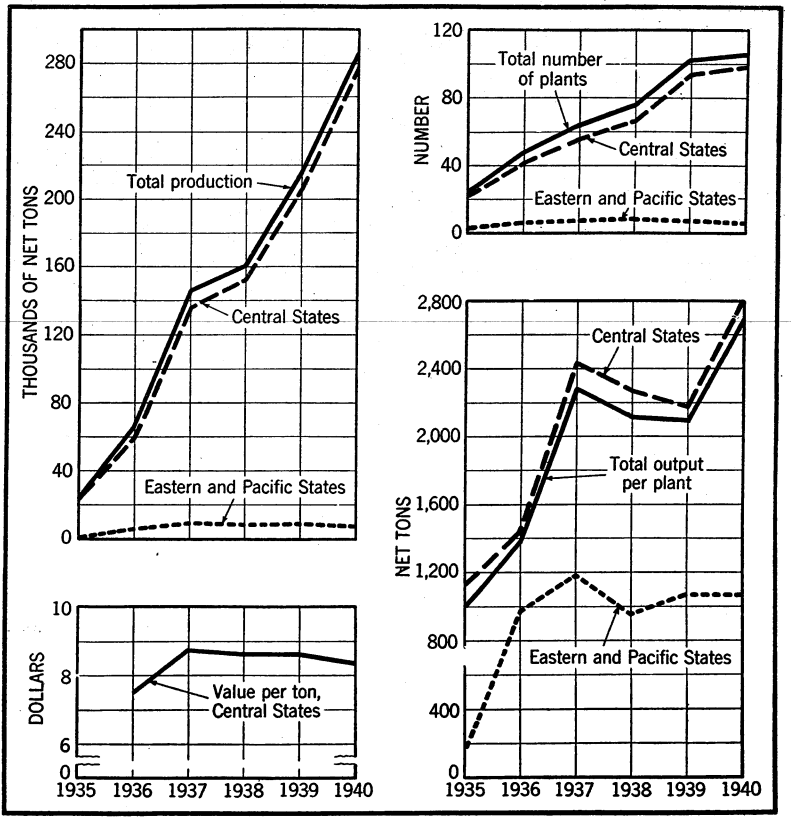

FIGURE 2.—Production of packaged fuel, number of plants in operation, output per plant, and average value per ton, f. o. b. plant (Central States), 1935–40.

over 1939 and the value a 28-percent increase. All States showed a considerable advance in tonnage except four, and the drop in production in these was but slight. However, only three more plants were active at the close of 1940 than at the same time in 1939. The States leading in production were, in order, Michigan, Ohio, Wisconsin, Minnesota, and Indiana.

Average values per ton were $10.15 in Minnesota; $9.58 in Illinois; $9.23 in Virginia; $8.67 in Wisconsin; $8.29 in Ohio; $7.93 in Michigan; $7.81 in Indiana; and $7.14 in Missouri.

Returns indicate that there were seven cities (in Indiana, Michigan, Minnesota, Missouri, and Ohio) where 3 to 12 plants operated in 1940 and that in this group there were idle plants in two cities only. Some plants were idle in 1940 because purchase of packaged fuel for resale was more profitable than operating. All cities showed large increases in production except one, where there was a small decrease. A lower average value per ton f. o. b. plant in 1940 as compared with 1939 was general in these cities, based upon total receipts of all operators in each locality.

Competing fuels and burning equipment, particularly the small oil space heaters which are gaining ground rapidly in some Michigan markets, are said to be particularly hard on the smaller retailers.[21]

Production of packaged fuel in the United States, 1939–40, by States

[Plants and production in this table not included in preceding fuel-briquet tables]

State	1939			1940		
	Plants	Net tons	Value	Plants	Net tons	Value
Central States:						
Idaho	1	(1)	(1)	1	(1)	(1)
Illinois	5	3,998	$40,487	6	3,813	$36,531

[1] Included under "Undistributed"; Bureau of Mines not at liberty to publish figures.
[2] Includes States entered as "(1)" above.
[3] Maine 2, Pennsylvania 1, Virginia 4, and Washington 1.
[4] Maine 2, Pennsylvania 1, Virginia 3, and Washington 1.

Before 1939 December and July were the high and low months of production; in 1939, however, peak production was attained in March and in 1940 in November.

The peak season of production is generally from October through April—7 months—but in 1940 the season for the Central States as a whole (which began in September 1939) lasted well into May and opened up again in September 1940, a month earlier than usual.

In addition to extremely cold weather in January 1940 in the North Central States, negative departures from normal extended through May in this area.[22]

[22] Reed, W. W., The Weather of 1940 in the United States: U. S. Department of Agriculture Monthly Weather Rev., vol. 68, No. 2, February 1941, p. 49.

In making comparisons between spring and fall production in 1940 it should be borne in mind that six new plants began operations in the fall.

Monthly production of packaged fuel in the United States in 1939–40, in net tons

Month	1939	1940	Month	1939	1940
January	27,722	36,160	August	4,605	7,350
February	28,047	29,460	September	14,743	21,680
March	28,532	34,035	October	26,280	29,564
April	25,621	31,518	November	25,524	36,181
May	5,417	17,429	December	26,981	35,656
June	1,180	2,811			
July	855	2,669		215,507	284,513

Number of plants.—As shown in the following table, the marked rise in number of plants before 1940 is somewhat offset by the increasing number of plants that were idle and went out of business in the last 3 years.

There were only 3 more plants active in 1940 than in 1939, but 15 of the total began operations in 1940. Five that operated part of the year went out of business; of the 15 that were idle, 9 also went out of business.

Activity in number of packaged-fuel plants, 1935–40

Year	Active	New	Idle	Out of business	Year	Active	New	Idle	Out of business
1935	25	(1)	5		1938	76	16	8	1
1936	48	23	5	2	1939	103	29	11	9
1937	64	17	6	3	1940	106	[2] 16	[3] 15	[4] 14

[1] Data not available.
[2] 6 in Ohio, 3 in Missouri, 2 each in Indiana and Michigan, and 1 each in Illinois, Minnesota, and Wisconsin.
[3] 6 in Ohio, 4 in Michigan, 2 in Virginia, and 1 each in Minnesota, Missouri, and Oregon.
[4] 4 each in Michigan and Ohio, 2 each in Minnesota and Virginia, and 1 each in Indiana and Oregon.

Size of plants.—The average production per plant rose from 2,100 tons in 1939 to 2,700 in 1940. The majority of the plants (82 out of a total of 106) produced less than 3,000 tons each in 1940—about the same proportion as in 1939; but the number of plants that produced over 10,000 tons increased from 2 in 1939 to 5 in 1940. The Johnson Coal Cubing Co. of Detroit, Mich., continues to be the largest operator in the industry.

Reports submitted on individual capacity indicate that the 106 active plants were equipped to produce about 777,000 tons (nearly three times the 1940 actual production) if operated at full capacity throughout the year.

Classification of packaged-fuel plants in the United States, 1939–40, by size of output and annual capacity

Output (net tons)	Plants		Annual capacity (net tons)	Plants	
	1939	1940		1939	1940
Less than 500	28	[1] 23	Less than 5,000	58	62
500 and less than 1,000	18	19	5,000 and less than 10,000	31	25
1,000 and less than 3,000	39	40	10,000 and less than 15,000	5	6
3,000 and less than 5,000	10	10	15,000 and less than 25,000	5	7
5,000 and less than 10,000	6	9	25,000 and less than 40,000	3	5
10,000 and less than 25,000	1	4	40,000 and less than 60,000		
25,000 and over	1	1	60,000 and over	1	1
	103	106		103	106

[1] 4 of these are new plants, which began operations in the fall of 1940.

Raw fuels.—The tonnage of raw fuels used in the manufacture of packaged fuel in 1940 totaled 281,334 net tons. Low-volatile bituminous slack continued to be the principal raw fuel, representing 87.4 percent of the total, with petroleum coke, bituminous high-volatile, and Arkansas semianthracite following in the order named. Petroleum coke increased from 5.0 percent of the total raw fuels used in 1939 to 10.9 percent in 1940; this type of packaged fuel was made in Minnesota, Missouri, Iowa, Nebraska, and Washington. The reported raw-fuel tonnages used in 1940 were as follows: Bituminous low-volatile, 245,881 tons by 91 operators; petroleum coke, 30,555 tons by 15 operators; and bituminous high-volatile and Arkansas semianthracite, 4,898 tons by 6 operators. Several used mixtures of these various fuels.

Of the total raw fuels used about 224,000 tons (80 percent) were shipped in by the operators from the mines and Lake docks; and the remainder (about 57,000 tons—or 20 percent) represents the total yard screenings used. Of the 106 operations in 1940, 47 operators used shipped-in slack exclusively; 22 packaged only their yard screenings; and 37 used both.

Raw fuels used in making packaged fuel in the United States, 1939–40

	Net tons		Percentage of total	
	1939	1940	1939	1940
Bituminous high-volatile and semianthracite	[1] 7,322	4,898	3.5	1.7
Bituminous low-volatile	194,023	245,881	91.5	87.4
Petroleum coke	10,696	30,555	5.0	10.9
	212,041	281,334	100.0	100.0

[1] Includes small tonnage of Pennsylvania anthracite.

Binders.—Cornstarches, averaging about 15 pounds per ton of packaged fuel produced, are the principal binders. Ninety-six operators used starch binders exclusively; 4, cement; 3, asphalt; 1, starch and asphalt; 1, starch and cement; and 1, a byproduct of sulfite pulp manufacture. The last type of binder, reported in 1940 for the first time, is described by the distributor as a neutralized and dehydrated product derived from the manufacture of sulfite pulp.

One operator, who makes both petroleum-coke and bituminous low-volatile cubes, reported using no binder in manufacturing his bituminous cubes.

PEAT

By Joseph A. Corgan

SUMMARY OUTLINE

The production of peat in 1940 totaled 70,097 short tons valued at $516,865, an increase of 26 percent in quantity and 43 percent in value over 1939. Peat output in the United States reached its peak in 1918, when 107,261 short tons were produced by 25 plants operating in 13 States. In that year the demand for processed peat exceeded the supply, and some producers could not serve even their regular customers because of inadequate facilities. Moreover, owing to war conditions, no peat was imported. Since 1918 annual production has been irregular in volume, ranging between a high of 73,204 tons in 1920 and a low of 30,406 tons in 1921.

Imports of peat moss fell from 78,611 short tons valued at $1,204,883 in 1939 to 21,689 tons valued at $454,632 in 1940, owing again to war conditions. No exports were reported in either year. Thus, on account of the drastic curtailment of peat moss imports the total quantity available for domestic consumption in 1940 (production plus imports) was only 91,786 tons—a substantial decrease from the 134,094 tons available in 1939. The loss of foreign supplies of peat moss has doubtless inconvenienced former users of that product materially; on the other hand, it presents an opportunity for United States producers of moss peat to capture a share of this market.

A directory listing the names and addresses of operators who reported production in 1940 to the Bureau of Mines has been prepared and will be sent upon request to those who may be interested.

Reserves.—The peat reserves in the United States are extensive, and about half of the 48 States contain some peat resources. The total, calculated as air-dried peat, has been estimated at 13,827,000,000 short tons.[1]

PRODUCTION

The Federal Government made no canvass of the peat industry from 1927 to 1933, inclusive, and no data for these years are available. Taking this into consideration, the production of 70,097 short tons in 1940 was the largest output since 1925, when 72,436 tons were produced.

[1] Soper, E. K., and Osbon, C. C., The Occurrence and Uses of Peat in the United States: Geol. Survey Bull. 728, 1922, p. 92.

As the following table indicates, the 1940 output was well ahead of the 1939 production. Upon a percentage basis 1940 showed an increase of 26 percent in quantity and 43 percent in value over 1939. The average value a ton in 1940 was $7.37, compared with $6.53 and $6.23 in 1939 and 1938, respectively. The trend of peat production and value is presented graphically in figure 1.

Peat produced in the United States, 1935–40

Year	Short tons	Value	Year	Short tons	Value
1935	37,060	$199,377	1938	45,933	$286,127
1936	46,126	266,883	1939	55,483	362,066
1937	51,223	305,156	1940	70,097	516,865

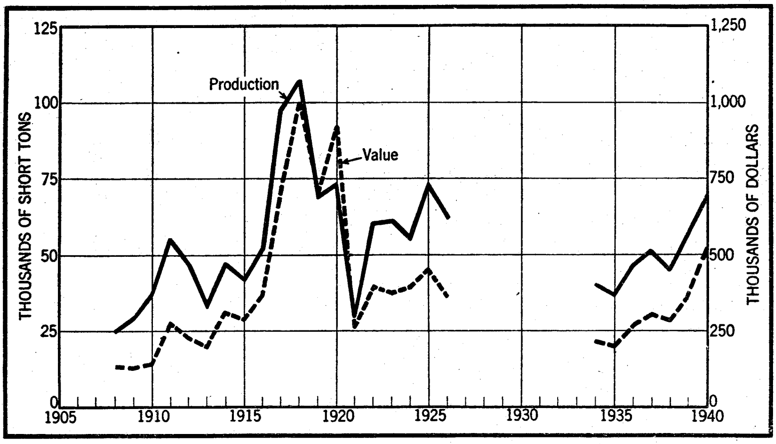

FIGURE 1.—Quantity and value of peat production, 1908–40. No data are available for 1927–33.

In 1940, 50 producers reported their output to the Bureau of Mines, a gain of 11 over 1939, and a large increase over 1918, when 25 plants operating in 13 States reported a total output of 107,261 short tons. Thus, it would seem that, should there be an increased demand for peat from domestic sources such as was experienced in 1918 the peat industry today, being more widespread and comprising more producing plants, would be better equipped to take care of it.

The same 15 States reported output in 1940 as in 1939, but their rank in terms of tons produced differed. In 1940 the producing States, in order of output, were: New York, New Jersey, Pennsylvania, Maine, Michigan, California, Connecticut, Florida, Ohio, Iowa, Minnesota, Colorado, Massachusetts, Washington, and New Hampshire.

Peat humus represented 45 percent of the total production, reed or sedge peat 36 percent, and moss peat and other 19 percent. Peat humus was produced in 10 States, reed or sedge in 8 States, and moss peat in 6 States.

The production of shredded peat was reported by 31 plants, while 17 reported raw peat and 10 cultivated peat.

USES

Of the total sales of peat in the United States during 1940, 93 percent was employed for soil improvement. Two percent of the sales were used in mixed fertilizers. Other uses, including litter for barns and poultry yards, took 5 percent. Peat is also utilized for other purposes, such as packing material for eggs, shrubs, fruits, vegetables, and fragile articles. As has been the case in recent years, no sales of peat for fuel were reported, although in 1918, in the war period, 20,567 tons were used for that purpose. In some European countries peat is utilized extensively for fuel and power purposes; but, except for regional emergencies, it has not been burned as fuel on a commercial scale in this country because of our vast resources of higher-grade fuels.

United States Government specifications.—There is a great difference in the kinds of peat, both in character and value, for specific uses. In purchasing its peat requirements the Federal Government has certain specifications that must be met. These may be obtained from the Procurement Division, United States Treasury Department, Washington, D. C.

IMPORTS [2]

The sharp decrease in peat-moss imports into the United States for 1940 is due chiefly to the war in Europe and the British blockade of Germany. In 1940 imports totaled 21,689 short tons valued at $454,632—a large decrease from 1939 when 78,611 tons valued at $1,204,883 were imported.

Germany has been for many years the principal source of peat moss imported by the United States. In 1939 imports from Germany were 28,127 short tons valued at $389,597; in 1940 the tonnage had fallen to 41 tons valued at $340. The Netherlands and Sweden together exported 35,181 tons of peat moss to the United States in 1939, but in 1940 the imports from these two countries totaled only 5,815 tons, a decrease of 83 percent. Canada and the United Kingdom supplied 15,298 tons or 71 percent of the total peat-moss imports in 1940. It will be noted that these two countries were the only ones from which imports were received during the last 6 months of 1940 and that several European countries that have supplied peat moss to the United States in recent years did not ship any here during 1940.

Peat moss imported for consumption in the United States, 1935–40

Year	Short tons	Value	Year	Short tons	Value
1935	54,547	$677,513	1938	69,509	$1,092,942
1936	75,066	955,807	1939	78,611	1,204,883
1937	86,871	1,219,127	1940	21,689	454,632

Peat moss was imported into continental United States through 22 customs districts. In 1939 the imports were received through 27 districts. In 1940 the New York district received 20 percent of the total imports and the Washington district 40 percent of the total.

The average value of the imported product a ton varies considerably with the country of origin. In 1940 the average value of the total imports was $20.96 a short ton—a large increase over 1939 and 1938, when the averages were $15.33 and $15.72, respectively. The increase in 1940 is due principally to the high valuation of the Canadian product. Of the total quantity imported, Canada shipped 61 percent to this country at an average value of $23.28 a ton.

[2] Figures on imports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

Peat moss imported for consumption in the United States, 1939–40, by countries

Country	1939		1940 [1]	
	Short tons	Value	Short tons	Value
Canada	6,922	$147,342	13,122	$305,544
Denmark	2,396	44,971	389	8,556
Estonia	1,424	28,566		
Finland	153	2,949		
Germany [2]	28,127	389,597	41	340
Latvia	1,701	33,820	146	2,889
Mexico	15	564		
Netherlands	17,824	185,828	3,136	44,394
Newfoundland and Labrador	1	27		
Norway	625	16,262		
Poland and Danzig [2]	764	11,436		
Sweden	17,357	323,158	2,679	64,749
U. S. S. R.[2]	517	9,593		
United Kingdom	785	10,770	2,176	28,160
	78,611	1,204,883	21,689	454,632

[1] Effective June 16, 1940, peat moss was broken down into two grades—poultry and stable and fertilizer; these have been combined in the above table. Since the change in classification was made imports have been received only from Canada and the United Kingdom, as follows: Canada, poultry and stable, 1,825 short tons, $46,857; fertilizer, 7,003 tons, $153,661; United Kingdom, 120 tons, $2,241 and 1,269 tons, $17,161, respectively.

[2] For statistical purposes trade with Danzig and that part of Poland occupied by Germany has been included with Germany, and trade with that part of Poland occupied by U. S. S. R. has been included with U. S. S. R. after November 16, 1939.

WORLD PRODUCTION

Unsettled conditions in Europe have made it difficult to obtain complete statistics on peat from the affected countries. The latest data are given in the following table.

World production of peat, 1937–40, by countries [1]

[Compiled by L. P. Lounsbery]

Country [1]		1937	1938	1939	1940

U. S. S. R.	do	23,822,000	26,460,700	(2)	(2)
United States	do	46,468	41,669	50,333	63,591

[1] In addition to the countries listed Argentina, Austria, France, Germany, Hungary, Norway, and Poland produce peat, but data of production are not available.

[2] Data not available.

[3] About 60 percent of the farmsteads in the country depend entirely on peat fuel, the annual consumption of which is estimated at 6 to 8 million tons. About 50,000 tons of peat-moss litter and peat mull are manufactured annually in Eire, and some 10,000 tons of air-dried turf are used annually for power purposes. (The Mineral Position of the British Empire, London, 1937, p. 30.)

CRUDE PETROLEUM AND PETROLEUM PRODUCTS[1]

By A. G. White, G. R. Hopkins, H. A. Breakey, and A. T. Coumbe

SUMMARY OUTLINE

The European war caused major changes in the World markets for petroleum and its products during 1940. In the first half of the year consumption was drastically curtailed in European countries, even where imports were still possible; in the latter half of the year, closing of the French and Mediterranean markets and the British blockade cut off the flow of oil to virtually all the principal markets of the continent. The effects of the international situation on the oil industry of the United States were to reduce exports by 58 million barrels—from 189 million in 1939 to 131 million in 1940—and to increase imports by 24 million barrels—from 59 million in 1939 to 83 million in 1940. Thus net exports (exports minus imports) were reduced from 130 million barrels in 1939 to only 48 million in 1940. The continuance of these trends, as indicated by available current data, may well result in an approximate balance between exports and imports in 1941.

The estimated world production of crude petroleum in 1940 was 2,149 million barrels—a gain of 70 million or 3.4 percent. United States production rose from 61 percent of the world total in 1939 to 63 percent in 1940—a gain of 87 million barrels; production in the rest of the world declined 16 million barrels. Russia showed no substantial change, while output in Venezuela decreased 21 million barrels, in Iraq 5 million, and in Rumania 3 million. Colombian production gained 4 million. Increased exports of crude and refined oils to the United States from Caribbean countries partly offset the loss of their continental European markets and helped to maintain their crude output at a higher level than might have been expected.

[1] Data for 1940 are preliminary; detailed statistics with final revisions will be released later

In the United States the new production of all oils increased by 91 million barrels, rising from 1,319 million in 1939 to 1,410 million in 1940. This output, however, exceeded demand, as indicated by an increase of 39 million barrels in the stocks of all oils compared to a decrease of 41 million in the stocks of all oils in 1939.

Domestic demand for all oils increased 92 million barrels—from 1,231 million in 1939 to 1,323 million in 1940. The domestic demand for motor fuel in 1940 was 6 percent greater than in 1939. The increase for residual fuel oil was 5 percent, for distillate fuel oil 19 percent, and for kerosene 14 percent. The large relative increase in the demand for heating oils was due to abnormally cold weather in the first quarter of the year. The effect of the defense program in increasing industrial activity and employment began to be felt in the last quarter of 1940.

At the beginning of 1940 stocks of gasoline were abnormally high as a result of increased output in expectation of a war export demand that did not materialize, whereas stocks of distillate and residual fuel oil were relatively low. During the first quarter of the year refinery runs were forced to high levels to meet an unexpected demand for fuel oils owing to unusually cold weather. The domestic demand for distillate fuel oil increased 26 percent over the same period of the previous year, almost half of the increase probably being abnormal. In spite of low gasoline yields, high fuel-oil yields, and large fuel-oil imports, there was a further excess build-up of gasoline stocks. This situation was accompanied by overproduction of crude, as indicated by an increase of 13 million barrels in crude stocks of domestic origin. During the quarter stocks of all oils increased by 19 million barrels.

Throughout the second quarter of 1940 refinery operations were maintained at a relatively high rate in an effort to build up fuel-oil stocks. Stocks of motor fuel remained abnormally high and exerted a depressing effect on refinery prices of gasoline. A further addition of 10 million barrels was made to stocks of domestic crude as well as an increase of 10 million in stocks of refined oils.

In the third quarter of 1940 an excellent balance was maintained between crude production and demand, and there was a retrenchment in refinery operations; however, the collapse of France and the closing of many markets in Europe resulted in a sharp reduction in refined exports and continued high inventories of gasoline, distillate, and lubricating oils. Stocks of domestic crude showed no material change, but stocks of refined products increased 10 million barrels.

During the fourth quarter of 1940 reduced exports and larger imports partly offset the increased demand for domestic oils caused by inauguration of the defense program; nevertheless, increasing industrial activity and employment did not exercise their full stimulus on oil demand until 1941. Comparatively mild weather combined with increasing imports from the Caribbean countries reduced fuel-oil requirements from domestic sources, but rising demands for gasoline reduced the seasonal build-up of gasoline stocks so that the relative position on March 31, 1941, was materially improved.

Total stocks of all oils rose from 525 million barrels at the close of 1939 to 564 million at the end of 1940. Total stocks of refinable and heavy crudes increased 24 million barrels, stocks of refined products gained 14 million, and stocks of natural gasoline rose over 1 million.

Total demand for all oils in the United States, 1931–40

[Millions of barrels]

Year	Domestic demand	Exports	Total demand	Year	Domestic demand	Exports	Total demand
1931	903.2	124.4	1,027.6	1936	1,092.7	132.0	1,224.7

[1] Subject to revision.

In view of increasing demand total stocks probably were close to economic levels at the end of 1940. During the year stocks of finished and unfinished gasoline increased over 1 million barrels, stocks of distillate fuel oil gained 9 million, and residual fuel-oil stocks decreased 3 million.

Salient statistics of crude petroleum, refined products, and natural gasoline in the United States, 1936–40

	1936	1937	1938	1939	1940 [1]
Crude petroleum:

[2] Imports of crude petroleum as reported to Bureau of Mines; all other imports and exports from Bureau of Foreign and Domestic Commerce.
[3] For comparison with 1940.

was offset to a considerable extent by a decline of over 19 million in exports. The total demand for distillate fuel oil rose from 167 million barrels in 1939 to 180 million in 1940—a gain of 8 percent. Domestic demand increased by 26 million barrels while exports declined by 13 million. The total demand for residual fuel oils amounted to 355 million barrels in 1940 compared to 341 million in 1939—an increase of 4 percent. Domestic demand was 16 million barrels greater than in 1939, and exports decreased by about 1½ million. The total demand for lubricating oil in 1940 was about 35 million barrels—a slight decrease compared to 1939—as a gain of about 1 million barrels in domestic demand was offset by a slightly larger decline in exports.

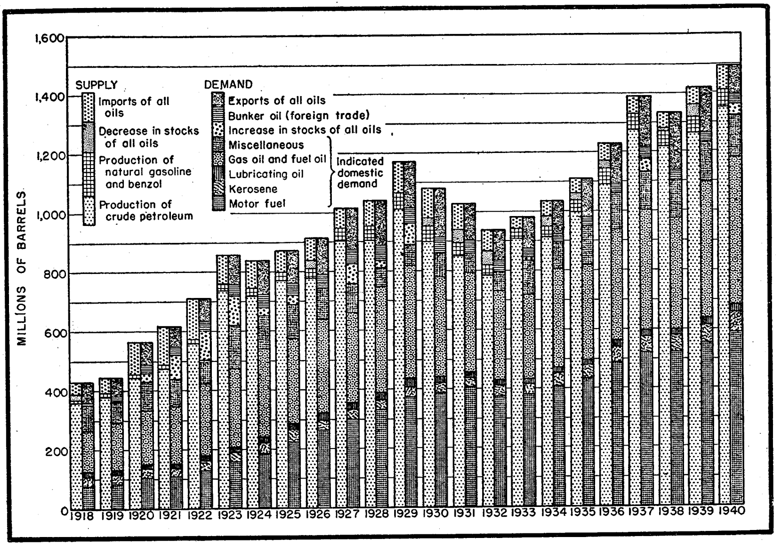

FIGURE 1.—Supply and demand of all oils in the United States, 1918–40.

The long-term trends in supply and demand are shown in figure 1. Rapid changes in the foreign situation and abnormally cold weather in the first quarter of the year resulted in a lack of adjustment between refinery production, seasonal stocks, and total demand for the various refined products during 1940, as shown by high gasoline stocks, by alternating periods of scarcity and overabundance of distillate fuel oil, and by large imports of residual fuel oil. Prospects for 1941 indicate that the domestic demand for all oils will substantially exceed all previous peaks in production and refinery operations. The expected gain in domestic demand probably will far exceed any further reduction in exports or the effects of any increase in imports.

RESERVES

Crude-oil reserves in sight or extractable by present methods and at approximately current prices reached a new peak on January 1, 1941. According to the American Petroleum Institute, the total reserve on that date was 19,025,000,000 barrels compared with 18,483,000,000 barrels on January 1, 1940. As production was about 1,352,000,000 barrels in 1940, it follows that the proved reserves discovered and developed in 1940 totaled 1,894,000,000 barrels.

Although the record-breaking total for proved reserves indicates at least no imminent danger of exhaustion, several aspects of the situation will bear watching. For example, in relation to total demand the reserves of January 1, 1941, represent about 13 years' supply, which is a drop from the number of years' supply in reserve the previous year. Furthermore, although the latest report of the American Petroleum Institute does not show the reserves of new fields separately, other surveys indicate a material decline in recent years in the proportion attributable to new fields as contrasted with the reserves added by extensions in the old fields.

Estimates of proved oil reserves in the United States on January 1, 1935, and 1937–41, by States [1]

[2] Final revised estimates of the amount of crude oil which may be extracted by present methods from fields completely developed or sufficiently explored to permit reasonably accurate calculations.
[3] Subject to revision.

LEGISLATION AND PRORATION

The most important legislative proposal before Congress in 1940 was the Cole bill providing for Federal regulation of production. Hearings on the Cole bill were held early in the year, but final action was still pending at the close of the year. The national defense program affected the industry in many ways, such as in connection with the export-control act and procurement contracts.

The interstate compact functioned throughout the year but with no important changes in membership until the spring of 1941.

State allowables and Bureau of Mines estimates of market demand[1] *compared with actual production*[2] *in the United States, in 1940*

[1] State figures are estimates of demand, hence in comparing demand data with actual production due regard should be given to changes in stocks by States of origin. (Changes in stocks and demand are given elsewhere in this chapter.)

[2] Comparisons of actual production with State allowables are complicated further by variations in the method of applying pipe-line deductions for B. S. and water. Thus it is believed that the allowables in Texas and California are on a 100-percent basis, in Oklahoma and Kansas on a 97-percent basis, in New Mexico on a 98-percent basis, and in Louisiana on a 99-percent basis. The bases used in reporting production to the Bureau of Mines are not definitely known, but indications are that the average for the United States is about 99 percent.

[3] Railroad Commission of Texas.

[4] Conservation Committee of California Oil Producers.

[5] Corporation Commission of Oklahoma. State allowable figures as shown do not include production permitted in accordance with "underage" and other special provisions of State orders.

[6] Department of Conservation, Louisiana. State allowable figures shown do not include production permitted under special orders of said Department.

[7] State Corporation Commission of Kansas.

[8] Oil Conservation Commission of New Mexico. State allowable figures as shown do not include production permitted in accordance with "underage" and other special provisions of State orders.

[9] Oil and Gas Commission.

EMPLOYMENT AND LABOR PRODUCTIVITY

The discussion of employment and productivity, which has been given here for several years, cannot be repeated for 1939 as the Bureau of Mines did not compile employment data for that year; however, complete information for 1939 was collected by the Bureau of the Census as part of its Decennial Census of Mines and Quarries (the first since 1919), and the results will probably be published before the end of 1941.

CRUDE PETROLEUM

SUPPLY AND DEMAND

The new supply of crude petroleum in 1940 was over 96 million barrels greater than in 1939—a gain of 87 million barrels in domestic production and an increase of over 9 million in imports; however, 24 million barrels were added to crude stocks compared with a reduction of 37 million in 1939. The total demand for crude petroleum was 1,371 million barrels in 1940—a gain of only 35 million barrels or less than 3 percent above the previous year. Exports of crude declined 20 million barrels while crude runs to stills increased 56 million.

Supply of and demand for crude petroleum in the United States, 1936–40

[1] Subject to revision. [2] As reported to Bureau of Mines.
[3] Exclusive of changes in stocks of heavy crude in California, 1936–37. [4] California only.
[5] Includes 2,091,000 barrels used for industrial purposes east of California, 279,000 barrels transferred to gas oil, etc., in California, and 4,070,000 barrels transferred to residual fuel oil in California.
[6] East of California.

PRODUCTION

As indicated in figure 2, the upward trend in production in 1939 was resumed in February 1940 and continued until June, July, and August, when there was a marked downward trend. A major influence was production in Illinois, which reached its peak in June.

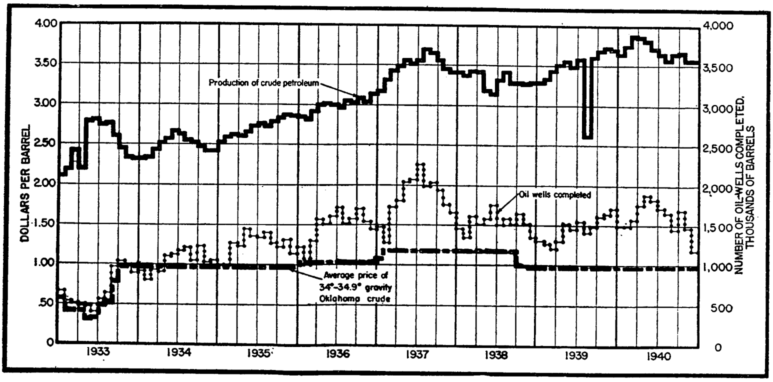

FIGURE 2.—Daily average production of crude petroleum, total number of oil wells completed, and average price per barrel of a selected grade of Oklahoma crude petroleum in the United States, 1933–40, by months.

The production of Pennsylvania Grade crude oil increased slightly in Ohio in 1940, but the output of this type of crude in each of the other three States—New York, Pennsylvania, and West Virginia—declined, and the total for the year fell from 27,220,000 barrels in 1939 to 26,972,000 in 1940.

The percentage of total crude petroleum produced by each of the three leading States—Texas, California, and Oklahoma—again decreased in 1940, and the three States combined produced less than two-thirds of the total for the first time in many years. The important gains were for Illinois, whose percentage rose from 7.5 in 1939 to 10.8 in 1940, and for "Other States," whose percentage rose from 3.8 in 1939 to 4.4 in 1940.

The relative rank of the producing States is shown graphically in figure 3.

The situation as to production by districts in 1940 was similar to that in 1939, with about half showing declines from the previous year but with the gain in Illinois–Southwest Indiana alone far outweighing all the decreases combined.

The rank of the first three leading producing fields—East Texas, Salem (Ill.), and Oklahoma City—remained unchanged in that order in 1940. The Midway-Sunset field of California ranks second to East Texas in cumulative production, but this is due mainly to its age—about 40 years—as it ranked only seventh in production in 1940.

Petroleum produced in the United States, 1936–40, and total 1859–1940, by States[1]

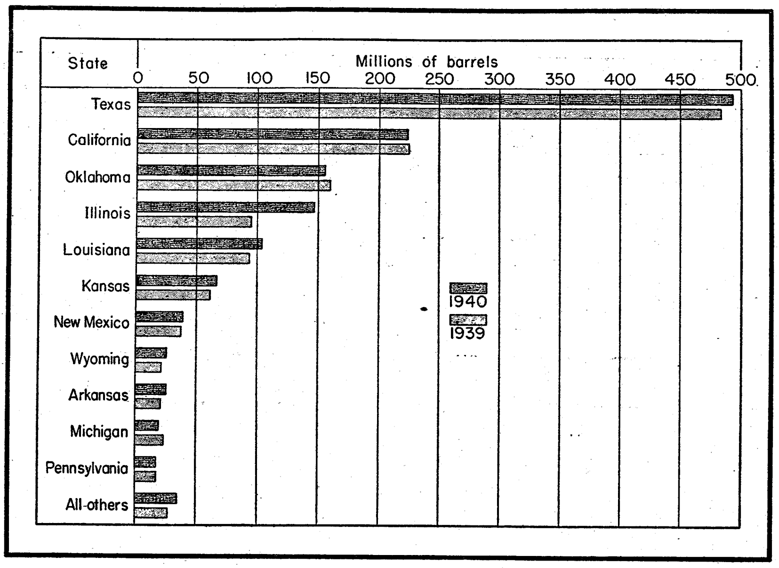

FIGURE 3.—Production of crude petroleum in the United States, 1939–40, by States.

Arkansas.—Production in Arkansas in 1940 was 25,583,000 barrels—about 20 percent higher than in 1939. The increase was largely attributable to gains in the comparatively new fields of Atlanta and Magnolia. Production at Magnolia rose from 3,639,000 barrels in 1939 to 7,383,000 in 1940; it is now the first-ranking field of the State in production.

Exploratory work and drilling in general declined in Arkansas in 1940, as only 114 oil wells were completed compared with 183 in 1939. One new field of promise was discovered; this was McKamie, a condensate field nearly 9,000 feet deep.

Production of crude petroleum in Arkansas, 1936–40, by fields

California.—Production in California in 1940 held consistently just above the 600,000-barrel-a-day mark, and the total of 223,881,000 barrels was only about 500,000 below the total for 1939.

Drilling in 1940 also was a counterpart of that in the previous year, as 859 oil wells were completed in 1940 compared with 852 in 1939.

The average initial daily production in 1940 was 890.5 barrels compared with 909.2 in 1939. In the number of dry holes there was a material difference—156 in 1940 compared with 251 in 1939. This decrease in failures probably reflects the effort of the majors to maintain their total "allowable" in the face of a declining allotment to top wells.

[1] American Petroleum Institute

Of the three major districts, San Joaquin Valley and Coastal increased in 1940 over 1939, but Los Angeles Basin declined. Wilmington, with a total output of 30,195,000 barrels, was again the leading field, but the old Midway-Sunset field displaced Kettleman

Hills in second place. Important gains in production in 1940 were made in the old Coalinga field, in the comparatively new fields of Coles Levee and Tupman, and at Santa Maria. In general, the increases were in fields where deep zones have been discovered in recent years.

New discoveries occurred in California in 1940; but only one new field—Del Valle, in the Coastal district—appears of importance. The Midway-Sunset, Rosecrans, and Coyote fields had notable extensions. According to the Oil and Gas Journal crude-oil reserves increased slightly in California in 1940, but nearly all the additions comprised extensions in old fields.

Colorado.—Although the preliminary figure of 1,350,000 barrels for production in 1940 indicates a decline for Colorado, the final figure probably will be about 1,550,000 barrels or nearly 150,000 barrels above the total in 1939. The increase followed development of an extension in the Wilson Creek field, which was the only field development of importance in another quiet year.

Production of crude petroleum in Colorado, 1936–40, by fields

Illinois.—The year 1939 had been outstanding in Illinois oil history, but even that was eclipsed by developments in 1940, as the total production was 146,788,000 barrels—56 percent above 1939.

Although the number of oil wells completed in 1940 was only moderately higher than in 1939 (3,049 compared with 2,943) the total daily initial production in 1940 was more than twice as large. In 1940 Illinois ranked second only to Texas in total initial and had nearly double that of California and Oklahoma combined. However, the major part of the initial in Illinois was from the Devonian lime, which because of its high porosity-permeability factor gives wells of large initial but no staying power. The peak daily production was just over 500,000 barrels in June; by the end of the year the State was down to about 333,000 barrels daily.

The Salem field maintained its place as second only to East Texas among the producing fields of the United States. In 1941 it is due to decrease sharply from its 1940 figure of 70,734,000 barrels but probably will retain second place. The Louden field was the second-ranking field in Illinois in 1940, with Centralia third.

Because of the size of the area and the number of producing formations, discoveries and extensions continued numerous in Illinois in 1940. Even the so-called Central Basin area of Clay, Richland, and Wayne Counties, where the hectic development of recent years began in 1937, yielded a number of new discoveries in 1940. Deep tests to the Devonian and Trenton limes and to the St. Peter sandstone were generally disappointing. Commercial Devonian production appears confined to the Du Quoin anticline in the general Centralia district. Trenton production was found in the Salem field, but its development does not appear promising economically. The St. Peter was barren in the few tests made.

Indiana.—Indiana continued to profit from the overflow of developments in Illinois, and in 1940 its production reached 4,843,000 barrels—the highest since 1907 and more than three times larger than that in 1939. The gain was due to increases in the Griffin and New Harmony fields. During 1940, 231 oil wells were brought in, compared with 176 in 1939. No important discoveries were made in Indiana in 1940, and the output in 1941 may show a decline.

Kansas.—In 1940 Kansas recovered from the slump induced by the Illinois development, and production rose to 66,270,000 barrels from 60,723,000 in 1939; however, output in 1940 fell short of the record (70,761,000 barrels) of 1937.

Routine drilling, which slumped in 1939, rose materially in 1940; 1,410 oil wells of 460 barrels average daily initial were brought in during 1940 compared with 977 wells averaging 432 barrels initial in 1939. Barton, Ellis, McPherson, Rice, and Russell Counties shared the major part of the drilling in 1940.

[1] Oil and Gas Journal.

Because of the tendency of the "shoestring" pools of Kansas to merge it is difficult to maintain comparable figures on production by fields; however, the production and potential figures for 1940 indicate that the enlarged Silica and Trapp fields are the two most important in the State. The old shallow fields in the eastern counties continued a "come-back" originating in the widespread application of water-flooding several years ago.

As usual, new discoveries and extensions in Kansas in 1940 were too numerous to mention separately. Trade-journal figures indicate, however, that the total new reserve added in 1940 was materially below that found in 1939.

Kentucky.—Drilling declined in Kentucky in 1940, and production fell to 5,193,000 barrels—the lowest since 1934. A wildcatting campaign in western Kentucky, which had been inaugurated largely because of developments in Indiana and Illinois, yielded one small field in 1940—Hebbardsville in Henderson County. Drilling in the eastern part of the State was confined largely to gas, with some success.

Louisiana.—Production in Louisiana in 1940 reached a new record of 103,961,000 barrels—the first time the output has exceeded the 100-million mark. The gain was entirely in the coastal district, as the decline at Rodessa was too great to be overcome by gains in other fields of north and north central Louisiana.

The output of the northern fields in 1940 was 24,406,000 barrels or about a million barrels less than in 1939. The important event of the year in the district in 1940 was the discovery of the Olla field in La Salle Parish. The production, which is from a sand in the Wilcox formation, totaled nearly 1,000,000 barrels in 1940. It opened up a vast area for exploration and greatly enhanced the possibilities of central Louisiana. Deep tests at Cotton Valley and Lisbon were successful, but the others were generally disappointing. There were 448 oil wells completed in 1940 compared with 289 in 1939, but the total initial declined.

As indicated above, the coastal district established a new record for production in 1940. The output of most of the old fields (like Jennings, Iowa, and Caillou Island) declined, but large increases were made at Eola, Golden Meadows, University, and other fields. The most active fields in drilling were Golden Meadows, Ville Platte, and Eola in that order.

The important Wilcox discovery at Eola in 1939 was actively followed up in 1940 but yielded only one small field—Neale in Beauregard Parish. Several domes were proved for production, but most of the new reserves probably came from flank extensions and new sands, as in the Anse La Butte field. Frio production was found by deeper drilling in the Iowa field. Several of the new discoveries were located offshore, and about half a dozen were over 10,000 feet in depth; both factors added materially to drilling costs.

Michigan.—Production in Michigan in 1940 was 19,764,000 barrels—a 16-percent decline from the peak of 1939. This pronounced drop in output was due to a material falling off in drilling and to the fact that no major discoveries were made. There were 536 oil wells brought in (compared with 813 in 1939), but the average initial was only 215 barrels daily against 535 in 1939. The number of dry holes (518) almost equaled the number of oil wells.

The Walker field, Kent County, was the leading producer in 1940, although it experienced a very rapid decline during the year, even speedier than the usual Traverse lime production. On the other hand, the old Porter field, producing from the Dundee sand, showed very little decrease in 1940.

A deep test near Bay City, which reached 7,776 feet at the close of the year, was closely watched. It was by far the deepest test ever drilled in the State. It only made about 50 barrels daily of light oil when tested, but the results were generally encouraging.

[1] Data from Department of Conservation, Michigan.

Mississippi.—In one year (1940) Mississippi rose to rank as a substantial producer, ahead of such oldtime States as West Virginia, Ohio, and Colorado. The rise was due almost solely to developments in the Tinsley field, which was proved to be of substantial size and importance. However, wildcatting in 1940 was generally disappointing, yielding but one small field—Pickens, in eastern Yazoo County.

Missouri.—Although interest in northwest Missouri continued as the result of developments in the Falls City (Nebr.) pool, no new oil fields were found, and production continued to be limited to the stripper area in and around Cass County. One new gas field was reported discovered in 1940.

Montana.—Production in Montana increased from 5,960,000 barrels in 1939 to 6,768,000 in 1940. Although this gain indicates a material growth in discovery it was due almost solely to drilling inside locations in the Cut Bank and Kevin-Sunburst fields, and no new fields or deeper horizons were found. There were 155 oil wells completed compared with 114 in 1939. The Cut Bank field produced 4,106,000 barrels in 1940, or just over 60 percent of the State total. The Frannie field of Wyoming was extended into Montana as perhaps the most noteworthy new development.

Production of crude petroleum in Montana, 1936–40, by fields

Nebraska.—The Falls City pool, discovered late in 1939, was proved as a field of some importance and in 1940 yielded 254,000 barrels compared with only 2,000 in 1939. There were 32 oil wells completed in the field in 1940; at the close of the year these were producing about 3,000 barrels daily, all from the Hunton lime.

The success at Falls City (the first discovery of the State) enhanced interest in Nebraska as oil territory, and wildcatting became fairly widespread; however, no further discoveries of importance were made.

New Mexico.—Production in New Mexico in 1940 rose to 39,001,000 barrels, which is slightly higher than the previous record (that of 1937). The number of oil wells completed and the total initial declined, but the output continued to be limited by proration in the southeastern fields. Production in the northwest corner of the State continued to fall parallel with the decline at Rattlesnake, the principal field. Monument and Eunice remained the leading producing fields, but Loco Hills and Vacuum made greater progress in relative importance. There were several new discoveries, of which Dayton, in Eddy County, and extensions at High Lonesome and Maljamar appeared most important.

Production of crude petroleum in New Mexico, 1936–40, by districts and fields [1]

[1] Oil and Gas Journal.
[2] Includes Grayburg, Jackson, and Maljamar.

New York.—The price of crude did not hold all the gains of 1939, and after an auspicious start in 1940 production declined so that the total fell to 4,999,000 barrels from 5,098,000 in 1939. New discoveries were limited to gas, for which there is brisk demand.

Production of crude petroleum in New York, 1936–40, by months

[1] Subject to revision.

Ohio.—Drilling again increased in Ohio, and the decline in production, starting in 1928, was arrested; the output in 1940 was 3,169,000 barrels compared with 3,156,000 in 1939. More than the usual amount of wildcatting was carried on; but the results, particularly in the deeper zones, were disappointing. The Clayton pool in Perry County was the outstanding Clinton-sand development.

Production of crude petroleum in Ohio, 1936–40, by months

[Thousands of barrels]

Year	Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Total

Oklahoma.—Although drilling and new discoveries increased in Oklahoma in 1940, the decline in production that began in 1938 was continued, and the output was 155,952,000 barrels compared with 159,913,000 in 1939. Except for the depression year 1932, the 1940 total was the lowest since 1922.

Drilling in 1940 resulted in more completions than in 1939, but there were fewer oil wells and more gas wells and dry holes. The total initial of the oil wells in 1940 (204,000 barrels daily) was virtually the same as in 1939.

The Oklahoma City pool was far ahead as the leading field in 1940, and its performance in showing a slight increase in output (from 35,728,000 barrels in 1939 to 35,970,000 in 1940) was notable. The Seminole district failed to maintain the come-back of 1939, and production dropped to the lowest since 1926, when the first well came in.

[1] Oil and Gas Journal.

Wildcatting was more successful in 1940 than in 1939. Most of the new finds were small; but one major field—Cumberland on the border of Marshall and Bryan Counties—was found. The principal zone at Cumberland is the Tulip Creek sand at about 5,000 feet. Other discoveries included extensions at Dill, Hewitt, and Cromwell and the Hunton-lime development in the Coyle and Ramsey fields. Okfuskee County led in new discoveries exclusive of Cumberland. The deepest wildcat ever drilled east of California—Continental's 1 Proctor in Washita County—was abandoned as a dry hole at 14,582 feet.

Pennsylvania.—In spite of higher average prices for crude oil, production in Pennsylvania declined slightly—from 17,382,000 barrels in 1939 to 17,353,000 in 1940. Of the 1940 total the Bradford field supplied 14,340,000 barrels (83 percent). Routine drilling continued, but discoveries were negligible.

[1] Subject to revision.

Tennessee.—Tennessee passed another quiet year, and the production, largely estimated, was only 50,000 barrels.

Texas.—Both the East Texas field proper and the Coastal district—the leading producing areas in Texas—declined in output in 1940; but this was more than made up in the rest of the State, and the total production rose to a new peak of 493,126,000 barrels compared with 483,528,000 in 1939. However, if the shut-down of August 1939 had not occurred there would probably have been a decrease in 1940.

Production in the South Texas district, which on January 1, 1941, was enlarged by the transfer of Kleberg, Kenedy, Willacy, and Cameron Counties from the Coastal district, increased from 29,392,000 barrels in 1939 to 32,320,000 in 1940. The most important source of new production was the Rincon field in Starr County. A number of new discoveries were made, including the Willamar field in Willacy County.

Nothing of importance occurred in the Central Texas district, which includes chiefly the Balcones fault-line pools, and production declined from 11,669,000 barrels in 1939 to 10,363,000 in 1940.

The come-back of the North Texas district was continued in 1940, when production was 48,148,000 barrels compared with 40,371,000 in 1939. Drilling, both routine and exploratory, increased. A number of discoveries were made, a large part of them in the so-called Fort Worth basin. Among these were the Bonita and Ringgold fields of Montague County. The Fargo field, farther west in Wilbarger County, was also considered an important discovery. The discovery of the Hults-Owen field in Montague County at just over 6,000 feet set a deep production record for the district. Deeper pays were found in the K-M-A and Hull-Silk pools. Wildcatting in the southern tier of Counties was confined largely to the search for new Palo Pinto lime pools, but the results were generally disappointing.

Production in the other fields of the East Texas district dropped from 31,340,000 barrels in 1939 to 27,837,000 in 1940. This loss was due mainly to the decrease at Rodessa; the only important gain was made at Cayuga.

Although output declined in the East Texas district in 1940 interest was high because of the deep discoveries at Chapel Hill and the finding of the important Hawkins field in Wood County in December. The Hawkins field touched off a lively drilling campaign in an area that had been disappointing since the East Texas field proper was discovered.

Production in the East Texas field proper under the rigid curtailment program totaled 141,023,000 barrels in 1940 compared with 144,615,000 in 1939. The field, which was 10 years old in October 1940, had produced about 1,571,000,000 barrels up to January 1, 1941.

[10] Includes Westbrook and other fields in Glasscock, Howard, and Mitchell Counties.

Drilling continued routine, with oil-well completions averaging less than one a day. The field had about 25,800 producing wells on December 31, 1940, a slight decrease for the year. The average bottom-hole pressure was 1,061.35 pounds on January 8, 1940, and 1,051.73 on January 8, 1941; this was by far the smallest annual decline ever recorded.

The Panhandle passed a rather quiet year in 1940. Drilling increased, and with higher allowables the yield was 26,700,000 barrels compared with 24,165,000 in 1939. New discoveries were few, but several important extensions were made.

Although drilling in the West Texas district during 1940 was about on a par with that in 1939, production and new discoveries increased. The output was a new record of 84,478,000 barrels compared with 79,453,000 in 1939.

Because the fields in this district tend to merge it is difficult to segregate production figures by individual pools. Gaines and Yoakum Counties were largely responsible for the gain in output in 1940, with the large Wasson pool the major factor.

The discoveries in West Texas in 1940 were important both from the standpoint of reserves and geologically. Deep production, or production below the prevailing Permian pays, was found in the Pennsylvanian, Silurian, and Ordovician. The Silurian strike, reportedly the first in Texas, opened up many possibilities for deeper production in many old fields.

In 1940, for the first time in a number of years, production in the coastal district declined, dropping to 122,257,000 barrels compared with 122,523,000 in 1939.

Drilling decreased for the second successive year; 1,072 oil wells of 276 barrels average initial were completed compared with 1,663 wells of 256 barrels initial in 1939.

The output for most of the fields in the Gulf Coast district was less in 1940 than in 1939, but some (like Old Ocean, West Ranch, and White Point) made material gains. The number of producing fields in this district has been increasing at the rate of a dozen or more for some years; hence, total yield can be maintained, even though that in most of the larger fields declines. Conroe continued to be the leading field, its output of 9,303,000 barrels in 1940 being only slightly below that of 1939.

Exploration revealed about 15 new fields in 1940, but less than half a dozen appeared important. Wildcatting on the Frio trend in Jackson County uncovered the Lolita, Texana, and Ganado fields, all of which looked promising. The Wilcox trend recovered from a number of disappointments and was extended westward by discovery of the Sheridan field in Colorado County. Offshore drilling, particularly in Galveston Bay, was continued with moderate success.

Utah.—Drilling in Utah in 1940 was confined to gas, and crude-oil production was only 3,000 barrels for the year.

West Virginia.—Production continued to decline in West Virginia during 1940, as the price improvement did not induce operators to clean out the wells. The total output in 1940 was 3,444,000 barrels compared with 3,580,000 in 1939. Virtually all the exploratory work was confined to gas, and the new reserves found were negligible.

Production of crude petroleum in West Virginia, 1936–40, by months

Wyoming.—Production in Wyoming again increased in 1940, with Lance Creek once more largely responsible for the gain. Production at Lance Creek in 1940 was 9,066,000 barrels (nearly 2,200,000 barrels above 1939) whereas the State output rose to 25,683,000 barrels (about 4,200,000 barrels above the total in 1939). The remainder of the gain came mainly from Oregon Basin and other heavy-oil fields.

[2] Includes crude oil consumed on leases and net change in stocks held on leases for entire State.

Drilling, both routine and exploratory, increased in Wyoming in 1940. The most important new discovery was the Shannon (sand) output in the Cole Creek field. Deeper pays and extensions were found in a number of fields; the La Barge field led in these developments.

WELLS

Drilling increased in the spring of 1940, but beginning in June the rate was retarded by a number of factors such as accumulations of crude-oil stocks and the adoption of more conservative development policies in Illinois. The number of oil wells brought in during December 1940 (1,178) was the lowest since February 1936; however, the total for the year—19,125—was 9 percent above 1939 (fig. 4).

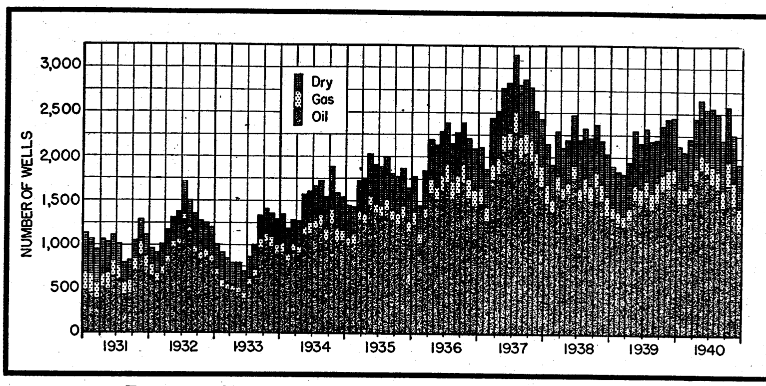

FIGURE 4.—Wells drilled in the United States, 1931–40, by months.

The percentage of dry holes declined from 24.6 percent in 1939 to 23.5 percent in 1940, probably because the percentage in Illinois (an active area in 1940) was considerably below the average.

There were 380,390 producing oil wells on December 31, 1939, 10,750 more than at the first of the year. These data indicate 6,735 abandonments in 1939, or considerably less than in 1938. The average production per well per day increased from 9.1 barrels in 1938 to 9.2 in 1939.

STOCKS

Crude-oil stocks increased about 24 million barrels in 1940. The major increase occurred in the first 5 months of the year, in a period of abnormal winter demand for heating oils and before spread of the war in Europe had cut off the exports of oil to France and Italy. Stocks of refinable grades increased by over 25 million barrels, or from 238,910,000 barrels on January 1 to 264,079,000 on December 31, while stocks of California heavy crude declined from 13,330,000 barrels to 11,906,000. Refinable grades of pipe-line and tank-farm stocks increased over 22 million barrels, stocks at refineries gained about 3 million, and producers' stocks showed a small decline.

Stocks of crude petroleum, natural gasoline, and refined products in the United States at end of year, 1936–40

[Thousands of barrels]

Product	1936	1937	1938	1939	1940 [1]
Crude petroleum (refinable):					
At refineries	46,846	51,041	51,551	49,215	52,448
Pipe line and tank farm	230,499	244,545 [2] 243,552	211,931 [2] 211,138	178,810	200,726
Producers	11,234	11,240	11,476	11,953	10,905
Total refinable	288,579	306,826 [2] 305,833	274,958 [2] 274,165	239,978 [2] 238,910	264,079
California heavy crude [3]	(3)	14,505	16,467	13,330	11,906
Total crude petroleum	288,579	306,826 [2] 320,338	291,425 [2] 290,632	253,308 [2] 252,240	275,985
Natural gasoline	4,055	4,758	4,830	4,421	5,704
Refined products [4]	226,595	253,413 [2] 239,901	259,665 [2] 272,241	268,109	282,265
Grand total	519,229	564,997	555,920 [2] 567,703	525,838 [2] 524,770	563,954

[1] Subject to revision.
[2] For comparison with succeeding year.
[3] California heavy crude included under refined products as residual fuel oil to end of 1937.
[4] Includes also equivalents for wax, coke, and asphalt in barrels.

The data on stocks of crude oil by States of origin for 1940 show that the largest increases were 12.5 million barrels for Texas, 3.4 million for Illinois, 3.4 million for Louisiana and Mississippi, 3.1 million for Oklahoma, 1.8 million for Kansas and Nebraska, 1.7 million for New Mexico, and 0.8 million for Arkansas. An increase of 0.4 million barrels in California refinable crude stocks was more than offset by a decrease of 1.4 million in stocks of heavy crude. The continued liquidation of old stocks of Wyoming origin resulted in a decrease of 1.8 million barrels during the year. Stocks of Michigan origin declined about 0.5 million barrels, while stocks of Pennsylvania Grade declined by about 0.3 million barrels.

Total stocks of all crude oils were 290 million barrels at the end of 1938, fell to 252 million at the end of 1939, and rose to 276 million at the end of 1940. In view of increasing demand, and measured in terms of days' supply, the stocks at the end of 1940 probably were close to the reasonably economic level required by industry operations.

Stocks of refinable crude petroleum [1] *in the United States in 1940 by States of location and origin and by months* [2]

[1] Excludes stocks of California heavy crude. [2] Subject to revision.

[3] Figuresf or 1939 (Minerals Yearbook, 1940, p. 973) are as follows (thousands of barrels): Pipe-line stocks: Illinois-Southwestern Indiana—January 31, 11,081; February 28, 11,459; March 31, 11,561; April 30, 11,770; May 31, 12,528; June 30, 12,969; August 31, 14,396; September 30, 14,698; October 31, 14,936; November 30, 14,612; December 31, 14,501. Rocky Mountain—January 31, 18,776; February 28, 18,784; March 31, 18,530; April 30, 18,138; May 31, 17,598; June 30, 17,025; July 31, 16,717; August 31, 16,342; September 30, 15,671; October 31, 15,251; November 30, 15,282; December 31, 15,115. Producers' stocks—January 31, 12,073; February 28, 11,778; March 31, 11,767; April 30, 11,830; May 31, 11,999; June 30, 12,017; July 31, 12,883; August 31, 11,730; September 30, 12,210; October 31, 12,205; November 30, 12,132; December 31, 11,953.

[4] For comparison with succeeding year.

CONSUMPTION AND DISTRIBUTION

Runs to stills.—Crude run to stills set a new record in 1940 of 1,294 million barrels—an increase of 56 million, or 4.6 percent on a daily average basis over 1939. Foreign crude runs, representing about 3 percent of the total, increased by over 8 million barrels, and domestic crude runs gained 48 million.

Refinery operations exceeded demand, as indicated by an increase of 14 million barrels in stocks of refined oils. As exports of refined oils slumped from 117 million barrels to 79 million the increase in the demand for refined products was due entirely to gains in the domestic market.

The rise in domestic demand and the decline in exports were reflected in the changes in refinery operations by districts. Crude runs in the Illinois-Indiana district rose from 192 million barrels in 1939 to 226 million in 1940—a gain of 34 million—the increase showing not only the strength of the domestic market but also the large local supply of cheap crude resulting from the expansion of Illinois production.

Crude runs in Texas and Louisiana were decreased owing to the weak export market and the increased competition of other districts. In the Texas Gulf Coast district runs increased from 334 million barrels to 338 million, but this gain was offset by an almost equal decline in the Texas Inland district. In Louisiana crude runs declined from 63 million barrels in 1939 to less than 59 million in 1940. Crude runs increased 12 million barrels in the East Coast district, over 4 million in the Appalachian district, almost 4 million in the Rocky Mountain district, and only about 2 million in California. The small gain in California was due to reduced exports and the liquidation of excess stocks of residual fuel oil.

Distribution.—Receipts of domestic and foreign crude petroleum at refineries in the United States totaled 1,237 million barrels in 1939 and 1,299 million in 1940. In 1940 receipts of foreign crude were 43 million barrels (3 percent of the total)—a fractional increase from 1939; interstate receipts of domestic crude were 487 million barrels (almost 38 percent of the total) compared to 36 percent in 1939; and intrastate receipts were 769 million barrels (59 percent of the total) compared to 61 percent in 1939.

Refinery receipts of crude in 1940, by methods of transportation, indicated that 72 percent of the total was delivered by pipe lines compared to 73 percent in 1939; that 25 percent was delivered by boat—a gain of 1 percent from 1939; and that 3 percent was delivered by tank car and truck.

The total demand for domestic crude in 1940 approximated 1,328 million barrels—a gain of about 27 million over 1939 or a little more than 2 percent. Domestic crude run to stills amounted to 1,252 million barrels—an increase of 48 million; crude exports declined from 72 million barrels in 1939 to less than 52 million in 1940; and crude used for fuel and losses totaled over 24 million barrels—a small decrease.

The most important changes in market demand by States of origin (computed from production and changes in crude stocks by origin) in 1940 compared to 1939 were an increase of over 54 million barrels in the demand for Illinois crude and declines of 23 and 17 million, respectively, for Texas and Oklahoma.

Runs to stills of crude petroleum in the United States in 1940, by districts and months [1]

[1] Subject to revision.

Data on receipts of crude petroleum at refineries represent one of the principal bases for determining the trends of distribution of the market demand by States of origin. In 1940, seven States—Texas, California, Oklahoma, Illinois, Louisiana, Kansas, and New Mexico—supplied 90 percent of the total refinery receipts of domestic crude compared to 91 percent in 1939.

The total demand for Texas crude was about 481 million barrels in 1940—23 million barrels less than 1939. This loss of market was due to the war and to the increased production in other States. The decrease in demand was so abrupt that production exceeded market demand, as indicated by an increase of over 12 million barrels in crude stocks of Texas origin in 1940. Exports declined by almost 17 million barrels owing to the closing of foreign markets as a result of the war. Deliveries to refineries decreased about 4 million barrels, the decline being attributable to intrastate shipments, as there was virtually no change in interstate deliveries.

The total demand for California crude in 1940 was 225 million barrels—a decrease of over 3 million from the previous year. Intrastate deliveries increased 3 million barrels to 200 million, interstate shipments to the East Coast remained at less than 1 million, and exports declined by 4 million to 18 million barrels. Production of crude remained about the same as in 1939, but a smaller decrease in crude stocks and a large decrease in residual fuel-oil stocks occurred.

The total demand for Oklahoma crude in 1940 was 153 million barrels—a decrease of 17 million barrels from 1939. Production exceeded market demand, as shown by an increase of 3 million barrels in crude stocks of Oklahoma origin. Interstate deliveries to refineries decreased 13 million barrels, the principal factor being declines of about 6 million barrels each in shipments to refineries in Indiana and Texas. There was a small decrease in intrastate deliveries and a further displacement of exports to Canada by crude from Illinois.

The total demand for Illinois crude increased from 89 million barrels in 1939 to over 143 million in 1940—a gain of about 54 million barrels. Production of crude exceeded demand, as indicated by an increase of about 3 million barrels in stocks of Illinois origin. Deliveries of crude to refineries in other States gained almost 36 million barrels, which includes an increase of about 24 million barrels in shipments to refineries in western Ohio, Indiana, Kentucky, and Michigan—an increase of 7 million barrels to Appalachian refineries and a gain of over 4 million barrels to East Coast refineries.

The total demand for Louisiana crude was almost 102 million barrels in 1940—5 million barrels greater than in 1939. Deliveries to refineries in the East Coast district increased by only 2 million barrels, while increased shipments to Texas were largely offset by declines in intrastate deliveries and crude exports.

The market demand for Kansas crude was about 65 million barrels in 1940—an increase of about 4 million; the major change was in

intrastate deliveries. The total demand for New Mexico crude in 1940 decreased by 2 million barrels to 37 million.

The demand for Wyoming crude rose to almost 28 million barrels in 1940—a gain of 3 million. Arkansas crude demand totaled 25 million barrels—an increase of over 3 million—and the demand for Michigan crude was 20 million barrels—a loss of 3 million, representing a large decline in interstate shipments and a smaller increase in intrastate shipments.

PRICES AND VALUE

As indicated in figure 5 the price of Pennsylvania crude was again active in 1940, with the essential difference that nearly all the changes in 1940 were decreases, whereas all in 1939 were increases. Most of the other quotations were unchanged throughout the year, hence the average is estimated at $1.00 compared with $1.02 in 1939.

REFINED PRODUCTS

The intensified industrial activity in the United States that resulted from supplying the war needs of Europe and the country's initial defense requirements pushed up the domestic demand for almost all petroleum products to unprecedented levels. The relative rate of increase was somewhat exaggerated by the extra leap-year day in 1940. The 589,424,000-barrel domestic demand for motor fuel was 6 percent above the 1939 record of 555,509,000 barrels, and the 339,284,000-barrel domestic demand for residual fuel oil was 5 percent higher than the 1939 demand of 323,488,000 barrels. The domestic demand for kerosene and distillate fuel oil (both greater than normal as the result of a severe winter) was 14 and 19 percent higher, respectively, than in 1939. Coke was the only principal product of petroleum in less domestic demand in 1940 than in 1939.

The recession in volume of exports that began in 1939 was continued in 1940; total shipments of refined products were only 79 million barrels compared with 117 million in 1939. Curtailment of foreign demand, caused at first by rationing and the risks attending ocean transportation, increased as western European countries fell. Exports of motor fuel decreased from 44,638,000 barrels in 1939 to 25,107,000 in 1940, and exports of most of the other petroleum products except coke and asphalt also declined. The increased domestic demand for fuel oils coupled with lower import duties and plentiful foreign supplies encouraged domestic consumers to obtain part of their requirements for heavy oils from Latin American sources. As a result, exports of

[2] Net transfers from crude oil to fuel oil; California only, 1936–38.
[3] Figures not available.
[4] Includes terminal stocks; compares with succeeding years.
[5] Upon new basis with transfers east of California included.
[6] California heavy crude included.
[7] For comparison with succeeding year; California heavy crude included in crude-oil stocks.
[8] For comparison with succeeding year.

residual fuel oil declined from 17,485,000 barrels in 1939 to 16,077,000 in 1940, whereas imports increased from 15,680,000 barrels in 1939 to 28,458,000 in 1940; exports of distillate fuel oil decreased from 32,020,000 barrels in 1939 to 19,172,000 in 1940; and imports, nonexistent in 1939, amounted to 3,333,000 barrels in 1940.

Crude oil runs to stills in 1940 totaled 1,294,283,000 barrels compared with 1,237,840,000 in 1939—an increase of 56,443,000 barrels. Foreign crude runs were 41,798,000 barrels (3.2 percent of the total) compared with 33,490,000 barrels (2.7 percent of the total) in 1939 and 26,187,000 barrels (2.2 percent of the total) in 1938.

Although the East Coast district—with 33,288,000 barrels of foreign crude runs in 1940 and 29,108,000 barrels in 1939—is the principal district using foreign crude, the Texas Gulf Coast district has shown the greatest relative increase, the 1940 runs being 7,458,000 barrels compared with 3,820,000 in 1939 and 1,567,000 in 1938. These increases of foreign crude runs to stills have had some influence on the lower yield of gasoline and higher yield of heavier oils.

Runs to stills and production at refineries in the United States of the various refined products, 1936–40 [1]

[1] Subject to revision.
[2] Negative quantity; represents net excess of unfinished oils rerun over unfinished oils produced.

The total refinery output of motor fuel—597 million barrels—exceeded that in 1939 by less than a million barrels and included 264 million barrels of straight-run gasoline, 294 million barrels of cracked gasoline, and 39 million barrels of natural gasoline.

The yield of gasoline decreased to a greater degree in 1940 than in any previous year, amounting to only 43.1 percent of the crude oil run to stills, compared with 45.0 percent in 1939. Yield of distillate fuel oils—14.2 percent—represented a gain of 1.1 percent; the yields of other oils changed slightly (see fig. 6). These changes in yields resulted largely from a more rapidly increasing demand for heating oil than for gasoline and the attempt of refiners to adjust their operations to the altered requirements of consumers.

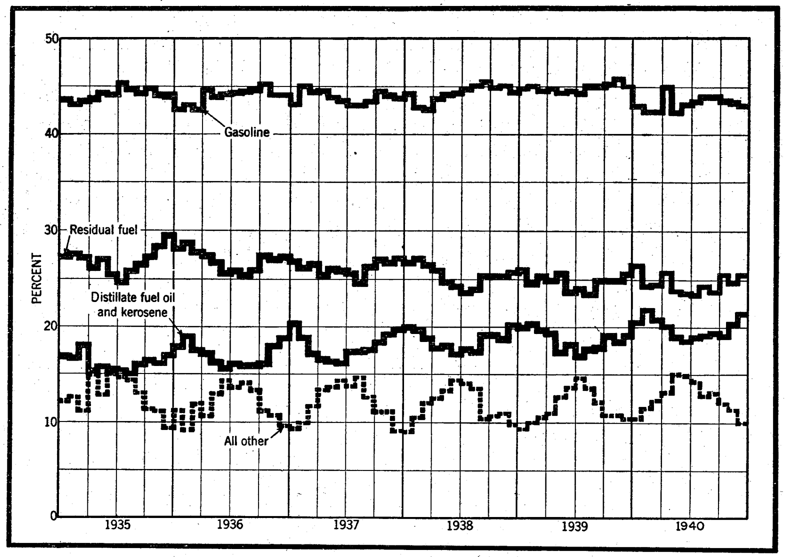

FIGURE 6.—Yields of principal petroleum products from crude oil run to stills in the United States, 1935–40, by months.

Summary of percentage yields of refined products in the United States, 1932–40.

The general trend of prices of refined products in 1940 was downward. Heavy exports and a severe winter were the principal factors in the brisk demand for heating oils that prevailed in late 1939 and the early part of 1940, but with mounting inventories and a more normal demand prices dropped. The price declines for lubricants and wax were as sharp as their rise in 1939. A record accumulation of gasoline stocks early in 1940 was indicated by the low prices that prevailed for this product during the year despite a substantial increase in domestic demand (see fig. 7).

Development in catalytic refining in 1940 centered in the search for new catalysts. The objectives of catalyst research is to find one that not only will produce a high yield of gasoline from any stock, but also function continuously. Under most present methods cracking must be interrupted every few minutes to permit purging and regenerating of the catalyst; in consequence, only about one-third of the operating time of a catalyst case is actually devoted to cracking, whereas, two-thirds of the operating time is consumed in regenerating the catalyst.

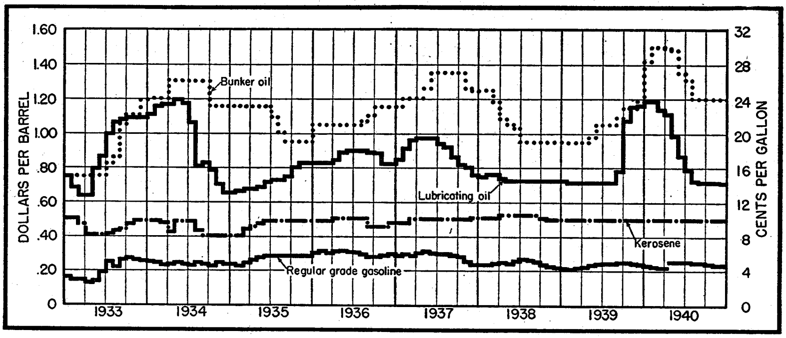

FIGURE 7.—Prices of refined petroleum products in the United States, 1933–40, by months.

Two sources have announced the discovery of catalysts that will speed up the catalytic cracking process. One catalyst is described as a synthetic product that will increase yield 15 to 20 percent, producing a better quality gasoline, and that can be purged more easily and quickly than commonly known types. The other is said to be a powder that becomes fluid in operation and flows like a liquid instead of being fixed in catalyst cases. Continuous cracking operations are maintained in one chamber, while the catalyst is regenerated in another.

During 1940 the attention of the petroleum industry was directed to the production of toluene. Although the lower-boiling-point portions of coal tar are the usual source of this essential base for the manufacture of trinitrotoluene, it can be made from petroleum gases also. One plant for manufacturing this commodity is in operation, and another with an annual capacity of 2 million gallons was scheduled to begin producing early in 1941.

The laboratory production of synthetic rubber from petroleum gases and the construction of plants for manufacturing it have been among the most interesting technological developments during the past 2 years. Germany and Russia, as well as the United States, have conducted experiments and research on synthetic rubbers for a number of years; more than 30 types—some closely related—have been developed.

Although Germany used a rubber made from coal, limestone, and gas products during the last war, it was not until 1927, when German chemists found that butadiene could be obtained commercially from coal and limestone, that the modern phase of synthetic rubber developed. Butadiene is the basic raw material for the production of Buna rubber. The discovery of the emulsion technique now used to produce copolymers of the Buna-S and Perbunan type led to abandonment of the metallic sodium method.

Butadiene may be produced from a number of raw materials, including acetylene, alcohol, and petroleum. In the process involving petroleum it is derived from butane, as well as from propylene and cyclohexane in still gases. Of the various types of Buna rubber the two most important are Buna-S, made from butadiene polymerized with styrene, and Perbunan (formerly Buna-N) and Perbunan Extra, made from butadiene polymerized with acrylonitrile.

Although none of the synthetic rubbers has all the qualities of natural rubber, most of them have qualities that are specifically desirable, such as better resistance to heat, water absorption, abrasion, and action of oil.

Although high cost makes competition of synthetic rubber with natural rubber difficult for ordinary uses under present economic circumstances, production facilities could be obtained quickly if the United States were deprived of its usual source of rubber for tire requirements, and mass production probably would lower the cost. At present Buna-S rubber is not produced commercially from petroleum in the United States. Two plants for the production of Perbunan rubber, however, are under construction, one at Baton Rouge, La., and the other at Borger, Tex.

REFINERY CAPACITY

The vital need in defense planning for current statistics on the production and capacity of refineries prompted the Bureau of Mines to compile its January 1, 1941, survey of refineries several months earlier than usual and to make available in this volume a discussion of both the 1940 and 1941 surveys.

Daily refinery capacity, including that of refineries under construction, was 4,860,194 barrels on January 1, 1941—138,981 barrels more than that on January 1, 1940, and 209,389 barrels more than that on January 1, 1939. Although the total number of plants increased from 557 on January 1, 1940, to 562 on January 1, 1941, the increase from 96 to 142 in the number of idle refineries and those under construction caused the number of operating refineries to decrease to 420 compared with 461 on January 1, 1940.

The number of idle refineries increased principally in Illinois and California. Coincident with the sharp decline in crude-oil production in Illinois the number of idle refineries increased from none on January 1, 1940, to 10 on January 1, 1941. The number of refineries operating in Illinois increased from 16 on January 1, 1939, to 24 on January 1, 1940, and refining capacity from 151,650 to 188,450 barrels. By January 1, 1941, the number of refineries operating decreased to 16, but capacity increased to 226,400 barrels, indicating that the increase in capacity in 1940 was at the large refineries, whereas the plants closed in 1940 were the small refineries that depended on a plentiful supply of cheap crude oil.

Summary of refinery capacity in the United States, January 1, 1937–41

Year	Number of refineries				Capacity (barrels per day)			
	Operating	Shut down	Building	Total	Operating	Shut down	Building	Total
1937	423	149	11	583	3,966,616	328,265	81,200	4,376,081
1938	431	120	10	561	[1] 3,970,196	[1] 380,955	[1] 283,020	4,634,171
1939	435	103	7	545	3,933,785	574,770	142,250	4,650,805
1940	461	86	10	557	4,196,694	431,952	92,567	4,721,213
1941	420	136	6	562	4,180,588	538,381	141,225	4,860,194

[1] New basis; for complete information see Bureau of Mines Information Circular 7034.

The combination of lower prices for gasoline and termination of a favorable distributing arrangement for independent refineries in the Los Angeles area caused the number of idle plants in California to rise from 11 on January 1, 1940, to 30 on January 1, 1941. Closing of 14 refineries operating in the State—73 were in operation on January 1, 1940, and 59 on January 1, 1941—reduced the net operating capacity from 799,110 barrels to 761,510.

Total refining capacity increased most in the East Coast and Texas Gulf Coast districts, the capacity of each rising about 55,000 barrels. The operating ratio in 1940, or the proportion of crude runs to capacity, was 82 percent, the same as in 1939.

The daily capacity of cracking plants on January 1, 1941, was 1,151,193 barrels of cracked gasoline output; this figure includes plants with a capacity of 48,145 barrels that were under construction and an idle capacity of 82,042 barrels, or 46,904 barrels more than the capacity of January 1, 1940.

Much of the construction at refineries in 1940 did not increase crude-oil capacity; some of it involved improved methods of refining

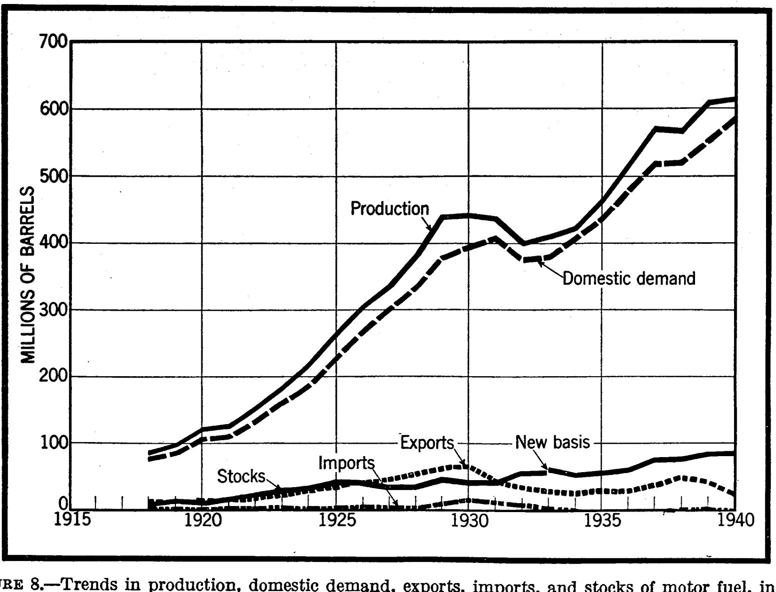

FIGURE 8.—Trends in production, domestic demand, exports, imports, and stocks of motor fuel, in the United States, 1918–40.

lubricating oils, such as solvent-extraction plants, and much of it consisted of plants for hydrogenating, catalytic cracking, polymerization, extraction of toluene, and of production of synthetic rubber.

MOTOR FUEL

Demand.—The usual new record for domestic motor-fuel demand was established in 1940 at 589,424,000 barrels, a 6-percent increase over the 1939 record—555,509,000 barrels. Total demand, however, increased only 2.4 percent owing to a 44-percent drop in exports from 44,638,000 barrels in 1939 to 25,107,000 in 1940 (see fig. 8).

[1] Subject to revision.

Domestic motor-fuel demand per motor vehicle in use increased from 19.33 barrels (812 gallons) in 1939 to 19.89 barrels (835 gallons) in 1940. The estimated number of motor vehicles in use on July 1 increased by more than 900,000 in 1940 to about 29,600,000; this record was partly attributable to an increase in new registrations from 3,140,000 in 1939 to 3,991,000 in 1940. The increasing number of motor vehicles scrapped, however, prevented the number in use from increasing to the full extent of the increase in new registrations.

Studies of traffic surveys, toll-bridge statistics, and other traffic statistics indicate that truck traffic in metropolitan areas has stabilized at about 18 to 19 percent of total motor-vehicle traffic. The proportion of truck traffic on the highways, however, is still increasing and is about 16 to 17 percent of the total.

August	−.1	−407			

[1] In degrees departure from 46-year normal.

Consumption of domestic motor fuel was reduced possibly 6 million barrels in 1940 by inclement weather. The gasoline-temperature index table shows that the index was minus 7.1° for January—the coldest month in the 16 years that the gasoline-temperature index has been employed. Calculations indicate that consumption of motor fuel during that month is estimated at over 3 million barrels less than it would have been under normal weather conditions, although the reduction in consumption owing to the diminished use of automobiles was offset by other factors. December was the only month in the year when the temperature index was not below the 1925–38 average (1° above the Weather Bureau's 46-year normal).

The decline in exports of motor fuel, well under way in the latter part of 1939, continued throughout 1940. The British blockade imposed at the beginning of the war prevented shipments to Germany during the last few months of 1939. The invasion of Denmark and Norway in April and of the Low Countries in May 1940, the fall of France, and the entry of Italy into the war in June so extended the blockade that the United States lost virtually all of its European oil market except that in the British Isles. Even Britain, as far as possible, bought its oil from South America or other sources to conserve exchange.

The pleasure use of automobiles was severely curtailed or even eliminated except in the Americas, and such motor vehicles as were permitted to operate abroad were encouraged to use gasoline substitutes. Aside from the motor fuel produced from coal in Germany, and to a smaller degree in England, Japan, and France, the most popular substitutes are liquefied gas, gas carried in bags on top of the automobile, and charcoal or producer gas generated by the motor vehicles using it. Alcohol was developed in many of these countries during peace times to secure an independent source of motor fuel, but the need for edibles is so great in most European countries that agricultural efforts are being directed toward raising food rather than toward the production of crops for the manufacture of alcohol.

Production.—Motor-fuel production increased less than 1 percent in 1940 but rose to 616,359,000 barrels from 611,043,000 in 1939. The small increase in the production of motor fuel in 1940 resulted from a decline in gasoline exports and an adjusted balance in refinery operations whereby needed heavy oils were obtained by increasing the yield of those products and reducing the yield of gasoline. The production of motor fuel in 1940 comprised 263,584,000 barrels of straight-run gasoline, 294,365,000 of cracked gasoline, 3,161,000 of benzol, and 55,249,000 of natural gasoline, the latter consisting of about 39 million barrels blended at refineries and about 16 million barrels utilized elsewhere.

Straight-run gasoline continued to represent 42.8 percent of all motor fuel produced; but the ratio for cracked gasoline—the trend of which had been upward for a number of years—declined from 48.3 percent to 47.8—the first decrease since 1934 and the second in the history of Bureau of Mines statistics. The ratio for natural gasoline blended at refineries declined from 6.5 percent to 6.4 in 1940, but that for "other" natural gasoline increased from 1.8 percent to 2.6, making the total ratio for natural gasoline 9.0 percent in 1940.

Yields.—Although technologic improvement advanced and much catalytic cracking, polymerization, and alkylation equipment was installed in 1940, the yield of gasoline dropped from 45.0 percent of the crude runs to stills in 1939 to 43.1 percent in 1940. An adjustment in refinery operations was necessary when the extremely cold weather of early 1940 increased the first-quarter demand for distillate fuel oil 25 percent compared with the demand for the first quarter of 1939. Refinery operations were concentrated on making heating oil, and the yield of gasoline dropped from 44.7 percent in the first quarter of 1939

[1] Subject to revision.

[2] Based on crude runs to stills.

[3] Includes aviation gasoline (thousands of barrels) as follows: October 981, November 845, December 1,048, total 2,784.

to 42.5 percent for the same period in 1940. During the remainder of the year an effort was made to increase heating-oil stocks and reduce gasoline stocks, with the result that yields of gasoline were kept low, and stocks, which were 16,589,000 barrels higher on March 31, 1940, than on the same date in 1939, were only 1,544,000 barrels higher on December 31, 1940, than at the end of 1939.

The decline in yield of gasoline was shared by both straight-run and cracked gasolines, the former decreasing 0.7 percent—from 21.1 to 20.4—and the latter 1.2 percent—from 23.9 to 22.7. Several factors account for the decrease. If the demand for heavy oils is strong the refiner may select crudes of low gasoline content. Foreign crude usually is of much lower gravity than domestic crude, and the increased runs of foreign oil in 1940 had some influence in lowering the yield. The diversion of cracking stock to supply heating-oil requirements, such as probably occurred in the early part of 1940, would lower the yield of cracked gasoline, whereas the decline in the quantity of unfinished oils rerun (from 11,731,000 barrels in 1939 to 3,845,000 in 1940) probably would account for more than 0.3 percent in the difference between the yield of cracked gasoline in 1939 and 1940.

The yield of gasoline in all of the districts except Arkansas and Louisiana Inland declined, the greatest difference being in the Texas Gulf Coast district, where the decrease from 44.1 percent in 1939 to 41.0 percent in 1940 amounted to 3.1 percent. The next largest was in the East Coast district, where a decrease of 3.2 percent in cracked gasoline was partly offset by a rise in straight-run, with the result that the 1940 yield was 37.0 percent—2.9 percent less than that for 1939. The decline for the Rocky Mountain district was 2.7 percent, shared by both straight-run and cracked gasoline, whereas the yield for the Inland Texas district decreased 3.7 percent in straight-run but gained 1.3 percent in cracked gasoline.

Texas Inland had the highest yield of any district, with 54.1 percent; and the Indiana, Illinois, Kentucky, etc., district was next, with 53.0 percent. California had the lowest, with 32.9 percent.

Prices.—Although the quality of gasoline has been improving steadily, there was no change in the grades on which prices are quoted between 1937 and 1940. The confusion and dissatisfaction resulting from the variety of knock-rating methods led the Western Refiners Association in April 1940 to adopt the A. S. T. M. (motor) method, which in 1939 had been made standard by the American Society for Testing Materials, instead of the L–3 method recognized by the association since 1937. At the same time the association established new grades.

The grade known in 1931 as 57 octane and below was changed in 1933 to 59 octane and below, in 1934 to 62 octane and below, and in 1940 to 61 octane and below. The regular grade was 57–65 octane from October 1931 to May 1933, when it was changed to 60–64 octane, and then in 1934 changed again to 63–70 octane. In 1936 this grade was split into two classifications—63–67 octane and 68–70 octane—the latter being designated as regular gasoline. In 1937, when the L–3 method of determining the octane number was adopted, these two grades were changed to 63–66 and 67–69 octane, and a new grade—70–72 octane—was added and designated as regular gasoline. In 1940 the 63–66 octane grade remained unchanged, whereas the 67–69 and 70–72 octane grades were eliminated and a 72–74 octane

311436—41——63

grade was designated as regular gasoline. Although prices were quoted on a premium grade of above 65 octane in 1931, which was changed in 1933 to 65 octane and above and in 1934 to 71 octane and above, sales of this grade on the open market were discontinued in 1934. The three grades now sold on the open market are 61 octane and below, 63–66 octane, and 72–74 octane.

Octane rating and refinery prices in cents per gallon for regular-grade gasoline in Mid-Continent (group 3) area, 1931–40

Year	Average price	Octane rating	Method of rating [1]	Date rating effective	Year	Average price	Octane rating	Method of rating [1]	Date rating effective
1931	[2] 4.08	57–65	C. F. R. research	Oct. 19	1936	5.95	68–70	A. S. T. M.	Apr. 15

[1] For description of various methods of octane rating see Bureau of Mines Minerals Yearbook, 1940, p. 1000.
[2] Average price, October 19 to December 31.

The accompanying table shows the annual average price of regular-grade gasoline, the octane ratings, and dates of change from 1931, when octane numbers were first used, through 1940.

The average refinery price for the new regular-grade (72–74 octane) gasoline from April 8 to December 31 was less than that of the premium grade (above 65 octane) during most of the depression in 1932 and 1933. Although it is only about 9 octane numbers higher than the premium grade of 1932–33, the difference in the method of determining the rating would make the spread considerably more.

[1] National Petroleum News. [2] American Petroleum Institute; compiled by The Texas Co.
[3] Revised figures. [4] 67–69 octane (L–3 method) discontinued April 11; 72–74 octane (A. S. T. M. method) initiated April 8.

During the last 2 years the Bureau of Mines has used the 67–69 octane gasoline to represent price changes because of its comparability with the 68–70 octane grade that preceded it, although the 70–72 octane gasoline was the grade recognized as regular. As shown in the table of monthly gasoline prices, the price for new regular grade gasoline (72–74 octane) was 0.57 cent higher on the date of change than that for the 67–69 octane gasoline. This difference, deducted from the 8-month average price for the 72–74 octane gasoline, would make the price for the latter 4.33 cents or 0.43 cent less than the 1939 average for the 67–69 octane gasoline.

Although the trend of prices in 1939 was upward, the 1940 trend was down. The old grade declined from 4.67 cents at the beginning of the year to 4.43 cents before it was discontinued, whereas the new grade, which started at 5 cents in April and maintained that price during the summer, dropped to 4.75 cents by the end of the year. The weak prices in 1940 can be attributed principally to the large stocks of motor fuel accumulated during the winter months.

The average service-station price for regular-grade gasoline (ex tax) dropped to 12.75 cents—only 0.34 cent above the depression low of 12.41 cents in 1933 and 0.56 cent lower than the 1939 average. From the 13.53-cent price on January 1 the trend was downward to 12.09 cents on December 1. By December 31, however, the average price had recovered to 12.17 cents.

In general, price changes were largest in the Rocky Mountain and Southeastern areas. The price at Helena, Mont., changed from 18.5 cents (ex tax) to 13—a decrease of 5.5 cents from January 1 to December 31—while at Cheyenne, Wyo., there was a decrease of 5 cents—from 15 to 10 cents.

The drop in the average price (ex tax) in the Rocky Mountain areas from 16.66 cents on January 1, 1940, to 13.55 cents on January 1, 1941, brought the January 1, 1941, average for the area 0.34 cent under the average of 13.89 cents prevailing in the Pacific Coast territory. The latter price represented a decline of 1.33 cents in the Pacific Coast area from 15.22-cent average on January 1, 1940. The cost of gasoline was lowest in the Atlantic and New England States, the average price being 10.50 cents on January 1, 1941.

The highest price paid by motorists for gasoline on January 1, 1941, was 23.6 cents (including 6.6 cents tax) at Twin Falls, Idaho. Knoxville, Tenn., ranked second with a price of 23.0 cents, including taxes of 8.5 cents. Syracuse (N. Y.) motorists paid the least for gasoline—13.2 cents, including 5.5 cents tax. This city was followed, in turn, by Boston, Mass., with 13.7 cents and Hartford with 14.0 cents; both included 4.5 cents tax.

The increase in the Federal tax on gasoline from 1 cent a gallon to 1½ cents on July 1 was the most important legislation of the year as regards the cost of gasoline to motorists. The only change in State taxes occurred in Minnesota, where payment of the 1-cent-a-gallon emergency gasoline tax ceased September 1, reducing the tax rate from 4 cents to 3.

In 1940 Idaho, Nevada, North Dakota, and South Dakota approved diversion prohibition amendments to their constitutions; a total of 11 States now forbid the diversion of gasoline-tax receipts to uses other than for highway purposes.

Aviation gasoline.—The production of finished and unfinished aviation gasoline in 1940 was 14,736,000 barrels. Comparable data are available for only the last 3 months of 1939, but it is believed that the 1940 total represented a gain of 40 percent. Transfers of low-octane material to regular-grade gasoline in 1940 were 723,000 barrels, exports were 4,649,000 barrels (including 1,203,000 barrels of antiknock compounds), and 6,658,000 barrels were domestic demand. Preliminary figures indicate that 2,259,000 barrels were consumed during the year by civilian aircraft, 1,797,000 barrels by 448 commercial planes, and 462,000 by 16,903 private planes, leaving about 4 million barrels for military purchases and miscellaneous consumption. Stocks of aviation gasoline on December 31, 1940, totaled 6,354,000 barrels compared with 3,648,000 barrels on hand the first of the year.

Comparative analyses of statistics for aviation gasoline in 1940, by months [1]

Domestic demand	504	397	457	761	362	641	741	371	602	701	612	509	6,658

[1] First data compiled were for October 1939; the production figures in thousands of barrels for October, November, and December 1939 were respectively, 981, 845, and 1,048; transfers, none; exports of antiknock compounds, none, the figures not being available but believed negligible; other exports, 287, 274, and 372; stocks, 3,386, 3,490, and 3,648; domestic demand, 234, 467, and 518. Data for 1939–40 are included in other tables of this report.

Exports of aviation gasoline, including antiknock compounds, amounted to 4,649,000 barrels in 1940. This is higher than the 1939 total (4,234,000 barrels) but the figures are not comparable as data on exports of antiknock compounds were not available before January 1, 1940. Up to the time of its collapse France led in the receipts of this product. Shipments to France were 514,000 barrels in the first 6 months of the year compared with 504,000 barrels shipped to the United Kingdom in the same period. The most important shipments for the year were United Kingdom 1,525,000 barrels, Netherlands Indies 578,000, Japan 528,000, and France 514,000.

Prices for aviation gasoline at the beginning of the year ranged from 14.2 cents a gallon (ex tax) at Kansas City, Mo., to 22.5 cents at Helena, Mont. Prices in the Ohio territory at the beginning of the year were 16, 17, and 18 cents, respectively, for 74-, 80-, and 87-octane gasoline. These prices dropped one-half cent during the year, and on September 1 a new grade was added at 14.5 cents as well as a 100-octane grade at 24.5 cents.

Stocks.—Motor-fuel stocks exceeded all records in 1940; finished and unfinished gasoline inventories amounted to 103,710,000 barrels on March 31, or 16,589,000 barrels more than on the same date in 1939. Refineries had not adjusted their operations to meet the growing demand for heating oil when they encountered a 25-percent increase over the previous year brought on by the severe weather in the early part of 1940. Heavy runs to stills to meet this demand for heating oil resulted in a rapid accumulation of gasoline. Only after drastic readjustments in operations whereby the yields of gasoline were reduced severely did adjustment of motor-fuel stocks to a normal ratio begin.

At the end of 1939 inventories of finished and unfinished gasoline totaled 82,865,000 barrels, whereas at the end of 1940, despite the rapid rise during the first few months of the year, they were only 84,409,000 barrels. The latter figure represented 55.2 days' supply compared with 60.2 days' supply at the end of 1939. If these figures are adjusted for stocks of aviation fuel accumulated for defense purposes the days' supply decreased from 57.5 at the end of 1939 to 51.0 at the end of 1940, which is even less than the 53.3 at the end of 1938.

Days' supply of motor fuel on hand in the United States at end of month, 1938–40

Month	1938			1939 [2]			1940 [3]

[1] Stocks divided by the daily average total demand (domestic demand plus exports) for succeeding month.
[2] Revised figures.
[3] Subject to revision.

More than half of the 1,544,000-barrel gain in finished and unfinished inventories from December 31, 1939, to December 31, 1940, is attributable to an increase in unfinished stocks from 5,564,000 barrels to 6,466,000. Only 642,000 barrels more of finished gasoline was available at the end of the year than at the beginning, the respective quantities being 77,301,000 and 77,943,000 barrels. The greatest expansion occurred in the Indiana, Illinois, Kentucky, etc., district, where stocks (finished and unfinished) of 15,883,000 barrels at the end of the year were 2,262,000 barrels higher than the 13,621,000 available at the beginning of the year. The Louisiana Gulf Coast district increase of 501,000 barrels (more than 20 percent) to a total of 2,941,000 compared with the 2,440,000 barrels available on December 31, 1939. Although the 503,000-barrel decrease in Texas Gulf Coast stocks, which dropped from 14,936,000 barrels to 14,433,000, was the greatest, finished stocks in California were reduced from 16,121,000 barrels to 14,927,000. A 680,000-barrel increase (66 percent) in unfinished stocks, however, partly offset this decline, so that the net reduction from 17,153,000 barrels to 16,639,000 was only 514,000 barrels.

Stocks of gasoline in the United States in 1940, by districts and months [1]

[1] Subject to revision.

[2] Includes all stocks of finished gasoline at refineries, bulk terminals, and pipe lines.

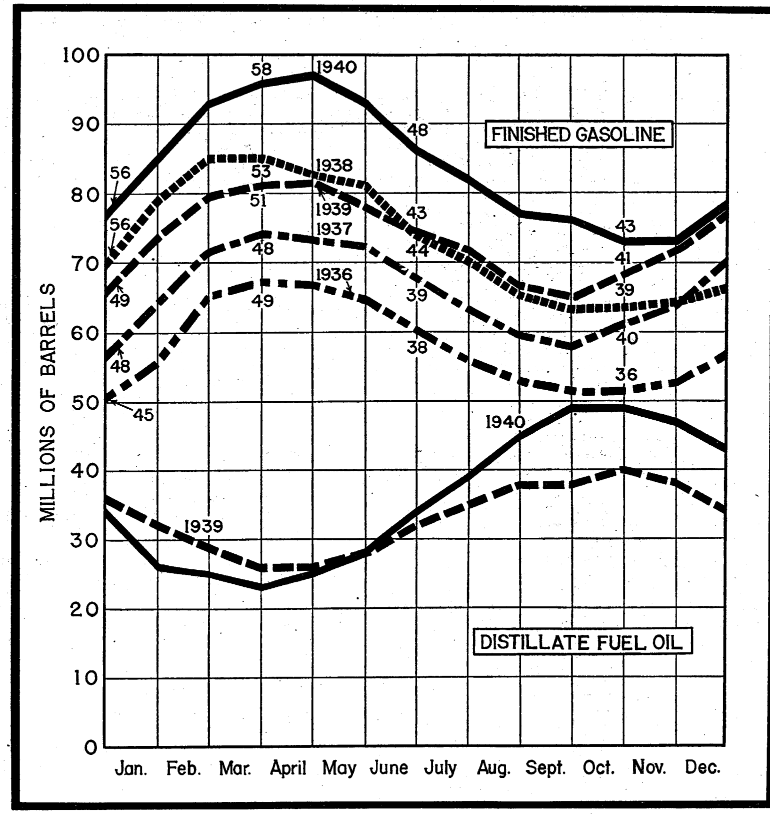

FIGURE 9.—Stocks of finished gasoline in the United States, 1936–40, by months, with figures representing days' supply at certain periods; also stocks of distillate fuel oil, 1939–40, by months.

Figure 9, showing the monthly figures for finished gasoline stocks in millions of barrels from January 1, 1936, to December 31, 1940, indicates how much more rapidly stocks in storage increased in the early part of 1940 than in normal years. This chart also shows the equivalent days' supply for certain periods. The figures for days' supply on the chart represent the quantity of finished gasoline on hand at the end of the month divided by the total demand for the succeeding month.

Figure 9 also shows the stocks of distillate fuel oil for 1939–40, to stress the contrast in seasonal variations in stocks of the two products. This chart shows further the unusual situation in heating oil, the stocks of which were 9,222,000 barrels higher at the end of 1940 than at the end of 1939, whereas the demand to be met in the succeeding month was 1,418,000 barrels less.

Production and consumption by States.—Texas, furnishing 31 percent, led in the production of gasoline. Percentages for the next important States were California, 13; Pennsylvania, 8; and Indiana and Illinois, 7 each.

New York's lead in consumption was reduced to only 0.2 percent in 1940 (see fig. 10). The percentage consumption of the principal States was as follows: New York, 8.2; California, 8.0; Pennsylvania, 6.5; Illinois, 6.3; Ohio, 6.1; and Texas, 5.9.

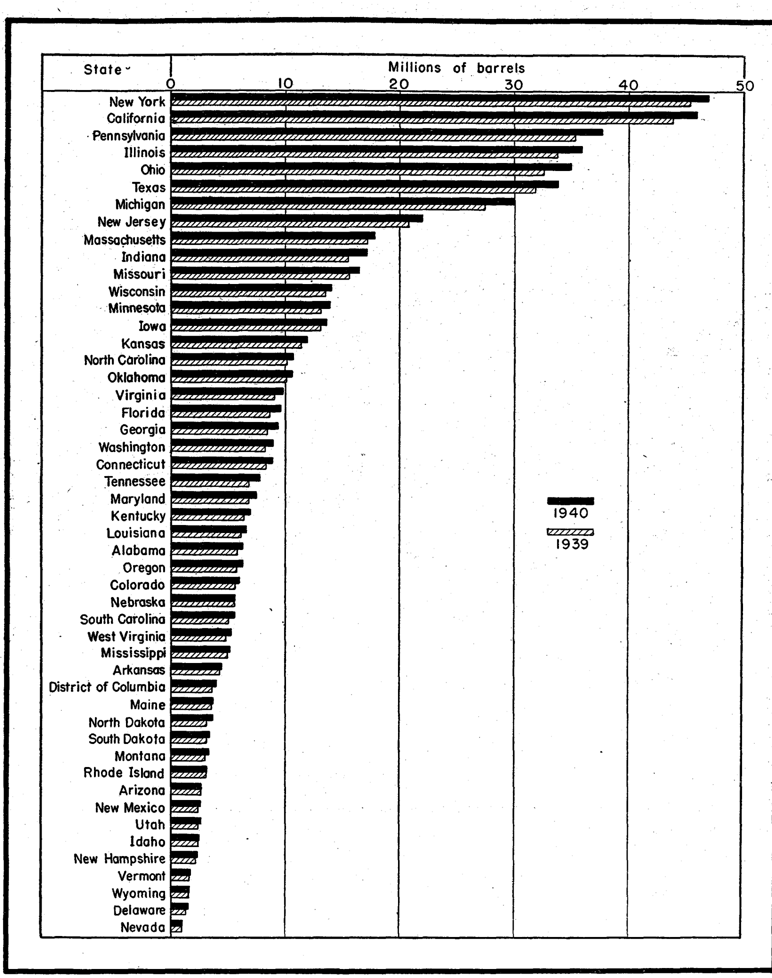

FIGURE 10.—Consumption of gasoline in the United States, 1939–40, by States.

Distribution.—Transportation of motor fuel by pipe line increased from 94,708,000 barrels in 1939 to 96,657,000 in 1940; this indicates a gain of only 2 percent, but actually the increase was much larger, as intercompany deliveries were eliminated beginning January 1, 1940. Water-borne shipments from California to the East coast increased from 3,665,000 barrels in 1939 to 3,966,000 in 1940 and those from the Gulf coast to the East coast from 114,633,000 barrels to 119,142,000. Domestic shipments on the Mississippi River and its tributaries increased from 51,808,000 barrels in 1938 to 59,183,000, in 1939.

KEROSENE AND RANGE OIL

The domestic demand for kerosene mounted sharply to a new record in 1940, but the export market, reflecting the general interruption of foreign trade in many countries, dropped to approximately a third of the 1939 volume. Domestic requirements for kerosene increased from 60,503,000 barrels in 1939 to 68,776,000 in 1940—a gain of 14 percent, or double the rate of expansion in 1939 over 1938; exports declined from 8,241,000 barrels in 1939 to 3,374,000 in 1940, an unprecedented "low." Total requirements of kerosene for both domestic and foreign markets increased from 68,744,000 barrels in 1939 to 72,150,000 in 1940—a 5-percent gain.

[1] Subject to revision.
[2] Figures not available.

On account of the 5-percent increase in crude runs to stills in 1940 and a higher yield of kerosene, refiners not only could meet the increased demand for kerosene but also added to the quantities held in storage during the year. The output of kerosene increased from 68,521,000 barrels in 1939 to 73,882,000 in 1940— an 8-percent gain. Most of the higher production can be attributed to the larger volume of crude runs; however, the improved yield of kerosene (5.7 percent in 1940 compared with 5.5 in 1939) was also a factor.

Stocks of kerosene, which declined in 1939 compared with 1938, expanded noticeably in 1940. Kerosene held in storage at the end of 1940—9,512,000 barrels—was 26 percent above the inventory at the close of 1939. Even with the increased demand, oil companies built up their stocks to a 51 days' supply at the 1940 rate of domestic consumption compared with a 46 days' supply for 1939. Outstanding gains in stocks of kerosene in 1940 were reported for the East Coast and Texas Gulf Coast refinery districts, where the increments were 84 and 65 percent, respectively.

The additions to kerosene storage in the Texas Inland, Arkansas and Louisiana Inland, Rocky Mountain, and California refinery districts were relatively unimportant, and actual declines in 1940 compared with 1939 were indicated for the Appalachian; Indiana, Illinois, Kentucky, etc.; Oklahoma-Kansas and Missouri; and Louisiana Gulf Coast areas.

War conditions plus the closing of many trade routes by blockades, reduced exports of kerosene in 1940 to 3,374,000 barrels compared with 8,241,000 in 1939. Incidentally, the 1940 quantity is about half the previous "low" for kerosene exports, of 6,651,000 barrels established in 1935. Little kerosene is imported into the United States, and the 204,000 barrels received in 1940 is the first consignment to be reported since 1932, when 71,000 barrels entered; the 1940 imports originated in Mexico and were received at the port of New York.

[1] Figures for 1940 by States not yet available.

Beginning in 1937, the Bureau of Mines has conducted an annual survey covering the distribution of sales of kerosene by States and principal uses. Deliveries of kerosene reported by oil companies for 1939 totaled 59,767,000 barrels compared with sales of 55,570,000 barrels in 1938—an 8-percent gain. The quantity in 1939 was divided as follows: Sold as range oil, 33,841,000 barrels compared with 30,805,000 in 1938; tractor fuel, 4,346,000 barrels in 1939 (3,955,-000 in 1938), and all other uses, 21,580,000 barrels in 1939 (20,810,000 in 1938). The proportion of kerosene sales reported as range fuel increased from 55 percent of the total in 1938 to 57 percent in 1939. Some light fuel oil (Grade 1) is also sold for range fuel in addition to kerosene delivered for the same purpose. Light fuel oil sold for this particular use totaled 3,220,000 barrels in 1939 and 2,902,000 in 1938. The demand for range oil in 1939, including both kerosene and light fuel oil, was 37,061,000 barrels compared with 33,707,000 in 1938.

Prices of kerosene in 1940 remained practically unchanged compared with 1939 quotations. The average price of 41°–43° gravity water-white kerosene at refineries in Oklahoma moved fractionally upward from 3.97 cents a gallon for 1939 to an average of 4.04 cents for 1940. A seasonal rise brought the Oklahoma refinery price from a monthly average of 3.88 cents a gallon for November 1939 to a peak of 4.13 cents a gallon for May 1940; from that point quotations declined slowly throughout the summer and fell to the low price for the year—3.94 cents a gallon—in November. The increasing demand for kerosene forced the price up to 3.99 cents a gallon in the final month of 1940.

The tank-wagon price of kerosene at Chicago—10 cents a gallon, effective October 8, 1938—remained unchanged throughout 1939 and 1940.

FUEL OIL

The demand for fuel oil in 1939—a record up to that time—was far surpassed in 1940. A gain in exports and a decline in imports of fuel oil in 1939 were just reversed in 1940 when, owing to adverse international trade conditions, exports dropped sharply below the record volume of 1939 while imports, because of an unusual demand for heating oils in the opening months of the year and an expanding industrial program, were double the quantity received from foreign sources in 1939. The running of more crude to stills and a greater percentage yield brought about increased production of fuel oil in 1940 compared with 1939. A downward trend in stocks in 1939, which resulted in a shrinkage of 12 million barrels in the fuel-oil inventory for that year, was checked in 1940 when 6 million barrels were added to storage.

Until recently all transfers of crude petroleum to the fuel-oil account in refinery districts east of California were considered to be light grades and therefore were embodied in the statistics covering distillate fuel oil. As some authorities maintain that some of these transfers at least are made up of heavier crudes, changes in the 1939 and 1940 transfer items have become necessary. Crude oil used as fuel on pipe lines is considered, under present accounting methods, to be light fuel oil and therefore remains in the distillate fuel-oil account as a transfer, and crudes used as fuel on leases and for general industrial purposes is counted as a transfer to the residual fuel-oil supply. These changes for 1939 and 1940 do not alter the total domestic demand for fuel oil, as the quantity representing crude oil used as fuel on leases and for general industrial purposes is merely deducted from the demand for distillate fuel oil and added to the requirements for residual fuel oil. In the 1939 statistics 3,750,000 barrels of crude oil, formerly part of transfers east of California, were taken from distillate fuel oil and added to the residual fuel oil. The corresponding item for 1940 is 3,629,000 barrels, representing a decline in the demand for distillate and a similar increase in the deliveries of residual grades.

Expanding requirements for industrial fuel during the year and a heavy heating-oil load in the first quarter brought the domestic demand for fuel oil to a new record volume of 500,103,000 barrels in 1940—a 9-percent gain over the 1939 total of 458,461,000 barrels. The demand for distillate or light fuel oil, which constitutes about one-third of total fuel-oil deliveries and which is largely used for heating purposes, rose from 134,973,000 barrels in 1939 to 160,819,000 in 1940 or 19 percent. This outstanding gain in deliveries of distillate fuel oil in 1940 was the result of prolonged cold weather in the opening months of the year, which caused a brisk market for heating oils. Although residual grades make up the bulk of fuel-oil deliveries the demand for these heavier oils depends largely on prevailing economic conditions. Accelerated industrial activities in 1940 forced the demand for residual fuel oils to a new peak of 339,284,000 barrels, a 5-percent gain over 1939 requirements of 323,488,000 barrels.

An examination of the fuel-oil demand by quarters shows that the market for light distillate grades was 26 percent higher in the first 3 months of 1940 than in the same period of 1939 due to the unusual requirements for heating oils. During the early months of 1940 the oil companies were called upon to supply unprecedented quantities of the light grades, and for January 1940 the demand actually reached an outstanding increase of 36 percent above the same month in 1939. The turn-over of distillate fuel oil was relatively high throughout 1940, being 16 percent above the 1939 demand in the second quarter, 8 percent up in the third quarter, and 20 percent up in the final 3 months. Quarterly totals pertaining to the residual fuel-oil demand in 1940 do not reveal such marked increases as are found in the distillate fuel-oil statistics. There was a 10-percent gain in the first quarter of 1940 compared with 1939, when the unusual demand for heavy heating oils inflated the total. Gains in deliveries were nominal in the second and fourth quarters of 1940 over similar periods of 1939; however, the demand in the third quarter of 1940 was slightly below that in the corresponding months of the previous year.

[1] Includes distillate fuel oil, residual fuel oil, and some crude oil burned as fuel.
[2] Figures for 1940 not yet available.
[3] Figures not available.

Data on the final distribution of fuel oil in 1940 by principal uses will not become available until the Bureau of Mines completes its annual survey of sales, made in cooperation with the oil companies. Preliminary figures released by the Interstate Commerce Commission covering fuel-oil and Diesel-fuel purchases by class I railroads indicate a total of 67,131,000 barrels in 1940 compared with 62,235,000 in 1939. Monthly statistics published by the Bureau of Foreign and Domestic Commerce, United States Department of Commerce, show that bunker loadings on vessels engaged in foreign trade were 32,925,000 barrels in 1940 compared with 35,711,000 in 1939. The fuel oil used by coastwise vessels in 1940 may raise the total to approximately 80,000,000 barrels for 1940 or slightly above the 1939 item of 79,254,000 barrels. Fuel oil used by public-utility electric-power plants declined from 17,423,000 barrels in 1939 to 16,724,000 in 1940, according to reports of the Federal Power Commission. It is believed that when the quantity of fuel oil required by the gas-manufacturing industry in 1940 becomes known through the American Gas Association the combined total for the electric-power and gas-manufacturing utilities will show little change from the 1939 demand of 32,039,000 barrels. Preliminary estimates for other principal fuel-oil demands in 1940 are as follows: Smelters, mines, and manufacturing industries, 73,000,000 barrels; heating oils, 162,000,000; United States Navy, Army, and Coast Guard, 14,500,000; and oil-company fuel, 52,900,000.

Figure 11 gives a graphic representation of fuel-oil deliveries in 1931–40 by principal uses. The columns for 1940 are based upon estimated items. Both light and heavy fuel oils are included, with kerosene sold as range oil.

Exports and shipments of fuel oil to noncontiguous Territories of the United States, which have mounted steadily in recent years to

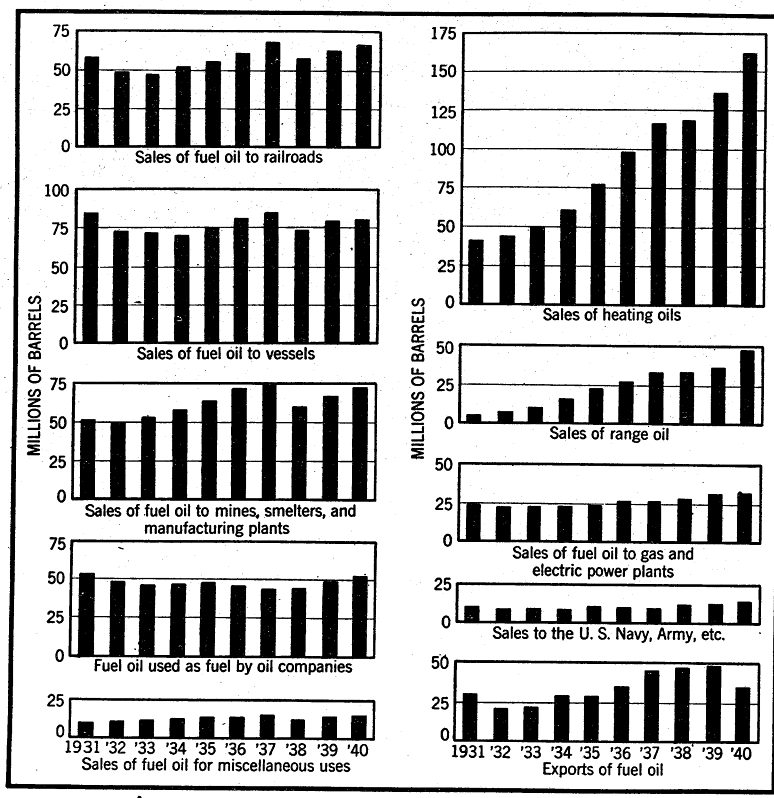

FIGURE 11.—Sales of fuel oil and range oil in the United States, 1931–40, by uses.

record volumes for both 1938 and 1939, declined sharply (29 percent) in 1940 to 35,249,000 barrels compared with 49,505,000 in 1939. This shrinkage in foreign requirements for American fuel oil is directly attributable to chaotic trade conditions in various war areas and the blockading of European ports. The loss in the fuel-oil export trade in 1940 was more pronounced for the distillate grades than for residual fuel oil. Overseas takings of light fuel oil declined from 32,020,000 barrels in 1939 to 19,172,000 in 1940, a 40-percent drop, but the foreign demand for heavy fuel oil was off only 8 percent or from 17,485,000 barrels in 1939 to 16,077,000 in 1940. Greatly expanded shipment of residual fuel oil to the noncontiguous Territories of the United States was a counterbalancing factor that held the 1940 foreign trade in heavy fuel oil near the level reported for 1939.

[1] Figures represent crude oil used as fuel on pipe lines.
[2] Subject to revision.
[3] Crude oil used on leases and for general industrial purposes credited to residual fuel oil.
[4] Figures not available.

A 7-percent increase in production of fuel oil from 467,690,000 barrels in 1939 to 499,522,000 in 1940 is mainly the result of 5 percent greater crude runs to stills and in a lesser degree to a small net gain in the percentage yields of fuel oil in 1940 over 1939. Most of the expansion in fuel-oil production during 1940 is found in the lighter grades, of which the percentage yield increased from 13.1 in 1939 to 14.2 in 1940. The output of distillate fuel oil advanced from 161,746,000 barrels in 1939 to 183,304,000 in 1940, a 13-percent increment owing to the pressure for light heating oils in the early months of 1940 and the effort to build up depleted stocks for the 1940–41 heating season. The percentage yields of both gasoline and residual fuel oil were lowered in 1940 to increase the production of the desired light-burning oils. As the percentage yield of residual fuel oil declined slightly in 1940, the small gain (3 percent) in the output—from 305,944,000 barrels in 1939 to 316,218,000—must be credited entirely to increased volume of crude runs by refineries.

The unprecedented demand for light fuel oil in areas east of California forced refiners to increase their production of distillate oil from 131,723,000 barrels in 1939 to 154,886,000 in 1940, an 18-percent gain, whereas in California, where stocks were increasing and the domestic demand remained at the same level in 1940 as in 1939, production dropped from 30,023,000 barrels in 1939 to 28,418,000 in 1940, or 5 percent. The bulk of the distillate fuel oil used for heating in eastern and north-central areas originates at refineries in the East Coast, Indiana, Illinois, Kentucky, etc., and Texas Gulf Coast refinery districts, and here, owing to the heavy demand, the production of distillate fuel oil increased 30, 26, and 14 percent, respectively, in 1940 compared with 1939. Large percentage gains were also made in production of light fuel oil in the Appalachian and Rocky Mountain refinery districts; however, the quantities involved were relatively unimportant. The Texas Inland, Louisiana Gulf Coast, and Arkansas and Louisiana Inland districts produced less distillate fuel oil in 1940 than in 1939. The production of residual fuel oil in areas east of California showed little gain (3 percent) in 1940 over 1939, as refiners there, curtailing the yields of both gasoline and heavy fuel oil, endeavored to satisfy the unusual demand for the light grades of fuel oil. An outstanding exception appears in the Indiana-Illinois, Kentucky, etc., refinery district, where with greatly increased production of crude oil and with runs to stills 18 percent above the 1939 level, the production of residual fuel oil increased 31 percent in 1940 compared with 1939. Substantial gains over 1939 in output of residual fuel oil were also made in the Appalachian and Rocky Mountain districts in 1940, but the quantities for both years were small. In other refinery areas east of California the production of heavy fuel oils gained but little in 1940, and actual declines were reported for the East Coast, Texas Inland, and Louisiana Gulf Coast districts. A downward trend in the production of residual fuel oil in California was reversed, and the output increased 3 percent (from 80,982,000 barrels in 1939 to 83,693,000 in 1940).

Non-gasoline-bearing crudes burned as oil fuel are entered as "transfers" and constitute an additional (though minor) as well as a diminishing source of supply at present. Transfers of crude petroleum to the fuel-oil account decreased from 12,409,000 barrels in 1939 to 10,275,000 in 1940—a shrinkage of 17 percent. Owing to lack of active demand, light crude transferred to distillate fuel oil in the California marketing area has dropped from 623,000 barrels in 1938 to 616,000 in 1939 and to 279,000 in 1940. Transfers of heavy crude oil to residual fuel in California declined from 10,037,000 barrels in 1938 to 5,918,000 in 1939 and to 4,070,000 in 1940 in spite of a rising domestic demand and diminishing stocks in 1939 compared to 1940, probably largely because of the lack of a price incentive and the scarcity of heavy crudes suitable for fuel purposes. Other light crudes, classed as transfers to distillate fuel oil, which under present accounting methods represent quantities used as fuel by pipe lines in areas east of California, totaled 2,125,000 barrels in 1939 and 2,297,000 in 1940, while shifts of crude petroleum to residual fuel oil, covering fuel used on leases and for general industrial purposes in these same areas, dropped from 3,750,000 barrels in 1939 to 3,629,000 in 1940.

Importations of fuel oils more than doubled in 1940 compared with 1939 owing to brisk domestic demand, a favorable duty rate of 10½ cents a barrel, and abnormally high tanker charges on coastwise shipments of domestic fuel oils from the Gulf to East Coast areas. Venezuela and Netherlands West Indies were the chief sources of imported fuel oils, which totaled 31,791,000 barrels in 1940 compared with 15,680,000 in 1939. Imports of fuel oil for some time have been limited largely to heavy or residual grades brought in under bond for the supply of vessels; however, with the ships' bunkering business on a decline and an active domestic market, this custom was reversed in 1940, so that the larger share of fuel-oil imports was entered as duty-paid and was intended for domestic consumption. Fuel oil imported in bond declined from 14,751,000 barrels in 1939 to 10,775,000 in 1940, while the duty-paid quantity increased from 929,000 barrels in 1939 to 21,016,000 in 1940. No distillate fuel oil of foreign origin was entered in 1938 or 1939; however, 3,333,000 barrels were received in 1940, consisting of 257,000 barrels imported in bond and 3,076,000 barrels duty-paid. Imported residual fuel oil entering bonded storage declined from 14,751,000 barrels in 1939 to 10,518,000 in 1940, a 29-percent shrinkage. Heavy fuel oils paying duty and intended for domestic use jumped from 929,000 barrels in 1939 to 17,940,000 in 1940, or almost to the record volume of 19,398,000 received in 1932.

A loss of 14 million barrels in exports of fuel oil in 1940 was partly absorbed in a rising domestic market, but a portion of the decline in foreign trade appears as a 6-million-barrel gain in stocks of fuel oil during the year. The relation between the loss in exports of fuel oil and the gain in stocks is obvious when it is noted that virtually all of the decline (about 13 million barrels) in exports was confined to distillate grades and that these light fuel oils, failing to find a market, went to storage; as exports of residuals showed only a small decline (about 1 million barrels) there was no excess beyond what could be sold in an active domestic market. Total fuel-oil stocks of 126,008,000 barrels held at the end of 1939 increased to 132,244,000 on December 31, 1940. The increment in stocks in 1940 is net, however, as distillate grades increased by about 9 million barrels from 33,718,000 in 1939 to 42,940,000 in 1940, while residual fuel oil in storage declined from 92,290,000 to 89,304,000.

[1] Includes distillate fuel oil, residual fuel oil, and some crude oil burned as fuel.
[2] Figures for 1940 not yet available.

A regional analysis of fuel-oil stocks reveals that practically all the increase in distillate grades was confined to refinery districts east of California, where inventories expanded from 24,056,000 barrels in 1939 to 32,875,000. Furthermore, most of the gains in stocks of distillate in eastern areas occurred in the East Coast district, where quantities in storage increased 53 percent from 10,381,000 barrels in 1939 to 15,922,000. Holdings of light fuel oil also increased noticeably in the Gulf Coast refinery districts supply areas for the East Coast and export markets—from 5,608,000 barrels in 1939 to 8,406,000 (50-percent increase) for the Texas Gulf district and from 935,000 barrels to 1,593,000 (70-percent increase) for the Louisiana Gulf district. Gains in stocks of distillate in other eastern areas were unimportant, and actual losses were reported for the Indiana-Illinois, Kentucky, etc.; Oklahoma, Kansas, and Missouri; and Texas Inland refinery districts. Although there was a net loss in the combined domestic and export markets for distillate fuel oil in California, the addition to stocks was only nominal, as both production and transfers of light crude to the fuel-oil account also declined during the year.

An increase of 4 million barrels in stocks of residual fuel oil in refinery districts east of California was offset by a decline of 7 million barrels in the California area, resulting in a net shrinkage in national totals. Heavy fuel oils held in storage east of California rose from 25,397,000 barrels in 1939 to 29,412,000. Most of this net gain in eastern markets was in the East Coast refinery district, where inventories of heavy fuel oils increased from 7,976,000 barrels in 1939 to 10,446,000. The Gulf areas also reported high percentage gains in stocks of residual oil; quantities in storage in the Texas Gulf Coast increased from 6,579,000 barrels to 8,486,000, and those held in the Louisiana Gulf Coast expanded from 1,213,000 barrels to 2,306,000. All other refinery districts east of California showed losses in heavy-fuel-oil stocks, except the Rocky Mountain area, where quantities held are relatively small. Although the production of residual fuel oil increased in the California district the added supply was not adequate to meet an increased domestic demand plus exports maintained at the 1939 level, so a 7-million-barrel draft on stocks became necessary, and the inventory declined from 66,893,000 barrels in 1939 to 59,892,000 in 1940. In recent years dwindling transfers of non-gasoline-bearing crude to the residual-fuel-oil supply, caused by the drop in production in California of crude of that type, were a secondary reason for the greater use of heavy fuels from storage.

The movement of residual fuel oil from California to Gulf and East Coast ports, which made a marked rise from 338,000 barrels in 1938 to 2,289,000 in 1939, dwindled to 566,000 in 1940, probably owing partly to the improved demand for heavy fuel oils on the West Coast. Shipments of distillate fuel oil from California to eastern markets, although small in volume, increased from 633,000 barrels in 1939 to 721,000.

The heavy demand for distillate fuel oil in the East Coast area in 1940 was responsible for the sharp rise in tanker shipments from the Gulf; the movement increased from 34,701,000 barrels to 44,429,000 a 28-percent gain. The eastern market for residual grades, depending more on industrial activities than on the demand for heating oils, did not expand proportionately; consequently boat shipments from the Gulf advanced only moderately from 65,446,000 barrels to 67,422,000, a 3-percent gain.

Gulf to North Atlantic Coast tanker rates, which are reflected in fuel-oil prices for eastern areas, advanced sharply from an average of 27.8 cents a barrel for clean boats in 1939 to 52.6 cents in 1940, and charges for carrying residual grades moved upward from an average of 25.8 cents a barrel in 1939 to 46.9 cents in 1940, owing to a general scarcity of tankers and removal of boats from the Gulf to East Coast run. Barrel rates for distillate grades on this route, which reached an average of 62.6 cents in December 1939, continued upward to a 72-cent average in February 1940, influenced by the heavy movement of light burning oils to meet the unusual demand in eastern markets. The desire of the oil companies to prevent a shortage of distillate oils in the North Atlantic area for the 1940–41 heating season maintained the traffic from the Gulf to North Atlantic points well into the middle of 1940, and because of this demand for boats the June 1940 rate averaged 55.5 cents a barrel compared with 19.3 cents for June 1939. The slack season "low" of 20.3 cents average a barrel was not reached until September 1940 and was somewhat above the 1939 "low" of 16.9 cents reported for August of the latter year. The removal of more tankers from oil-company control in the final months of the year, coming with the opening of the heating season, forced up tanker prices for clean boats on the Gulf to North Atlantic run to a top quotation of 80 cents a barrel in December 1940—a monthly average of 79 cents compared with 62.2 cents for December 1939. The Gulf to North Atlantic rate on "dirty" boats used for transporting residual fuel oil continued to increase from the 1939 peak of 52.9 cents average a barrel reached in December to 63.8 cents for March 1940. There was a small decline in April; however, the May average of 69.5 cents a barrel was the high price for 1940. Quotations declined from that point to 20 cents in September, the lowest average monthly price of the year, then moved upward again as the winter demand developed, until an average price of 61.2 cents a barrel was asked in December 1940.

A rising demand, depleted stocks, and increased tanker rates were responsible for higher fuel-oil prices in some areas in 1940 compared with 1939. The Oklahoma refinery price of No. 2 straw fuel oil—a representative domestic heating grade—averaged 3.47 cents a gallon in 1940 and 3.37 cents in 1939. Bunker C at New York harbor averaged $1.34 a barrel in 1940 compared with $1.04 in 1939, while the Gulf price of the same product advanced 7 cents a barrel over the 1939 average to 90 cents in 1940. There was very little change in the average price for Bunker C on the Pacific coast, and the Los Angeles quotation was 82 cents a barrel in 1940, only 1 cent over the 1939 average. Diesel-fuel prices for ships' bunkers were also correspondingly higher in 1940.

The Oklahoma refinery price for No. 2 straw fuel oil went to an average of 3.56 cents a gallon in February 1940, the high quotation of the year, compared with the 1939 maximum of 3.49, which came in January of that year. As the spring heating season of 1940 drew to a close the Oklahoma refinery quotation declined to 3.46 cents in March and to 3.44 in April and remained at that slack-season level compared with 3.31 cents a gallon in the summer of 1939, until the fall demand brought the price to an average of 3.48 cents in October and to 3.54 in December 1940.

Bunker C (including No. 6) fuel-oil prices at New York harbor, which are influenced by Gulf-to-North Atlantic tanker rates (the latter were higher in 1940 than in 1939) averaged $1.34 a barrel in 1940 compared with $1.04 in 1939. Advancing demand and the shortage of supplies forced the price quoted by some dealers at New York for heavy fuel oils from $1.15 a barrel to $1.50 late in December 1939. The new price was not adopted immediately by all suppliers, so that the average for January 1940 remained at $1.42 a barrel; however, it became fixed at $1.50 in February and March. There was a tendency toward a price cut to $1.35 a barrel in the middle of April as the question of supplies became easier; however, it was June before the lower quotation became generally established. A slackened demand and lower tanker rates brought about further price cuts in July, until an average of $1.20 a barrel for Bunker C was quoted for August, and that value held until the end of 1940. Bunker C fuel oil at Gulf ports advanced from an average of 83 cents a barrel in 1939 to 90 cents in 1940. The price of 95 cents in effect late in 1939 held until February 1940, when the quotations of some dealers reached $1.05 a barrel in response to the pressure for heavy fuel oils on the Atlantic coast. March initiated slightly lower prices, and by August quotations had settled to an average of 85 cents a barrel, which lasted for the remainder of the year. The average price of Bunker C at Los Angeles—82 cents a barrel in 1940—was only slightly above the 1939 average—81 cents. The price of 82 cents in January 1940 increased to 88 for the spring months, followed by some slackening to an average price of 83 cents a barrel in June, then a return to 88 cents in August and a gradual decline to 68 cents average in November, the low price of the year. A slight rise in December 1940 made the monthly average 70 cents a barrel.

[1] National Petroleum News.

Representative retail prices for heating oils are compiled by the Bureau of Labor Statistics, United States Department of Labor. The consumers' price of No. 2 grade at Chicago averaged 7.73 cents a gallon as of March 15, 1940, compared with 7.44 cents on the same date in 1939. Second- and third-quarter quotations for this grade averaged 7.30 cents a gallon, or lower than the corresponding prices of 7.44 cents in the second quarter and 7.62 cents in the third quarter of 1939. The December 15, 1940, price of 7.73 cents a gallon was about one-fourth cent above the average in December 1939. The average price of No. 2 heating oil at New York was reported at 7.14 cents a gallon for March 15, 1940, compared with 6.22 cents a year previous. Quotations for this grade declined to 6.73 cents on June 15, 1940, and to 6.12 cents on September 15, corresponding to average prices of 5.87 and 6.38 cents a gallon, respectively, in June and September 1939. The December 15, 1940, average price of 6.94 cents a gallon compares with 6.69 cents in December 1939.

LUBRICATING OIL

Not only was the substantial gain in domestic consumption of lubricating oil in 1939 maintained in 1940, but also the 24,657,000 barrels in the latter year constituted a new record that was 4 percent higher than the 1939 record of 23,713,000 barrels. Production also increased, rising to 36,765,000 barrels from 35,036,000 in 1939, and exports declined from 11,881,000 barrels to 10,494,000, resulting in a rise in stocks from 7,142,000 to 8,767,000 barrels.

[1] Subject to revision.

The usual correlation between the consumption of industrial lubricating oil and business activity is reflected in the table of distribution of domestic demand for lubricating oil by uses. This table shows that with the increase in business activity during 1940 the largest part of the gain in demand was in industrial consumption. The increasing mileage of automobile travel per unit of oil used is shown in only a small gain in consumption of oil by motor vehicles.

Preliminary statistics indicate that about 30,500 barrels of lubricating oil was used in commercial air transport in 1940 and about 13,600 barrels in private flying compared with 21,933 and 10,957 barrels, respectively, in 1939. The newer planes, particularly the fighting ships, which require oil that can withstand extreme conditions, have given the manufacturer of lubricants new problems. The severe demands of the last few years by both automobiles and aircraft resulted in solvent refining generally displacing the older methods. Efforts for improvement are now centering on additives that will supply qualities to the oil needed to meet the new demands.

Comparative analyses of statistics for lubricating oil in the United States, 1939–40, by months and districts

[2] Figures not available.

The Texas Gulf Coast district became the leading producer of lubricants with an output of 9,142,000 barrels, displacing the East Coast district, where the production was 8,550,000 barrels. The Texas Gulf Coast district's 24.9-percent share of the United States production is the highest proportion that this region has had and compares with 19.6 percent in 1935, the beginning of the upward trend. The 23.3-percent share of the East Coast is the lowest proportion in a long downward trend for this district. Although the 680,000 barrels produced in the Arkansas and Louisiana Inland district represents only 1.8 percent of the total for the country; it is the highest for this district and compares with only 0.1 percent in 1929. The Louisiana Gulf

Coast district, which has increased its share of production from 1.3 percent in 1932 to 4.4 percent in 1940, and the California district, which has increased its share from 6.5 percent in 1935 to 9.1 percent in 1940, established new records, both in quantity produced and in their respective shares of the national total. The Rocky Mountain district, where the proportion has declined from 1.8 percent in 1929 to 0.5 percent in 1940, now has the smallest production of any area.

Stocks of lubricating oil began to accumulate with the decline in exports during the latter half of the year and by December 31 totaled 8,767,000 barrels—the largest year-end inventory since 1931. Gains in stocks were distributed throughout all of the districts.

Average monthly refinery prices of five selected grades of lubricating oil in the United States, 1939–40, in cents per gallon [1]

[1] National Petroleum News.

The monthly trends in exports in 1940 were directly opposite from those in 1939. Whereas total exports for the year decreased from 11,881,000 barrels in 1939 to 10,494,000 in 1940, 6,624,000 barrels of the 1939 shipments were made in the latter half of the year compared with only 3,735,000 barrels in the same period in 1940. Export statistics appear in the section on Foreign Trade near the end of this chapter.

The slump in exports was reflected not only in accumulating stocks, as indicated above, but also in declines in the price of lubricating oil. After the sensational rise in 1931, prices for most grades shown in the accompanying table, were approximately the same at the end of 1940 as at the end of 1938. The one exception was the price for Pennsylvania neutral, which increased from an average of 15.20 cents a gallon in January 1939 to 31.64 cents in January 1940 and then decreased to 21.50 cents in December 1940—6.30 cents higher than the January 1939 average. At the same time the price for 600-steam-refined cylinder oil in western Pennsylvania, which averaged 8 cents a gallon during December 1938, averaged 7.61 cents in December 1940—a further reflection of the trend toward lighter oil for automobiles and the difficulty of disposing of the heavy lubricants. One company is converting its bright stocks to neutrals by cracking them.

A new process redistills the cylinder stock with kerosene. The kerosene, acting as a carrier, permits distillation to be conducted at a temperature low enough so that the lubricant is not cracked. Removal of the very viscous asphaltic material from the cylinder stock permits separation of the charge into a light and a heavy component, the specifications of which are better than the products of usual refining methods.

OTHER PRODUCTS

WAX

Domestic demand for paraffin wax established a new record in 1940 and increased to 356,653,000 pounds from 325,461,000 in 1939. In addition to the growing demand for this product in the manufacture of waxed paper and waxed cartons, paraffin waxes are being substituted for some imported waxes that are now difficut to obtain.

Exports declined from 232,664,000 pounds in 1939 to 190,065,000 in 1940. Production increased from 464,520,000 to 513,240,000 pounds, causing stocks to rise again to a normal level of 125,272,000 pounds from the unusually low level of 75,648,000 pounds at the end of 1939.

The drop in prices of wax in 1940 was almost as sharp as the increase in 1939. The price of the Pennsylvania grade of crude scale wax quoted by the Bureau of Mines declined from 6.75 cents a pound early in January to 2.85 cents at the end of the year, only one-half cent higher than the 2.33-cent price at the end of December 1938. Prices for fully refined wax decreased to a lesser extent, that of 5.6 cents for 122° to 124° on the Chicago market being only one-half cent below the high for the year but 1.6 cents above the price at the end of 1938.

According to predictions, a new emulsion process for deoiling wax, introduced during 1940, will eliminate the old sweating method. Although the process is still in the pilot-plant stage its sponsors claim that it will reduce the cost of producing wax materially.

Average monthly refinery price of 122° to 124° white crude scale wax at Pennsylvania refineries, 1936–40, in cents per pound [1]

[1] Subject to revision. [2] Less than 0.1 percent. [3] Figures not available.

tons sold in 1940 were 18,200 tons less than the 1939 demand of 1,421,700 tons. This deficiency, however, was nearly offset by an increase of 15,900 tons in exports, making the total demand for the 2 years approximately the same. The exports—302,100 tons—established a new record; Canada, the principal customer, took 181,000 tons, and Japan 58,000 tons, 35,000 in the last 2 months of the year alone.

Production of coke amounted to 1,526,600 tons compared with 1,666,400 produced in 1939. The Indiana, Illinois, Kentucky, etc., district continued to lead, supplying 62 percent of the total output.

ASPHALT AND ROAD OIL

The domestic demand for asphalt in 1940 amounted to 5,123,600 short tons—197,500 tons more than the 1939 demand. Imports nearly doubled, while exports leaped from 42,400 tons to 296,800.

The domestic demand for road oil (7,847,000 barrels) was only 1,000 barrels higher than in 1939. Production declined 99,000 barrels and stocks 78,000.

Detailed statistics on asphalt and road oil appear in the chapter on Asphalt and Related Bitumens.

STILL GAS

The production of still gas in 1940 was 272,536 million cubic feet (71,720,000 barrels)—11,176 million cubic feet higher than in 1939. Despite the tendency to use still gas for the manufacture of high-octane gasoline, the amount burned as refinery fuel reached a new peak of 246,188 million cubic feet in 1939, which, in terms of British thermal units, supplied about one-half of all the heat utilized at refineries.

The principal districts maintained their usual rank in the production of still gas; Texas Gulf Coast led, and Indiana, Illinois, Kentucky, etc., and East Coast followed in order.

Production of still gas in the United States, 1938–40, by districts

District	1938		1939		1940 [1]

MISCELLANEOUS PRODUCTS

The output of miscellaneous products in 1940 amounted to 3,202,000 barrels compared with 2,359,000 in 1939. Although the export total of 944,000 barrels for 1940 indicates a large gain over the 123,000 barrels exported in 1939 this is because exports of anti-knock compounds for the first 5 months and exports of liquefied petroleum gases, petrolatum, and greases for the entire year were included beginning January 1, 1940. Considering these reclassifications, the indicated domestic demand for 1940 also made a sizable gain over 1939.

Detailed data for 1940 by products are not available, but the 1939 figures show that liquefied petroleum gas, the first ranking product, increased in relative importance and that petrolatum, medicinal oil, and absorption oil retained second, third, and fourth places, respectively.

Production of miscellaneous oils in the United States, 1938–39, by districts and classes [1]

[Thousands of barrels]

District	Petrolatum	Absorption oil	Medicinal oil	Specialties	Liquefied petroleum gas	Other	Total
1938

WORLD PRODUCTION[2]

In spite of the disruption caused by the war in Europe the world production of petroleum was even larger in 1940 than in 1939, if numerous unofficial statistics and estimates can be considered reliable. Again a record-breaking figure was attained, and the total of 2,149,-378,000 barrels in 1940 marked a 3.4-percent increase over 1939; but the increase was due principally to the 7-percent augmented output in the United States, which accounted for 61 percent of the world total in 1939 and 63 percent in 1940. Outside the United States, with few exceptions, production declined.

The Western Hemisphere supplied 77 percent of the world output in 1939 and 78 percent in 1940. Production of crude in Venezuela, third in rank in the world, declined 10 percent from 1939 to 1940, as the interruption of normal shipping by the war blockade and the loss of European markets reduced the demand for residual fuel oil, the chief product manufactured from heavy Maracaibo crude. The production in Mexico increased 3 percent; European markets lost by the blockade were replaced by shipments to the United States. The entry into production of the Barco concession was chiefly responsible for the 18-percent increase in Colombian output of oil. In Argentina, in spite of a decline in the output of private companies, governmental enterprise (Y. P. F.), by increasing production especially in Mendoza and Salta, raised the national yield 10 percent in 1940 over 1939; but the country still depended on imports for 40 percent of its petroleum supply. In Canada, a 14-percent increase in petroleum production, chiefly in Alberta, did not reduce the dependence of the Dominion on the United States for the major part of its supply of mineral oils.

In Europe the U. S. S. R. and Rumania continued to furnish over 95 percent of the petroleum production of the Continent. In the U. S. S. R., second largest petroleum producer in the world, the output remained virtually stationary. In Rumania there was a decline of 6 percent from 1939 to 1940.

The most marked decline in the major producing countries of the world was in Iraq, where output decreased 16.5 percent from 1939 to 1940. The closing of the branch pipe line to Tripoli, Syria, after the defeat of France in June and the entry of Italy into the war in the same month suspended the westward movement of Iraq oil through the Mediterranean; and the branch pipe line to Haifa, Palestine, and the new refinery at Haifa furnished the only outlet for this crude. On the other hand, Iran increased its output slightly from 1939 to 1940. In the Netherlands Indies petroleum production was 2 percent less in 1940 than in 1939.

Of the minor producing countries Egypt showed the most marked increase—30 percent—owing to the output of the Ras Gharib field.

FOREIGN TRADE[3]

Imports.—Imports of mineral oils, crude and refined, into continental United States increased 23,856,000 barrels in 1940 over 1939. At the same time the domestic demand for all oils rose 92,324,000 barrels, whereas exports declined 58,370,000 barrels, giving an increase of 33,954,000 barrels in total demand from 1939 to 1940. As the production of crude petroleum, natural gasoline, and benzol was 91,147,000 barrels higher in 1940 than in 1939, altogether 38,116,000 barrels of all oils were added to stocks during 1940 compared with withdrawals of 42,933,000 barrels from storage during 1939. Imports of mineral oils, crude and refined, constituted 5.6 percent of the total new supply in continental United States during 1940 compared with 4 percent during 1939.

Imports of crude petroleum, especially for direct consumption, were considerably larger in 1940 than in 1939, probably because of the reduction in the excise tax on imported crude as a result of the Venezuelan Trade Agreement effective December 16, 1939, and the general increase in domestic demand, as well as the loss of European markets for Venezuelan and especially Mexican oils. Imports of crude from Venezuela were greater in 1940 than in 1939, but the principal increase was in receipts of crude from Mexico for direct consumption. Because of the low prices at which they were sold, these could enter the United States market in spite of the full excise tax of 21 cents a barrel which was applied to most of the Mexican imports of crude. The quota for Mexico and "all other countries" for 1940, to be admitted at the reduced rate of 10½ cents a barrel, was only 2,352,000 barrels; and only 1,336,000 barrels of the 12,262,000 barrels imported from Mexico in 1940 were admitted at the reduced rate. The settlement of the controversy between the Mexican Government and one of the expropriated companies facilitated imports of Mexican crude into the United States; but this did not account for more than a minor part of the increase in such imports.

Imports of refined oils consisted chiefly of residual fuel oil and unfinished oils for further processing, with some distillate fuel oil imported for the first time in quantity during 1940. Most of the residual fuel oil imported for direct consumption came from Venezuela, where refining activity has increased, and from the Netherlands West Indies, with minor amounts from Mexico and other countries; virtually all of the residual fuel oil imported in bond for supplies of vessels came from the Netherlands West Indies and Venezuela. The distillate fuel oil for direct consumption came chiefly from Mexico, with minor amounts from the Netherlands West Indies and Venezuela; that imported in bond, chiefly for manufacture and export, came from Venezuela and the Netherlands West Indies. Topped petroleum and unfinished oils (other than gasoline) were imported almost entirely from the Netherlands West Indies.

[1] Bureau of Foreign and Domestic Commerce. [2] By Bureau of Foreign and Domestic Commerce through April 9, 1941. [3] Negative quantity. [4] Net imports.

The chief increase in imports of this group of oils was in residual fuel oil for direct consumption and in distillate fuel oil, which was not imported into continental United States in 1939. These increases may be due largely to the reduction in the excise tax on imported fuel oils from 21 cents a barrel to 10½ cents as a result of the Venezuelan Trade Agreement effective December 16, 1939, as well as to the general increase in demand for both residual and distillate fuel oils. The loss of European markets on account of the war and the consequent accumulation of stocks in the Netherlands West Indies and Venezuela exercised a pressure that tended to force shipments to the United States, the nearest available large-scale market.

Exports.—The United States continued to be a net exporter of mineral oils, but the excess of exports and Territorial shipments over imports was reduced from 129,899,000 barrels in 1939 to 47,673,000 in 1940. The greater decrease in net exports and shipments was in refined products (52,107,000 barrels), due to the falling-off of exports, especially to Europe, as well as to an increase in imports of fuel oil.

Exports and Territorial shipments of mineral oils, crude and refined, comprised 9 percent of the total demand in 1940 compared with 13 percent in 1939.

Exports of crude petroleum from the United States were 28 percent less in 1940 than in 1939. Canada, the major purchaser of United States crude both in 1939 and 1940, increased its takings slightly in 1940. Fully 71 percent of the loss in crude exports was in shipments to Europe. No crude petroleum was exported from the United States to France after its surrender in June 1940; Germany, Belgium, the Netherlands, Finland, and Norway were eliminated by the war blockade, and Sweden virtually so. Italy ceased to receive United States crude after its entry into the war in June. Of all Europe only the United Kingdom and Portugal remained open to shipments of crude from the United States; and the United Kingdom curtailed its purchases from the United States to conserve dollar exchange, apparently obtaining its refinery requirements from Iran and Venezuela. Portugal, where petroleum refining has begun, increased its takings of United States crude in 1940 over 1939. On the other hand the Netherlands West Indies, where refining had to be curtailed because of the decline in European demand, decreased its receipts of crude petroleum from the United States in 1940 from 1939. Exports of crude petroleum to Japan, chiefly from California, were reduced, largely for lack of dollar exchange.

Any hopes remaining from 1939 that the war in Europe would increase the demand for petroleum products were disappointed. The requirements of armies, navies, and air forces were met by curtailing civilian consumption to an extent that had not been forseen. Europe, the major theater of war, actually took 60 percent less of major refined products from the United States in 1940 than in 1939. The United Kingdom reduced its purchases of major liquid petroleum products from the United States 34 percent from 1939 to 1940. Because of the losses of European markets the Netherlands West Indies, which ordinarily receives from the United States high-volatile gasoline, kerosene, and distillate fuel oil to blend with the products of its own refineries, decreased its receipts in 1940 from the level of 1939.

Mineral oils, crude and refined, shipped from continental United States and including shipments to noncontiguous Territories, 1939–40, by classes and months [1]

[1] Compiled from the records of Bureau of Foreign and Domestic Commerce; figures may differ slightly from those used throughout other sections of this report.
[2] Includes benzol, natural gasoline, and (since June 1, 1940) antiknock compounds.
[3] Includes antiknock compounds beginning with June. Data for January to May, inclusive, may be found in motor-fuel section.

Motor-fuel exports and Territorial shipments made a 44-percent drop. Exports of ordinary gasoline were cut in half—from 32,512,000 barrels in 1939 to 16,478,000 in 1940. The chief loss was in shipments to the United Kingdom. Canada, the United Kingdom, Brazil, and New Zealand reduced their takings from 1939 to 1940; none was shipped to France after June 1940. Although Japan, Australia, China, and the U. S. S. R. purchased more ordinary gasoline from the United States in 1940 than in 1939, their increased purchases did not compensate for the decline in shipments to the other major customers.

Exports of high-grade gasoline decreased one-fourth—from 4,001,000 barrels in 1939 to 2,992,000 in 1940. Less was shipped to Canada, Japan, the Netherlands West Indies, and Brazil in 1940 than in 1939. None was shipped to France or to Italy after June 1940. The United Kingdom, however, received more aviation gasoline in 1940 than in 1939.

The largest recession in the motor-fuel group was in exports of natural gasoline. These decreased 59 percent—from 4,111,000 barrels in 1939 to 1,707,000 in 1940. The principal declines were in exports to Japan, the United Kingdom, France, the Netherlands West Indies, and Italy.

Territorial shipments of motor fuel, undifferentiated, increased 9 percent from 1939 to 1940. Hawaii was the principal destination of these shipments.

A considerable drop was registered in exports and Territorial shipments of kerosene. Although China increased its purchases of illuminating oil from the United States, this did not compensate for the declines in shipments to the United Kingdom, the Netherlands West Indies, Japan and Kwantung, and Canada.

The loss of the German market was especially severe on exports of fuel oil. Less distillate fuel oil was exported to the Netherlands West Indies, to Japan, to France, and to the United Kingdom in 1940 than in 1939. Although more distillate fuel oil was shipped to Italy, the U. S. S. R., and Australia and to the noncontiguous Territories, this did not equalize the decreases in shipments to major foreign purchasers.

The decline in exports and Territorial shipments of residual fuel oil was less than it had been for distillate fuel oil from 1939 to 1940. The principal decreases in exports of residual fuel oil were in shipments to Japan and to Italy. These were offset in part by larger shipments to Canada, Spain, the United Kingdom, Cuba, and New Zealand and to the noncontiguous Territories.

Exports of lubricating oil are widely distributed and in consequence suffered less from the effects of the war in Europe. The greatest loss in 1940 was in shipments to Germany; but Europe in general took less lubricating oil from the United States in 1940 than in 1939. Although more lubricating oil was shipped to the United Kingdom, Japan, Australia, Brazil, China, and New Zealand in 1940 than in 1939, declines in shipments to Europe resulted in a net loss in exports of lubricating oils.

Exports and shipments of wax were 18 percent lower in 1940 than in 1939. The greatest decrease was in exports to Europe, especially to Italy, Belgium, the Netherlands, Spain, and Sweden. Although the United Kingdom and France took more paraffin wax from the United States in 1940 than in 1939 this did not serve to arrest the general decline in exports of wax to Europe.

Major petroleum products shipped from continental United States by countries of destination and shipments to and exports from noncontiguous Territories, 1939–40 [1]

[5] Negative quantity.

Less wax was exported from the United States to other North American countries (except Mexico), to South America, and to Asia (except Japan) and less to Australia, but more to New Zealand. Of the continents, only Africa took more wax from the United States in 1940 than in 1939; the increase was principally in exports to the Union of South Africa, to Morocco, and to Egypt.

Motor fuel exported and shipped to noncontiguous Territories from continental United States in 1940, by refinery districts and months[1]

INTERCOASTAL SHIPMENTS[4]

Receipts of mineral oils, crude and refined, on the East coast from Gulf coast ports were 6.5 percent larger in 1940 than in 1939. Crude petroleum was the largest single item in these shipments and constituted 38 percent of the total shipments in 1940. Receipts of refined oils from Gulf coast ports were 9 percent larger in 1940 than in 1939.

Receipts of California mineral oils at East coast ports were smaller in 1940 than in 1939. Larger intercoastal shipments of gasoline did not suffice to offset a sharp drop in shipments of residual fuel oil.

NATURAL GAS[1]

By F. S. Lott and G. R. Hopkins[2]

SUMMARY OUTLINE

Vigorous growth in the demand for natural gas accompanied the intense industrial activity and rising national income incident to the

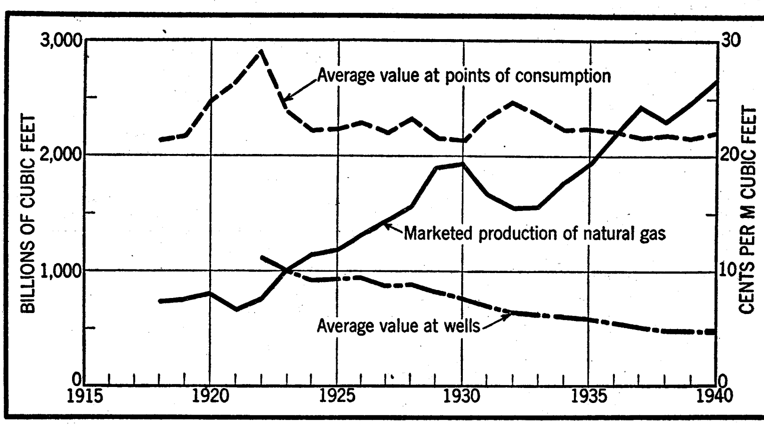

FIGURE 1.—Production and value of natural gas in the United States, 1918–40.

defense program of 1940. Marketed production gained 8 percent over 1939 to attain a total of about 2,672 billion cubic feet, a new high for the industry (see fig. 1). In several States, including the leaders—Texas, California, and Louisiana—production exceeded that of any previous year.

Estimated consumption (marketed production less exports) in 1940 was 2,667,010 million cubic feet, a gain over the 2,473,765 million consumed in 1939. All major classes of consumers except petroleum refineries and electric power plants apparently used more gas in 1940 than ever before. Unusually cold weather early in 1940 stimulated the domestic and commercial demand, and larger requirements for gas were general in industrial areas. The urgency of demand taxed the facilities of several major pipe-line systems and caused them to undertake construction programs to increase capacity.

[1] Data for 1940 are preliminary; detailed statistics with final revisions will be released later.

The number of domestic meters in service reached a new record of 8,887,460 in December 1939, a gain of 317,000 during the year. Since 1930, when separate data on domestic meters were first compiled, the number of homes connected to natural-gas distribution systems has consistently increased each year despite depression influences. There was a total growth of 76 percent in the 9-year period—an average of over 8 percent annually. The commercial market followed a similar trend, with a total gain of 73 percent in meters to a new peak of 715,390 at the end of 1939. The average consumption of gas for each domestic and commercial meter dropped sharply (21 percent) in 1931 and has remained relatively stable since then within the range of 50 to 55 thousand cubic feet a year.

The average value of domestic gas at points of consumption is estimated to have declined from 73.5 cents per thousand cubic feet in 1939 to 73.0 in 1940. Similarly, the value of commercial gas dropped from 49.4 to 49.2 cents. These estimates indicate that the total value of domestic consumption was about $322,660,000 and that of commercial consumption $64,944,000 in 1940. The average value of industrial consumption is thought to have increased one-tenth cent in 1940 to 9.7 cents per thousand cubic feet, making the indicated total value at points of consumption $203,022,000. The total value of all marketed production in the United States in 1940 therefore reached a new record of about $590,626,000—11 percent above 1939.

Exports to Mexico in 1940 increased 61 percent to 4,900 million cubic feet, and natural gas piped to Ontario, Canada (mixed with manufactured gas), amounted to 90 million compared to 76 million in 1939. No natural gas was imported in 1940, the former movement from Canada into Montana having been discontinued in June 1939.

EMPLOYMENT AND PRODUCTIVITY

The discussion of employment and productivity that has been given in this chapter for several years cannot be repeated for 1939, as the Bureau of Mines did not compile employment data for that year; however, complete information for 1939 was collected by the Bureau of the Census as part of its Decennial Census of Mines and Quarries, and the results should be published before the end of 1941.

GROSS PRODUCTION

The estimated gross production of natural gas in the United States in 1939 was 3,333,500 million cubic feet—9 percent more than in 1938. The output of gas wells increased 17 percent in 1939, stimulated chiefly by growth in the market demand for gas. Another important factor, however, was the sharp rise in the volume of gas processed at recycling plants in Texas "condensate" fields.

The indicated production of gas from oil wells was virtually the same in 1939 as in 1938, as rather sharp declines in Kansas, New Mexico, and Oklahoma were offset by gains in Illinois, Louisiana, and Wyoming. New information on the volume of gas produced at oil wells in several States was available for 1939. Its inclusion in the table that follows distorts to some extent the year-to-year changes in volume because similar information for 1938 is lacking. The 1938 totals for "gas from oil wells" and "losses and wastage" would be larger than shown if comparable data had been used for both years.

The increased volume of gas reported as used for repressuring (and pressure maintenance) is due entirely to reinjection of gas at high pressures into "condensate" reservoirs in Texas. Most States reported moderate declines in 1939.

The decrease of almost 50 percent in the storage of gas in natural underground reservoirs during 1939 resulted from reduced operations of this type in Kansas, Ohio, and Pennsylvania. In Kansas 19 billion cubic feet of gas were reported as stored from 1935 to 1938, inclusive. The recession in volume for 1939 suggests that stored reserves are regarded as adequate for current needs and facilities. In the eastern fields a rather widespread movement to store natural gas in depleted pools followed discovery of the prolific Oriskany sand production which—temporarily at least—provided productive capacity beyond local requirements. Because of competitive conditions much Oriskany gas was produced rapidly from its original site in 1937 and 1938 and piped to other areas to be stored for future use. The movement subsided in 1939 as some Oriskany pools approached depletion.

Gross production and disposition of natural gas in the United States, 1938–39, by States, in millions of cubic feet

[1] Marketed production plus quantities used in repressuring, stored in the ground, lost, and wasted (see footnote [2]).
[2] Includes gas (mostly residue gas) blown to the air, shrinkage at natural-gasoline plants, and transportation losses but does not include direct waste on producing properties, except where data are available.
[3] Produced approximately as follows—2,770 million cubic feet in Texas, 1,780 million in Oklahoma, and 893 million in Kansas.
[4] Produced approximately as follows—1,981 million cubic feet in West Virginia, 530 million in Kentucky, and 1,021 million in Ohio.
[5] Produced approximately as follows—736 million cubic feet in West Virginia, 216 million in Kentucky, 59 million in New York, and 1,349 million in Pennsylvania.
[6] North Dakota, South Dakota, Tennessee, Utah, Virginia (1939 only), and Washington.
[7] Subject to revision.
[8] Produced approximately as follows—220 million cubic feet in Texas, 122 million in Oklahoma, and 83 million in Kansas.
[9] Produced approximately as follows—86 million cubic feet in Kentucky, 4 million in Pennsylvania, 406 million in West Virginia, and 191 million in Ohio.
[10] Produced approximately as follows—227 million cubic feet in New York, 444 million in Pennsylvania, 128 million in West Virginia, and 32 million in Kentucky.
[11] Produced approximately as follows—58 million cubic feet in Kentucky and 48 million in West Virginia.

Indicated losses and wastage equaled 20 percent of the gross production in 1939 and 21 percent in 1938. There were material declines in California, Kansas, and New Mexico due principally to declining pressures in certain important fields with high gas-oil ratios. The apparent increases in Illinois, Louisiana, and Wyoming may in part be ascribed to less complete information on operations during 1938.

MARKETED PRODUCTION

An 8-percent expansion is estimated for marketed production in 1940 in the United States, which rose to 2,672 billion cubic feet—a new high for the industry. All leading producing States contributed to the increase.

Final data for 1939 show that production of gas was larger in most States than in 1938, the only notable exceptions being Oklahoma, where the output of casinghead gas continued to drop, and New York. California, Michigan, Mississippi, New Mexico, and Texas attained new peaks in marketed production in 1939.

In 1939 the same nine States as in 1938 reported greater production than consumption. The most important of these was Texas, with a net excess output of 182.9 billion cubic feet that was consumed in other States and Mexico. Louisiana had net exports of 129.7 billion cubic feet, West Virginia 89.8 billion, Kentucky 31.2 billion, and New Mexico 21.3 billion.

The average value of gas at the wells in 1939 was 4.9 cents per thousand cubic feet, unchanged from 1938. Small increases were noted in a number of States, those in Missouri and Pennsylvania being the most significant. Eleven States showed decreases; those in California, Texas, and West Virginia were the more important.

Natural gas produced in the United States and delivered to consumers, 1935–39, by States, in millions of cubic feet

[1] Less than 0.05 percent.
[2] Includes 131,000 M cubic feet piped from Canada.
[3] Includes 28,000 M cubic feet piped to Canada.
[4] Includes 48,000 M cubic feet piped to Canada.
[5] A small amount of gas produced in Virginia and consumed in Tennessee included with Virginia; separate figures not available.
[6] Includes 3,046,000 M cubic feet piped to Mexico.

WELLS

Gas-well completions increased 11 percent in 1940 to 2,382, reversing a declining trend evident since 1937. More active drilling for gas was reported in 11 States and moderate declines in 5. The greatest stimulus was felt in the Appalachian region, where an expanded demand for gas has caused local shortages in supply. A strong upward trend in gas completions was reported in Indiana, Missouri, Montana, and Oklahoma as well. In the first two States known gas supplies are very limited, and drilling activity usually is dominated by the status of development in one or two fields.

The number of producing gas wells reported as of December 31, 1939, was 53,530—a net reduction of 240 during that year. Adding 240 to the total gas completions—2,145—makes a total of 2,385 gas wells abandoned in 1939, a 32-percent reduction from 1938 but still above other recent years. Abandonments continued to be very numerous in Pennsylvania and Ohio and in most of the southwest region, probably hastened by higher market prices for scrap iron and steel.

Gas wells in the United States, 1938–40

State	Producing Dec. 31, 1938	Drilled during 1939 [1]	Producing Dec. 31, 1939	Drilled during 1940 [1]

[1] From Oil and Gas Journal and State sources.
[2] Tennessee included with Kentucky.
[3] New York included with Pennsylvania.

In a few States the figures used for gas-well completions in 1940 were taken from data compiled by the Geological Survey, United States Department of the Interior. The 1940 total for New York includes only producers from the Oriskany sand.

TECHNICAL DEVELOPMENTS

An outstanding achievement in gas engineering was the construction in 1940 of the first large-scale commercial equipment for storage of natural gas in liquid form. After several years of research and experimental operation of a small plant a successful process for liquefying natural gas by refrigeration to minus 250° F. was evolved, and suitable containers and auxiliary equipment were designed to store the liquid and regasify it as required. A number of interesting technical problems were introduced by the extreme physical conditions imposed, involving behavior of the gas as well as of the materials comprising the processing equipment.

Three spherical tanks were built at Cleveland, each of 600,000 gallons capacity and insulated with a 3-foot layer of cork. As 1 cubic foot of liquefied gas is equivalent to about 600 cubic feet in gaseous form the total storage space provides for 150 million cubic feet of gas, a volume that could not be stored above ground economically by any other known method. The plant is designed to liquefy and store gas at 4 million cubic feet a day and to regasify the liquid at a rate of 3 million cubic feet an hour when the demand for gas is heavy.

The investment in and operating costs of the plant are moderate, and its effect is to substantially improve the ability of the system to meet peak-load demands for gas in Cleveland, thus eliminating the need for a much larger investment in pipe-line facilities to accomplish the same purpose. The availability of this large storage at the point of market demand makes it a valuable stand-by for emergencies and helps to maintain more constant conditions of flow and pressure in the pipe-line system. Essentially, therefore, the plant provides the same benefits as would underground storage of gas in a natural reservoir, where such storage facilities are not available.

Problems of transportation and storage of liquefied natural gas are being investigated to determine possible commercial uses and methods of handling. Increased transportation range for natural gas and added use for many purposes are possible results. The following trends are evident. Dehydration processes are being employed more widely to prevent trouble from gas hydrates and moisture in high-pressure lines. An increasing number of gas companies are utilizing butane and propane to supplement their gas supplies during periods of peak load. Quick-setting gypsum cements are finding more favor in wells in high-pressure gas areas because their action is not affected by gas.

The importance of natural gas in defense and other industries is growing rapidly both as a source of controlled heat in a great variety of applications and as a raw material in the production of such commodities as plastics, textile fibers, explosives, and industrial chemicals.

REVIEW OF FIELD DEVELOPMENTS BY STATES

Arkansas.—According to the Arkansas Department of Revenue, natural-gas production in Arkansas during 1940 increased 19 percent to 22,409 million cubic feet, of which 1,385 million was casinghead gas from fields in Miller, Ouachita, and Union Counties. Output of the northwestern gas fields continued to increase, amounting to 5,410 million cubic feet in 1940 and 4,061 million in 1939. The southern district produced 16,998 million cubic feet in 1940—16 percent more than in 1939.

The only important gas discovery in 1940 was made on June 8 by the Bodcaw Lumber Co. No. 1 in sec. 29, T. 17 S., R. 23 W., Lafayette County, and was known as the McKamie field. Initial production was about 2 million cubic feet of gas with 240 barrels of condensate from the Smackover limestone at about 9,200 feet. Two additional producing wells drilled in 1940 indicated an important reserve.

In Union County one well in sec. 3, T. 18 S., R. 13 W., was completed for 6 million cubic feet of gas a day from a total depth of 3,255 feet. A well in sec. 27, T. 15 S., R. 18 W., Ouachita County, was reported with an initial daily capacity of 15 million cubic feet from 1,660 feet. Two small gas wells were drilled in secs. 4 and 9, T. 14 S., R. 20 W., Nevada County.

The northwestern counties reported six gas completions—four were in Franklin County and two in Sebastian. All of the Franklin County wells were in the southern part of T. 10 N., R. 26 W., in a newly developed area that was connected to the Fayetteville-Little Rock trunk gas line in 1940. The total daily initial capacity was 58 million cubic feet from depths of 1,280 to 3,960 feet. In Sebastian County one well with a total depth of 2,690 feet and an initial daily production of 1.5 million cubic feet was drilled in sec. 21, T. 8 N., R. 29 W. Another in sec.

15, T. 9 N., R. 29 W., was completed for 2 million cubic feet daily from 2,480 feet.

State officials are making vigorous attempts to find economic uses for the large volume of natural gas now available in southern Arkansas. The high sulfur content of this gas has retarded its commercial utilization, although proved reserves have been estimated at 732 billion cubic feet.

California.—Natural-gas production in California increased about 1 percent to 189.4 billion cubic feet in the first half of 1940 over the same period in 1939. Information for the second half of 1940 is not yet available, according to a report from E. F. McNaughton, California Railroad Commission. Gas was blown to the air in 1940 at approximately the same rate as in 1939 (17 billion cubic feet in the first half of 1940).

Sixteen gas completions were reported in 1940, including one discovery well. Gas wells drilled in proved gas fields were as follows: Buena Vista Lake, 1; Rio Vista, 4; and Trico (Delano), 10. The proved area at Trico was expanded about 2,300 acres. In December 1940 the Blewett No. 1 in San Joaquin County near Vernalis and 9 miles southeast of the Tracy gas field discovered gas at a total depth of 3,873 feet. It made 10 million cubic feet a day from 32 feet of "pay" formation, believed to be Cretaceous. The well is situated close to two large gas lines. Early in 1940 the Paloma field in the south end of the San Joaquin Valley near Buena Vista Lake was proved to be a condensate field, the first in California, and plans were made to unitize operations if possible.

In the Los Angeles Basin available casinghead gas was increased by discovery of the Del Valle field and new deep zones at Aliso Canyon and Inglewood. Gas production at Montebello, much of which was wasted in 1939 and 1940, declined, so that less waste is probable in 1941. To reduce waste of gas an arrangement was made to store about 20 million cubic feet of Montebello gas a day during summer months in another field.

Gas production increased from most fields in the Coastal district, and gas waste rose from 8 percent in 1939 to 12 in 1940 owing to development of the Santa Maria Valley field. Plans were made to utilize the La Goleta field as a gas storage reservoir.

Defense activities are having a very material effect on the gas markets, particularly in the San Francisco Bay, Los Angeles, and San Diego areas. New and expanded military camps, large housing projects, and sharply accelerated activity in aviation, shipbuilding, and related industries are adding important new loads to gas systems. Several minor gas-line extensions were made to serve the new markets, and additional line construction is expected soon. The gas-utility systems at San Diego and San Luis Obispo probably will find it necessary to contract for new gas supplies to fulfill heavy new requirements.

Colorado.—Production of natural gas in 1940 increased 21 percent to 2,082 million cubic feet, as reported by L. G. Snow, acting supervisor, Geological Survey, United States Department of the Interior, Casper, Wyo. The gain was due to larger withdrawals from the Hiawatha field, amounting to 1,843 million cubic feet. Other fields produced as follows: Berthoud, 54.9 million; Craig, 4.5 million; Garcia, 82.4; and Thornburg, 97. In addition, 60.6 million cubic feet of gas were produced with oil (gas-oil ratio, 252 cubic feet a barrel) in the Wilson

Creek field, and 3 million were used for drilling and field purposes at Hiawatha.

One gas well was completed in the Hiawatha field, with an initial daily production of 675,000 cubic feet. There were no new gas discoveries, extensions, or gas-line construction.

Illinois.—Natural gas was marketed in 1940 from two gas fields in Illinois—Ayers and Russellville—and two oil fields—Salem and Louden—according to a report from A. H. Bell and G. V. Cohee, Illinois Geological Survey. Marketed production increased about 20 percent to 1,165 million cubic feet, including 247 million of casinghead.

Production from the Ayers field (Bond County) was 13,777,300 cubic feet in 1940 and that from Russellville 890,400,000. Continued development at Russellville (Lawrence County) raised the productive acreage to 1,600, an increase of 680 acres over 1939. As of January 1, 1941, 41 wells were producing from about 10 feet of Buchanan sand at a depth of 1,090 feet. The total output through 1940 was 1,955,500 thousand cubic feet.

The gross production of gas from Illinois oil fields in 1940 is estimated as 130 billion cubic feet. The Louden field supplied approximately 11 billion. Two gasoline plants in the field processed 10 million cubic feet of gas a day and extracted 3.2 gallons of liquid products per thousand cubic feet. 2.5 million cubic feet a day of residue gas were injected into the oil sands through 63 input wells. The town of St. Elmo and local industries were supplied with 215,376 thousand cubic feet of residue gas and 13,575 thousand cubic feet of dry gas from one lease in the Louden field. In December 1940 about 3 million cubic feet of wet gas were used daily for field purposes and 15 million burned in flares.

Approximately 71 billion cubic feet of natural gas were produced from the Salem field in 1940, the December production being 117 million cubic feet a day. Fifty-two million daily were handled by three gasoline plants, which extracted an average of 2.6 gallons of liquid hydrocarbons a thousand cubic feet of gas. Beginning about October 1, 1940, the city of Salem was supplied with approximately 350,000 cubic feet of residue gas daily. Small quantities of gas are used for field operations and for return to the oil reservoir, and the remainder is burned in flares.

Production of gas in the Centralia field in 1940 totaled about 10 billion cubic feet, chiefly from the Devonian limestone. Output declined sharply to about 4 million cubic feet daily in December 1940 after the peak in flush oil production was passed. About 100,000 cubic feet daily are injected into the Bethel sandstone through three input wells, and 60,000 daily are pumped into the Cypress sand through one well.

The Storms field, White County, where gas-oil ratios are generally high, is estimated to have produced 22 billion cubic feet of gas in 1940. Daily production slumped from about 100 million cubic feet in January to 18 million in December. As yet no gas has been marketed from this field.

The Central Basin fields of Jasper, Richland, Clay, Wayne, and northwest White Counties produced about 16 billion cubic feet of gas in 1940, much of which was used in lease operations and heat treatment of oil.

Gas was discovered on the Panama dome by No. 1 Sharf in sec. 27, T. 7 N., R. 4 W., Bond County. Initial daily production was 500,000 cubic feet from a sand of lower Pennsylvanian age at 556 to 595 feet. An offset well was completed for about 1 million cubic feet, and further drilling is planned.

Indiana.—Natural-gas production in Indiana in 1940 recovered the 30-percent decrease experienced in 1939, as reported by G. F. Fix, State gas supervisor. The total volume was 1,244 million cubic feet, almost the exact amount produced in 1938. Most of the increase was due to flush output from the Rockport field, a 1939 discovery in Spencer County, which yielded 394.5 million cubic feet of gas from 45 wells. The Oaktown field—the other major gas area of the southwest part of the State—produced 119.8 million cubic feet in 1940 as against 92 million in 1939. The output of most other fields declined in 1940, as many of them have virtually reached economic limits.

No important new developments in natural gas occurred in 1940, but interest was revived in the old Trenton gas field in Randolph County, by completion of four gas wells on the east flank ranging up to 1 million cubic feet in initial daily capacity and having a rock pressure about equal to that originally found in the Trenton area. Considerable gas has been found in the new Buffkin oil pool, Posey County, but none has been marketed as yet.

Gas-well completions increased from 44 in 1939 to 77 in 1940; 7 were wildcats or extensions of productive areas. New gas wells, by fields, included Blairsville, 2 (no market); Greensburg, 17; Harrison County, 5; Rockport, 27; Shelburne-Graysville, 3; Old Trenton, 6; Buffkin, 5; and Randolph County, 4.

Production in 1940 by fields, in millions of cubic feet, was: Alford, 65; Francisco, 5; Greensburg, 185.4; Harmon, 15; Harrison County, 182.5; Hudsonville, 22; Loogootee, 7; Oaktown, 119.8; Rockport, 394.5; Shelburne-Graysville, 35.8; Old Trenton, 200; and Troy-Tell City, 12.2.

A small pipe line was built from the Unionville gas field in Monroe County to intercept a trunk line north of Bloomington which serves several towns with gas from the Texas Panhandle field. The Unionville field, which has 15 wells, has been shut in since its discovery about 10 years ago. It will now serve as a stand-by source of gas.

Kansas.—The volume of natural gas produced and marketed in Kansas reached an all-time peak of about 85 billion cubic feet in 1940, according to data supplied by J. H. Page, engineer, State Corporation Commission. Production from most of the important fields increased, the sharpest gain being shown by the Cunningham-Cairo area, which quadrupled its output to 11,934 million cubic feet to rank second in the State. The output of other major fields was reported as follows: Hugoton, 33,127 million cubic feet; Otis, 9,710 million; Medicine Lodge, 7,676; McPherson County, 5,123; Burrton, 4,675; Lyons, 2,956; and Eastern Kansas, 6,872.

Ninety-eight gas completions were reported with a total initial daily capacity of 1,330,859,000 cubic feet, slightly more than in 1939. Of these wells 72, with a capacity of 1,288,959,000 cubic feet, were in western Kansas and 26, with only 41,900,000 cubic feet, in eastern Kansas. Development information is taken from a report by R. P. Keroher, geologist, Kansas Geological Survey.

The most important addition to production in western Kansas was in the Cunningham-Cairo area in Pratt and Kingman Counties, where

813.9 million cubic feet—59 percent of the new potential in the State—were developed from 22 wells. In the Hugoton field 17 wells were drilled with a total initial production of 209.5 million cubic feet. Nine of these, with 105.8 million cubic feet open flow, were in Grant County. Eight new wells were drilled in the Otis-Albert pool in Barton and Rush Counties, with a total daily potential of 164.6 million cubic feet.

Four new gas pools were discovered in 1940, only one—the Coons pool, McPherson County—being in western Kansas. The discovery well, Coons No. 1, in sec. 13, T. 19 S., R. 1 W., made 3 million cubic feet from the Mississippi lime. The Kath field, Johnson County, was opened by Kath No. 1 in sec. 33, T. 13 S., R. 22 E., with gas from the Squirrel (upper Cherokee) sand. Four additional small wells were drilled in 1940, giving the entire pool a daily potential of about 1 million cubic feet.

The Lemert No. 1, in sec. 11, T. 34 S., R. 4 E., Cowley County, discovered the Lemert pool. It made 2.3 million cubic feet from the Mississippi lime. The Nice pool, Douglas County, was discovered by Nice No. 1 in sec. 3, T. 13 S., R. 21 E., which was completed for about 250,000 cubic feet daily from the Squirrel sand. Two additional gas wells were drilled in 1940.

Other gas completions were reported in 1940 in the following fields: Iola, Allen County, 5; Strong City, Chase County, 4; McLouth, Jefferson County, 4 (32 million cubic feet open flow waiting for pipe-line connection); Medicine Lodge, Barber County, 2 (74 million); Krier and Silica pools, Barton County, 1 each; Zenith, Stafford County, 6; Lyons, Rice County, 2; Kipp, Stafford County, 1; Thurber, Rice County, 1. Several wells that produced substantial volumes of gas with oil were drilled in pools in the Barton arch area.

Kentucky.—Gas drilling and leasing were substantially more active in 1940 than in the preceding 3 years, according to a report by C. D. Hunter and G. M. Straughan of the Kentucky West Virginia Gas Co. Most important was the extensive gas development in eastern Kentucky, chiefly in the Big Sandy gas field in Floyd, Pike, Knott, and Martin Counties. In this area 103 gas completions were reported out of a total of 113 in eastern Kentucky.

During 1940 four deep tests were drilled in eastern counties. One in Knox County was dry in the Knox dolomite, having missed the St. Peter sand. Some gas was reported in both the St. Peter and the Knox dolomite in a Lee County well. Four deep tests were being drilled to the Knox dolomite in Ellicott, Magoffin, Clark, and Laurel Counties in search of production from the Trenton, St. Peter, or Knox. The success of any of these may cause a marked increase in deep development. The demand for gas from outside markets increased in 1940 and promises to expand further in 1941.

The year 1940 was uneventful in western Kentucky, where only 12 gas wells were reported. Exploratory drilling had little success.

Louisiana.—About 75 gas and condensate wells were reported in north Louisiana in 1940—11 less than in 1939. The most active field was Monroe, where 53 completions had total initial daily capacity of 125 million cubic feet. The average capacity of new wells at Monroe is declining materially as depletion lowers the pressure in the producing sand. Eighteen wells with a large gas and condensate capacity were drilled in the Cotton Valley field. Plans were nearing completion to exploit, upon a cooperative basis, the great condensate reserve in the Cotton Valley structure.

At Logansport, De Soto Parish, a gas well was reported that produced 68 million cubic feet. This field, which covers a large area in Louisiana and in adjoining Shelby County, Tex., contains an important gas reserve. A large pipe line is projected to connect it with a system that serves markets in States as far east as Georgia.

Three gas fields and one gas-condensate area were discovered in northern Louisiana in 1940. In La Salle Parish the Standard and Summerville fields, producing gas from the Wilcox at moderate depths, were opened by wells that made 20 and 12 million cubic feet initially. The Greenwood field, Caddo Parish, was discovered by No. 1 Dunn, which made 3.3 million cubic feet of gas from the Ozan sand at 2,543 to 2,551 feet. At Athens, Claiborne Parish, the No. 1 Valentine produced 3 million cubic feet of gas and 50 barrels of condensate from a sand in the Hosston formation (Travis Peak). Deep exploration at Lisbon resulted in gas-condensate production from the Cotton Valley formation, which may indicate important reserves.

In southern Louisiana 39 completions were reported as producing considerable volumes of gas; of these, 17 were classified as gas wells. Ville Platte was the most active area, with 16 wells. Others were scattered in 17 fields, principally in the Lake Charles and Houma districts.

A gas discovery was made in June at Ritchie (East Tepetate), Acadia Parish, by No. 1 McManus, which produced from the Miocene at 3,525 to 3,535 feet. A deep gas-condensate discovery was reported at Section 28 Dome, St. Martin Parish, in December 1940. The No. 1 Steuart was completed in the Miocene at a depth of 9,300 to 9,330 feet. Additional gas reserves were developed in connection with discoveries of oil on the flanks of several salt-dome structures in the Gulf Coast area.

The quantity of gas marketed from Louisiana fields in 1940 is estimated to have increased 10 percent over 1939 to 324 billion cubic feet. Gas processed for extraction of gasoline probably increased about 15 percent to approximately 130 billion cubic feet.

The prospect is for enlarged markets for Louisiana gas in other States because of expansion in the facilities of interstate gas pipe-line systems originating within the State.

Michigan.—Discoveries in 1940 added materially to Michigan's natural-gas reserves and improved the prospects of developing production at greater depths, according to a review by F. R. Frye, petroleum engineer, Michigan Department of Conservation.

The Marion pool in Clare and Osceola Counties was discovered on June 25, 1940, by the Woodin & Baughan No. 30 in sec. 19, T. 20 N., R. 6 W. Its initial daily open-flow capacity was 6.7 million cubic feet from the Michigan Stray sand at 1,419 feet. During 1940, 14 gas wells were drilled in this field, proving several thousand acres for production.

On June 19, 1940, the Quist No. 29, in sec. 22, T. 21 N., R. 7 W., Missaukee County, opened the Riverside pool. Its initial daily production was 7.3 million cubic feet from the Michigan Stray sand at a depth of 1,415 feet, with a closed pressure of 640 pounds. Three additional gas wells were completed in the area during 1940, indicating a pool of considerable size. Market outlets for these two pools were provided by pipe lines.

Another pool in the Michigan Stray sand apparently was discovered on November 15, 1940, near Reed City, Osceola County, by the Cornell-Lomp No. 55, in sec. 30, T. 18 N., R. 10 W. It came in for 7.5 million cubic feet daily from 1,245 feet. A second well in the same section was reported to have been completed for 12 million cubic feet. Active development is planned during 1941.

Interest in deep drilling for oil and gas in strata below the Monroe formation was stimulated by the appearance of wet gas in the Bateson No. 1, in sec. 2, T. 14 N., R. 4 E., Bay County. The well was intended as a test of the St. Peter sand, expected below 9,500 feet, but a gas blow-out occurred at 7,776 feet, causing a fire that destroyed the rig. The gas pressure at the wellhead was about 3,100 pounds. During a period of several months, while attempts were made to recover lost drill pipe, the well made 50 to 100 barrels daily of 71° B. condensate.

Gas-well completions numbered 59 in 1940—an increase of 3 over 1939; 34 gas wells were abandoned, leaving 503 producing gas wells in the State on January 1, 1941.

Reported natural-gas production in 1940 was 14,126,364,000 cubic feet—almost 40 percent more than in 1939 and the largest on record. Of the total production 3,362,025,000 cubic feet were casinghead gas, approximately three times the amount reported for 1939.

A gasoline plant in the Walker field near Grand Rapids, which began operations in December 1939, processed 1,750 million cubic feet of casinghead gas in 1940. A new gasoline plant was put in operation in March 1940 in the Redding oil pool, Clare County.

Mississippi.—The sharp decline in natural-gas output from the 1939 peak of 15,233 million cubic feet to 6,449 million in 1940 was due to declining capacity of the State's only producing gas field at Jackson. Data have been furnished by H. M. Morse, supervisor, Mississippi State Oil and Gas Board.

The number of productive gas wells in the Jackson field declined 10 percent further to 27 at the end of 1940; 19 of these were making salt water. Two wells were drilled on the Jackson structure; one was a dry hole, and the other was completed as a gas well in early 1941. Two dry holes were drilled during the year in the Amory gas field. Active wildcatting in 1940, which resulted in 79 completions, failed to locate commercial gas production.

Missouri.—The following data were received from Frank C. Green, geologist, Missouri Geological Survey. Wildcatting in northern and northwestern Missouri, which was begun in 1939, continued in 1940. Two new gas fields were found, and one discovered in 1939 was extended further. The total number of completions was 94; 30 were gas wells, with an initial open-flow capacity of 37,655,000 cubic feet.

The outstanding discovery was the Polo gas field in Caldwell County. Wells in a sand, now believed to be a lens in the Bandera shale, yielded flows of more than 12,000,000 cubic feet at a depth of 400 feet. Ten wells, with 31,490,000 cubic feet total initial capacity, were drilled. The rock pressure was 80 pounds. At present no arrangements have been made for an outlet.

In Platte County the Prairie Point gas pool in sec. 7, T. 51 N., R. 33 W., and sec. 12, T. 51 N., R. 34 W., and the Lakeside pool in secs. 5 and 6, T. 50 N., R. 33 W., were developed further; both oil and gas have been found in the latter. Six gas wells were drilled, with a total capacity of 2,775,000 cubic feet.

Drilling for gas continued in proved areas in Clay County, where five gas wells were completed, and for both oil and gas in proved areas in Jackson and Cass Counties, where five and four new gas wells, respectively, were reported.

Montana.—Forty-nine gas wells were completed in old fields in 1940 with a total initial daily capacity of 119.4 million cubic feet. Information has been supplied by L. G. Snow, acting supervisor, Geological Survey, United States Department of the Interior, Casper, Wyo. About 30 shallow gas wells were drilled in the Bowdoin and Cedar Creek fields, which were linked by a 135-mile gas line. Bowdoin now shares the markets supplied by Cedar Creek and will furnish a considerable part of the steady consumption, so that Cedar Creek may be conserved to supply peak demands.

Devon, a shallow gas field in Toole County, was placed on production in June 1940 after being shut in since 1929. The field had four gas wells, and two more were drilled in 1940.

Gas production increased 14 percent in 1940 to 25,544,047,000 cubic feet; all fields except Bowes and Boxelder showed larger output.

A total of 10,051,367,000 cubic feet of gas was processed at two gasoline plants—182,062,000 at Dry Creek and the remainder at Cut Bank. It was estimated that 60 million cubic feet of gas were wasted in oil and gas fields.

Source and distribution of natural gas in Montana in 1940 [1]

Field	Utilization				Location of principal markets
	Total production (M cubic feet)	Domestic and commercial (M cubic feet)	Industrial		
			M cubic feet	Consumer	
Bowdoin	718,946	239,986	958,932	Steam boilers	Glasgow, Malta, Fort Peck, etc.
Bowes	311,611	311,611	623,222	Sugar refinery	Havre and Chinook.
Boxelder	231,303	77,101	308,404	Cement and sugar factories.	Miles City, Sydney, Glendive, Montana; Rapid City, S. Dak.; Bismarck, Bowman, Williston, N. Dak., etc.
Cedar Creek	2,672,886	4,852,356	7,525,242	Electric power plants	
Cut Bank	4,290,668	6,436,003	10,726,671	Smelter and steam boilers.	Anaconda, Butte, Helena, etc.
Devon	40,188	40,187	80,375	do	Great Falls, Shelby, etc.
Dry Creek	980,259		980,259		Big Timber, Bozeman, Livingstone, etc.
Hardin	83,519		83,519		Hardin.
Kevin-Sunburst	1,733,982	1,733,981	3,467,963	Smelters, steam boilers.	Great Falls, Shelby, etc.
Whitlash	526,306	263,154	789,460	do	Great Falls, etc.
Total	11,589,668	13,954,379	25,544,047		

[1] Data supplied by H. J. Duncan ,supervisor, Geological Survey, U. S. Department of the Interior.

New Mexico.—In southeastern New Mexico seven gas wells were completed in 1940 with a total initial daily capacity of 77.3 million cubic feet, according to a report from T. G. Taylor, acting supervisor, Geological Survey, United States Department of the Interior, Roswell, N. Mex.

Natural gas marketed by distributing companies totaled 28,079 million cubic feet—an increase of 1,723 million over 1939. About 4 billion cubic feet were used for producing petroleum by gas lift and 2 billion for other oil-field purposes. Gasoline plants processed 96,392 million cubic feet of casinghead gas in 1940—an increase of 7,721 million over the 1939 throughput.

Three gas discoveries were reported in trade papers. On February 10, 1940, the Johnson No. 1 in sec. 24, T. 15 S., R. 28 E., Chaves County, made 800,000 cubic feet of gas a day from a Permian sand at 1,456 to 1,500 feet. In sec. 25, T. 16 S., R. 30 W., northern Eddy County, the Etz No. 1 was completed in Permian sand at 2,553 to 3,082 feet with an initial gas production of 2.4 million cubic feet on October 28. Farther south, in sec. 12, T. 20 S., R. 30 E., Eddy County, 5 million cubic feet of gas were found in Permian lime at 1,540 to 1,553 feet in Hale No. 1 early in December.

Gas production from fields in the northwestern district increased about 11 percent in 1940 to 2,862 million cubic feet, of which 1,942 million were withdrawn from the Kutz Canyon field, 762 million from Ute Dome, 125 million from Fulger Basin, and 34 million from Blanco. In previous reports the Fulger Basin production has been included in that from Kutz Canyon.

One new gas well was completed in the Kutz Canyon field, one at Fulger Basin, and two at unreported locations.

New York.—The more important drilling operations for natural gas were in the Oriskany sandstone area of southwestern New York. Data have been furnished by C. A. Hartnagel, State geologist. In all, 50 wells were drilled, of which 20 were listed as producers with total initial daily capacity of 100.9 million cubic feet in 1940—an increase of 2 producers but a slight drop in capacity compared to 1939.

In 15 of the wells drilled in 1940 the daily capacity ranged from 1 to 16 million cubic feet. The spectacular well of the year was a wildcat on the Crandall farm in the town of Independence, Allegany County. An estimated flow of 44 million cubic feet was struck at 4,912 feet. The well blew wild for 19 days, and when brought under control the daily volume was only 1.5 million cubic feet.

Only 6 of the 50 wells drilled were in developed fields—5 at Beech Hill, Allegany County, and 1 at Greenwood, Steuben County. About two-thirds of the new production was from wildcat wells, but it is evident that a still wider search will be necessary if production is to be maintained at the 1935–38 level.

Two successful wells in the town of Allen, Allegany County—one with an initial flow of 8 million cubic feet—and important new production in the Independence-Andover area indicate further developments in these localities. One well drilled near Elmira in Chemung County had an initial production of 1.5 million cubic feet. Two other wells produced smaller amounts. Late in the year two of these wells were connected to the Elmira City gas mains and were reported to have supplied about 1 million cubic feet daily for the pipe lines during most of the winter. One well in the town of Erwin was dry in the Oriskany and was deepened to 6,825 feet, where it was abandoned as a dry hole in the Medina (Queenston) red shale.

A new pipe line was built to bring additional gas from West Virginia fields. Its northern terminus is near Olean, where it joins the old gas line which crosses the southern tier of counties and reaches a point not far north of New York City.

Ohio.—Although drilling in Ohio increased about 20 percent in 1940 the number of gas-well completions reported was 491—10 less than in 1939, according to a report by Kenneth Cottingham, chief geologist, Ohio Fuel Gas Co. The average initial volume declined slightly to 581,900 cubic feet a well in 1940 from 596,000 in 1939, because there were smaller wells in all strata under active development, except those above the Berea, which averaged about 20 percent larger than to 1939.

Clinton sand gas completions increased about 35 percent to 229 in 1940 with a total volume of 221.4 million cubic feet, equal to 77 percent of all new output in the State (287.3 million). Shallow sand completions numbered 92, with 29.9 million cubic feet of total capacity; Berea completions, 125 with 13.0 million cubic feet; Ohio shale, 18 with 1.5 million; Oriskany, 3 with 0.4 million; Newburg, 21 with 20.5 million; Trenton, 3 with 0.6 million.

New gas wells were reported in 30 counties; the most active were Licking (90), Athens (57), Noble (30), Washington (29), Muskingum (27), Knox (25), and Guernsey (22). The greatest Clinton gas activity continued to be in the pool northeast of Newark in Licking County.

The largest well drilled in Ohio in 1940 was in sec. 5, Butler township, Knox County, which made 12 million cubic feet initially from the Clinton sand at 2,792 feet, with a rock pressure of 935 pounds. Other large Clinton sand wells were reported in sec. 4, Wayne township, Muskingum County (depth, 3,800 feet, and rock pressure, 518 pounds); and in sec. 15 and 16, Brush Creek township, Muskingum County (depth, 4,200 feet, and rock pressure, 1,150 pounds).

Drilling to the Trenton lime in northwestern Ohio has declined steadily in recent years. In 1940 only 18 completions were reported; 3 were small gas wells. The search for production from the horizon, 500 to 700 feet below the top of the Trenton—known as the "Green sand" in western Ohio and as the St. Peter in the eastern part of the State—continued in 1940, but results were not encouraging. Eight wells were drilled in Allen, Franklin, Medina, Clinton, Greene, Putnam, and Union Counties. Seven were dry, and one in Allen county was a very small oil well.

A dry hole drilled through the Clinton sand at 5,620 to 5,689 feet in sec. 23, Center township, Noble County, reached a total depth of 5,800 feet. Early in 1941 an unsuccessful test of the Clinton was completed in sec. 19, Smith township, Belmont County, at a depth of 7,887 feet.

In eastern and northeastern Ohio several large companies were conducting active geophysical exploration. Test wells drilled thus far upon the basis of this work have been unsuccessful.

Oklahoma.—Natural-gas production in 1940, as reported to the Oklahoma Tax Commission, declined about 1 percent to 272,584 million cubic feet owing to continued shrinkage in the output of casinghead gas. Dry-gas production (from gas wells) increased 17 percent to 87,404 million cubic feet, reflecting larger demand for gas for most purposes.

About 180 gas wells were drilled in 1940 with a total initial daily capacity exceeding 1,000 million cubic feet. Completions were scattered in 34 counties with the largest number in the old eastern belt of fields. Seventeen new discoveries and 5 new pay horizons were reported; 4 were in Hughes County, 3 in Okfuskee, 3 in Pontotoc, 2 in Caddo, and 1 each in 10 other counties.

Important added gas reserves were developed in the Chickasha field, Grady County, where seven very large wells were completed in the "Charlson zone." In the Cement field, Caddo County, the productive area was extended, and a new deep horizon is thought to have been opened by No. 2 Wagner which made 18 million cubic feet daily from sand at 4,332 feet.

In Texas County, Okla., nine wells with a total capacity of 170 million cubic feet were completed in a south extension of the vast Hugoton field. More than 100 square miles of new productive area appear proved.

The total gas capacity of the wells in the recently developed Hobart oil field in T. 7 N., R. 17 W., Kiowa County, probably exceeds 50 million cubic feet a day, but no outlet for this gas is available.

The Cumberland oil field in Marshall and Bryan Counties, opened in April 1940 and since proved the most important oil discovery of the year in Oklahoma, has very large reserves of gas in several horizons below the Viola lime. A gasoline plant is planned that will make several million cubic feet of residue gas available daily for an extended period.

Shows of wet gas at great depths in several wildcat wells completed in 1940 in the Anadarko Basin of western Oklahoma may have important implications for future development of that great region. Such shows were reported in deep tests in western Washita County, southeastern Woods County, and southeastern Dewey County near Oakwood. At the latter location efforts may be made to unitize a large block of acreage with the purpose of instituting the first high-pressure recycling project in the State for recovery of liquid condensate while returning stripped gas to the reservoir.

As of October 1940 Oklahoma Conservation Department tests indicate that there were 107 gas wells in the Oklahoma City field with a total daily open-flow capacity of 274 million cubic feet. This represents an increase of 6 wells in a 1-year interval and a decrease of 148 million cubic feet in daily capacity. One company in this field has begun withdrawing gas from a partly depleted gas sand that is subject to competitive drainage and storing the gas in another sand at 400 pounds pressure where it can be effectively held against future market demand.

No large gas lines were built in 1940. Enlargement of military activity at Fort Sill prompted the laying of 15 miles of 8⅝-inch line in the vicinity of Lawton to handle the increased demand for gas.

Pennsylvania.—Drilling for gas increased in 1940 under the stimulus of more active market demand and declining productive capacity in Pennsylvania. Information has been supplied by J. G. Montgomery, Jr., vice president, United Natural Gas Co. Perhaps the most significant development was the slump in production from Oriskany sand fields in Potter and Tioga Counties to only 6.5 billion cubic feet in 1940 from 30 billion in 1939, foreshadowing total exhaustion of these gas reserves.

In the Potter-Tioga County fields 19 wells were drilled to the Oriskany sand, of which only 7 were productive. Their aggregate daily open-flow capacity was less than 6 million cubic feet; rock pressures ranged from 287 to 2,200 pounds. All were within the limits of previously discovered pools except one, which was separated from the south edge of the Hebron field by a fault. Inasmuch as the reported initial daily capacity of this well was only 143,000 cubic feet, its value appears slight. No drilling was being done at the end of the year.

In the South Union township field, Fayette County, two additional wells were completed which produced from both the Onondaga chert zone and the Oriskany sand with a volume of 2.4 and 2.5 million cubic feet daily and a rock pressure of about 2,950 pounds. Two wells previously completed in the Onondaga chert beds were deepened and found added gas in the Oriskany. Three more wells were being drilled in the area, and a fourth (on Laurel ridge east of the field) had reached a depth of 8,002 feet without encountering the Onondaga lime.

Two dry holes in McKean County were the only other completions to the Oriskany sand. Late in the year a test scheduled for the Oriskany was begun in New Sewickley township, Beaver County. In northwestern Beaver County an exhausted Oriskany sand well was deepened through the Lockport dolomite and Medina or Clinton sand horizons without obtaining new commercial production.

Increased leasing and geophysical activity in 1940 points to early future exploration of deeper and previously untested strata. In extreme northwestern Erie County a well was being drilled below 1,500 feet to test the Trenton lime.

Drilling for gas from the shallow horizons increased sharply in 1940, but much of it was confined to proved territory. Wildcatting along Muddy Creek in Crawford County developed several small producers. One failure was drilled in the Union City area of Erie County. Several wells with a daily capacity exceeding 1 million cubic feet from the Injun sand rewarded prospecting in Menallen township, Fayette County, and Monongahela township, Greene County. This production is reported as very spotty, however.

Withdrawals of gas from shallow sands increased sharply to meet growing demand as the Oriskany production declined. A new pipe line from Monaca, Pa., to Olean, N. Y., was put in service in the fall of 1940 and provided increased facilities for moving gas from West Virginia to northern market areas.

All drilling in 1940 was done with cable tools. One small Oriskany sand well in Potter County was treated experimentally with hydrofluoric acid, but results were not encouraging.

South Dakota.—There was no change in the natural-gas situation in South Dakota in 1940, according to E. P. Rothrock, State geologist. The small gas production at Fort Pierre, estimated at 7.8 million cubic feet, continued to be marketed in Pierre. A small flow of gas with water was struck at Cheyenne Crossing, Potter County, and was utilized at a tourist camp, although considerable waste resulted from rapid corrosion of pipe and fittings. One dry hole was reported in Harding County.

Texas.—Reports of the Texas Railroad Commission show that the pronounced upward trend in production of natural gas continued in 1940, attaining new high levels. The reported total was 1,566.4 billion cubic feet—20 percent above 1939. Production of gas wells increased 26 percent to 1,095 billion, and gas from oil wells increased 10 percent over 1939 to 466.6 billion.

Most of the gain in gas-well production is attributable to recycling-plant operations, which almost tripled their throughput in 1940 to total 318.6 billion cubic feet. Of this quantity, about 286 billion were returned to the high-pressure reservoirs to minimize pressure drop. In December 1940, 32 recycling plants were operating (an increase of 10 during the year) using a daily average of 1,234.6 billion cubic feet of gas. These plants processed an average daily volume of 38.6 million cubic feet in December 1940 compared to 21.4 million in December 1939. The number of producing wells connected to plants was 87 at the end of 1939 and 243 a year later.

Carbon-black plants consumed 326.1 billion cubic feet of gas in 1940—a 3-percent increase over 1939. Pipe lines increased their takings 7 percent in 1940 to 494.9 billion, and gas used on leases and as plant fuel was reported as 24 percent higher in 1940 at 211.8 billion.

Reported gas-well completions in 1940 totaled 289—a decline from 314 in 1939. The only areas showing gains were eastern Texas, where 38 gas wells were reported in 1939 and 59 in 1940, and West Texas, where 4 and 11 were drilled, respectively. The Panhandle continued to lead with 81 new wells, the same number as in 1939. Activity declined in other areas, particularly the Gulf Coast, which reported only 31 gas wells in 1940, or just half the 1939 total. Southwest Texas had 70 gas completions in 1940 (87 in 1939) and West Central and North Texas 37 (42 in 1939).

Three gas discoveries were reported in West Texas—the Hayes and South Magnolia fields in Ward County and the Embar field in Andrews County. The Hayes field produced from the Delaware and the other two from Permian lime.

In Shackelford County, West Central Texas, the No. 1 Kendrick discovered 9.7 million cubic feet of gas in the Cisco series at 1,605 to 1,612 feet. The Lee field, producing gas from the Strawn at 2,900 feet, was discovered in Coleman County in February, and a new gas pay was opened in the Triplett field, Palo Pinto County, at 4,330 feet in the Bend formation.

In the Panhandle district an important wildcat in Sherman County—the No. 1–A Bryant—found 33 million cubic feet of gas in lime at 2,868 to 3,343 feet after plugging back from 5,138 feet. The location is several miles from the nearest production of gas.

Twenty-five gas or condensate fields were discovered in 1940, and 14 new gas horizons were opened in old fields. South Texas had the greatest number of additions to gas reserves with eight new fields, of which two were of the condensate type and nine new pay horizons, including two condensate. In the Thomaston area, DeWitt County, condensate was discovered in April by No. 1 Conwell, which produced from the Wilcox at 7,855 to 7,885 feet. This is the first production from the Wilcox in southwest Texas. In Victoria County three new pay horizons were found in the McFadden field, and the Bloomington and Edwards condensate fields were opened. The Nueces Bay gas field and East Agua Dulce condensate field were opened in Nueces County. Important extensions and new productive sands were found at Rincon, Starr County, as well as new pay sands at Hayden and Arroyo Grande. Discoveries were reported in seven other counties.

On the Gulf coast nine condensate fields were discovered in 1940 in eight counties. Discovery of the Sheridan pool (condensate) in Colorado County extended Wilcox-trend production 100 miles westward. The Shepherd pool was the first discovery in San Jacinto County. It also produced condensate from the Wilcox at 8,215 feet.

Utah.—Natural-gas production increased about 3 percent in 1940 to a new peak of 4,301 million cubic feet, according to a report by L. G. Snow, acting supervisor, Geological Survey, United States Department of the Interior, Casper, Wyo. Except for 35.6 million cubic feet produced from the Ashley Valley field, the State's entire production was from the Clay Basin field.

Two gas wells with a total daily open-flow capacity of 21.5 million cubic feet were drilled at Clay Basin in 1940. These more fully outlined the productive area of the field and helped to equalize withdrawals.

About 35 million cubic feet of gas, in addition to that recorded above, were used in the Clay Basin field for drilling and field operations.

The production of carbon dioxide gas from the Farnham dome increased 33 percent in 1940 to 67.9 million cubic feet.

Washington.—Information from Sheldon L. Glover, assistant supervisor, department of conservation and development, Pullman, Wash., indicates a continued sharp decline in natural-gas production from the Rattlesnake Hills field, the only commercial source in the State. The 1940 output—39 million cubic feet—was 42 percent less than in 1939. Actual sales were 36,323,000 cubic feet valued at $30,370.

One test well was begun in an attempt to find gas production on the nonproducing flank of the Rattlesnake Hills arch. A wildcat near Yakima, on an anticlinal fold in basalt, was reported to have struck gas at 800 feet with higher rock pressure than the original pressure in the Rattlesnake Hills field.

Production of carbon dioxide from wells near Klickitat increased almost 20 percent to 26 million cubic feet; 2,559,638 pounds of dry ice with a value of $75,000 were made from it. The daily capacity of the dry-ice plant was enlarged in 1940 to 10 tons from 6 tons in 1939.

West Virginia.—The largest demand of recent years for West Virginia gas stimulated drilling activity in 1940, resulting in 468 gas-well completions compared to 366 in 1939. Data have been supplied by David B. Reger, consulting geologist, Morgantown, W. Va.

The total new daily gas capacity developed was 678 million cubic feet, including 44.8 million from deepening operations. Completions in the Oriskany sand represented 452.4 million cubic feet (67 percent of the total). In Kanawha County 66 producers were completed in the Oriskany sand, with a total daily capacity of 217.8 million cubic feet. Activity increased sharply in Jackson County, where 39 Oriskany wells had an initial daily production of 233 million cubic feet. About 8,000 additional acres were proved in the Elk-Poca pool.

An important wildcat—the Riggs No. 1—was completed in Ravenswood district, Jackson County, with an initial capacity of 6 million cubic feet from the Oriskany sand at 5,042 feet. The Riggs is 3 miles south of Oriskany production in the Buttermilk pool. Another wildcat in the Ripley district 7 miles northwest of the Elk-Poca pool made 455,000 cubic feet from the Oriskany sand in January 1941. Large additions to gas reserves in Jackson County are indicated by these wells and nearby developments.

Two Oriskany sand wells of 450,000 and 959,000 cubic feet capacity were drilled in 1940 in the Bull Creek pool in Peytona district, Boone County. A well northwest of Saulsbury, Wood County, made 119,000 cubic feet from the Oriskany; and in Teays Valley district, Putnam County, 40,000 cubic feet of gas were found in this formation.

An old well in southern Kanawha County was deepened from the Oriskany sand and found 733,000 cubic feet of gas in the White Clinton sand (Silurian) with a rock pressure of 1,800 pounds. This well is 6.5 miles northeast of a small Clinton sand well completed in 1939 in

Boone County and is similarly placed on the western limb of the Warfield anticline. Farther north, two more wells in the Charleston field are being deepened to the Clinton sand.

The old Porter Knob gas pool in Cabell County was actively developed in 1940. About 4,000 acres now appear to be proved for production, mostly from the Berea sand with some gas from the Brown shale. The Bowen Creek gas pool in Cabell and Wayne Counties—a 1939 discovery—was expanded by completing 23 wells in the Brown shale, which proved about 10,000 acres. Scattered wells to the north suggest a very large productive area.

The Villa Nova gas pool in Clay and Braxton Counties—another 1939 discovery—reported about 35 completions in 1940, including 18 gas wells with an average capacity of 2.8 million cubic feet and rock pressure of 500 pounds. The field now includes about 3,500 acres.

In Putnam County, Curry district, the Trace Fork gas pool—a late 1939 discovery—had 26 producing wells by the end of 1940, which proved approximately 10,000 acres for gas production from the Salt sand, Big Lime, Berea, and Devonian Brown Shale. Initial capacity averages 800,000 cubic feet a well, with a rock pressure of about 500 pounds. Eleven wells were being drilled at the end of 1940.

The Lorentz gas pool in Buckhannon district, Upshur County, was opened in 1940 by Marple No. 1, which produced 243,000 cubic feet from the Benson sand. Four gas wells were drilled in 1940, producing from the Benson and Gordon sands and indicating a productive area of about 1,000 acres.

Other gas areas were extended or discovered in 11 counties. The leading counties in gas-well completions were: Boone, 36; Braxton, 17; Cabell, 25; Calhoun, 16; Clay, 22; Gilmer, 47; Jackson, 38; Kanawha, 77; Lincoln, 18; Putnam, 32; Ritchie, 40; and Wayne, 31.

In Grant district, Harrison County, a test well is being drilled with rotary tools below a depth of 9,800 feet—the deepest hole ever drilled in the Appalachian region. The Oriskany sand was topped at 7,290 feet (probably unproductive), and the White Clinton may be tested not far below present depth.

Several small gas lines were laid in the Oriskany sand area near Charleston, but none of major importance was reported. However, industrial development in States to the north and east forecast greater demand for gas from West Virginia wells.

Wyoming.—Because the supply of gas, except in the Buffalo-Sheridan region, is ample for present markets drilling for gas in Wyoming was at low ebb during 1940, according to information compiled by L. G. Snow, acting supervisor, Geological Survey, United States Department of the Interior, Casper, Wyo. Only four gas wells were drilled, all in old fields, with a total initial volume of 56.1 million cubic feet. Three old wells were plugged back and recompleted with a total volume of 1.8 million cubic feet. The Hiawatha gas field was apparently extended three-quarters of a mile north by a well that made 8.6 million cubic feet daily.

The gross production of gas in 1940 increased 4 percent to 38,943 million cubic feet, including an estimated use of 880 million cubic feet in the field and a waste of 503 million. Production of the eight major fields increased 639 million cubic feet, a marked decline at Big Medicine Bow being largely offset by higher production and use of gas at

Lance Creek. Production from the Baxter Basin-Clay Basin-Hiawatha area (Wyoming, Utah, Colorado), most of which is consumed in Salt Lake City and vicinity, increased from 11,937 million cubic feet in 1939 to 13,152 million in 1940.

Production of gas in the principal fields was as follows: Salt Creek, 9,379 million cubic feet; Baxter Basin (entire field), 6,409 million; Lance Creek, 5,803 million; Big Sand Draw, 4,019 million; Muskrat, 2,231 million; Little Buffalo Basin, 1,792 million; Elk Basin, 1,697 million; and Big Medicine Bow, 1,437 million.

Of the gross measured production, approximately 20.4 billion cubic feet were utilized for domestic, commercial, and industrial purposes, 10.9 billion for recycling and repressuring, and 6.2 billion for other field purposes. At Salt Creek 6.4 billion cubic feet of gas were returned to formations for repressuring and recycling, at Lance Creek 3.4 billion, and at Rock Creek, Elk Basin, Grass Creek, and La Barge comparatively small amounts.

About 20 billion cubic feet of gas were processed at gasoline plants—9.4 billion at Salt Creek, 5.7 billion at Lance Creek, 4 billion at Big Sand Draw, 615 million at Rock Creek, 169 million at Elk Basin, and 118 million at Grass Creek.

In August 1940 the Billy Creek field south of Buffalo and Sheridan was shut in after producing about 250 million cubic feet of gas in 1940. Depletion had reduced the productive capacity of the field below requirements of the two towns, and a new gas supply from the Big Sand Draw-Muskrat trunk line was made available.

CONSUMPTION

All classes of consumers except petroleum refineries increased their takings of gas in 1939 over 1938. Less gas was used at refineries in 1939 because of sharp curtailment in California owing to substitution of fuel oil for natural gas at several plants. The "other industrial" load gained most sharply (19 percent), followed by gas burned at electric power plants (12 percent). The latter was abnormally stimulated by drought in some sections of the country, which curtailed the available supply of hydroelectric power.

The average consumption per domestic and commercial meter rose in 1939 to 53,100 cubic feet from 52,000 in 1938, whereas the average value of such gas decreased four-tenths cent to 67.9 cents per thousand cubic feet. These two related items have changed little since 1932. The small decline in average value of domestic and commercial gas outweighed the rise in the industrial average value from 9.4 to 9.6 cents and caused the average for all gas consumed to drop from 21.8 cents in 1938 to 21.6 cents per thousand cubic feet in 1939.

Treated for natural gasoline.—The volume of gas processed at natural-gasoline plants in 1940 is estimated to have been 2,380 billion cubic feet, 11 percent more than in 1939. The largest gain was in Texas, where recycling-plant throughput (which is included) was about three times as large as the 1939 record. These operations also caused a probable small decline in average gasoline recovery for the entire country. Gas treated equaled about 89 percent of the natural-gas consumption in the United States in 1940 and 87 percent in 1939.

Natural gas consumed in the United States, 1935–39

Year	Domestic and commercial consumption

Gasoline-plant operations increased in six States in 1939, particularly in Texas, West Virginia, and Ohio. From 1935 to 1939 the most pronounced expansion of gasoline-plant activity was in New Mexico, Kansas, and Arkansas.

Domestic and commercial.—Domestic consumers are estimated to have used 442 billion cubic feet of natural gas in 1940—13 percent more than in 1939 and the highest volume on record. Factors contributing to the larger demand were rising national income, an unusually cold January and February in 1940, and continued growth in the number of domestic meters. Commercial consumption in 1940, similarly stimulated, increased 12 percent to 132 billion cubic feet. Average values of domestic and commercial gas are estimated to have declined slightly in 1940 to 73.0 and 49.2 cents per thousand cubic feet, respectively.

The average value of gas used for domestic and commercial purposes was lower in 1939 than in 1938 in the majority of States. Significant declines were recorded in Arizona, Minnesota, Michigan, Tennessee, California, and New Mexico. Substantial increases took place in Ohio and Wyoming.

[1] Gas used at portland-cement plants included under "Miscellaneous" for United States total and under "Other industrial" for State total to avoid disclosing figures of individual operators.

[2] Maryland includes District of Columbia and Virginia.

[3] Gas used in carbon-black manufacture included under "Miscellaneous" for United States total, and under "Other industrial" for State total to avoid disclosing figures of individual operators.

[4] Utah includes North Dakota.

[5] A small amount of gas distributed in Tennessee included with Virginia; separate figures not available.

Field.—Gas reported as used for field purposes is estimated to have risen to a new high in 1940 at 700 billion cubic feet—3 percent above 1939. Sharp expansion in field gas in Texas has dominated the national trend for several years, and this condition probably continued in 1940. Exploitation of Texas condensate fields now adds substantially to the total use in the field.

Among other producing States, definite upward trends in volume of field gas were evident in 1938 and 1939 in New Mexico, Illinois, and Wyoming; however, decreases were noted in Oklahoma, California, and Kansas. The curtailment in the use of field gas in Oklahoma has been particularly sharp since the peak of flush production from the Oklahoma City and Fitts fields passed.

Carbon-black manufacture.—Gas burned in carbon-black manufacture totaled about 369 billion cubic feet in 1940 and exceeded the previous peak of 1939 by 6 percent. Larger consumption was indicated in Texas and probably in Kansas and Oklahoma, where new plants commenced operations in 1940.

Petroleum refineries.—Refineries are thought to have used about 100 billion cubic feet of natural gas as fuel in 1940—about 2 percent above the 1939 total. California refineries reduced their consumption of natural gas almost 50 percent in 1939 as a result of substitution of fuel oil for gas for part of their fuel requirements. The change was made because declining prices for heavy fuel oil made possible a reduction in fuel costs. Texas, Louisiana, and Oklahoma, which rank high in this class of gas use, showed moderate expansion over 1938 in 1939.

Kentucky was added to the list of States in which gas is consumed at petroleum refineries in 1939, making 20 States in all.

Electric public-utility power plants.—Consumption of natural gas at electric power plants in 1940 fell 8 billion cubic feet to 183 billion, despite an 11-percent increase in production of electric power.

In 1939 the use of natural gas for generating electricity was abnormally stimulated, especially in California, by drought which limited the output of hydroelectric plants. Thus a heavy load was carried by the steam power plants. Consumption at power plants was less in New York, Pennsylvania, and Ohio in 1939 than in 1938, doubtless owing to reduced gas supplies, and in a few southeastern and Rocky Mountain areas.

Portland-cement plants.—Cement production in 1940 was 8 percent above 1939, and gas consumed at cement plants increased to 41,949 million cubic feet from 40,233 million in 1939. The consumption in 1940 was slightly larger than the previous high point of 1929.

Other industrial.—Consumption of natural gas by miscellaneous industries is estimated to have gained about 15 percent in 1940, rising to 699 billion cubic feet—the largest volume on record. Demand, particularly from the metal-working trades, was heavy, as the defense program necessitated capacity operations in many types of manufacturing.

All important industrial areas within the range of natural-gas service apparently participated in the increase except western New York State. In this region many plants were compelled to change from natural gas to other fuel because of a local shortage of gas; in consequence, industrial consumption was reduced abruptly in 1940.

The market for "other industrial" gas has grown most rapidly of any of the major classes of consumption since the depression low point in 1932. The volume in 1939 was 121 percent larger than in 1932, having gained in every year since then except in 1938. In the same period the total consumption of natural gas in the United States increased 59 percent. Most of the group of States that provided the largest markets for industrial gas in 1939 have about doubled their rate of consumption since 1932. In Illinois the rate has more than quadrupled, and there have been comparable gains in a number of other States where developed markets are smaller.

Mixed gas.—After several years of recession the number of consumers served with mixed gas increased 2 percent in 1939 owing to small additions in all areas except Pennsylvania. The volume of mixed gas taken by domestic and commercial consumers increased 5 percent, but industrial consumption continued to slump to 8,039 million cubic feet from a peak of 11,532 million in 1936. Domestic use of natural gas mixed with manufactured gas increased materially in Illinois, Minnesota, and Ohio in 1939.

Consumption of natural gas used with manufactured gas in the United States in 1939, by States

State	Domestic		Commercial		Industrial (M cubic feet)	Total

NEW MARKETS

More than 80 municipalities in 15 States were supplied with natural gas for the first time in 1940, adding about 300,000 population to the territory served. Important additions were made in Indiana, where 19 new towns were connected, including Bloomington, Bedford, and Jeffersonville. In Illinois, Kewanee, Lawrenceville, Olney, and Salem were included in 11 new markets. Smaller but substantial new areas were acquired in Iowa, Nebraska, New Mexico, Ohio, and Pennsylvania.

Important industrial consumers—chiefly connected with the mining, chemical, and clay industries—were reached by new pipe lines in Arizona, Arkansas, Michigan, New Mexico, and Texas.

In many parts of the country minor extensions were made to meet the gas requirements of new or expanded military establishments and industrial plants involved in the national defense effort. Most of these projects are of only local importance to the gas industry, but in the aggregate they will be a substantial addition to gross sales of gas.

INTERSTATE SHIPMENTS

Interstate shipments of natural gas in 1939 recovered the volume lost in 1938 and advanced to a new peak—689,795 million cubic feet. Increased withdrawals from the three leading source States (Texas, Louisiana, and West Virginia) accounted for almost the entire net gain and continued the trend toward larger shares of the total market for these areas. Exports from most States increased, however, with the conspicuous exception of New York, whose shipments declined almost 50 percent after an abrupt rise in 1938. The Oriskany sand fields of New York, which supplied the flush gas production, have been quickly depleted by competitive drilling and pipe-line activities.

The movement from Kentucky to Maryland increased sharply, and Oklahoma gas in some volume began supplying markets in Iowa, Minnesota, and South Dakota. The movement from Kentucky to Illinois was reversed in 1939 after new gas supplies were developed in Illinois.

Most importing States consumed more out-of-State gas in 1939 than in 1938. Pennsylvania and West Virginia imported much less gas from New York and Kentucky, respectively. The Kentucky shipments were curtailed because of large available gas supplies in West Virginia.

PIPE-LINE DEVELOPMENTS

Vigorous expansion of natural-gas pipe-line facilities continued in 1940 under the stimulus of growing markets. About 2,000 miles of new line were laid in 1940—30 percent more than in 1939.

Almost a third of the mileage constructed was devoted to looping projects on major lines originating in the Southwestern States. The largest installation involved 160 miles of 20- to 24-inch pipe in several loops along the Texas-Detroit transmission system. The capacity of the Louisiana-Memphis line was augmented by addition of 92 miles of 18-inch. Loops with a total length of 80 miles of 22-inch pipe were installed in the Southern line, which carries gas eastward from northern Louisiana to points in central Georgia and intervening States.

Fuel requirements for enlarged mining and smelting operations in Arizona and New Mexico were supplied by construction of 78 miles of 6⅝- to 16-inch loop lines along trunklines of the system serving these areas from southeast New Mexico fields. The carrying capacity of the line to Minneapolis from the Texas Panhandle was enlarged by adding 75 miles of looped line in Kansas and Nebraska, mostly 24-inch diameter. Smaller loop programs increased the capacity of lines near Beaumont, Tex.; Farmington, N. Mex.; and Lawton, Okla.

In Montana 120 miles of 8-inch line were laid from Fort Peck to Wolf Point and Glendive to carry gas from the Bowdoin field, supplementing supplies of the Baker-Glendive district. An additional 56 miles of branch and gathering lines were installed. A 20-inch line was started northward from Geneseo, Ill., as a branch of the Texas-Chicago trunk line, with Milwaukee as the intended terminus. Work on the Wisconsin portion of the project was halted, however, in January 1940 because of legal difficulties. A new line of 8- to 16-inch pipe laid from connections at Monaca, Pa., northeastward 117 miles to Olean, N. Y., will bring a substantial volume of West Virginia gas to established markets in western New York, where local supplies became inadequate.

In Michigan several new lines were constructed to tap gas reserves of the Lake George, North Star, Temple, and other fields in Missaukee, Osceola, and Clare Counties. The largest of these consisted of 58 miles of 12-inch discharging into a trunk line 6 miles west of Midland and 55 miles of 6-inch used to supply gas to a Midland chemical plant.

In Wyoming 100 miles of 4-, 6-, and 8-inch line were laid to bring gas to the depleted Billy Creek field from the Big Sand Draw and Muskrat fields via Casper. In New Mexico four extensions totaling 59 miles in length were built to serve new markets at Lordsburg, Belen, Los Lunas, Isleta, and potash mines near Carlsbad.

In Texas 18 minor pipe-line projects were reported which connected 11 fields to new or established markets. The total length of new lines was about 300 miles, the longest—48 miles of 8-inch—running from the Page field to San Angelo. Another important line consisted of 41 miles of 8- and 10-inch pipe laid from the Bay City field to serve a new chemical plant at Freeport.

Four lines of 90 miles total length were laid in Louisiana to connect the Abbeville, Lirette, Sligo, and Terrebonne Parish fields to markets. The largest—35 miles of 12-inch—brings gas from Lirette to New Orleans.

In Kansas 65 miles of 12-inch were run from the Cunningham pool to Wichita, 30 miles of 8-inch from Hutchinson to Lyons, and 12 miles of 6-inch from Finney County wells to Garden City.

Minor extensions and gathering lines were built in Arizona, Arkansas, California, Indiana, Kentucky, Minnesota, Nebraska, Oklahoma, and Ohio. In many localities connections were made to military establishments, flying fields, or manufacturing plants connected with the national defense program.

Construction of several important interstate gas lines was proposed during 1940, but actual work must await approval of the Federal Power Commission. Prospective market areas to be served with gas from southwestern fields include southern Wisconsin, eastern Tennessee and western North Carolina, New Jersey, and metropolitan New York. A new line from eastern Kentucky toward Pittsburgh, Pa., is also reported to be under consideration.

NATURAL GASOLINE

AND LIQUIFIED PETROLEUM GASES [1]

By G. R. Hopkins and A. T. Coumbe [2]

SUMMARY OUTLINE

NATURAL GASOLINE

A new record for production—2,320,458,000 gallons—was established by the natural-gasoline industry in 1940. This output was 86,770,000 gallons (4 percent) above the previous record of 1929, which included one less day. In spite of this peak output, the industry did not experience a particularly profitable year compared with 1929 or 1939, because the average value at the plants fell from 7.1 cents a gallon in 1929 to 4.2 cents in 1939 and then to 3.0 cents (estimated) in 1940. The recycling division of the industry expanded rapidly in 1940, with considerable evidence of prosperity, but profits at the conventional plants must have declined to low levels in consequence of the abnormally low prices for refinery gasoline.

Although the proportion of natural gasoline in refinery gasoline changed little in 1940 there was an actual loss in refinery deliveries from 1,663,452,000 gallons in 1939 to 1,651,860,000 in 1940. This loss in business with the premier customer, in spite of lower prices, probably reflected the results of reduction in the yield of gasoline in favor of fuel oils. This situation, in conjunction with the gain in production, reversed the trend of stocks from a net withdrawal in 1939 to a sizable gain in 1940. As a further depressing factor, exports continued to drop as a result of the war and totaled only 71,694,000 gallons in 1940 compared with 172,662,000 in 1939.

The average vapor pressure of the deliveries of natural gasoline fell to a new low of 19.3 pounds in 1940, probably an effect of the installation of stabilizing equipment at recycling plants, although the older establishments doubtless were forced to produce a more stable commodity to compete with them.

[1] Data for 1940 are preliminary; detailed statistics with final revisions will be released later.

[4] Deliveries to refinery-owned bulk plants included in "jobbers and retailers."

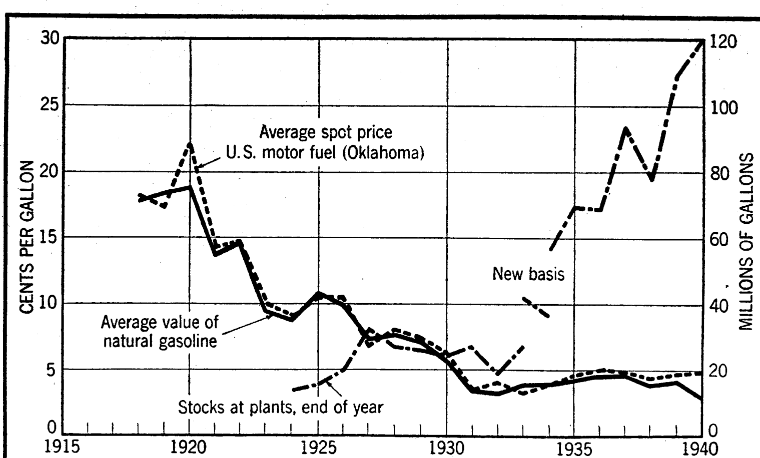

FIGURE 1.—Trends in average value of natural gasoline, spot price of gasoline, and stocks of natural gasoline, 1918–40.

PRICES AND MARKET CONDITIONS

Natural gasoline sold at record low prices in 1940. The average for 26–70 grade in the Mid-Continent area was 1.94 cents a gallon compared with 3.19 cents in 1939. The average for June was only 1.5 cents, from which the price advanced to a high of 3.0 cents late in October.

Figure 1 shows that the average value of natural gasoline (estimated for 1940) has dropped far below the refinery price of gasoline in Oklahoma.

Prices to blenders of Mid-Continent natural gasoline, grade 26–70, with dates of price changes in 1940 and monthly and yearly average in cents per gallon

EMPLOYMENT AND PRODUCTIVITY

The discussion of employment and productivity included in this chapter for several years cannot be given for 1939, as the Bureau of Mines did not compile employment data for that year; however, complete information for 1939 was collected by the Bureau of the Census as part of its Decennial Census of Mines and Quarries, and the results should be published before the end of 1941.

PRODUCTION

Trends in total output.—Although the respective percentage increases in the production of crude oil and natural gasoline in 1940 tallied (both increased 7 percent over 1939) the monthly trends for the two differed markedly (see fig. 2). Daily average production of crude oil was at its peak in March and April, but the highest months for natural gasoline were October and November. This diversity of trends is explainable largely in Illinois (where crude-oil production was highest in June but where natural-gasoline production increased steadily throughout the year) and in Texas (where crude-oil production was highest in March but where the output of natural gasoline was much higher in December than in January because of the growth in recycling).

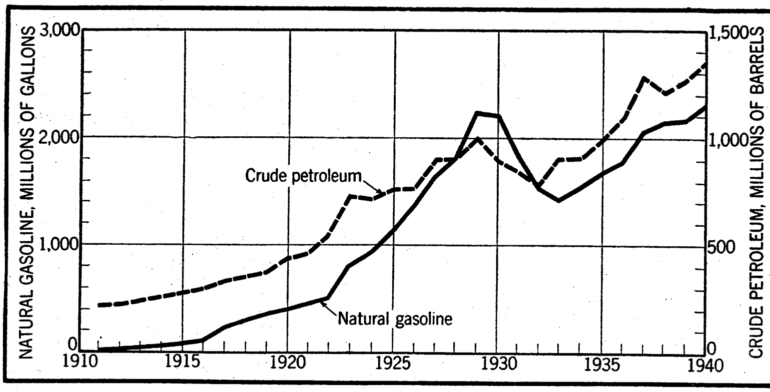

FIGURE 2.—Annual production of natural gasoline and crude petroleum, 1911–40.

[1] Subject to revision.
[2] Includes Utah.

California.—The newer and smaller fields of California, designated "Rest of State" as separate from Kettleman Hills and several other large fields, gained sharply in output in 1940; but most of the larger fields decreased, and the State total dropped from 607,200,000 gallons in 1939 to 586,000,000 in 1940. Nearly all the production is from casinghead gas, so there was close relationship between the production of natural gasoline and crude oil; neither fluctuated much in 1940.

Monthly production of natural gasoline in the United States, 1939–40, by fields, in millions of gallons

[1] Subject to revision.

Louisiana.—Production in Louisiana reached a new peak of 109,100,000 gallons in 1940. Most of the 15,000,000-gallon gain over 1939 was obtained in the coastal district, where deep drilling has found large reserves of gas.

Oklahoma.—The "Rest of State" in Oklahoma gained slightly in output in 1940; but Seminole and Oklahoma City, the two largest producing fields, reported a material loss, and the State total dropped from 436,100,000 gallons in 1939 to 399,200,000 in 1940—the lowest since 1935.

Texas.—Production in Texas made a new record of 920,700,000 gallons—a gain of 150,600,000 gallons (20 percent) over 1939. This increase about equaled the gain in the national total. The fact that most of the increase in 1940 was in the Gulf Coast district indicates that recycling again was largely responsible for the new record.

The Texas Panhandle output rose slightly, and the district retained its leadership, but it probably will be superseded by the Gulf Coast in the near future.

Other States.—Most of the other producing States showed increased production, and several attained new peaks. The most spectacular gain was in Illinois, where the construction of several new plants represented a step toward reducing the enormous waste of gas in flares.

Natural gasoline produced and natural gas treated in the United States in 1939, by States [1]

State	Number of operators [2]	Number of plants operating	Natural gasoline produced: Thousands of gallons	Value at plants: Thousands of dollars	Value at plants: Average per gallon (cents)	Natural gas treated: Millions of cubic feet	Natural gas treated: Average yield per M cubic feet (gallons)

[1] Complete figures for 1940 not yet available.
[2] A producer operating in more than 1 State is counted only once in arriving at the total for the United States.

CONSUMPTION AND MOVEMENTS

The demand for natural gasoline in 1940 will total about 2,300,000,000 gallons compared with 2,186,478,000 in 1939. According to company reports refinery consumption receded slightly and exports were off materially, so the gain was in "direct sales" and losses. Actually, refinery utilization probably increased, and actual losses were less than indicated, as it is virtually impossible to obtain separate figures on all natural gasoline or condensate mixed with crude oil.

Refinery utilization.—The proportion of natural gasoline in refinery gasoline during 1940 remained unchanged from the 1939 ratio of 6.6 percent. Although this marks a decline from the 7.2 percent in 1938, it is close to the average of 6.8 percent for the past 8 years.

California yielded first place to the Texas Inland district in the utilization of natural gasoline when the ratio in the former district dropped from 18.0 percent in 1939 to 15.7 in 1940 and that in the latter increased from 14.3 percent to 16.6. A further decrease of 1.7 percent in the Arkansas and Louisiana Inland district brought the ratio in this district to 3.3 percent, the lowest on record. The East Coast district, which established its peak in 1939, slumped to 2.0 percent in 1940.

"Direct" sales.—Sales of natural gasoline to jobbers and retailers increased materially in 1940, as the producers sought new outlets to replace lost refinery connections.

The intrastate movement in Texas remained the most important item in "direct sales;" the largest interstate movement was from Texas to Minnesota replacing that from Oklahoma to Illinois.

Percentage of natural gasoline in refinery gasoline in the United States, 1936–40, by districts

Year	East Coast	Appalachian	Indiana, Illinois, Kentucky	Oklahoma Kansas, Missouri	Texas Inland	Texas Gulf Coast	Louisiana Gulf Coast	Arkansas and Louisiana Inland	Rocky Mountain	California	Total
1936	1.6	1.6	4.4	9.7	11.5	3.9	1.8	5.4	7.8	15.5	6.7
1937	1.9	1.8	4.3	8.5	13.1	5.3	4.6	6.5	6.1	15.7	7.0
1938	1.6	1.4	4.7	8.8	15.5	4.3	2.2	6.8	5.8	17.6	7.2

[1] Subject to revision.

Water-borne shipments.—Natural gasoline suffered a greater relative recession in exports than any of the petroleum products, and the total for 1940 was only 71,694,000 gallons, or 58 percent below the total in 1939. The most severe cuts in shipments were those to Netherlands West Indies—from 63,177,000 gallons to 4,362,000; United Kingdom—from 33,629,000 gallons to 8,361,000; and Japan—from 7,611,000 gallons to 213,000. The decline in exports was due principally to the United States Government ban against exporting materials suitable for aviation fuel. Shipments to Canada increased from 33,446,000 gallons in 1939 to 44,157,000 in 1940; these comprised 62 percent of the total exports. Shipments of 4,374,000 gallons to Trinidad and of 1,354,000 gallons to Portugal, neither of which received natural gasoline from United States in 1939, constituted the only other gains in 1940 over 1939. Exports from Texas Gulf Coast ports totaled 44,000,000 gallons in 1940—a 63-percent loss from 120,000,000 gallons exported in 1939. Exports from California decreased 40 percent—from 30,000,000 gallons to 18,000,000.

STOCKS

The situation as regards natural-gasoline stocks was not as favorable in 1940 as in 1939; in place of a net withdrawal of 17,178,000 gallons in 1939 there was a net increase of 53,886,000 gallons. This reversal probably was related to the shift in refinery yields from gasoline to distillate fuel oil; in other words, the refiners did not need to buy as much natural gasoline in the fall for winter volatility. California refinery stocks again held the key to the general situation, and a substantial decline in 1939 was followed by almost as large a gain in 1940.

TECHNICAL DEVELOPMENTS

Recycling plants.—Rapid expansion of recycling-plant operations in Texas continued in 1940. Reports of the Texas Railroad Commission indicate that the number of active plants increased from 21 to 32 and that the volume of gas processed in December 1940 was 1,235 million cubic feet a day—almost three times the December (1939) average. Producing wells connected to plants numbered 243 at the end of 1940 contrasted with 86 a year earlier.

The daily output of liquid products was 22,357 barrels in December 1940 compared with 6,487 in December 1939. The tendency is to install fractionating equipment to make a higher percentage of finished products; thus in December 1940 about half of the output was gasoline.

There are several recycling projects in other States, either contemplated or active, but complete information is not available.

[4] Drip gasoline.

Yield.—The average yield of natural gasoline declined from 1.06 gallons per thousand cubic feet of gas treated in 1938 to 1.01 gallons in 1939. There was probably a further small decrease in 1940 as recycling continued to expand; recovery by this process is well below that of the conventional plant.

The yield in Oklahoma rose to 1.98 gallons in 1939, but that in both Texas and California—the two leading producing States—decreased. Colorado again had the highest average yield (3.00 gallons in 1939), but the output is very small.

Production, by processes.—In 1940 the number of compression plants increased as the number of recycling plants added exceeded the number of old units dismantled. On the other hand, the number of absorption (and combination) plants decreased in 1939 for the first time since 1935. Production by processes followed the trend in number of plants, except that the output of charcoal plants dropped in 1939, even though the number stayed at 9.

Trends in vapor pressures.—The average vapor pressure, which had increased in 1939, fell to a new low of 19.3 pounds in 1940. The average for refinery shipments in 1940 was 20.2 pounds and for shipments to jobbers and retailers 13.8 pounds, both lower than in 1939.

Technical improvements.—Progress in the chemistry of the lighter hydrocarbons continued, particularly in relation to aviation gasoline.

Although the production of aviation gasoline is centered at refineries, increasing quantities of certain natural-gasoline fractions such as isopentane are being utilized. Considerable advance was noted in projects relating to the high-pressure characteristics of the lighter hydrocarbons.

NUMBER AND CAPACITY OF PLANTS

The concentration of natural-gasoline manufacture in fewer establishments, which has been under way for more than 10 years, lost some of its impetus in 1938 and 1939, as on January 1, 1940, there were 729 plants—only 12 fewer than on January 1, 1938. The number of plants in Oklahoma continued to decrease rapidly, but this was largely offset by a sizable gain in Texas and a smaller gain in Illinois, which had shown a steady decline until the oil boom of recent years.

Number and capacity of natural-gasoline and recycling plants as of January 1, 1940, by States, with biennial summary for January 1, 1928–38

[1] Data compiled by E. T. Knudsen, Los Angeles office, Bureau of Mines.
[2] 500 gallons or less.

The total daily capacity of the plants on January 1, 1940, was 11,662,000 gallons—the highest ever recorded. Part of the gain was due to the construction of recycling plants, which are classed as natural-gasoline plants. A much larger gain in capacity probably will be recorded in the next 2 years—1940 and 1941—as the construction of recycling plants has by no means reached a stalemate. The low prices of natural gasoline in 1940 probably were unfavorable to the smaller conventional establishments, so the number of such plants may continue to decline.

LIQUEFIED PETROLEUM GASES

The rapidly growing interest in liquefied petroleum gases, stimulated by their numerous uses as fuels, is evidenced in a 40-percent gain in sales in 1940, when deliveries increased to 313,456,000 gallons compared with 223,580,000 in 1939. The expansion of approximately 90 million gallons in sales during 1940 is remarkable, when it is observed that this increment nearly equals the total requirements in 1936 and that the volume of the marketed production of liquefied petroleum gases has about trebled in 4 years.

Sales of liquefied petroleum gases in the United States, 1934–40, in thousands of gallons

Year	Propane	Butane	Propane-butane mixtures	Pentane	Total
1934	18,681	25,553	10,271	1,922	56,427
1935	26,814	34,084	13,493	2,464	76,855

1938	54,130	52,768	56,050	2,253	165,201
1939	79,323	71,351	69,020	3,886	223,580
1940 [1]	109,216	77,056	123,348	3,836	313,456

[1] Subject to revision.

All principal uses of liquefied petroleum gases made important gains in 1940 compared with requirements in 1939. Sales for domestic consumption or in the "bottled-gas" trade increased 53 percent, while gas-manufacturing companies purchased 31 percent more liquefied petroleum gases in 1940 than in 1939 for mixture with their manufactured gas and for direct distribution through their lines to consumers. Deliveries of liquefied petroleum gases for consumption as industrial fuel, which made an outstanding gain of 59 percent in 1939 in contrast to a loss in 1938, increased only 12 percent in 1940 over 1939—the lowest rate of expansion for the several principal uses. Manufacturers of chemicals, who bought smaller quantities of liquefied petroleum gases in 1939 than in 1938 (due partly to overstocking in the latter year) purchased 29 percent more of these gases in 1940 than in the preceding year. The rapidly increasing use of liquefied petroleum gases as fuel for internal-combustion engines is indicated by the 81-percent gain in sales for this purpose in 1940 compared with 1939.

Exports of liquefied petroleum gases, as reported by the producers, totaled 1,616,000 gallons in 1940—a 3-percent gain over the 1939 quantity of 1,570,000 gallons.

Sales of liquefied petroleum gases in recent years have, broadly speaking, comprised nearly equal proportions of propane, butane, and propane-butane mixtures plus an unimportant percentage of pentane. Deliveries reported in 1940 show a deviation from former annual surveys in that, although there was little change in the propane share (about 35 percent of total sales in both 1939 and 1940), the relative percentages of butane and propane-butane mixtures in the total have changed noticeably. Butane declined from 31.9 percent of the total sales in 1939 to 24.6 percent in 1940, while propane-butane mixtures gained correspondingly from 30.9 percent in 1939 to 39.4 percent in 1940. It is believed that this shift in the percentages of butane and propane-butane mixtures in total deliveries probably is due to the fact that distributors were asked to follow specifications for liquefied petroleum gases adopted by the Natural Gasoline Association of America, effective September 1, 1940, in reporting 1940 sales, while for preceding years no agreed-upon or exact specifications were used to separate the several gases covered in the survey. The fact that, under the newly adopted specifications, the proportion of propane in the 1940 total remained virtually the same as in recent years and that conversely there was quite a change in the relative percentages of the butane and propane-butane mixtures reported is not surprising, as previously nearly all producers and distributors of liquefied petroleum gases agreed fairly well as to the specifications for propane but were at some variance as to the dividing line between butane and propane-butane mixtures.

Deliveries of propane increased from 79,323,000 gallons in 1939 to 109,216,000 in 1940 or by 38 percent compared to a 47-percent gain in 1939 over 1938. Sales of butane under the newly adopted specifications mentioned in the paragraph above showed an 8-percent expansion from 71,351,000 gallons in 1939 to 77,056,000 in 1940, while the demand for propane-butane mixtures rose from 69,020,000 gallons in 1939 to 123,348,000 in 1940 or by 79 percent. Until comparative statistics become available under the new specifications a better idea of the increase in the demand for butane and propane-butane mixtures can be obtained by grouping them; then it is found that the total sales for these two items increased from 140,371,000 gallons in 1939 to 200,404,000 in 1940—a gain of 43 percent. The pentane marketed in 1940—3,836,000 gallons—was slightly below the 1939 quantity—3,886,000 gallons.

The proportion of total liquefied-petroleum-gas sales reported for domestic consumption continued its strong upward trend from 35 percent of deliveries for all purposes in 1938 to 39 percent in 1939 and to about 43 percent of the marketed production in 1940. Gas-manufacturing companies use more liquefied petroleum gases each year, but their proportionate share of the total demand has decreased from 6.8 percent for 1938 and 6.9 for 1939 to 6.5 percent in 1940. Industrial requirements for liquefied petroleum gases in 1940 failed to show a large gain, as did the other principal uses; furthermore, sales reported in this classification slumped from 27.9 percent of the total in 1939 to 22.3 percent in 1940. The chemical use of liquefied petroleum gases increased in 1940 compared with 1939; however, the percentage of this trade dropped from 12 percent of the total market in 1939 to 11.1 percent in 1940. The consumption of liquefied petroleum gases as fuel for internal-combustion engines is rapidly becoming important, as evidenced by deliveries for this purpose, which increased from approximately 13.3 percent of the total sales in 1938 and 1939 to 17.2 percent in 1940.

[1] Subject to revision.

Deliveries of propane increased from 79,323,000 gallons in 1939 to 109,216,000 in 1940. Propane is in greatest demand as a domestic fuel, and the quantity sold for household use was reported as 68,927,000 gallons in 1940—31 percent above the 1939 total of 52,533,000 gallons. Although the domestic consumption of propane is expanding rapidly, the proportionate share of propane sales credited to this particular use has fallen from 69 percent of the total in 1938 to 66 percent in 1939 and to 63 percent in 1940. Propane is gaining in importance as an industrial fuel; deliveries for this purpose increased to 33,122,000 gallons in 1940—a quantity 40 percent over the 1939 total of 23,685,000 gallons. Incidentally, the industrial consumption of propane represented 30 percent of all deliveries in both 1939 and 1940. Additional uses for propane are now of minor importance; however, it should be mentioned that purchases of propane by gas manufacturers increased from 2,083,000 gallons in 1939 to 5,201,000 in 1940—an outstanding gain for this trade.

As sales of butane reported under the new specifications showed only an 8-percent increase to 77,056,000 gallons in 1940 compared with a demand of 71,351,000 gallons in 1939 and deliveries of propane-butane mixtures expanded disproportionately from 69,020,000 gallons in 1939 to 123,348,000 in 1940—a 79-percent gain—the 1939 and 1940 quantities are not considered comparable; therefore, no comments will be attempted until a second year's distribution of sales under the present specifications becomes available.

The demand for pentane declined slightly from 3,886,000 gallons in 1939 to 3,836,000 in 1940. The chemical-manufacturing industry absorbs the larger share of the marketed pentane, and sales reported in that trade increased from 2,644,000 gallons in 1939 to 3,038,000 in 1940. Some pentane is used for domestic fuel; however, the quantity fell sharply from 1,023,000 gallons in 1939 to 656,000 in 1940.

The American Gas Association cooperates each year in furnishing the Bureau with statistics pertaining to the distribution of liquefied petroleum gases by manufactured-gas companies. Details for 1940 are as follows:

At the end of 1940, liquefied petroleum gas was being delivered through mains to consumers in 168 communities in 31 States by 87 companies supplying 57,900 customers.

Butane-air gas with heating value ranging from 520 to 1,300 B. t. u. per cubic foot was supplied to 136 communities in 30 States by 69 companies. A mixture of undiluted butane and propane gas, with a heating value of 2,800 to 3,000 B. t. u. per cubic foot, was supplied to 15 communities in Arizona, California, and Nevada by 6 companies. Undiluted propane gas, with a heating value of 2,550 B. t. u. per cubic foot, was supplied to 18 communities in Maryland, New Jersey, North Dakota, Virginia, and Wisconsin by 5 companies.

The larger proportion of liquefied petroleum gases is handled in bulk or in tank cars and tank trucks, and quantities transported in this way increased from 170,813,000 gallons in 1939 to 245,177,000 in 1940, or from 76.4 percent of total sales in 1939 to 78.2 percent in 1940. Cylinder-and-drum shipments of 52,767,000 gallons in 1939 and 68,279,000 in 1940 constituted, respectively, 23.6 percent of all sales in 1939 and 21.8 percent in 1940. The decrease in the proportionate amount of liquefied petroleum gases conveyed in cylinders is the first decline in percentage reported since 1937. Virtually all petroleum gases handled in cylinders are intended for domestic consumption; this demand absorbed 97 percent of all package shipments in 1940 compared with about 96 percent in 1939.

CARBON BLACK

By G. R. Hopkins and H. Backus

SUMMARY OUTLINE

Carbon-black production established a new record in 1940; but domestic sales declined slightly, and because of the war, exports were off 13 percent from the 1939 peak. The gain in output and the loss

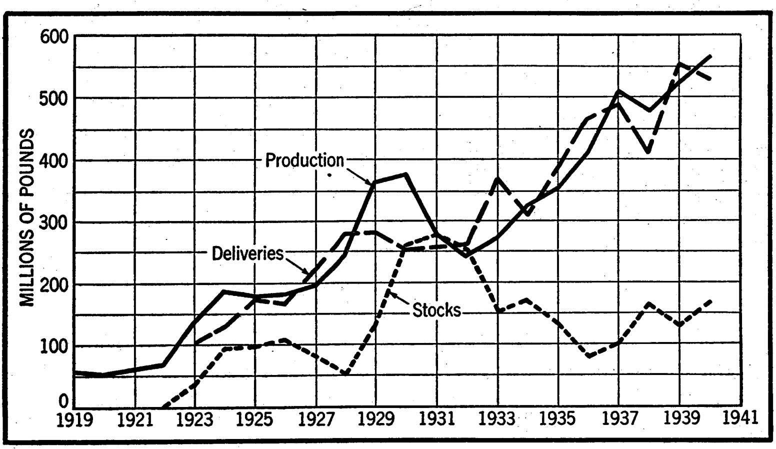

FIGURE 1.—Production, stocks, and deliveries of carbon black, 1919–40.

in sales terminated withdrawals from producers' stocks; in consequence, total stocks at the end of the year had risen to slightly above the total on hand January 1, 1939 (see fig. 1). In spite of this weakening in the market statistics prices were advanced on April 1 and on July 1 and held both gains to the end of the year.

Nearly 90 percent of the domestic sales of carbon black are used in the manufacture of rubber, an important defense commodity included in the Army and Navy Munitions Board list of strategic materials. Considerable carbon black is also being used in connection with the defense program to reduce glare on airport runways. Doubtless other special uses are being developed; hence, the expected loss in exports in 1941 may be balanced by increased domestic sales.

[2] Gain.

PRODUCTION

By States.—Production in Texas during 1940 reached a new peak of 479,895,000 pounds, which is 6 percent higher than in 1939. Although this is equivalent to 84 percent of the national total, the share contributed by Texas actually declined because of larger gains in other States. The come-back in Louisiana was continued, and the State produced 55,610,000 pounds in 1940 compared with 51,734,000 pounds in 1939. One more plant was added in both Kansas and Oklahoma in 1940, and the output of the two States combined increased from 20,258,000 pounds in 1939 to 33,287,000 in 1940.

By months.—Production apparently was influenced by the loss in exports, as the highest daily average (obtained by prorating the Bureau's annual total upon the basis of monthly figures of the National Gas Products Association) was for March and the lowest for November.

Carbon black produced from natural gas in the United States in 1940, by States and by major producing districts

July	41,503,190	47,722,000	1,539,000		494,453,003	568,792,000	1,554,000

[1] Monthly figures obtained by allocating the Bureau's annual total proportionately to the association's monthly data.

Methods and yields.—The channel process is still the most widely used method of producing carbon black, but in 1940 the output of the other processes—Lewis, roller, "Special," and thermatomic—achieved the larger relative gain. Comparison of the Bureau's channel figures with those of the National Gas Products Association (which are for contact black) indicates that the gain in other processes was made by the so-called furnace or high-yield blacks. This contention is supported by the average yield figure, which increased from 1.51 pounds a thousand cubic feet in 1939 to a new peak of 1.54 pounds in 1940.

Number and capacity of plants.—Only 2 new plants were added to the number operated in 1939; 3 were dismantled or shut down, making a total number of 48 operating at the end of the year.

The total capacity of the plants recovered the loss of 1939 and amounted to 1,735,865 pounds daily compared with 1,713,865 for 1939 and 1,735,855 for 1938. The addition of one plant in both Kansas and Oklahoma caused a small increase in the combined capacity of those two States, but most of the gain was in Texas outside of the Panhandle. The operating ratio, or the ratio of daily average production to average capacity, increased from 84 percent in 1939 to 90 percent in 1940.

Number and daily capacity of carbon-black plants operated in the United States, 1939–40, by counties or parishes

[1] Kansas included with Oklahoma.
[2] 1 plant, in both Carson and Hutchinson Counties, counted in Hutchinson County.

Producers.—Changes in the list of carbon-black producers in 1940 are as follows: The Cabot Co. discontinued operations, and its plant at Skellytown, Tex., was purchased by the Cabot Carbon Co.; the Columbian Carbon Co. shut down its plant at Magic City, Tex.; the Charles Eneu Johnson & Co. began operations at a plant (channel) near Stonewall, Pontotoc County, Okla.; and the United Carbon Co. began operations at a plant (roller) near Ryus, Grant County, Kans., and dismantled plants at Phillips, La., and Borger, Tex.

The latest complete list of producers and plants (as of December 31, 1937) was published in Minerals Yearbook, 1938, page 967. Changes in 1938 and 1939 were published on page 1073 of Minerals Yearbook, 1939 and page 1099 of the 1940 volume, respectively.

DEMAND

Total deliveries.—Domestic sales in 1940 were only slightly below the total for 1939—352,156,000 pounds in 1940 compared with 356,705,000 in 1939—but exports declined 13 percent, so total sales of 529,774,000 pounds represented a decrease of 5 percent compared with the preceding year (see fig. 2).

Domestic consumption.—Domestic sales of 352,156,000 pounds in 1940 were only 1 percent below the record of 1939. Reports from producers indicate the division of domestic sales as follows: Rubber companies, 310,179,000 pounds (88 percent); ink companies, 24,159,000 pounds (7 percent); paint companies, 6,806,000 pounds (2 percent); and miscellaneous purposes, 11,012,000 pounds (3 percent). These data indicate chiefly a slight loss in the relative importance of sales to rubber companies in favor of ink.

According to E. G. Holt, of the Bureau of Foreign and Domestic Commerce, who has again supplied the data on rubber consumption, the apparent world consumption of crude rubber was 1,054,800 long tons compared with the revised figure of 1,099,400 long tons in 1939. As this was a decrease and rubber consumption was substantially higher in the United States it follows that the war is strengthening the relative position of this country as a rubber manufacturer.

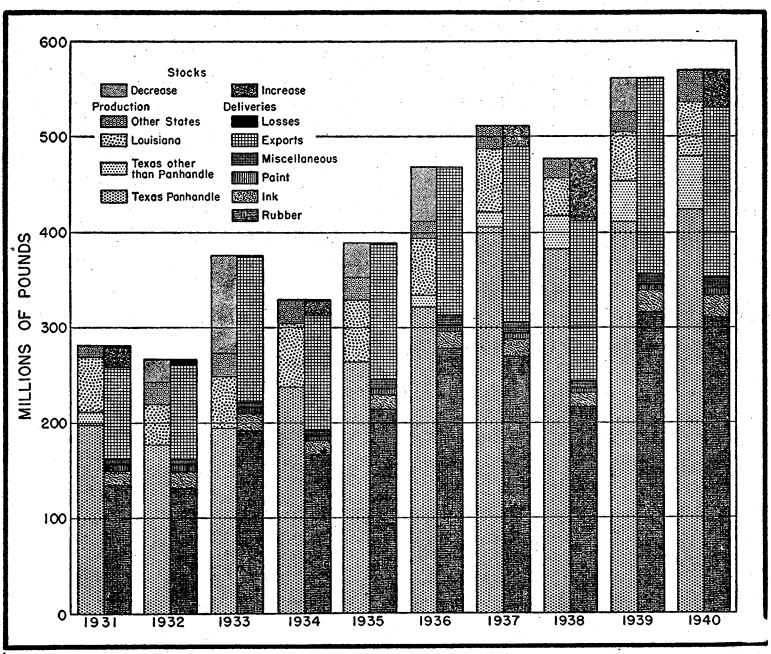

FIGURE 2.—Production and consumption of carbon black, 1931–40. Production in "Texas other than Panhandle" included in "Other States," 1932–35.

The consumption of rubber in the United States reached the record-breaking total of 842,700 long tons or 10 percent above that in 1939. Of the 1940 total, 648,500 tons were crude rubber, 190,200 tons reclaimed rubber, and 4,000 tons synthetic rubber. All amounts but that for reclaimed rubber were new peaks. According to statistics of the Rubber Manufacturers Association 59,186,000 casings were produced in 1940 compared with 57,613,000 in 1939. (The official figure of the Bureau of the Census for 1939 is 57,344,645.) Stocks of casings held by manufacturers increased from 8,665,000 on January 1, 1940, to 9,127,000 on December 31. Returns from the Federal excise tax on tires and tubes indicate that the total weight of the two products was 9.5 percent higher in 1940 than in 1939. These data indicate that the average casing was at least 5 percent heavier in 1940 than in 1939. As more casings were made in 1940 it appears that the average use of carbon black per pound of rubber must have declined appreciably. The production of camelpack for retreads, a product with a relatively high carbon-black content, reached 54,223,000 pounds in 1939, but only a small gain in 1940 is indicated.

The apparent consumption of newsprint continued to gain as, according to B. M. Frost, of the Bureau of Foreign and Domestic Commerce, the supply of newsprint available for consumption increased 5 percent in 1940 or from 3,556,000 short tons in 1939 to 3,732,000 in 1940. These data substantiate the gain in sales of carbon black to ink companies from 21,929,000 pounds in 1939 to 24,159,000 in 1940. The latter is the highest since the boom years 1928 and 1929.

Sales of carbon black to paint companies increased from 6,382,000 pounds in 1939 to 6,806,000 in 1940. This gain roughly checks the rise in value of paint sales as compiled by the Bureau of the Census, although this value covers many varieties of paint besides black paint.

Sales of carbon black for miscellaneous purposes almost held its own in 1940, when the total was 11,012,000 pounds compared with 11,773,000 in 1939. No data are available on the break-down of this item by uses.

Exports and imports.[1]—Exports of carbon black receded from the 1939 peak and totaled 177,618,000 pounds in 1940 compared with 203,828,000 in 1939. If it had not been for the war the total might have increased, as the decline was less than the loss in shipments to Europe.

Exports were valued at $7,823,820 in 1940, an average of 4.40 cents a pound compared with 4.36 cents in 1939.

Carbon black exported from the United States, 1938–40, by countries

Country	1938		1939		1940

[1] For statistical purposes trade with the Sudeten area, as far as ascertainable, is included with Germany, while trade with the other Czechoslovak provinces occupied by Germany, Hungary, and Poland has been included with these countries since March 18 or 19, 1939. After November 16, 1939, trade with Danzig and that part of Poland occupied by Germany has been included with Germany, and trade with that part of Poland occupied by the U. S. S. R. has been included with U. S. S. R.

[1] Figures on exports and imports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

The only gains of importance in 1940 were in exports to the United Kingdom and Japan. The United Kingdom and other parts of the British Empire took 63 percent of total exports in 1940.

The heaviest exports of 1940 were during the first quarter; after that they decreased as Belgium, France, and other countries were invaded. Nearly two-thirds of the exports in 1940 were shipped through Galveston; however, this ratio was somewhat lower than in 1939.

Imports of "gas black and carbon black" in 1940 were negligible. Imports of acetylene black (all from Canada) continued to increase; the total in 1940 was 3,235,273 pounds valued at $342,126.

Carbon black exported from the United States, 1939–40, by months and customs districts

STOCKS

The situation as to stocks of carbon black at the plants reversed again during 1940; and in place of a decline, as in 1939, there was an increase from 130,792,000 pounds the first of the year to 169,587,000 at the close. This gain raised the total to about what it was at the end of 1938.

Stocks of carbon black in the form of finished rubber goods probably showed some increase as stocks of the most important item—casings—rose from 8,665,000 on January 1 to 9,127,000 on December 31.

PRICES AND VALUES

The average value at the plants rose from 2.45 cents a pound in 1939 to 2.90 cents in 1940. This represents a material improvement, although prices now are only about a third of what they were in the early twenties. The average value apparently conforms closely with the spot price of regular, uncompressed carbon black in bags, in carload lots, f. o. b. plants, the average of which was 2.88 cents a pound in 1940.

The Oil, Paint, and Drug Reporter—the source of the Bureau's spot prices for carbon black—discontinued reporting prices by Zones A to G and Grades 1 to 7, a series that had been established under the N. R. A. Code. The following table therefore gives the quoted prices for new grades, which appear representative. Because of the brisk demand in the first half of the year prices were generally increased about one-half cent—one-quarter cent on April 1 and the other quarter on July 1. Despite the decrease in exports in the latter half of the year prices remained firm and unchanged up to May 1, 1941.

Quoted prices on various grades of carbon black in carload lots in 1940, in cents a pound

[Oil, Paint, and Drug Reporter] [1]

Date	Regular, uncompressed, bags, f. o. b. plants	Beads, compressed, bags, f. o. b. plants	Bulk, cars	
			F. o. b. plants	F. o. b. N. Y. harbor
Jan. 1	2.55	2.425	2.30	3.18
Apr. 1	2.80	2.65	2.50	3.38
July 1	3.075	2.925	2.75	3.63
Average	2.88	2.73	2.58	3.46

[1] The Oil, Paint, and Drug Reporter ceased reporting prices by Zones A to G and Grades 1 to 7 early in 1940.

The table indicates in a general way the price differentials as a result of manufacturing the black in the form of pellets or beads and compressing before shipment. This type of black was priced at about 0.15 cent a pound less than the standard, uncompressed variety. The charge for packing in bags is apparently about the same, as the price for bulk, f. o. b. shipments was still lower by about 0.15 cent. The freight differential between the plants and New York harbor appears to be 0.88 cent a pound.

HELIUM

By R. A. Cattell and C. W. Seibel

SUMMARY OUTLINE

Operation of Amarillo plant.—During the fiscal year 1940 the Bureau of Mines helium plant near Amarillo, Tex., continued to operate at a fraction of its capacity and produced 9,450,855 cubic feet of helium; the cumulative output from April 1929 to June 30, 1940, was 99,992,000 cubic feet. During the first half of the fiscal year 1941, 6,822,000 additional cubic feet of helium were produced, making the total output at the Amarillo plant from April 1929 to December 31, 1940, 106,814,000 cubic feet of helium. As about 49 million cubic feet were produced at Fort Worth before the Amarillo plant was put in operation, the total Government output to the end of the calendar year 1940 was approximately 156 million cubic feet, or more than 90 percent of all helium that has been produced in the world.

Sales of residue natural gas, from which the helium was extracted, in the fiscal year 1940 totaled 468,059,000 cubic feet valued at $21,062. The cumulative sales of such gas for the 11-year period of operation of the Amarillo helium plant (to June 30, 1940) totaled 5,152,208,000 cubic feet, for which $266,980 was received.

Cliffside gas field.—In the fiscal year 1940, 547,674,000 cubic feet of helium-bearing natural gas were produced by the Bureau of Mines from the Government's Cliffside gas field to supply the Amarillo plant, giving a cumulative output of 5,983,889,000 cubic feet of natural gas from the field.

As the Government owns the gas mineral rights in the 50,000 acres covering the entire Cliffside geologic structure, it can operate the field according to approved engineering practice and produces the gas only when helium is required. Therefore, conservation is effected by retaining the gas in its natural underground reservoir until helium is needed to meet current demands.

The Government operates five producing gas wells and about 16 miles of pipe lines that supply the helium plant with helium-bearing natural gas. The main pipe line from the field to the plant is of heavy pipe 6 inches in diameter, and all of the pipe lines are operated at a pressure of more than 600 pounds a square inch. The gas reserve, which is estimated to have had an original content of more than 2 billion cubic feet of recoverable helium, is largely available for future use, because production of approximately 106 million cubic feet of helium during 11 years of operation has depleted the reserve only about 5 percent. The closed-in pressure of the wells—originally 723 pounds a square inch—is still more than 700 pounds a square inch.

Historical background.—Since the Civil War helium has advanced from a line in the spectrum of the sun that did not correspond with any line of known elements to a commodity, produced in millions of cubic feet, that transports man through the air, permits him to penetrate to greater depths in the sea, relieves his suffering, helps meteorologists in forecasting weather, and aids scientists in developing new information that may make life more comfortable or more interesting. The United States Army and Navy have used helium for more than 2 decades, but it became available for non-Government activities at prices that make its use practicable only about 3½ years ago.

Production of helium for military use was initiated during the World War of 1914–18 in consequence of experimental work directed by the Bureau of Mines and financed from War and Navy Department appropriations. After a process of extraction had been developed a full-scale plant was built at Fort Worth, Tex., under the jurisdiction of the Navy Department, using funds supplied jointly by the Army and Navy. This plant was placed under the control of the Bureau of Mines on July 1, 1925, by an act of Congress approved March 3, 1925.

In January 1929 the Fort Worth plant was closed because its supply of helium-bearing natural gas was approaching exhaustion, and in April 1929 the plant near Amarillo, Tex., designed and constructed by the Bureau of Mines, was put in operation. This plant is supplied with helium-bearing natural gas from the Cliffside gas field, which was brought under complete Government control by purchase of the gas rights in fee in 50,000 acres covering the entire geologic structure.

Government use of helium.—The Navy, which continues to buy the most helium, purchased 3,531,410 cubic feet during the fiscal year 1940. In addition to using helium for inflating lighter-than-air craft, the Navy employs it in observation and meteorological balloons, in diving operations, and for other purposes relating to operation of the fleet. The Navy has authorization for a much larger number of nonrigid airships than in the past, and their inflation will require a larger supply of helium.

The Weather Bureau received 2,624,355 cubic feet of helium during the fiscal year 1940 for use in inflating meteorological balloons employed to obtain three types of information. First, several thousand small balloons of 1½ cubic feet capacity are flown daily from various observation stations to determine the height of clouds or ceiling. Second, pilot balloons of 5 or 32 cubic feet capacity are used at 140 stations, where 4 observations are made each day; the rate and angle of ascent of the pilot balloon are observed through an instrument, and data are thus obtained from which the direction and velocity of the wind may be computed for any height. Third, the balloons employed in radiosonde observations hold 85 cubic feet of helium and are used at 40 stations for 2 observations each day. The radiosonde is an instrument for measuring temperature, humidity, and air pressure; it transmits automatically signals that are recorded on the ground and gives physical information for various heights. The Weather Bureau's use of helium increased from 900,000 cubic feet in the fiscal year 1939 to 2,624,000 cubic feet in the fiscal year 1940, and it is estimated that 3,600,000 cubic feet will be purchased in the fiscal year

1941. The Amarillo plant is shipping helium to 450 observation stations of the Weather Bureau (including points in Alaska and outlying possessions), and to 2 Coast Guard cutters.

The Army uses helium for inflating both captive and motorized observation balloons, as well as meteorological balloons. In addition, the Army is experimenting with barrage balloons for protecting cities and military objectives against aerial attack. The National Bureau of Standards, the Department of Agriculture, the Bureau of Mines, the Public Health Service, and other Government agencies also use helium in various types of scientific and medical research.

Sales of helium for medical, scientific, and commercial use.—From the time purchase of helium by the public was authorized by the amendatory Helium Act approved September 1, 1937, until June 30, 1940, 2,655,537 cubic feet of helium were sold for medical, scientific, and commercial use under 73 sales contracts. In the fiscal year 1940 such sales totaled 1,514,155 cubic feet, 16 percent of the plant output. More than 400,000 cubic feet of that helium were employed for medical purposes, and it is estimated that this quantity provided 34,000 hours of treatment.

Non-Government use of helium.—In 1925 the Bureau of Mines reported the results of experiments on helium-oxygen mixtures to mitigate caisson disease.[1] A little later a paper by members of the Bureau's staff on the use of such mixtures during compressed-air work appeared in a technical journal,[2] and a press release [3] on the use of helium in diving was issued. The research upon which these reports were based was the forerunner of later developments in the employment of helium-oxygen mixtures by the medical profession for treatment of asthma.[4]

In 1940 the Public Health Service issued a report on the application of helium-oxygen mixtures to alleviation of tubal and sinus blocks in compressed-air workers,[5] which is indicative of the continued research of the medical profession in the use of helium. Another phase of such research, dealing with use of helium for diluting anesthetics to prevent fires and explosions, is being conducted cooperatively by the Bureau of Mines and a committee under the direction of the Department of Industrial Hygiene, School of Medicine, University of Pittsburgh. A portion of this research dealing with helium as a diluent of cyclopropane was reported by the Bureau of Mines in May 1940.[6]

Thus, by supplying helium for medical, scientific, and commercial use at a fraction of its former cost, the Bureau of Mines is aiding commercial aeronautics, relieving those who suffer from respiratory diseases, reducing hazards in use of anesthetics, contributing to the safety and comfort of divers and caisson workers, promoting science, and fostering many industrial developments.

Prices.—The estimated cost of producing helium for the fiscal year 1940, as approved by the Secretary of the Interior and upon which deposits for sales to the public are based, in accordance with the law and regulations, was $14.25 a thousand cubic feet. The demand was greater than had been anticipated, hence the unit cost was much less than the estimate. The actual sale prices for the fiscal year 1940, as approved by the Secretary, were therefore only $11.17 for helium to be used for medical purposes, $11.73 for helium for scientific use, and $13.14 for helium for commercial use. After the total charges against the various purchasers of helium were deducted from the deposits the surplus to their credit was refunded.

The price charged Government agencies was $8.43 a thousand cubic feet, irrespective of the use to which the helium was put.

The prices a thousand cubic feet for helium produced in the fiscal years 1938, 1939, and 1940, exclusive of service charges, are shown in the following table.

Prices charged for 1,000 cubic feet of helium

[Exclusive of service charges]

	Fiscal year		
	1938	*1939*	*1940*
Helium requisitioned by Government agencies	$11.16	$11.47	$8.43
Helium sold to non-Government purchasers:			
Medical use	13.471	12.80	11.17
Scientific use	13.471	13.44	11.73
Commercial use	15.088	15.05	13.14

Future outlook and plans.—Demands for helium by the War and Navy Departments, the Weather Bureau, and other users have increased so rapidly that production during the fiscal year 1941 is expected to be at least 1⅓ times that in the fiscal year 1940 and more than twice that in the fiscal year 1939. Although the demand is still considerably below the capacity of 24 million cubic feet a year provided by the two helium-production units now installed in the Amarillo plant and the capacity of about 20 million cubic feet a year provided by the gas wells already drilled in the Cliffside field, estimates of future demands indicate that these capacities will soon be reached and probably exceeded by the consumption.

In view of the increase in normal demand and the expected large requirements for national defense, the Congress has appropriated $175,000 to the Bureau for drilling another gas well in the Cliffside field to raise the well capacity to the plant capacity of 24 million cubic feet of helium a year, for augmenting and improving auxiliary equipment in the plant, and for renewing the Bureau's survey of fields that produce helium-bearing natural gas, which has been in abeyance since 1934. Moreover, addition of a third production unit to the Amarillo plant and the drilling of more wells to bring both plant and well capacity to 36 million cubic feet annually are being considered by the Congress.

Information to be obtained by testing gas samples for helium, making detailed studies of the characteristics of gases that have a promising helium content, and conducting engineering research in favorable areas will enable the Bureau to plan to establish other helium-production plants whenever they are needed to meet the requirements of national defense.

ASPHALT AND RELATED BITUMENS

By A. H. Redfield [1]

Exports	3,097,799	4,004,173

[1] Revised figures.

The total domestic and foreign demand for petroleum asphalt (including small quantities of lake asphalt and grahamite) was 9 percent larger in 1940 than in 1939. Refinery production of pe-

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

troleum asphalt was enlarged sufficiently to meet the increase in domestic demand. The increase in imports of petroleum asphalt, lake asphalt, and grahamite was a little greater than the increase in exports of petroleum asphalt. Accordingly, the growth in inventories at the refineries in 1940 was a little larger than the growth during 1939. In terms of daily demand, however, the stocks held at the end of 1940 represented 43.5 days' supply compared with 42.1 days' supply at the end of 1939 and 40.6 days' supply at the end of 1938.

Total imports showed a high percentual increase from 1939 to 1940. They constituted, however, only 2.5 percent of the total domestic and foreign demand in 1940 compared with 1.5 percent (revised) during 1939.

Exports of petroleum asphalt were 30 percent greater in 1940 than in 1939 but comprised only 5 percent of the total refinery output of asphalt in the United States in 1940 compared with 4 percent in 1939.

Bituminous rock shared in the general increase in demand for asphaltic substances in 1940 over 1939 as far as quantity sold was concerned, although prices were lower. The entire increase in tonnage sold was in States west of the Mississippi.

Sales of gilsonite and wurtzilite declined as both domestic and foreign demand decreased.

NATIVE ASPHALT AND BITUMENS

Bituminous rock.—Bituminous rock shared the general increase in demand for asphaltic substances in 1940 over 1939. Sales of rock asphalt by producers in the United States increased 9 percent in quantity—from 422,484 short tons in 1939 to 458,665 tons in 1940. Prices, however, were lower in 1940; in consequence, the total sales declined 3 percent in value—from $2,007,810 in 1939 to $1,949,166 in 1940.

Operators in Texas and Oklahoma sold 221,497 tons valued at $684,808 in 1939 and 282,250 tons valued at $833,248 in 1940. More rock asphalt was sold by producers in California and in Missouri during 1940 than during 1939. None, however, was mined in New Mexico, either in 1939 or in 1940. In eastern United States, sales of rock asphalt by operators in Kentucky and Alabama dropped from 175,602 tons valued at $1,214,476 in 1939 to 150,312 tons valued at $1,031,646 in 1940.

Gilsonite and wurtzilite.—Decreased demand both in the United States and in foreign countries caused sales of gilsonite by producers in northeastern Utah to decline 14 percent in quantity—from 37,289 short tons in 1939 to 31,930 tons in 1940—and 27 percent in value—from $1,053,192 in 1939 to $770,711 in 1940. Export demand was reduced, especially from Europe. Germany was eliminated as a market by the British blockade; and France was eliminated after June by the German conquest. The United Kingdom reduced its purchases of gilsonite through licensing and exchange restrictions as well as through lack of shipping. The domestic market for gilsonite likewise receded from 1939 to 1940. Certain producers were able to maintain their prices firm; others either cut prices or sold a greater proportion of seconds. As a result, the average sales value of gilsonite at the mine or railhead decreased from $28.24 a ton in 1939 to $24.14 in 1940.

Sales of wurtzilite decreased from 75 tons valued at $5,842 in 1939 to 70 tons valued at $5,460 in 1940.

Sulfonated bitumen.—In 1940, as in 1939, a small quantity of natural sulfonated bitumen was produced near Ogden in Box Elder County, Utah.

Exports.—Exports of natural asphalt, unmanufactured, decreased from 13,784 short tons valued at $577,031 in 1939 to 11,303 tons valued at $443,449 in 1940. Of the total tonnage exported Europe took 74 percent in 1939 but only 55 percent in 1940; Canada 8 percent in 1939 but 13 percent in 1940; South America 4 percent both in 1939 and in 1940; and Asia, chiefly Japan, 10 percent in 1939 but 25 percent in 1940.

MANUFACTURED OR PETROLEUM ASPHALT

Production.—Petroleum refineries in the United States produced 8 percent more asphalt in 1940 than in 1939. Output increased most strongly west of the Mississippi. East of the Mississippi and north of the Ohio and Potomac Rivers, the increases in asphalt production of the Indiana, Illinois, Kentucky, etc., district and of the Appalachian district were small; and the asphalt output of the East Coast refineries actually declined, in contrast to the general increase in production.

Stocks.—To meet an increase of 392,586 short tons in the indicated domestic demand for asphalt and of 59,519 tons in the export demand, petroleum refineries in the United States enlarged their output of asphalt 392,500 tons in 1940. Imports of petroleum asphalt, lake asphalt, and grahamite increased 64,005 tons from 1939 to 1940. As the increase in refinery output virtually equalled the increase in domestic demand and the increase in imports exceeded the increase in exports, no reduction in inventories was possible. In fact, 64,000 tons were added to stocks during 1940 compared to an increase of 59,600 tons in stocks during 1939. Yet, in view of the increasing demand, the stocks at the end of 1940 represented only 43.5 days' supply upon the basis of the daily demand in 1940 compared with stocks representing 42 days' supply at the end of 1939 and 41 days' demand at the end of 1938.

The principal advances in inventories were in the Arkansas and Louisiana Inland district; in the Indiana, Illinois, Kentucky, etc., district; and in the Louisiana Gulf Coast district. In contrast to the general increase, stocks were reduced in the Oklahoma, Kansas, and Missouri district; in the Appalachian district; in California; and in the Texas Gulf Coast district.

Sales.—Total sales of petroleum asphalt by refineries increased 7 percent in quantity and 15 percent in value from 1939 to 1940. The average value at the refinery of asphalt sold in 1940 was $9.09 a short ton in 1940 compared with $8.47 in 1939.

Of the total sales of petroleum asphalt in 1940, 25 percent was manufactured from foreign petroleum (imported chiefly from Venezuela and Mexico), compared with 26 percent in 1939. Although runs of foreign crude to stills rose from 33,490,000 barrels in 1939 to 41,798,000 barrels in 1940, total sales of asphalt made from foreign crude remained virtually stationary—1,278,786 short tons in 1939 and 1,278,349 tons in 1940. Apparently, more of the foreign crude was run to fuel oil in 1940 than in 1939. East Coast refineries sold 96 percent of the asphalt made from foreign crude in 1939 and 91 percent in 1940.

Production, receipts, stocks, consumption, transfers and losses, and sales of asphalt (exclusive of road oil) at petroleum refineries in the United States in 1940, by districts, in short tons

District	Production	Receipts from other sources	Stocks		Consumption by companies, transfers, and losses	Sales	
			Dec. 31, 1939	Dec. 31, 1940		Domestic	Foreign

[1] DEFINITIONS

Paving asphalt.—Refined asphalt and asphaltic cement, fluxed and unfluxed, produced for direct use in the construction of sheet asphalt, asphaltic concrete, asphalt macadam, and asphalt block pavements, and also for use as joint filler, in brick, block, and monolithic pavements.
Roofing asphalt.—Asphalt and asphaltic cement used in saturating, coating, and cementing felt or other fabric and in the manufacture of asphalt shingles.
Waterproofing asphalt.—Asphalt and asphaltic cement used to waterproof and dampproof tunnels, foundations of buildings, retaining walls, bridges, culverts, etc., and for constructing built-up roofs.
Briquetting asphalt.—Asphalt and asphaltic cement used to bind coal dust or coke breeze into briquets.
Mastic and mastic cake.—Asphalt and asphaltic cement for laying foot pavements and floors, waterproofing bridges, lining reservoirs and tanks, capable of being poured and smoothed by hand troweling.
Pipe coatings.—Asphalt and asphaltic cement used to protect metal pipes from corrosion.
Molding compounds.—Asphalts used in the preparation of molded composition, such as battery boxes, electrical fittings, push buttons, knobs, handles, etc.
Miscellaneous uses.—Asphalt and asphaltic cement used as dips and in the manufacture of acid-resisting compounds, putty, saturated building paper, fiber board and floor coverings, and not included in the preceding definitions.
Flux.—Liquid asphaltic material used in softening native asphalt or solid petroleum asphalt for paving, roofing, waterproofing, and other purposes.
Cut-back asphalt.—Asphalt softened or liquefied by mixing with petroleum distillates.
Emulsified asphalt and fluxes.—Asphalts and fluxes emulsified with water for cold-patching, road laying, and other purposes.
Other liquid products.—Petroleum asphalt, exclusive of fuel oil used for heating purposes, not included in the preceding definitions.

In general, such statistics as are available indicate an increase in State highway construction in 1940 over 1939 but no comprehensive statistics are available to show the yardage of the various types of surface laid on city and town streets. It is this field of highway construction that furnishes the major demand for the harder types of paving asphalt. Domestic sales of paving asphalt of less than 200 penetration increased 9 percent from 1939 to 1940—from 1,176,534 short tons in 1939 to 1,277,961 tons in 1940. The principal increases were in the Louisiana-Arkansas, East Coast, and California districts. There was a smaller increase in the Oklahoma, Kansas, and Missouri district. In contrast, sales of paving asphalt by Texas refineries were much lower in 1940 than in 1939; and there was a slight decrease in the Indiana, Illinois, Kentucky, etc., district.

Paving asphalt sold at petroleum refineries in the United States, 1939–40, by districts, in short tons

District	1939	1940
East Coast	567,670	609,717
Appalachian	34,819	31,270
Indiana, Illinois, Kentucky, etc	111,628	110,762
Oklahoma, Kansas, and Missouri	24,561	31,753
Texas:		
Gulf Coast	43,259	26,029
Inland	68,173	58,499
Total, Texas	111,432	84,528
Louisiana-Arkansas:		
Louisiana Gulf Coast	97,166	118,586
Arkansas and Louisiana Inland	39,692	87,632
Total, Louisiana-Arkansas	136,858	206,218
Rocky Mountain	10,498	8,165
California	179,068	195,548
Total	1,176,534	1,277,961

Increased construction of the lighter types of surface, both on State highways and secondary roads, as well as continued use of cut-back asphalts for soil stabilization and revetments, is indicated by an 18-percent gain in sales of cut-back asphalts from 1,454,846 short tons in 1939 to 1,722,475 in 1940. The principal gains in sales of cut-back asphalts were made by refineries of the following districts: Indiana, Illinois, Kentucky, etc.; California; the Gulf Coasts of Louisiana and Texas; and Oklahoma, Kansas, and Missouri. In contrast to the general increase, refineries of the East Coast district and of Arkansas and Louisiana Inland sold less cut-back asphalt in 1940 than in 1939. Sales of both types of cut-back asphalt were larger in 1940 than in 1939; but the greater gain was in sales of rapid-curing cut-backs.

Petroleum refineries sold 55,881 tons (13,164,691 gallons) of asphalt emulsions valued at $635,881 in 1939 and 85,570 tons (20,162,003 gallons) valued at $887,202 in 1940. In addition, 49,826,902 gallons valued at $3,899,958 were sold in 1939 by major industrial companies that purchased asphalt from petroleum refineries and 45,924,626 gallons valued at $3,385,468 in 1940. Accordingly, total known sales of emulsified asphalts and fluxes increased in quantity from 62,991,593 gallons in 1939 to 66,086,629 gallons in 1940 but declined in value from $4,535,839 in 1939 to $4,272,670 in 1940.

Cut-back asphalts sold at petroleum refineries in the United States, 1939–40, by districts, in short tons

District	1939	1940
East Coast	533,622	449,368
Appalachian	43,947	50,940
Indiana, Illinois, Kentucky, etc.	213,199	340,173
Oklahoma, Kansas, and Missouri	220,903	253,039
Texas:		
Gulf Coast	45,003	73,908
Inland	46,083	48,520
Total, Texas	91,086	122,428
Louisiana-Arkansas:		
Louisiana Gulf Coast	70,291	125,738
Arkansas and Louisiana Inland	80,623	45,835
Total, Louisiana-Arkansas	150,914	171,573
Rocky Mountain	89,461	100,634
California	111,714	234,320
Total	1,454,846	1,722,475

Roofing manufacture made the second largest demand for asphalt, absorbing 25 percent of the total sales in 1939 and 24 percent in 1940. Shipments of prepared roofing and asphalt siding reported to the Bureau of the Census decreased slightly—from 35,099,823 squares in 1939 to 34,222,139 squares in 1940. This decrease was paralleled by a small decline in domestic sales of roofing asphalt and roofing flux combined—from 1,229,046 tons in 1939 to 1,218,695 tons in 1940. A considerable decrease in sales by refineries of the Indiana, Illinois, Kentucky, etc., district and smaller decreases in sales by refineries of the East Coast and Arkansas-Louisiana Inland districts offset increased sales in the other districts, notably in the Appalachian district and in California.

Roofing asphalt and flux sold at petroleum refineries in the United States, 1939–40, by districts, in short tons

District	1939	1940
East Coast	434,404	410,728

FOREIGN TRADE

Imports.—Imports of natural asphalt and bitumen into the United States decreased from 26,586 short tons valued at $362,559 in 1939 to 11,571 tons valued at $142,903 in 1940. Imports of lake asphalt from Trinidad dropped from 21,440 tons valued at $227,223 in 1939 to 7,959 tons valued at $81,428 in 1940. Imports of grahamite from Cuba likewise decreased—from 4,676 tons valued at $83,734 in 1939 to 3,147 tons valued at $55,732 in 1940.

On the other hand, imports of solid petroleum asphalt increased from 47,261 short tons valued at $189,052 in 1939 to 87,846 tons valued at $388,585 in 1940. Of the 1940 imports, 86,131 tons valued at $335,756 came from the Netherlands West Indies and 1,634 tons valued at $51,380 from Mexico. All of the imports of solid petroleum asphalt in 1939 came from the Netherlands West Indies.

In addition, 211,392 barrels (38,435 short tons), valued at $177,569, of liquid asphalt, including cut-backs and road oil, were imported from Mexico. No corresponding imports were recorded for 1939.

Exports.—Exports of petroleum asphalt increased 30 percent in quantity—from 199,695 short tons in 1939 to 259,214 tons in 1940—and 29 percent in value—from $3,097,799 in 1939 to $4,004,173 in 1940. Shipments of asphalt to all continents, except Africa were larger in 1940 than in 1939. Canada took 47 percent more asphalt from the United States in 1940 than in 1939; and work on the Pan-American Highway explained the increased asphalt sales to Mexico and Central America. In Europe, a remarkable increase in shipments to Spain more than offset a sharp drop in shipments to the United Kingdom; for other European countries, the increases and decreases in asphalt receipts from the United States virtually canceled each other. In Asia, increased exports of asphalt to British India and to Burma, Ceylon, the Philippine Islands, and Hong Kong more than counteracted decreased shipments to the Netherlands Indies and French Indochina. A sharp rise in asphalt exports to New Zealand contrasted with decreased exports to Australia.

DOMESTIC DEMAND

The indicated average monthly domestic demand for petroleum asphalt (including small quantities of imported lake asphalt and grahamite) was 8 percent greater in 1940 than in 1939, increasing from 397,396 short tons (revised figure) in 1939 to 430,112 tons in 1940.

In order to cover the most recent developments the long-time trend of monthly asphalt demand has been revised to include 1908 to 1940. The effect of including the last 4 years (which were characterized by high demand) has been to raise the general level of the trend for recent years and to lower the relation between the actual demand for these years and the expected demand according to the trend. This is illustrated by the following table, which shows the relation between the actual average monthly demand from 1925 to 1940 and the expected monthly demand for that period. This comparison indicates that the 5 years 1936–40 have been characterized by rising demand for asphalt and that the upward trend had shown no signs of downturn to the end of 1940.

In terms of the revised long-term trend, the indicated demand was 26 percent above the expected demand for 1940, whereas it was 20 percent above the expected demand for 1939; that is, if the national demand had continued the average rate of growth it manifested from 1908 to 1940, it would have averaged 331,741 tons a month in 1939 and 341,728 tons a month in 1940. If these averages are used as a standard of comparison the indicated demand of 397,396 tons a month (revised figure) in 1939 was 120 percent of the expected demand (331,741 tons), and the indicated demand of 430,112 tons a month in 1940 was 126 percent of the expected demand (341,728 tons).

Relation of indicated average monthly asphalt demand in the United States to basic trend, 1925–40, by years

Year	Long-time trend, 1908–40	Indicated average monthly demand	Relation of indicated average monthly demand to trend	Year	Long-time trend, 1908–40	Indicated average monthly demand	Relation of indicated average monthly demand to trend
	Short tons	*Short tons*	*Percent*		*Short tons*	*Short tons*	*Percent*
1925	190,518	242,502	127.3	1933	271,566	191,337	70.5
1926	200,697	266,937	133.0	1934	281,628	214,116	76.0
1927	210,867	296,340	140.5	1935	291,676	252,304	86.5
1928	221,028	260,577	117.9	1936	301,711	330,188	109.4

1931	251,397	228,711	91.0	1939	331,741	397,396	119.8
1932	261,489	191,277	73.1	1940	341,728	430,112	125.9

The demand for asphalt is seasonal to a marked degree, reaching its maximum in August and its minimum in February. From 1925 to 1940, 66.5 percent of the indicated consumption of asphalt has occurred in the 6 months from May 1 to October 31; in 1939 and 1940, as much as 71 percent of the annual total apparently was consumed in these 6 months. Consequently, to furnish an adequate standard of comparison the monthly trend values have been multiplied by a "seasonal factor" for each month, obtained by the method of "link relatives" over the 16-year period, 1925–40.

Relation of indicated asphalt demand in the United States to basic trend, multiplied by seasonal factors, 1939–40, by months

[1] Revised figures.

In the first quarter of 1940 the indicated demand averaged 94 percent of the long-time trend multiplied by seasonal factors compared with 101 percent in the first quarter of 1939, as revised. In the second quarter of 1940 it increased to 117 percent of the expected demand compared with 117 percent of the expected demand during the second quarter of 1939. From July to September 1940 the demand was highest, averaging 142 percent of the expected demand compared with

127 percent for the same months of 1939. In the last quarter of 1940 the indicated demand averaged 132 percent of the expected demand compared with 125 percent during the last 3 months of 1939.

DISTRIBUTION BY RAIL

The tonnage of asphalt (natural, byproduct, or petroleum) terminated by class I railroads in the United States increased from 4,826,245 short tons in 1939 to 5,279,056 tons in 1940, according to freight-commodity statistics compiled by the Interstate Commerce Commission. The largest gains were in terminations by railroads of the Western district, operating west of the Mississippi and Illinois Rivers; and of the Southern district, operating east of the Mississippi and south of the Ohio and Potomac Rivers. In the Eastern district (lying east of the Mississippi and Illinois, and north of the Ohio and Potomac) only 1 percent more asphalt was terminated by class I railroads in 1940 than in 1939. These figures do not consider terminations outside these districts by branch lines of the railroads, but they do give an approximate picture of the demand for asphalt by geographic areas. They indicate, for example, that half of the asphalt terminated in the United States is delivered to consumers in the northeastern quarter of the country.

Asphalt (natural, byproduct, or petroleum) terminated by class I railroads in the United States, 1939–40, by districts and regions, in short tons

District and region	1939	1940
Eastern district:		
New England region	224, 677	205, 093
Great Lakes region	1, 013, 442	1, 088, 482

ROAD OIL

Refinery sales of road oil increased 5 percent in quantity—from 8,108,400 barrels in 1939 to 8,500,000 barrels in 1940. Higher prices brought an increase of 13 percent in value—from $8,458,600 in 1939 to $9,543,000 in 1940.

Road oil sold by petroleum refineries in the United States, 1939–40, by districts

District	1939		1940	
	Barrels	Value	Barrels	Value
East Coast	881,900	$1,208,100	863,000	$1,499,000
Appalachian	121,400	147,000	159,000	178,000
Indiana, Illinois, Kentucky, etc	2,102,600	2,142,800	2,219,000	2,620,000
Oklahoma, Kansas, and Missouri	987,400	735,300	878,000	892,000
Texas	369,200	574,300	246,000	472,000
Louisiana-Arkansas	190,600	181,100	130,000	149,000
Rocky Mountain	1,025,800	1,373,400	1,259,000	1,433,000
California	2,429,500	2,096,600	2,746,000	2,300,000
	8,108,400	8,458,600	8,500,000	9,543,000

Of the 1940 sales of road oil, 56,000 barrels were shipped to foreign destinations compared with 19,500 barrels exported in 1939. East Coast refineries exported 17,000 barrels in 1940, Texas refineries 24,000, and California refineries 15,000.

Of the road oil sold in the United States in 1940, only 396,367 barrels valued at $679,165 were made from foreign petroleum, imported chiefly from Venezuela and Mexico. Of the road oil made from foreign crude, 93 percent was sold by refineries of the East Coast district in 1940.

Production, receipts, stocks, consumption, transfers and losses, and sales of road oil in the United States in 1940

[Thousands of barrels]

District	Production	Receipts from other sources	Stocks		Consumption by companies, transfers, and losses	Sales
			Dec 31, 1939	Dec. 31, 1940		
East Coast	271	609	59	44	32	863
Appalachian	154	1	5	1		159
Indiana, Illinois, Kentucky, etc	2,274	59	26	114	26	2,219
Oklahoma, Kansas, and Missouri	722	139	60	34	9	878
Texas	216	34	43	37	10	246
Louisiana-Arkansas	224		34	53	75	130
Rocky Mountain	1,267	95	136	107	132	1,259
California	2,641		339	234		2,746
Total: 1940	7,769	937	702	624	284	8,500
1939	7,868	1,223	680	902	960	8,109

Petroleum refineries in the United States reported the production of 7,769,000 barrels of road oil in 1940 compared with 7,868,000 barrels in 1939. The refinery production of road oil was augmented in 1940 by 937,000 barrels of other petroleum products (chiefly fuel oil) transferred to road-oil stocks compared with 1,222,700 barrels similarly transferred in 1939. Stocks of road oil and of transferred oils declined 78,000 barrels during 1940 in contrast to a stock increase of 22,000 barrels in 1939. Consumption of road oil at refineries in operations, transfers, losses, and adjustments were 284,000 barrels in 1940 compared with 960,000 barrels in 1939.

CEMENT

By Oliver Bowles and E. V. Balser

SUMMARY OUTLINE

Production of portland cement in the United States increased from 122,259,154 barrels (376 pounds) in 1939 to 130,216,511 barrels in 1940—a 7-percent gain—according to final annual returns submitted by cement companies to the Bureau of Mines. Shipments increased from 122,651,459 barrels valued at $180,893,208 to 130,349,786 barrels valued at $190,078,068—a gain of 6 percent in quantity and 5 percent in value. The preliminary figures on production for 1940 (published by the Bureau of Mines in January 1941) were 0.06 percent more and shipments 0.03 percent less than the final figures. For the first 3 months of 1940, shipments were considerably lower than for the corresponding period in 1939, but in each month thereafter they were higher.

The Federal Reserve Board annual index (1935–39=100) for cement production in 1940 was 122 compared with 135 for the durable-goods industries and 141 for the construction industries. Corresponding figures for 1939 were: Cement 114, durable-goods industries 108, and construction industries 125.

In 1940 portland cement was manufactured at, and shipments were made from, 152 plants compared with 150 plants producing and shipping in 1939.

The average factory value was $1.46 a barrel in 1940 compared with $1.47 in 1939.

Shipments included 4,401,274 barrels of high-early-strength portland cement valued at $8,241,879 (an average of $1.87 a barrel) in 1940 compared with 3,693,460 barrels valued at $6,964,608 (an average of $1.89 a barrel) in 1939 (revised figures).

The quantity of natural, masonry (natural), and puzzolan cements produced increased 4 percent and shipments 5 percent compared with 1939. The value of shipments of these varieties gained 0.7 percent.

The preceding data give a brief survey of conditions in the cement industry in 1940, and the following tables present its outstanding features during recent years.

Salient statistics of the cement industry in the United States, 1937–40

PORTLAND CEMENT

PRODUCTION, SHIPMENTS, AND STOCKS

The process of making portland cement was discovered in 1824, but the crude product then made has been improved immeasurably through years of research and experimentation. Its uses have expanded until today it is one of the principal building materials and is regarded as indispensable to modern construction activities.

Portland cement is obtained by pulverizing to a fine consistency a clinker produced by calcining, to incipient fusion, an intimate mixture of properly proportioned argillaceous and calcareous substances, with only such additions after calcining as may be necessary to control setting and certain other properties. Such additions, which usually comprise about 3 to 3½ percent by weight of the calcined product, consist largely of gypsum or mixtures of gypsum and anhydrite. The principal combinations of raw materials are (1) limestone with clay or shale, (2) cement rock (argillaceous limestone) either alone or with high-calcium limestone, (3) blast-furnace slag and limestone, (4) marl and clay, and (5) oyster shells and clay.

Some years ago all portland cement had fairly constant and uniform properties; in other words, there was only one standard portland cement. In recent years, however, several distinct types have been developed to meet specialized uses and to satisfy new conditions that have arisen in construction. These include high-early-strength, masonry, low-heat, and oil-well cements. Statistics for all varieties are given in the general portland-cement tables, and the special varieties are discussed in more detail, with statistics wherever available, in a later section of this report. The special portland cements are to be distinguished from certain other types, such as natural and slag-lime cements, which are not true portland cements, and are covered in a separate section of this chapter.

The following tables present the principal statistics for portland cement. In the first, which relates to production, shipments, and stocks by States and districts, the term "active plant" is applied to a mill or group of mills situated at one place and operated by one company. If a company has establishments at different places, its mill or group of mills at each place is counted as one plant. The districts are groups of States related geographically and commercially.

The tables giving data by months, compiled from monthly reports of the producers, include figures on clinker or unground cement produced and in reserve at the mills awaiting manufacture into finished cement. Although the figures may differ slightly from those based upon annual reports of the producers, they reflect accurately seasonal fluctuations in the industry.

Cement shipments usually fluctuate widely. Figure 1 (page 1113) shows the estimated volume of portland cement shipped each month compared with the monthly average shipments for each year. Cement shipments reflect the movement of cement to construction projects, either directly from the mill to the construction job or to dealers for replenishment of stocks. As this chart clearly shows, the large variations in the volume of shipments are gradually lessening, and, with improvement of cements and continued effort of the construction industry to overcome prejudice against winter building, seasonal fluctuations probably will continue to decrease.

Portland cement produced, shipped, and in stock in the United States and Puerto Rico, 1939–40, by States and districts

	Active plants		Production			Shipments							Stock at mills (Dec. 31)

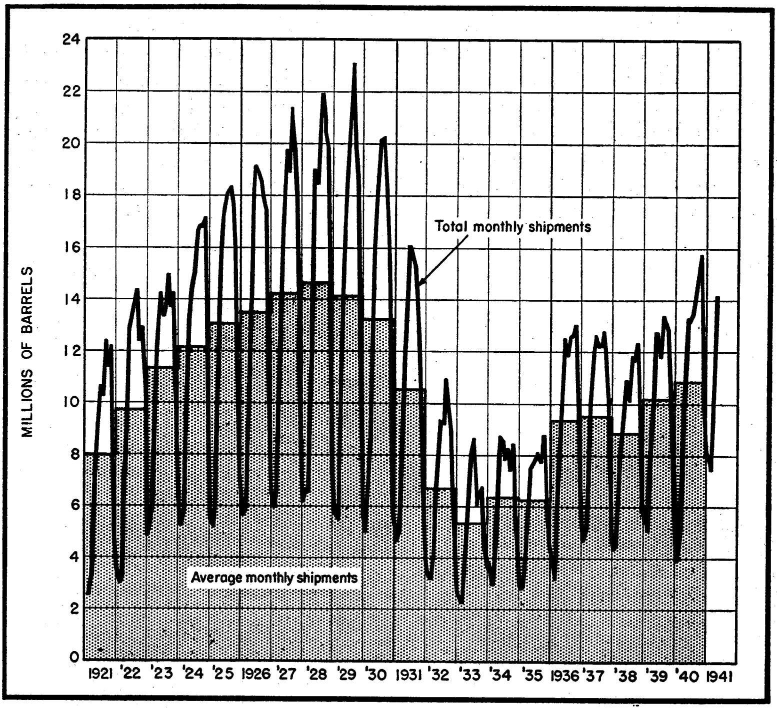

FIGURE 1.—Total monthly and average monthly shipments of portland cement in the United States, 1921–40.

Producers' stocks of portland cement on hand at the mills were 0.6 percent lower at the end of 1940 than at the end of 1939. The following table gives stocks on December 31 and the seasonal fluctuations in stocks from 1936 to 1940.

Producers' stocks of finished portland cement and clinker (unground cement) on hand at mills in the United States on Dec. 31 and monthly range, 1936–40

		Dec. 31 (barrels)	Monthly range			
			Low		High	
			Month	Barrels	Month	Barrels

	Clinker	[1] 4,886,000	do	4,470,000	April	6,606,000

[1] Includes Puerto Rico.
[2] Revised figure.

DOMESTIC CONSUMPTION

Apparent consumption (shipments plus imports minus exports) for a series of years is indicated in the salient statistics presented as the first table in this chapter. The only available gage of consumption by States is the record of shipments into States by manufacturers; it is therefore merely approximate. Cement shipped to destinations within a State in which it is manufactured is, of course, added to that shipped from other States. Shipments into a State during any year may not equal the consumption during that year but over a series of years should afford a fair index of consumption. The following table shows shipments into States in 1939 and 1940 and per capita consumption in each State.

Shipments of domestic portland cement from mills into States and per capita, 1939–40, in barrels [1]

State	1939		1940	
	Total	Per capita [1]	Total	Per capita [1]
Alabama	1,368,138	0.47	1,458,811	0.51

Total shipped from cement plants	3, 893, 000	4, 907, 000	7, 716, 000	10, 829, 000	13, 206, 000	13, 223, 000	13, 442, 000	14, 018, 000	14, 741, 000	15, 776, 000	10, 372, 000	8, 192, 000

The official figures for exports of cement differ from those reported by manufacturers in the table on page 1114, because cement forwarded from mills and destined to foreign countries and to Alaska, Hawaii, and Puerto Rico is reported by shippers as exported, whether or not it leaves the country during the calendar year, whereas the export figures of the Bureau of Foreign and Domestic Commerce record the cement that actually leaves the country during the period specified. Furthermore, the exports recorded by the Bureau of Foreign and Domestic Commerce include all hydraulic cement exported, whereas the figures supplied by producers relate to portland cement only.

The per capita consumption indicated in the table falls short of the total apparent consumption by the quantity of imports, which affects to a limited extent certain States near the Canadian border and the seaboard.

The preceding table of monthly shipments from portland-cement mills into States in 1940 is based upon monthly reports of producers. Although the totals may vary slightly from figures shown in tables based upon annual reports, they show seasonal fluctuations with fair accuracy.

USES

The Bureau of Mines has no facilities for collecting statistics on the consumption of portland cement by uses. The following estimates covering the principal uses were made by engineers of the Portland Cement Association, who are in touch with the many users of cement throughout the country.

Estimated distribution of portland cement in the United States in 1939, by uses [1]

Classification	Percent	Barrels
Paving: Roads, streets, and airports	20	24,530,000
Structural: Buildings (including multiple dwellings), bridges, and railroads	30	36,796,000
Conservation: Reclamation, water supply, and sewerage	18	22,077,000
Housing (1- and 2-family dwellings) and miscellaneous uses	22	26,983,000
Farm	10	12,265,000
	100	122,651,000

[1] Compiled by the Portland Cement Association, based upon limited available data.

LOCAL SUPPLIES

The following table compares the shipments from mills within a State or group of States with the estimated consumption (State receipts of mill shipments) and indicates the surplus or deficiency in the supply of cement locally available. Consumption in the States that do not produce cement is indicated in a preceding table showing shipments into each State.

The surplus cement shown in this table was distributed as follows: In 1939—to non-cement-producing States 13,743,088 barrels, to foreign countries, Alaska, and Hawaii 1,311,901 barrels, and to unspecified destinations 148,737 barrels; in 1940—to non-cement-producing States 13,703,729 barrels, to foreign countries, Alaska, and Hawaii 2,649,223 barrels, and to unspecified destinations 213,811 barrels.

Estimated surplus or deficiency in local supply of portland cement in cement-producing States, 1939–40, in barrels

TRANSPORTATION

The following table for 1936, 1939, and 1940, showing quantities of portland cement shipped from mills by truck, railroad, and boat, in bulk and in containers, is added because charges for transportation and delivery are important items in the cost of cement to consumers. Data for mode of shipping were lacking in 1936 for 16,870,730 barrels—nearly 15 percent of total shipments; in 1939 for 5,681,405 barrels—about 5 percent of total shipments; and in 1940 for 1,726,649 barrels—about 1 percent of total shipments for the year.

The table presented herein is based upon the quantities of cement actually apportioned by the reporting companies; as it represents a very large proportion of the total quantity shipped, it may be assumed that the percentages thus obtained are approximately correct for the industry as a whole.

The earliest data obtained by the Bureau of Mines were for 1928, when 2.4 percent of the total was shipped in bulk and 97.6 percent in containers. Shipments in bulk were reported in 1936 by 130 plants, representing 33 States; in 1939 by 137 plants, representing 33 States; and in 1940 by 144 plants, representing 32 States.

Shipments of portland cement from mills in the United States in 1936, 1939, and 1940 in bulk and in containers, by types of carriers

[Unit of measure, barrels of 376 pounds]

Type of carrier	In bulk		In containers				Mode of shipping not stated	Total shipments	
			In bags		In other containers [1]	Total in containers

[1] Includes steel drums and iron and wood barrels.
[2] Includes cement used at mills by producers as follows: 1936, 103,893 barrels; 1939, 132,238 barrels; 1940, 118,710 barrels.
[3] Includes cement for which mode of shipping is not stated as follows: 1936, 8,081,196 barrels; 1939, 4,493,317 barrels.
[4] Includes shipments by pipe line.
[5] Includes shipments by truck and railroad in paper bags for Puerto Rico.

PRICES

The average selling price of portland cement, f. o. b. factories (excluding the price of containers and cash discounts), as reported to the Bureau of Mines, is stated on page 1108 in the table of shipments by States and districts during 1939 and 1940. The average factory value in some States is higher than the average for ordinary structural cement because considerable quantities of certain special cements that command relatively high prices are included. Thus, white portland cement is manufactured in California and Pennsylvania and high-early-strength portland cement in many States. The average selling price per barrel, f. o. b. factory, of white portland cement in 1940 was $3.89; in 1939 it was $3.72. The average price f. o. b. mill of high-early-strength portland cement was $1.87 a barrel in 1940 and $1.88 a barrel in 1939. The sales value of other hydraulic cements is given later in this chapter.

The following table shows the average factory value of portland cement from 1936 through 1940.

Average factory value per barrel in bulk of portland cement in the United States, 1936–40

1936	$1.51	1939 [1]	$1.47
1937	1.48	1940 [1]	1.46
1938	1.45		

[1] Includes Puerto Rico.

PLANT CAPACITY

At the end of 1940, the capacity for producing finished portland cement of the 152 plants active and shipping in 1940 and the 8 plants inactive in 1940 but producing or shipping from stock on hand within the 7 previous years is shown in the following table, with similar figures for 1939. Figures for plant capacity are based upon manufacturers' reports, supplemented by a few estimates.

Portland-cement-manufacturing capacity of the United States and Puerto Rico, 1939–40, by commercial districts

District	Estimated capacity (barrels)		Percent of capacity utilized	
	1939	1940	1939	1940
Eastern Pennsylvania, New Jersey, and Maryland	49,545,000	48,718,000	47.7	51.3
New York and Maine	17,199,000	17,408,000	42.5	50.5
Ohio, western Pennsylvania, and West Virginia	28,627,000	27,526,000	39.6	48.6
Michigan	16,605,000	15,196,000	49.5	56.6
Wisconsin, Illinois, Indiana, and Kentucky	29,046,000	29,724,000	42.3	42.6
Virginia, Tennessee, Alabama, Georgia, Florida, and Louisiana	25,778,000	25,786,000	51.8	57.0
Eastern Missouri, Iowa, Minnesota, and South Dakota	22,915,000	22,871,000	45.7	45.1
Western Missouri, Nebraska, Kansas, Oklahoma, and Arkansas	16,159,000	17,113,000	49.7	44.4
Texas	12,058,000	12,240,000	60.8	60.3
Colorado, Montana, Utah, Wyoming, and Idaho	5,765,000	5,690,000	53.1	52.1
California	25,280,000	24,040,000	43.5	59.1
Oregon and Washington	7,095,000	7,447,000	82.9	57.3
Puerto Rico	350,000	386,000	92.6	100.0
	256,422,000	254,145,000	47.7	51.2

The following estimates, based upon the monthly reports of producers, of the relationship between the production of finished portland cement and the manufacturing capacity of the industry for each month in 1939 and 1940 and for the 12 months ended with each month indicate the seasonal changes in capacity utilized.

Ratio (percent) of finished portland cement produced to manufacturing capacity of the United States and Puerto Rico, 1939–40

Month	Monthly		12 months ended—		Month	Monthly		12 months ended—	
	1939	1940	1939	1940		1939	1940	1939	1940
January	24.2	28.6	41.3	47.9	July	57.8	55.9	44.9	47.9
February	26.9	24.8	41.9	47.8	August	56.5	57.8	45.5	48.0
March	37.3	36.3	42.8	47.5	September	56.4	61.8	46.0	48.6
April	45.7	47.5	43.4	47.5	October	57.3	63.7	46.4	49.3
May	51.1	57.8	43.7	48.1	November	52.2	60.1	46.7	49.9
June	56.4	58.8	44.3	48.1	December	42.9	51.2	46.8	50.6

The following table gives statistics of capacity, 1938–40, by the two general methods—the "wet" and the "dry"—used in manufacturing portland cement at plants in the United States:

Portland-cement-manufacturing capacity of the United States, 1938–40, by processes

Process	Estimated capacity: Thousands of barrels 1938	1939 [1]	1940 [1]	Estimated capacity: Percent of total 1938	1939 [1]	1940 [1]	Percent of capacity utilized 1938	1939 [1]	1940 [1]	Percent of total finished cement produced 1938	1939 [1]	1940 [1]
Wet	119,776	121,337	122,266	46.8	47.3	48.1	46.1	51.8	55.4	52.4	51.4	52.0
Dry	135,921	135,085	131,879	53.2	52.7	51.9	36.9	43.9	47.4	47.6	48.6	48.0
	255,697	256,422	254,145	100.0	100.0	100.0	41.2	47.7	51.2	100.0	100.0	100.0

[1] Includes Puerto Rico.

RAW MATERIALS

For 1940 producers reported that approximately 42,204,488 short tons of raw materials (exclusive of fuels and explosives) entered into the manufacture of 130,216,511 barrels (24,480,704 short tons) of portland cement in the United States—an average of about 648 pounds to a barrel of finished cement (376 pounds). The totals were as follows: 33,986,327 tons of limestone and cement rock, 4,021,709 tons of clay and shale (including kaolin for making white cement), 581,873 tons of blast-furnace slag, 932,339 tons of marl, 121,544 tons or iron ore, 806,971 tons of gypsum, and 1,753,725 tons of other materials, such as oystershells, sandstone, sand, cinders, fluorspar, diatomite, diatomaceous shale, pumicite, fuller's earth, bentonite, silica, quartz, ashes, pyrite ore, pyrite cinder, roll scale, calcium chloride, and hydrated lime.

NEW DEVELOPMENTS

Plant rehabilitation.—Additions to plant equipment during 1940 are too numerous to be covered individually in a condensed review. At least 25 cement companies report important additions or replacements whose total cost is several million dollars. These changes include additional kilns, grinders, storage silos, recuperators, and dust collectors. An outstanding trend is exemplified by the introduction, at many cement plants, of unit coal pulverizers that discharge directly into kilns or driers.

In this connection, it is interesting to note that in the latest biennial census, the Census of Manufactures obtained data on expenditures made by the cement industry for plant and equipment during 1939. Such figures have not been obtained heretofore. Preliminary statistics show a total expenditure of about $7,913,000, of which approximately 60 percent was expended for new machinery, 36 percent for new buildings or other fixed structures, and the balance for land and used or second-hand equipment.

Specifications.—New specifications (C150–40T) covering five standard types of cement, promulgated after much study by Committee C–1, have been formally adopted by the American Society for Testing Materials and became effective September 2, 1940. The five types were defined in the chapter on Cement of Minerals Yearbook, 1940 (p. 1137).

Research.—Elaborate plans have been made by a committee of 12, headed by P. H. Bates of the National Bureau of Standards, to conduct a long-time experimental study of cement performance in concrete. An extensive program of tests was adopted in August 1940.

Experimental roads have been built to determine the effect of organic admixtures on the endurance of concrete in cold climates. The admixtures include resins, oils, stearates, and tallow, materials that tend to produce foaming and thus increase the air content of the concrete.

Grinding aids.—Minerals Yearbook, 1940 (p. 1137) referred to the use of grinding aids — substances that, when added in small quantities to a clinker charge, assist grinding materially. The Mellon Institute developed new data on the subject in 1940. As a result of comprehensive studies, it was found that as small a quantity as 0.32 percent of carbon black added to cement clinker increases the fineness of the cement by 30 percent when the time of grinding is constant or decreases the grinding time by 28 percent when constant fineness is maintained.

Technical progress.—Froth flotation is being applied increasingly to cement raw materials. Limestones that are inferior or actually unusable under conventional practice are now conditioned by flotation to make them suitable for the manufacture of any type of portland cement. A remarkable feature of the process is the successful use of flotation with materials as fine as 325-mesh.

The new plant of the Permanente Corporation near Los Altos, Calif., has set what is probably an all-time low cost for raw grinding. Grinding is done in two stages; the first gives a minus-48-mesh product, and the second gives a product of which 96 percent is minus-200-mesh. The power consumption is said to be 10 to 11 kw.-hr. per barrel of cement.

This company is also pioneering in byproducts, which may eventually include limestone for beet-sugar factories and concrete aggregate, lime, stone sand, carbon dioxide, and potash. The stone for beet-sugar manufacture must be virtually chert-free. The cherty limestone is similar in appearance to the pure stone, but under a fluorescent light the chert assumes such a distinctive coloration that it can be removed by hand selection on a picking belt. Quite a number of cement plants are equipped with dust collectors, but the dust can rarely be regarded as a byproduct because it is blended with the mill feed as a supplementary raw material.

FUELS AND POWER

Fuels.—According to monthly reports of producers, supplemented by a few estimates by the Bureau of Mines, the following quantities of fuel were consumed at portland-cement plants in the United States and Puerto Rico in 1940 in making 130,141,000 barrels of clinker (unground cement) and 130,216,511 barrels of finished cement: Coal, 5,633,156 short tons; oil, 2,424,976 barrels (42 gallons); and natural gas, 41,948,699,007 cubic feet. Corresponding figures for 1939 are: Clinker produced, 121,620,000 barrels, and finished cement produced, 122,259,154 barrels. Fuels consumed were: Coal, 5,274,463 short tons (revised figure); oil, 2,440,951 barrels (revised figure); and natural gas, 40,211,858,789 cubic feet (revised figure).

The accompanying table shows detailed data on fuels used in 1939 and 1940. Similar data were published in Minerals Yearbook, 1937 (p. 1156), covering 1934 and 1935.

Portland cement burned in the United States and Puerto Rico, 1939–40, by kinds of fuel

Fuel	Finished cement produced			Fuel consumed [1]		
	Number of plants	Barrels of 376 pounds	Percent of total	Coal (short tons)	Oil (barrels of 42 gallons)	Natural gas (cubic feet)
1939						
Coal [2]	99	[3] 79,350,367	64.9	4,775,859		
Oil	11	[3] 8,617,586	7.1		1,936,952	
Natural gas	15	[3] 11,775,964	9.6			18,006,059,152

[1] Figures compiled from monthly estimates of the producers.
[2] In addition to the coal shown for this group, 1 plant reported the use of petroleum coke with coal.
[3] Average consumption of fuel per barrel of cement produced was as follows: 1939—coal, 120.4 pounds; oil, 0.2248 barrel; natural gas, 1,529 cubic feet. 1940—coal, 119.5 pounds; oil, 0.2174 barrel; natural gas, 1,561 cubic feet.
[4] In addition to the coal, oil, and natural gas included for this group, 1 plant reported the use of petroleum coke with coal, oil, and natural gas.
[5] Includes 79,839 short tons of anthracite and 5,194,624 short tons of bituminous coal.
[6] Revised figures.
[7] In addition to the coal and natural gas included for this group, 1 plant reported the use of petroleum coke with coal and natural gas.
[8] Includes 74,437 short tons of anthracite and 5,558,719 short tons of bituminous coal.

The two following tables show the quantities of natural gas and oil used at portland-cement plants in the United States in 1939 and 1940, by States.

Natural gas used at portland-cement plants in the United States, 1939–40, by States in cubic feet [1]

State	1939	1940
California	(2)	8,318,812,000
Kansas	6,245,652,772	5,750,642,479
Texas	9,802,705,474	10,037,845,725
Other States [3]	24,163,500,543	17,841,398,803
	40,211,858,789	41,948,699,007

Electric power.—The accompanying table gives the electric energy produced at portland-cement plants and that purchased from power companies during 1939 and 1940. The cement industry generated 49 percent of its electric-power requirements in 1940 compared with 50 percent in 1939 and 51 percent in 1938.

Electrical energy used at portland-cement-producing plants in the United States and Puerto Rico, 1939–40, by processes, in kilowatt-hours

Process	Electrical energy used						Finished cement produced	Average electrical energy used per barrel of cement produced
	Generated at portland-cement plants		Purchased		Total			
	Active plants	Kilowatt-hours	Active plants	Kilowatt-hours	Kilowatt-hours	Percent	Barrels	Kilowatt-hours
1939

SPECIAL CEMENTS

Regular or standard portland cements have been greatly improved during recent years. They attain adequate strength for ordinary use in a much shorter time and have higher ultimate strength and better workability than cements made some years ago. Although these cements are well-adapted for all ordinary uses, new conditions have arisen in industry that demand cements having special qualities, such as high early strength, unusual plasticity, low or moderate heat of setting, or high resistance to chemical action. Special types of cement are discussed in the following paragraphs, and available figures for sales are tabulated at the end of this section.

White portland cement.—White cement has been manufactured for many years in Pennsylvania and since 1932 in California. It is simply a standard cement, the raw materials of which are unusually pure, with an especially low iron content. To avoid contamination and discoloration from fuel, white cement is calcined with gas. It is produced at so few plants that the Bureau is not at liberty to publish figures of output separately.

Alumina cement.—A product known as alumina or high-alumina cement was first manufactured in France under the name of "ciment fondu." Modifications of alumina cement have been made in the United States for many years under patent. The raw materials are bauxite and limestone or lime, which are ground to fine consistency and fused in a furnace. The melted product is cooled rapidly and ground to a fine powder. Production figures cannot be published separately.

High-early-strength portland cement.—For street work where traffic is so heavy that interruptions for long periods are undesirable, in building enterprises where one step must follow another rapidly, or in any type of construction where speed has primary importance, a cement that attains adequate strength in 24 hours or less is much in demand. This has led to the development of the special high-early-strength cements that are now manufactured in many States. These are simply portland cements modified by more complete calcination of raw materials relatively high in calcium carbonate and by grinding the resulting clinker to an extremely fine state of subdivision. They are more costly to manufacture than standard portland cements. Statistics of sales from 1937 to 1940 are given in the table at the end of this section.

Masonry cement.—Masonry or mortar cements must be plastic and of low shrinkage. A good masonry cement should not be harsh or gritty and should not stick to the trowel. It should spread freely and smoothly and should make a perfect bond without shrinkage cracks or air pockets. "Masonry portland" is a variety of portland cement well-suited for mortar uses. It may contain small additions of special ingredients to improve its plasticity or reduce its shrinkage, but it remains essentially a portland cement. The quantities of such cement sold from 1937 to 1940 are recorded in a table later in this section.

Producers also report certain masonry cements that are not true portlands, although they employ portland-cement clinker and finished portland cement as a base. To this base, however, considerable quantities of lime or other constituents of various kinds are added. These specially prepared masonry cements are sold under proprietary names. Production, which was reported from 49 plants in 1940, totaled 2,312,155 barrels and shipments 2,260,636 barrels valued at $3,175,088—an average of $1.40 a barrel. Corresponding data for 1939, representing the output of 33 plants (revised) are: Production 1,765,170 barrels (revised figure) and shipments 1,754,887 barrels (revised figure), valued at $2,362,885 (revised figure)—an average of $1.35 a barrel (revised figure). As the finished portland cement and clinker used in making these types of masonry cement have been reported elsewhere by producers, to avoid duplication the above figures are not included in the totals.

Low- and moderate-heat-of-hardening portland cement.—The construction of enormous dams during recent years has led to the development of cements having low heat of hydration, a desirable quality for mass concrete work. This was accomplished by decreasing the cement compounds primarily responsible for the generation of heat—namely, the tricalcium silicate and tricalcium aluminate. Such reduction necessitated an increase in the percentages of dicalcium silicate and tetracalcium aluminoferrite, which resulted in a much slower development of strength. Because of the slow gain in strength of low-heat cement a compromise product known as the moderate-heat type was developed. It reverted to standard portland cement in its content of tricalcium and dicalcium silicates but retained the low percentage of tricalcium aluminate used in low-heat cement. With very fine grinding this moderate-heat type develops strength at about the same rate as standard portland cement, attains higher ultimate strength in mass concrete work, and generates 10 percent less heat than standard cement, whereas the low-heat type develops 27 percent less heat. The moderate-heat type has proved most satisfactory and has been used in the Grand Coulee Dam and similar large projects. Quantities of low- and moderate-heat cements produced and shipped in recent years are indicated in the following table. Both the quantities used and the number of plants manufacturing these types of cement have increased greatly in recent years.

Portland-puzzolan cement.—Portland-puzzolan cements, including those reported as "high-silica" cements, are made by adding to portland cement small quantities of pumicite, slag, burned clay, or other materials that react with the calcium content of the cement. The so-called "active lime" is thus fixed by the puzzolanic materials, and the concrete made from such cements resists chemical attack as, for instance, the reaction with salts contained in alkali soil or in sea water.

Oil-well portland cement.—Cement is important to the oil industry particularly when employed to shut off water-bearing strata. The cement slurry sometimes is used at great depth and may be forced into the crevices of the water-bearing rock surrounding the well. Several types of cement are made to suit the varying conditions of use. By employing retarders or accelerators, the time of set is regulated accurately so that the cement will not set until it reaches its destination but will set immediately thereafter. Oil-well cements are also modified to satisfy conditions of high or low temperature and to make them resistant to chemical action. These special cements are prepared in the oil-producing States, particularly California, Texas, and Wyoming.

Miscellaneous.—Other special portland cements include those suitable for resisting high temperatures.

The following table presents statistical data for recent years in so far as they are available. All figures given in this table except those for masonry cement (hydraulic but not portland) and "masonry natural" are included in the general tables earlier in this chapter.

Special portland cements produced and shipped in the United States, 1937–40, by kinds

Kind and year	Active plants	Production (barrels)	Shipments		
			Barrels	Value	
				Total	Average
High-early-strength:					
1937	64	4,192,959	3,845,314	$7,134,468	$1.86
1938	72	3,340,582	3,385,523	6,247,699	1.85

NATURAL, MASONRY (NATURAL), AND PUZZOLAN CEMENTS

Natural cement is made by calcining argillaceous limestone at comparatively low temperature and grinding the calcined material to fine powder. Some of these cements have special properties that adapt them peculiarly for laying brick and stone, and they are classed as masonry (natural) cements. Masonry cements are therefore of three distinct types—masonry portland and special masonry cements having a portland-cement base, both of which have been discussed, and masonry of the natural-cement class, which is included in the following table.

Hydraulic lime differs from natural cement chiefly in its content of free lime, which is so high that the clinker will slake when water is added to it. The materials are, however, so closely related to natural cement that hydraulic lime is included in this chapter. Two companies (with one plant each, located respectively at Riverton, Va., and Highcliff, Wis.) reported production in 1940.

In addition to portland-puzzolan cement, discussed previously, another type, known as slag-lime cement, is made at Birmingham and Graystone, Ala., by mixing granulated blast-furnace slag with hydrated lime and grinding them to fine consistency. The mixture is not subsequently calcined.

Producers of these special nonportland cements reported that 42,873 short tons of coal were consumed in their manufacture in 1940. They also reported the use of a small quantity of gas having a total fuel value equivalent to about 68 short tons of coal. The fuel consumed in 1939 consisted of 55,193 short tons of coal together with gas having a total fuel value equivalent to about 97 short tons of coal.

Production and shipments of these special types of cement combined are indicated in the following table.

Natural, masonry (natural), and puzzolan (slag-lime) cements produced, shipped, and in stock at mills in the United States, 1936–40

Year	Production		Shipments		Stock (Dec. 31)
	Active plants	Barrels (376 pounds)	Barrels (376 pounds)	Value	Barrels (376 pounds)
1936	13	1,819,488	1,760,993	$2,362,396	230,788
1937	12	1,900,643	1,873,400	2,578,885	253,518
1938	12	1,820,795	1,867,949	2,725,776	373,816
1939	12	2,439,110	2,405,135	3,361,724	[1] 239,938
1940	12	2,534,566	2,514,597	3,386,801	259,907

CEMENT CONSUMPTION IN RELATION TO CONSTRUCTION CONTRACTS

[Prepared by Shirley F. Colby]

Cement is an important construction material, therefore it is of interest to determine the quantity used in relation to the value of contracts in various sections of the country and to trace trends in the relative quantities used over a series of years. In presenting these relationships in figure 2 the scales for plotting the curves have been so chosen that a coincidence of the cement-consumption curve with the construction curve would indicate that 2½ barrels of cement were used for each $100 of construction contracts awarded; that is, the number of dollars shown on the right margin is 40 times the number of barrels shown at the left. Identical scales have been used for each chart.

The curves begin in 1928, when construction activity had dropped only slightly from the high points of the preceding few years; consequently the patterns presented show the decline from prosperity levels and the subsequent partial recovery.

Total for 37 Eastern States.—As no comparable construction data are available for the 11 Western States, the comparisons in figure 2 concern only the 37 Eastern States covered by the F. W. Dodge Corporation's statistics of construction contracts awarded. However, as indicated in the lower right chart, cement consumption in the 48 States displays a pattern very similar to consumption in the 37 Eastern States. Indications are, however, that the number of barrels of cement used per $100 of construction contracts awarded was considerably above the average for the entire country because a large part of the construction in these States consists of dams, highways, and other concrete structures.

Considering the 37 Eastern States as a whole, it may be observed that in 1928 and 1929 the ratio of cement used to contracts awarded was comparatively small, but by 1930 it had increased considerably. This was caused, no doubt, by the growth of the public works program and the curtailment of industrial and residential building, where relatively smaller proportions of cement are generally used. Since 1938, however, the proportion of cement to contracts awarded has been falling, and in 1940 the ratio stood at 2⅗ barrels of cement to each $100 of construction contracts awarded. This figure is somewhat exaggerated because some cement was used in work for which no contracts were let and in small jobs not included in the statistics of construction contracts awarded. However, as such quantities are relatively small and are fairly constant from year to year, they do not materially affect the general relationships.

Eastern Pennsylvania, New Jersey, Maryland, Delaware, and the District of Columbia.—Considerably more cement is produced than used in this district. In 1940, there were 22 active plants, including 2 in Maryland, 1 in New Jersey, and the remaining 19 in Eastern Pennsylvania—an area that furnishes large quantities of the cement used in New York and the New England States. The quantity of cement used per $100 of contracts awarded ranged from 2.3 barrels in 1928 to 3.8 in 1932 and 3.1 in 1940.

New York and New England.—Two relationships displayed by these curves distinguish this district from the others—less cement was used per value of contracts awarded, and more cement was imported from other States than was produced. There were 12 active plants in 1940—1 in Maine and the remaining 11 scattered throughout New York State. The balance of the cement used comes chiefly from Eastern Pennsylvania. The sharp drop in value of construction contracts awarded (from 2,017 million dollars in 1928 to 328 million dollars in 1932—a fall of 84 percent) was reflected in only a 56-percent decline in cement consumption. Large cities are important centers of construction activity, and the adverse effect of the depression on residen-

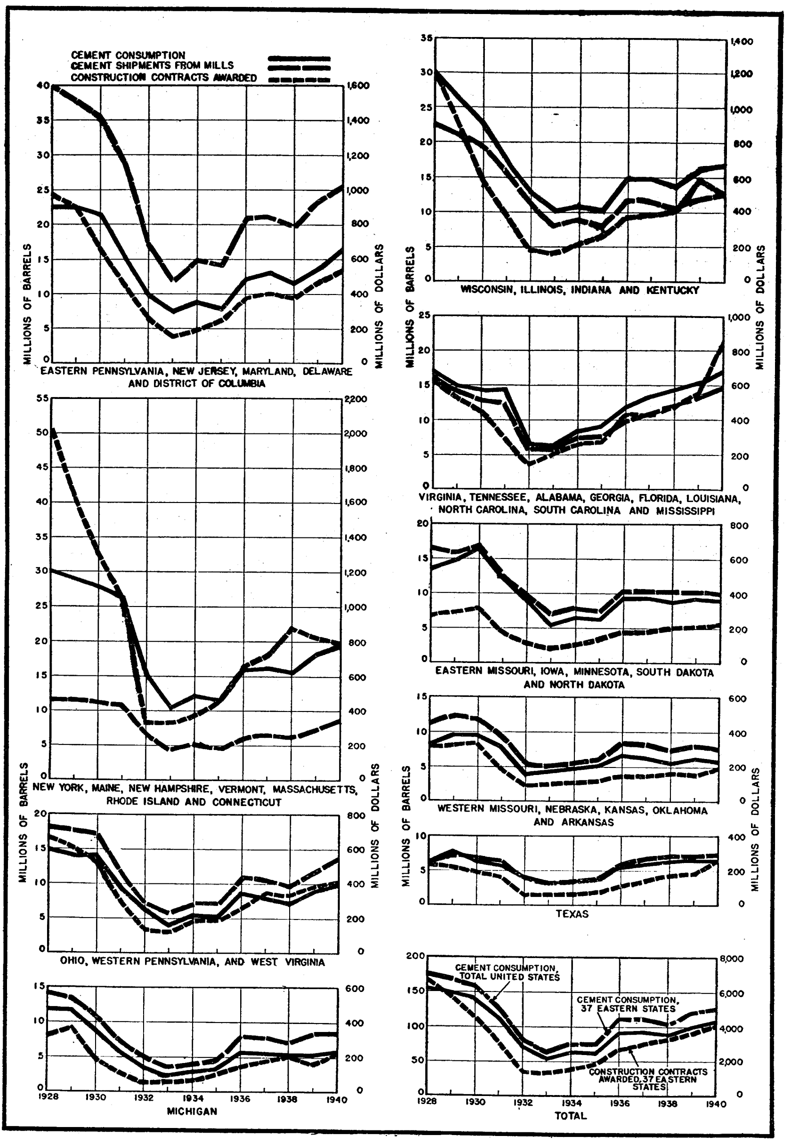

FIGURE 2.—Portlant cement consumption and shipments from mills compared with construction contracts awarded by districts, 1928–40. Data on consumption and shipments of cement from sections of this chapter on Production, Shipments and Stocks, and Domestic Consumption and from corresponding sections of earlier reports. Data on construction contracts awarded from F. W. Dodge Corporation.

tial, commercial, and industrial construction was more serious than on cement consumption, where the decline was cushioned by large expenditures for highways and their maintenance and for other forms of public works. Cement consumption in this area was 1.5 barrels per $100 of contracts awarded in 1928, 4.6 in 1932, 1.8 in 1938, and 2.4 in 1940.

Ohio, western Pennsylvania, and West Virginia.—Eighteen active plants in this district furnished more portland cement than was used; Ohio had 9 plants, western Pennsylvania 6, and West Virginia 3. The average amount of cement used per $100 was similar to that used in New York and New England, rising from 2.2 barrels in 1928 to 4.8 in 1932 and dropping to 2.4 barrels by 1940.

Michigan.—This State had nine active plants in 1940, which supplied almost 50 percent more cement than was used in the State that year. More cement in relation to construction was used in Michigan than in any of the districts already considered. In 1928, 3.6 barrels of cement were used per $100 of construction contracts awarded, 7.6 barrels in 1932, and 2.7 barrels in 1940.

Wisconsin, Illinois, Indiana, and Kentucky.—This district produces less cement than it consumes. Of the 11 active plants, 1 was in Wisconsin, 4 in Illinois, 5 in Indiana, and 1 in Kentucky. The steep 85-percent drop in contracts awarded between 1928 and 1932 and the 56-percent drop in cement consumption in these years parallel closely the condition that existed in New York and the New England States, already discussed. Consumption of cement rose from 2.5 barrels per $100 of construction contracts awarded in 1928 to 7.1 in 1932 and by 1940 had declined to 3.2 barrels.

Virginia, Tennessee, Alabama, Georgia, Florida, Louisiana, North Carolina, South Carolina, and Mississippi.—Production of cement during the 13 years covered was somewhat below consumption. Of the 18 plants active in 1940, 2 were in Virginia, 6 in Tennessee, 6 in Alabama, 2 in Georgia, 1 in Florida, and 1 in Louisiana. Construction activity in this district in 1940 surpassed the 1928 level by over $100,000,000. Virginia and Florida accounted for over half of the rise—nearly $300,000,000—from 1939 to 1940, and most of the increase in these States was in residential and nonresidential construction. For this reason, the rate of increase in cement consumption was less than the rate of increase in construction contracts awarded.

T. V. A. construction has been directed by the Authority itself, no contracts having been let. Therefore, the Dodge construction data do not cover the value of this activity. The number of barrels of cement shipped to the T. V. A. each fiscal year was as follows: 1935, 1,280,520; 1936, 1,073,610; 1937, 820,050; 1938, 579,580; 1939, 895,100; 1940, 702,580; and 1941 (through April) 1,249,990—a total of 6,601,430 barrels since this program was initiated. Considering the fact that the value of T. V. A. construction is not included in the statistics of contracts awarded, the consumption of cement in this district has been very low indeed. Only 2 barrels per $100 of awards were used in 1940, 2.7 barrels in 1928, and 4.5 barrels in 1932.

Eastern Missouri, Iowa, Minnesota, South Dakota, and North Dakota—This district produced a little more cement than was used. Iowa had 5 of the 11 active plants in 1940, eastern Missouri 4, Minnesota 1, and South Dakota 1. The outstanding characteristics of this district are the large proportionate use of cement and the smooth trend displayed by the curve of contracts awarded. Even in 1928, 5.0 barrels of portland cement were used per $100 of awards. In 1932 the ratio had grown to 8.1 barrels, but by 1940 it dropped to 3.9 barrels.

Western Missouri, Nebraska, Kansas, Oklahoma, and Arkansas.—This district also had a net surplus of cement in each of the 13 years. Of 12 active plants in 1940, Kansas had 6, Oklahoma 2, Arkansas 1, western Missouri 1, and Nebraska 2. Cement consumption here was fairly typical of the country as a whole, with 2.6 barrels per $100 of construction used in 1928, 4.4 barrels in 1932, and 3.0 barrels in 1940.

Texas.—This State shares the distinction with the Southeastern States of having surpassed the 1928 levels of both cement consumption and contracts awarded. The 10 plants active in 1940 supplied a little more cement than was required. This extra amount probably went to States west of Texas. Cement consumption was 7.0 barrels per $100 of contracts awarded in 1932 compared to 2.7 barrels in 1928 and 2.6 barrels in 1940.

FOREIGN TRADE[1]

Imports.—The figures in the following table cover imports of hydraulic cements of all kinds. The values assigned are supposed to represent those in the foreign countries from which the materials are exported, including the cost of containers or coverings.

Hydraulic cement imported for consumption in the United States, 1936–40

Year	Barrels	Value	Year	Barrels	Value
1936	1,658,902	$1,421,620	1939	1,913,853	$1,860,543
1937	1,803,932	1,392,633	1940	538,060	506,191
1938	1,727,411	1,436,730			

The following table of imports, by countries of origin and import districts, includes all hydraulic cements except "white, nonstaining portland cement," which was reported "imported for consumption" as follows: 1940—2,441 barrels valued at $8,353, of which 496 barrels valued at $1,874 came from Belgium, 202 barrels valued at $763 from Denmark, 384 barrels valued at $624 from France, and 1,359 barrels valued at $5,092 from the United Kingdom; 1939—22,883 barrels valued at $75,983, of which 2,323 barrels valued at $7,405 came from Belgium, 11,029 barrels valued at $42,864 from Denmark, 4,279 barrels valued at $7,686 from France, and 1,278 barrels valued at $4,413 from the United Kingdom.

Exports.—Although the United States is the major cement-producing country of the world, its export trade is small. Shipments to North and Central America increased substantially in 1940, but exports to South America decreased—a condition that indicates the growing self-sufficiency of that area. The value of exports is the actual cost at United States ports, as indicated by the shippers on the export declarations.

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

WORLD PRODUCTION

The following table of world production has been compiled by the Bureau of Mines from consular reports, official statistics, and trade literature. The figures are in metric tons (1 metric ton equals 2,204.622 pounds). The table shows the latest reported plant capacity and the production from 1936 to 1940, inclusive. Although figures for certain countries are still lacking the table presents a reasonably complete picture of the cement industry throughout the world. Figures on capacity are the best estimates that can be made from available data.

World production of cement, 1936–40, and latest reported plant capacity, by countries, in metric tons [1]

[8] 12 months ended March 31 of the year indicated.

STONE

By Oliver Bowles and M. S. Jensen

SUMMARY OUTLINE

Sales of crushed and dimension stone combined, totaling nearly 154,000,000 tons, attained an all-time record in 1940 and exceeded by 4 percent the sales in 1939, which had also been a record-breaking year. The value of sales was the highest since 1930 and was 1 percent greater than in 1939. Sales of dimension stone (exclusive of slate) were 8 percent lower in quantity and 16 percent lower in value. The relatively large decrease in value indicates a trend toward lower unit prices. The crushed-stone industry gained 4 percent in both quantity and value of output in 1940.

The present chapter follows the general plan inaugurated in 1938, whereby the data on dimension stone are separated from those on crushed stone, except in the introductory general tables.

The tables of this report give the quantities sold or used by producers and the values f. o. b. quarries and mills insofar as these figures are obtainable. Stone quarried and used by producers is considered as sold and is included in the statistics of sales. The data, however, do not include stone made into abrasives (such as grindstones) or that used in making lime and cement. These materials are reported in terms of finished products in the Abrasive Materials, Lime, and Cement chapters of this volume. The following tables show the total sales of stone by kinds, uses, and States.

Stone sold or used by producers in the United States, 1936–40, by kinds

[Quantities approximate]

Year	Granite		Basalt and related rocks (trap rock)		Marble		Limestone	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value
1936	15,442,150	$22,893,289	14,014,440	$13,386,933	165,760	$5,761,554	87,735,740	$81,559,984
1937	9,265,830	20,192,882	13,581,460	12,508,276	207,760	5,456,191	94,577,270	90,901,877

DIMENSION STONE

The term "dimension stone" is applied to blocks or slabs of natural stone, most of which are cut to definite shapes and sizes. These products are quite distinct from crushed, broken, and pulverized stone, which comprises irregular fragments or grains sized chiefly by mechanical screening or air separation. Crushed and broken stone is covered in a later section of this chapter.

Dimension-stone producers may be divided into three main groups upon the basis of plant operation. The first group includes operators who quarry stone and sell it as rough blocks or slabs; the second group quarries stone and also manufactures it into finished products; and the third buys sawed slabs or rough blocks of stone and manufactures them into finished products but does not operate quarries. The Bureau of Mines statistical canvass covers the first and second groups, but as the third group comprises manufacturers rather than quarrymen it is canvassed by the Bureau of the Census. Bureau of Mines statistics are compiled from reports of quantities and values of original sales; hence they include some material sold as rough blocks and some sold as finished products.

Total sales of dimension stone in 1940 declined 9 percent in quantity and 16 percent in value compared with 1939. These figures include slate, but details of the slate industry are given in a separate chapter. Marble, sandstone, and basalt suffered the most serious declines.

The following table of salient statistics includes figures for 1939 and 1940 and the percentage of change from 1939, for each type of stone, by principal products.

Dimension stone sold or used by producers in the United States, 1939–40, by kinds and uses

Quantity..approximate short tons..	2,298,360	2,106,730	−8.3
Value	$25,553,026	$21,416,910	−16.2
Slate as dimension stone [4]..approximate short tons..	179,600	154,450	−14.0
Value	$4,101,125	$3,436,368	−16.2
Total, including slate:			
Quantity..approximate short tons..	2,477,960	2,261,180	−8.7
Value	$29,654,151	$24,853,278	−16.2

[1] To avoid disclosing confidential information, paving blocks in 1939 are included under "Curbing."
[2] Includes paving blocks.
[3] Includes soapstone, mica schist, volcanic rocks, argillite, and other varieties that cannot be classified in the principal groups.
[4] Details of production, by uses, are given in the chapter on Slate in this volume.

BUILDING STONE

The largest use of dimension stone is for building. The following table gives the quantity and value of each kind of stone used for construction in 1940.

Building stone sold or used by producers in the United States in 1940, by kinds

Kind	Rough			
	Construction		Architectural	
	Cubic feet	Value	Cubic feet	Value
Granite	1,074,620	$245,385	563,270	$515,442
Basalt	184,520	17,548		
Marble			176,680	430,052
Limestone	1,265,060	174,148	2,344,440	982,842
Sandstone	425,190	80,750	252,410	199,607
Miscellaneous	680,690	754,757		

Kind	Finished				Total	
	Sawed [1]		Cut [1]			
	Cubic feet	Value	Cubic feet	Value	Cubic feet	Value
Granite	155,470	$522,343	385,850	$1,809,297	2,179,210	$3,092,467
Basalt					184,520	17,548
Marble	232,500	563,508	373,420	2,330,469	782,600	3,324,029
Limestone	1,148,080	673,948	1,144,430	1,768,621	5,902,010	3,599,559
Sandstone	176,280	247,268	59,780	184,714	913,660	712,339
Miscellaneous					680,690	754,757

[1] For granite, sawed stone corresponds to dressed stone for construction work (walls, foundations, bridges) and cut stone to architectural stone for high-class buildings.

GRANITE

Sales of granite as dimension stone fell 10 percent in quantity but increased 2½ percent in value in 1940 compared with 1939. Cut stone and rubble made substantial gains, and monumental stone declined 2 percent in quantity and gained 4 percent in value, but granite for rough construction, paving blocks, and curbing dropped far below the 1939 totals. The paving-block and curbing industries are dwindling rapidly toward almost total extinction. More than 37 million granite paving blocks were made in 1925, whereas in 1940 the number had slumped to only about 1,800,000.

Granite (dimension stone) sold or used by producers in the United States in 1940, by States and uses

The following tables show sales of monumental granite in the Quincy (Mass.) and Barre (Vt.) centers.

Monumental granite sold by quarrymen at Quincy, Mass. 1936–40 [1]

Year	Active plants	Cubic feet	Value	Year	Active plants	Cubic feet	Value
1936	3	46,570	$85,013	1939	3	25,620	$61,955
1937	3	36,020	80,248	1940	3	24,540	60,139
1938	3	33,360	73,832				

[1] Quincy granite is sold also for construction, curbing, rubble, riprap, and crushed stone.

Monumental granite sold by quarrymen in the Barre district, Vermont, 1936–40 [1]

Year	Cubic feet	Value	Year	Cubic feet	Value
1936	771,230	$2,109,526	1939	684,310	$2,029,801
1937	847,740	2,390,377	1940	601,190	2,039,960
1938	605,660	1,849,607			

[1] Barre granite is sold also for construction and crushed stone.

Estimated output of monumental granite in the Barre district, Vermont, 1938–40 [1]

	1938	1939	1940
Total quarry output, rough stock .... cubic feet	589,440	614,256	548,412
Shipped out of Barre district in rough .... do	117,888	122,852	109,682
Manufactured in Barre district .... do	471,552	491,404	438,730
Light stock consumed in district .... do	294,720	307,128	274,206
Dark stock consumed in district .... do	176,832	184,276	164,524
Number of cutters in district	1,550	1,550	1,295
Average daily wage	$8.00	$8.50	$8.50
Average number of days worked	220	220	220
Total pay roll for year	$2,813,250	$2,898,500	$2,421,650
Estimated overhead	1,406,625	1,449,250	1,210,825
Estimated value of light stock	1,176,987	1,247,714	1,199,651
Estimated value of dark stock	934,347	990,494	874,033
Estimated polishing cost	372,938	388,639	346,980
Output from saws	124,312	129,546	115,660
Total value of granite	6,828,459	7,104,143	6,168,799

[1] Through the kindness of the Granite Manufacturers' Association, Barre, figures covering the entire granite industry of the Barre district are given in this table to supplement figures of sales reported by quarrymen.

BASALT AND RELATED ROCKS (TRAP ROCK)

Because of its dark color, basalt is not used extensively for building. In 1939 considerable quantities were used for rubble, but this use declined greatly in 1940. The tonnage sold in 1940 was only about one-fifth and the value two-fifths as great as in 1939. Some of these dark rocks are used for memorials; but such stones are classed commercially as black granites, and are therefore included with the figures for monumental granite.

Basalt and related rocks (trap rock) (dimension stone) sold or used by producers in the United States in 1940, by States and uses

State	Active plants	Building stone: Rough construction: Short tons	Building stone: Rough construction: Value	Building stone: Rubble: Short tons	Building stone: Rubble: Value	Total: Short tons	Total: Value

[1] Included under "Undistributed."

[2] 184,520 cubic feet, approximate.

MARBLE

Sales of marble in 1940 declined 28 percent in quantity and 24 percent in value compared with 1939. The recession was shared by all types of products sold, but interior finished building stone and finished monuments suffered the least. There were drastic declines in sales in Georgia, Tennessee, and Missouri, but sales of building marble made large gains in Vermont. Sales in Massachusetts were a little higher in 1940 than in 1939.

Marble (dimension stone) sold by producers in the United States, 1939–40, by uses

Use	1939: Cubic feet	1939: Value	1940: Cubic feet	1940: Value

[1] Includes 11,880 cubic feet of serpentine marble (verde antique) valued at $70,738, which was sold as building and ornamental stone.
[2] Included under "Undistributed."
[3] Onyx rough blocks for the manufacture of mantels, lamp bases, desk sets, clock cases, and novelties.

LIMESTONE

Limestone is used in the United States more extensively than any other type of building stone, and Indiana supplied about 70 percent of the rough architectural and finished (cut and sawed) limestone sold in 1940. All the better grades of building stone (those classed above rubble) suffered serious declines in 1940. Only about one-third as much rough construction stone was sold in 1940 as in 1939. The quantity of rough architectural and finished building stone sold in 1940 was 68 percent and the value 57 percent of the corresponding figures for 1939. On the other hand, rubble sold in 1940 was about three times as great both in quantity and value as in 1939. Flagging also made decisive gains. The total quantity of dimension limestone sold in 1940 was a little higher than in 1939, but as the gains were confined to the lower-priced products the total amount realized from sales was only about two-thirds as great as in 1939.

[3] Includes stone for mausoleums and curbing.

SANDSTONE

Sales of sandstone declined 12 percent in quantity and 27 percent in value in 1940 compared with 1939. Stone for rough construction declined about 50 percent. The quantity of rough architectural and dressed stone sold in 1940 decreased 8 percent and the value 35 percent, compared with 1939. Sales of curbing also slumped greatly. The only principal classifications to gain were rubble and flagging, but the value of the flagging sold was lower than in 1939.

The second table presents a 20-year history of the bluestone industry. This type of sandstone is used for building stone and for curbing and flagging. As "sidewalk stone" it has been replaced generally by concrete, but this loss of market has been compensated to some extent by enlarged demands for ornamental flagging. Sales in 1940 were 1 percent higher in quantity and 15 percent lower in value than in 1939.

Sandstone (dimension stone) sold or used by producers in the United States in 1940, by States and uses

[1] New York and Pennsylvania are the only States that produce bluestone.

MISCELLANEOUS STONE

The following table gives data on certain types of dimension stone not included in the major groups already discussed. The principal varieties are mica schist, argillite, various light-color volcanic rocks, soapstone, and greenstone. The quantity sold was almost the same in 1940 as in 1939, but the value was much higher.

Miscellaneous varieties of stone (dimension stone) sold or used by producers in the United States in 1940, by States and uses

[2] Building stone, approximately 680,690 cubic feet; flagging, approximately 33,610 cubic feet.

TRENDS IN USE OF DIMENSION STONE

Figure 1 shows graphically the history of production of dimension stone, by kinds, for a 25-year period. Dimension stone includes all classes of building stone, as well as memorial stone, paving blocks, curbing, and flagging. Wars and depressions evidently affect the output of these products adversely. Although the output of certain mineral products, particularly the metals, is stimulated greatly by a program of national defense, this group does not include dimension stone. An environment of peace and general prosperity is requisite for active growth and development of the dimension-stone industries.

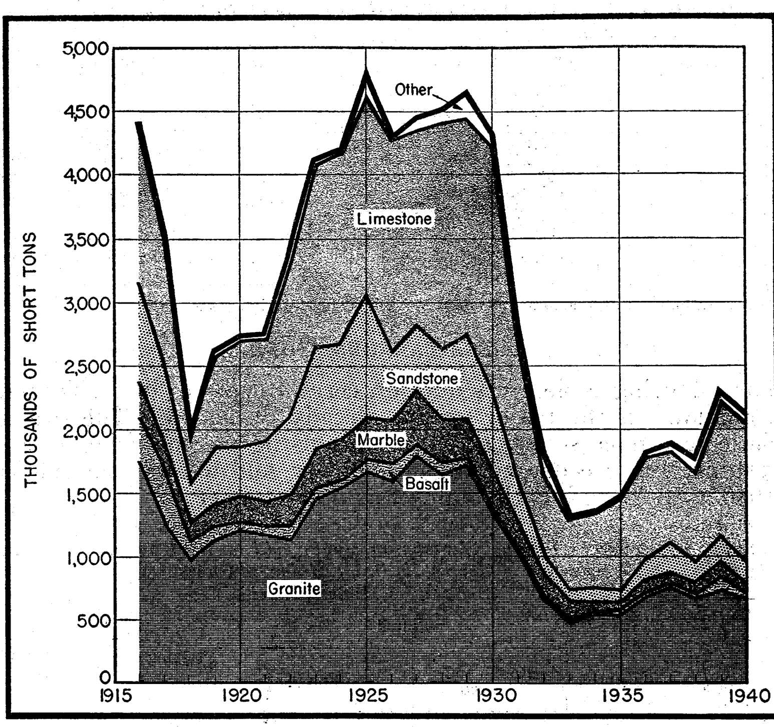

FIGURE 1.—Sales of dimension stone in the United States, by kinds, 1916-40.

Figure 2 traces the history of production of all building stone and of the principal variety, limestone, in their relation to nonresidential building, which is the class of construction in which stone is used most

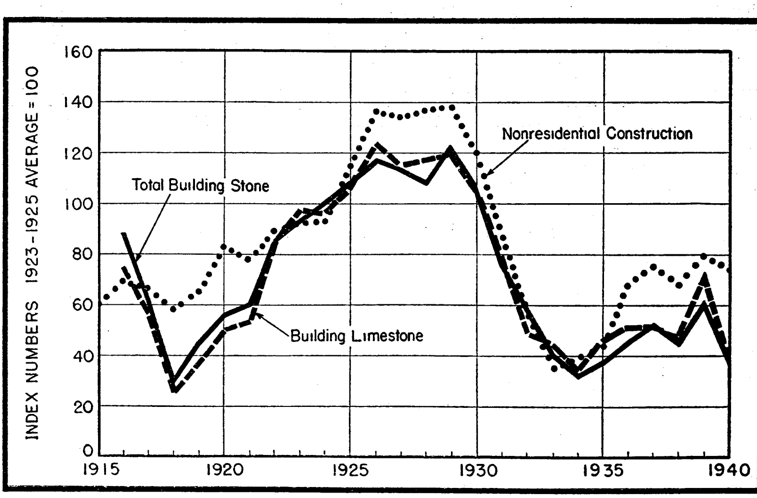

FIGURE 2.—Sales of all building stone and building limestone compared with physical volume of new nonresidential building activity, 1916-40. Data on nonresidential building construction from Bureau of Foreign and Domestic Commerce.

extensively. Building-stone production was at a low ebb in 1918 at the close of the World War of 1914–18, but recovered rapidly. However, it failed to reach the high level attained by building construction during the prosperous years 1926–29. Sales of stone followed the rapid decline in nonresidential building during the depression years that followed. The substantial recovery in building since 1935 has, however, failed to stimulate corresponding activity in stone output, although there was a promising upward trend in 1939, which was reversed, however, in 1940 when building-stone sales fell almost as low as during the depression period.

NEW DEVELOPMENTS

The results of exhaustive studies of 116 commercial granites produced for dimension stone uses in the United States are included in a recent report of the National Bureau of Standards.[1] This report is obtainable as a separate pamphlet under the designation Research Paper 1320 from the Superintendent of Documents, Government Printing Office, Washington, D. C.

Onyx marble and travertine are used moderately in the United States for novelties and decorative building, but most of our supplies are obtained from foreign sources—onyx from Mexico and Argentina and travertine from Italy. A recent report[2] describes both foreign and domestic deposits of these materials and outlines their characteristics and uses.

CRUSHED AND BROKEN STONE

Nearly 152,000,000 tons of crushed and broken stone were sold in 1940, exclusive of that used for making cement and lime. Sales increased 4 percent in both quantity and value compared with 1939. The largest proportional gains were in metallurgical, refractory, and agricultural stone and for limestone used in calcium carbide manufacture. Sales of concrete aggregate, road stone, and riprap declined.

The following table of salient statistics shows the quantity and value of crushed and broken stone sold during 1939 and 1940, by uses. Detailed data on asphaltic stone and slate granules and flour are given in the chapters on Asphalt and Slate.

[1] Included under "Undistributed."
[2] To avoid disclosing confidential information certain totals are somewhat incomplete, the figures not included being combined under "Undistributed."

Commercial and noncommercial operations.—The following table shows the production of crushed stone for concrete and road metal and railroad ballast during recent years by Government agencies of various kinds contrasted with that by commercial enterprises. Production by commercial companies increased 6 percent in 1940 compared with 1939, whereas production by Government agencies declined 16½ percent. Sixty-three percent of the total production was made by commercial companies.

Concrete and road metal and railroad ballast sold or used by commercial and noncommercial operators in the United States, 1936–40

[Figures for "noncommercial operations" represent tonnages reported by States, counties, municipalities, and other Government agencies, produced either by themselves or by contractors expressly for their consumption, often with publicly owned equipment; they do not include purchases from commercial producers. Figures for "commercial operations" represent tonnages reported by all other producers]

Year	Commercial operations				Noncommercial operations				Total	
	Short tons	Average value per ton	Percent of change in quantity from preceding year	Percent of total quantity	Short tons	Average value per ton	Percent of change in quantity from preceding year	Percent of total quantity	Short tons	Percent of change in quantity from preceding year
1936	57,494,430	$.93	+50.9	65.9	29,776,390	$.95	+78.7	34.1	87,270,820	+59.4
1937	62,315,350	.88	+8.4	70.5	26,117,220	1.06	−12.3	29.5	88,432,570	+1.3
1938	60,254,170	.88	−3.3	63.6	34,508,880	1.04	+32.1	36.4	94,763,050	+7.2
1939	59,516,270	.86	−1.2	57.3	44,374,750	.97	+28.6	42.7	103,891,020	+9.6
1940	63,203,240	.87	+6.2	63.0	37,065,150	1.02	−16.5	37.0	100,268,390	−3.5

Methods of transportation.—The following table shows the quantities of concrete and road metal conveyed during 1939 and 1940 by each of the principal methods of transportation.

Concrete and road metal sold or used by commercial producers in the United States, 1939–40, by methods of transportation [1]

Method of transportation	1939		1940	
	Short tons	Percent of total	Short tons	Percent of total
Truck	33,495,870	63.8	36,069,110	64.7
Rail	11,712,330	22.3	10,911,260	19.5
Waterway	4,886,820	9.3	6,072,270	11.0
Unspecified	2,424,450	4.6	2,696,300	4.8
	52,519,470	100.0	55,748,940	100.0

[1] For practical purposes the entire output of noncommercial operations commonly is moved by truck. Including noncommercial production, crushed stone for concrete and road metal moved as follows: 1939: Truck 80 percent, rail 12 percent, waterway 5 percent, and unspecified 3 percent; 1940: Truck 79 percent, rail 12 percent, waterway 6 percent, and unspecified 3 percent.

GRANITE

Sales of crushed and broken granite declined 10 percent in quantity and 9 percent in value in 1940 compared with 1939. Riprap declined to about one-half the tonnage sold in 1939, but sales of stone for miscellaneous uses were about 2½ times as great as in 1939.

Noncommercial production, which is a substantial part of the total, is reported by city, county, and State governments, highway commissions, or other Government agencies. From the reports submitted it is impossible to determine the number of plants that supply materials. Because the number of individual operations supplying noncommercial crushed stone cannot be determined with any degree of accuracy, the columns indicating the number of active plants (which have appeared in the granite and other tables covering the crushed-stone industry for many years prior to 1939) have been omitted in this report.

Granite (crushed and broken stone) sold or used by producers in the United States in 1940, by States and uses

[1] Includes stone used for artificial stone, asphalt filler, chips, fill material, poultry grit, spalls, stone sand, and terrazzo.
[2] Included under "Undistributed."

BASALT AND RELATED ROCKS (TRAP ROCK)

Basalt, gabbro, diorite, and other dark igneous rocks (known commercially as trap rock), are used widely for highway construction and concrete aggregate. Sales of crushed and broken trap rock declined 2 percent in quantity but gained 7 percent in value in 1940 compared with 1939. Sales of riprap declined greatly and railroad ballast moderately. Stone used as concrete aggregate and for road construction made modest gains, and that sold for miscellaneous uses increased nearly elevenfold. Sales of riprap in the major producing States fluctuate greatly, as they depend chiefly on special reclamation and other projects. Prices per ton of trap rock at the quarry for all forms of trap rock increased from an average of 88 cents in 1939 to an average of 97 cents in 1940.

Basalt and related rocks (trap rock) (crushed and broken stone) sold or used by producers in the United States, 1940, by States and uses

[1] Includes stone sold for concrete blocks, fill material, roofing granules, stone sand, and tennis courts.
[2] Included under "Undistributed."

MARBLE

Marble producers accumulate large quantities of waste material, consisting either of defective blocks or of cuttings and spalls that result from marble dressing, and they are constantly seeking profitable outlets for this waste. As the following table indicates, the price per ton realized varies greatly, because some States produce relatively high priced products, such as terrazzo, stucco, and marble flour, that may be worth several dollars a ton, whereas other States find outlets only in the form of riprap, road stone, and concrete aggregate that may command prices of only $1 or less a ton.

Marble (crushed and broken stone) sold by producers in the United States in 1940, by States [1]

State	Active plants	Short tons	Value	State	Active plants	Short tons	Value
Georgia	1	17,000	$17,829	Texas	2	9,690	$63,875
Massachusetts	1	3,510	4,256	Utah	1	4,400	21,727
Missouri	2	12,860	17,553	Other States [2]	10	30,620	135,814
New York	3	16,520	74,265				
Tennessee	5	56,090	65,702		25	150,690	401,021

[1] Includes stone used for agriculture, artificial stone, crushed stone, flux, magnesite floors, mineral food, poultry grit, riprap, spalls, stucco, terrazzo, tile, and whiting (excluding marble whiting made by companies that purchase their marble).
[2] Alabama, Arkansas, California, Maryland, New Jersey, Virginia, and Washington

LIMESTONE

Limestone is the most widely used type of rock employed in crushed and broken form. It is used more extensively than other rocks because it can be quarried and crushed at moderate cost, is available to a multitude of markets, and is essential to many chemical and manufacturing industries. In 1940 limestone comprised 74 percent of all crushed and broken stone sold (excluding that used for making cement and lime). Sales in 1940 were 12 percent higher in both quantity and value than in 1939. Sales of riprap increased 45 percent in quantity and 73 percent in value. The high level of iron and steel production in 1940 was reflected in a 32-percent increase in sales of fluxing stone. Sales of stone for concrete aggregate and road building declined slightly, but average prices were higher than in 1939. Railroad ballast gained 16 percent, and stone for agriculture made a remarkable 60-percent advance over 1939. An 18-percent advance in sales of stone for miscellaneous uses (chiefly in the chemical and processing industries) reflects the increased tempo of industrial activity. The following tables show production by States and uses in 1940 and sales for miscellaneous industrial uses in 1939 and 1940.

Limestone (crushed and broken stone) sold or used by producers in the United States in 1940, by States and uses

	9,122,820	8,997,793	10,731,990	10,629,560

[1] Includes stone for filler for artificial leather, asbestos cement, calcimine, explosives, linoleum, paint, parting compounds, pottery, putty, regrinding, rubber, sealing wax, tanning, and toothpaste.
[2] Includes stone for asphaltic concrete, acid neutralization, chemicals (unspecified), chips, concrete blocks and pipes, foundry facings, fill, motion-picture snow, oil wells, rayon, rice milling, spalls, and waste rock.

Sales of dolomite (calcium-magnesium carbonate) and its primary product of calcination—dolomitic lime—for certain special uses are covered in the following table:

Dolomite and dolomitic lime sold or used by producers in the United States for specified purposes, 1939–40

	1939	1940
Dolomite for—		
Basic magnesium carbonate:		
Short tons	89,390	80,210
Value	$147,129	$105,028
Dead-burned dolomite or refractory stone:		
Short tons	824,930	857,950
Value	$713,991	$632,582
Dolomitic lime for—		
Refractory (dead-burned dolomite):		
Short tons	671,561	867,909
Value	$5,447,554	$6,925,328
Paper mills:		
Short tons	41,000	59,000
Value	$267,000	$390,000
Total (calculated as raw stone) short tons	2,339,000	2,792,000

Limestone is quarried not only for use raw but also for manufacture into cement and lime. The large and important industries manufacturing these products are covered in separate chapters. It is of interest, however, to show in one table the total tonnage of limestone consumed for all purposes.

Limestone sold or used for all purposes in the United States, 1938–40, in short tons

Use	1938	1939	1940
Limestone (as given in this report) (approximate)	81,680,000	100,846,000	112,658,000
Portland cement (including "cement rock") [1]; Natural cement ("cement rock") [1]	26,193,000	30,463,000	33,986,000
Lime [2]	6,694,000	8,509,000	9,774,000
	114,567,000	139,818,000	156,418,000

[1] Value reported as cement in chapter on Cement.
[2] Value reported as lime in chapter on Lime.

SANDSTONE

The crushed-sandstone industry, which made substantial gains in 1938 and 1939, receded in 1940. In that year sales were 27 percent lower in quantity and 28 percent lower in value than in 1939. Refractory stone, however, continued the marked upward trend of 1939, because steel plants experienced unusual activity. Sales of refractory stone were 32 percent higher in quantity and 29 percent higher in value than in 1939. Sales of riprap made small gains, but the output of concrete aggregate and stone for road construction declined 41 percent in quantity and 45 in value. Railroad ballast declined 16 percent in tonnage and 19 in value. Stone applied to various miscellaneous uses dropped 12 percent in quantity and 8 in value. The average sales value at the mill or quarry for all crushed sandstone was $1.12 a ton in 1940, whereas it was $1.13 in 1939.

Sandstone (crushed and broken stone) sold or used by producers in the United States in 1940, by States and uses

State	Refractory stone (ganister)		Riprap		Crushed stone				Other uses [1]		Total	
					Concrete and road metal		Railroad ballast

[1] Includes sandstone used for fill material, manufacture of spun glass, poultry grit, rock dust, rock wool, roofing granules, spalls, stone sand, and terrazzo.
[2] Included under "Undistributed."

MISCELLANEOUS STONE

Stone other than the five principal varieties already discussed includes light-color volcanic rocks, schists, boulders from river beds, serpentine, and flint. The following table shows sales of stone of these types by uses in 1940. Total sales declined 18 percent in quantity and 27 percent in value compared with 1939.

Miscellaneous varieties of stone (crushed and broken stone) sold or used by producers in the United States in 1940, by States and uses

[1] Includes stone used for linoleum filler, filler (unspecified), poultry grit, refractory, road base, roofing granules, spalls, and terrazzo.
[2] Included under "Undistributed."

MARKETS

As indicated in figure 3, sales of crushed stone have since 1936 followed closely the trend of highway construction and maintenance. Sales of aggregates, however, failed in 1940 to pace the physical volume of total construction activity or the shipments of portland cement. Commercial operations fared better than the chart would indicate because they gained 6 percent in 1940 over 1939, whereas the noncommercial output dropped 17 percent. The trend toward an increase in the proportion of total aggregates produced by commercial operators will be welcomed by the industry.

Sales of limestone for use as a flux in blast furnaces producing pig iron, which rose phenomenally in 1939, continued their upward trend in 1940 in consonance with increasing activity at furnaces. As indicated in figure 4, sales of fluxing stone follow closely the output of pig iron.

Sales of dolomite and ganister for use as refractories in steel furnaces, which made a much greater proportional gain than the output of steel ingots in 1939, continued upward in 1940. With steel mills running at virtually 100 percent of capacity, sales of refractories apparently have nearly reached their peak. Figure 4 shows that the abnormal upward trend of refractories was checked to some extent in 1940.

NEW DEVELOPMENTS

The deepest limestone mine in the United States is that now being developed by the Columbia Chemical Division of the Pittsburgh Plate Glass Co. at Barberton, Ohio, where a 40- to 50-foot bed of high-grade limestone will be tapped by a shaft 2,250 feet deep. The new mine will have two shafts—one for service and one for production. The room-and-pillar mining method will be used; and the crusher, which will be situated below the haulage level, will discharge to a skip-loading compartment at a still lower level on the production shaft. The mine will attain full operation in about 2 years and will be capable of furnishing 300 tons of high-grade chemical limestone an hour.

As limestone is extremely important to many industrial processes connected directly or indirectly with the national defense program, the Bureau of Mines has prepared a report [3] covering the numerous applications of limestone in industry.

FOREIGN TRADE [4]

Exports.—The export trade in stone is relatively small, but it increased somewhat in 1940 compared with 1939, probably on account of the fact that stone from most European sources was not available.

Venezuela			14,490
Other countries	571	2,613	20,491
	77,896	158,008	264,949

Imports.—As might be expected from the disturbed conditions throughout the world, imports of stone declined greatly in 1940. The value of marble imports was about two-thirds as great as in 1939. Imports of granite, of which a large part normally originates in the Scandinavian countries, decreased to less than one-fourth of the 1939 figure, in quantity and even more in value. Imports of the other categories were maintained at a higher rate.

Stone [1] imported for consumption in the United States in 1940, by classes

Class	Quantity	Value
Marble, breccia, and onyx:

SLATE

By Oliver Bowles and M. S. Jensen

SUMMARY OUTLINE

Sales of slate as dimension stone decreased 14 percent in quantity and 16 percent in value in 1940 compared with 1939, but the totals are still substantially higher than in 1938. In general, unit prices were lower than in 1939.

Roofing-slate sales were considerably lower, both in quantity and value, than in 1939; they were, in fact, very little higher than the 1935–39 average. The average value a square in 1940 was $7.02, whereas in 1939 it was $7.18. Sales in the Pennsylvania slate area were 9 percent lower in quantity and 10 percent lower in value than in 1939. In the New York-Vermont area sales dropped 18 percent in quantity and value. Although Virginia sales, in 1940, dropped 22 percent in quantity and 26 percent in value compared with the preceding year, they were the highest of any year in the history of the Virginia industry except 1939.

Mill-stock sales declined 23 percent in quantity and 20 percent in value. The total physical volume of building construction advanced from 80 percent of the 1923–25 average in 1939 to 85 percent in 1940, yet sales of structural and sanitary slate dropped 27 percent in both quantity and value, indicating that other products are displacing slate in the construction field. Electrical slate, which enjoyed a decided recovery in 1939, continued its gains in 1940; the quantity sold advanced 36 percent and the value 35 percent compared with 1939. Sales of blackboards and bulletin boards, which made large gains in 1939, declined 51 percent in quantity and 54 percent in value in 1940. This drastic reduction in sales is not, however, inconsistent with expected demands because the erection of new school buildings also declined more than 50 percent. The output of vaults and covers declined slightly, but sales of billiard table tops—a relatively small item—were nearly two and one-half times as great in 1940 as in 1939. Sales of school slates, which were very low in 1939, increased 50 percent in both quantity and value in 1940. Sales of slate for flagging, cross walks, and stepping stones increased moderately, but average unit prices declined for the third consecutive year.

Statistics on slate granules and flour are included in this chapter, although these products have little connection with the dimension-slate industry except that granules compete in the roofing-slate market. For the most part, slate used for the manufacture of granules is unsuited for other slate products. In 1940 sales of granules declined whereas sales of flour increased, a condition just the reverse of that in 1939. The average sales value of granules f. o. b. mill was $8.72 and flour $3.31 per short ton in 1940 compared with $8.70 and $3.13, respectively, in 1939. Figures for sales of granules made of rock other than slate are given in the Stone chapter of this volume.

The following table, giving the principal statistical data for the slate industry during 1939 and 1940, is arranged to permit ready comparison for the 2 years.

Salient statistics of the slate industry in the United States, 1939–40

[4] Exclusive of structural slate; Bureau of Mines not at liberty to publish figures.
[5] Bureau of Mines not at liberty to publish figures.

SALES

Dimension slate.—All slate products except granules and flour are classed as dimension slate because they consist of blocks or slabs cut to specified sizes and shapes. The following table shows sales of these products for a 5-year period.

Slate (other than granules and flour) sold by producers in the United States, 1936–40

Year	Roofing			Mill stock		Other [1]		Total	
	Squares	Approximate equivalent short tons	Value	Approximate short tons	Value	Approximate short tons	Value	Approximate short tons	Value
1936	336,130	138,190	$2,607,402	20,100	$1,175,668	6,820	$55,358	165,110	$3,838,428
1937	365,800	137,400	2,728,109	21,480	1,225,645	8,670	73,554	167,550	4,027,308
1938	322,040	119,590	2,247,910	16,310	853,602	7,790	63,839	143,690	3,165,351
1939	399,320	149,410	2,868,961	21,710	1,168,671	8,480	63,493	179,600	4,101,125
1940	347,130	127,600	2,436,123	17,070	935,810	9,780	64,435	154,450	3,436,368

[1] Includes flagstones, walkways, stepping stones, and miscellaneous slate.

Figure 1 compares sales of roofing slate, as well as all slate except granules and flour, with the physical volume of construction activity and the number of new residential dwelling units from 1915 to 1940. Sales of slate products experienced a drastic decline from 1915 to 1918, from which they have never recovered. Since 1929 slate has followed closely the trend of total building construction.

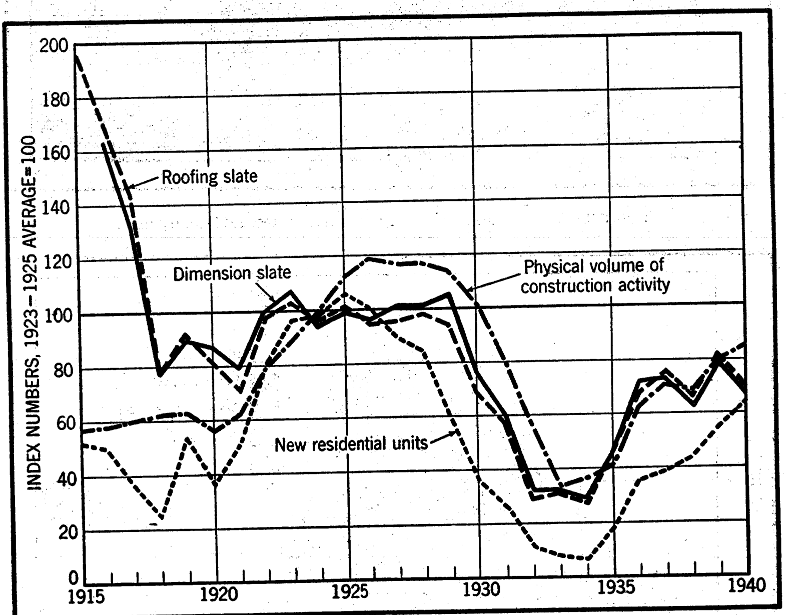

FIGURE 1.—Sales of dimension slate and roofing slate compared with total building and residential building, 1915–40. Data on construction activity from the Bureau of Foreign and Domestic Commerce and on residential building from the Bureau of Foreign and Domestic Commerce and the Bureau of Labor Statistics.

Figure 2 presents graphically a statistical history of all slate products except school slates over a 26-year period. The industry reached its peak of productive activity in 1925 and had already experienced a moderate decline at the beginning of the depression that culminated in 1933 in the smallest sales of any year since the period when slate production was an infant industry. Subsequent recovery was strong at first but has not been sustained.

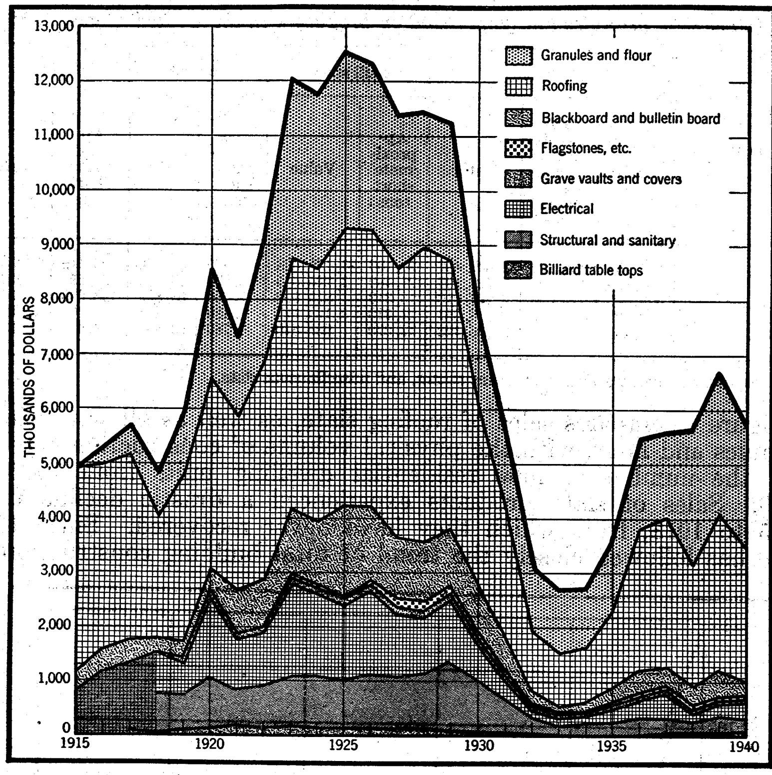

FIGURE 2.—Value of slate sold in the United States, 1915–40, by uses.

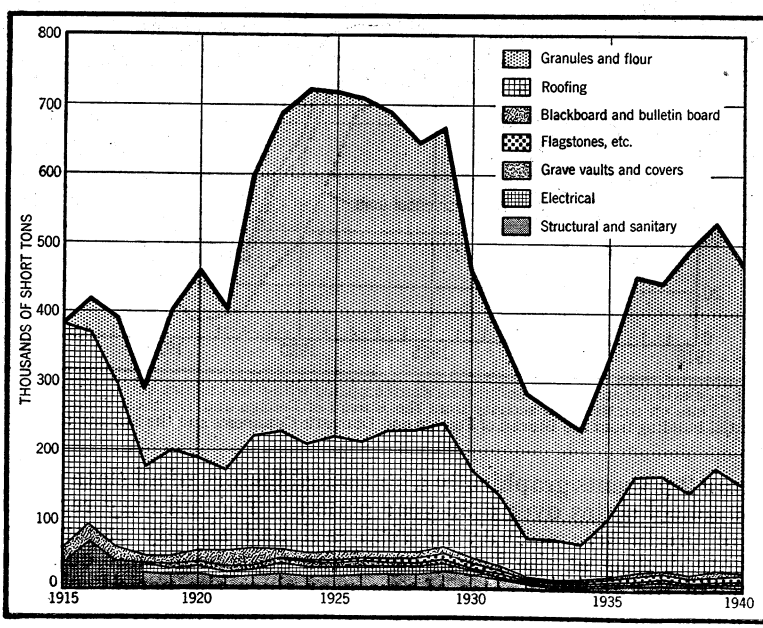

FIGURE 3.—Quantity of slate sold in the United States, 1915–40, by uses.

Figure 3 presents the same data as figure 2, except that quantities rather than values are used. Roofing granules and flour are most important on a tonnage basis. Mill stock has a relatively high unit value, and the quantities involved are not great. It is noteworthy that for the year of peak production the value of mill stock was considerably greater than that of granules and flour, but on a quantity basis mill-stock sales amounted to scarcely one-tenth of the tonnage of granules and flour.

Granules and flour.—Slate granules are used extensively in surfacing prepared roofing, and slate flour is employed as a filler in paints, road asphalt-surface mixtures, roofing mastic, oilcloth, linoleum, and various other products. The following table shows sales of granules and flour by producers from 1936 to 1940.

Crushed slate (granules and flour) sold by producers in the United States, 1936–40

Year	Granules		Flour		Total	
	Short tons	Value	Short tons	Value	Short tons	Value

PRICES

The average price of roofing slate f. o. b. quarry or mill, as reported to the Bureau of Mines, declined 16 cents a square in 1940 compared with 1939. In Pennsylvania it declined 10 cents, in the Vermont-New York area 5 cents, and in Virginia 47 cents a square.

The price of mill stock increased from 29 cents in 1939 to an average of 30 cents a square foot in 1940. Average values of electrical, structural and sanitary, and school slates remained virtually unchanged; those for vaults and covers declined 1 cent; and those for blackboards and bulletin boards dropped 2 cents.

Price history.—Figure 4 shows the trend of slate prices over a 26-year

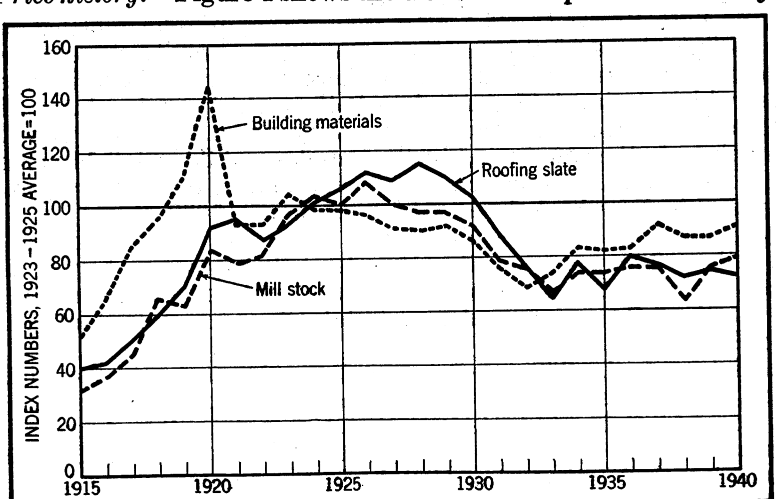

FIGURE 4.—Prices of slate compared with wholesale prices of building materials in general, 1915–40. Wholesale prices are from the Bureau of Labor Statistics.

period compared with prices of building materials in general. Slate responded only moderately to the skyrocket prices of other building materials that culminated in an unprecedented peak in 1920, but from 1924 to 1932 prices of both roofing and mill stock were well above the average of all building materials. Since 1932, however, slate prices have remained considerably below that average.

REVIEW BY STATES AND DISTRICTS

The following table gives sales of slate in 1940 by States and uses.

Slate sold by producers in the United States in 1940, by States and uses

State	Operators	Roofing		Mill stock		Other uses [1] (value)	Total value
		Squares (100 square feet)	Value	Square feet	Value		
Arkansas	1					(2)	(2)
California	2					(2)	(2)
Georgia	1					(2)	(2)
Maine	3	2,950	$25,877	305,140	$253,836	$6,947	$286,660
Maryland	1					(2)	(2)
New York	13	2,900	24,972			454,081	479,053
Pennsylvania [3]	27	216,020	1,444,696	2,658,260	603,118	561,987	2,609,801
Vermont	44	86,270	610,691	[4] 156,720	[4] 78,856	[4] 865,683	1,555,230
Virginia	6	38,990	329,887			(2)	(2)
Undistributed [5]						477,638	807,525
	98	347,130	2,436,123	[4] 3,120,120	[4] 935,810	2,366,336	5,738,269

[1] Flagging and similar products, granules, and flour.
[2] Included under "Undistributed."
[3] For details of production in Pennsylvania, see following table.
[4] A small amount of mill stock in Vermont included under "Other uses."
[5] Includes output of States entered as "(2)" above.

Maine.—Electrical slate, the principal product of the Maine quarries, made substantial gains in 1940, as shown in a 33-percent increase in the value of slate products sold in the State during 1940 compared with 1939. Sales of roofing slate, which is of minor importance in Maine, declined 23 percent.

New York-Vermont.—The attractive green, purple, mottled, and red roofing slates of this northern area are generally popular with architects and builders, but in 1940 there was a decided shrinkage in sales, which declined 18 percent in both quantity and value. Mill-stock sales receded 4 percent in quantity and 18 percent in value. The value of other products, chiefly granules and flour, fell 14 percent. The value of all slate products sold in Vermont in 1940 was 20 percent lower and in New York 3 percent higher than in 1939.

Peach Bottom district.—Blue-black slate has been quarried for more than 200 years on the Maryland-Pennsylvania border near Delta, Pa. Roofing slate is now produced only on the Pennsylvania side of the line, but granules and slate flour are manufactured in both States.

Lehigh district.—The most productive slate area in the United States is comprised within Lehigh and Northampton Counties, Pa. All kinds of slate products are manufactured in this district. As separate figures cannot be shown for York County, Pa., it is included with Northampton County in the accompanying table for Pennsylvania.

Slate sold by producers in Pennsylvania in 1940, by counties and uses

County	Operators	Roofing slate		Mill stock					
				Electrical		Structural and sanitary		Vaults and covers	
		Squares (100 square feet)	Value	Square feet	Value	Square feet	Value	Square feet	Value
Lehigh	9	12,280	$79,256	29,600	$15,117	7,140	$2,542	(1)	(1)
Northampton and York [2]	18	203,740	1,365,440	18,840	6,993	670,800	202,174	[1] 251,070	[1] $57,604
	27	216,020	1,444,696	48,440	22,110	677,940	204,716	251,070	57,604

County	Mill stock—Continued						Other uses (value)	Total value
	Blackboards and bulletin boards		Billiard-table tops		School slates			
	Square feet	Value	Square feet	Value	Square feet	Value		
Lehigh	316,480	$72,055			413,860	$8,637	(3)	[1 3] $177,607
Northampton and York [2]	706,770	157,632	243,700	$80,364			[3] $561,987	[1 3] 2,432,194
	1,023,250	229,687	243,700	80,364	413,860	8,637	561,987	2,609,801

[1] Small amount of slate for grave vaults and covers produced in Lehigh County included under Northampton and York Counties.
[2] York County produced roofing slate, granules, and flour only.
[3] Small amount of flagging produced in Lehigh County included under Northampton and York Counties.

The value of total sales of slate products in the district was 15 percent lower in 1940 than in 1939. Sales of roofing slate declined 9 percent in quantity and 10 percent in value. Items that show increases in 1940 are electrical slate (10 percent in both quantity and value), school slates (50 percent in quantity and value), billiard-table tops (143 percent in quantity and 121 percent in value), and vaults and covers (4 percent in quantity and 6 percent in value). Mill-stock items that show recession in sales in 1940 are blackboards and bulletin boards, with a loss of 50 percent in quantity and 54 percent in value, and structural and sanitary slate products, which declined 26 percent in quantity and 25 percent in value. Other products, chiefly granules and flour, show a slight increase in value in 1940.

Virginia.—Sales of blue-black roofing slate, which constitute the principal product of the Buckingham County area, suffered a sharp decline in 1940. Small quantities of flagging are produced, but no mill-stock products are made. Granules are manufactured at Esmont, Albemarle County, and New Canton, Buckingham County.

Other districts.—Small quantities of granules alone, or granules and flour, were produced near Mena, Polk County, Ark.; at Placerville, Eldorado County, and near Jamestown, Tuolumne County, Calif.; and near Fair Mount, Bartow County, Ga.

NEW DEVELOPMENTS

The possibility of using waste slate for making lightweight aggregate has been demonstrated at the Eastern Experiment Station of the Bureau of Mines. One company that manufactures roofing slate

311436—41——75

is now investigating the feasibility of making such products from its mill waste.

Slate producers in Pennsylvania, who operate wire saws to great advantage in their quarries, may be interested in a new type consisting of a single ribbon-shaped steel strand twisted in the form of a wire. It has not yet been used in quarries, but when employed in slabbing marble blocks its rate of cutting was twice as great as that obtained with the ordinary three-strand wire. The accomplishments of this new type of equipment are described in a forthcoming paper entitled "The Single-strand Wire Saw," by Oliver Bowles and P. de Vitry, to be published by the American Institute of Mining and Metallurgical Engineers, 29 West 39th Street, New York, N. Y.

FOREIGN TRADE [1]

Imports.—Imports of slate for consumption in the United States are unimportant in normal times, and in 1940 they were insignificant. No roofing slate was imported in that year. The value of slate imports by country of origin, 1936–40, appears in the following table.

Slate imported for consumption in the United States, 1936–40, by countries

Country	1936	1937	1938	1939	40
Canada	$1,074	$826	$543	$570	
China			3	26	$21
Czechoslovakia	1,904	990	1,037		
France			895		
Germany		17			
Hong Kong	21	20	59	4	
Italy	1,386	349	994	356	324
Japan	195	222	68	61	175
Norway		381			
United Kingdom	271	2,019	3,089		
	4,851	4,824	6,688	1,017	520

Exports.—The following table lists exports of slate products from 1938 to 1940, as reported to the Bureau of Mines by shippers. School slates, electrical slate, and billiard-table tops made substantial gains, while roofing and blackboard exports declined. The value of slate exports was 11 percent higher than in 1939.

Slate exported from the United States, 1938–40, by uses [1]

Use	1938		1939		1940	
	Quantity	Value	Quantity	Value	Quantity	Value
Roofing squares	660	$5,070	569	$5,244	475	$5,547

SAND AND GRAVEL

By Duncan McConnell and G. E. Tucker

SUMMARY OUTLINE

Production of sand and gravel reached a new peak in 1940, surpassing the output for 1939 as well as that for 1929. Commercial operations accounted for the entire increase, as there was a slight decrease in the tonnages from plants operated by or for States, counties, municipalities, and other Government agencies. The steady rise in quantity and value produced since 1933 was interrupted only in 1938 (see fig. 1).

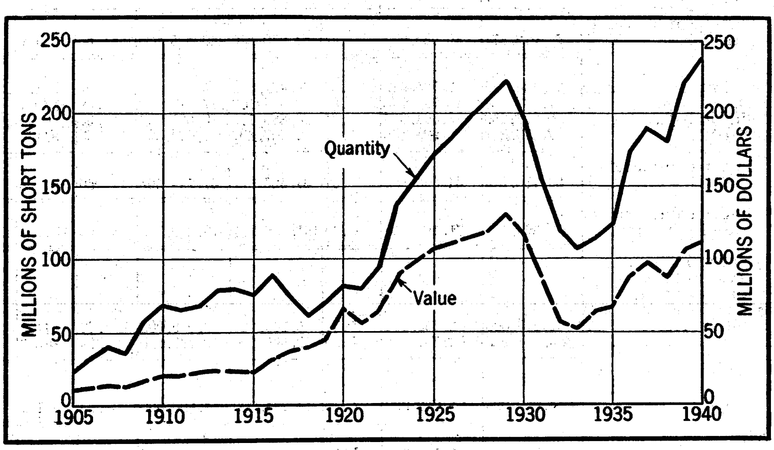

Figure 1.—Total production of sand and gravel in the United States, 1905-40. Data for 1939 revised.

According to the Bureau of Foreign and Domestic Commerce, the value of total construction during 1940 was moderately larger than in 1939. There was little change in public construction, as the increase in defense activities merely compensated the curtailment of work-relief construction; the net effect, according to preliminary figures, was a slight decline for 1940. New private construction gained 16 percent in value, with the percentage of increase in factory building much larger than that in residential building.

Total sand and gravel for building and paving increased in 1940, although Government-and-contractor[1] output declined slightly. All industrial uses of sand except sand for filtering gained in 1940. The change in volume was greatest in molding sand, as might be expected from the increase in defense activity.

Salient statistics on sand and gravel for 1939 and 1940 are summarized in the following table.

[1] Formerly classified as "noncommercial"; details of change in designation given in Minerals Yearbook, 1940, p. 1213.

Sand and gravel sold or used by producers in the United States, 1939–40, by commercial and Government-and-contractor operations and by uses

[1] Includes blast sand as follows: 1939, 220,240 short tons valued at $542,915; 1940, 256,104 tons, $597,198.
[2] Includes ballast sand produced by railroads for their own use as follows: 1939, 152,723 short tons valued at $21,998; 1940, 57,741 tons, $9,506.
[3] Includes some sand used by railroads for fills and similar purposes as follows: 1939, 137,158 short tons valued at $21,366; 1940, 207,941 tons, $44,064.
[4] Includes ballast gravel produced by railroads for their own use as follows: 1939, 4,617,468 short tons valued at $752,670; 1940, 4,913,809 tons, $914,990.
[5] Includes some gravel used by railroads for fills and similar purposes as follows: 1939, 824,959 short tons valued at $80,090; 1940, 793,709 tons, $133,405.
[6] Approximate figures for States, counties, municipalities, and other Government agencies directly or under lease.
[7] Revised figures.

PRODUCTION

In the sand and gravel industry stocks are inconsequential, therefore the quantities of materials sold or used are virtually equivalent to production. Throughout this report, sales and production are used interchangeably.

Incomplete coverage by the canvass for 1939 has necessitated significant upward revision of the Government-and-contractor output for that year. This production reached its peak in 1939 and declined slightly during 1940. In contrast with Government-and-contractor production, the output of commercial sand and gravel increased 10.9 percent from 1939 to 1940.

Sand and gravel sold or used by commercial and Government-and-contractor producers in the United States, 1936–40

Year	Sand		Gravel (including railroad ballast)		Total	
	Short tons	Value	Short tons	Value	Short tons	Value
1936	60,303,394	$35,926,994	118,026,420	$54,380,758	178,329,814	$90,307,752
1937	63,385,071	40,412,497	126,275,352	57,060,500	189,660,423	97,472,997

1939 [1]	72,542,000	41,608,000	153,466,000	64,458,000	226,008,000	106,066,000
1940	78,674,000	45,332,000	159,634,000	65,356,000	238,308,000	110,688,000

[1] Revised figures.

New York, California, Illinois, Ohio, Michigan, and Pennsylvania were the leading States in commercial output of sand and gravel in 1940—each produced over 8 million tons; Pennsylvania, however, ranked first according to value, followed by New York and Ohio.

Details for production in 1940, according to States and uses, are presented in the following tables.

Sand and gravel sold or used by commercial and Government-and-contractor producers in the United States in 1940, by States

State	Short tons	Value	State	Short tons	Value

[1] Included under "Undistributed."
[2] Includes in addition to items entered as "1," sand and gravel produced on W. P. A. projects.
[3] Includes 256,104 short tons of blast sand valued at $597,198.
[4] Includes 57,741 short tons of ballast sand valued at $9,506, produced by railroads for their own use.
[5] Includes 207,941 short tons of sand valued at $44,064, used by railroads for fills and similar purposes.
[6] Includes 4,913,809 short tons of ballast gravel valued at $914,990, produced by railroads for their own use.
[7] Includes 793,709 short tons of gravel valued at $133,405, used by railroads for fills and similar purposes.

Government-and-contractor production.—The quantity of sand and gravel reported by State governmental agencies for 1940 increased slightly over that reported for 1939 and represented 34 percent of the total Government-and-contractor output during 1940. Of this amount, 56 percent was produced by contractors; counties reported 20 percent and municipalities 2 percent of the total. The remaining 44 percent was produced largely by Federal agencies, including the Forest Service, National Park Service, Bureau of Public Roads, Bureau of Reclamation, Soil Conservation Service, and W. P. A.

In general, the average values of the materials declined slightly, except the production by or for municipalities. Other details are shown in the following tables.

Sand and gravel sold or used by Government-and-contractor producers in the United States, 1936–40, by uses

Year	Sand				Gravel				Total Government-and-contractor sand and gravel

[1] Revised figures.

Method of transportation.—Although the quantity of sand and gravel shipped by commercial producers by rail increased in 1940, the percentage of the total declined from 1939. This decline in percentage of sand and gravel movements by rail has been continuous since 1934, when rail shipments were 57.4 percent of the total.

Sand and gravel sold or used by commercial producers in the United States, 1939–40, by methods of transportation [1]

Method of transportation	1939		1940	
	Short tons	Percent of total reported	Short tons	Percent of total reported
Truck	48,040,422	45.2	54,063,146	45.8
Rail	42,118,042	39.6	45,254,984	38.4
Waterway	16,208,607	15.2	18,600,060	15.8
Total reported	106,367,071	100.0	117,918,190	100.0
Percent of total commercial production		89.8		89.8

[1] For practical purposes the entire output of Government-and-contractor operations commonly is moved by truck. Including Government-and-contractor production, sand and gravel moved as follows—1939: Truck 73 percent, rail 20 percent, and waterway 7 percent (revised); 1940: Truck 72 percent, rail 20 percent, and waterway 8 percent.

Preparation.—The average value per ton of sand and gravel reported by commercial producers is characteristically much higher than that of Government-and-contractor operations. The difference is explainable in terms of the cost of washing, screening, or other preparation, as 88 percent of the commercial material was prepared, compared with 33 percent of the Government-and-contractor production.

Sand and gravel (prepared or unprepared) sold or used by producers in the United States, 1939–40, by commercial and Government-and-contractor operations

	1939			1940		
	Quantity		Average value per ton	Quantity		Average value per ton
	Short tons	Percent		Short tons	Percent	
Commercial operations:						
Prepared	103,771,791	88	$0.64	115,425,213	88	$0.63
Unprepared	14,621,329	12	.31	15,831,054	12	.36

[1] Revised figures.

Size of plants.—More than half of the commercial sand and gravel plants are small—have annual tonnages of less than 25,000—and the percentage of total production contributed by these plants was only 8.3 percent in 1939. However, 61 percent of the total commercial output came from plants having an annual production of less than 200,000 tons. Details of production, by size groups, for 1938 and 1939, are given in the following table.

Comparison of number and output of commercial sand and gravel plants in the United States, 1938–39, by size groups [1]

Size groups in short tons	1938				1939			
	Plants [2]		Production		Plants [2]		Production	
	Number	Percent of total	Short tons	Percent of total	Number	Percent of total	Short tons	Percent of total
Less than 25,000	1,195	56.6	10,300,000	10.2	1,133	54.5	9,398,000	8.4

[1] Plants operated by or for States, counties, and municipalities are not included; also not included are approximately 186 railroad plants with an output of 4,941,000 short tons of sand and gravel in 1938 and 194 plants with an output of 5,840,000 tons in 1939.
[2] May include a few companies operating more than 1 plant but not submitting separate returns for individual plants.
[3] Less than 0.1 percent.

PRINCIPAL TRENDS

The steady improvement in sales of sand and gravel that has prevailed since 1932—with the exception of the regression in 1938—is expected to continue as the demand becomes adjusted to the expanding construction program. The acceleration of the national defense program, which has lately given added impetus to production of aggregates, probably will stimulate the preparation of certain industrial sands to an even greater degree.

Sand and gravel for construction.—Before 1926 the quantities of sand and gravel used were approximately equal, but during recent years the proportion of gravel to sand has increased greatly. The marked increase in the use of gravel is to be attributed primarily to the growing demand for aggregates to satisfy the expanded program of highway construction that was begun in 1924. Figure 2 shows the correlation between highway construction and sales of gravel, as well as the relation of sand output to construction activity in general.

A more complete study of the trends of various building materials, including sand and gravel, has recently been presented in a report by Colby.[2]

Industrial sands.—Figure 3 shows graphically the history of production of industrial sands since 1916. Molding sand is the most important upon a quantity basis, and is subject to greater fluctuations than the other types. The 7 years 1923–29 marked a period of major productivity, the peak of production occurring in 1929. In 1940 production reached 81 percent of that for 1929.

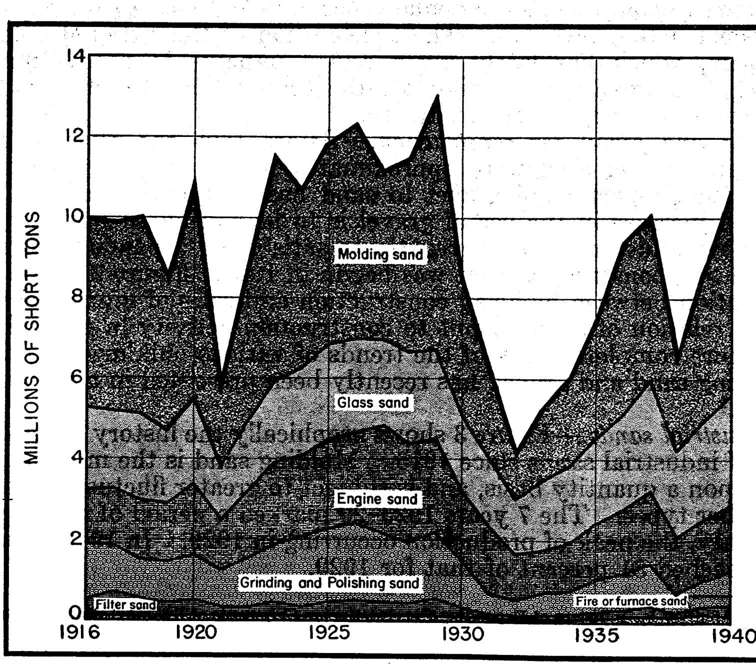

Figure 3.—Production of industrial sands in the United States, 1916–40.

With the advent of mass production of automobiles, sales of molding sand show marked correlation with the number of automobiles manufactured. These relations, with a comparison of industrial production, are shown in figure 4.

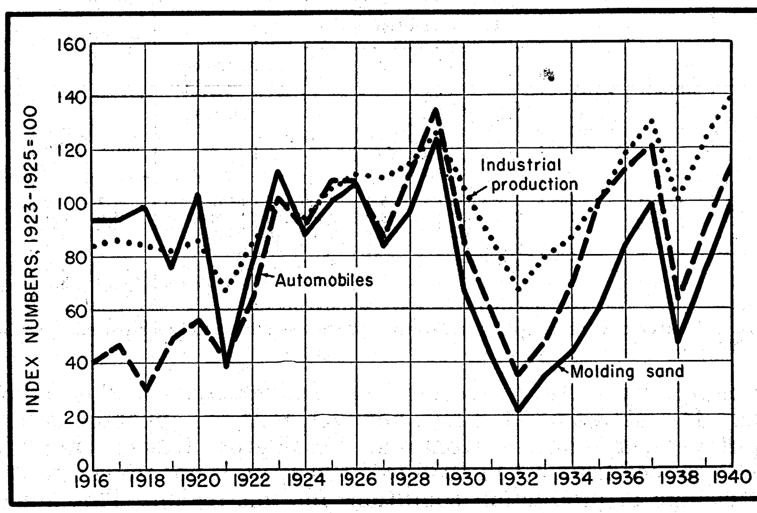

FIGURE 4.—Trends in sales of molding sand compared with automobiles manufactured and industrial production, 1916–40. Statistics on automobiles from Bureau of the Census. Index of industrial production from Federal Reserve Board.

EMPLOYMENT AND PRODUCTIVITY [3]

Data for 1939 are based upon operations reporting about four-fifths of the total production of commercial sand and gravel. The number of men employed increased about 4 percent, and the average number of days employed increased 6 percent, accompanied by a small decrease in the average time for each shift.

The average productivity increased from 3.2 to 3.5 short tons per man per hour—a new high since 1933, when employment data were first recorded by the Bureau of Mines. The increase probably is due to numerous improvements in plants and equipment, as expenditures for improvements during 1939 were higher than at any time during the previous decade.[4]

[1] Does not include plants operated by or directly for States, counties, municipalities, and other Government agencies.

Productivity data by regions are summarized in the following table. It must be pointed out, however, that the apparent decline in output per man-hour in Montana, Washington, Oregon, and Idaho, which dropped from 6.1 in 1938 to 4.1 in 1939, is not to be interpreted as a change in production conditions for this region. This apparent decline arises through the calculation of an average figure for operations that differ widely in their output per man-hour, combined with reclassification of one major producer as noncommercial. In other words, the change is due to differences in coverage of the industry during the two periods.

Comparable data, by regions, for 1935 to 1938 were published in Minerals Yearbook, 1940 (pp. 1219–1221), for 1934 in Minerals Yearbook, 1936 (p. 844), and for 1933 in Minerals Yearbook, 1935 (p. 942).

PRICES

In general, there was little change in the prices of commercial sand and gravel from 1939 to 1940. Higher values were reported for engine sand and filter sand—gains from 58 to 65 cents and from $1.13 to $1.38, respectively. Grinding and polishing sand dropped 27 cents from $1.34 a ton. Other changes were less than 5 percent of the 1939 figures; glass sand, fire or furnace sand, and paving sand advanced, whereas building sand declined from 54 to 52 cents and molding sand from $1.08 to $1.05.

Average values reported for commercial gravel did not change more than 2 cents a ton. Paving gravel declined to 59 cents, and railroad ballast advanced to 33 cents; both of these were changes of 2 cents from values reported in 1939. Building gravel showed no change from 65 cents.

The average values for Government-and-contractor materials likewise remained nearly stationary and were much lower than those for commercial sand and gravel because large tonnages of unprepared material are included. Sand for building advanced to 40 cents, but paving sand declined to 29 cents, both changes being 1 cent a ton. Gravel for building declined 1 cent and paving gravel 2 cents—to 50 and 28 cents, respectively.

NEW DEVELOPMENTS

Although many medium and small plants were built during 1940, expenditures by producers were made chiefly for improving or enlarging existing plants.[5] A large-capacity portable plant was put into operation near Burnett, Minn.[6] Nearly 3 miles of conveyor belting are used in the plant that is supplying aggregate for the Friant dam near Fresno, Calif.[7]

The installation of crushing equipment continues to expand,[8] and one plant in California has adopted the unique arrangement of mounting its crusher on rails.[9]

The series of articles on washing and classification by Shaw [10] have continued to appear. In October the Georgia Department of Natural Resources issued Information Circular 11, Glass Sands and Glass Making Materials in Georgia. Parker [11] contributed a rather comprehensive article on slag aggregates, dealing particularly with the industry in England.

Seasonal exemption from the hours provision of the Fair Labor Standards Act for the northern branch of the industry was made final and extended to certain additional plants as applicable.

The graduate research fellow of the National Sand and Gravel Association at the University of Maryland is investigating the effect of characteristics of aggregates on the durability of concrete.

FOREIGN TRADE[12]

Imports of sand and gravel in 1940 were 63 percent higher than in 1939; however, they were considerably below those of 1938 (700,976 short tons).

Approximately 94 percent of all sand and gravel imports during 1940 represented movements of construction materials from Canada. Imports of glass sand from Belgium dropped to less than one-fifth of the quantity obtained from that source in 1939.

Exports of sand and gravel were not recorded separately during 1940; they were included in a classification with various other nonmetallic mineral substances.

2 Not separately classified.

BLAST-FURNACE SLAG

It is appropriate to include all available statistics on production of blast-furnace slag because this material is used for purposes similar to those of sand and gravel and crushed stone.

Continuing the policy inaugurated in 1938, the National Slag Association conducted a canvass of 34 companies (70 plants) that prepare blast-furnace slag. The total output for 1940 was 10,353,042 short tons valued at $7,780,641, which represents an increase in tonnage of 14 percent over 1939. Of the total, 78.6 percent (8,132,396 short tons) was screened air-cooled slag valued at $7,015,616 or an average of 86 cents a ton. Air-cooled slag increased 18 percent in tonnage compared with 1939.

About 75 percent of all slag is processed in Ohio, Alabama, and Pennsylvania; however, it is marketed in all States east of the Mississippi River except several New England States too far removed from sources of supply to permit economic utilization.

As in previous years, blast-furnace slag is used chiefly for highway and building construction and for railroad ballast. These uses consumed 89 percent of the total air-cooled output in 1940. Other uses and the quantities involved are shown in the accompanying table.

Shipments of slag, by methods of transportation, were as follows: Railroad, 53.9 percent; truck, 44.7 percent; and waterway, 1.4 percent.

Air-cooled blast-furnace slag sold or used by producers in the United States, 1939–40, by States [1]

State	1939			1940		
	Quantity		Value	Quantity		Value

GYPSUM

By Forrest T. Moyer

SUMMARY OUTLINE

Stimulated by the advanced rates of building activity and industrial production, sales of gypsum products in 1940 reached an aggregate value of nearly 53½ million dollars—an annual volume of business 16 percent higher than in 1939 and comparing favorably with that of the peak year of the industry in 1925. The total supply of crude was 13 percent greater than the 1939 tonnage, mainly because of the sharply increased domestic production, and for the first time since 1929 exceeded 5 million tons. The improvement in the calcining division of the industry is indicated by the 15-percent gain in production of calcined gypsum (kettle and kiln output). Contrary to the general uptrend of commodity prices, those of most calcined products for building uses declined slightly from 1939 levels; however, prices of uncalcined products and those calcined for industrial uses were higher in 1940 than in 1939.

According to sales volumes listed in the Bureau of Mines Quarterly Gypsum Reports, most gypsum building products showed an increasing rate of consumption through the first three quarters of the year and, after allowing for seasonal variations, were in greater demand during the October-December quarter than in any other quarter. This strong year-end position resulted principally from the sustained demand of a persistently high level of private residential construction to which, in the last 4 to 6 months of the year, were added the requirements of the emergency housing necessitated by the defense program for industrial workers and conscriptees into the Army. Continuation of this high rate of consumption into 1941 was indicated by F. W. Dodge Corporation data on dollar volumes of residential contracts awarded, which were higher for December and the last quarter of 1940 than for any other similar periods of the year. Letting of contracts usually precedes actual purchase of gypsum products by 2 to 4 months.

Although strikingly increased sales over 1939 were recorded for agricultural gypsum, lath, and wallboard, the outstanding product in 1940 was gypsum sheathing board, which heretofore had been a backward product with only a limited market. Sales jumped from 5¼ million square feet in 1939 to more than 89½ million square feet in 1940. The new demand for this product was created by the rapid construction of cantonments to house the selective service draftees—a totally unexpected and sizable market that caused a temporary shortage of and a rise in the price of the common sheathing material, wood. These combined factors gave gypsum sheathing a decided price advantage over wood and other competitive materials, both in original cost and in cost of the finished wall, so that producers were able to secure a considerable portion of the market. This demonstration of its availability and adaptability plus the continued high price of lumber reportedly induced more widespread use of gypsum sheathing in private residential construction—a market that annually consumes many millions of square feet of sheathing material.

Consumption of lath continued to grow throughout 1940 as it has in every year since 1933 and advanced to a record annual total of nearly 1½ billion square feet. Indicative of the strong market for lath, the net gain over 1939 of 313 million square feet was one of the largest annual increments in the history of the product.

The record volume of crude imports in 1940—7 percent greater than the previous high in 1939—apparently represented the efforts of operators to increase and maintain large stocks at tidewater calcining plants, which depend on deposits outside the country for supplies of crude. This precautionary measure against possible interruption of shipments is predicated by experience in 1918 during the World War, when no ships were available to transport gypsum from Canada and imports of crude fell to 50,653 short tons. In the present war shipping facilities for gypsum were greatly reduced at the close of 1940, and history may repeat itself.

Salient statistics of the gypsum industry in the United States, 1937–40

	1937	1938	1939	1940
Active establishments [1]	92	90	92	91
Crude gypsum: [2]				
Mined short tons	3,058,166	2,684,205	3,226,737	3,699,015
Imported do	897,484	789,429	1,308,078	1,405,210
Apparent supply do	3,955,650	3,473,634	4,534,815	5,104,225
Calcined gypsum produced: [3]				
Short tons	2,411,362	2,252,878	2,881,269	3,307,709
Value	$11,076,205	$10,989,626	$14,620,597	$17,254,667
Gypsum products sold: [3]				
Uncalcined:				
Short tons	860,825	756,565	867,782	929,119
Value	$1,920,706	$1,681,371	$1,927,415	$2,250,857
Calcined:				
Short tons	2,643,075	2,556,296	3,224,216	3,704,110
Value	$36,879,814	$34,574,937	$44,000,824	$51,241,787
Total value	$38,800,520	$36,256,308	$45,928,239	$53,492,644
Gypsum and gypsum products:				
Imported for consumption	$1,167,872	$1,002,001	$1,363,967	$1,427,966
Exported	$271,142	$282,782	$309,453	$264,128

[1] Each mine, plant, or combination mine and plant is counted as 1 establishment.
[2] Excludes byproduct gypsum.
[3] Made from domestic, imported, and byproduct crude gypsum.

The Federal grand jury investigation of the gypsum industry, instigated in 1940 by the Antitrust Division of the Department of Justice, resulted in indictments [1] involving five corporations and nine individuals on charges of illegal control of resale prices of gypsum board and use of an allegedly invalid patent to fix prices on perforated lath. The Department of Justice also filed a civil action [2] against

[1] United States of America v. Certain-teed Products Corporation et al., No. 66007, in the District Court of the United States for the District of Columbia, April term 1940, 54 pp.
United States of America v. United States Gypsum Company et al., No. 66008, in the District Court of the United States for the District of Columbia, April term 1940, 22 pp.
[2] United States of America, Plaintiff, v. United States Gypsum Co., et al., Defendants, Civil Action No. 8017, in the District Court of the United States for the District of Columbia, Filed August 15, 1940, 127 pp.

six companies and eight officers of these companies, charging the use of allegedly improper methods to establish a monopoly and to control prices of gypsum products in violation of sections 1, 2, and 3 of the Sherman Antitrust Act.

[1] Includes portland-cement retarder, agricultural gypsum, fillers, and miscellaneous uncalcined products.
[2] Includes plasters sold to plate-glass, terra-cotta, and pottery works and orthopedic, dental, and all other plasters sold or used for industrial or manufacturing uses.
[3] Includes calcined gypsum sold to mixing plants and sanded, gaging, molding, prepared finishing, insulating, roof-deck, and all other plasters sold or used for building.
[4] Revised figures, partly estimated.
[5] Data not available.
[6] Includes data on all plasters, except Keene's cement, used for building.
[7] Revised figures.
[8] Includes all types of gypsum wallboard and sheathing board.
[9] Includes partition, roof, floor, soffit, shoe, and all other gypsum tiles and gypsum plank.

Bureau of Mines canvasses of the gypsum industry since 1927 have undergone several changes in classification of products and one change in coverage, so that comparable data on sales are available only for the relatively short periods between changes in the canvass. In 1928 a new classification separated the industrial or manufacturing plasters from building plasters and also requested data on square footages of lath and wallboard for the first time. This was changed somewhat for the 1931 canvass, in which square footages of gypsum tile and block were obtained for the first time. In 1937 a new classification that differed but slightly from the preceding one was used; however, the scope of this and subsequent canvasses was enlarged to include sales of products made from byproduct crude and also those made by companies that neither mined nor calcined gypsum but only processed the calcined material into finished products. This expanded survey represents complete coverage of the domestic market for gypsum products, regardless of the source of raw material. In the accompanying table annual sales of gypsum products from 1928 through 1936 are made comparable with those of 1937 and later years, partly by reports from producers not included in the canvasses before 1937 and partly by estimations from the data on hand. The new classification that became effective for the first time in 1928 precludes any extension of the series to preceding years—an unfortunate situation with regard to prices or average unit values, which were forced considerably below normal by the vicious price war in 1928 and 1929.

Noteworthy features of the series are the precipitous declines in sales volumes of all products from 1929 through 1932 and 1933 and the slow, steady recovery (interrupted only in 1938) from the depression years to the present. Lath is the only product for which sales in 1940 were greater (3½ times in square footage) than in 1928; annual sales of all other products were well below those of the late 1920's.

DOMESTIC PRODUCTION

The increased output of domestic mines—15 percent greater than in 1939—was obtained in 15 States from 59 active operations, which comprised 28 underground mines, 26 open quarries, and 5 combinations of mine and quarry. Production increased in 1940 in all States except Utah and Wyoming. New York continued to be the leading producing State, followed in order of tonnage by Michigan, Iowa, and Texas. The largest proportional gain—38 percent over 1939—was recorded for California, which ranked fifth.

The average value of run-of-mine gypsum (not an open-market value) in 1940 was $1.41 a ton, 4 cents higher than in 1939. Data in the accompanying table apply only to natural crude and do not include byproduct gypsum.

Crude gypsum mined in the United States, 1938–40, by States

State	1938			1939			1940

[1] 1938: 1 active mine each in Idaho, South Dakota, and Wyoming; 2 each in Kansas, Montana, Ohio, and Virginia. 1939: 1 active mine each in Arizona and South Dakota; 2 each in Kansas, Montana, Ohio, Virginia, and Wyoming. 1940: 1 active mine each in South Dakota and Wyoming; 2 each in Kansas, Montana, Ohio, and Virginia.

PROCESSING PLANTS AND EQUIPMENT

Calcined gypsum was produced in 25 States by 55 plants; 42 processed domestic crude, 12 imported crude, and 1 byproduct crude gypsum. The total output was 3,307,709 short tons—a net gain of 426,440 tons over 1939. Reflecting rising fuel and other costs, the average unit value of this intermediate material in 1940, as estimated by the producers, increased slightly to $5.22 a ton.

Active calcining plants and equipment in the United States, 1938–40, by States

[1] Includes 2 grinding-calcining units.
[2] Includes 3 grinding-calcining units.
[3] 1938: 1 calcining plant each in Arizona, Connecticut, Florida, Illinois, Indiana, Massachusetts, Nevada, New Hampshire, Oklahoma, Pennsylvania, South Dakota, Vermont, and Wyoming; 2 each in Colorado, Kansas, Montana, New Jersey, Ohio, and Virginia. 1939–40: 1 calcining plant each in Arizona, Connecticut, Georgia, Indiana, Massachusetts, Nevada, New Hampshire, Oklahoma, Pennsylvania, South Dakota, Vermont, and Wyoming; 2 each in Colorado, Florida, Kansas, Montana, New Jersey, Ohio, and Virginia.

Although record sales of lath and sheathing, plus sharply increased sales of wallboard, taxed the capacity of the manufacturing machines it is reported that producers could meet commitments for all standard types and in only a few instances were shipments delayed. According to Minerals Yearbook 1940 (p. 1230) the average capacity of the active board machines is estimated to be 87,500 square feet in 8 hours or 78,750,000 square feet of ⅜-inch lath per 300-day operating year. Applying this figure to the 34 active board machines the producing capacity of the industry at the end of 1940 would be about 2,700 million square feet of ⅜-inch lath. The total surface area of all gypsum board sold in 1940 was just over 2,000 million square feet, which is estimated—by allowing for different thicknesses and types (thicker boards and certain types slow the process)—to be equivalent to roughly 2,333 million square feet of ⅜-inch lath. These figures indicate that the board machines operated at approximately 85 percent of capacity during 1940.

DISTRIBUTION OF SALES

Sales of agricultural gypsum in 1940 were 23 percent above 1939, principally because of sharply increased consumption in the peanut-growing regions of the Southeastern States—an area that consumed roughly 60,000 short tons of this fertilizer and soil conditioner. Although most of the tonnage was used in the Jumbo peanut region of southern Virginia the consumption of gypsum in the Spanish peanut region of South Carolina and Georgia is said to be expanding. Sales of the other major uncalcined product—portland-cement retarder—increased 6 percent over 1939—a gain in close agreement with the 7-percent rise in production of cement.

The indicated consumption of the major classes of building plasters—"base-coat" and "gaging and molding"—were 4 and 9 percent, respectively, above 1939 data. The 14-percent increase in sales of ready-sanded plasters by the primary producers more than compensated for the recession in tonnage of calcined gypsum sold to mixing plants and indicated a further withdrawal of the independent mixing plants from the ready-sanded plaster market.

Gypsum products (made from domestic, imported, and byproduct crude gypsum) sold or used in the United States, 1939–40, by uses

Grand total value		45,928,239		53,492,644

[1] Includes uncalcined gypsum sold for use as filler and rock dust, in paint manufacturing, and for minor purposes.
[2] Includes joint filler, patching and painter's plaster, and unclassified building plasters.
[3] 1939: 1,137,415 M square feet. 1940: 1,450,069 M square feet.
[4] 1939: 405,655 M square feet. 1940: 491,291 M square feet.
[5] 1939: 5,221 M square feet. 1940: 89,631 M square feet.
[6] 1939: 30,191 M square feet. 1940: 30,026 M square feet.
[7] Includes statuary, industrial casting and molding plasters, dead-burned filler, and miscellaneous sales.

Sales of all types of gypsum board were exceptionally good in 1940—those of lath climbing 27 percent to a new high annual total and those of wallboard advancing 21 percent over the square footages of 1939. Data on sheathing board, listed separately for the first time in this chapter, had been included in prior years in the "wallboard" classification because only small quantities were sold annually. To provide a measure of the new demand for gypsum sheathing created by the construction of Army and Navy barracks in the latter part of 1940 the producing companies supplied sales data for both 1939 and 1940. The exceptional 16-fold increase to 89½ million square feet occurred almost entirely in the last half of 1940 and indicates ready acceptance of this board as a common building material. The extensive construction of barracks in the latter part of 1940 also is responsible for most of the large gain in sales of wallboard over the 1939 volume.

The square footage of gypsum tile sold in 1940 was virtually unchanged from that in 1939, a year in which consumption had advanced markedly to the highest rate since 1930. Sales of partition tile, which comprise the major part of the classification, were nearly 10 percent higher in 1940, but sales of all other tile (roof, floor, etc.) declined approximately one-fourth from 1939.

Sales of all groups of industrial plasters were greater than in 1939; plate-glass and terra-cotta plaster made the largest gain—14 percent. Total shipments of industrial plasters were 12 percent above 1939.

PRICES

As indicated by the average unit values, f. o. b. plant, prices of most calcined gypsum products in 1940 were slightly lower than in 1939. Base-coat plasters declined 21 cents to $8.82 per ton, and lath was off 30 cents to $12.54 per M square feet, but the prices of wallboard and Keene's cement differed only slightly from 1939. This weak but comparatively stable condition of prices of gypsum building products has proved advantageous in securing markets from competitive materials that have been advanced in price, as has been pointed out for gypsum sheathing and wallboard. The 59-cent increase to $5.45 a ton for agricultural gypsum in 1940 was caused by the growing difficulty of obtaining supplies from Canada for the market in the Southeastern States. The price of portland-cement retarder rose slightly to $1.95 a ton—a figure 27 percent lower than in 1925.

RECENT DEVELOPMENTS

Results released by the Bureau of Mines of a comprehensive study [3] of the thermodynamic properties of materials in the $CaSO_4$-H_2O system show the existence of six substances with individual properties—one double hydrate, two hemihydrates (alpha and beta), two soluble anhydrites (alpha and beta), and one insoluble anhydrite. Application of the data listed in this important publication may help to explain some of the perplexing properties exhibited by commercial calcined gypsum. A so-called "elementary application" analyzing the heat utilization of the kettle-calcining process shows that only 10 percent of the total heat supplied to the kettle may be considered usefully consumed. Stability diagrams are included in the report.

Research [4] on flotation of impurities from gypsum indicates that certain cationic reagents have merit for removing silica from crude gypsum.

[3] Kelley, K. K., Southard, J. C., and Anderson, C. T., Thermodynamic Properties of Gypsum and Its Dehydration Products: Bureau of Mines Tech. Paper 625, 1941, 73 pp.
[4] Clemmer, J. Bruce, and DeVaney, F. D., Cationic Reagents in the Flotation of Silica from Gypsum Ores: Bureau of Mines Rept. of Investigations 3553, 1941, 12 pp.

A statistical study [5] of production and employment in operations on crude gypsum reveals a rise in productivity per man-hour in underground mines from 0.30 short ton in 1900 to 1.06 tons in 1938 and for open-pit mines from 0.40 ton to 2.59 tons for the same years.

Descriptions [6] of the properties of pottery plasters that indicate good serviceability for jigger or casting services were published recently. Other papers [7] discussed some factors that cause early failure of plaster molds used to form ceramic ware and point out that the pottery plaster seldom is at fault.

In Europe experimental work [8] on the new sursulfate (or supersulfate) cements indicates that one of the best mixtures is 81 percent slag, 4 percent portland cement, and 15 percent anhydrite. The most suitable slags are free of manganese and high in alumina. These slag cements are claimed to have normal hardening action, low heat of set, and high resistance to salt and sulfate waters.

A process [9] of producing a high-strength hemihydrate by heating gypsum in a magnesium sulfate solution was claimed to be feasible upon a commercial basis after being tested by pilot-plant operation. The process consists of four steps: (1) Cooking in an agitated, jacketed kettle, (2) filtering in a centrifugal or Vallez filter, (3) drying in a steam-jacketed rotary drier, and (4) evaporating in a forced-circulation, vertical-tube evaporator.

A new use for gypsum was developed by the kraft-paper industry by utilizing a mixture of gypsum and salt in the manufacturing process as a substitute for salt cake, which formerly had been supplied from continental Europe.

In 1940 two new gypsum-board plants began operations; one in New Jersey replaced an old plant destroyed by fire early in the year, and the other was in New York. Both use calcined gypsum made from imported crude. A new operation producing crude gypsum for use as portland-cement retarder was begun in Kern County, Calif., during the year.

Committee C-11 on Gypsum of the American Society for Testing Materials made further progress on specifications. Definitions of gypsum lath, gypsum sheathing board, gypsum wallboard, and perforated gypsum lath were revised and advanced to standard. The tentative revision of the Standard Specification for Gypsum (C22-25), raising the $CaSO_4.2H_2O$ content from 64.5 to 75 percent, met some objection and was continued as tentative. Progress was made in developing the ammonium acetate method for determining the purity of calcined gypsum.

FOREIGN TRADE [10]

Imports.—Imports of crude gypsum for processing at tidewater calcining plants constitute the bulk of foreign trade in gypsum. Although a record annual tonnage was brought into the country in 1940 some importers were reported to have had difficulty in obtaining shipping facilities during the latter part of the year. As usual, more than 90 percent of the crude imports came from tidewater quarries in Nova Scotia and New Brunswick, Canada. The small tonnage of alabaster nodules imported from Italy each year since 1935 ceased in the middle of 1940, when the consuming firm stopped making lamp bases.

Gypsum and gypsum products imported for consumption in the United States, 1936–40

Year	Crude (including anhydrite)		Ground		Calcined		Keene's cement		Alabaster manufactures [1]	Other manufactures n. e. s.	Total value

[1] Data not available; value reported as follows: "Crude, crushed, calcined, or ground," $107,732; "Plasterboard, wallboard, plaster, and manufactures, n. e. s.," $148,171.

WORLD PRODUCTION

Although few figures are available regarding the production of gypsum in the various countries the United States doubtless has continued to be the principal producer. The European War probably has curtailed the output of all other countries that formerly produced large quantities, except Canada, where mining activity is determined largely by the condition of the gypsum market in the United States.

World production of gypsum, 1936–40, by countries, in metric tons [1]

LIME

By Duncan McConnell and A. T. Coons

SUMMARY OUTLINE

Production of lime attained a new peak in 1940—an output of 4,886,929 short tons. The previous record—4,580,823 short tons—was established in 1925. The total quantity in 1940 exceeded that in 1939 by 14.9 percent; this marked increase in output was accompanied by a decrease of 11 cents a ton in average value for all lime at producing plants.

Agricultural lime declined most sharply in value, although sales in 1940 increased slightly from 1939 and were about the same as for 1938. The quantity of lime used for application to the soil fluctuates, but it does not undergo pronounced changes, such as those experienced by the building, chemical, and industrial outlets.

Sales of building lime in 1939 made substantial gains over 1938 both in quantity and unit value; in 1940 there was a further 1-percent advance in volume of sales compared with 1939, but the value declined 1.3 percent.

Sales of lime for chemical and industrial purposes increased for all of the major categories. The total advance from 1939 was 19.1 percent. Sales of refractory lime gained 29.2 percent from 1939 to 1940, but imports from Canada ceased.

Among chemical and industrial uses the most noteworthy gains were that of metallurgical lime, which advanced 33 percent, and that of lime for paper manufacture, which increased 22 percent compared with 1939. The quantity of metallurgical lime consumed reached a new record during 1940, surpassing the previous one established in 1939. Of special interest is the fact that, although production of steel ingots was unusually high in 1940, sales of metallurgical lime were proportionately much higher and far outstripped normal requirements. As indicated in the chapter on Stone, the same condition prevailed with respect to metallurgical limestone.

Data on prices indicate a gradual, steady decline in averages since 1937, interrupted by a rise in the value of building lime during 1939 and of chemical and industrial lime during 1938.

Exports of lime—31,912 short tons—established a new peak in 1940. The previous record (29,475 short tons) was in 1913. Exports to

Latin American countries increased considerably; and imports of lime, which are always rather insignificant and come chiefly from Canada, increased slightly during 1940.

Salient statistics of the lime industry in the United States, 1939–40

	1939			1940				
	Short tons	Value		Short tons	Value		Percent of change in—	
		Total	Average		Total	Average	Tonnage	Average value
Lime sold or used by producers:								
By classes:								
Quicklime	2,936,295	$19,925,153	$6.79	3,501,104	$23,433,807	$6.69	+19.2	−1.5

Chemical and industrial	2,219,954	13,823,289	6.23	2,643,762	16,404,388	6.20	+19.1	−.5
Refractory (dead-burned dolomite)	671,561	5,447,554	8.11	867,909	6,925,328	7.98	+29.2	−1.6
Imports for consumption:								
Quicklime and hydrated lime	7,694	71,902	9.35	9,205	81,888	8.90	+19.6	−4.8
Dead-burned dolomite [1]	186	4,260	22.90					
Exports	21,477	236,497	11.01	31,912	311,619	9.76	+48.6	−11.4

[1] Dead-burned basic refractory material containing 6 percent or more lime and consisting chiefly of magnesia and lime.

PRODUCTION

Quicklime is a semiperishable commodity; and for this reason, stocks are inconsequential. Quantities sold or used may be considered equivalent to production, and these terms are employed interchangeably in this chapter.

In 1940 the production of quicklime gained about 19 percent compared with 1939, and hydrated lime increased about 5 percent.

Average values declined slightly, except for agricultural lime, which decreased appreciably. Other data on values appear in a later part of the chapter. Data for recent years are presented in the following table.

Lime sold or used by producers in the United States, 1936–40

Year	Plants in operation	Short tons [1]	Value [2]	
			Total [1]	Average
1936	301	3,749,383	$26,933,719	$7.18
1937	314	4,124,165	30,091,168	7.30
1938	321	3,346,954	24,137,638	7.21
1939	311	4,254,348	30,049,394	7.06
1940	314	4,886,929	33,956,385	6.95

[1] Includes lime used by producers (captive tonnage) as follows—1936, 224,693 short tons valued at $1,179,820; 1937: 270,192 tons, $1,388,052; 1938: 168,245 tons, $985,003; 1939: 270,087 tons, $1,454,285; 1940: 339,441 tons, $1,804,017.

[2] Value given represents value of bulk lime f. o. b. at point of shipment and does not include cost of barrel or package.

Production by States.—Lime was produced in 38 States and 2 Territories during 1940. This output came from 314 plants (3 more than in 1939) and gained during 1940 in most States. Ohio, Pennsylvania, Missouri, and West Virginia produced 61 percent of the total; Ohio alone contributed 26 percent.

Production by uses.—The average values of lime used for tanning, sugar refining, water purification, and metallurgical purposes were higher in 1940 than in 1939. The value of lime used by sugar refineries increased from $8.89 in 1939 to $10.33 in 1940. The unit value of lime for all other purposes decreased; the most pronounced drop was for agricultural lime, which decreased from $6.11 to $5.71.

Production of hydrated lime rose in tonnage but declined slightly in proportion of the total from 31 percent in 1939 to 28.4 in 1940. The increase in output was accompanied by a decrease of 9 cents a ton in average value.

Lime sold or used by producers in the United States in 1940, by States and uses

[2] Includes lime used by producers (captive tonnage) as follows—1939: 270,087 short tons valued at $1,454,285; 1940: 339,441 tons, $1,804,017.

Agricultural lime and other liming materials.—Although lime has certain advantages for application to soil, it is not used as extensively as pulverized limestone because of the low cost and availability of the latter. Data on the use of various liming materials are given in the following table.

Agricultural lime and other liming materials sold or used by producers in the United States, 1939–40, by kinds

[3] Data not yet available.

Building lime.—The quantities and average values per ton for lime sold or used in construction during 1940 were as follows: Finishing lime, 444,996 short tons, $8.97; mason's lime, 427,956 short tons, $8.18; for manufacture of prepared masonry mortars, 75,517 short tons, $6.49; and for unspecified purposes, 61,966 short tons, $9.03.

Chemical and industrial lime.—The quantities and average values a ton reported by producers of metallurgical lime during 1940 are as follows: Flux for open-hearth steel manufacture, 721,459 short tons, $5.64; flux for electric steel furnaces, 26,185 short tons, $6.73; flux for smelting nonferrous metals, 4,504 short tons, $7.57; ore concentration (including cyanidation), 196,053 short tons, $5.97; wire drawing, 11,973 short tons, $6.86; other uses (including unspecified), 39,041 short tons, $6.76.

The quantity and value of chemical and industrial lime, listed as "Other uses" in a previous table, were reported for 1940 as follows:

Chemical and industrial lime sold or used by producers in the United States for "Other uses" in 1940

Use	Short tons	Value	Use	Short tons	Value
Alcohol	2,530	$16,742	Insecticides, fungicides, and disinfectants	54,630	$376,437

Grease, lubricating	1,614	12,026		552,091	3,605,944

[1] Includes acid neutralization, calcium phosphate, cement, chemicals (unspecified), chromates and bichromates, citric acid, depilatories, explosives, ice, poultry food, retarder, rock wool, starfish control, and sulfur.

HYDRATED LIME

Production.—Hydrated lime was reported by 161 plants during 1940 (159 reported for 1939). The increase from 1,318,053 short tons in 1939 to 1,385,825 in 1940 was accompanied by a decrease of 9 cents a ton in average value. Three States—Ohio, Pennsylvania, and Missouri—produced 62 percent of the total. Other data on hydrated lime appear in the following tables.

Hydrated lime sold or used by producers in the United States, 1936–40

Year	Plants in operation	Short tons	Value	
			Total	Average
1936	168	1,225,829	$9,529,743	$7.77
1937	170	1,301,333	10,344,470	7.95
1938	165	1,169,804	9,111,575	7.79
1939	159	1,318,053	10,124,241	7.68
1940	161	1,385,825	10,522,578	7.59

Uses.—Sales of hydrated lime were higher than in 1939 for all major uses except agriculture and sugar refining; both of these declined in 1940 and had also declined from 1938 to 1939. Sales of hydrated lime for water purification and for metallurgy increased in 1940 by 17 and 10 percent, respectively.

Hydrated lime sold or used by producers in the United States, 1939–40, by uses

Use	1939		1940	
	Short tons	Value	Short tons	Value
Agricultural	212,432	$1,461,434	199,059	$1,281,785
Building	694,919	5,849,189	723,888	6,002,015
Chemical and industrial:

TRENDS IN PRINCIPAL USES

All major uses of lime increased during 1940. Chemical and industrial uses gained 19 percent from 1939, whereas agricultural and building uses gained only 0.7 and 1 percent, respectively.

The gains in metallurgical and refractory lime were disproportionate, however, being 33 and 29 percent, respectively. The increase

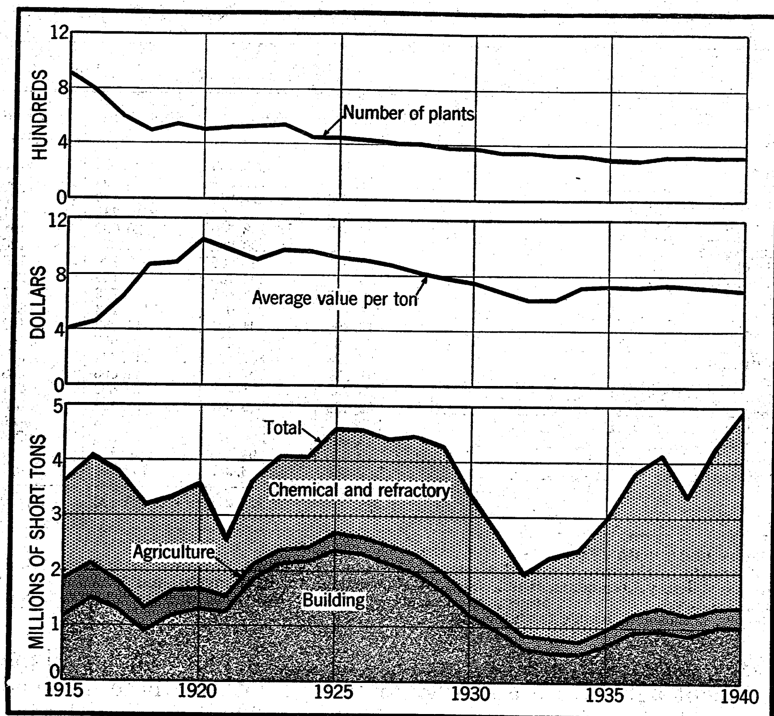

FIGURE 1.—Trends in number of active lime plants, average value per ton, and principal uses, 1915–40.

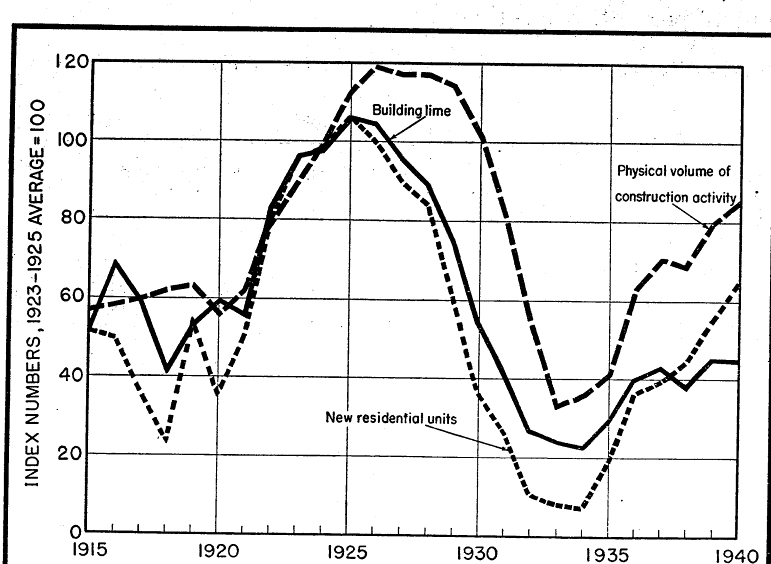

FIGURE 2.—Building-lime (quick and hydrated) sales compared with total construction and residential building, 1915–40. Data for physical volume of construction, 1915–39, from Bureau of Foreign and Domestic Commerce. Data for new residential dwelling units from Bureau of Foreign and Domestic Commerce and Bureau of Labor Statistics.

in chemical and industrial uses also was accentuated by a marked increase in the use of lime by paper mills (22-percent increase over 1939), part of which is attributed to use of lime in treating wastes. Trends in the principal uses over a 26-year period are indicated in figure 1.

A graphic comparison of the total quantity of lime consumed in building with construction activity for the past 26 years is shown in figure 2.

Successive increases in the consumption of metallurgical lime have taken place since 1932, except for the regression of 1938, but the rate of increase has never been as great as it was during the period 1939–40 (see fig. 3.) The gain in production of metallurgical lime has been accompanied by a similar increase (32 percent from 1939 to 1940) in limestone for flux. Inasmuch as the curve for metallurgical lime is rising more rapidly than that of steel-ingot production, a relative decrease in the amount of scrap iron and steel being employed is indicated.

Raw dolomite, as well as refractory lime, is used for lining furnaces. During 1940, 857,954 short tons of raw dolomite were sold, although part of this may have been calcined by the consumer before use. The data on dolomite are given in the chapter on Stone.

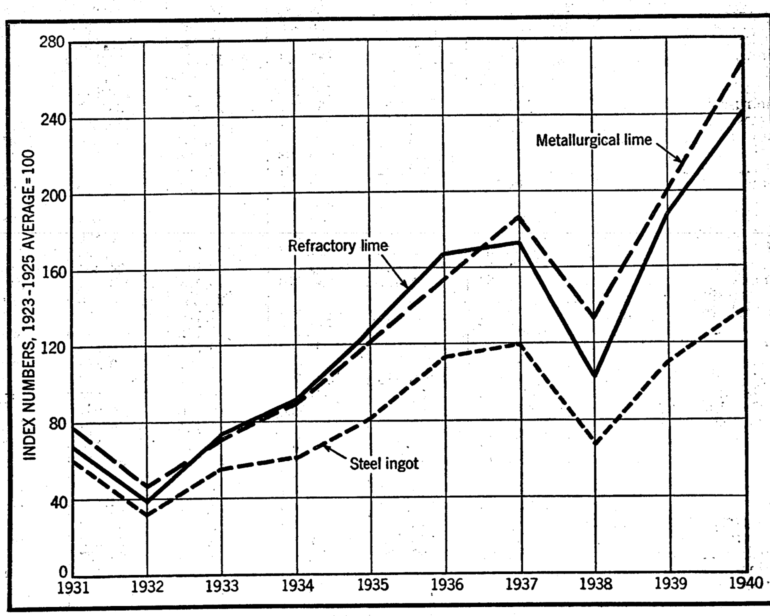

FIGURE 3.—Sales of metallurgical lime and refractory lime (dead-burned dolomite) compared with steel-ingot production, 1931–40. Index numbers for steel ingots computed by Federal Reserve Board from data of American Iron and Steel Institute.

SHIPMENTS

Total shipments.—Sales, shipments, and supplies of lime available for consumption in continental United States by States and groups of States that comprise approximate freight zones are listed in the two tables that follow. Reshipments beyond original destinations are not indicated, and foreign shipments and tonnages for which distribution is not recorded are omitted.

Production of lime exceeds apparent consumption in 12 States, but only Ohio, Missouri, and Tennessee show large tonnages moving out of the State in excess of inward-moving shipments. Four leading apparent consumers—Pennsylvania, New York, Illinois, and Michigan—consumed more than they produced.

Lime supplies available in continental United States in 1940, by States, in short tons

State	Sales by producers	Shipments from State [1]	Shipments into State	Supply

Hydrated lime.—Apparent consumption of hydrated lime in the Middle Atlantic States has been high during recent years. During 1940 it increased in all regions, but the percentage of increase from 1939 to 1940 was greatest in the Western States.

Lime shipped (supply) in continental United States in 1940, by origin and destination of shipments, in short tons

1 Less than 1 ton.

PRICES

During the past decade the highest average prices were those during 1937, except for building and chemical and industrial lime, which were slightly higher in 1935. Since 1937 the price of lime for all uses except building has declined steadily. The price of building lime, however, decreased from 1939 to 1940. Values for the past 10 years are compared in the following table.

Average values of lime according to uses, 1931–40 [1]

Use	1931	1932	1933	1934	1935	1936	1937	1938	1939	1940
Agricultural	$6.47	$5.59	$5.36	$6.66	$6.73	$6.26	$6.74	$6.52	$6.11	$5.71
Building	7.33	6.45	7.18	8.33	8.70	8.52	8.66	8.38	8.56	8.45
Chemical and industrial	6.51	6.13	5.73	6.52	6.50	6.42	6.47	6.53	6.23	6.20
Refractory	7.66	7.78	7.89	8.31	8.32	8.19	8.45	8.44	8.11	7.98
Total	6.90	6.28	6.28	7.16	7.28	7.18	7.30	7.21	7.06	6.95
Hydrated	6.91	6.30	6.69	7.63	7.90	7.77	7.95	7.79	7.68	7.59

1 Value at place of manufacture, exclusive of containers.

SIZE OF PLANTS

A study of active commercial companies, comparing volumes of sales for groups of companies of similar size, was made by Bowles and Coons in 1939.[1] This study indicated that companies producing 25,000 to 49,999 short tons were increasing in numbers and total output. The accompanying table indicates that such a trend was pronounced from 1935 to 1940. Thus it seems that smaller companies increase their production to fall within this range when operating near capacity and larger companies limit their output to fall within this range when conditions are less favorable, because this size range is generally the most economic in that it attains a favorable balance between efficiency of operation and cost of transportation to market.

Comparison of number of companies and sales of lime (including dead-burned dolomite) in the United States, 1930, 1935, and 1940, by size groups

Size groups in short tons	1930			1935			1940

NEW DEVELOPMENTS

Interest in the use of lime for stabilizing clay roadbeds has prompted the National Lime Association to publish a bulletin on this subject.[2] Lime is being employed for this purpose on highways in Texas, and a potential market involving large tonnages is anticipated.

During 1940 one new plant was under construction, and several existing plants were improved or enlarged.[3]

Lime-putty plants were erected at Richmond, Va., and Birmingham, Ala. Two Florida concerns are supplying plant-mixed colored plaster.[4]

A research development of note was the establishment of a project at Rutgers University for investigation of the uses of lime in treating sewage and industrial wastes. This project is sponsored by the National Lime Association.

The problem of obtaining virtually complete hydration of the magnesia in dolomitic limes is attracting widespread attention. When hydration is conducted in pressure hydrators the conversion of magnesium oxide to the hydrate is relatively rapid and complete. Several companies in Ohio are cooperating in research on hydration equipment and methods.

4 Candell, Newell, Colored Plaster Winning Favor; Rock Products, vol. 43, No. 10, October 1940, p. 55.

X-ray investigation [5] has permitted distinction between soft- and hard-burned high-calcium limes and points toward particle shape as a factor controlling the plasticity of lime hydrates. Clark, Bradley, and Azbe found that good plastic hydrates contained thin, flake-shaped crystals, which result from slow hydration with a minimum accumulation of heat. Calcination in the presence of an alkali chloride vapor is said to produce a more porous and more friable quicklime.[6]

Moyer [7] studied fuel efficiencies in the lime industry and found that the average efficiency for all types of fuel and for all operations was greatest for pot kilns, intermediate for shaft kilns, and least for rotary kilns. However, shaft kilns using coke or producer gas showed higher efficiencies than any of the pot kilns. Azbe's contributions to the technology of lime manufacture have continued as a portion of an extended series.[8]

In 1940, 43 plants participated in the National Lime Association Safety contest conducted by the Bureau of Mines in cooperation with the National Lime Association. Of these 43 plants, 11 had accident-free records for a period of time equal to 935,113 man-hours.[9]

FOREIGN TRADE [10]

Imports.—Production of magnesian refractories in the United States has increased, compensating to some extent a marked decline in the importation of dead-burned dolomite from Canada; none of this material was imported during 1940. The quantities, values, and sources of lime imports are given in the accompanying tables.

Figure 4 gives the data for exports and imports since 1915.

Lime imported for consumption in the United States, 1936–40

Year	Hydrated lime		Other lime		Dead-burned dolomite [1]		Total	
	Short tons [2]	Value	Short tons [2]	Value	Short tons	Value	Short tons	Value

[1] Exclusive of dead-burned basic refractory material.
[2] Includes weight of immediate container.
[3] Less than 1 ton.

Exports.—In 1940 exports of lime reached a new record of 31,912 short tons valued at $311,619, the previous record was established in 1913, when 29,475 short tons valued at $212,345 were exported. The marked decline in exports to Canada during 1940 was more than compensated by the increase in exports to Latin American countries.

Lime exported from the United States, 1936–40

CLAYS

By Paul M. Tyler and A. Linn [1]

SUMMARY OUTLINE

Extending previous trends and favored by the broad upturn in general industrial and building activity, the domestic clay-mining industry reached new high ground in 1940. Shipments of kaolin or china clay, ball clay, and bentonite increased notably above their previous high records established in 1939. Fire-clay shipments rose sharply above those in 1939 but fell a little short of the figures in 1937, which in turn were below those of the late 1920's, notwithstanding the greater activity in consuming industries. Consumption of natural bleaching clay or fuller's earth in recent years has failed to pace the steady expansion in oil-refining industries in which it is used, the increased output of artificially activated bleaching clays, made from bentonite, being only one of several retarding factors. The total production of all kinds of merchant clay in 1940 was 4,847,519 short tons valued at $19,633,568—an all-time record in both tonnage and value that compares with 3,927,764 tons valued at $17,046,773 produced and sold in 1939.

Increased use of American clays in ceramic whiteware, the last stronghold of imported clays, is reported. The European War eliminated further shipments of German and Czechoslovak clays but did not cut off deliveries of English clays. Even heavy bombing of the Channel ports failed to hinder seriously the shipping of clay from Devon and Cornwall. Ocean freight rates tended to be higher, although clay served as excellent ballast for some of the ships returning to the United States for more munitions. Notwithstanding increased consumption and some additions to already substantial stocks carried by American manufacturers of paper and sanitary ware, imports of china clay in 1940 were smaller than in 1939 and less than one-third the annual average for the 5-year period 1925–29. Sales of domestic kaolin in 1940 were nearly twice their 1925–29 average.

Total imports of clay of all kinds were 140,447 short tons valued at $1,159,790 compared with 151,957 tons having a foreign market value of $1,395,012 in 1939 and the 1925–29 annual average of 420,310 tons valued at $3,841,462. Notable is the increase in imports of "common blue and Gross Almerode" clays (chiefly English ball clay), which in 1940 were approximately three times the 1925–29 average,

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce. Domestic figures for fuller's earth compiled by R. W. Metcalf, of the Bureau of Mines.

reflecting the broad increase in demand for ball clays in the pottery and sanitary-ware industries.

Exports jumped to 184,168 tons valued at $2,071,336 in 1940 compared with 136,480 tons valued at $1,873,110 in 1939 and the 1925–29 annual average of 109,344 tons valued at $1,217,769.

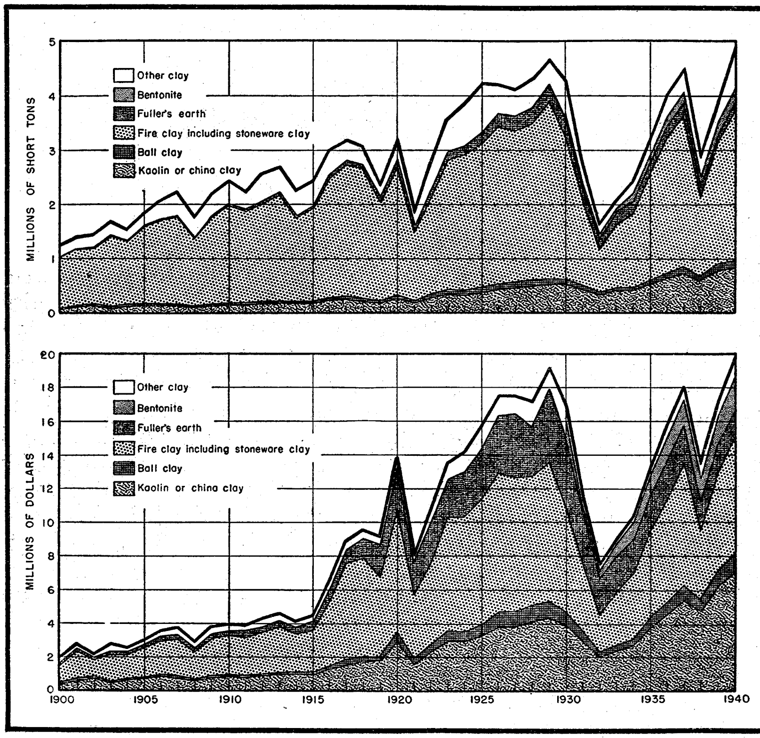

FIGURE 1.—Sales of domestic clay, by kinds, quantity and value, 1900–1940.

Bureau of Mines production figures as reported in this chapter refer only to clay sold or shipped raw. They do not include the many-times-greater quantities of clay mined by manufacturers of brick, tile, and other heavy-clay products for their own use in nearby plants.

Salient statistics of the clay industry in the United States, 1925–40

	1925–29 (average)	1930–34 (average)	1935–39 (average)	1939	1940
Domestic clay sold or used by producers:

Total exports:					
Quantity do	109,344	108,687	149,071	136,480	184,168
Value	$1,217,769	$1,323,744	$1,819,242	$1,873,110	$2,071,336

CONSUMPTION AND USES

The accompanying table, which gives sales of specified domestic clays by kinds and uses in 1940, continues a series begun in 1921. Data for total clay used in 1939 and earlier years by major uses (except refractories) were summarized in a bar chart in Minerals Yearbook 1940 (p. 1268). Reference should also be made to figure 2 of the present chapter showing changes in the distribution of sales of kaolin only.

Fuller's earth is not included in this table; in 1940, all but 8,237 short tons (valued at $53,699), or 6 percent of the output, was used in refining oils, chiefly mineral oils.

Clay (excluding fuller's earth) sold or used by producers in the United States in 1940, by kinds and uses, in short tons

Use	Kaolin	Ball clay	Fire clay and stoneware clay	Bentonite	Miscellaneous clay including slip clay	Total
Pottery and stoneware:						
Whiteware, etc	71,646	110,447	2,109			184,202

CHINA CLAY OR KAOLIN

Sales of kaolin or china clay by domestic miners continued their almost uninterrupted upswing since 1921 and rose in 1940 to another new record of 833,450 short tons valued at $6,994,106 compared with 780,804 tons worth $6,200,606 in 1939. Imports, virtually all from the heavily bombed Channel ports of southwest England, declined only moderately to 105,567 tons having a nominal value of $870,421 compared with 114,696 tons valued at $1,015,813 in 1939.

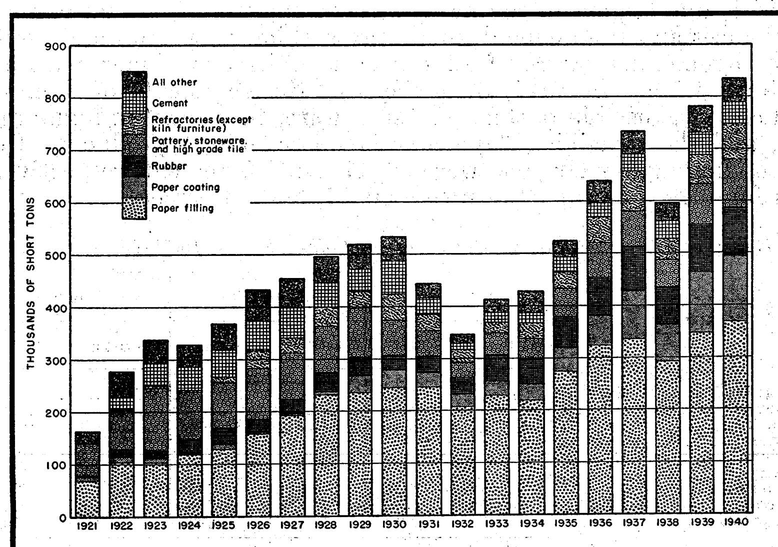

FIGURE 2.—Kaolin sold by domestic producers for specified uses, 1921–40.

Further expansion of the demand for American paper clays—both for coating and filling paper—explained most of the increased sales reported to the Bureau of Mines by the miners. There were substantial gains, however, in sales of high-grade clays to pottery manufacturers and of lower-price clays for refractory purposes. Of the total quantities sold or used the paper industry consumed 59 percent and the rubber industry 11 percent; another 11 percent went to pottery and tile manufacturers, 9 percent for refractories, and 5 percent for cement; the remaining 5 percent was used in the manufacture of a variety of commodities, of which paints, linoleum and oilcloth, chemicals, and miscellaneous fillers were of chief importance in the order named.

Price quotations for domestic clays have remained virtually unchanged for several years, and readjustments of English clay prices largely represent changes in ocean freight rates. The increase in the average value of domestic sales of kaolin from $7.94 a ton in 1939 to $8.39 in 1940 shows a larger proportion of the higher-grade clays rather than a general rise in prices.

BALL CLAY

Production of domestic ball clay advanced to 140,707 short tons valued at $1,065,432 in 1940 compared with 128,601 tons valued at $935,721 in 1939 and 121,470 tons valued at $890,705 in 1937, the previous record. Imports classified as "common blue and ball clay," all from the United Kingdom, also increased, amounting to 32,141 tons valued at $255,597 in 1940 compared with 28,540 tons valued at $233,094 (including 1,208 tons from Germany) in 1939. Consumption of ball clays, as calculated by adding domestic production and imports, has increased from an annual average of 128,257 tons in 1925–29 to 172,848 tons in 1940, exhibiting a growing tendency to use more ball clay in proportion to kaolin for various ceramic mixtures. This trend is due largely to mechanization or the use of new mechanical appliances and the demand for better working properties and denser body by manufacturers of American semivitreous dinner ware and sanitary ware. In 1940, 80 percent of the shipments of domestic ball clay was used in pottery and stoneware, 14 percent in high-grade tile, and the remaining 6 percent in miscellaneous products. Corresponding figures for 1935 were 70, 17, and 13 percent, respectively, and for 1929 the proportions were 60, 27, and 13 percent.

FIRE CLAY

Shipments of domestic fire clay were 2,765,247 short tons valued at $7,046,746 in 1940 compared with 2,222,295 tons valued at $5,801,993 in 1939. Although the 1940 figures represented a substantial gain over the preceding year, they did not quite reach the 1937 total of 2,785,344 tons valued at $7,180,938. Ordinarily, consumption of fire clay follows fairly closely the index of iron and steel production, which made a new record in 1940, topping the previous high in 1929 by a 6-percent margin. In 1937, as noted in Minerals Yearbook, 1940, the sales of fire clay and other domestic clays for refractories ran well ahead of its principal barometer, but in 1940 sales of clay as well as other raw materials for refractories did not begin to respond to the rising tempo of the metallurgical industries until late in the year. During periods of industrial recovery sales of refractories always tend to lag behind the increasing activity in consuming industries at first and then to pyramid later when the upturn in industrial demand is confirmed. Total sales of clay for refractories, as shown by Bureau of Mines consumption figures (which date back to 1921), were larger in 1940 than in any previous year except 1937, whereas sales of fire clay alone were substantially less in 1940 than in the late 1920's, a peak being reached in 1929 when the total sales of fire clay and so-called "Stoneware clay" were 3,266,261 tons. A partial explanation of this apparent failure of sales of fire clay to pace demand for clay in the manufacture of refractories more closely has been the increased consumption of refractory kaolins. The latter, which were scarcely used at all in 1921, reached a peak of 37,771 tons in 1928 and, after recovering from the general depression, rose to 77,170 tons in 1937 and 70,347 in 1940. Other variable factors are the better quality and longer life of modern clay refractories, larger and better-designed furnaces, substitution of nonclay refractories for high-duty service, and variations in the relative requirements of steel makers, nonferrous metal smelters, public utilities, cement plants, and other consumers.

BENTONITE

Topping by a wide margin their 1939 all-time record, sales of bentonite rose in 1940 to a new peak of 251,032 short tons valued at $1,919,461. The 1939 output was 219,720 tons valued at $1,702,393 and the previous record 194,768 tons valued at $1,500,758 in 1937. Although bentonite clay was used by pioneers in the Western country to grease the wheels of their covered wagons and instead of soap, this mineral is a relatively new commodity. As recently as 1925 the total output was less than 5,000 tons.

Bentonite is important to the defense effort principally because of its use in foundry molding and core sands. Although small admixtures of this remarkable clay have come to be employed extensively in sands for gray iron, malleable iron, and steel castings it is rarely used in casting aluminum and is not essential in making airplane motor blocks and certain other castings. In other words, foundry consumption of bentonite tends to increase when the output of castings, especially iron and steel castings, increases, but not necessarily in direct proportion. In 1939, 53,872 tons—25 percent of the total sales of domestic bentonite—were used in foundries and steel works, whereas in 1940 the quantity so used jumped to 74,135 tons comprising 30 percent of the total. By far the greater part of this bentonite is the swelling type produced in Wyoming and South Dakota. However, increasing quantities of southern bentonite are used for foundry work. This type, which exhibits no extraordinary swelling properties when moistened, is not a complete substitute but is even better than the Wyoming type for some kinds of castings.

As regards tonnage, oil refining is still the principal use of bentonite. Nonswelling clay, mostly Mississippi clay, is acid-treated or activated to convert it into an efficient bleaching agent, and a moderate quantity of raw bentonite is used as a filter aid and for other purposes in the oil-refining industry, which accounted for 95,300 tons or 38 percent of the 1940 sales compared with 95,247 tons or 43 percent of the total in 1939. The third largest use is in rotary well-drilling mud for the petroleum and natural-gas industries, which required 45,296 tons in 1940 as against 35,880 tons in the preceding year, the proportion of the total increasing slightly to 18 percent compared with 16 percent in 1939. Most of this was mined in South Dakota and Wyoming, although 5,000 tons, some of which may also have been swelling-type bentonite, were produced in California and another 5,000 tons in Texas and other States. Miscellaneous uses, including cement manufacture, took 36,301 tons in 1940 and 34,721 in 1939, most of which was from South Dakota or Wyoming.

A canvass of producers by the Bureau of Mines indicates that no shortage of bentonite for making essential munitions is anticipated. Production capacity has increased, and with the addition of certain items of equipment (which could be installed within 90 days or less) output in South Dakota and Wyoming could be stepped up 50 percent over maximum capacity last year. Reserves in the ground are more than ample, and the larger producers maintain extensive stock piles that could be drawn upon in emergency.

Imports of bentonite are insignificant, aggregating 23 short tons valued at $928 in 1940 compared with 62 tons valued at $895 in 1939 and 8 tons valued at $228 in 1938. Exports, as reported by producers to the Bureau of Mines and excluding any foreign shipment by dealers, increased in 1940 to over 27,000 tons. In addition, large quantities of acid-treated bentonite are exported to oil refineries throughout the world.

Notwithstanding increased demand, bentonite prices were not increased in 1940; in fact, some of the largest buyers were able to purchase at lower prices, and the average value of all sales declined to $7.65 a short ton compared with $7.75 in 1939, even though the proportion of high-price specialties actually increased. The most widely used bentonite is 200-mesh powder, which continued to be quoted at $10.25 a ton f. o. b. Black Hills shipping point in 100-pound bags, carload lots. However, Wyoming-type bentonite is also prepared in pellet form, 30- to 40-mesh; and a dried and finely crushed product, mostly 4- to 20-mesh, is sold in carload lots at $7 a ton in bulk and $8.75 in bags. Bags are an important item in cost and while not included in Bureau of Mines valuations represent as much as 14 percent of the sales dollar of certain companies.

According to a preliminary report of the Bureau of the Census the domestic production of bentonite in 1939 was 223,381 short tons valued at $1,982,129. This tonnage is only 2 percent larger than that reported by the Bureau of Mines (219,720), but the value is substantially higher because it includes packages and also the value added by or received for milling minerals other than bentonite. Of the total output of bentonite, the Census figures show 152,459 tons valued at $1,678,995 were prepared by such methods as crushing, screening, drying, and grinding; most of that reported as "crude" was intended for acid activation. The average number of wage earners was 357, and salaried employees numbered 62; and the average output (based upon wage earners at mines and preparation plants but excluding acid or other chemical treatment) was 0.33 ton a man-hour.

FULLER'S EARTH

Domestic production of fuller's earth or natural bleaching clays as reported to the Bureau of Mines was 146,568 short tons valued at $1,471,083 in 1940 compared with 167,070 tons valued at $1,691,855 in 1939 and a peak of 335,644 tons valued at $4,326,705 in 1930. The Bureau of the Census reports an output of 185,761 tons valued at $2,106,721 for 1939 compared with 369,933 tons valued at $4,811,629 in 1929 when production was close to the 1930 peak. Both sets of figures reveal an apparent shrinkage of over 50 percent in demand for fuller's earth, whereas the petroleum-refining index, which formerly served as a reliable barometer of demand for this material, has expanded about 35 percent.

The Census figures exceed those compiled by the Bureau of Mines chiefly in respect to the output in Texas, where a substantial quantity of material used for oil refining has been reported to the Bureau of

Mines as "miscellaneous clay" or "bentonite," rather than as "fuller's earth." The distinction between fuller's earth and other clays having more or less bleaching power is not sharply drawn, and the proper classification of 20,000 to 30,000 tons a year of this borderline material is largely a matter of opinion; in fact, producers in their reports to the Bureau of Mines have altered the classification of their respective products from one year to the next.

Fuller's earth sold or used by producers in the United States, 1938–40, by States

State	1938		1939		1940

[2] 1938: California, Colorado, Illinois, Mississippi, and Tennessee; 1939: California, Colorado, Illinois, Nevada, and Tennessee; 1940: Colorado, Illinois, Nevada, New Mexico, and Tennessee.

Imports of fuller's earth declined further in 1940 to only 474 short tons valued at $6,105 compared with 1,818 tons valued at $22,215 in 1939. Exports are not recorded separately by the Department of Commerce, but reports to the Bureau of Mines by producers show shipments to foreign countries aggregating 6,290 short tons valued at $53,886 compared with 11,090 tons valued at $90,117 in 1939.

The decline in use of fuller's earth, as noted in previous annual chapters of this series, has been due partly to new methods of oil refining and partly to substitution of other oil-bleaching and clarifying agents. In Minerals Yearbook 1940 (p. 1263) reference was made to Magnesol, a synthetic magnesium silicate used in refining petroleum and for clarifying solvents used by dry-cleaning establishments. Reference was also made to United States Patent 2,183,590 issued to Ernest Wayne Rembert on December 19, 1939, but it seems that this patent is not owned by the manufacturers of the product known as Magnesol, the manufacture and use of which are covered by Patents 2,163,525, 2,163,526, and 2,163,527 issued to Lyle Caldwell on June 20, 1939. Acid-activated bentonite and, to a smaller extent, bauxite have invaded heavily the field for fuller's earth in oil refining. Still another factor in the reduced requirement for fuller's earth is the relative decrease in the production of lubricating oils compared with gasoline and other petroleum products that require less or no bleaching.

MISCELLANEOUS CLAY

Hitherto no figures have been available on the total quantity of clay dug and used in the manufacture of brick, title, sewer pipe, and other heavy-clay products. Bureau of Mines figures for "miscellaneous clay" include a substantial tonnage used in making these products, but only when it is sold to another company or shipped by the mining company to a plant some distance from the pit. For 1939 the Census of Mines and Quarries has collected figures for all clay dug, including material produced at integrated plants adjacent to clay pits and representing a tonnage probably six to nine times as large as the total for all kinds of merchant clay.

[1] Includes slip clay as follows: From Michigan and New York, in 1937, 6,087 short tons valued at $39,889; 1938, 2,227 tons, $13,955; 1939, 2.564 tons, $17,654; and from Michigan, New York, and Ohio, in 1940, 4,365 tons, $29,268.

[2] Included under "Other States."

[3] Includes States indicated by "(2)" above, and Connecticut, Georgia, Illinois, Kansas (1939-40 only), Kentucky (1937 and 1939 only), Maine (1937 and 1939 only), Maryland, Massachusetts, Michigan, Minnesota, Mississippi (1938-40, inclusive), Missouri (1940 only), Montana, Nevada (1937, 1939, and 1940 only), New Jersey, New Mexico (1938-40, inclusive), New York, Oklahoma, Tennessee (1937 and 1940 only), and Utah.

The second largest use of miscellaneous clay is for rotary-drilling mud. Additional tonnages of unclassified clays are employed in cement manufacture, in foundries and steel works, in flowerpots and other earthenware, in oil refining, and for a variety of minor uses.

HEAVY-CLAY PRODUCTS

Preliminary figures for shipments and employment at brick, tile, and terra-cotta works indicate that production and sales lagged far behind the corresponding figures in 1939 during the first half of 1940 but ran well ahead during the latter half. The net result was that, although the industry did not do so well for the 12-month period, it ended the year with a strong rising trend in contrast to the marked slump that developed before the beginning of the year.

Production trends for many heavy-clay products from 1920 to 1938 were plotted in Minerals Yearbook, 1940 (p. 1266).

POTTERY

Census figures for specified pottery products for 1939 (1937 figures in parentheses) follow: Vitreous china plumbing fixtures $21,978,821 ($20,392,532); hotel china $9,359,660 ($10,415,249); whiteware $27,800,677 ($25,688,838); pottery products not elsewhere classified $16,593,344 ($14,569,850). Earthenware, household, table, and kitchenware articles—the largest item in domestic production of pottery—compete intensively with cheap grades of Japanese pottery and probably will show a marked increase in 1940, probably to an all-time record.

Value of production, imports, and exports of pottery in the United States, 1929–40 [1]

Year	Production	Imports [2] (foreign value)	Exports
1929	$112,019,000	$18,538,000	$5,036,000
1931	66,582,000	7,853,000	2,150,000
1932	40,373,000	4,539,000	859,000

REFRACTORIES

According to Ramsay,[2] plant capacity for making silica brick and fire-clay brick in the United States has been reduced from a maximum of 1,725,000,000 in 1931 to approximately 1,525,000,000 in 1940, and even the latter figure is roughly twice as large as the quantity needed for filling the requirements of consuming industries. Further evidence of overcapacity is the great number of concerns that have gone through receivership or bankruptcy. Clay-brick capacity represents about three-fourths and silica-brick capacity about one-fourth of the combined capacity as estimated above.

Ramsay affirms that the steel industry does not consume more than half the number of refractory units per ton of iron or steel that it did even 10 years ago, and the reduction in requirements of the oil industry is still greater. The following quotations from his informative analysis are especially interesting:

> In going back over the last 70 years I find that the combined shipments of silica brick and fire-clay brick in 1870 were, roughly, 60,000,000 9-inch equivalent; in 1880 they had reached to 163,000,000; in 1890 to 391,000,000; while in 1899 the shipments were probably 800,000,000 brick. Twenty years later—1919, the shipments were 1,174,000,000 brick, while in 1926 the shipments were 1,300,000,000. From 1926 on, the average shipments were very much less than they were in the period from 1909 to 1926. We all know that 1929 was a good year in nearly all lines, and yet the shipments in that year were not much in excess of 1,000,000,000 9-inch equivalent. The nearest approach to those shipments was in 1928, when they were approximately 900,000,000. Nineteen thirty-six and 1937 were both rather active years, and yet the shipments in each of those years were less than 800,000,000—or, not as much as they were in 1899. In 1932 they fell below 300,000,000. A survey of the average shipments of the 12-year period from 1928 to 1939, both inclusive, indicates that the shipments were probably not much, if any, in excess of 600,000,000. Prior to 1926 the industry probably operated at close to capacity, and in the year 1926 it is my belief that the shipments were at least 90 percent of the capacity of the industry. . .
>
> One of the outstanding points where the consumption is reduced is in the larger units of furnaces or kilns being built by the consumer. Many blast furnaces are now built to produce 1,000 tons of pig iron per day. The linings in these larger furnaces often last for years and produce anywhere from 1 million tons of pig iron to 2 million tons out of a single lining. This means that the life of blast-furnace linings has been probably doubled in the last 10 years. It does not take many more brick to line the large furnace than the small one. Open-hearth furnaces have been enlarged from 100 tons to 150 tons. Glass tanks have been enlarged, and the life in many instances has been doubled as a result of a better product on the part of the producer and better engineering and care on the part of the con-

[2] Ramsay, John D., Backbone of Industry; chap. 9, Economics of the Refractories Industry: Brick and Clay Record, vol. 97, No. 5, November 1940, pp. 58, 60, 62.

sumer. Of course we must not overlook the fact that many consumers today have pyrometric control over their equipment where refractories are used and, obviously, this prevents premature failure. Large, high-pressure boilers take the place of a number of small ones. The high-pressure stills in the oil industry take the place of rows of small units. The central power stations have eliminated thousands of small power plants. The use of tunnel kilns in the ceramic industry, thus displacing the periodic kiln, has made the consumption of refractories an insignificant amount as compared with those required to build and maintain the periodic kilns. During this century, and particularly during the last 30 years, the introduction and construction of byproduct coke ovens require a great many fire brick and silica brick for the original installation, but the maintenance following that is practically nil for 10 or 15 years, and in many cases for 20 years. This has made a great change in the consumption of refractories for the production of coke because the old beehive ovens required continuous repairs, all requiring refractories. One of the greatest losses we have sustained in the consumption of refractories is the byproduct coke-oven installations. I could go on and enumerate and give similar cases in nearly every industry, but the net result of these larger units and better engineering is that the consumption of refractories per unit of production, whether it be steel ingots or glass or electric current, is probably not over 50 percent of what it was 10 years ago.

TECHNOLOGY

Paralleling the marked improvement in commercial clays of domestic origin, laboratory studies are probing deeper into clay molecules and finding sound technologic reasons and replacing rule-of-thumb traditions to explain and predict the behavior of clays in ceramic and other applications. New techniques for speeding identification of the constituents of clays by staining have been perfected in the Bureau of Mines laboratories.[3] At Urbana, Ill., R. E. Grim has been finding that certain behaviors commonly attributed to *p*H alone must be viewed in the light of adsorbed water and the nature of the cation. In the potteries is noted a growing trend toward dry-mixing raw materials, particularly for manufacturing chemical stoneware, electrical porcelain, and certain whitewares. Other recent trends have been summarized as follows:[4]

To simulate the casting properties of standard English clays, synthetic domestic clays or blends, in which grain size is controlled, have been produced. All of them are more refractory than English clay but suit the purpose well when used with additional or more active flux. Even in the enameling industry, one of the few remaining strongholds of continental clays in this country, blended domestic clays have been used successfully and may permanently displace even the highly reputed Vallendar clay.

A new automatic molding (jiggering) machine for plates and other simple shapes, an outstanding advance in pottery making, was developed by Homer Laughlin China Co. Electric firing studies for ceramics were continued at Norris, Tenn., as research continued on all-American bodies. New organic flocculants for sanitary-body casting slips were developed. Lignin and papermakers' byproducts are being used as plasticizers for even cheap structural products. The Overstrom mud screen, previously employed for thick, oil-well drilling muds, has been suggested for heavy ceramic slips. Automatic stokers are being tested at brick plants in various States, not so much to save labor as to assure more uniform firing.

The fire-clay resources of northern Ontario are being studied as a means of relieving Canada's dependence on imports. Those of the United States are discussed in a new book by A. F. Greaves-Walker.[5]

T. V. A. announces the discovery of a new process which it claims will yield alumina commercially for aluminum production from clay; technical details are withheld.

THE INDUSTRY IN FOREIGN COUNTRIES

Germany.—Germany has huge kaolin resources that were increased greatly by the annexation of Czechoslovakia. Before occupation of the Sudeten area in October 1938 Germany's production of kaolin from plants subject to statistical control rose from about 390,000 metric tons in 1932 to 730,000 in 1936, most of which came from deposits in Bavaria. Czechoslovakia's output meanwhile rose from 356,000 tons in 1932 to 407,000 in 1936. Virtually all the famous china and porcelain plants of western Bohemia and the associated clay deposits were acquired by the 1938 coup, which is the more significant in view of the fact that (in 1937) 76 percent of the 236,898 metric tons of china clay that Germany imported came from Czechoslovakia. In 1938 Germany's imports of china clay totaled 189,310 tons, of which Czechoslovakia supplied 140,689, the United Kingdom 45,304, Denmark 3,228, and other countries 89. Czechoslovak imports of china clay on the other hand were negligible—only 4,357 tons in 1937, of which 3,890 were from Germany.

The United States has imported a variety of specialty clays from central Europe, chiefly for enameling, special refractories, and pencil leads. For many years the famous Zettlitz kaolins were considered the highest type of clay for porcelain manufacture. Imports of German and Czechoslovak clay into the United States in recent years have not been very large, but when they were finally cut off by the British blockade certain minor readjustments were necessitated. The transition to blends of American or of American and English clays was made easier by reason of fairly large stocks in the hands of consumers. Most of the crucible manufacturers, for example, still have stocks of Klingenberg clay, which hitherto was considered essential for this purpose—probably because it becomes dense at a comparatively low temperature, thus sealing the carbon grains and protecting them from oxidation. Gross-Almerode glass-pot clay is a German clay that formerly was used extensively in the United States in making pots and tanks in which glass was melted; imports of this clay aggregated 2,145 tons in 1936 but dwindled to insignificant proportions even before the outbreak of the European war. Other special German clays were used in making tobacco pipes, emery wheels, and a variety of other ceramic products. In the enameling field the complete answer to the clay problem only a quarter century ago was Vallendar clay, which was produced in Germany northeast of Koblenz. During the World War of 1914–18 the American hollow-ware industry began to use domestic clays, usually with admixtures of English clay; and after 1918 some use of domestic clays persisted, especially in grey-ware enameling. Long before the outbreak of the present war American enamelers had escaped dependence on Vallendar clay. Some quantities of this clay were still imported, but it was perfectly possible to get along without it. One effect of the present conflict may be to establish American clay in the enameling industry as well as in other industries to such an extent that German clays will not be needed in the United States.[6]

India.—Illustrating further the world-wide trend toward self-sufficiency in clays as well as other materials and products was the

[6] Irwin, J. T., What Have We Learned About Clay Since World War I: Enamelist, vol. 17, No. 8, May 1940, pp. 5–12.

establishment of a Government porcelain factory in the State of Mysore, India, in 1931. China clay, quartz, and feldspar are found in abundance near Bangalore. It is reported [7] that the factory supplies not only the requirements of the electrical department of the State (which is probably the largest consumer of electrical goods in India) but even sells its products elsewhere in India. The manufacture of stoneware is being considered.

Italy.—Before the present war the production of china clay in Italy more than trebled in 4 years or from 37,830 metric tons in 1934 to 119,286 in 1938. Imports meanwhile dwindled from 52,594 tons in 1934 to 28,446 tons in 1938. The following résumé is based upon reports from United States Vice Consul Charles T. Terry, Venice:[8]

Up to the period of the sanctions (1936) Italy depended entirely on foreign nations for high-grade clays both for porcelain and rubber making. Today the situation is greatly changed. Kaolins of a low purity and plasticity, of which Italy has abundant supplies, are being pulverized, washed, and decanted to furnish material suitable for many purposes in the ceramics industry, for the manufacture of paints, mastic, and, for the present in lesser degree, paper. If subjected to an adequate mechanical, chemical, or electrical-osmotic treatment, it is believed Italy's kaolin might be adapted to still other uses for which it cannot be employed at present. Plants for purifying kaolin already exist at Torniella in the Province of Grosseto and at Tretto in the Province of Vicenza.

National production of kaolin in 1936 was 73 percent more than in 1935. All Italian kaolin mines contributed to the 73-percent jump in national output in 1936, but more especially those at Furtei Serrenti in Sardinia, those in the mining district of Vercelli in the Piedmont Province, and those at Tornella and Valle Pozzatello in Tuscany Province. The mines at Tretto in Vicenza (Venice consular district) and those opened in 1935 on the island of Ponza in the Naples mining district contributed substantially to the total production.

Italy is fairly rich in kaolinic strata, but much of the domestic product, after washing, is not suitable for use in porcelain. To approximate that which is being imported from abroad, the raw kaolin must undergo a process of enrichment and purification. The raw kaolin produced at Furtei, which is well-adapted also to the manufacture of refractories, is the variety that lends itself best to this process. It yields a product with 35 percent alumina or 95 percent kaolinite. The spectrum of this variety of kaolin, known as "Bex di Monte Porceddu," more nearly approximates that of the best English kaolin. Clays mined at Tretto in Vicenza, Roccastrada in Grosseto, Pozzatello in Pisa, and Ponza in Naples, do not lend themselves to this process because they are not rich enough in Al_2O_3.

It may be said that even yet only a very limited quantity of kaolin has been produced in Italy for porcelain and hard white crockery. On the whole, the known Italian strata of kaolin yield kaolinic earth only for pottery and refractories. Impure kaolin, after having been ground, is used in the manufacture of refractories, and part, after it has been washed (the so-called refined kaolin, in the form of loaves and powder), is extracted for use in pottery, paint, mastic, and paper.

United Kingdom.—Because of the war official statistics for china clay, ball clay, and china stone in the United Kingdom were discontinued in November 1940. The output of china clay during the first 10 months of the year totaled 423,016 long tons compared with 748,402 tons during the 12 months of 1939 and a record of 830,946 tons during 1937. For ball clay the 10-month output was 17,522 long tons compared with the 1937 record of 31,812 tons for a full year. The china-clay works in Devon and Cornwall were operated at only a slightly lower rate during the first 4 months of 1940 than during the corresponding 1939 period—before the war. However, when the Scandinavian market was cut off stocks began to grow; and later when Italy

[7] Bureau of Foreign and Domestic Commerce, Foreign Commerce Weekly, vol. 2, No. 13, March 29, 1941, p. 539.

[8] Terry, Charles T. (United States vice consul, Venice), Consular Repts., July 14 and July 21, 1939; abs. Bureau of Mines Mineral Trade Notes, vol. 9, No. 3, September 20, 1939, pp. 29-31.

and the rest of the continental market, except Spain, stopped buying English clay hundreds of workers had to be laid off. During the latter half of the year trade was virtually confined to home consumption and exports to the United States, and even these outlets were restricted.

A comprehensive report on the English china-clay industry was submitted in August 1938 to the Bureau of Mines by Rollin R. Winslow, United States consul, Plymouth, England, and was abstracted in Mineral Trade Notes (vol. 7, No. 4, October 20, 1938, pp. 23–26, and No. 5, November 20, 1938, pp. 13–14), from which many of the data in the following paragraph are taken:

Kaolin, or china clay, is the most important natural material produced in Great Britain, next to coal, and virtually all of it comes from an area 10 miles square in Cornwall. In 1913, the St. Stephens district provided more than 50 percent of the estimated world production; for many decades before that English production was rivaled only by that of China. In later years, it has constituted only about 15 percent of the world total—not because production has declined in England (it was even larger in 1937 than in 1913) but because production elsewhere, notably in the United States, has increased. Cornish clays have held a high reputation for uniformity, high average quality, and good color, and the development of international markets has been facilitated by the existence of large deposits close to seaports. Taking normal production of English china clay as 800,000 long tons a year, it has been estimated that its uses, foreign and domestic, are distributed as follows: 450,000 tons in paper, 250,000 in pottery, 50,000 in textiles, and 50,000 in other products. In respect to sales in the United States, the uses of English clay are divided approximately as follows: Paper filler, 40; paper coating, 19; pottery, 33; textiles, paints, etc., 5; and oilcloth and linoleum, 3 percent. In 1913, American imports of English kaolin were more than 10 times American production, but by 1919 American production exceeded imports, and in 1940 it was almost 8 times as great. Between 1920 and 1930, 56 percent of all English china clay exported went to the United States but in recent years scarcely 15 percent. Normally, about two-thirds of the English output is marketed overseas. Before the outbreak of hostilities in 1939 Germany had become the largest buyer next to the United States. France was third, Netherlands ranked fourth, and other European countries were consistent consumers.

Scottish fire clays[9] are almost as famous in their field as the china clays of Southwest England. About 600,000 tons of fire clay of various classes are mined annually in Scotland, roughly 30 percent of the entire output of the United Kingdom. Much of the output is used in the local steel works and Tyneside shipyards. It is also used in making various articles ranging from fire brick to sanitary ware and in chemical plants. Roughly, 25 percent is exported. Ordinary fire clay is distributed widely along coal seams, but the more refractory clays seldom occur near workable coal. These clays appear in the two principal areas in Scotland—the Saltcoats-Mauchline deposits in Ayrshire and the Cardowan-Bonnybridge deposits in the Counties of Lanark, Dumbarton, and Stirling. The industry is centered between Bonnybridge and Cumbernauld, where there are nine mines, and between Glenboig and Cardowan, where six mines are operating. There are four other mines in North Ayrshire, with others near Polmont, Bathgate, Fauldhouse, and Morningside. This producing area is within a radius of 25 miles of Glasgow.

ABRASIVE MATERIALS

By Robert W. Metcalf

SUMMARY OUTLINE

The total value of products of the industries comprising the natural abrasives group showed a small increase in 1940 compared with 1939. Offsetting decreases in the value of sales of tripoli, millstones, and garnet, were healthy advances for quartz, ground sand and sandstone, grindstones and pulpstones, pumice and pumicite (a new record), and emery. The reported tonnage of pumice and pumicite, however, was somewhat less than the record output of 1939, and the quantity of garnet sold increased 16 percent in 1940 compared with 1939.

Salient statistics of the abrasives industries in the United States, 1939–40

	1939	1940	Percent of change in 1940
Domestic production (sold or used by producers):			
Natural silica abrasives:			
Diatomite	(1)	(1)	
Tripoli	$466,380	$366,569	−21
Quartz	153,038	176,390	+15
Ground sand and sandstone	1,930,301	2,088,314	+8
Special silica-stone products:			
Grindstones and pulpstones	426,375	496,448	+16
Oilstones and related products	115,805	(1)	
Millstones	11,084	6,558	−41
Flint lining and grinding pebbles	(1)	(1)	
Natural silicate abrasives:			
Pumice and pumicite	424,780	449,914	+6
Garnet	278,534	259,345	−7
Natural alumina abrasives:			
Emery	6,828	9,349	+37
Total natural abrasives	[2] 3,813,125	[2] 3,852,887	+1
Total artificial abrasives [3]	6,504,403	10,142,691	+56
Foreign trade:			
Imports	10,246,945	11,517,117	+12
Exports	1,415,589	1,605,961	+13

[1] Bureau of Mines not at liberty to publish figures. Average for diatomite for 1936–38 was $1,459,118.
[2] Excludes in 1939 value of diatomite and of flint lining and grinding pebbles and in 1940 value of diatomite, flint lining and grinding pebbles, and oilstones and related products, which the Bureau of Mines is not at liberty to publish.
[3] Includes some material produced in Canada; Bureau of Mines not at liberty to publish United States data separately.

Output of crude manufactured abrasives established an all-time record in 1940, and the total value of products was only 6 percent under the 1929 figure—the highest yet recorded. All three classes of artificial abrasives—silicon carbide, aluminum oxide, and metallic abrasives—reached new highs in 1940, silicon carbide and aluminum oxide far outstripping the 13-percent increase in general industrial activity over 1939 and the 25-percent gain in durable goods manufacture. Continued heavy imports of smaller industrial diamonds, large increases in receipts of corundum and emery ores, radical decreases in imports of Italian pumice and of flint, flint stones, etc., for grinding and ceramic use, and a sizable increase in value of exports featured the foreign trade of the United States in abrasive materials during 1940.

This chapter includes data for most of the materials used chiefly as abrasives, although certain clays, oxides, and substances mentioned later under "Miscellaneous abrasive materials" are not included in the statistics presented herein. On the other hand, some commodities listed as abrasives for which data are given also have important nonabrasive uses.

President Roosevelt on July 2, 1940, designated industrial diamonds as one of a large group of commodities subject to export by license only,[1] such license to be issued by the Division of Controls of the State Department. On recommendation of the Administrator of Export Control the President placed some 15 additional articles in this category on December 20, 1940. Included in this later group subject to restrictive export were: Abrasives and products containing emery, corundum, or garnet, as well as abrasive paper and cloth; and tools incorporating industrial diamonds.[2]

The general trends in the natural and artificial abrasives industry, including reference to coated products and grinding wheels, were described in one of a series of studies, by the Bureau of Mines, of nonmetallic minerals necessary to the defense program.[3] A brief history and description of the uses of each of the principal types of abrasives were given, with tables for imports and domestic production in selected years and a compilation of Census data since 1880. Unprecedented demands for abrasives are forecast in the rapidly growing airplane output, in the mechanization of armed forces, and in the resultant activity of steel mills and other factories using large quantities of abrasives in the manufacture of finished munitions and other articles needed for defense.

A general discussion of the vital necessity for long grinding and polishing in the production of the highly efficient engines, machinery, and instruments with precision-ground tolerances essential for modern war and peace requirements is presented in an article in Priorities, a chemical-firm house organ.[4] A recent book by Swigert [5] devotes a chapter to abrasives, tracing their history from early development to the present-day use of bonded abrasives. British specifications for abrasive papers and cloths were published recently.[6]

[6] British Standards Institute, Abrasive Papers and Cloth (Technical Products): British Standard Specifications 871 and 872, London, 1939.

An improved polishing method utilizes an abrasive film on metal laps, thereby providing a greater number of active cutting particles than a fixed abrasive and avoiding scratches and waviness such as are produced by a freely rolling abrasive.[7] Greater speed also is obtained through the use of the special technique recommended, as a mounted surface can be ground and polished in 10 to 60 minutes compared with 3 to 12 hours using standard methods.

A detailed discussion of the complicated nature of the factors involved in abrasives and grinding was presented by Milligan,[8] under the four following headings: (1) Characteristics of abrasive grains, including consideration of hardness characteristics and testing methods, toughness, refractoriness, and a listing and classification of the different abrasive materials; (2) bonding characteristics, including consideration of the various kinds of bonds employed commercially for grinding wheels, coated goods, polishing, and buffing and lapping wheels, the structural relationship in bonded abrasive products, and grading of abrasive products; (3) characteristics of the substance or work undergoing the abrasive process; and (4) conditions under which the abrasive is used.

Following the success of the electrostatic method in coating sandpaper its possible usefulness in textiles was indicated. One such application has been in the manufacture of pile fabrics,[9] such as women's dress goods decorated with a pile design and all-over covered pile products for such service as car interiors and upholstery. The wearing properties of an electrocoated pile fabric are increased as a result of the density of pile attainable—as high as 275,000 fibers per square inch.

NATURAL SILICA ABRASIVES

Diatomite.—The Bureau of Mines has not been at liberty to publish annual production figures on diatomite since 1926. Total output (sales) for 3-year periods, however, may be shown, and the annual fluctuation up to 1926 and 3-year averages since that date are plotted in figure 1. Total sales during the period 1936–38 totaled 279,645 short tons valued at $4,377,353 compared with 244,342 tons valued at $3,618,428 in the period 1933–35. Sales in 1940 were slightly higher than in 1939, continuing this gradual upward trend.

California and Oregon remained the chief producing States in 1940; other States that produced diatomite were Florida, Idaho, Nevada, New Mexico, New York, and Washington.

The principal uses for diatomaceous earth are for polishes, in insulation board and similar products, and as fillers, admixtures, and filter aids. Precoating the papers in plate and frame presses with diatomaceous earth, in which a special technique developed by Bitzer [10] is employed, has proved of value in filtering cyanide precipitate.

Tripoli.—Sales of tripoli (including Pennsylvania rottenstone) decreased in 1940 to 30,212 short tons valued at $366,569—10 percent in tonnage and 21 percent in value less than in 1939. Except for 1937

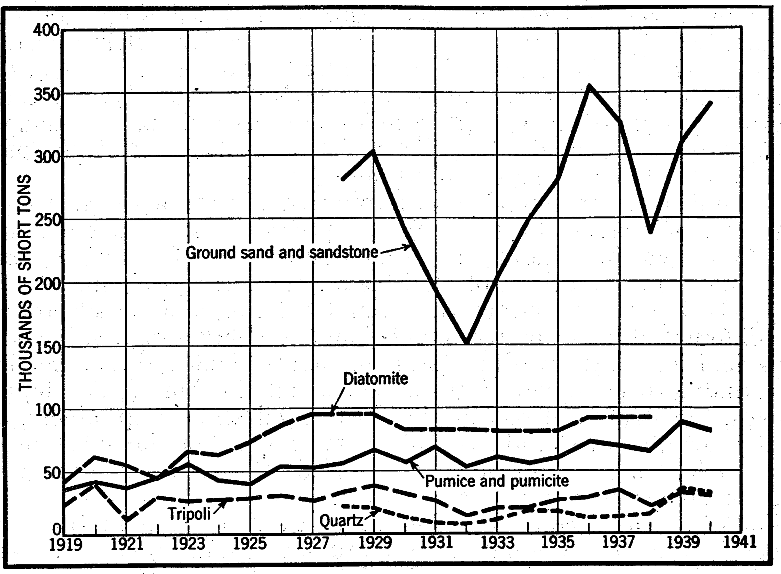

FIGURE 1.—Trends in production of diatomite, tripoli, pumice and pumicite, quartz, and ground sand and sandstone, 1919–40.

and 1939 the quantity sold was larger than in any year since 1930. In 1940 tripoli or amorphous silica was mined in Arkansas, California, Illinois, Missouri, Oklahoma, and Texas. Production is largely from the Seneca (Mo.), and Gate (Okla.) areas and from southern Illinois. Rottenstone was produced in Pennsylvania only.

Tripoli (including Pennsylvania rottenstone) sold or used by producers in the United States, 1936–40

Year	Illinois		Other States [1]		Total	
	Short tons	Value	Short tons	Value	Short tons	Value
1936	10,981	$138,063	17,506	$253,815	28,487	$391,878
1937	11,647	151,154	23,289	299,416	34,936	450,570
1938	8,141	117,107	14,047	211,974	22,188	329,081
1939	11,134	148,310	22,340	318,070	33,474	466,380
1940	11,521	155,576	18,691	210,993	30,212	366,569

[1] 1936: Arkansas, California, Missouri, Oklahoma, and Pennsylvania; 1937–38: Arkansas, California, Missouri, Oklahoma, Pennsylvania, and Tennessee; 1939: Arkansas, California, Missouri, Oklahoma, Pennsylvania, Tennessee, and Texas; 1940: Arkansas, California, Missouri, Oklahoma, Pennsylvania, and Texas.

Abrasives remained the largest outlet for tripoli, followed by sales for fillers of various kinds. These two uses combined represented 62 percent of the total sales. Sales for concrete admixture and for oil-well drilling mud in 1940 were 1,683 and 1,840 short tons, respectively.

Quartz.—Production of quartz from pegmatite veins or dikes and from quartzite totaled 31,865 short tons valued at $176,390 in 1940—a 9 percent decrease in tonnage, but a 15-percent increase in value compared with 1939. Except for 1939 sales were larger than in any year since 1920. The decrease in tonnage was due entirely to the drop in sales of crude material, as sales of both crushed and ground quartz rose substantially.

Tripoli (including Pennsylvania rottenstone) sold or used by producers in the United States, 1938–40, by uses

Use	1938		1939		1940	
	Short tons	Value	Short tons	Value	Short tons	Value
Abrasives	8,097	$138,807	10,953	$169,370	10,279	$119,609
Concrete admixture	2,170	12,634	1,653	24,580	1,683	15,895
Filler	5,584	78,900	9,016	120,284	8,451	113,862
Oil-well drilling			(1)	(1)	1,840	16,949
Other uses [2]	6,337	98,740	11,852	152,146	7,959	100,254
	22,188	329,081	33,474	466,380	30,212	366,569

[1] To avoid duplication, the ground material shown here is only that ground by the original producers of the crude quartz or by grinders who purchase from small miners not reporting their production.
[2] "Crushed" included under "Crude."

Output of crude quartz in 1940 was reported from 13 States compared with 12 in 1939. No sales in 1940 were reported from Ohio, and New Jersey and Pennsylvania reappeared in the list of producing States. Otherwise quartz was mined in the same States in 1940 as in 1939.

Quartz (crude, crushed, and ground)[1] sold or used by producers in the United States, 1938–40, by States

Ground sand and sandstone.—Except for 1936, sales of ground sand and sandstone in 1940 were the largest since 1917 and totaled 342,218 short tons valued at $2,088,314—10 percent in tonnage and 8 percent in value higher than in 1939. Important producing States were Illinois, New Jersey, Ohio, and Pennsylvania.

Ground sand and sandstone sold or used by producers in the United States, 1936–40

Sales of ground sand and sandstone for pottery, porcelain, and tile in 1940 totaled 137,228 short tons—40 percent of the total. Sales for abrasive use and for foundries were the next most important. These three markets combined comprised 83 percent of the total in 1940.

Ground sand and sandstone sold or used by producers in the United States in 1940, by uses

Total reported, by uses	342,218	2,088,314	6.10

Abrasive sand.—Natural sands with a high silica content, employed for sand blasting, scouring stone, grinding glass, sandpaper, and other abrasive use, increased in 1940 to 856,309 short tons valued at $915,925 compared with 668,027 tons valued at $895,989 in 1939—a rise of 28 percent in tonnage and 2 percent in value, although still considerably under the 1937 level. The 1940 total included 256,104 tons of blast sand valued at $597,198, or 16 percent in quantity and 10 percent in value higher than the 220,240 tons valued at $542,915 reported for this use in 1939. More detailed data on abrasive sands are shown under the classification "Grinding and polishing sand" in the chapter on Sand and Gravel.

SPECIAL SILICA-STONE PRODUCTS

Grindstones and pulpstones.—The total sales value of grindstones and pulpstones made from quarried stone increased in 1940 to $496,448—a 16-percent gain over 1939. Sales of grindstones in 1940 were 11 percent higher in both tonnage and value and pulpstones 80 percent larger in tonnage and 25 percent in value than in 1939. The value of pulpstones sold in 1940 was the highest since 1937 and the reported tonnage larger than in any year since 1929. As in other recent years, grindstones were quarried in Ohio and West Virginia and pulpstones in Washington and West Virginia.

Grindstones and pulpstones sold by producers in the United States, 1936–40

Year	Grindstones		Pulpstones		
			Quantity		Value
	Short tons	Value	Pieces	Equivalent short tons	
1936	10,703	$334,363	685	2,472	$163,643
1937	11,617	352,377	761	2,924	220,331
1938	4,653	149,019	417	1,553	90,987
1939	7,917	257,350	672	2,517	169,025
1940	8,790	284,809	901	4,533	211,639

The development of wood grinders and the relation of the size, texture, and hardness of pulpstones used in the pulp and paper industry were described by Shipman and Stephenson.[11] Different stones produced differing grades of pulp and reacted differently to dressing. Grading of the stones according to the predominant size of grit and texture became necessary, as stones, even from the same quarry, varied somewhat and those from other localities had distinct characteristics. Thus, English pulpstones, long considered best in quality, differed from those quarried in Ohio, West Virginia, or New Brunswick. As the pulp grinders increased in width, larger stones were required—sizes up to 54 inches in width and 62 and then 72 inches in diameter, instead of the 27-inch-width by 54-inch-diameter size largely used in earlier years. The difficulty of finding quarries with suitable sandstone beds thick enough to produce these large stones led to the cementing together of two thin stones or the use of bonding material to improve the natural qualities of the stone. Artificial stones made from aluminum oxide and silicon carbide also have been adapted for use as pulpstones in recent years.

Oilstones and related products.—Sales of natural sharpening stones—including oilstones, whetstones, scythestones, and rubbing stones—were higher in 1940 than in 1939. The Bureau of Mines, however, is not at liberty to publish the 1940 data. States contributing to the total were as follows: Arkansas, oilstones and whetstones; Indiana, rubbing stones; New Hampshire, scythestones; and Ohio, whetstones, scythestones, lathestones, and holystones.

Oilstones and other whetstones, hones, scythestones, and rubbing stones sold by producers in the United States, 1936–40

Year	Short tons	Value	Year	Short tons	Value
1936	752	$121,196	1939	620	$115,805

1938	511	130,277			

[1] Bureau of Mines not at liberty to publish figures.

Millstones.—The value of sales of millstones in 1940 dropped to $6,558—41 percent lower than in 1939 and 21 percent less than in 1937. Millstones in 1940 were produced from Ulster County, N. Y. ("Esopus" stone); Rowan County, N. C. (granite); and Montgomery County, Va. (quartzite). The diameter of the millstones produced in Virginia ranges from about 12 to 72 inches; they are quarried by hand from underground operations, as the surface rock has been found unsatisfactory on account of its objectionable lining and lamination.

Tube-mill lining and grinding pebbles.—Stimulated by the threatened curtailment of supplies of foreign mill liners and grinding pebbles, an intensive search for possible new sources and likely substitutes for grinding pebbles formerly imported chiefly from Denmark and France and for silex liners from Belgium was undertaken during the year. The sharp drop in imports of "Flint, flints, and flintstones, unground" in 1940 to 2,840 short tons from 11,987 in 1939 confirmed the likelihood of a curtailed supply from abroad.

Fortunately, fairly large stocks had been built up at plants, and the partial stoppage of imports already has been offset by increased production of artificial pebbles in the United States and by various substitutes (including selected pegmatite quartz) from certain feldspar mines. One company found that granite liners gave better service than Belgian silex. Some operators also have discovered that steel balls and liners caused less serious contamination by iron than had hitherto been supposed. The Board of Directors of the National Industrial Sand Association in the fall of 1940 recognized the need for looking ahead for a future supply of grinding pebbles for making silica flour. At the semiannual meeting in November it discussed the desirability of an interchange among member companies of information and experience with substitute materials. At that time one of these members was using porcelain and another testing corundum pebbles.

The Canadian Mining and Metallurgical Bulletin for September 1940 reported that large consumers in the United States were becoming interested in several southwestern Saskatchewan deposits containing hard, dense quartzite pebbles whose performance is said to compare favorably with European material formerly imported. Deposits in the best locations already had been taken up, and the Canadian Flint & Spar Co. was beginning production at Gouverneur and Knollys immediately.[12] The Clinchfield Sand & Feldspar Corporation, Baltimore, Md., producer of feldspar and other ceramic raw materials, imported about 2,000 tons of beach pebbles from Newfoundland in 1940. These pebbles were reported to be high in flint and fairly low in iron. As many of them, however, were quite soft, it was found necessary to sort them carefully. The sorted product was quoted at $35 a short ton, f. o. b. New York.

The Jasper Stone Co., Sioux City, Iowa, marketing liners and artificially rounded pebbles of quartzite from its Jasper (Minn.) quarries, was again the principal commercial producer of mill lining and grinding pebbles, but at least two others reported small sales in 1940—Southern Products & Silica Co., Lilesville, N. C. (granite cubes and liners, also some large quartz pebbles), and John T. Momand, Carlsbad, Calif. (beach pebbles). J. Howard Swaim, Nashville, Tenn., has taken over the property near Iron City, Tenn., formerly operated by the American Flint Co. and is expecting to begin shipments during 1941. Although the Harris Granite Quarries Co., Salisbury, N. C., shipped practically only sample lots in 1940, it is making both liners and pebbles "in considerable quantities" in 1941. The Crystal Silica Co., Los Angeles, Calif., is said to be producing several grades of pebbles at its plant, Oceanside, Calif. In addition to handling Newfoundland pebbles the Clinchfield Sand & Feldspar Corporation is reported to have tested various quartzite pebbles. Experimental work on topaz as a grinding medium was undertaken by the United Feldspar & Minerals Corporation, Spruce Pine, N. C. Porcelain balls have been used by a silica firm. Use of "self-material" or lumps of the same material being ground, silica flour compressed into balls under pressure with sodium silicate as a binder, white-iron grinding mediums, and hard-iron liners of special composition in place of silex have been suggested as possible substitutes for imported material.[13] A general review of the silex and grinding-pebble industry appeared in 1940.[14]

NATURAL SILICATE ABRASIVES

Pumice and pumicite.—Sales of pumice and pumicite in 1940 decreased to 82,407 short tons—8 percent under the record output of 1939 (89,159 tons), although they were considerably higher than in other years. The value of sales in 1940, however, totaled $449,914, and was a new high—6 percent greater than that reported in 1939.

	65,742	312,886	89,159	424,780	82,407	449,914

[1] Included under "Other uses."
[2] 1938: Asphalt, filtering, rock gardens and landscaping, building tiles, and some unspecified uses; 1939: Asphalt, heat or cold insulation, or other abrasive use, insecticide, building tile and blocks, roofing, stucco, and unspecified uses; 1940: Asphalt, heat or cold insulation, insecticide, stucco, lime mortar, and unspecified uses.

Production of pumice in 1940 was reported in California, Kansas, Nebraska, Oklahoma, and Oregon and output of pumicite or volcanic ash in Colorado, Kansas, Nebraska, and Oklahoma.

Sales of pumice and pumicite in 1940 for use in concrete (as admixture and aggregate) increased 6 percent to 22,045 short tons compared with 20,719 tons in 1939. Consumption in other uses for which comparisons are available, however, was less than in 1939—cleansing and scouring compounds and hand soaps, 49,359 tons in 1940 compared with 52,521 tons in 1939, a decrease of 6 percent; and acoustic plaster, 3,712 tons in 1940 compared with 5,444 tons in 1939, a decrease of 32 percent (see figure 2).

The American Pumice Co., Los Angeles, Calif., with a plant 30 miles north of Bishop was incorporated [15] and started production. The Pumice Processing Co., 556 San Fernando Road, Los Angeles, Calif., also obtained a certificate to go into business.[16] Owing to the increased demand for its lightweight concrete block and roofing tile utilizing ground pumice the Basalt Rock Co., Napa, Calif., installed a second tamper-type machine and a new Besser Vibrapac during 1940.[17] Pumice and volcanic ash deposits in Mono County, Calif., were described.[18] Pumicite is being used in the concrete mix for the Friant (Calif.) dam.[19] Pence [20] has studied the behavior of a white-firing volcanic ash as a ceramic body constituent. The alteration of volcanic ash and its relation to the silicification of wood were discussed by Murata.[21]

French pumice deposits were described in 1940.[22] Italian tests of pumice used for lightweight concrete were reported.[23] Experiments to determine physical and chemical properties of the volcanic ash near the village of Gorenki, Voronezh Oblast, U. S. S. R., indicated suitability of the material for portland, lime-porcelain, or acid-resisting cements.[24] A projected revival of pumice production in the Canary Islands, financed by Spanish capital, has been reported. A profitable export trade with the British Isles and continental ports was carried on many years ago.[25]

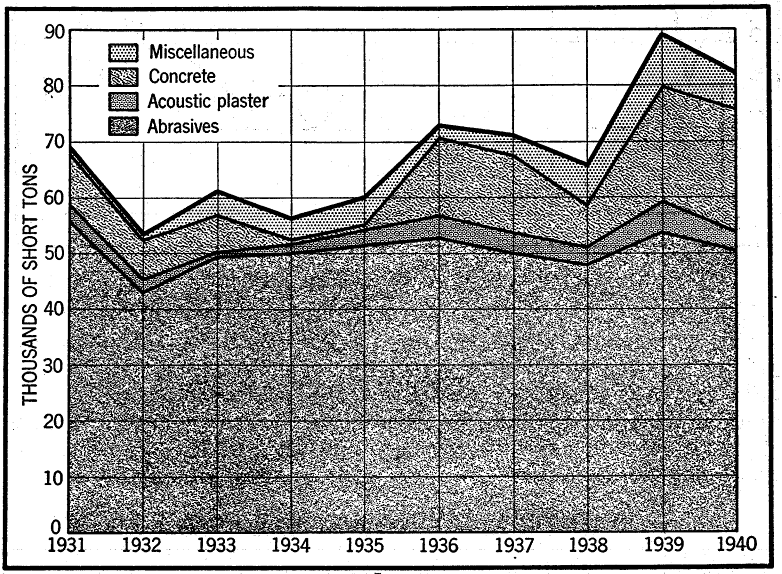

FIGURE 2.—Trend, by uses, of pumice and pumicite sold or used by producers in the United States, 1931–40.

Garnet.—Sales of garnet in 1940 increased to 4,716 short tons, or slightly under the 1937 level and 16 percent higher than in 1939 (see fig. 3). The total sales value in 1940, however, decreased 7 percent compared with 1939. In 1940 garnet was produced for sale in New York, North Carolina, Vermont, and Idaho. A small screening and classifying plant was built in Benewah County, Idaho, by Garnet Mines, Inc., Paulson Building, Spokane, Wash., and put in operation during 1940.[26] As in 1939, no imports of garnet were reported.

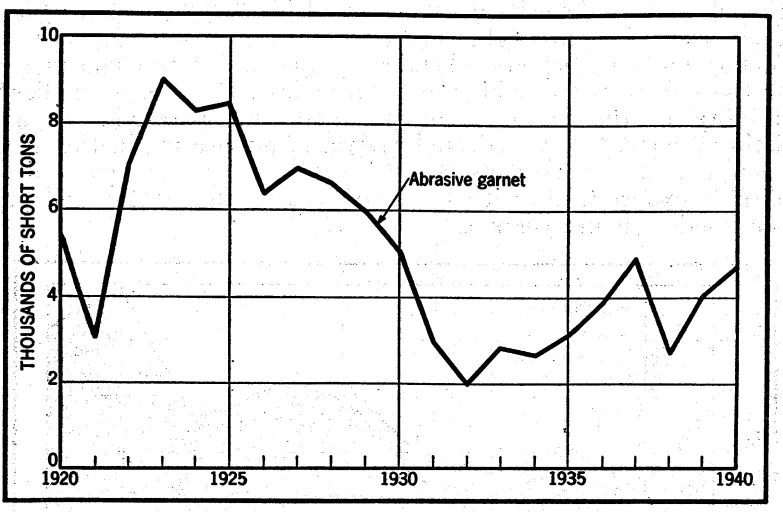

FIGURE 3.—Marketed production of abrasive garnet in the United States, 1920–40.

In certain localities in the State of Mysore, India, garnets occur in crystalline schists and to a small extent in some river sands in sufficient quantities (it is alleged) to justify commercial exploitation.[27] Levin [28] discussed the properties of South African garnets, comparing them with foreign garnets as to size, color, appearance, fracture, inclusions, and impurities. Results of the magnetic treatment of the South African product also were given.

NATURAL ALUMINA ABRASIVES

Corundum.—Corundum has not been mined in the United States in recent years. Imports of corundum ore in 1940, however, increased sharply to 5,718 short tons valued at $73,935—more than two and one-half times that imported in 1939. Most of the corundum and emery is imported crude and is crushed and graded in this country for domestic consumption. Corundum is reported to be widely distributed in the State of Mysore, India.[29] Varieties range in color from deep red to pink and light gray. No sustained effort has yet been made to market a clean concentrate.

Emery.—Sales of emery in 1940 rose to 1,046 short tons valued at $9,349—37 percent greater in both tonnage and value than in 1939, and practically equaling the quantity sold in 1933—when sales were higher than in any recent year—although much smaller in total value. As in recent years, production of emery was reported only from the Peekskill district, Westchester County, N. Y. Shipments in 1940 were reported by three producers—DiRubbo & Ellis, Joe DeLuca, and the Howard Emery Corporation, all of Peekskill.

Figure 4 shows trends in sales of domestic emery and imports of emery and corundum from 1924 through 1940.

1938	------------	------------			

NATURAL CARBON ABRASIVES

Abrasive or industrial diamonds.—The demand for abrasive or industrial diamonds in the United States is met through the importation of black diamonds or carbonados (largely from Brazil) and bort (chiefly from the Union of South Africa). Some diamond dust also is imported. However, both the value of diamond dust and the quantity of bort entering this country in recent years have tended to decline. On the other hand, imports of "Glaziers' and engravers', unset, and miners' " diamonds (a classification that comprises largely if not entirely diamonds for industrial use) have shown an upward trend and an almost phenomenal growth within the last year or two. In 1940 imports under this heading increased to 3,809,071 carats valued at $11,026,563—240,341 carats and $1,300,880 more than in 1939. The average value rose to $2.89 a carat in 1940 compared with $2.73 in 1939, $3.02 in 1938, and $3.47 in 1937.

Approximately two-thirds of the annual diamond production by weight or one-fourth by value is consumed in industrial uses.[30] About 45 percent of the industrial application, on a value basis, is for diamond drilling in mining and mineral-exploration operations, 30 percent in diamond-set tools used by many industries in cutting, grinding, and machining metal and for trueing and resurfacing abrasive wheels, about 10 percent for diamond dies employed in drawing fine wire and filaments of uniform diameter, and 15 percent for miscellaneous industrial uses. As a result of rapidly expanding industrial activity in the United States, the percentage used in diamond-set tools for various manufacturing operations probably will increase at a greater rate than for other uses. Detailed procedure in the preparation of industrial diamonds for diamond-set tools and diamond dies was described by Kraus and Slawson.[31] Industrial jewels, including diamonds and other natural stones, and synthetic rubies and sapphires were discussed.[32]

ARTIFICIAL ABRASIVES

Production of manufactured abrasives in 1940 broke all existing records and compared with 1939 generally ran far ahead of industrial production and of durable goods manufacture as measured by Federal Reserve Board indexes. Output of silicon carbide reached 33,042 short tons—37 percent over 1939 and 9 percent above the former high in 1937—while production of aluminum oxide in 1940 jumped to 98,531 tons—95 percent higher than in 1939 and 14 percent greater than the previous peak of 86,401 tons in 1937. Sales of metallic abrasives (steel shot and grit) surpassed the high mark established in 1939 and rose to the new record of 50,016 tons.

Crude artificial abrasives sold, shipped, or used, from manufacturing plants in the United States and Canada, 1936–40 [1]

Year	Silicon carbide [2]		Aluminum oxide [2]		Metallic abrasives		Total

[1] Bureau of Mines not at liberty to publish data for United States separately.
[2] Includes also material used for refractories and other nonabrasive uses.
[3] Production.

The production of silicon carbide and aluminum oxide is concentrated chiefly in the Niagara Falls region of the United States and Canada, with some output of aluminum oxide from Alabama. The manufacture of steel shot and grit is centered largely in northern Ohio and Pittsburgh, Pa., with some output from Michigan and New Hampshire.

Since 1937 producers of silicon carbide and aluminum oxide have been requested to indicate the approximate percentages of their

[32] Rocks and Minerals, United States Well Supplied with Industrial Jewels; March 1941, p. 91.

products consumed for refractory or other nonabrasive uses. Estimates based upon these percentages show an increase to 32 percent in the nonabrasive uses of silicon carbide compared with 29 percent in 1939, 26 percent in 1938, and 29 percent in 1937. The relative importance of the nonabrasive uses of aluminum oxides, however, dropped to 2 percent of the total output compared with 4 percent in each of the 3 preceeding years for which comparisons are available.

An excellent summary of the history and development of artificial abrasives from Dr. Acheson's discovery of carborundum or silicon carbide in 1891 to the present appeared at the beginning of 1941.[33] Natural abrasives only were used until 1891. Gem cutters employed diamond dust for cutting, forming, and polishing precious stones. Sandstone "wheels" were the principal means of sharpening tools until about the middle of the nineteenth century, when the natural abrasives emery and corundum were bonded into wheels. Because of their flexibility and the exact control of desired characteristics possible with their use, the manufactured abrasives aluminum oxide and silicon carbide soon were widely adopted by industry and have contributed largely to modern large-scale operations, especially in accurate precision grinding. Cut-off operations using aluminum oxide and silicon carbide bonded into wheels were described by Wiese.[34] General recommendations for types of cutting wheel, bond, and grain for cutting various kinds of materials are presented. Aluminum oxide wheels are utilized most commonly for cutting off metal, and in different grain sizes are employed for almost everything from aluminum to tungsten. The cutting of cast iron, copper tubing, and pure copper slabs is effected best with silicon carbide, which also is used for hard rubber, for plastics, and for nicking porcelain. For cutting very hard materials, such as cemented carbides, diamond grains bonded into thin wheels are employed.

Nöganäs-Billesholm, manufacturer of abrasive and refractory materials, has achieved a virtual monopoly of the Swedish abrasives industry through acquisition of all the shares of Svenska Naxos and of a majority interest in Slipmateriel at Västervik.[35] For many years Nöganäs-Billesholm has been manufacturing silicon carbide for use in special-type firebrick and for abrasives and also makes aluminum from bauxite or if necessary from a special type of clay found in Skåne. The combined value of output of the two recently acquired firms approximated 6,000,000 crowns, and together they supplied about 25 percent of the Swedish demand for abrasives.

MISCELLANEOUS ABRASIVE MATERIALS

In addition to the manufactured and natural abrasives material discussed above, many other mineral substances have abrasive uses. Various oxides, including tin oxide, rouge and crocus, chromium oxide, magnesium oxide, and manganese oxide, are utilized as polishing agents. Finely ground as well as calcined clays, high-grade lime, talc, river silt, whiting, feldspar, and other substances also are used for abrasive purposes.

FOREIGN TRADE [36]

Imports of "Glaziers' and engravers', unset, and miners'" diamonds in 1940 rose above 1939 by a substantial margin, contributing largely to the 12-percent increase in value of imports of all classes of abrasive materials. Imports of tripoli and rottenstone remained at a low level, while imports of crude or unmanufactured pumice dropped 44 percent. Receipts of both emery ore and corundum ore, however, increased sharply.

Abrasive materials imported for consumption in the United States, 1938–40, by kinds

Kind	1938		1939		1940

[4] Quantity not recorded.

The value of all exports of natural abrasive materials in 1940 was 13 percent higher than in 1939. The value of exports of grindstones and of emery and corundum abrasive wheels rose to $215,156 and $179,514, respectively—the highest figures since 1930. The classification "All other natural abrasives, hones, whetstones, etc.," increased in 1940 to $1,211,291—the largest value reported for this item since 1921.

Value of domestic abrasive materials exported from the United States, 1936–40

Material	1936	1937	1938	1939	1940
Grindstones	$140,614	$193,112	$122,720	$173,575	$215,156

SULFUR AND PYRITES

By Robert H. Ridgway, Allan F. Matthews, and A. W. Mitchell [1]

SUMMARY OUTLINE

World production of sulfur advanced appreciably in 1940, chiefly as a result of increased shipments from mines in the United States to its own defense industries and to those of the British Empire. World markets are supplied largely by the United States and Italy; the fairly large Japanese output is consumed at home. How the war affected the Italian sulfur industry during 1940 is not known, but the prices guaranteed to producers in Italy by the official Italian Sulfur Board were raised 20 percent in the middle of 1940. The United Kingdom doubled its takings of American sulfur in 1940. The largest producers of pyrites in 1940 doubtless continued to be Spain, Japan, Norway, and Italy, but the war has prevented publication of specific data. Spanish pyrites, the source of most of our imports and the only foreign pyrites quoted in American trade journals, ceased to be quoted after January 1941, and deliveries from Spain to the United States slumped heavily during the first quarter of 1941.

In the United States during 1940 shipments of sulfur reached an all-time record, and production fell just short of equaling the 1937 peak. Most of the sulfur shipped in 1940 was used at home in making sulfuric acid, for which there was increased demand in defense industries, but 21 percent was exported, mainly to the British Empire. The price of sulfur remained steady throughout 1940, and early in 1941 one of the largest American sulfur producers informed the Advisory Commission to the Council of National Defense that there would be "no increase in the base price of its product with respect to an amount of sulfur sufficient to meet demands of customers for 1 year at the current rate of sales." [2]

The position of the American sulfur industry in the present national defense effort as compared with that during the World War of 1914–18 is one of plenty instead of want. In 1914 less than 3 percent of the domestic sulfuric acid production came from native sulfur, and 50

[2] Steel, vol. 108, No. 2, January 13, 1941, p. 96.

percent of it was derived from imported Spanish pyrites. An acute shortage of sulfuric acid had developed by the summer of 1915, but the building of new plants and the stepping up of imports relieved the situation somewhat. After the unrestricted submarine campaign was begun in January 1917, however, it became difficult to obtain Spanish pyrites, and the problem of sulfur and pyrites supplies became increasingly grave. By Presidential proclamation in March 1918 sulfur, pyrites, and sulfuric acid were placed under a license system, and in July 1918 the War Industries Board assumed complete control of both production and allocation of sulfur and pyrites. Construction was commenced on a plant in Texas for large-scale production of sulfur, but 4 months later the Armistice was signed.

Salient statistics of the sulfur industry in the United States, 1925–29 (average) and 1937–40

1 Less than 1 ton.
2 Figures not yet available.

Since 1918 large sulfur deposits have been discovered in Texas and Louisiana, and the growth of American industry has created a demand for increasing tonnages of sulfur that has been ample to sustain large-scale production facilities both of sulfur and its principal product, sulfuric acid. Known reserves of unmined sulfur in the United States were expanded in 1940, and stocks of sulfur above ground at the mines on December 31, 1940, totaled 4,200,000 long tons—enough to last 1⅔ years, even at the increased current rate of consumption. Production of pyrites in the United States in1940 established a new record. New sulfuric acid plant capacity totaling more than 200 tons a day of contact acid (100-percent basis) went into operation in 1940, and new capacity planned for 1941 amounts to some 900 tons a day.[3] Sulfuric acid is important as a war material because it is a fundamental heavy chemical in the manufacture of fertilizers, refining of petroleum, preparation of other chemicals, pickling of steel, pro-

3 Chemical and Metallurgical Engineering, Mineral Acids and Sulfur: Vol. 48, No. 2, February 1941, pp. 90–92.

cessing of textiles, and—more directly strategic—the making of explosives. From the standpoint of munitions more can now be accomplished with fewer pounds of sulfur than during the earlier World War, according to Duecker.[4] At that time every 1,000 pounds of either smokeless powder or TNT made took 800 pounds of sulfur; but today 200 pounds of sulfur will produce 1,000 pounds of smokeless powder and 30 to 40 pounds of sulfur will yield 1,000 pounds of TNT.

An important publication issued in 1940 described the effects of sulfur dioxide fumes on vegetation.[5] It is the result of a 10-year research program by Canadian experts with the cooperation of United States Government specialists.

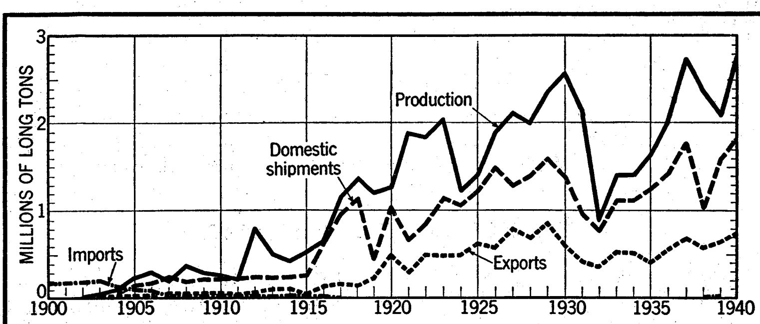

FIGURE 1.—Domestic production, domestic shipments, exports, and imports of crude sulfur, 1900–1940.

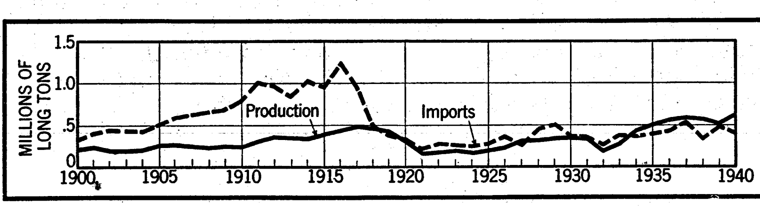

FIGURE 2.—Domestic production and imports of pyrites, 1900–1940.

SULFUR

Domestic production.—Production of crude sulfur in the United States in 1940 increased 31 percent over 1939, came within one-half percent of the 1937 peak, and was the second largest on record. Shipments from the mines in 1940 exceeded those of 1939 by 15 percent and those of 1937 (the previous high) by 4 percent to establish a new all-time record.

Sulfur produced and shipped in the United States, 1936–40

Year	Produced (long tons)	Shipped		Year	Produced (long tons)	Shipped	
		Long tons	Approximate value			Long tons	Approximate value
1936	2,016,338	1,968,820	$35,400,000	1939	2,090,979	2,233,817	$35,500,000
1937	2,741,970	2,466,512	44,300,000	1940	2,732,088	2,558,742	40,900,000
1938	2,393,408	1,628,847	27,300,000

[5] National Research Council of Canada, Effect of Sulfur Dioxide on Vegetation: Report 815, 1940, 447 pp.

Of the domestic output of sulfur reported for 1940, 81 percent came from Texas, nearly 19 percent from Louisiana, and less than 1 percent from California and Utah. The production of these last two States totaled 6,314 long tons in 1940 compared with 2,979 tons in 1939. The Bureau of Mines is not at liberty to publish figures for California and Utah separately. Active mines in 1940 are listed in the following table.

Mines that produced sulfur in the United States in 1940

Operating company	Name of mine	Location of mine
California:		
Big Pine Sulphur Co.	Crater Group	Bigpine, Inyo County.
Pacific Sulphur Co.	do	Do.
Louisiana: Freeport Sulphur Co.	Grande Ecaille	Port Sulphur, Plaquemines Parish.
Texas:		
Duval Texas Sulphur Co.	Boling Dome	Boling, Wharton County.
Do	Orchard Dome	Orchard, Fort Bend County.
Freeport Sulphur Co.	Hoskins Mound	Freeport, Brazoria County.
Jefferson Lake Sulphur Co., Inc.	Clemens Dome	Brazoria, Brazoria County.
Texas Gulf Sulphur Co.	Boling Dome	Newgulf, Wharton County.
Utah: Utah Sulphur Industries	Utah Sulphur Industries	Beaver, Beaver County.

THE INDUSTRY IN 1940 BY STATES

California.—Big Pine Sulfur Co. and Pacific Sulfur Co. reported production in 1940 from the Crater group of claims at Bigpine, Inyo County. The literature dealing with California sulfur deposits has been abstracted by the Works Projects Administration under the supervision of the California State Division of Mines.[6]

Louisiana.—Production of sulfur in Louisiana in 1940 totaled 512,935 long tons and was made by the Freeport Sulphur Co. from its operations at Grande Ecaille, Plaquemines Parish. The Jefferson Lake Sulphur Co., Inc., Brazoria, Tex., explored by drilling the Bay St. Elaine Dome, Terrebonne Parish, La., but the results of the work have not yet been ascertained.

Texas.—Texas supplied 81 percent of the domestic sulfur output in 1940. Five operations contributed to the total, but by far the largest output came from the Boling Dome property of the Texas Gulf Sulphur Co. at Newgulf, Wharton County. The following table, compiled from information issued by the Texas State Comptroller's Office, shows the quarterly production of sulfur in Texas for 1940.

Sulfur produced in Texas in 1940, by companies, in long tons

Company	First quarter	Second quarter	Third quarter	Fourth quarter	Total
Texas Gulf Sulphur Co.	334,113	340,224	375,299	378,571	1,428,207
Freeport Sulphur Co.	93,645	88,840	81,420	83,595	347,500
Jefferson Lake Sulphur Co., Inc.	58,102	50,809	59,044	51,714	219,669
Duval Texas Sulphur Co.	60,698	45,284	57,657	53,819	217,458
	546,558	525,157	573,420	567,699	2,212,834

The Freeport Sulphur Co. continued operations at Hoskins Mound, Freeport, Brazoria County; the Jefferson Lake Sulphur Co., Inc., at Clemens Dome, Brazoria, Brazoria County; and the Duval Texas

[6] California State Division of Mines, Sulfur: Mineral Abstracts, 1940, 22 pp.

Sulphur Co. at Boling Dome, Boling, Wharton County, and at Orchard Dome, Orchard, Fort Bend County.

Utah.—Sulfur production in Utah in 1940 came from the Utah Sulphur Industries plant at Beaver, Beaver County.

Recovery as byproduct.—The treatment of copper and zinc ores yields large quantities of sulfur, which is recovered at the mills as pyrites concentrate or at the smelters as sulfuric acid. The production of pyrites concentrate is discussed in the pyrites section of this report. In smelting copper and zinc concentrates sulfur is driven off as sulfur dioxide gas, which in some cases is reduced to elemental sulfur[7] but which at many smelters is used in the manufacture of sulfuric acid. The equivalent of about 162,000 long tons of sulfur was recovered as sulfuric acid annually from this source during the 5 years ended in 1939. Such sulfur is not included in the sulfur-production figures for the United States, but the following table shows the output of byproduct acid at both copper- and zinc-smelting plants. The acid reported is only that made from the sulfur content of sulfide ores but does include, for 1935 to 1938, inclusive, the relatively small amount of acid made from pyrites concentrate in Wisconsin.

Byproduct sulfuric acid (expressed as 60° B.) produced at copper and zinc plants in the United States, 1935–39, in short tons [1]

	1935	1936	1937	1938	1939
Copper plants	160,151	226,738	[2] 291,638	[2] 220,297	[2] 249,569
Zinc plants	443,476	505,882	542,356	466,879	528,872
	603,627	732,620	[2] 833,994	[2] 687,176	[2] 778,441

[1] Figures for 1940 not yet available.
[2] Includes a small amount of sulfuric acid produced as a byproduct in the roasting of high-sulfide gold and silver concentrates.

Byproduct sulfur is also recovered from coke-oven gas, water gas, refinery-still gas, natural gas, and other fuel gases. The removal of hydrogen sulfide from manufactured gases has long been accomplished by passing the gas through trays of iron hydroxide to form iron sulfide, known as spent oxide. This material has been used as a source of sulfur in Europe but not to any appreciable extent in the United States. During the last decade, however, the recovery of sulfur from fuel gases has been expanding in this country as a result of developments in various liquid-purification processes. Not all such processes are designed to permit recovery of sulfur as a byproduct, but those that do may be divided into two classes—those that recover elemental sulfur and those that give hydrogen sulfide as an end product. The latter has received increasing attention in recent years. Typically, processes that recover elemental sulfur operate on manufactured fuel gases, while those that recover hydrogen sulfide are applied to refinery still gas and natural gas, and usually these gases are under high pressure. Investigation has indicated, however, that the phenolate processes, at least, are adapted to the removal and recovery of sulfur from low-pressure, low-sulfur gases,[8] such as coke-oven gas.

[7] Howatt, D. W., Removal and Recovery of Sulfur from Smelter Gases: Chem. Age, vol. 43, Nos. 1118–1120, November 30, 1940, pp. 249–251, 255; December 7, 1940, pp. 259–261; December 14, 1940, pp. 273–275.
[8] Powell, Alfred R., Recovery of Sulfur from Fuel Gases: Ind. Eng. Chem., vol. 31, No. 7, July 1939, p. 795.

Most of the elemental sulfur recovered from gas purification results from operations using the Thylox process; only relatively minor amounts are recovered from Ferrox-process or Nickel-process operations. Production in 1940 (reduced to 100 percent sulfur) totaled 3,942 long tons, of which 3,528 tons valued at $143,769 were shipped. Output came from Illinois, Maryland, Missouri, New Jersey, New York, Washington, West Virginia, and Wisconsin, with New York the largest producer. The sulfur is produced and marketed either as a paste containing 39 to 57 percent sulfur or as dried, relatively pure sulfur. The fine particle size of the sulfur makes it valuable as a fungicide and insecticide for agricultural purposes, which absorb most of the shipments; some has been exported for such use. Of the 1940 shipments (reduced to 100 percent sulfur), 45 percent was in the form of paste and the remainder dried sulfur.

Most of the hydrogen sulfide recovered as a byproduct from fuel gases is either converted to sulfuric acid or burned as fuel. Recovery is by the phenolate, phosphate, and Girbotol processes. In 1940 the output of hydrogen sulfide extracted from fuel gases and, for the most part, converted to sulfuric acid was equivalent to 15,918 long tons of sulfur. Most of this was recovered by petroleum refineries in California and the remainder by companies in Indiana, New Jersey, Pennsylvania, and Texas.

The figures on byproduct yield of sulfur from gas purification are not included in the sulfur-production figures for the United States.

Stocks.—As production exceeded shipments in 1940, stocks at the mines increased during the year and on December 31 amounted to 4,200,000 long tons.

Price.—Sulfur is not quoted on any commodity exchange, and the sellers issue no list prices; however, the average quoted contract price for sulfur as reported by trade journals was unchanged at $16 a long ton f. o. b. mines throughout 1940.

Consumption.—The apparent domestic consumption of sulfur in 1940 increased 14 percent over 1939 and 2 percent over the previous peak in 1937 to attain a new record.

Apparent consumption of sulfur in the United States, 1936–40, in long tons

	1936	1937	1938	1939	1940
Shipments	1,968,820	2,466,512	1,628,847	2,233,817	2,558,742
Imports	729	628	2,603	13,976	27,845
	1,969,549	2,467,140	1,631,450	2,247,793	2,586,587
Exports:					
Crude	547,199	675,297	579,107	627,819	746,468
Refined	19,708	13,533	12,707	25,005	19,745
	566,907	688,830	591,814	652,824	766,213
Apparent consumption	1,402,642	1,778,310	1,039,636	1,594,969	1,820,374

The consumption of sulfur in various industries from 1936 through 1940 has been estimated by Chemical and Metallurgical Engineering as follows:

Sulfur consumed in the United States, 1936–40, by uses, in long tons [1]

Use	1936	1937	1938	1939	1940
Chemicals	620,000	777,000	484,000	695,000	800,000
Fertilizer and insecticides	266,000	415,000	220,000	370,000	410,000
Pulp and paper	260,000	302,000	174,000	240,000	320,000
Explosives	53,000	68,000	50,000	64,000	74,000
Dyes and coal-tar products	46,000	49,000	40,000	46,000	51,000
Rubber	39,000	37,000	29,000	43,000	47,000
Paint and varnish	54,000	64,000	50,000	49,000	54,000
Food products	4,500	6,000	5,500	6,000	6,000
Miscellaneous	78,000	82,000	47,500	82,000	86,000
	1,420,500	1,800,000	1,100,000	1,595,000	1,848,000

[1] Figures for 1937 and 1938 are not truly representative of consumption but rather of shipments to these specified industries. In 1938 consumers carried over large stocks from 1937, so that actual consumption in 1937 was less than the figures indicate and consumption in 1938 was larger than the above total.

Most of the sulfur and virtually all of the pyrites are consumed as sulfuric acid—one of the most fundamental of heavy chemicals. Consumption of sulfuric acid in 1940 increased 14 percent over 1939. The largest consumer—the fertilizer industry—used 15 percent more sulfuric acid in 1940 on account of increased demand for superphosphate. Second in importance as an outlet for sulfuric acid, petroleum refineries needed 5 percent more in 1940 than in 1939. Use of the alkylation process, which employs sulfuric acid as a catalyst, may reverse the long-time trend toward reduction of requirements in the refining industry. On the other hand, the hydrogen sulfide recovered in the refining process is being converted to sulfuric acid. The iron and steel industry—the third largest consumer—used 22 percent more sulfuric acid in 1940 than in 1939; practically all of this acid was used for pickling purposes.

Chemical and Metallurgical Engineering has estimated the consumption of sulfuric acid, by industries, from 1936 through 1940 as follows:

Sulfuric acid (expressed as 50° B.) consumed in the United States, 1936–40, by industries, in short tons

Industry	1936	1937	1938	1939	1940
Fertilizer	1,987,000	2,230,000	1,900,000	1,970,000	2,260,000
Petroleum refining	1,100,000	1,100,000	1,100,000	1,210,000	1,270,000
Chemicals	955,000	1,020,000	800,000	975,000	1,090,000
Coal products	770,000	865,000	585,000	740,000	900,000
Iron and steel	770,000	1,100,000	590,000	980,000	1,200,000
Other metallurgical	560,000	625,000	350,000	570,000	640,000
Paints and pigments	450,000	525,000	430,000	520,000	570,000
Explosives	222,000	180,000	140,000	160,000	175,000
Rayon and cellulose film	330,000	380,000	320,000	405,000	470,000
Textiles	108,000	112,000	90,000	116,000	125,000
Miscellaneous	380,000	450,000	355,000	384,000	450,000
	7,632,000	8,587,000	6,660,000	8,030,000	9,150,000

Sulfur is being sintered with soda ash at Mathieson Alkali Works, Lake Charles, La., to produce a synthetic salt cake used in the manufacture of pulp for kraft paper. Although not an emergency measure, appearance of the product has helped to stabilize the price of salt cake in the face of interrupted imports from Germany. Research work on the use of sulfur as an insecticide and fungicide is being sponsored by the Texas Gulf Sulphur Co., Inc., at Boyce Thompson Institute, Yonkers, N. Y.

FOREIGN TRADE

Exports of crude sulfur in 1940 were 19 percent above those in 1939 and the largest since 1929. Exports of treated sulfur, minor in comparison, dropped 21 percent in 1940 to previous levels from a 1939 high induced by large purchases in Greece. About 85 percent of the crude sulfur exported in 1940 went to the British Empire, and the United Kingdom doubled its take to supplant Canada as this country's principal sulfur market. Treated sulfur exported from the United States in 1940 went chiefly to British India, Canada, Brazil, Turkey, and the United Kingdom. Greece, which took more treated sulfur than any other country in 1939, was not a purchaser in 1940.

[1] Less than 1 ton.

Imports of sulfur into the United States in 1940 totaled 27,845 long tons. They were mostly byproduct sulfur from the Trail smelter in Canada and were used in the pulp mills of the Northwestern States.

WORLD PRODUCTION

World production of sulfur in 1940, including elemental sulfur recovered in the treatment of pyrites and as a byproduct from the treatment of industrial gases, is estimated at 3,500,000 long tons. The following table shows the output of native sulfur for the world from 1936 through 1940.

World production of native sulfur, 1936–40, by countries, in long tons [1]

[Compiled by L. P. Lounsbery]

Country	1936	1937	1938	1939	1940
Bolivia (exports)	935	1,712	1,632	2,126	4,065
Chile	[2] 25,525	[2] 16,766	20,959	26,999	(3)

United States	2,016,338	2,741,970	2,393,408	2,090,979	2,732,088

[1] Sulfur is also believed to be produced in Argentina, China, Spain, and the U. S. S. R., but the quantity is unknown.
[2] In addition, the following quantities of sulfur rock are reported: 1936, 11,612 tons (40–80 percent sulfur); 1937, 1,050 tons.
[3] Data not available.
[4] In addition, the following quantities of sulfur rock are reported: 1936, 20,743 tons; 1937, 19,793 tons; 1938, 16,545 tons. Similar data are not available for 1939 and 1940.
[5] In addition, the following quantity of sulfur rock is reported: 1936, 31,576 tons. Similar data are not available for 1937–40.
[6] Crude sulfur product.

Canada.—Elemental sulfur is being produced in the treatment of base-metal smelter gases at Trail, British Columbia, by the Consolidated Mining & Smelting Co., Ltd. The plant has a reported daily capacity of 150 tons of sulfur. The company states that the proportion of sulfur dioxide recovered from flue gases was increased to 70 percent in 1939 compared with 62 percent in 1938 and 53 percent in 1937. In 1940, 27,774 long tons of this byproduct sulfur were exported to the United States by Canada. In Quebec the Aldermac Copper Corporation, Ltd., has been building a plant to produce 50 to 100 tons of elemental sulfur daily from pyrites concentrates, but construction has been suspended because of the favorable market in the United States for pyrites concentrates.

The Trail smelter and a plant at Copper Cliff, Ontario, operated by the International Nickel Co. of Canada, produce sulfuric acid from waste gases. The former has a capacity of 600 tons of sulfuric acid a day and the latter 150 tons a day. In 1939 Canada recovered 86,437 long tons of sulfur as elemental sulfur or in sulfuric acid manufactured from smelter gases.

Chile.—Chile is the principal sulfur producer in South America. Production data for 1940 are not yet available, but exports were 27,643 long tons in 1940 compared with 7,495 tons in 1939. The increased demand for Chilean sulfur came principally from Argentina, which on May 27, 1940, discontinued importing sulfur from the United States.

Germany.—Germany does not produce native sulfur; but the output of byproduct sulfur from coking plants, low-temperature carbonization plants, and coal-hydrogenation plants now supplies a large proportion of the domestic demand.

Italy.—Italy, including Sicily, is the world's second largest producer of sulfur, and the output is subsidized with minimum prices to mine operators guaranteed by the Government through its Italian Sulfur Board (Ente Zolfi Italiani or ENZI). The guaranteed minimum prices announced on May 31, 1940, for various grades of Italian sulfur were as follows:

Gialla superiore (guaranteed 99.5 percent sulfur), 420 lire a metric ton.
Gialla inferiore (guaranteed 99.25 percent sulfur), 410 lire a metric ton.
Buona (guaranteed 98 percent sulfur), 398 lire a metric ton.
Corrente (guaranteed 97 percent sulfur), 383 lire a metric ton.

These prices represent an increase of 70 lire a metric ton for the first three grades and 65 lire a ton for the Corrente grade compared with the prices announced in 1939.

Japan.—Recent data on the output and exports of sulfur in Japan—the third largest producer—are not available. The industry in Japan suffered a great set-back in 1940 from a disaster that wrecked the important Matsuo mine in the Province of Rikuchu. On the other hand, a new sulfur deposit discovered at the Seishin River in Hokkaido is expected to yield 3,000,000 tons of sulfur out of a probable content of 6,000,000 tons. Initial production from the new deposit is expected to be 3,000 to 4,000 tons a month.[9]

Mexico.—Production of sulfur in Mexico has been negligible in recent years. Late in 1940, however, the British-owned Colima & Ransburg Syndicate, incorporated in California, began development of a sulfur deposit near Cuidad Guzman at the borders of the western States of Colima and Jalisco. An initial daily output of about 300 tons, soon to be doubled, is expected. The company will establish a refining plant at San Pedro, Calif., and ship its sulfur to Vancouver, Canada.

[9] Chemical and Metallurgical Engineering, vol. 47, No. 12, December 1940, p. 863.

Norway.—Production of sulfur in Norway results from the treatment of cupriferous pyrites at the Thamshavn plant of the Orkla Metal Co. Output in 1939 was reported [10] to be about 108,263 long tons.

Portugal.—Elemental sulfur is produced from the San Domingos mine in Portugal. Production during 1940 was 9,917 long tons compared with 11,221 in 1939. Imports of sulfur in 1940 were 4,012 long tons compared with 3,157 in 1939.

Spain.—The output of native sulfur in Spain is supplemented by elemental sulfur obtained in the treatment of pyrites. Figures for recent years are not available.

Sweden.—Elemental sulfur recovered as a byproduct from smelter gases by the Boliden Co. at Ronskar in northern Sweden is the only sulfur produced in Sweden. The output at this plant in 1938 was 17,512 long tons.

PYRITES

Domestic production.—Production of pyrites (ores and concentrates) in the United States in 1940 exceeded that of 1939 by 20 percent and reached a new record. Of the 1940 total 92 percent was fines and the remainder lump, the bulk of the former being flotation concentrates.

Pyrites (ores and concentrates) produced in the United States, 1936–40

Year	Quantity		Value	Year	Quantity		Value
	Gross weight (long tons)	Sulfur content (percent)			Gross weight (long tons)	Sulfur content (percent)	
1936	547,236	39.6	$1,666,194	1939	516,408	42.2	$1,550,449
1937	584,166	39.7	1,777,787	1940	617,513	41.7	1,892,000
1938	555,629	39.4	1,685,766				

In 1940, 422,092 long tons were consumed by the producing companies and 196,015 tons were sold compared with 323,027 tons and 188,712 tons, respectively, in 1939. Prices of domestic pyrites are not quoted on any commodity exchange, but the trade journals listed Spanish pyrites, c. i. f. Atlantic ports, bulk, at 12–13 cents per long-ton unit of sulfur throughout 1940. This quotation has remained unchanged for a decade but ceased to be given after January 1941.

Tennessee continued in 1940 as the principal producer of pyrites. Other producing States were California, Colorado, Illinois, Indiana, Missouri, Montana, New York, Virginia, and Wisconsin. There was no output from Kansas during 1940.

THE INDUSTRY IN 1940 BY STATES

California.—The Mountain Copper Co. was the only producer of pyrites in California in 1940; output came from the Hornet mine in Shasta County.

Colorado.—The output of pyrites in Colorado in 1940 totaled 14,473 long tons and was produced by Minnesota Mines, Inc., Clear

[10] Mining Journal (London), Norway in 1939: Vol. 208, No. 5455, March 9, 1940, p. 147.

Creek County, and by P. E. Hamm and John Andrew from a mill-tailings dump in Lake County.

Illinois.—From its coal-cleaning operations at the Atkinson mine in Henry County the Midland Electric Coal Corporation produced and shipped 13,021 long tons of pyrites (coal brasses) containing 46 percent sulfur in 1940.

Indiana.—The Snow Hill Coal Corporation produced and shipped 2,734 long tons of pyrites (coal brasses) containing 40–45 percent sulfur from its Talleydale mine in Vigo County in 1940.

Missouri.—The pyrites production of Missouri totaled 29,325 long tons in 1940 and came principally from the Moselle mine in Phelps County, operated by R. E. Carney. Other output came from the Libhart mine, Franklin County, operated by Roy C. Libhart, and the Cherry Valley mine, Crawford County, operated by H. H. Lark.

Montana.—The pyrites produced in Montana in 1940 came from the Anaconda Copper Mining Co. at Anaconda, where it is recovered as a flotation concentrate in copper-plant operation.

New York.—In 1940 New York produced 64,498 long tons of pyrites containing 49.45 percent sulfur.

Tennessee.—The pyrites output in Tennessee during 1940 came from the Tennessee Copper Co., Ducktown Basin, Polk County. It is produced as a flotation concentrate but does not enter the market, as all of it is used by the company in the manufacture of acid.

Virginia.—The only pyrites mined in Virginia in recent years has been by the General Chemical Co. from the Gossan mine at Cliffview, Carroll County. The entire output is concentrated by air tables for the manufacture of sulfuric acid in the company plant at Pulaski.

Wisconsin.—The one company reporting production of pyrites in Wisconsin in 1940 was the Vinegar Hill Zinc Co., which recovers pyrites by flotation from ores produced from several mines in the Platteville district, Grant County.

FOREIGN TRADE

Imports of pyrites in 1940 dropped 16 percent compared with 1939, although they were still 22 percent more than in 1938. Spain, the principal source, increased shipments in 1940, but this was more than counteracted by decreased imports from Canada.

Pyrites, containing more than 25 percent sulfur, imported into the United States, 1936–40, by countries

Country	1936		1937		1938		1939		1940

More than half of the pyrites imports in 1940 moved into Philadelphia. Shipments to Baltimore dropped heavily, but this was partly made up by increased amounts to Buffalo, New York City, and Philadelphia.

Pyrites, containing more than 25 percent sulfur, imported into the United States, 1936–40, by customs districts, in long tons

Customs district	1936	1937	1938	1939	1940

WORLD PRODUCTION

Recent figures on the pyrites output of the various countries are not obtainable, but annual world production has been running close to 10,000,000 metric tons of pyrites containing about 4,300,000 metric tons of sulfur.

World production of pyrites (including cupreous pyrites), 1938–40, by countries, in metric tons

[1] In addition to countries listed Belgium, China, Chosen, Czechoslovakia, Japan, Spain, and the U. S. S. R. produced pyrites, but production data are not available.
[2] Data not available.

Australia.—The principal output of pyrites is as a byproduct to the flotation treatment of copper ore at the Mount Lyell mines, Tasmania. In 1940 the Lake George lead-zinc mine at Captains Flat, New South Wales, began producing daily about 60 tons of pyrites carrying 60 percent sulfur. The Commonwealth Government has placed a bounty on pyrites and byproduct sulfur recovered from waste gases.

Canada.—Byproduct to the treatment of copper ores, about 500 tons of pyrites concentrate are produced daily at the Aldermac mine and about 100 tons daily at the Noranda mine, both in Quebec. The Britannia copper mine in British Columbia is also a large producer of pyrites. Canada exported 81,157 long tons of pyrites to the United States in 1940 and 176,804 tons in 1939.

Germany.—There was a reported intensification of pyrites mining in Germany and Poland in 1940 as a result of difficulties of obtaining adequate supplies from abroad.

Greece.—Early in 1940 Greece was reported to have sold 50,000 tons of pyrites to Italy and to be in hopes of making additional shipments to that country later in the year.[11] Greek exports of pyrites in 1939 totaled about 182,000 metric tons and went primarily to Netherlands, France, and Germany.

Italy.—Three pyrites mines at Gavorano in the Tuscan Moaremma are now said to be producing 600,000 tons annually. An additional 300,000 tons comes from mines in the Trentino, Agordo, and Aosta Valleys.

Japan.—Japan is one of the leading producers of pyrites, but data on production have not been available since 1936. Japanese production of pyrites in 1940 was stimulated by a disaster that wrecked the Matsuo sulfur mine. Pyrites recovered from treatment of copper ores is said to yield about 200,000 tons of sulfuric acid a year. Japan is believed to be self-sufficient in pyrites supplies.

Norway.—Norway is the third largest producer of pyrites, but the state of the industry since German occupation in April 1940 is uncertain. The major deposits occur at Orklatal and Roros south of Trondhjem, at Sulitjelma on the southern shore of Narvik Fjord, and in the vicinity of Bergen, at all of which localities fighting was reported to have taken place in the spring of 1940.

Portugal.—The largest source of pyrites in Portugal is the San Domingo property at Mertola in the province of Alemtejo; it supplies one-fourth of the Portuguese output. Of the 432,895 metric tons of pyrites exported in 1939, about three-fourths went to France and the remainder to Belgium and Great Britain.

Spain.—Spain is normally the principal world producer of pyrites, but since official production figures have not been released in recent years it is not known how war conditions have affected the industry. Unofficial data indicate that exports dropped in 1939. The Rio Tinto mines in the Province of Huelva yield most of the output.

Sweden.—Most of the Swedish pyrites production comes from one of the Boliden mines in northern Sweden.

United Kingdom.—In 1940 orders were issued making all kinds of pyrites and sulfur subject to licensing restrictions.

Yugoslavia.—Two-thirds of the Yugoslav pyrites production comes from the Stantrg, Vojetin, and Dobrevo mines in Serbia; these formerly were operated by Trepca Mines, Ltd., but have been in German hands since April 1941.

PHOSPHATE ROCK

By Bertrand L. Johnson and K. G. Warner

SUMMARY OUTLINE

Domestic demand for phosphate rock in 1940 jumped 16 percent over that in 1939, an increase of 442,597 long tons, and far more than counterbalanced the 21-percent decrease—a little less than 200,000 tons—in exports, which declined to 751,495 tons. Total shipments of phosphate rock from American mines in 1940 were 4,002,700 long tons (see fig. 1) valued at $12,334,662, an increase over 1939 of nearly a quarter of a million tons (7 percent) but about 100,000 tons less than the 1920 record peak. Mine output likewise passed the 4-million-ton mark, exceeding 1939 but considerably below the 4,261,416-ton peak of 1937. Imports of phosphate rock were restricted to 2,953 long tons from Curaçao. No apatite was imported during the year. By a Presidential proclamation of March 4, 1941, effective March 24, 1941, phosphate rock was placed under export-license control.

Production.—Phosphate rock was mined in Florida, Tennessee. Idaho, and Montana, and apatite was recovered from titanium-bearing ores in central Virginia. Total mine production of 4,068,077 long tons in 1940 was a little greater than in 1939, but this increase did not raise production to the 4,261,416-ton record attained in 1937. Production in Florida fell slightly, but the decrease was more than overcome by increases in both Tennessee and the Western States, where the mined production reached all-time highs. In 1939 and in 1940 the mine production in Tennessee exceeded a million tons.

Phosphate rock mined in the United States, 1931–40, by States, in long tons

Year	Florida	Tennessee	Western States	United States	Year	Florida	Tennessee	Western States	United States
1931	2,155,903	393,925	116,681	2,666,509	1936	2,645,819	[1] 737,866	79,152	3,462,837

[1] Includes small quantity of apatite from Virginia.
[2] Includes small quantity of apatite from Virginia and phosphate rock from South Carolina.

Sales.—The quantity of phosphate rock sold or used by producers in 1940 was nearly a quarter of a million tons (7 percent) more than in 1939 but was about 100,000 tons less than the 1920 record. The total value of the shipments was only slightly larger than in 1939, and the average value a ton dropped from $3.27 in 1939 to $3.08 in 1940, a slump not evident in the published price quotations. The average value of total sales as well as of land pebble has trended downward slightly in recent years. (See fig. 2.)

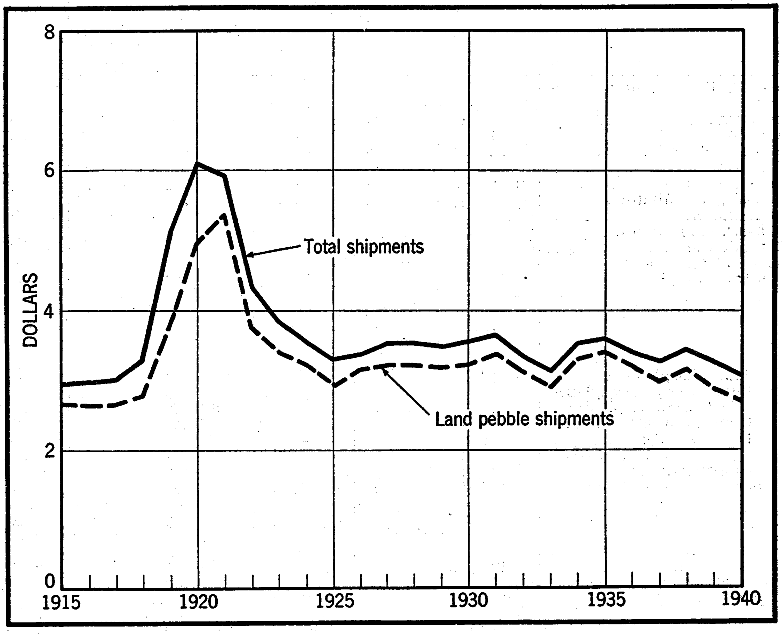

FIGURE 2.—Average values f. o. b. mine shipping point a long ton of total phosphate rock and land pebble phosphate rock shipped, 1915–40. (From reports of producers.)

Phosphate rock sold or used by producers in the United States, 1936–40

Year	Long tons	Value at mines		Year	Long tons	Value at mines	
		Total	Average			Total	Average
1936	3,351,857	$11,406,132	$3.40	1939	3,757,067	$12,294,042	$3.27
1937	3,956,189	12,975,268	3.28	1940	4,002,700	12,334,662	3.08
1938	3,739,238	12,952,143	3.46				

Distribution of sales.—Shipments of domestic phosphate rock have in the recent past fallen into two distinct groups according to grade—one below 60 percent B. P. L. (bone phosphate of lime) and the other containing 68 percent B. P. L. and higher grades. An intermediate group, which rose to 55,359 tons in 1940, appears to be developing, with grades between 60 and 66 percent B. P. L. Ninety percent of the phosphate rock shipped in 1940 was of 68 percent or higher grades. Nearly 60 percent of the total sales are of grades containing 72 to 75 percent B. P. L., inclusive. In 1940, 64 percent of the domestic phosphate rock sold or used by producers went into the manufacture of superphosphates compared with 58 percent in 1939, while the percentage exported decreased from 25 in 1939 to 19 in 1940. Relative percentages of quantities used for other purposes were unchanged in 1940 from 1939.

[1] Bone phosphate of lime.
[2] Figures not available.
[3] Included under "Undistributed"; Bureau of Mines not at liberty to publish figures.
[4] Includes grades of B. P. L. content between 68 and 70; 69/66; 71; 73; 73.8; 74.8; 76; 76.55; 78/76; 78; and above 85 percent; also ground phosphate rock and dust, B. P. L. content not known.
[5] Less than 0.5 percent.
[6] Includes some calcined phosphate and phosphatic material used in pig-iron blast furnaces, in concrete aggregates, and in the manufacture of concentrated fertilizers.
[7] As reported to the Bureau of Mines by producers (exclusive of exports by dealers, etc.).

The preceding table, showing the distribution of phosphate rock sold or used by producers, by grades, uses, and classes of consumers, is compiled from reports to the Bureau of Mines by the domestic producing companies. In the past 10 years gradually increasing quantities of phosphate rock have entered into superphosphates, chemicals, and "all other" uses, as shown in the accompanying diagram. (See fig. 3.)

Consumption.—The apparent domestic consumption of phosphate rock in 1940 was 3,254,158 long tons, the greatest ever recorded, exceeding the previous maximum of 3,034,333 tons in 1920 by 219,825 tons. The main factor in this increase was the greatly augmented quantity of Florida land pebble going into the manufacture of domestic superphosphates.

Prices.—Trade-journal quotations for various grades of domestic phosphate rock were unchanged during 1940 from the latter part of 1939. Florida land pebble, 68 percent B. P. L., continued at $1.90 a ton; 70-percent grade at $2.15; 72-percent grade, $2.40; and the

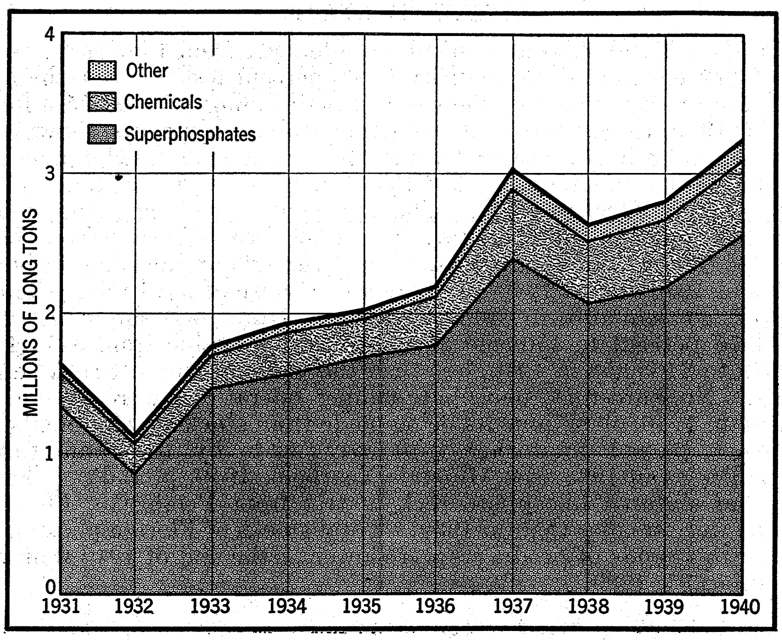

FIGURE 3.—Phosphate rock sold or used by producers in the United States, 1931–40, by uses.

75-percent grade at $2.90. The Florida high-grade hard-rock quotation remained at $4.35 throughout the year, and the Tennessee quotations for the 72-percent grade stayed at $4.50 and for the 75-percent grade at $5.50.

On February 10, 1941, the special Federal grand jury, which has been engaged at Winston-Salem, N. C., for nearly a year in an investigation of the fertilizer industry, returned an indictment of 102 defendants, comprising 2 associations (the National Fertilizer Association and the Superphosphate Association), 64 fertilizer manufacturing and distributing corporations, and 36 officials of the associations and corporations, on two counts, charging combination and conspiracy (1) to fix prices and (2) to restrict competition.

Brief reports covering the activities during 1939 and 1940 of the Joint Congressional Committee to Investigate the Adequacy and Use of the Phosphate Resources of the United States, pursuant to Public Resolution 112, have been published.[1]

General reports published in 1940 covering the phosphate-rock industry include papers by Barr, Jacob, and Johnson.[2]

Scientific papers published include one by Mansfield [3] on the part played by fluorine in the deposition of phosphate rock and a description by McConnell[4] of a carbonate-apatite from Magnet Cove, Ark.

REVIEW BY STATES

Florida.—Total shipments of phosphate rock from Florida in 1940 were 6 percent greater in quantity but 2 percent less in value than in 1939, the average value of the shipments declining from $2.95 a long ton in 1939 to $2.72 in 1940. Land-pebble shipments, however, increased in both quantity and value; the tonnage increased 9 percent, but the total value increased less than 3 percent. The average value dropped from $2.89 to $2.71. The land-pebble-producing companies were the same as those operating in 1939 (see Minerals Yearbook 1940, p. 1305). Shipments of soft rock were about the same in both 1939 and 1940 and in 1940 nearly doubled those of hard rock. They dropped considerably in value, however. Hard-rock shipments declined 75 percent in tonnage and decreased in value from $411,455 in 1939 to $100,353 in 1940, less than the value of the soft-rock shipments. No hard-rock phosphate-mining operations were active in Florida in 1940, all shipments being made from stocks. Shipments of hard-rock phosphate during 1940 were made by the same three companies as in 1939 (see Minerals Yearbook 1940, p. 1305). Shipments of sintered phosphate rock matrix from Pembroke, Fla., to Europe were smaller than in 1939. Total stocks of Florida phosphate rock in the hands of producers were lower at the end of 1940 than on December 31, 1939.

[2] Includes sintered matrix.

Electrostatic separation has been applied to recleaning land-pebble phosphate-rock flotation concentrates in Florida. A full-size refining plant built by the American Agricultural Chemical Co. in conjunction with the Ritter Products Co. of Rochester, N. Y., adjacent to the drying plant of the former company at Pierce, Fla., for electrostatic refining of phosphate-rock flotation concentrates by the Johnson process, was put in operation in September 1938. The process and the operating results are described in a recent article by H. B. Johnson.[5]

Cash and Colbert [6] describe the pebble-phosphate mining district, its production, mining methods, safety organizations, and accident experience and give a digest of the Florida Workmen's Compensation Act.

Roundy's[7] detailed description of the results of the Federal Geological Survey investigations in both the hard-rock and land-pebble phosphate-rock fields in 1934 and 1935 was published early in 1941.

Four comprehensive illustrated articles describing in detail the mining, washing, flotation, and drying technique of the various companies in the Florida land-pebble phosphate-rock field, by A. H. Hubbell, associate editor of the Engineering and Mining Journal, were published in that journal during the latter part of 1940.[8] The mining, washing, and flotation operations of the Swift & Co. Fertilizer Works, 2 miles south of Fort Meade, Fla., in the land-pebble field are described by Bror Nordberg.[9]

A new fertilizer plant recently erected by the American Agricultural Chemical Co. near Pierce, Fla., began operations in February 1940 Sulfuric acid is made by burning sulfur in an adjacent acid plant, and phosphate rock is treated with this acid to produce ordinary superphosphate.

The International Agricultural Corporation enlarged its central dry-grinding plant by adding a large bowl mill as well as storage and loading facilities to meet an increasing demand for ground phosphate rock.

During 1940 a flotation plant was installed by the Phosphate Mining Co., operating in the land-pebble field, to recover fertilizer-grade phosphates from washer tailings and waste. This company is also constructing a plant to manufacture sulfuric acid by the contact process and produce phosphoric acid by the wet method, supplementing the output from its electric furnace. Triple superphosphate and other fertilizer phosphate chemicals will be produced.

Recent practice in the mining and preparation of Florida hard rock phosphate is described in a paper by Kibler.[10]

Tennessee.—The tonnage of phosphate rock sold or used by producers in Tennessee, plus a small quantity of apatite from Virginia—994,361 long tons in all—topped the previous all-time high of 1939 (938,448 long tons) by 6 percent and fell only a little short of 1 million tons. No blue or white phosphate rock was marketed in 1940. All of that shipped from Tennessee was brown-rock phosphate. Stocks of phosphate rock in the hands of Tennessee producers at the close of 1940, slightly larger than on December 31, 1939, were a little over a quarter of a million tons.

A comprehensive discussion of the Tennessee phosphate deposits, by R. W. Smith and Geo. I. Whitlatch,[11] was published in 1940. This

[1] Separate figures for brown rock and blue rock cannot be given without disclosing confidential data regarding blue-rock production.
[2] Includes sintered matrix.

Six phosphate-rock mining companies produced 96 percent of the entire phosphate-rock production of Tennessee in 1940: The Armour Fertilizer Works, Charleston Mining Co., Federal Chemical Co., Hoover & Mason Phosphate Co., International Agricultural Corporation, and Monsanto Chemical Co.

The mining and treatment of brown-rock phosphate at the properties of the above companies (with the exception of the Federal Chemical Co.) are described in two recent articles by A. H. Hubbell.[12]

The Armour Fertilizer Works erected and began to operate a brown-rock-phosphate flotation plant at its Century property to treat the lower grades of washed phosphate rock. The Federal Chemical Co. and the Charleston Mining Co. completed the remodeling of their plants. The Hoover & Mason Co. began extensive alterations in the method of feeding phosphate rock to its washing plant. The Victor Chemical Works did no actual mining of phosphate rock but purchased all its requirements of Tennessee brown rock. In August 1940 it began to construct a fourth electric furnace at its Mount Pleasant plant. The International Agricultural Corporation installed a unit for producing defluorinated phosphate at its Wales (Tenn.) plant; the commodity is to be used in animal feeds to replace bone meal.

The Monsanto Chemical Co. added to its phosphate-rock holdings in Tennessee and early in January 1941 also put in operation a fourth electric furnace to produce elemental phosphorus from Tennessee brown rock. The operations of this company are described and illustrated in detail in a paper by W. E. Trauffer.[13]

According to its Annual Report,[14] the Tennessee Valley Authority produced about 80,000 tons of concentrated superphosphate and shipped 82,000 tons in the fiscal year ended June 30, 1940. More than 4,000 tons of calcium metaphosphate were produced and about 8,000 tons shipped. Limited quantities of fused phosphate rock, potassium metaphosphate, and potassium-calcium metaphosphate were produced for experimental tests. Raw rock for making elemental phosphorus was obtained both from the Florida land-pebble

[14] Tennessee Valley Authority, Annual Report for the Fiscal Year Ended June 30, 1940: Washington, D. C., 1941, 414 pp.

and the Tennessee brown-rock fields. Recent improvements in the electric-furnace method of smelting rock phosphate have lowered the cost of producing concentrated superphosphate and calcium metaphosphate. To reduce costs still further the T. V. A. is giving attention to salable byproducts of fertilizer manufacture. Additional phosphate land was purchased during the fiscal year, and seven tracts in Maury County were sold to the Monsanto Chemical Co. Holdings of phosphate lands, as of June 30, 1940, approximated 2,900 acres and contained 16,000,000 tons of phosphate-rock matrix. Construction is reported to have been commenced on a sintering plant at Godwin, Tenn., and a large washing and processing plant at the Akin place.

Some elemental phosphorus of Tennessee origin was purchased by the T. V. A. in 1940 for use in manufacturing phosphoric acid for production of superphosphate.

Regarding operations at Muscle Shoals, the T. V. A. states that "The requirements of national defense can be met without interrupting the Authority's work on phosphatic fertilizer conducted at this plant."

Virginia.—Apatite-bearing titanium ore (nelsonite) was mined by the Southern Mineral Products Corporation, a subsidiary of the Vanadium Corporation of America, in Amherst County, Va., and milled at its nearby plant, Piney River, Nelson County, Va.

Moore,[15] in Economic Geology, discusses the origin of the nelsonite dikes of this region, suggesting a slightly different origin for the nelsonites from that proposed in earlier papers by Watson and Taber and by Ross and favoring an igneous origin for the dikes from hypersthene granodiorite, with contemporaneous and later alteration of the dikes by hydrothermal solutions from the cooling granodiorite magma.

Western States.—In 1940, as usual, Idaho and Montana were the only Western States that produced phosphate rock. The Anaconda Copper Mining Co. operated its No. 3 mine at Conda, Caribou County, Idaho, and shipped 99,088 long tons. There were two producers in Montana. The Montana Phosphate Products Co. of Trail, British Columbia, the larger of the two, operated the Anderson and Graveley mines and some Federal Government leases near Garrison, Mont., supplying the requirements of the Consolidated Mining & Smelting Co. of Canada, Ltd., at Trail. The Mineral Hill Mining Co. shipped several thousand tons of phosphate rock from its mine near Avon, Powell County, Mont., to the Anaconda (Mont.) plant of the Anaconda Copper Mining Co.

The mine and plant of the Anaconda Copper Mining Co. at Conda, Idaho, and the methods of mine haulage are described in recent articles.[16]

Late in 1940, Mansfield[17] revised his earlier estimate[18] of the reserves of 50-percent or better grade phosphate rock in Utah, raising the quantity to 634,050,000 long tons.

In an address before the Fourth Regional Phosphate Conference, Ogden, Utah, September 5–6, 1940, Brand[19] discussed in considerable

detail the future economic possibilities of the phosphate industry in the Western States; he estimated 600,000 tons of 33-percent P_2O_5 phosphate rock as the ultimate market upon the basis of a complete-fertilizer-use economy for that region, normally destined to be supplied its phosphates from the western deposits (the Dakotas, Nebraska, Colorado, Montana, Wyoming, Idaho, Utah, Nevada, and that part of Oregon and Washington east of the Cascade Range), and discussed the not unduly promising possibility of wider geographical extension of the use of western phosphate.

In August 1940 the A. R. Maas Chemical Co. began direct production of phosphoric acid from elemental phosphorus at Los Angeles, Calif.; its plant was reportedly the first of its kind in the West.

Western States phosphate rock sold or used by producers, 1936–40

FOREIGN TRADE [20]

Imports.—Imports of phosphate rock into the United States continued to recede, dropping in 1940 to 2,953 long tons valued at $19,536; all came from the island of Curaçao in the Netherlands West Indies. No apatite was imported during the year. Imports of guano were only 785 tons and continued a marked decline that began in 1938. Imports of basic slag, although only 3,397 tons in 1940, were over eight times as great as in 1939 and more than four times as great as in any recent year. Imports of ammonium phosphate used as fertilizer continued their steady increase, reaching 44,782 tons in 1940.

Phosphate rock and phosphatic fertilizers imported for consumption in the United States, 1936–40

Fertilizer	1936		1937		1938		1939		1940

[1] Not shown separately; included with "Phosphates, crude, not elsewhere specified" beginning January 1, 1937.
[2] New classification beginning January 1, 1937.

[20] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

Exports.—A 21-percent decrease (nearly 200,000 long tons) in exports in 1940 brought down the total to 751,495 tons valued at only $3,845,495 from 949,006 tons valued at $5,233,104 in 1939. Not only was a smaller quantity of a lower total value exported, but the average value a ton declined further—from $5.51 in 1939 to $5.12 in 1940. Most of the exports were from Florida, but some were from the Western States.

The quantity and value of exports of both high-grade hard rock and land pebble again were less in 1940 than in 1939. The quantity of exports of other phosphatic materials, including sintered phosphate rock material, was also less, but there was a slight increase in value, possibly owing to smaller shipments of sintered matrix. No high-grade hard-rock phosphate or land pebble was exported to Germany, formerly one of the leading consumers of domestic rock. In 1940 the United Kingdom, in sharp contrast with its usual custom, took extremely large quantities of land pebble (218,872 tons)—nearly a third of the total exports—and was the leading importer of that commodity. Japan was a very close second with 218,456 tons, but accepted a much lower grade rock. These two countries bought nearly two-thirds of the total land-pebble exports. The Union of South Africa received 51,311 tons, and Canada increased its imports to 87,112 tons. The following tables show the total exports of high-grade hard rock and land-pebble phosphate rock, as well as shipments of each type of rock to various countries from 1936 to 1940, inclusive.

Phosphate rock exported from the United States, 1936–40

Year	Long tons	Value		Year	Long tons	Value	
		Total	Average			Total	Average
1936 [1]	1,208,951	$6,776,917	$5.61	1939	949,006	$5,233,104	$5.51

1938 [2]	32,581	208,550			

[1] Includes bone ash, dust, and meal; animal carbon for fertilizer; basic slag; etc.
[2] Includes sintered matrix.

The following table shows exports of high-grade hard rock from the various customs districts. In 1940 the relative positions of the Florida and Montana-Idaho customs districts as exporters of this type of rock were reversed because it was impossible to make shipments from Florida to various European markets and Florida shipments consequently dropped from 87,821 long tons in 1939 to 19,377 in 1940. On the other hand, shipments from the Montana-Idaho customs district to Canada increased 38 percent.

Shipping conditions created by the European war have diverted to the American route through Buffalo a large movement of phosphate rock from Florida to Canada. Previously, Canadian-bound phosphate rock has moved to inland ports over the St. Lawrence River.

High-grade hard-rock phosphate exported from the United States, 1939–40, by customs districts

Customs district	1939		1940	
	Long tons	Value	Long tons	Value
Buffalo	2	$25		
Dakota	23	260	16	$230
Florida	87,821	564,353	19,377	133,508
Michigan	251	2,595	402	2,756
Montana and Idaho	44,873	273,373	61,975	372,872
New York			673	3,365
Ohio			912	8,247
St. Lawrence	13	119	19	257
Virginia			760	7,352
Washington			458	2,862
	132,983	840,725	84,592	531,449

WORLD PRODUCTION

Phosphate mining on the island of Curaçao in the Netherlands West Indies ceased in 1940, presumably for the duration of the war. The Mijnmaatschappij Curaçao, an affiliate of John Godden & Co., Ltd., of London, had mined phosphate rock at Newport, Curaçao, since 1875. In recent years shipments had averaged about 86,000 metric

World production of phosphate rock, 1936–40, by countries, in metric tons

[Compiled by L. P. Lounsbery]

[1] Estimated.
[2] Data not available.
[3] Estimated (Imp. Inst., London).
[4] Including exports as follows: 1936, 1,247,923 tons; 1937, 1,484,562 tons; 1938, 1,427,643 tons; 1939, 1,465,673 tons; 1940, data not available.
[5] Exports during fiscal year ended June 30 of year stated.
[6] Apatite concentrates. Production of apatite ore in 1936 totaled 2,000,000 tons. In addition, low-grade phosphate rock is produced, but production data are not available.

tons of 77- to 79-percent B. P. L. grade. Germany was formerly the principal market, but in late years Finland, Denmark, Netherlands, Sweden, and Lithuania were also important outlets. Some had also been exported to the United States. A skeleton staff remained at the plant to keep the machinery in order and protect the property;[21] it has been learned that operations were renewed early in 1941 by this concern.

The phosphate works on Nauru Island were reported to have been shelled by German raiders near the end of 1940 and were considerably damaged; several phosphate-carrying boats were sunk. The deposits in this British-controlled island in the Pacific are operated by the British Phosphate Commission for the Governments of Australia, New Zealand, and the United Kingdom.

TECHNOLOGY

Besides the numerous technical articles cited in other parts of this chapter, several papers have appeared on various phases of processing or utilizing phosphates.

In a study of the methods of processing phosphate rock Jacob[22] considers ordinary superphosphates, double superphosphates, phosphoric acid, ammoniated superphosphates, ammonium phosphates, organic phosphates, dicalcium and tricalcium phosphates, basic slag, defluorinated phosphate, calcium metaphosphate, raw phosphate rock, and other phosphates. Jacob, Marshall, Reynolds, and Tremearne[23] describe the volatilization of fluorine in the manufacture of superphosphates; the fluorine volatilized from the rock in the production of superphosphate ranged from 10.7 to 42.1 percent of the fluorine content and in the production of double superphosphate from 30 to 75 percent. Copson and Newton[24] discuss the proportioning of phosphate-rock dust and phosphoric acid in making superphosphate; Brunauer and Schultz,[25] the oxidation of phosphorus by steam; Shuey,[26] the free acids in superphosphate; and Frear, Deese, and Lefforge,[27] the effects of impurities on various properties of calcium metaphosphate. In a recent article, Davies[28] covers the use of phosphoric acid or phosphates in clarifying sugar. A series of papers presented before the forty-third annual meeting of the American Ceramic Society, April 1, 1941, included reports on the characteristic properties of phosphate glasses by Kreidl and Weyl,[29] on phosphorous compounds as reducing and fining agents for glasses by Weyl and

Superphosphate was officially defined by the Association of Official Agricultural Chemists at its annual meeting in Washington in October 1940 as: "A product obtained by mixing rock phosphate with either sulfuric acid or phosphoric acid, or with both acids. The grade that shows the available phosphoric acid shall be used as a prefix to the name, for example, 20 percent superphosphate."

At the annual meeting in 1939 a definition had been tentatively adopted which specified merely that the P_2O_5 content must be chiefly mono-calcium phosphate but did not name the materials from which it might be produced. This definition would have permitted the inclusion, as superphosphate, of a product made by mixing concentrated phosphoric acid with limestone. The recently approved definition, however, is virtually the same as that which has prevailed in recent years and limits the term "superphosphate" to a product made from phosphate rock.

The manufacture of superphosphate by the Davison Chemical Corporation at Curtis Bay, Baltimore, Md., was described in detail in two recent reports.[32]

Marshall, Hendricks, and Hill, in one of a series of papers on the composition and properties of superphosphate, discuss the conditions that affect the distribution of water, with special reference to the calcium sulfate constituent.[33]

BASIC SLAG

Basic slag is an important source of phosphorus. Little is produced in the United States—only a few thousand tons a year in the Birmingham iron district of Alabama—and only a small quantity is imported annually; in Europe, however, where it is produced in abundance, basic slag has become an important competitor of phosphate rock and superphosphate as a source of fertilizer phosphorus.

No figures for the production of basic slag in European countries during 1939 or 1940 are available. Output in the United States for these years probably was comparable with that in years recently preceding. Production data for 1935–38 are given in Minerals Yearbook 1940 (p. 1319).

Imports of basic slag into the United States in 1940—3,397 long tons valued at $10,656—were much larger than in recent years, but the average value was much lower.

The history of the development of the basic process of steel making, which yields the basic slag used as a phosphatic fertilizer, is related in a recent biography [34] of its inventor, Sidney Gilchrist Thomas. He is so well known for the application of his invention to the basic Bessemer process that in Europe it is known as the Thomas process.

TALC, PYROPHYLLITE, AND GROUND SOAPSTONE[1]

By Bertrand L. Johnson and K. G. Warner

SUMMARY OUTLINE

Sales of talc, pyrophyllite, and ground soapstone made another new record in 1940, exceeding the 1939 peak by over 27,000 short tons

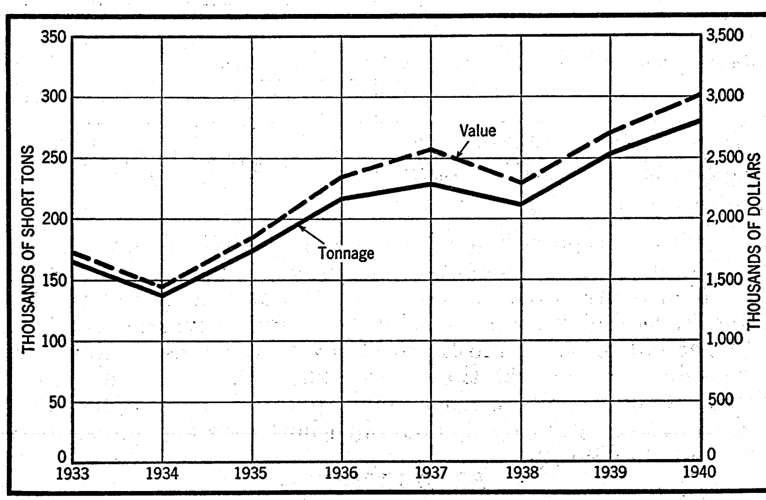

Figure 1.—Sales of domestic talc, pyrophyllite, and ground soapstone, 1933–40.

(see fig. 1.); both quantity and value increased 11 percent, reaching 281,375 tons valued at $3,008,320. Sales of crude, sawed and manufactured, and ground all rose in both quantity and value, the greatest increase being in ground products. Imports of crude materials were less in 1940 than in 1939, both as to quantity and value, but imports of "ground, washed, or pulverized" materials and "cut and sawed" products were larger in both quantity and value. Exports of "talc, steatite, soapstone, and pyrophyllite, crude and ground," were slightly larger in 1940 than in 1939, but the value of talcum powder exported was less.

Pyrophyllite is included with talc in this discussion solely because the custom was established many years ago in these annual reports of the Bureau of Mines. Although pyrophyllite resembles talc in certain physical properties, it is a hydrous aluminum silicate ($Al_2Si_4O_{10}(OH)_2$) instead of a hydrous magnesium silicate like talc ($Mg_3Si_4O_{10}(OH)_2$). Some mineralogists class pyrophyllite as one of the kaolin minerals (see Minerals Yearbook, 1939, p. 1273).

[1] Soapstone sold in slabs or blocks is included in the chapter on Stone.

Salient statistics of the talc, pyrophyllite, and ground-soapstone industries in the United States, 1939–40

	1939		1940	
	Short tons	Value	Short tons	Value
Sales by producers:				
Crude	15,722	$82,188	[1] 17,724	[1] $118,424
Sawed and manufactured	1,871	77,915	1,894	140,565
Ground	236,383	2,540,731	261,757	2,749,331
	253,976	2,700,834	[1] 281,375	[1] 3,008,320
Imports for consumption:				
Crude and unground steatite and French chalk	133	2,392	93	1,479
Ground, washed, or pulverized	25,943	408,178	28,145	465,049
Cut and sawed	94	14,651	125	20,739
	[2] 26,170	[2] 425,221	[2] 28,363	[2] 487,267
Exports:				
Talc, steatite, and soapstone, crude and ground	9,047	162,426	[3] 9,402	[3] 167,992
Powder—talcum (in packages), face, and compact	(4)	1,115,176	(4)	945,530
		1,277,602		1,113,522

[1] Includes a small quantity of pinite from Nevada.
[2] Exclusive of "manufactures n. s. p. f.; except toilet preparations," as follows: 1939, 98 short tons valued at $27,398; 1940, quantity not available, valued at $21,588.
[3] Includes pyrophyllite.
[4] Quantity not recorded.

Eleven States reported sales of talc, pyrophyllite, ground soapstone, or pinite in 1940 compared with nine in 1939. Eight of these States, which contributed 86 percent of the output, are in the East; the other three—California, Washington, and Nevada—which supplied 14 percent of the domestic total, are in the West. New Jersey reported sales for the first time since 1935. Nevada (reporting for the first time since 1930, when a small quantity of pyrophyllite was shipped from Pershing County) supplied both talc and pinite in 1940 from Esmeralda County.

PRODUCTION

The following list of producers of talc, pyrophyllite, soapstone, and pinite in the United States is compiled from reports made to the Bureau of Mines covering operations in 1940.

Producers of talc, pyrophyllite, and soapstone in the United States in 1940

Producer	Material [1]	Product	Location	
			County	Nearest town
CALIFORNIA				
Blue Star Mines, Ltd., 840 San Julian St., Los Angeles.	Talc	Crude, ground	Inyo	Bigpine.

SALES

Sales of talc, pyrophyllite, and ground soapstone by producers again increased in 1940 and reached an all-time record of 281,375 short tons valued at $3,008,320, a rise of 27,399 tons in quantity and $307,486 in value over 1939, an increase of 11 percent in both quantity and value. Sales of crude, sawed and manufactured, and ground materials all rose in 1940 over 1939 levels; sales of sawed and manufactured materials were only slightly greater, while sales of crude were up 13 percent and those of ground products increased 11 percent. Sales of ground materials alone in 1940 again exceeded the total sales of all classes in any previous year.

Talc, pyrophyllite, and ground soapstone sold by producers in the United States, 1936–40, by classes

Year	Crude		Sawed and manufactured		Ground		Total	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value
1936	10,910	$59,556	618	$90,542	204,663	$2,193,073	216,191	$2,343,171
1937	11,087	52,750	1,101	111,680	217,811	2,397,323	229,999	2,561,753
1938	13,498	72,845	1,729	70,268	197,548	2,159,447	212,775	2,302,560
1939	15,722	82,188	1,871	77,915	236,383	2,540,731	253,976	2,700,834
1940	[1] 17,724	[1] 118,424	1,894	140,565	261,757	2,749,331	[1] 281,375	[1] 3,008,320

[1] Includes a small quantity of pinite from Nevada.

Sales by States.—In 1940 larger tonnages were sold in all States for which figures can be published, except Vermont and Washington; in both of these, however, the value of the material sold was higher than in 1939. The greatest advances in tonnage sold were in New York, California, and North Carolina. All-time high records were again established in California, Georgia, North Carolina, and New York. Although more talc was sold in California in 1940 than in 1939 the value of the sales was slightly less. In all the other listed States the total values of sales were higher in 1940 than in 1939. New York was by far the leading State, with a production of 113,611 short tons valued at $1,402,524; California, North Carolina, and Vermont ranked about equally, but each produced only about one-third as much as New York.

Talc, pyrophyllite, and ground soapstone sold by producers in the United States, 1939–40, by States

State	1939		1940	
	Short tons	Value	Short tons	Value
California	33,796	$483,839	36,282	$476,926
Georgia	20,090	177,881	20,104	219,959
New York	99,880	1,252,525	113,611	1,402,524
North Carolina	36,772	283,789	39,206	298,382
Vermont	39,393	378,492	38,516	423,368
Washington	190	1,225	4	1,394

[1] 1939: Maryland, Pennsylvania, and Virginia; 1940: Maryland, Nevada, New Jersey, Pennsylvania, and Virginia.
[2] Includes a small quantity of pinite from Nevada.

MARKETS

Five industries—paint, ceramics, roofing, paper, and rubber—use 75 percent of the talc, pyrophyllite, and ground soapstone of domestic production. As indicated by reports from producers to the Bureau of Mines the paint industry—the leading market for these materials—took only 24 percent of the total sales in 1940 compared to 27 percent in 1939, or less than its share in recent years. The ceramic industry increased its hold on second place, taking 18 percent in 1940 as against 15 percent in 1939. Rubber dropped to fifth place from its tie with the roofing and paper industries for third place in 1939. The quantities consumed in the paint industry were only very slightly greater in 1940 than in 1939, whereas 10,254 more tons went into ceramics. There were increases during 1940 in the quantities sold to the roofing, paper, and foundry facings industries, whereas decreases were indicated in the rubber and toilet preparation industries.

Talc, pyrophyllite, and ground soapstone sold by producers in the United States, 1939-40, by uses

Use	1939		1940	
	Short tons	Percent of total	Short tons	Percent of total
Paint	67,859	27	67,875	24
Ceramics	38,407	15	48,661	18
Roofing	30,516	12	34,347	12
Paper	30,177	12	31,657	11
Rubber	31,078	12	28,501	10
Toilet preparations	9,672	4	8,818	3
Foundry facings	3,986	2	5,532	2
Other uses [1]	12,918	5	31,331	11
Use not reported	29,363	11	24,653	9
	253,976	100	[2] 281,375	100

[1] Includes crayons, bleaching, insecticides, plaster, textile, and other minor uses.
[2] Includes a small quantity of pinite.

PRICES

The average value of sales of all grades of talc, pyrophyllite, and ground soapstone, as reported to the Bureau of Mines by producers, has been about $11 a ton, ranging from about 60 cents below that figure to $1.50 above it; in 1940 it was $10.69. The average values for the past 5 years are given in the following table.

Average value per short ton of talc, pyrophyllite, and ground soapstone sold by producers in the United States, 1936-40

1936	$10.84	1939	$10.63
1937	11.14	1940	10.69
1938	10.82		

Quotations on finely ground domestic talc, f. o. b. works, carlots, in April 1941, were as follows according to the Oil, Paint, and Drug Reporter: California, $17 to $20; New York, $14 to $19.25; and Vermont, $14, all virtually unchanged from a year earlier. No quotations were available on imported talcs.

The price of pyrophyllite, standard, 200-mesh, carlots, mines, was $9 a ton; 325-mesh, $12; No. 3, 200-mesh, carlots, mines, $7.50 a ton; 325-mesh, $12. The trade journal quotations showed the same range in April 1940.

DEVELOPMENTS IN THE INDUSTRY

Pyrophyllite.—The results of the comprehensive study of pyrophyllite dust as an industrial hazard by H. F. Easom and others was published in 1939 by the division of industrial hygiene of the North Carolina Board of Health and Industrial Commission.[2] In February 1940 M. F. Trice of that organization presented a paper on this work before the American Institute of Mining and Metallurgical Engineers (see Minerals Yearbook, 1940, p. 1327).

In a recent report Spence[3] summarizes available data on the properties and uses of pyrophyllite and its occurrences in North Carolina and Newfoundland and also describes the Canadian deposits on Vancouver Island, British Columbia, and in the Lake Memphremagog district, Quebec.

The use of pyrophyllite in the manufacture of unfired refractories has been developed in the department of ceramic engineering of the University of North Carolina.[4]

Lyamina[5] presents the results of an X-ray study of the mineral composition of some pyrophyllites.

Emrich[6] describes tests on the use of pyrophyllites containing 4.2 to 9.3 percent sericite in vitreous ceramic bodies.

Pyrophyllite is the principal mineral constituent of Brazilian agalmatolite; an extensive deposit is now being exploited on a very small scale at Pará de Minas in the State of Minas Gerais.[7] The agalmatolite outcrops in a narrow strip that trends southeasterly for 6 kilometers. Six quarries are in operation, but no production statistics are available. The product is used as a substitute for talc, for construction purposes, and for sculpture.

A unique pyrophyllite-bearing rock is the so-called "Wonderstone" of the Transvaal, Union of South Africa. Detailed studies have been printed[8] of the occurrence and properties of this material. Wonderstone occurs as bands or lenses of sedimentary material intercalated in a thick mass of volcanic rocks composed predominantly of acid lavas. According to the evidence available the rock is said to appear to be a metamorphosed clay derived from volcanic ash. The quantity available is said to be enormous.

Natural wonderstone is light bluish gray, but the fired material ranges from white to gray and pink. The rock is compact and very fine grained, the average grain size of the principal constituent being about 10 microns or less. The hardness of the rock is less than that of the average slate, and it can be readily sawed, chiseled, drilled, and finely carved with ordinary wood-working tools; it can also be turned on a lathe. It takes and retains a very good polish. Chemical

analyses show this rock to be composed principally of silica, alumina, and water. Pyrophyllite forms about 89 percent of the rock; the remainder is chloritoid or epidote, rutile, and hematite. According to Bosazza, wonderstone on firing shows a slight permanent volume expansion of about 3 percent, owing mainly to the growth of cristobalite crystals in a dense matrix. Firing to high temperature increases the hardness and mechanical strength. Some wonderstone has been imported into the United States and used in the ceramic industry.

A hydrothermally altered acidic tuff, composed of a mixture of sericite and pyrophyllite and termed "pinite," has been mined recently at American Canyon, Nev., for use as a refractory in rotary cement-kiln linings. The occurrence and properties of this material have been described by Kerr [9] and the ceramic properties by Page, Raine, and Sullivan.[10] It is said to be highly refractory, with a fusion point of cone 32, and to fire snow-white.

Talc.—The results of an experimental study at the National Bureau of Standards of the treatment of ceramic talcose whiteware bodies in an electrically heated tunnel kiln of semicommercial size and capable of heating ware on a wide range of temperatures and time cycles is described in a paper by Geller and Creamer.[11]

Inuzuka [12] showed that when talc is heated at 1,100° C. it dissociates as follows:

$$H_2Mg_3(SiO_3)_4 \longrightarrow H_2O + SiO_2 + 3\ MgSiO_3,$$

and that the X-ray pattern shows that the resultant silica is cristobalite.

Thurnauer [13] describes the uses of talc as carving stone and as an insulating and refractory material. Powdered talc is used extensively in ceramic bodies, and in steatite bodies powdered talc is the chief raw material. Smaller amounts of talc are used in cordierite bodies.

Akhyan [14] noted that $MgSiO_3$ and mullite crystallized from the glass, the former as clinoenstatite, and that the addition of corundum dust increases the deformation temperature and solidifies the crystalline skeleton of the ware.

Romodan [15] suggested that the durability of saggers can be improved by adding talc.

Zodac [16] describes the Carlton quarry of the Vermont Mineral Products Co., Inc., now operated for grit talc.

Fuller [17] describes the use of talc as an inert material in paint in a recent bulletin of the American Society for Testing Materials.

Policard [18] described the results of his experiments that showed the effects on white rats of the foliaceous industrial talc dust used in powdering rubber.

In a recent comprehensive report Spence [19] has assembled the

salient information on occurrences of Canadian talc and soapstone in earlier publications, with later data on the world talc and soapstone industry, methods of mining and milling, utilization, and markets.

The talc-magnesite rock of the Eastern Magnesia Talc Co., Inc., Johnson, Vt., contains numerous accessory minerals, constituting, however, less than 2 percent of the rock. According to a letter from W. P. Mould to Dr. Oliver Bowles, Bureau of Mines, dated May 29, 1940, the following minerals have been identified: Chlorite, augite, tourmaline (var. dravite), hornblende, spinel, siderite, chromite, pyrrhotite, pentlandite, magnetite, pyrite, gersdorffite, and breunnerite. The rock runs about 0.67 percent Ni. The pyrrhotite carries about 6 percent Ni, but the main source of the nickel is believed to be the gersdorffite. Chemical analyses also show the presence of cobalt, arsenic, antimony, and manganese, but the minerals carrying these elements have not been determined.

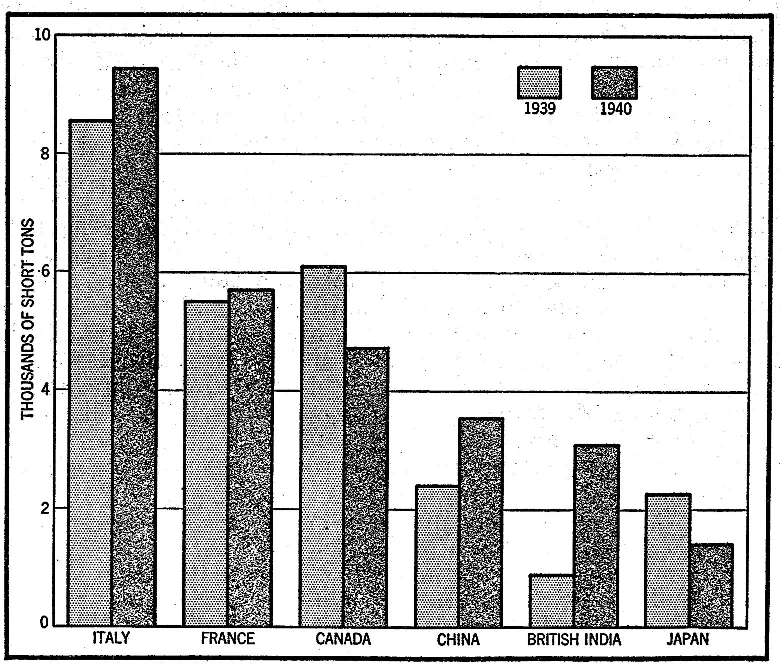

FIGURE 2.—Imports of ground, washed, or pulverized talc, steatite or soapstone, and French chalk for consumption in the United States, 1939–40, by leading countries.

FOREIGN TRADE

Imports.—By far the greatest proportion of the imports of talc, steatite or soapstone, and French chalk into the United States is of "ground, washed, or pulverized" materials. In 1940 these totaled 28,145 short tons valued at $465,049 compared with only 93 tons of crude and unground valued at $1,479 and 125 tons of cut and sawed materials valued at $20,739. The total value of all materials imported including some "manufactured n. s. p. f." was slightly over one-half million dollars.

The tables in this section this year are not strictly comparable with those in previous chapters. As the import tonnage of certain manufactures of these materials was not available in 1940 in the official statistics certain figures were eliminated and the tables rearranged.

Imports from the various countries are listed in detail for the three types of imported material in the accompanying tables (see also fig. 2). In 1940 most of the crude and unground material came from China and the Union of South Africa and the cut and sawed varieties from Italy and Japan. Ground talc, steatite or soapstone, and French chalk came from seven countries, with Italy the leading source, followed by France, Canada, China, British India, Japan, and Egypt in the order named.

Talc, steatite or soapstone, and French chalk imported for consumption in the United States, 1936–40

1 Less than 1 ton. 2 Quantity not recorded.

Exports.—The quantity of "talc, steatite, soapstone, and pyrophyllite, crude and ground," exported in 1940 was about 400 tons greater than in 1939, and the value was over $5,000 above 1939. The value of "powders—talcum (in packages), face, and compact," however, was the lowest since 1936.

Talcum and other powders exported from the United States, 1936–40

Year	Description	Short tons	Value
1936	Talc, steatite, and soapstone, crude and ground	6,670	$115,434
	Powders—talcum (in packages), face, and compact	(1)	803,571
1937	Talc, steatite, and soapstone, crude and ground	8,878	149,625

WORLD PRODUCTION

Production figures for talc, pyrophyllite, and soapstone in foreign countries in 1940 are available at this time only for Indochina, Union of South Africa, and Uruguay, where the quantities produced were comparatively small; in these three countries an increase occurred in the Union of South Africa only. The data available show no marked changes in the generally established production trends. The United States, long by far the leading producing nation, apparently retained that position in 1939 and 1940.

World production of talc and soapstone, 1936–40, by countries, in metric tons [1]

Uruguay (exports)	772	437	952	2,460	1,699

[1] In addition to the countries listed talc is produced in Brazil, Bulgaria, Newfoundland, Spain, and the U. S. S. R., but data on production are not available.
[2] Data not available.
[3] Excludes soapstone, which is reported only by value and was as follows: 1936, $32,770; 1937, $40,513; 1938, $35,038; 1939, $41,471; 1940, data not available. Soapstone is sold in the form of both blocks and powder.
[4] Talc, pyrophyllite, and ground soapstone sold or used by producers.
[5] Includes a small quantity of pinite.

FLUORSPAR AND CRYOLITE

By H. W. Davis and M. E. Trought [1]

SUMMARY OUTLINE

FLUORSPAR

Greatly expanded operations at steel mills, the chief consumers of fluorspar, coupled with increased production of hydrofluoric acid, which is essential in the manufacture of artificial cryolite (an aluminum raw material), stimulated activity in the fluorspar industry in 1940 and resulted in the mining, milling, and shipment of substantially larger quantities of fluorspar than in 1939. In fact, so great was the demand for fluorspar that shipments from domestic mines in 1940 were the second highest on record. Shipments from Kentucky and Nevada established all-time highs, and the movement from Illinois was the largest since 1920. Shipments by river or river-rail also made a new record. Sales of imported fluorspar, however, were 41 percent less than in 1939. On the other hand, exports, which usually are small, jumped to 8,482 tons, some of which went to India.

Sales of fluorspar to consumers in the United States totaled 236,042 short tons in 1940 (225,118 tons from domestic mines and 10,924 from foreign sources) compared with 198,198 tons in 1939 (179,795 tons from domestic mines and 18,403 from foreign sources). Total sales to the steel industry increased to 172,047 tons in 1940 (139,060 in 1939), while sales to manufacturers of hydrofluoric acid advanced to 35,242 tons (31,966 in 1939). Sales to makers of glass and enamel, however, dropped to 20,280 tons (22,018 in 1939).

Despite the large demand for fluorspar in 1940, the average composite selling price ($20.40 a ton) of all grades (both domestic and foreign) delivered to consumers in the United States was slightly less than in 1939 ($20.45). The average selling price f. o. b. Illinois-Kentucky mines of fluorspar shipped to domestic steel plants was $18.93 a short ton ($18.24 in 1939), of that shipped to manufacturers of hydrofluoric acid $26.10 ($27.34 in 1939), and of that to makers of glass and enamel $28.26 ($26.87 in 1939). The average selling price at seaboard (duty paid) of imported fluorspar shipped to steel plants was $22.03 a short ton in 1940 ($20.64 in 1939) and of that shipped to makers of hydrofluoric acid $27.44 ($29.76 in 1939).

[1] Figures on imports (unless otherwise indicated) compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce; those on exports of fluorspar supplied by the producers. No exports recorded by the Bureau of Foreign and Domestic Commerce.

Salient statistics of the fluorspar industry in the United States, 1939–40

	1939		1940

[1] Figures not available.

Because of the emphasis that has centered lately upon minerals from the defense standpoint, the following historic tables comprising data on production and imports may be of interest in studying the position of fluorspar.

The total quantity of fluorspar shipped in and imported into the United States from about 1870 through 1940 was about 5,579,000 short tons, including about 81 percent from domestic mines and 19 percent from foreign sources.

The total shipments since commercial production was begun (about 1870) in the United States through 1940 were approximately 4,528,000 short tons, of which Illinois and Kentucky contributed 56 and 36 percent, respectively. Imports of fluorspar into the United States from 1910 through 1940 were 894,231 short tons, and imports before 1910 are estimated at 157,000 tons—a total of about 1,051,000 tons, of which the United Kingdom and Germany contributed 50 and 20 percent, respectively.

Fluorspar shipped[1] from mines in the United States, 1880–1940, by States[2]

Year	Arizona		Colorado		Illinois		Kentucky		Nevada		New Hampshire		New Mexico		Tennessee		Utah		Other States		Total

[1] Imports Aug. 1 to Dec. 31, 1909, 6,971 short tons valued at $26,377; not separately recorded before Aug. 1, 1909. Imports before Aug. 1, 1909, virtually all from the United Kingdom, estimated at 150,000 short tons.
[2] Argentina, Australia, Austria-Hungary, Belgium, China, Czechoslovakia, Mexico, Netherlands, Norway, Tunisia, and Soviet Russia in Asia.
[3] Quantity not recorded.
[4] Optical fluorspar.

Production and shipments.—Production of merchantable fluorspar amounted to 244,000 short tons in 1940 compared with 173,000 in 1939. Of the production in 1940, 6 mines producing over 10,000 tons each accounted for 106,600 tons or 44 percent, 10 mines producing 5,000 to 10,000 tons each accounted for 67,800 tons or 28 percent, 22 mines producing 1,000 to 5,000 tons each accounted for 44,700 tons or 18 percent, and 16 mines producing 500 to 1,000 tons each accounted for 10,900 tons or 4 percent. Thus, 54 mines produced 230,000 tons or 94 percent of the total. The remainder (14,000 tons or 6 percent) was produced in quantities ranging from a few tons to 500 from an undetermined but large number of small mines and prospects and reclaimed from mill ponds, waste dumps, and old workings of abandoned mines.

Fluorspar shipments from domestic mines in 1940 were the second highest on record and aggregated 233,600 short tons valued at $4,744,808, increases of 28 percent both in quantity and total value over 1939. In 1940 they were equivalent to 187 percent of the average annual tonnages shipped in the 5-year period 1926–30. Of the 1940 shipments, 66,428 tons (an all-time high) were shipped by river or by river-rail for delivery to consumers in Illinois, Kentucky, New Jersey, Ohio, and Pennsylvania and for export to India. In 1939, 48,648 tons were so shipped.

In 1940, mines operated by or for consumers shipped 53,162 short tons of fluorspar for use in their own plants compared with 36,335 tons in 1939.

The average value of all grades of domestic fluorspar shipped in 1940 was $20.31, or virtually the same as the 1939 average. The value recorded for domestic fluorspar is the price paid f. o. b. mine shipping point and excludes the cost of containers.

The following table shows shipments of fluorspar by States for 1939 and 1940.

Fluorspar shipped from mines in the United States, 1939–40, by States

State	1939			1940		
	Short tons	Value		Short tons	Value	
		Total	Average		Total	Average
Colorado	7,569	$107,459	$14.20	11,032	$163,285	$14.80
Illinois	75,257	1,638,693	21.77	104,698	2,313,747	22.10
Kentucky	89,563	1,773,063	19.80	103,939	2,043,866	19.66
Arizona / New Mexico	6,477	132,408	20.44	7,986	139,675	17.49
Nevada	3,520	53,336	13.66	5,803	84,235	14.17
Utah	385			142		
	182,771	3,704,959	20.27	233,600	4,744,808	20.31

Shipments, by uses.—The predominance of the steel industry as a purchaser of fluorspar is evident from the following table.

Fluorspar shipped from mines in the United States, 1939–40, by uses

Use	1939				1940			
	Quantity		Value		Quantity		Value	
	Percent of total	Short tons	Total	Average	Percent of total	Short tons	Total	Average
Steel	68.59	125,371	$2,234,996	$17.83	69.68	162,772	$2,998,054	$18.42
Foundry	1.31	2,391	42,428	17.74	1.21	2,829	50,758	17.94
Glass and enamel	11.97	21,884	569,349	26.02	8.68	20,269	548,069	27.04
Hydrofluoric acid	15.03	27,463	730,383	26.60	14.39	33,608	852,139	25.36
Miscellaneous	1.47	2,686	53,360	19.87	2.41	5,640	117,321	20.80
	98.37	179,795	3,630,516	20.19	96.37	225,118	4,566,341	20.28
Exported	1.63	2,976	74,443	25.01	3.63	8,482	178,467	21.04
	100.00	182,771	3,704,959	20.27	100.00	233,600	4,744,808	20.31

Uses.—As figure 1 shows graphically, the steel industry is the chief consumer of fluorspar in the United States, followed in order by the hydrofluoric acid, glass, and enamel industries. Comparatively small quantities of fluorspar are used in a number of miscellaneous operations, such as production of the finer grades of iron castings, nickel and Monel metal, cement, ferro-alloys, carbon electrodes, and calcium carbide and cyanamid; reducing aluminum; refining lead and silver; extracting various rare metals from their ores; smelting refractory ores of gold, silver, and copper; as a paint pigment; and as a binder in abrasives.

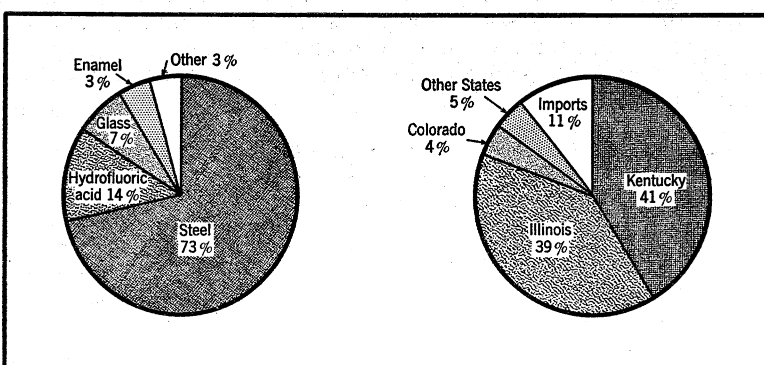

FIGURE 1.—Average annual fluorspar sales (domestic and foreign) to consumers in the United States, 1936–40, by consuming industries and by sources.

Schwerin [2] has discussed the use of fluorspar as a metallurgical flux and has outlined the results of his research in that field.

According to Lightner,[3] the advantages obtainable in open-hearth operation by the use of low-silicon iron include the requirement of less lime and fluorspar to control the sulfur and phosphorus.

[2] Schwerin, Lenher, Fluorspar—Its Chemical and Industrial Applications: Chem. Education, vol. 17, No. 4, April 1940, pp. 160–165.

[3] Lightner, M. W., Open-hearth Operators Discuss Advances in Steel-making Methods: Metal Progress, June 1940, pp. 647–652.

Chief commercial grades of fluorspar

Name	Chief use	Form	Specifications, in percent		
			CaF_2 (minimum)	SiO_2 (maximum)	Fe_2O_3 (maximum)
Metallurgical	Basic open-hearth steel.	Washed gravel, less than 1 inch and not more than 15 percent of fines.	85	5	
Ceramic	Glass and enamel	Ground: Coarse, fine, and extra fine	95	3	0.12
Acid	Hydrofluoric acid	Lump, gravel, and ground	98	1	

Consumption and consumers' stocks.—The following tables give data on consumption and stocks of fluorspar.

Fluorspar (domestic and foreign) consumed and in stock in the United States, 1939–40, by industries, in short tons

[Partly estimated by Bureau of Mines]

Industry	1939		1940	
	Consumption	Stocks at consumers' plants Dec. 31	Consumption	Stocks at consumers' plants Dec. 31
Basic open-hearth steel	116,200	69,900	143,800	79,800
Electric furnace steel	7,600	1,400	11,700	1,700
Foundry	2,400	800	2,700	900
Ferro-alloys	1,100	400	1,900	900
Hydrofluoric acid	26,300	14,100	35,700	14,300
Enamel and glass	21,400	3,100	18,900	4,400
Miscellaneous	1,800	700	2,500	1,400
	176,800	90,400	217,200	103,400

Consumption and stocks of fluorspar (domestic and foreign) at basic open-hearth steel plants, 1936–40

	1936	1937	1938	1939	1940
Production of basic open-hearth steel ingots and castings long tons	43,615,000	46,361,000	25,868,000	43,368,000	55,038,000
Consumption of fluorspar in basic open-hearth steel production short tons	133,900	138,900	73,600	116,200	143,800
Consumption of fluorspar per ton of steel made pounds	6.1	6.0	5.7	5.4	5.2
Stocks of fluorspar on hand at steel plants at end of year short tons	59,200	71,400	55,000	69,900	79,800

The quantity of fluorspar used by individual plants per ton of basic open-hearth steel produced ranges from 1 to 50 pounds—a relatively small proportion of the furnace charge. The average is generally 5 to 8 pounds, but it decreased to 5.22 pounds in 1940 from 5.36 pounds in 1939. It is noteworthy that since 1921—the first year for which these data were collected—the average consumption of fluorspar per ton of basic open-hearth steel made has declined almost steadily from 8.2 to 5.2 pounds. The following table shows the variation in average consumption of fluorspar per ton of basic open-hearth steel over a 5-year period in certain plants that make about 88 percent of the total.

Average consumption of fluorspar (domestic and foreign) per ton of steel, 1936–40, in pounds

1936	1937	1938	1939	1940	1936	1937	1938	1930	1940
13.187	13.867	12.548	14.079	15.973	6.734	7.360	8.420	6.337	5.972
4.792	5.623	4.457	3.623	3.453	10.495	6.623	11.984	8.506	8.369
4.541	4.376	3.845	3.793	3.929	5.104	4.358	3.831	3.171	.807
10.519	8.795	8.297	8.095	5.566	5.027	6.619	6.448	6.551	7.447
4.105	3.550	6.843	6.814	6.137	6.357	8.895	8.340	9.370	8.692
5.160	5.275	3.694	3.709	4.183	5.917	5.236	6.195	4.578	5.043
7.416	6.404	6.806	4.958	4.599	6.789	6.816	6.097	6.896	7.356

Quoted prices.—In 1940 the quoted price f. o. b. Illinois-Kentucky mines for fluxing gravel fluorspar ranged from $19 to $22 a short ton for rail delivery and $20 to $22 a ton for barge delivery at Ohio River and tributary landings. Imported fluxing gravel fluorspar (at seaboard, duty paid) was quoted at $25 to $25.50 a short ton.

Stocks at mines or shipping points.—According to reports of producers the quantity of fluorspar in stock at mines or shipping points at the close of 1940 totaled 74,725 tons, or 14 percent more than in 1939. These stocks comprised about 30,900 tons of crude fluorspar (calculated to be equivalent to 20,000 tons of ready-to-ship fluorspar) and 43,866 tons of ready-to-ship fluorspar.

Stocks of fluorspar at mines or shipping points in the United States, Dec. 31, 1939 and 1940, by States, in short tons

State	1939			1940		
	Crude [1]	Ready-to-ship	Total	Crude [1]	Ready-to-ship	Total
Arizona		209	209			
California	150		150	150		150
Colorado	565	329	894	205	364	569
Illinois	17,667	17,163	34,830	23,934	18,269	42,203
Kentucky	4,570	20,333	24,903	3,906	22,707	26,613
New Mexico	3,686	585	4,271	2,604	2,483	5,087
Texas	48		48		43	43
Utah	60		60	60		60
	26,746	38,619	65,365	30,859	43,866	74,725

[1] The greater part of this crude (run-of-mine) fluorspar must be beneficiated before it can be marketed.

Technologic developments.—Interest in the flotation of fluorspar continued in 1940. New plants were completed by the Rosiclare Lead & Fluorspar Mining Co. at Rosiclare, Ill., and by the Southwestern Mineral Co. at Fox, Ariz., and a plant is being constructed by the Non-Metallic Corporation at Silver City, N. Mex. The plants planned at Lordsburg, N. Mex., by the Fluorspar Milling Co., and at Skyline, Mont., by Paul E. Flynn, noted in the chapter of this series for 1940, were not installed. Output of flotation concentrates was 41,467 short tons in 1940 compared with 22,450 in 1939.

A method of producing fluorspar-bearing metallurgical flux is covered by United States Patent 2,232,242 granted to Fred A. Jordan, assignor to Mahoning Mining Co. The principal object of this invention is to provide a synthetic metallurgical flux of the required fluorspar content as well as physical form from fluorspar concentrates or other fluorspar-bearing materials which cannot be used as metallurgical fluxes because of their finely divided condition. A further objective is the production of a metallurgical flux from such materials by initially agglomerating a mass thereof and then treating the agglomerated mass to yield relatively large lumps of hard, water-resistant, fluorspar-bearing material having physical and chemical properties that adapt it for substantially all the purposes served hitherto by the natural flux. Another objective is to provide a novel method of producing, from finely divided fluorspar concentrates or like materials heretofore considered virtually useless for fluxing, a synthetic metallurgical fluorspar flux which is in such physical condition that it can be handled and charged readily and which conforms to or even excels the usual chemical and physical trade specifications for natural flux. The method of making fluorspar-bearing metallurgical flux comprises preparing a dry mixture of fluorspar concentrate and petroleum coke, then spraying the mixture with water while continuing the mixing to form damp pellets of the mixed solids, subjecting the pelletized material to a sintering operation to effect substantially complete combustion of the coke and then cooling the residual solid while maintaining, in the resultant irregularly shaped lumps thereof, the voids produced by combustion of the coke.

The Mahoning Mining Co., which operates a flotation plant at Rosiclare, Ill., shipped several thousand tons of fluorspar to the steel trade in 1940, presumably pelletized material produced by the above method.

A process of concentrating minerals of the class comprising phosphate, calcite, barite, and fluorspar is the subject of United States Patent 2,222,728. This patent describes flotation tests of fluorspar from Hillside Fluor Spar Mines.

INDUSTRY IN 1940, BY STATES

Arizona.—Except for a small quantity from Pima County, production in Arizona came from mines and prospects in Greenlee County, and most of it was shipped to steel plants. Some, however, was shipped to the flotation plants at Fox, Ariz., and at Deming and Lordsburg, N. Mex. Instead of the run-of-mine material produced, the flotation concentrates recovered from the fluorspar have been credited to Arizona in the statistics. The new flotation mill of the Southwestern Mineral Co. at Fox, Ariz., was completed and put into operation during 1940; the mill feed comprised ore chiefly from the company's Mohawk and Great Eagle mines in Grant County, N. Mex., and shipments of concentrates were made to the chemical, ceramic, and metallurgical industries.

California.—Some development work was done at the Big Horn mine, San Bernardino County. Development work was also in progress at the Warm Springs prospect near Shoshone, Inyo County, from May to August 26, when operations were discontinued. Some Nevada fluorspar was ground at the grinding plant at West Berkeley and shipped to the ceramic trade during 1940. The ground fluorspar has been credited to Nevada in the statistics.

Colorado.—Increased production at the mines of the American Fluorspar Corporation and the Colorado Fluorspar Corporation in Chaffee County and at the Wagon Wheel Gap mine in Mineral County is indicated by the shipments of 11,032 short tons of fluorspar from

Colorado in 1940 compared with 7,569 tons in 1939. Most of the 1940 shipments went to steel plants, but some went to iron foundries and to ferro-alloy, cement, glass, and enamel plants. Production in 1940 came from Boulder, Chaffee, Jackson, Jefferson, and Mineral Counties, but mines in Chaffee and Mineral Counties supplied 94 percent of the total for Colorado.

At the 125-ton combination flotation-jig mill of the Colorado Fluorspar Corporation at Salida (which was completed the latter part of 1939 but was closed after a short test run) mechanical changes were made in the flow sheet; the mill was again put into operation during November 1940, and over 200 tons of flotation concentrates were produced. The Western Feldspar Milling Co. shipped 493 tons of ground fluorspar to the ceramic trade from its mill at Denver.

Illinois.—Approximately 213,000 short tons of fluorspar-bearing ore, equivalent to 111,000 tons of merchantable fluorspar, were mined in 1940 compared with about 128,000 tons, equivalent to 71,000 tons of merchantable fluorspar, in 1939. Of the merchantable fluorspar produced in 1940, 61,000 tons were from mines where the fluorspar occurs in veins, chiefly fault fissures, and 50,000 from mines where the fluorspar occurs in flatlying tabular masses, locally called blanket formations. Except for a small output at the Clay Diggings prospect and the Douglas mine in Pope County, production came from Hardin County.

Fluorspar-bearing material milled in Illinois in 1940 totaled 208,000 tons, from which 105,000 tons of fluorspar were recovered—a ratio of 1.98 : 1.

Shipments from Illinois—the largest since 1920—totaled 104,698 tons in 1940 compared with 75,257 in 1939; 36,756 tons were shipped by river or river-rail to consumers in 1940 compared with 23,989 in 1939.

The Air Shaft, Argo, Cave in Rock, Crystal, Daisy-Blue Diggings, W. L. Davis, Hamp, Hillside, Humm, Midway-North Boundary, Spar Mountain, Stewart, and Victory mines supplied about 95 percent of the total merchantable fluorspar produced in Illinois during 1940. Most of the remainder came from the Big Creek, Boundary Shaft, Dimick, Douglas, Eureka No. 5, Guard & Kamm, Lead Hill, Pell, and Preen mines.

At the Argo mine of the Aluminum Ore Co. crosscuts were driven north and south on the 500-foot level, and at its Hamp mine a three-compartment shaft was begun during 1940 and sunk vertically to 178 feet by the end of the year. The flotation plant of the company was inactive during November on account of a strike at its East St. Louis plant, but otherwise it operated three shifts during the year; the capacity was increased, and drying and grinding equipment were added to the mill. The company output of flotation concentrates was 32 percent greater than in 1939.

Production at the Crystal mine of Crystal Fluorspar Co. increased 37 percent over that in 1939. The mine was operated on a two-shift basis from June 24 to August 19 and the mill on a two-shift basis from June 24 to October 24.

Output of the Hillside Fluor Spar Mines (Hillside mine at Rosiclare, Ill., and Keystone near Marion, Ky.) was 56 percent more than in 1939. The flotation plant, which was completed late in 1939, produced 1,464 tons of concentrates in 1940.

The Rosiclare Lead & Fluorspar Mining Co. operated the Air Shaft, Boundary Shaft, Daisy-Blue Diggings, Eureka No. 5, and Midway-North Boundary mines in 1940, and output was about 7 percent greater than in 1939. Its Rosiclare mine, which has been flooded since January 1924, has been dewatered to below the 600-foot level, and work has been begun on cleaning the mine and retimbering shafts preparatory to production. At the 600-foot level, four station pumps having a capacity of 1,000 gallons per minute each have been installed. These pumps, with a deep-well-type pump having a capacity of 3,200 gallons a minute at 620-foot head and equipped with a 600-horsepower motor installed in the main shaft, give a pumping capacity of 7,200 gallons a minute, or more than double the inflow of water. The large pump will be used as a stand-by unit. A small flotation plant for handling low-grade fluorspar fines was added to the Rosiclare plant in 1940 and produced 491 tons of concentrates.

The Cave-in-Rock Spar Co. completed a mill at Cave in Rock during 1940. In addition to increased production from its own mines, the company treated a larger quantity of purchased ore in its mills; as a consequence, shipments were about four times greater than in 1939.

Production of fluorspar concentrates at the mill of Mahoning Mining Co. increased 254 percent in 1940. The mill was put into operation in June 1939 and produces fluorspar, lead, and zinc concentrates by selective flotation. In 1940 the mill feed comprised ore from the company W. L. Davis mine and a small quantity of tailings from the old Benzon mill. Of the fluorspar flotation concentrates shipped in 1940, 21.9, 0.5, and 59.1 percent, respectively, went to domestic steel, glass, and hydrofluoric acid plants, and 18.5 percent was exported to Canada.

The Big Creek Fluorspar Co. did prospecting and development work at its Big Creek mines and is considering erection of a mill that will produce 2½ to 3 tons of finished fluorspar hourly.

Knight, Knight & Clark operated its mill on ore from the Douglas mine in Pope County, purchased ore from the Spar Mountain mine, and ore from the Ellis mine in Livingston County, Ky.

The Fluorspar Products Co. operated the Lead Hill and Stewart mines and in addition milled purchased ore from the Spar Mountain and other properties.

Production at the Humm mine, operated by C. C. Mackey, was somewhat less than in 1939.

Beecher Williams operated the Cox and Pell mines and in addition milled purchased ore from the Spar Mountain and other properties.

Kentucky.—Production of merchantable fluorspar in Kentucky was 107,000 short tons in 1940 compared with 81,000 in 1939; and shipments, which established an all-time high, were 103,939 tons compared with 89,563 in 1939. Of the 1940 shipments, 29,672 tons were shipped by river or river-rail to consumers compared with 24,659 in 1939.

The effect of resuming operation at the S. L. Crook Corporation properties by J. D. Summers & Co., W. H. Crider, and others and at the Hollowell & Hobby mine by the New York & Kentucky Mining Co., plus output at the H. & W. mine by H. W. Morse, is mirrored in the output of about 5,000 tons of fluorspar in Caldwell County in 1940.

Production in Crittenden County, totaling 80,000 short tons, came chiefly from the Bachelor, Davenport, Keystone, Mary Belle, Pigmy, Summers, Tabb, and Watson (Eagle) mines, which contributed 83 percent of the county total. Most of the remainder came from the Beard, Blue, Butler, Dyke, Haffaw, Susie Beeler, and Two Brothers mines, which supplied 6 percent of the county total.

The Beard, Brown, Cross, Haffaw, Mary Belle, Memphis, Split Nickel, and Susie Beeler mines of the Aluminum Ore Co. were operated by lessees, and output was 185 percent more than in 1939. Most of the output, as well as a small quantity of purchased ore, was milled in the company plant at Marion. Production of finished fluorspar at the mill was 69 percent greater than in 1939.

The Watson (Eagle) mine of the Eagle Fluor Spar Co. was operated on a two-shift basis, and the output of finished fluorspar was 29 percent larger than in 1939.

R. J. Forester's Summers mine, inactive since 1937, was reopened in 1940.

The Tabb mines and mill of the United States Coal & Coke Co. were worked on a two-shift basis during 1940, and production of finished fluorspar was 18 percent higher than in 1939. Shipments, however, increased 50 percent. In addition to the production from the Tabb mines, contractors made a considerable output on the company properties; most of it was treated in the company mill.

The Two Brothers mine was operated by J. D. Summers & Co. the first half of 1940, after which the lease was surrendered. Production was about 65 percent less than in 1939.

The Kentucky Fluor Spar Co., which has a mill a short distance south of Marion, shipped 15 percent more fluorspar than in 1939. The company does not operate any mines but buys part or all of the output of many local mines and prospects. In 1940 the company obtained its supply chiefly from the Babb, Blue, Crook, Dyke, Eagle, H. & W., Hollowell & Hobby, and Nancy Hanks mines in Kentucky and the Guard & Kamm and Spar Mountain mines in Illinois.

The Keystone mine of Hillside Fluor Spar Mines was operated on a two-shift basis, and output was substantially greater than in 1939. Although the fluorspar from the Keystone mine is finished at the company mill at Rosiclare, Ill., production and shipments are credited to Kentucky in the statistics.

Production at the Pigmy mine of Pigmy Corporation was about 300 percent more than in 1939. Some of the fluorspar from the Pigmy mine is processed further at the Rosiclare (Ill.) mill of the Rosiclare Lead & Fluorspar Mining Co., but the finished product so recovered is included in the statistics for Kentucky.

The Davenport mine of National Fluorspar Co. made a 35-percent increase in output in 1940 compared with 1939. Extensive development was done on the east vein at the 260-foot level of No. 3 shaft, and a winze was sunk from the 260- to the 300-foot level.

Production at the Bachelor mine of the Delhi Fluorspar Corporation was 21 percent greater than in 1939. A new shaft was sunk 350 feet at the Bachelor mine.

Shipments of fluorspar by the Howard Easley Corporation were 81 percent larger than in 1939. This concern does not operate any mines but purchases fluorspar from numerous mines and prospects; it also operates a mill at Marion, where much of the purchased fluorspar is finished and where considerable tonnages are milled for others on a custom basis.

W. H. Crider made some production at the Crook property in Caldwell County and at the Haffaw mine in Crittenden County. Virtually all fluorspar from the Haffaw mine was sold to the local mill of Aluminum Ore Co. The output from the Crook property, with fluorspar purchased from many local mines, was shipped to consumers.

In Livingston County 21,000 short tons of merchantable fluorspar were produced in 1940 compared with 28,000 tons in 1939. The decline was due chiefly to suspension of operations at the Klondike mine of the Klondike Fluorspar Corporation. Of the production in 1940, the C. R. Babb, Ellis, Nancy Hanks, and Klondike mines and the jig plant reclaiming fluorspar from Klondike tailings supplied about 96 percent of the county total.

Output at the Alvis, C. R. Babb, Ellis, and Wright mines, operated by Roberts & Frazer, was slightly greater than in 1939.

Knight, Knight & Clark resumed operations at a shaft at the Ellis mine in 1940.

Production at the Nancy Hanks mine, operated by Haynes Fluorspar Co., increased 9 percent over that in 1939. Sales by Haynes Fluorspar Co. and Standard Fluorspar Co., however, were about 38 percent higher than in 1939.

In 1940 the Faircloth mine of Ralph E. Jones near Wilmore, Woodford County, produced and shipped 877 tons of fluorspar.

Nevada.—Shipments of fluorspar from Nevada—5,803 short tons in 1940 compared with 3,520 in 1939—established an all-time record. Most of the 1940 shipments went to steel mills and hydrofluoric-acid plants, but some went to iron foundries and cement and ceramic plants.

The chief producing mine in Nevada in 1940 was the Daisy, in Nye County, operated by J. Irving Crowell, Jr., which shipped 2,960 tons. The other active mine was the Baxter, in Mineral County, operated by V. S. Baxter, which shipped 2,843 tons. The Tonopah & Tidewater Railroad, the only line serving Beatty, the shipping point for the Daisy mine, discontinued operation on June 14, 1940. As a consequence, shipments are now made from Las Vegas, a distance of 116 miles; a 20-ton truck was purchased for this purpose. The mill serving the Daisy mine was revamped and Diesel power installed.

New Mexico.—Shipments of fluorspar from New Mexico and Arizona were 7,986 short tons in 1940 compared with 6,477 in 1939. Shipments in 1940 comprised flotation concentrates, which went chiefly to ceramic and hydrofluoric-acid plants, and metallurgical grade, which went chiefly to steel plants.

Production in 1940 was from Catron, Grant, Luna, Sierra, and Valencia Counties. Output at the flotation mill of Indian Metals Co. at Lordsburg increased more than 400 percent over 1939. The flotation mill of General Chemical Co. at Deming operated only part of 1940; in consequence, production was less than in 1939. Shipments from inventories, however, were continued throughout the year. A flotation mill is being built at Silver City by the Non-Metallic Corporation.

Texas.—A small quantity of fluorspar was produced (but not shipped) by U. B. Melton from a property near Hot Wells, in Hudspeth County.

Utah.—Shipments of fluorspar from Utah were 142 short tons in 1940 compared with 385 tons in 1939, all from the Fred Staats mine in Beaver County; they were consigned to steel plants and iron foundries.

Development work was under way at a new property near Milford, Beaver County, by the Western Fluorite Co. The company is constructing a mill.

IMPORTS AND EXPORTS

Imports of fluorspar for consumption in the United States in 1940 totaled 11,871 short tons (3,050 containing more than 97 percent and 8,821 containing not more than 97 percent calcium fluoride) valued [4] at $142,931 compared with 16,302 tons (3,351 containing more than 97 percent and 12,951 containing not more than 97 percent calcium fluoride) valued [4] at $176,691 in 1939. The value assigned to the foreign fluorspar in 1940 averaged $12.04 a ton. The cost to consumers in the United States also includes duty, loading charges at the docks, ocean freight, insurance, consular fee, and freight from docks to consuming points. The duty on fluorspar containing not more than 97 percent calcium fluoride is $7.50 a short ton and on fluorspar containing more than 97 percent calcium fluoride $3.75 a short ton.

Fluorspar imported for consumption in the United States in 1940, by countries and customs districts

Country and customs district	Containing more than 97 percent calcium fluoride		Containing not more than 97 percent calcium fluoride		Total

Total: 1940	3,050	59,398	8,821	83,533	11,871	142,931
1939	3,351	79,088	12,951	97,603	16,302	176,691

[4] As defined in sec. 402 of the tariff act of 1930, "The value of imported merchandise * * * is the foreign value or the export value, whichever is higher—that is, the market value or the price at which the merchandise, at the time of exportation to the United States, is offered for sale in the principal markets of the country from which exported, including the cost of containers or coverings and all expenses (including any export tax) incident to placing the merchandise in condition ready for shipment to the United States."

France was the chief source of imported fluorspar in 1940; however, no fluorspar has been received in the United States from France since February 1940. Imports of acid-grade fluorspar from Mexico gained substantially, and indications point to further increase in receipts from that source in 1941.

Of the 1940 imports, 74.3 percent was metallurgical gravel fluorspar, 25.6 percent acid-grade fluorspar, and 0.1 percent ceramic ground fluorspar. The metallurgical gravel fluorspar was imported from France, Newfoundland, Spain, and Tunisia; the ceramic ground fluorspar from France; and the acid-grade fluorspar from France, Mexico, and Newfoundland. Imports were equivalent to 5 percent of the total shipments of domestic fluorspar in 1940 compared with 9 percent in 1939.

The following table, compiled from data furnished to the Bureau of Mines by importers, shows the quantities of imported fluorspar delivered to consumers in the United States in 1939 and 1940 and the selling price at tidewater (duty paid), irrespective of the year of importation into the United States; it differs from the preceding table, which shows the quantities received in the United States during 1939 and 1940. The quantities in the following table are based upon the actual outturn weights ascertained by sworn weighers and represent the weights on which duty was paid and entries were liquidated. Stocks of foreign fluorspar in the hands of importers in the United States were only 3 short tons at the close of 1940 compared with 466 in 1939.

Imported fluorspar delivered to consumers in the United States, 1939–40, by uses

Use	1939			1940		
	Short tons	Selling price at tidewater, including duty		Short tons	Selling price at tidewater, including duty	
		Total	Average		Total	Average
Steel	13,689	$282,487	$20.64	9,275	$204,342	$22.03
Glass and enamel	134	5,240	39.10	11	361	32.82
Hydrofluoric acid	4,503	134,014	29.76	1,634	44,845	27.44
Miscellaneous	77	1,597	20.74	4	160	40.00
	18,403	423,338	23.00	10,924	249,708	22.86

Producers of fluorspar reported exports of 8,482 short tons of fluorspar valued at $178,467 in 1940 compared with 2,976 valued at $74,443 in 1939. Of the 1940 exports, 7,922 tons went to Canada and 560 to India. In 1940 some of the fluorspar exported to Canada was shipped by rail to Chicago, thence by water to Canada. In 1939 all the exported fluorspar went to Canada, and the greater part of it was shipped from the Illinois-Kentucky district by rail to Chicago, thence by water over Lakes Michigan, Huron, Erie, and Ontario and the St. Lawrence and Saguenay Rivers to Quebec.

Fluorspar reported by producers as exported from the United States, 1936–40

Year	Short tons	Value		Year	Short tons	Value	
		Total	Average			Total	Average
1936	240	$4,079	$17.00	1939	2,976	$74,443	$25.01
1937	456	9,091	19.94	1940	8,482	178,467	21.04
1938	788	9,061	11.50				

WORLD PRODUCTION

The following table shows the world production of fluorspar by countries from 1936 to 1940, insofar as statistics are available. Although complete returns for 1938, 1939, and 1940 are not yet available, it is evident that the upward trend in world production, which began in 1933, was arrested in 1938 but was resumed in 1939. The greatly increased world production in recent years has been due chiefly to gains in the output of steel and aluminum in many European countries. Despite the fact that fluorspar is produced in about 20 countries, 5—United States 32 percent, Germany 29 percent, U. S. S. R. 13 percent, United Kingdom 9 percent, and France 7 percent—supply 90 percent of the world total.

World production of fluorspar, 1936–40, by countries, in metric tons [1]

[1] In addition to countries listed, China, Mexico, and Spain produce fluorspar but data of output are not available.
[2] Railway shipments.
[3] Data not available.
[4] Estimate included in total.
[5] Estimated.

Canada.—According to the Northern Miner: [5]

Moira Fluorspar Mining Syndicate, Ltd., advises the Northern Miner that it is at present working the old Noyes property near Madoc. All buildings and equipment with minor exceptions are installed and the milling plant is in process of tuning in. Officials of the syndicate report that large tonnages of good ore are blocked out on three sides with more indicated. The syndicate is figuring on a shipping schedule of 15,000 tons this year and it is expected that this will likely be produced from the present workings on the 100-foot level. Development continues to 250 feet with a total of about 2,600 feet of drifting and numerous raises, stopes, and chutes. The syndicate holds 300 acres in this block and controls about 2,500 acres in addition.

The geology of the Madoc area, its structure, age, and ore deposits have been described recently by Emery.[6]

Newfoundland.—Shipments of fluorspar from Newfoundland in 1940 were 16,201 short tons; of this, 2,242 tons of fluxing grade went to the United States, and 6,699 tons of acid grade and 7,260 tons of fluxing grade to Canada. Shipments in 1939 totaled 12,376 tons. Considerable new equipment, including a pump for the Black Duck mine where water has hindered mining, has been installed at the property of the St. Lawrence Corporation of Newfoundland, Ltd.

South-West Africa.—Production of fluorspar in South-West Africa during the first 9 months of 1940 was 260 short tons; none was shipped. According to the Department of Mines [7] of the Union of South Africa:

A revival in fluorspar production has followed the opening up of extensive deposits on the farm Aukam in the Bethanie district. The material is of excellent quality and the veins are strong and persistent. Active mining operations ceased during September 1940.

Union of South Africa.—Figures of production of fluorspar in the Union of South Africa are available for only the first 9 months of 1940 and totaled 5,562 short tons. Shipments during this period were 5,023 short tons, of which 3,243 were exported to Japan, 19 exported to England, and 1,761 sold to local consumers. Production in 1939 was 11,378 short tons, and shipments were 10,724 tons, the greater part of which was exported to Japan.

CRYOLITE

Cryolite occurs in commercial quantity and is mined at only one place—Ivigtut, Greenland. It is used in the metallurgy of aluminum, in the manufacture of glass and enamels, and in insecticides.

Gibbs [8] has described the mine at Ivigtut, grades of ore produced, methods of processing and purification, and various uses of cryolite.

Imports.—The following table shows imports of cryolite into the United States in 1939 and 1940. As cryolite is mined only in Greenland, it is evident that importations credited to countries other than Greenland probably include artificial cryolite.

FELDSPAR

By Robert W. Metcalf

SUMMARY OUTLINE

Stimulated by new high records in glass-container output and shipments and a substantial pick-up in residential building, both crude and ground feldspar set new production (sales) records in 1940. Sales of crude spar advanced to 290,763 long tons—8 percent higher than the previous peak in 1937 and 14.7 percent more than the 1939 figure of 253,466 tons. Sales of ground feldspar in 1940 rose to 285,713 short tons—2 percent above the 1937 high and 10.2 percent greater than in 1939.

Salient statistics of the feldspar industry in the United States, 1939–40

	1939	1940	Percent of change in 1940
Crude feldspar:			
Domestic sales:			
Long tons	253,466	290,763	+14.7
Value	$1,112,857	$1,271,995	+14.3
Average per long ton	$4.39	$4.37	−.5
Imports:			
Long tons	7,460	12,522	+67.9
Value	$52,141	$80,274	+54.0
Average per long ton	$6.99	$6.41	−8.3
Ground feldspar sold by merchant mills:			
Short tons	259,194	285,713	+10.2
Value	$2,862,278	$3,065,482	+7.1
Average per short ton	$11.04	$10.73	−2.8

Imports of crude feldspar (all from Canada) jumped to 12,522 long tons valued at $80,274 in 1940 compared with 7,460 tons valued at $52,141 in 1939 and nearly equaled the 1937 imports.

The majority of States produced more spar in 1940 than in the previous year. South Dakota and Connecticut produced record tonnages of crude, and South Dakota and Colorado also sold more ground spar than in any previous year.

DOMESTIC PRODUCTION

In accordance with the usual practice in the industry crude feldspar is reported in long tons of 2,240 pounds and ground spar in short (net) tons of 2,000 pounds, although an increasing number of producers report sales of crude in short tons.

Crude feldspar.—Crude feldspar sold or used in 1940 rose to 290,763 long tons valued at $1,271,995, a new record in tonnage—8 percent greater than in 1937 (the previous high) and 15 percent more than in 1939. The total value, however, was $111,254 less than the 1937 high of $1,383,249.

Crude feldspar sold or used by producers in the United States, 1936–40

[Value at mine or nearest shipping point]

Year	Long tons	Value		Year	Long tons	Value	
		Total	Average			Total	Average
1936	244,726	$1,303,090	$5.32	1939	253,466	$1,112,857	$4.39
1937	268,532	1,383,249	5.15	1940	290,763	1,271,995	4.37
1938	196,119	895,081	4.56				

Crude feldspar sold or used by producers in the United States, 1938–40, by States

Undistributed [2]	10,465	59,126	8,503	46,582	9,022	38,286
	196,119	895,081	253,466	1,112,857	290,763	1,271,995

[1] Included under "Undistributed." [2] Includes States indicated by "1."

Crude feldspar was produced in 1940 in the same States where crude was mined in 1939. North Carolina produced 3 percent more spar in 1940 but supplied only 27 percent of the national total compared with 30 percent in 1939 and 35 percent in 1937. Output in South Dakota increased 13 percent to 54,692 long tons, the highest yet recorded for that State, and New Hampshire with 38,589 tons produced more crude than in any year since 1924. Connecticut also produced more feldspar in 1940 than in any previous year and advanced to fifth place in size of output.

The average sales realization for all crude spar decreased slightly in 1940 to $4.37. Except for New Hampshire and Connecticut, however, most of the chief producing States for which data may be shown (including the western producers) indicated moderate increases in the average value per ton as follows: South Dakota, 1939—$2.77, 1940—$2.88; Colorado, 1939—$3.59, 1940—$3.62; Maine, 1939—$4.10, 1940—$4.61; and North Carolina, 1939—$5.18, 1940—$5.38.

Ground feldspar.—Ground feldspar sold by merchant mills in the United States in 1940 broke all records and rose to 285,713 short tons—10.2 percent higher than in 1939 and 2 percent above the previous record in 1937. The total value in 1940, while considerably more than in 1939, did not reach the 1937 figure. As in 1938 and 1939, South Dakota and Colorado supplied about 35 percent of the total ground spar sold or used compared with 30 percent in 1937. The share of total sales furnished in 1940 by Tennessee and North Carolina mills dropped slightly to 27 percent compared with approximately 29 percent in 1938 and 1939 and 32 percent in 1937. Three percent of the total sales of ground feldspar from United States mills in 1940, 4 percent in 1938 and 1939, and 6 percent in 1937 was of Canadian origin.

South Dakota—the leading producer of ground feldspar—again shipped more processed spar than in any previous year (54,783 short tons valued at $374,024), surpassing the former record in 1939 by 11 percent in tonnage and 10 percent in value. Colorado, third in order of sales, reported a record tonnage of ground spar (44,260 tons). Tennessee and North Carolina ranked second and fourth, respectively. Sales by mills in California, Maine, New Hampshire, and New Jersey were substantially higher in 1940 than in 1939.

Ground feldspar sold by merchant mills [1] in the United States, 1936–40

Year	Active mills	Domestic			Canadian			Total

[1] Excludes potters or others who grind for consumption in their own plants.

Continuing the general downward trend of recent years, the average sales realization for ground spar in 1940 was $10.73 compared with $11.04 in 1939 and $11.50 in 1938. Average sales values for individual States ranged from $6.38 to $17.96 in 1940, from $6.42 to $18.01 in 1939, and from $6.55 to $21.09 in 1938. The sales realization for North Carolina-Tennessee in 1940 was $11.97; for Colorado and South Dakota $6.38 and $6.83, respectively; for New Jersey (including Connecticut) $17.96; and for Maine $13.02.

Quoted prices on ground feldspar, however, remained unchanged during the year, according to Engineering and Mining Journal Metal and Mineral Markets. As of February 6, 1941, quotations were reported as follows: Potash spar, f. o. b. North Carolina, 200-mesh, white, $17 per ton in bulk; soda spar, $19 per ton; potash spar, f. o. b. Maine, 200-mesh, white, $17 per ton in bulk; North Carolina granular glass spar, 20-mesh, white, f. o. b., $12.50 per ton in bulk; semigranular, $11.75 per ton; Virginia feldspar, No. 1, 230-mesh, $18, 200-mesh, $17; No. 17 glassmakers' spar, $11.75, No. 18 glassmakers' spar, $12.50; and enamelers' spar, $14 to $16 (quotations upon Spruce Pine, N. C., or Keene, N. H., basis).

Ground feldspar sold by merchant mills [1] in the United States, 1938–40, by States

State	1938			1939			1940		
	Active mills	Short tons	Value	Active mills	Short tons	Value	Active mills	Short tons	Value

[1] Excludes potters or others who grind for consumption in their own plants.
[2] Included under "Undistributed."
[3] Connecticut included with New Jersey.

CONSUMPTION AND USES

Crude feldspar.—Most crude feldspar is sold to merchant mills, which obtain material from a number of mines or localities, store and sort it according to grade and source, blend and grind it to required purity and fineness, and sell the ground product. However, some pottery and enamel manufacturers purchase part of their feldspar requirements crude and process it as needed with their own equipment; and at least two sanitary-ware manufacturers mine and grind spar for their own use. Makers of soap, cleansers, and sweeping compounds also mine crude feldspar or purchase it—chiefly in New England, Virginia, and North Carolina—and (after grinding or other processing) utilize it as an abrasive in their products. Manufacturers of artificial teeth each year use a small tonnage of carefully selected crude material, which is sold at a substantial premium over No. 1 grade commercial feldspar.

Ground feldspar.—The quantity of feldspar consumed by the glass industry in 1940 rose to 149,623 short tons—an 8-percent increase over 1939—although the proportion of total sales used by the industry declined to 52.4 percent in 1940 compared with 53.4 percent in 1939 and 54.9 percent in 1938. These figures do not include nepheline syenite, aplite, or other sources of alumina in the making of glass, whose importance in the competitive pattern is increasing steadily. Sales to potteries, however, increased 20 percent. Sales of ground spar to enamel manufacturers by merchant mills decreased somewhat both actually and relatively. Ground spar sold for use in soap and abrasives, a minor sales outlet for ground material, increased sharply. The remainder was utilized for other purposes not specified and for various ceramic uses other than glass, pottery, or enamel.

Ground feldspar sold by merchant mills in the United States, 1938–40, by uses, in short tons

Use	1938		1939		1940	
	Short tons	Percent of total	Short tons	Percent of total	Short tons	Percent of total
Ceramic:						
Glass	117,800	54.9	138,336	53.4	149,623	52.4
Pottery	74,035	34.5	87,209	33.7	104,586	36.6

Other uses	186	.1	2,391	.9	1,753	.6
	214,514	100.0	259,194	100.0	285,713	100.0

The distribution of ground feldspar sold by merchant mills according to chief consuming States, as reported by mills grinding 99 percent of the feldspar ground in 1939 and 100 percent in 1940, is shown in the accompanying table. Ohio, taking 18 percent of the ground spar sold, again proved to be the largest market, although it did not consume as much spar as in 1939. Pennsylvania was second in 1940 with 16 percent, followed by New Jersey (15 percent), Illinois (11 percent), Indiana (10 percent), West Virginia (8 percent), and New York (5 percent). Shipments to "Other States"—comprising in each year about 10 percent of the total distribution—included sizable tonnages to Maryland, Mississippi, Oklahoma, Missouri, and South Carolina and smaller amounts to 19 other States, the District of Columbia, and Puerto Rico. Small shipments to Mexico, England, and Canada also were reported.

Shipments of ground feldspar from mills into States, 1939–40, in short tons

State	1939 [1]	1940	State	1939 [1]	1940
California	7,590	7,897	Tennessee	5,077	5,911
Illinois	15,948	32,811	West Virginia	19,188	21,889
Indiana	38,189	28,634	Wisconsin	5,134	6,967
New Jersey	34,309	42,381	Other States [2]	25,463	27,721
New York	14,995	13,236			
Ohio	53,410	50,835		256,769	285,713
Pennsylvania	37,466	47,431			

[1] Data include 99 percent of total ground feldspar.
[2] Arkansas, Colorado, Kentucky, Maryland, Mississippi, Missouri, Oklahoma, South Carolina, and other States for which shipments cannot be segregated. Small shipments to Puerto Rico, Mexico, England, and Canada also included.

Names and addresses of merchant grinders of feldspar in the United States follow:

Western Feldspar Milling Co., 1333 West Maple Avenue, Denver, Colo.
White Hill Mineral Co., Inc., Gouverneur. N. Y.

NEPHELINE SYENITE

Although commercial production of nepheline syenite has been reported from the Kola Peninsula in northern U. S. S. R.[1] and deposits have been discovered in a number of countries (including the United States and more recently Chosen (Korea)[2] the only commercial development in North America remains that in Ontario, Canada. Shipments from a small mill near Lakefield, Ontario, were begun in 1936, the raw material coming from Blue Mountain in Peterborough County. The American Nepheline Corporation, Rochester, N. Y.—a subsidiary of the original company, Canadian Nepheline, Ltd.—later erected a modern mill particularly to supply the American glass trade. The Canadian Nepheline, Ltd., has announced its consolidation with the American Nepheline Corporation, Rochester, N. Y., and will be known as the American Nepheline Corporation, Canadian Branch, with office and plant at Lakefield, Ontario.[3] Other companies have entered the field more recently, for the most part American feldspar producers who import crude nepheline syenite from Hastings and other counties and blend it with granular glass spar.

Within 5 years of the initial development of the Canadian nepheline deposits, the tonnage of crude nepheline syenite imported from Canada into the United States approaches in quantity the high feldspar imports in the nineteen twenties and greatly exceeds the current production of Canadian feldspar. Crude nepheline syenite imports in 1940 totaled 27,848 short tons valued at $87,162 compared with 29,231 tons valued at $95,453 in 1939. Imports of ground nepheline syenite in 1940 were 6 short tons valued at $25. No imports of ground material were reported in 1939.

A recent customs court decision (U. S. Customs Court, Third Division, C. D. 293) directed that ground nepheline syenite be admitted into the United States free of duty as "manufactured sand." However, it is reported that this action has been nullified through instructions to its collectors by the Bureau of Customs to assess on this material in the ground condition a duty of 15 percent ad valorem under the Tariff Act of 1930. The United States Department of Justice, coop-

erating with the Bureau of Customs, is understood to be preparing a court case to effect this change in classification.[4]

The glass industry continues to be the chief market for nepheline. Research, however, gradually is broadening its field of usefulness, and fine-grinding for the pottery and enamel trades is increasing. Flotation followed by a final magnetic separation to remove traces of finely divided magnetite has produced good results, according to the Canadian Bureau of Mines.[5]

The use, advantages, and behavior of nepheline syenite in various classes of ceramic manufactures were described by Koenig.[6] The higher fluxing action of nepheline compared to feldspar in hotel chinaware of commercial body specification permitted a lower firing temperature, reduced the quantity of the principal flux, and curtailed or eliminated the auxiliary flux, according to Koenig.[7] An investigation of the effect of using nepheline syenite in enamel frits and in ground-coat enamels on sheet-steel was reported.[8] A resultant lighter color and semimat surface obtained by the use of nepheline syenite in ground coats are offset by smoother enamel coats, less tendency to reboil, and better control of maturing temperature. Nepheline syenite does not decrease adherence, shock resistance, or marketability, if properly used.[9] Using 17 percent nepheline syenite in ground-coat compositions, Cook [10] effected a saving in cost amounting to about ¾ cent per pound or approximately 60 cents per 1,000 square feet of ware. The color of the fired enamel altered but slightly, and no problems in draining, blistering, or reboiling were encountered. Increased percentages of nepheline syenite may affect adherence, but Cook used up to 20 percent without trouble. Nepheline syenite also produces a base ground coat that makes more stable white coats in continuous furnace firing.

TECHNOLOGIC DEVELOPMENTS

The gradual exhaustion of the better-grade deposits and the relatively high cost of small-scale mining as practiced in many feldspar-producing States have tended more or less inevitably to encourage new enterprises utilizing larger-scale operations in the extraction of their raw material. The successful competition of aplite from Virginia and nepheline syenite from Ontario are outstanding examples of these newer methods of operation. Considerable research also has been undertaken in the extraction of feldspar from so-called lower-grade materials, in the recovery of feldspar as a byproduct of other mining or processing operations, and in the development of substitutes or various mixtures of feldspar and other ceramic raw materials for specified uses. Feldspathic waste from titanium operations, consisting mainly of sodic plagioclase, quartz, and iron-bearing gedrite, with an Fe_2O_3 content of about 5.3 percent, was reduced by magnetic concen-

tration to a feldspar-quartz mixture containing 0.81 percent Fe_2O_3. Recovery of 85 to 90 percent of the spar with an iron content of 0.41 to 0.52 percent Fe_2O_3 was achieved by agglomerate tabling and flotation, with a lower limit of 0.36 Fe_2O_3 possible under present methods.[11] An investigation of mixtures of soda spar, potash spar, and spodumene as fluxes in vitreous and semivitreous whiteware bodies showed that considerable reduction in maturing temperatures and flux content was possible through their use.[12] It has been found that zircon added to talc whiteware bodies increases resistance to breakage, while the moisture expansion of feldspar bodies is reduced when zircon is added.[13] A glass-batch ingredient consisting of a mixture of pyrophyllite and feldspar was the subject of a patent granted to Peddrick.[14] A new method for determining quickly the quartz content in feldspars utilizing the polarizing microscope has been devised by McIntyre and Bozsin [15] of the Ferro-Enamel Corporation.

OTHER DEVELOPMENTS

An interesting cooperative venture is the Western North Carolina Feldspar Market established recently at Sylva, N. C. A nonprofit organization, sponsored by the Sylva Chamber of Commerce, Feldspar Market Committee, A. F. Clouse, chairman, it is modeled somewhat after the pattern of the farm cooperatives. The object is to encourage development of the feldspar deposits in Swain, Macon, and Jackson Counties by supplying a ready cash market for producers in this region. The plan provides for the purchase of feldspar from many small miners, sorting and blending of the spar, and shipping in carlots. A site convenient to highway and railroad has been procured, and arrangements have been made for buyers representing different companies to be present on designated periodic "feldspar-market" days. The farmers or other small producers are then assured a fair competitive price for their feldspar. According to a recent informant the venture seems to be functioning successfully, and the erection of a grinding mill is under consideration.

A detailed account of the mining and milling operations and history of the West Paris plant of the United Feldspar & Minerals Corporation appeared during the year.[16] A historical summary, including a chronological index of the principal events in the feldspar industry, was published.[17] The feldspar and other mineral deposits in the Black Hills, South Dakota, were described in a comprehensive report listing mines and prospects in this region.[18] The anorthosites of

IMPORTS [21]

Feldspar.—Imports of crude feldspar in 1940 nearly reached the 1937 level, totaling 12,522 long tons valued at $80,274 compared with 12,956 tons valued at $91,885 in 1937. Although over 60 percent greater than in 1938 and 1939 the tonnage imported in 1940 approximated only about half that received in many previous years. All shipments originated in Canada. No receipts of ground feldspar were reported in 1940.

Feldspar imported for consumption in the United States, 1936–40

Year	Crude		Ground		Year	Crude		Ground	
	Long tons	Value	Short tons	Value		Long tons	Value	Short tons	Value
1936	10,786	$68,198	132	$1,276	1939	7,460	$52,141	2	$54
1937	12,956	91,885			1940	12,522	80,274		
1938	7,651	56,126							

Cornwall stone.—Despite wartime restrictions, imports for consumption of unmanufactured Cornwall stone, all from the United Kingdom, climbed to 2,261 long tons valued at $20,812 in 1940 (the highest figure reported since 1930) compared with the recent low in 1938 of 513 tons worth $4,976. The tonnage of ground Cornwall stone imported in 1940, however, dropped to 228 long tons, or less than the 1938 figure, although the average value increased from $11.39 a ton in 1939 to $12.10 in 1940. As in former years, imports of ground Cornwall stone also were from the United Kingdom.

Cornwall stone imported for consumption in the United States, 1936–40

Year	Unmanufactured		Ground		Year	Unmanufactured		Ground	
	Long tons	Value	Long tons	Value		Long tons	Value	Long tons	Value
1936	2,061	$18,402	357	$4,730	1939	1,684	$17,233	348	$3,965
1937	1,899	16,864	323	4,267	1940	2,261	20,812	228	2,758
1938	513	4,976	233	1,797					

WORLD PRODUCTION

Feldspar sold or used in the United States represents the greater portion of this mineral produced or marketed in the world, according to available data. In addition, usually over half of the production

(shipments) of Canadian crude is ground in the United States. Data for 1940 show a 76-percent gain over 1939 in total Canadian shipments—19,894 metric tons in 1940 compared with 11,306 tons in 1939—and a substantial increase in United States output.

Feldspar produced in Sweden, Norway, and Finland in normal times is exported largely to the United Kingdom, Germany, and other European destinations. Small but steady outputs of spar are reported from other widely separated regions, including Argentina, Brazil, India (British), and Australia.

World production of feldspar, 1936–40, insofar as figures are available, appears in the following table.

World production of feldspar, 1936–40, by countries, in metric tons

[Compiled by L. P. Lounsbery]

Country [1]	1936	1937	1938	1939	1940
Argentina (shipments)	1,082	1,346	620	1,051	(2)
Australia:

United States (sold or used)	248,654	272,842	199,267	257,534	295,430

[1] In addition to countries listed, feldspar is produced in Czechoslovakia. Official figures of output are not available, but it is estimated that the annual production is approximately 30,000 metric tons (Stat. Comm. Czechoslovak Ceram. Soc.).
[2] Data not yet available.
[3] Includes some china stone.

ASBESTOS

By Oliver Bowles and K. G. Warner

SUMMARY OUTLINE

Sales of domestic asbestos attained an all-time high of 20,060 short tons in 1940, a 30-percent increase over 1939, which was a record year. Their value was 32 percent more than in 1939. Consumption was 3 percent greater than in 1939 but 17 percent less than in 1937. Sales from domestic mines totaled less than 8 percent of domestic requirements. Asbestos produced in the United States is predominantly of the shorter grades, hence domestic production of the longer and more essential grades is considerably less than 8 percent of requirements.

During recent years there has been a marked increase in imports of asbestos from Africa. Some of the African fibers are interchangeable with Canadian fibers and compete with them upon a price basis. Other kinds, particularly the amosite and blue asbestos, obtainable in quantity only in Africa, with certain grades of Rhodesian chrysotile, are utilized in special products for which no other fibers are suitable. Consequently, it is highly desirable that imports of such kinds and grades should continue. Although importers and users were concerned to some extent over possible delays, there was no evidence of interruptions to shipping because of war conditions; in fact, importations from Africa in 1940, amounting to more than 17,000 short tons, were the highest on record, exceeding those of 1939 by 54 percent.

The famous asbestos deposits of Quebec, Canada, have for many years furnished the United States with a large part of its supplies of both long and short fibers. Imports from Canada were a little higher in 1940 than in 1939. As Canada has lost all of her continental European asbestos markets, there is no shortage of the supply available for United States needs.

During recent years domestic production has been centered chiefly in the extensive deposits of slip fiber near Hyde Park, Vt. A somewhat similar occurrence of slip fiber in serpentine has been noted in Somerset County, Maine, but no development work has been done and no data are available on the extent of the deposit. Excellent fiber is obtainable in Arizona, and a moderate increase in activity is to be noted in this area.

Because of its resistance to chemicals and high temperatures, amphibole asbestos is well-adapted for certain special products, such as acid filters and coatings for welding rods. Small quantities are shipped from various States. During 1940 there was a growing demand for information on new sources of supply of high-grade anthophyllite and tremolite.

The following table of salient statistics compares 1940 data with those of 1939. Comparable figures are given for 1890–1938 in Minerals Yearbook, 1939, page 1311. Of special interest is the upward trend in domestic production. Consumption of raw asbestos and value of exports of asbestos products show small increases.

Salient statistics of the asbestos industry in the United States, 1939–40

	1939		1940	
	Short tons	Value	Short tons	Value
Domestic asbestos—				
Produced:				
Chrysotile	14,686	(1)	17,481	(1)
Amphibole	450	(1)	1,693	(1)
Total produced	15,136	(1)	19,174	(1)
Sold or used by producers:				
Chrysotile	15,043	$503,097	18,672	$664,520
Amphibole	416	9,691	1,388	9,988
Total sold or used by producers	15,459	512,788	20,060	674,508
Imports (unmanufactured)	242,561	9,094,538	246,613	10,034,433
Exports (unmanufactured)	2,473	218,830	4,474	449,105
Apparent consumption [2]	255,547	9,388,496	262,199	10,259,836
Exports of asbestos products	(1)	3,354,920	(1)	3,473,246

[1] Figures not available.
[2] Quantity sold or used by producers, plus imports, minus exports.

The following table shows production of asbestos during recent years.

Asbestos sold or used by producers in the United States, 1936–40, by varieties

Year	Chrysotile		Amphibole		Total	
	Short tons	Value	Short tons	Value	Short tons	Value
1936	10,719	$302,301	345	$11,860	11,064	$314,161
1937	11,547	332,747	532	11,897	12,079	344,644
1938	(1)	(1)	(1)	(1)	10,440	247,264
1939	15,043	503,097	416	9,691	15,459	512,788
1940	18,672	664,520	1,388	9,988	20,060	674,508

[1] Bureau of Mines not at liberty to publish figures separately for chrysotile and amphibole.

REVIEW BY STATES

Arizona.—According to reports received by the Bureau of Mines, sales of asbestos in Arizona, which were considerably larger in 1940 than in 1939, were made by the following companies: Arizona Chrysotile Asbestos Co., Arizona Asbestos Corporation, Bear Canyon Asbestos Co., Emsco Asbestos Co., Arthur Enders, Roger Q. Kyle, and Guy Phillips, all of Globe, Gila County, Ariz.; and Johns-Manville Products Corporation, New York, N. Y. Several other producers sold small quantities to the larger operators.

California.—A small quantity of amphibole asbestos was mined near Lone Pine, Inyo County, by R. B. McIllroy.

Georgia.—Philip S. Hoyt produced amphibole asbestos near Clayton and the Powhatan Mining Co., the same variety near Dillard, both in Rabun County.

Maryland.—The Powhatan Mining Co., Woodlawn, Baltimore, Md., obtains a high-grade tremolite near Pylesville, Harford County. It is used chiefly for making chemical filters.

North Carolina.—Near Greenmountain and various other points in the State the Powhatan Mining Co. and Philip S. Hoyt mined small tonnages of amphibole asbestos.

Pennsylvania.—The Foote Mineral Co. obtained amphibole asbestos in Chester County.

Vermont.—The extensive slip-fiber chrysotile deposits near Eden, Lamoille County, were operated continuously during the summer months of 1940 by Vermont Asbestos Mines, division of the Ruberoid Co., 500 Fifth Avenue, New York, N. Y. Production is increasing steadily; and high-grade fibers, chiefly of shingle-, paper-, and cement-stock grades are becoming important factors in the United States market.

Trends in consumption.—The following table shows trends in the asbestos-products industries in the United States during recent years.

Raw asbestos consumed in the United States and asbestos products manufactured in and exported from the United States, 1935–40

Year	Raw asbestos—apparent consumption (short tons)	Asbestos products—Manufactured [1]	Asbestos products—Exported [2]	Year	Raw asbestos—apparent consumption (short tons)	Asbestos products—Manufactured [1]	Asbestos products—Exported [2]
1935	174,655	$62,420,944	$2,261,929	1938	187,150	(1)	$2,533,916
1936	250,922	(1)	2,479,273	1939	255,547	$97,944,735	3,354,920
1937	316,263	96,347,570	3,047,078	1940	262,199	(1)	3,473,246

[1] Figures of Bureau of the Census (collected biennially for odd years) include value of certain gaskets, packing, and similar products in which little asbestos was employed.
[2] Compiled from records of Bureau of Foreign and Domestic Commerce.

The consumption of asbestos depends chiefly on the manufacture of automobiles, on building construction, and on certain types of industrial activity. All kinds of automotive transport equipment require large quantities for brake bands and clutch facings. Building construction employs many products in which asbestos is an important constituent; these include asbestos-cement shingles and siding, wallboard, and various heat-insulation and fireproofing materials. Consumption of asbestos bears a definite relationship to the manufacture of steam engines and similar equipment, because it is used extensively for packings and gaskets and also for heat insulation in the form of boiler lagging and pipe covering. Figure 1 shows the relationship of asbestos consumption to these three major activities for a period of years.

Market conditions.—Markets were depressed because of war uncertainties during the most of 1940; but in the fourth quarter demands became more active owing to the national defense program.

Prices.—All prices for asbestos are quoted on a short-ton basis from Metal and Mineral Markets, published by the McGraw-Hill Publishing Co., Inc., New York City. Canadian prices are f. o. b. Quebec mines, tax and bags included; Rhodesian, South African, and Russian prices, c. i. f. New York; and Vermont prices, f. o. b. mines, Vermont.

Prices were constant throughout the year, except that for certain grades, where indicated in parentheses, they were advanced in August for the remainder of the year:

Canadian: Crude No. 1, $700–$750; Crude No. 2 and sundry crudes, $150–$350; spinning fibers, magnesia and compressed sheet fibers, $110–$200; shingle stock, $57–$78; paper stock, $40–$45; cement stock, $21–$25 (advanced to $22–$26); floats, $18–$20 (advanced to $19–$21);

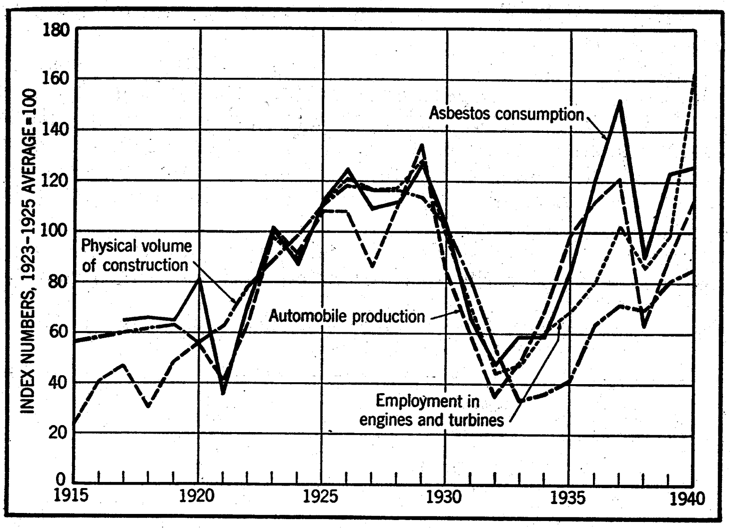

FIGURE 1.—Consumption of asbestos compared with automobile production, construction activity, and employment in engine and turbine manufacture in the United States, 1915–40. Units are reduced to percentages of the 1923–25 average. Statistics on automobiles are from the Bureau of the Census, physical volume of construction from the Bureau of Foreign and Domestic Commerce, and employment in engine and turbine manufacture from the Bureau of Labor Statistics.

and shorts, $12–$16.50 (advanced to $13–$17.50). Canadian quotations are in American dollars rather than Canadian dollars.

Rhodesian: Crude No. 1, $300; and Crude No. 2, $260.

South African: Amosite: Grade B 1 (white), $140 (advanced to $150); Grade B 3 (dark), $120. Transvaal Blue: Grade B (long fiber), $400; Grade S (short fiber), $140 (advanced to $150).

Russian: Crude AA $750; Crude No. 1, $275; Crude No. 2, $240; and shingle stock, $67.50 and up.

Vermont: Shingle stock, $57; paper stock, $40; cement stock, $25; and shorts and floats, $12–$18 (advanced to $13–$18).

NEW DEVELOPMENTS

Interest has been revived in the blue asbestos deposits of the Cochabamba district of Bolivia, which have been known for some years. Fibers from this area examined at the Bureau of Mines are somewhat lower in strength and flexibility than South African blue. It is reported that Japan purchased several hundred tons of this fiber during recent years and that small quantities have reached the United States market.

After 5 years of laboratory research, Germany has developed brake linings that can be substituted for those consisting essentially of asbestos. The new lining consists of aluminum or steel wool, incorporated with synthetic rubber as a binder. It is said to have good braking power and to resist wear and heat.

Much interest has centered recently in a deposit of chrysotile near Cuddapah in the Madras Presidency about 125 miles northwest of Madras, British India. A specimen received by the Bureau of Mines is light amber, resembling closely the fiber mined in Arizona. The maximum fiber length of this sample is 3½ inches; the material is exceptionally soft and silky and has superior strength and flexibility. No information is yet available as to the nature or extent of the occurrence. Small quantities have reached the United States market.

FOREIGN TRADE [1]

The following table shows imports of unmanufactured asbestos into the United States in 1939 and 1940, by countries and classes. Total imports in 1940 increased 2 percent in quantity and 10 percent in value over 1939. Imports from Africa (including that which comes via United Kingdom) were 50 percent greater than in 1939. In view of disturbed conditions in the Mediterranean it is surprising that imports from Cyprus were only 17 percent less in 1940 than in 1939. No asbestos was obtained in 1940 from the U. S. S. R.

Asbestos (unmanufactured) imported for consumption in the United States, 1939–40, by countries and classes

Country	Crude (including blue fiber)		Mill fibers		Short fibers [1]		Total

[1] Asbestos, n. e. s., containing not over 15 percent of foreign matter.
[2] Less than 1 ton.

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

Figure 2 shows, for a period of years, the principal sources of supply of asbestos used in the United States. Canadian fiber dominates the picture because most of our requirements of short fiber originate there. As a source of spinning, magnesia and compressed sheet fibers, Canada occupies a less-dominant, though still important place.

The following table shows imports and exports of unmanufactured asbestos for the 5-year period, 1936–40.

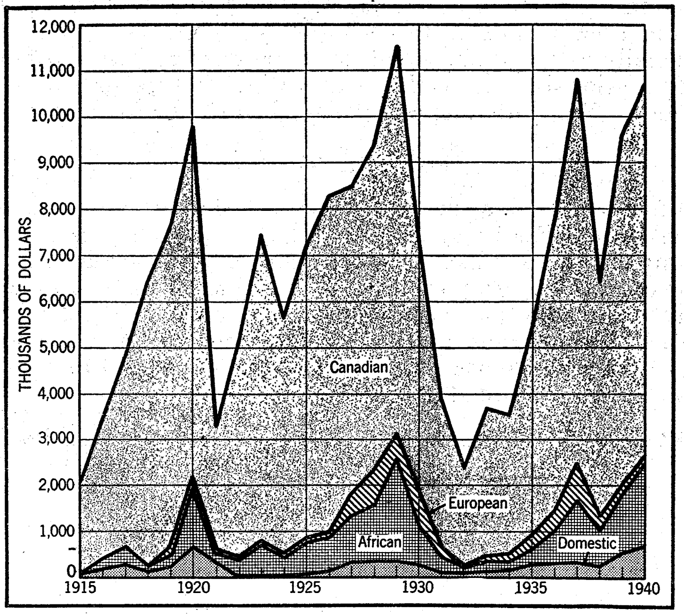

FIGURE 2.—Sources of asbestos consumed in the United States, 1915–40. Data on imports from Bureau of Foreign and Domestic Commerce. Material classified as European includes in some years small quantities from other sources.

Asbestos (unmanufactured) imported for consumption in and exported from the United States, 1936–40

Year	Imports		Exports	
	Short tons	Value	Short tons	Value
1936	243, 602	$7, 524, 937	3, 744	$310, 197

Venezuela	71	(2)	(2)	(2)	(2)

[1] In addition to countries listed, a small quantity of asbestos is produced in Madagascar.
[2] Data not available.
[3] Less than 1 ton.
[4] Exclusive of sand, gravel, and stone (waste rock only), production of which is reported as follows: 1936, 2,815 tons; 1937, 3,611 tons; 1938, 2,975 tons; 1939, 3,535 tons; 1940, data not available.

CANADA

Sales of asbestos in Canada were a little lower in 1940 than in 1939. Exports to the United States show a small gain, but this is more than offset by the loss of all the continental European markets. Because of wartime restrictions on publication of statistics, data are less complete for 1940 than for previous years.

For some time interest has centered in a deposit of good-quality chrysotile in Bannockburn Township, Ontario. A small tonnage was produced in 1939, but there is no report of production in 1940. However the Johnson's Company, a pioneer producer in the Thetford Mines district of Quebec, has acquired an interest in the Rahn Lake Mines Corporation, Ltd., and has taken steps toward more systematic development of the property. It is possible therefore that Ontario may become an important asbestos producer.

Sales of asbestos in Canada, 1939–40

	1939			1940

AFRICA

Southern Rhodesia.—Beginning with June 1940, publication of figures for production of asbestos were discontinued for the duration of the war. In the following table production for 1940 includes only the first 5 months. Production for the same period in 1939 was 24,296 tons valued at £448,451.

Asbestos produced in Southern Rhodesia, 1936–40

Year	Short tons	Value	Year	Short tons	Value
1936	56,346	£836,469	1939	58,313	£1,088,782
1937	57,014	840,025	1940 [1]	24,391	474,617
1938	58,811	1,020,921			

1 Figures cover period January–May.

Union of South Africa.—Data for only 9 months of 1940 are available at the time of writing. Figures for the corresponding period in 1939 were: Transvaal, 11,761 short tons; and Cape Province, 4,611 short tons. Total value, £364,132.

Asbestos produced in the Union of South Africa, 1936–40, by sources

Year	Short tons				Total[1] value
	Transvaal	Cape Province	Natal	Total	
1936	21,188	4,048	(2)	[2] 25,236	£337,229
1937	23,921	4,712	(2)	[2] 28,633	431,212
1938	16,505	6,484	[2] 187	[2] 23,176	416,401
1939	15,811	6,143	79	22,033	509,278
1940	[3] 15,303	[3] 4,653	(4)	[3] 19,956	[3] 360,111

[1] Value of local sales plus value of exports.
[2] Small production in Natal in December 1936 and in 1937 included in 1938 figures.
[3] Figures cover period January–September.
[4] Data not available.

The following table shows the tonnage of each variety produced from 1936 to 1940 but includes only the first 9 months of 1940. Figures for the corresponding 9 months of 1939 are as follows: Amosite (Transvaal), 8,229 short tons; chrysotile (Transvaal), 444; blue (Transvaal), 3,088; and blue (Cape), 4,611.

Asbestos produced in the Union of South Africa, 1936–40, by varieties and sources, in short tons

Variety and source	1936 [1]	1937 [2]	1938 [2]	1939 [2]	1940 [2,3]
Amosite (Transvaal)	4,823	6,531	8,793	11,378	12,628
Chrysotile (Transvaal)	16,149	16,855	[4] 5,573	[4] 582	374
Blue (Transvaal)	216	535	2,326	3,930	2,301
Blue (Cape)	4,048	4,712	6,484	6,143	4,653
	25,236	28,633	23,176	22,033	19,956

[1] Data from Government Mining Engineer, Union of South Africa, Department of Mines, Annual Report.
[2] Data from Union of South Africa, Department of Mines, Monthly Reports.
[3] Figures cover period January–September.
[4] Includes 187 short tons in 1938 and 79 tons in 1939 produced in Natal.

Swaziland.—The Havelock mine, which began production in June 1939, has become an important factor in the asbestos industry of Africa. Publication of data on production was discontinued for the duration of the war, beginning with August 1940. For the first 7 months of 1940 production amounted to 13,125 short tons compared with 7,973 for the entire year 1939.

CYPRUS

No data are available on production of short-fiber chrysotile in Cyprus during 1940, but imports into the United States from that source were about four-fifths as great as in 1939.

Asbestos exported from Cyprus, 1936–40

Year	Long tons	Value	Year	Long tons	Value
1936	9,506	£80,343	1939	9,813	(1)
1937	11,704	126,371	1940	(1)	(1)
1938	5,578	88,290			

[1] Data not available.

U. S. S. R.

No recent data are available on the Russian asbestos industry. An increasingly large proportion of the output is used for domestic asbestos-products manufacture.

Asbestos produced in and exported from U. S. S. R., 1936–40, in metric tons

Year	Production	Exports	Year	Production	Exports

BARITE, WITHERITE, AND BARIUM CHEMICALS

By Bertrand L. Johnson and K. G. Warner[1]

SUMMARY OUTLINE

New all-time peaks were again reached in 1940 for domestic production of crude barite (390,462 short tons), domestic crude barite sold or used by producer (409,353 tons), and reported consumption of domestic and imported crude barite (404,388 tons). The apparent new supply (barite sold or used by producer plus imports) was greater in 1940 than in 1939 but did not reach that of 1937, when an exceptionally large quantity of crude barite was imported. A new record was also set for the total value of domestic crude barite sold or used by producers ($2,596,743). This was accompanied by a rise in the average value a ton from $6.11 in 1939 to $6.34 in 1940. Increased demands for crude barite came from the ground- (and crushed-) barite and barium chemical industries. There was a slightly decreased demand for crude barite for lithopone manufacture. Imports of crude barite in 1940 were considerably less than in 1939 and came entirely from Cuba; the average value, however, rose quite sharply from $4.83 in 1939 to $5.59 in 1940. Imports of witherite were slightly less in 1940 than in 1939.

Total sales of barium chemicals[2] were higher than in 1939 or 1938 but did not reach the figure for 1937. The value of total sales was higher in 1940 than in 1939 but less than for 1937 and 1936. The quantities of lithopone, blanc fixe, artificial barium carbonate, and "other barium chemicals" sold or used by producers in 1940 were all greater than in 1939.

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

[2] Data for "barium chemicals" not comparable directly with those for "barium products" in previous Minerals Yearbooks because of separation of data for "ground (and crushed) barite" and "witherite," given separately in this chapter.

Salient statistics of the barite, witherite, and barium chemical industries in the United States, 1936–40

	1936	1937	1938	1939	1940
Barite:					
Crude:					
Produced short tons	274,062	360,877	335,433	365,870	390,462
Sold or used by producers:

Value	$338,925	$368,133	$254,874	$172,490	$9,045
Exports of lithopone:					
Short tons	2,538	2,671	1,734	4,845	14,298
Value	$229,942	$231,622	$153,567	$392,798	$1,112,362

[1] F. o. b. mine shipping point.
[2] Declared value f. o. b. foreign market.
[3] Barite sold or used by producers plus imports.
[4] To avoid duplication, the barium chemicals reported here do not include the output of firms that make these chemicals from such products as barium chemicals and imported barite and witherite purchased in the open market.

BARITE

CRUDE

Production.—Barite was mined in 1940 in 10 States—Arkansas, California, Colorado, Georgia, Missouri, Nevada, South Carolina, Tennessee, Texas, and Virginia—compared with 11 in 1939. States productive in 1939 but not in 1940 were Alabama, Arizona, and Montana. Added producers were Arkansas and Texas. Mine production in 1940 totaled 390,462 short tons, a 7-percent increase from that of 1939 (365,870 tons).

Sales.—A new peak was made in 1940 in the quantity of crude barite sold or used by producers in the United States—409,353 short tons—and the total value was higher than ever before ($2,596,743). Missouri continued to lead in sales of crude barite in 1940, with Georgia second; both States had increases over 1939.

Prices.—The market quotation for crude barite from Georgia, f. o. b. mines, has remained unchanged at $7 a long ton from 1935 to 1940, inclusive, according to the Engineering and Mining Journal Metal and Mineral Markets.

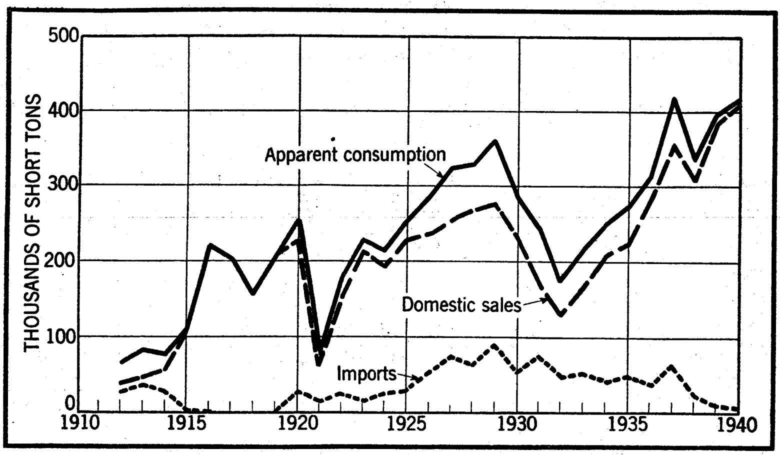

FIGURE 1.—Trends in domestic sales, imports, and apparent consumption of crude barite, 1912–40.

Crude barite sold or used by producers in the United States, 1939–40, by States

State	1939		1940	
	Short tons	Value	Short tons	Value
Georgia	86,589	$438,378	92,302	$464,590
Missouri	171,642	1,163,870	179,455	1,216,069
Tennessee	57,140	372,348	70,767	503,204
Other States [1]	68,238	369,507	66,829	412,880
	383,609	2,344,103	409,353	2,596,743

[1] 1939: Alabama, Arizona, California, Colorado, Montana, Nevada, South Carolina, and Virginia; 1940: Arkansas, California, Colorado, Nevada, South Carolina, Texas, and Virginia.

The price of Missouri crude barite (95 percent $BaSO_4$, less than 1 percent iron) was quoted at $6.50 to $7.00 a short ton from January 1, 1940, to August 15, 1940, after which the quotations were $6.25 to $7.00 a ton. The 93-percent-grade quotations remained at $6.00 to $6.50 a ton throughout 1940.

The average value, f. o. b. mine shipping point, of crude barite for the entire United States rose from $6.11 in 1939 to $6.34 in 1940.

Consumption.—The following tables show the consumption of crude barite by uses and by States.

Crude barite (domestic and imported) used in the manufacture of ground barite and barium chemicals in the United States, 1936–40, in short tons

Year	In manufacture of—			Total	Year	In manufacture of—			Total
	Ground barite	Lithopone	Barium chemicals			Ground barite	Lithopone	Barium chemicals	
1936	83,990	167,014	52,445	303,449	1939	[1] 192,112	141,556	58,015	391,683
1937	148,930	162,681	72,371	383,982	1940	[1] 200,899	136,885	66,604	404,388
1938	[1] 193,728	117,007	54,250	364,985					

[1] Includes crushed barite as follows: 1938, 7,121 short tons; 1939, 11,678 tons; 1940, 11,601 tons.

Crude barite (domestic and imported) used in the manufacture of ground barite and barium chemicals in the United States in 1940, by States

State	Product manufactured	Plants	Barite used (short tons)
Missouri	Ground barite and chemicals	3	116,400
Delaware, New Jersey, and Pennsylvania	Lithopone and chemicals	5	81,391
California	Ground barite, lithopone, and chemicals	8	47,545
Illinois	do	7	41,254
Colorado	Chemicals	1	106,197
Rhode Island	do	1	
West Virginia	do	2	
Kansas	Lithopone	1

Georgia	Ground barite and chemicals	2	
New York	do	2	
South Carolina	Ground barite	1	
Louisiana and Texas	do	3	
		[1] 37	[2] 404,388

[1] A plant producing more than 1 product is counted but once in arriving at State totals.
[2] Includes 11,601 short tons of crushed barite not separable by States.

Deposits and technology.—Several articles descriptive of barite deposits and technology [3] appeared in 1940.

Foreign trade.—All of the imports of crude barite into the United States in 1940 came from Cuba; they were 36 percent below those of 1939 in quantity and 26 percent lower in total value. The average value a ton of the crude barite imported increased from $4.83 in 1939 to $5.59 in 1940. Exports of crude barite from the United States are not separately recorded.

Crude barite imported for consumption in the United States, 1939–40, by countries

Country	1939		1940	
	Short tons	Value	Short tons	Value
Algeria	51	$161		
Canada	1	7		
Cuba	11,536	55,817	7,391	$41,342
	11,588	55,985	7,391	41,342

World production.—Few figures are available for 1940 regarding the barite production of the various barite-producing countries.

K. V. Hicks, in two consular reports,[4] and W. S. Dyer, Toronto, Canada, in a letter to the author, state that a large barite deposit was discovered in October 1940 near Walton, Nova Scotia, at an elevation of about 300 feet above sea level and 3 miles from tidewater.

[1] In addition to the countries listed, barite is produced in Canada, China, Czechoslovakia, Spain, and the U. S. S. R.
[2] Data not available.
[3] Official figures which, it is reported, cover only output of mines included under the mining law.

The geology of the area adjacent on the west has been described in Memoir 155 of the Canadian Geological Survey, The Horton-Windsor District, by W. A. Bell, published in 1929, and a sketch of a vertical section of the barite deposit has recently been published.[5] The barite deposit lies near the contact of the gently dipping sedimentary Horton and Windsor series of the Upper Carboniferous. Sixteen drill holes have shown an eastward-pitching ore body at least 600 feet long, 200 feet wide, and over 100 feet thick, with reported reserves of over 1,500,000 tons of barite. The barite is of medium-grained crystalline texture, and its color is reddish. It is reported to have an average specific gravity of 4.41. A composite surface sample is said to have contained over 98 percent $BaSO_4$ and less than 1 percent ferric oxide. About 3,000 tons of barite had been taken out by May 1941 and shipped for treatment to the mill site at Walton, where a grinding plant is to be installed to prepare the barite for use as a weighting material in the Trinidad oil wells. The property is owned by the Springer Sturgeon Gold Mines, Ltd., of Toronto, Canada.

Cuban barite deposits are being developed further, and a grinding plant is under construction at Regla, Havana Bay, to treat barite from the Province of Pinar del Rio.

GROUND (AND CRUSHED)

Sales.—The quantity of ground barite sold or used by producers in the United States in 1940 reached a new high of 184,390 short tons,

[5] Northern Miner, Springer Sturgeon Drilling Quickly Indicates Huge Tonnages: May 8, 1941, p. 7

311436—41——85

with a total sales value of $3,697,806—a marked increased over 1939. The number of plants producing ground or crushed barite increased from 13 in 1939 to 16 in 1940 (see accompanying table).

Ground (and crushed) barite sold or used by producers in the United States, 1936–40

	1936	1937	1938	1939	1940

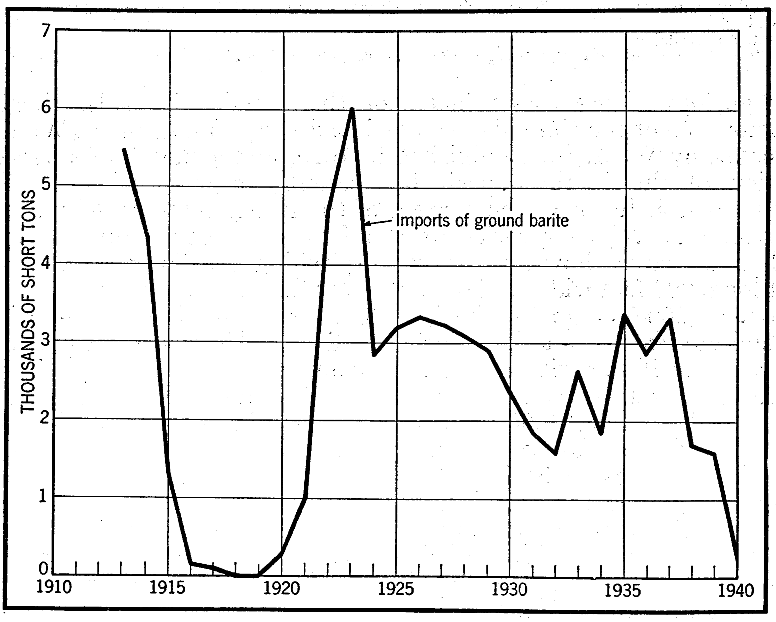

FIGURE 2.—Imports of ground barite into the United States, 1913–40.

The preparation and use of ground barite for weighting drilling muds have been described by Harding [6] and Stern.[7]

[6] Harding, A. C., Work cited in footnote 3.
[7] Stern, A. G., Role of Clay and Other Minerals in Oil-Well Drilling Fluids: Bureau of Mines Rept. of Investigations 3556, 1941, 88 pp.

Prices.—Prices quoted from The Chemical Industries, New York, for ground barite, carlots, 350-pound barrels, works, were $25.15 a short ton for 1940 compared with $23.65 for 1939.

Foreign trade.—Considerable ground barite is exported from the United States, but the data regarding these exports are not separately recorded. A few thousand tons of ground barite have been imported annually. (See fig. 2.)

Ground barite imported for consumption in the United States, 1936–40

[Value at port of shipment]

Year	Short tons	Value	Year	Short tons	Value
1936	2,873	$28,397	1939	1,590	$14,999
1937	3,313	35,046	1940	314	3,299
1938	1,700	15,466			

WITHERITE

Production.—Productive deposits of witherite occur in England and in the United States. The English deposits yield a nearly pure witherite and the American deposits a barite-witherite mixture. In England there are but two producing companies—The Owners of Settlingstones Mines, Ltd., in Northumberland County, and The Holmside & South Moor Collieries, Ltd., in County Durham. Details of these operations are given in a booklet recently issued jointly by the two producing companies.[8] In the United States there is but one producer, the Baroid Sales Division of the National Lead Co., which operates a barite-witherite mine near El Portal, Calif.[9] Current witherite-production figures are combined with those of barite in the production statistics.

Prices.—Prices of ground witherite in 1940, according to The Chemical Industries, New York, ranged from $43.00 to $47.00 in carlots, bags, works, for the 90-percent grade.

Foreign trade.—Imports of witherite into the United States come entirely from England and total only a few thousand tons a year. (See fig. 3.)

Exports of witherite from the United States, if any, are not separately recorded in the foreign trade statistics.

Witherite, crude, unground, imported for consumption in the United States, 1936–40

Year	Short tons	Value	Year	Short tons	Value
1936	2,464	$44,475	1939	3,819	$64,106
1937	4,556	82,341	1940	3,584	70,126
1938	2,115	43,568			

BARIUM CHEMICALS

Sales.—Both the total quantity and the value of barium chemicals sold or used by producers in 1940 were greater than in 1939. Greater quantities of lithopone, blanc fixe, artificial barium carbonate, and

[8] Holmside & South Moor Collieries, Ltd., and Owners of Settlingstones Mines, Ltd., Witherite (Natural Barium Carbonate) and Its Industrial Uses: Newcastle-upon-Tyne, 1940, 56 pp.
[9] Julihn, C. E., and Horton, F. W., Work cited in footnote 3, pp. 168–170.
Harding, A. C., Work cited in footnote 3.

other barium chemicals were sold, but no new records were made except for artificial barium carbonate (chemically precipitated). An increase in value was attained only in the sales of blanc fixe.

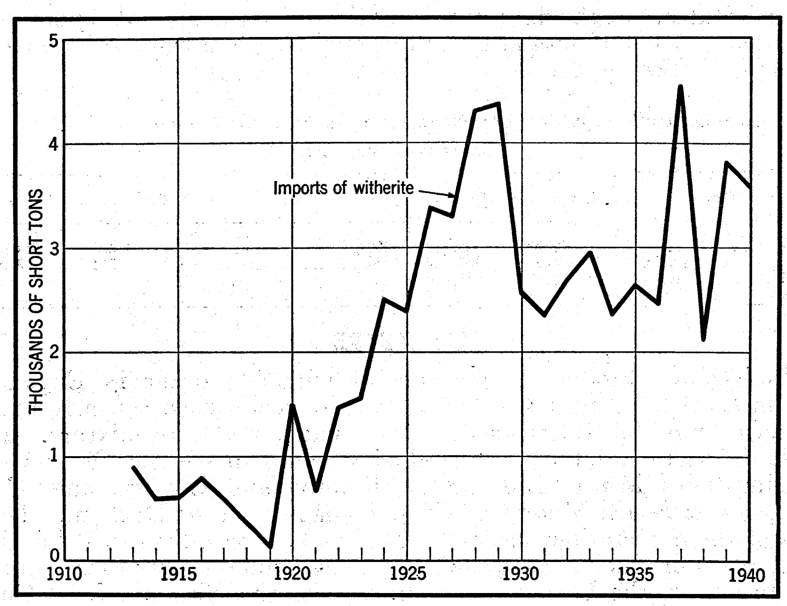

FIGURE 3.—Imports of witherite, crude, unground, into the United States, 1913–40.

[1] To avoid duplication, the barium chemicals reported here do not include the output of firms that make these chemicals from such products as barium chemicals and imported barite and witherite purchased in the open market.

[2] Does not include cadmium lithopones.

[3] Figures cover chemicals, in order of value, as follows: 1936 and 1938: Chloride, dioxide, sulfide, hydroxide, and oxide; 1937: Chloride, dioxide, sulfide, and hydroxide; 1939: Chloride, dioxide, hydroxide, sulfide, and oxide; 1940: Chloride, dioxide, hydroxide, sulfide, oxide, and nitrate.

Lithopone is used principally in the paint industry, which took 77 percent of the total sold or used by producers in 1940.

Lithopone [1] sold or used by producers, 1938–40, by consuming industries

Industry	1938		1939		1940	
	Short tons	Percent of total	Short tons	Percent of total	Short tons	Percent of total
Paints, enamels, and lacquers	101,924	81	113,995	80	117,075	77

Other	5,274	4	8,146	6	12,602	8
	125,746	100	142,759	100	151,802	100

[1] Does not include cadmium lithopone.

Prices.—Quoted prices for domestic and high-strength lithopones in 1940 were lower than those for 1939. The prices for titanated lithopones in 1940 were the same as the lowest prices of 1939. Prices for precipitated barium carbonate in 1940 were \$45 to \$62.50 a short ton compared with \$52.50 to \$62.50 in 1939. There was no change in barium chloride prices. Barium chlorate prices were up considerably in 1940—20 to 45 cents a pound as against 16½ to 25 cents in 1939. Barium dioxide ranged from 10 to 12 cents a pound in 1940 compared with 11 to 12 cents in 1939. Barium hydrate prices ranged from 5½ to 7 cents in 1940 and from 4½ to 5½ cents in 1939. Barium nitrate prices ranged only between 9½ and 10½ cents in 1940 compared with 6¾ and 10½ cents in 1939. Blanc fixe was quoted at \$50.00 to \$80.00 in 1940, a slightly narrower range than that of 1939—\$40.00 to \$80.00.

[1] Chemical Industries (formerly Chemical Markets), New York (monthly).
[2] Lowest price for pulp grade, highest for high-grade precipitated.

Foreign trade.—The only barium chemicals imported into the United States in 1940 were barium nitrate, barium hydroxide, and "barium compounds (n. e. s.)"; imports of all these were much less, both in quantity and value, than in 1939.

Exports of lithopone in 1940 nearly tripled those of 1939 and were accordingly greater than in any year since 1922 when exports of barium products were first recorded separately. The average value of the exports in 1940 (\$77.80) was less than in 1939 and the lowest ever recorded.

Barium chemicals imported for consumption in the United States, 1936–40

POTASH

By J. H. Hedges

SUMMARY OUTLINE

The upward trend of production by potash mines and plants in the United States continued in 1940. An output of 658,249 short tons of merchantable salts containing approximately 379,679 tons of K_2O represents a gain over 1939 of 20 percent in material produced and 22 percent in K_2O. Producers sold 677,892 tons containing about 393,058 tons of K_2O, the average grade being 57.98 percent. A 7-percent increase in sales was proportionately less than the 15-percent rise in consumption, because gains by producers in the domestic market were partly offset by voluntary restriction of exports to conserve supplies in anticipation of reduced imports. Resales for export, by customers of the producers, of salts containing around 32,000 tons of K_2O tended to defeat this program; in consequence, potash was placed under export-license control by an Executive order of January 10, 1941, effective February 3, 1941. Producers and importers sold 477,495 tons of K_2O for use in agriculture and industry in the United States and its possessions; American producers supplied 77 percent (366,344 tons). This figure includes 32,000 tons resold for export.

Contrary to expectation, imports (K_2O content) increased 19 percent from the 18-year low of 1939, owing to heavy shipments from France during the first 5 months of the year. Fertilizer materials imported totaled 274,473 short tons containing 115,241 tons of K_2O valued at $5,148,852, and chemical materials totaled 14,564 tons containing 3,449 tons of K_2O valued at $2,411,919.

Exports of fertilizer materials decreased 32 percent, to 93,060 short tons containing 55,836 tons of K_2O valued at $3,141,170. Chemical materials exported increased fourfold to 14,180 tons valued at $3,096,909. The increase represented shipments to the United Kingdom and British possessions of salts normally obtained from European sources.

The potash industry developed in the United States since the World War of 1914–18 through coordinated efforts of Government and private agencies has ended definitely the dependence on foreign supplies that plagued consumers for 20 years after cartelization of the German industry under Government control in 1910. The serious shortage that developed during the war years 1915 to 1918 sent the prices of meager supplies skyrocketing and further stimulated the study of domestic resources. Government investigations of all phases of the industry have demonstrated its stability and economic soundness. In recent years it has supplied up to 70 percent of expanding domestic needs, and during 1940 produced all grades of salts in ample quantities to supplement dwindling receipts from foreign sources. Although output exceeded that of any previous year by a wide margin, the ultimate capacity of existing mines and plants has not been reached. The third mine to be opened in the Carlsbad (N. Mex.) district, which began operations in late 1940, will be in full production in 1941, adding materially to the domestic supply. The statistical position, with respect to the potential supply and the probable demand in 1941, is set forth in the following table:

Estimated capacity of domestic plants and requirements for 1941

	Short tons of K_2O
Requirements—1941	
Consumption—1940	
United States and possessions	445, 705
Canada	21, 203
Cuba	2, 504
Total consumption—1940	469, 412
10-percent increase for 1941	46, 941
Anticipated consumption—1941	516, 353
Other Western Hemisphere	2, 000
Britain and British possessions	10, 000
Total American market—1941	528, 353
Available supply—1941	
Domestic capacity—7 plants	
Refined salts	475, 000
Run-of-mine (25 percent K_2O)	50, 000
Imports (sodium-potassium nitrate from Chile)	8, 000
Total supply—1941	533, 000

In addition to the prospective new supply indicated above, stocks in the hands of producers and importers at the beginning of the year totaled about 45,000 short tons of K_2O, and run-of-mine ore averaging 25 percent K_2O could be produced at the rate of 150,000 tons of K_2O annually if necessary. Thus it appears that no shortage is likely to develop in 1941. Three companies are now producing sulfate on a large scale and one plant is turning out sulfate of potash-magnesia, so that these salts, formerly available only from abroad, now can be supplied in quantity adequate to meet domestic needs.

Receipts of potash from German and French sources virtually ceased immediately after the outbreak of hostilities in September 1939. During the last quarter of that year imports from Europe totaled only 23,000 short tons of salts in contrast to 180,000 tons entered in the corresponding period of 1938. However, the French took advantage of the stalemate on the western front that characterized the early months of 1940 to resume operation of the Alsatian mines that had been seriously hampered in the confusion of mobilization. Before access to the sea was cut off by the German drive in May, they had shipped 186,000 tons of potash salts to the United States. Later in the year a number of cargoes, aggregating 30,882 tons, were imported from Spain, but these shipments likewise ceased in November and had not been resumed when this chapter was written (April 1941).

Except for crude nitrate from Chile, receipts of potash salts from abroad are likely to be inconsequential in 1941. As indicated above, the industry doubtless can meet domestic needs, but the exportable surplus of high-analysis salts may fall below the requirements of neighbors who will look to the United States for supplies. Up to a certain point, deficiencies can be made up from run-of-mine salts without inconvenience to users. This material can be employed without disadvantage in certain low-analysis fertilizer mixtures where it simply replaces some of the inert filler customarily used, and in some of the higher mixtures part of the potash can be supplied in this form. By these expedients domestic requirements should be met and a large enough quantity made available for essential exports.

More than 99 percent of the 1940 output of potash was derived from natural brines and bedded saline deposits. The four major companies (American Potash & Chemical Corporation, United States Potash Co., Potash Company of America, and Union Potash & Chemical Co.) produced over 97 percent of the total. Bonneville, Ltd., reported a small increase in production from brine of the Salduro marsh near Wendover, Utah, and the North American Cement Corporation and United States Industrial Chemicals recovered a small quantity of potash salts as a byproduct of their operations.

Salient statistics of the potash industry in the United States for 1939 and 1940 are summarized in the following table.

Salient statistics of the potash industry in the United States, 1939–40

[1] Revised figures.

PRICES

Price schedules issued by producers and importers in June 1939 for the 1939–40 fertilizer season governed all transactions up to May 31, 1940. Schedules for the 1940–41 season issued in June 1940 retained unchanged the base price, ex-vessel at Atlantic, Gulf, and Pacific ports, of 53½ cents a unit for muriate and $36.25 a ton for sulfate but advanced the price of manure salts 1½ cents, to 60 cents a unit. The long-established seasonal discounts of 12 and 6 percent were changed as follows: 8 percent on orders accepted before July 26, 1940, for delivery in June or July or for delivery of the total order in substantially equal monthly quantities from August 1, 1940, to January 31, 1941, and 4 percent additional upon acceptance of the entire tonnage under contract by January 31, 1941; 4 percent on orders accepted before November 1, 1940, for spot delivery or for delivery of the total order in substantially equal monthly quantities from November 1, 1940, to January 31, 1941, and 2 percent additional upon acceptance of the entire tonnage under contract by January 31, 1941. On orders accepted on or after November 1, 1940, no discount was allowed. The split-discount method of pricing is designed to discourage the tendency to overorder by penalizing cancelations and rewarding acceptance of the full tonnage under contract. The burden of balancing the supply with a fluctuating demand is thus divided between producers and their customers. Cancelations, long a bugbear of the industry, doubtless will be kept at a minimum by this expedient.

In addition to the prices quoted ex-vessel at the customary coastal basing points, the 1940–41 schedules offer salts f. o. b. cars at Carlsbad, N. Mex., at 11.2 cents a unit below net ex-vessel port prices, and at Trona, Calif., at 8 cents below the net ex-vessel price at Pacific coast ports. The net ex-vessel price is the base ex-vessel price less the appropriate seasonal discount. This multiple price system and the revised multiple discount system were adopted as a corollary of the investigation of the industry by the United States Department of Justice, on recommendation of the United States Department of Commerce, after an extended economic study of the potash industry. The effect of pricing f. o. b. Carlsbad and Trona in addition to the customary coastal basing points, at a suitable differential, is to reflect in lower delivered prices the natural advantage of those consumer areas that are nearer freightwise to the points of production than to the base points on the coast. It is expected to eliminate certain relatively higher price inland areas, where the f. o. b. mill price plus rail freight from the nearest source of supply will be much less than the port price plus transportation from the nearest base port. A saving of $1 to $2 a ton should accrue to consumers west of the Alleghenies, while prices in the so-called watershed areas representing over 60 percent of consumption will not be affected.

Importers of French and Spanish potash offered muriate, sulfate, and kainite in limited amounts at established prices and customary terms. Importers of German potash announced to the trade in June that on account of the war in Europe they were not in a position to offer any potash salts for shipment from Europe and therefore would postpone issuing price lists until such shipments could be resumed.

The following table shows the prices prevailing during 1940 in accordance with published schedules and discounts.

Prices f. o. b. Carlsbad were $5.60 a ton less than port prices for 50-percent muriate and $3.36 less for 30-percent manure salts. The f. o. b. Trona price for 50-percent muriate was $4.00 a ton below the port price.

Ex-vessel port prices per ton of potash salts in the United States in 1940

Period	Muriate of potash, 50 percent K_2O, in bulk	Sulfate of potash, 90 percent K_2SO_4, in bags	Manure salts, 30 percent K_2O, in bulk	Kainite, 20 percent K_2O, in bulk
January to May, inclusive	$26.75	$36.25	$17.55	$12.75
June 1 to July 25	23.54	31.90	15.84	10.78
July 26 to October 31	25.14	34.07	16.92	11.51
November and December	26.75	36.25	18.00	12.25

CONSUMPTION AND USES

Producers and importers of potash salts sold and delivered approximately 477,000 short tons of potash in 1940 for consumption in the United States and its possessions, of which 366,344 tons (77 percent) came from domestic sources. About 32,000 tons of this material were resold for export, hence domestic consumption appears to have been about 442,000 tons of agricultural salts and muriate of chemical grade; 92 percent was for fertilizer and 8 percent for industrial use. In addition, 14,564 tons of chemical salts containing 3,449 tons of K_2O were imported for consumption in the United States, bringing the total used in this country to approximately 446,000 tons of K_2O. Apparent consumption, calculated by subtracting exports (62,836 tons) from the sum of imports (118,690 tons) and producers' sales (393,058 tons), was 448,912 tons of K_2O.

The following table gives as accurate a picture of sales of potash of domestic and foreign origin for consumption in the United States and for export as can be drawn by combining information from numerous sources adjusted to a comparable basis.

Sales of primary potash in the United States for consumption and export, 1939–40, in short tons of K_2O

	1939	1940
Deliveries of potash of domestic and foreign origin reported by American Potash Institute—		
In United States and possessions:		
Agricultural	340,765	417,943
Chemical	24,284	37,815
For export	77,675	24,046
	442,724	479,804
Imports not included above plus sales of nonmember producers	28,500	21,737
	471,224	501,541
Total exports	83,800	55,836
Actual sales for consumption in the United States	387,424	445,705

PRODUCTION AND SALES

Mines and plants in the United States produced more marketable potash salts in 1940 than ever before, recording a 20.4-percent gain over 1939 in gross tonnage and a 21.6-percent gain in K_2O. Sales increased 7.3 percent, exceeding production by 13,379 tons of K_2O.

The refining processes employed by the major producers yield muriate of 95 to 98 percent purity. Other grades for which there is a gradually abating demand are manufactured by blending this high-grade salt with run-of-mine to produce the desired mixture.

Production and sales of marketable potassium salts and stocks in the hands of producers for the last 5 years are summarized in the following table. Only the final weight of marketable salts after refining or mixing is shown.

Potassium salts produced, sold, and in producers' stocks in the United States, 1936–40

Year	Production			Sales				Producers' stocks		
	Operators	Potassium salts (short tons)	Equivalent as potash (K_2O) (short tons)	Operators	Potassium salts (short tons)	Equivalent as potash (K_2O) (short tons)	Value f. o. b. plant	Operators	Potassium salts (short tons)	Equivalent as potash (K_2O) (short tons)
1936	7	431,470	247,340	7	396,690	222,810	$6,969,190	5	73,139	34,000
1937	7	486,090	284,497	7	466,933	266,938	9,019,534	5	105,900	55,620

[1] Revised figures.

GOVERNMENT ACTIVITIES

Prosecution of the three major producers and the principal importer of potash by the United States Department of Justice on an indictment returned May 26, 1939, charging a combination to fix prices and otherwise restrain trade was concluded when the Department, on May 21, 1940, submitted to the court a proposed civil decree dismissing the indictment and terminating the litigation. The decree absolves the defendants from violation of the antitrust laws charged in the indictment but prohibits them from agreeing (1) to fix prices or terms and conditions of sale; (2) to refrain from competing with each other; or (3) to refuse to sell potash to individual consumers, farm cooperatives, or fertilizer mixers not approved by all the defendants.

Following the indictment in May 1939 the United States Department of Commerce, at the suggestion of the United States Department of Justice, undertook an economic study of the potash industry to examine its performance and to recommend such changes in practice as appeared to be in the public interest. The three companies concerned and the importer cooperated fully in this study. In a report submitted to the Department of Justice by the Department of Commerce and published in May 1940 certain changes in merchandising practices were recommended. These recommendations were agreed to by the companies and formed the basis of the consent decree.

The changes recommended and subsequently adopted included establishment of prices f. o. b. Carlsbad, N. Mex., and Trona, Calif., at suitable differentials below the price at the seaboard, permitting the customer to purchase f. o. b. point of production at the differential price or on a delivered basis; establishment of a multiple discount system to encourage advance purchases and discourage concellations; and modification of the sales policy to permit consumers to purchase direct from producers in carload lots for their own use at regular prices and discounts. These conditions were embodied in the new price schedules issued in June 1940.

The congressional investigation of the potash industry by a subcommittee of the Senate Committee on Public Lands under the chairmanship of the late Senator Pittman, begun in 1936, now doubtless will be concluded by the issuance of a report. Except during the early stages this investigation has not been pressed but has been kept alive by continuing resolutions in each succeeding Congress extending the time for submission of a final report. The committee was interested primarily in determining the extent and manner of foreign ownership and control of the major companies.

The question of discovery and valuation for depletion allowance of a potash deposit in New Mexico was argued at length before the United States Board of Tax Appeals during the summer of 1940. The Bureau of Internal Revenue claimed that two holes drilled into the deposit showing the presence of potash constituted discovery and that the price received shortly thereafter for an interest in the property established its value. The company, on the other hand, contended that discovery was not made until the existence of a workable deposit was proved by sinking a shaft to the potash-bearing formation and carrying out extensive underground development. The hearing was concluded last fall, but as yet no decision has been rendered in the case.

REVIEW BY STATES

California.—The American Potash & Chemical Corporation, operating at Trona continuously since 1915 on Searles Lake brine to produce muriate of potash, turned out a considerable tonnage of sulfate in the first complete year's operation of the sulfate plant begun in 1939. Borax, soda ash, salt cake, sodium-lithium phosphate, and bromine are other products of the Trona plant.

Maryland.—United States Industrial Chemicals, Baltimore, and North American Cement Corporation, Hagerstown, again produced the only byproduct potash offered on the market.

New Mexico.—In the Carlsbad area, a third mine which has been under development since 1936, attained productive status in October when the plant of the Union Potash & Chemical Co. began operation. The products of this plant are muriate and sulfate of potash and double sulfate of potash-magnesia. This is the first time that the double sulfate, for which there is a moderate demand, has been available from a domestic source. In spite of inevitable new plant adjustments a substantial tonnage of salts was made and sold in the final quarter of the year. The Union Potash & Chemical Co. is controlled and operated by International Agricultural Corporation, which is reported to own 95 percent of the preferred and 56 percent of the common stock. A proposed merger of the two companies awaits approval of minority stockholders. Both the United States Potash Co. and the Potash Co. of America stepped up their output notably. This was accomplished, without plant enlargement, by increased efficiency and more continuous operation. The tonnage of crude ore mined in the Carlsbad area passed 1,200,000 tons in 1940 to establish a new high record in the continuing upward trend. The mines are equipped to handle around 2,000,000 tons a year, but output is restricted to the capacity of concentrating and refining plants and the moderate demand for manure salts for direct shipment or blending. The ore as mined averages around 25 percent K_2O.

Utah.—Bonneville, Ltd., 540 West Seventh South, Salt Lake City, recovers potash from Salduro marsh brine at its plant near Wendover.

Solar evaporation is utilized to purify the brine through successive concentration and crystallization to a crystalline mixture of potassium and sodium chlorides, which are then separated by flotation. The final product is high-grade muriate of potash. Technical difficulties experienced during early stages of development have been largely overcome, and increased output is anticipated in the near future. The Bonneville company is the only producer of potash in the State.

FOREIGN TRADE [1]

Imports.—The quantity, average grade, and total declared value of the various potash salts imported in 1939 and 1940, the countries from which shipments were made in 1940, and the approximate K_2O equivalent of imports are shown in the following tables.

Potash materials imported for consumption in the United States, 1939–40

Material	Approximate equivalent as potash (K_2O) (percent)	1939				1940			
		Short tons	Approximate equivalent as potash (K_2O)		Value	Short tons	Approximate equivalent as potash (K_2O)		Value
			Short tons	Percent of total			Short tons	Percent of total	
Used chiefly in fertilizers:									
Kainite	14.0	301	42	(1)	$1,923	---	---	---	---
	20.0	20,591	4,118	4.1	153,233	36,175	7,235	6.1	$231,426

[1] Changes for 1939 in Minerals Yearbook, 1940, p. 1396: Imports of sulfate should read 42,463 short tons (Germany, 24,444). Total should read 255,812 short tons (Germany, 91,184). Value not affected.

Exports.—Shipments of fertilizer materials to countries outside the immediate American market, which is considered by producers to include Canada and Cuba, were restricted voluntarily by the producers to protect consumers from shortage due to cessation of imports. Actually receipts of European potash were much greater than anticipated, and the supply was adequate. Customers of the producers sold abroad material containing the equivalent of about 32,000 tons of K_2O or more than half of the total quantity exported. Most of this went to Japan.

Potash materials exported from the United States, 1936–40

Year	Fertilizer		Chemical		Year	Fertilizer		Chemical

[1] In addition to countries listed, Chile and Iran are reported to produce a small quantity of potash salts, but statistics of production are not available.
[2] Content of merchantable products.
[3] Data not available.
[4] Includes some natural kieserite.
[5] Exports.
[6] Estimated production (Imperial Institute, London).
[7] Extracted from waters of the Dead Sea.
[8] Extracted from waters of the Red Sea.

FOREIGN DEVELOPMENTS

France.—No statistics on production of the Alsatian potash mines have been published since August 1939; however, it is known that, although operation of the mines was disrupted by the confusion of mobilization and the induction of many of the operating staff into the army when war broke out in September, the staff was reorganized and the mines began working on a substantial scale by the end of the year. The French Potash Co., afterward changed to the French Potash & Import Co., was established in New York to handle the sale of French potash in the United States. The mines were thought to be too near the Maginot line to permit continued commercial exploitation. Nevertheless, during the early months of 1940, 30,000 to 50,000 short tons a month of potash salts were shipped to the United States. Some may have come from accumulated stocks, but the bulk is believed to have been new production. The total thus exported to the United States in 5 months was 186,257 tons and comprised muriate, sulfate, manure salts, and kainite.

Since 1919, when Alsace—a German province for nearly 50 years—was returned to France at the close of the World War, its potash deposits have been exploited by the State-controlled Mines Domaniales de Potasse d'Alsace and the privately owned Mines de Kali Sainte-Thérèse. For a few years after the war the German and French mines competed strongly for the business of importing countries until in 1924 they reached an agreement fixing sales quotas in the world market at 70 percent for the German Potash Syndicate and 30 percent for the French. Between that time and the outbreak of the present war the French and Germans collaborated closely to control the market through an international cartel. As new sources of potash were developed in Poland, Spain, Russia, and Palestine the producers in those countries were induced to make agreements with or to join the cartel, which was enabled thereby effectively to control the international potash trade. The N. V. Potash Export My. was established in 1927 in Amsterdam as a sales agency to handle the export business of German and French producers.

When war came in 1939 the mutual sales agency was dissolved; with the fall of France in June 1940 Alsace was reincorporated into the German Reich, and it is supposed that the potash mines will be returned to the control of their former German owners. Deposits near Bordeaux, hitherto unexploited, remain to France. Elaborate plans for developing these deposits, announced several years ago, apparently have not been carried out, and their extent and importance are not known. Early announcements predicted that production would begin about 1941.

Germany.—The potash reserves of Germany have been vastly increased by reacquisition of the Alsatian mines, which doubtless will have post-war economic repercussions. Cut off from overseas markets for surplus potash, Germany is understood to be making strenuous efforts to increase its use in conquered countries and others within its sphere of influence, for the double purpose of disposing of potash and increasing the yield of sorely needed crops. The shortage of manpower for cultivating the fields may be partly overcome by increasing the fertility of the soil through liberal use of fertilizer. The British blockade appears to have been effective in stopping exports to overseas destinations. In the United States the Pioneer Potash Co. was formed to import and sell potash of German origin, but since the war began only a few thousand tons have been received in this country, and none has been reported since April 1940.

Japan.—Difficulty experienced in obtaining supplies of potash from the usual European and American sources led Japanese importers to purchase a quantity of potassium-sodium nitrate from Chile and caused the Japanese Government to explore the possibility of a trade pact with Spain to exchange Japanese raw silk and camphor for Spanish potash salts and mercury. Restriction of exports from the United States reduced shipments of potash salts to Japan 53 percent—from 59,098 short tons in 1939 to 27,654 in 1940. Now that export licenses are required for all shipments of potash to foreign countries, exports outside the Western Hemisphere are likely to be reduced still further.

Norway.—The United States commercial attaché at Oslo reports that a fairly large plant is being erected by a Norwegian hydroelectric company for experiments concerned with the economic recovery of potash salts from sea water. The process is said to involve the use of certain reagents that yield insoluble potassium salts precipitated in the form of a filterable compound. This intermediate product is then treated for recovery of the reagents. More detailed information is withheld by the company pending the granting of patents.

Palestine.—Exports of potassium chloride rose to 63,527 metric tons in 1939. Since the outbreak of war export movement of potash salts has been closely guarded, and all information regarding shipments is considered confidential. However, London newspapers have carried the statement that exports have more than doubled. The destination of exports in 1939 has not been published; but in 1938 they were widely distributed, the chief recipients being the United Kingdom, United States, Japan, Australia, Netherlands, Belgium, and Ceylon. Palestine Potash, Ltd., operating plants at both ends of the Dead Sea for the recovery of potash salts and bromine from the brine, is the only producer in Palestine and the only important producer in the British Empire.

Spain.—Potash production, which ceased in 1936 soon after the outbreak of the Spanish civil war in spite of the efforts of a workers' committee to operate the mines, was resumed late in 1939 by the three operating companies, Union Española de Explosivos, Minas de Potasa de Suria, and Potasas Ibericas, S. A. Stocks on hand at Barcelona at the end of 1939 totaled about 12,000 metric tons of potash, and stocks available at the mines amounted to about 30,000 tons. Despite these generous supplies, augmented by current production, shipments in late 1939 and early 1940 were small. One of the producers explained that the low export price prevailing for potash salts, combined with the unfavorable exchange rate, did not yield enough pesetas to pay for the cost of mining and transportation and leave a margin for profit; hence, more attention is being given to the domestic market.

Operation of the mines is hampered by a number of difficulties growing out of the destruction of machinery and equipment at the mines and of bridges and rolling stock of the railroads during the civil war. Replacements for this lost equipment are difficult to obtain; and although the railroads are in operation, a main bridge at Monistrol was still being rebuilt in early 1940, and there is a shortage of rolling stock. The port in Barcelona is reportedly in normal condition, and by the end of April about 30,000 tons of potash salts had accumulated in the warehouse there.

Since the Franco-German cartel is no longer operative, the three Spanish companies have made an agreement for the regulation of exports. It is understood to allot 65 percent of exports to Union Española de Explosivos and 35 percent to Potasas Ibericas, while the output of Minas de Potasa de Suria is reserved for local consumption.

The Spanish Government in commercial agreements has sought to provide an outlet for Spanish potash. Thus a Norwegian agreement signed in 1939 and continuing in effect until July 31, 1940, provided for the exportation of potash fertilizers valued at £20,000. What effect later events may have had on this arrangement is not known. More recently, a trade treaty with Japan has been under consideration to provide for exchange of potash for Japanese products. During the first quarter of 1940 exports to Sweden, Norway, Great Britain, and Japan were reported.

Beginning in July, about 30,000 tons of potash salts were exported to the United States. Cessation of these shipments in November was said to be due to the fact that better prices could be obtained in other markets. Producers estimate that 1941 output may be as much as 250,000 tons.

United Kingdom.—The use of available supplies of fertilizer potash is directed by the British Ministry of Agriculture to insure its application only to soils deficient in potash and to essential crops. Control measures, including price fixing, likewise have been applied to caustic potash and carbonate of potash. The possibility of recovering potash from blast-furnace and cement-flue dusts, as was done during the World War, is being investigated.

U. S. S. R.—Reserves of potash under control of the Soviet Government were greatly increased by acquisition of the Polish mines in the agreement reached by Germany and Russia after the German conquest of Poland. Heretofore, Russia has not been much of a factor in world trade in potash because most of the potash salts produced at Solikamsk has been required for local consumption. If post-war readjustments find Russia still in possession of the Polish mines and previously announced plans for increasing output from deposits in the Urals are accomplished, it may be possible to produce a substantial surplus for export in competition with other major sources of world supply.

MICA

By Paul M. Tyler and K. G. Warner

SUMMARY OUTLINE

The apparent consumption of sheet mica in the United States during 1940 exceeded all previous records. Notwithstanding a 100-percent increase over 1939, domestic production fell a little short of the 1937 total and was much less than it was during earlier boom years, but imports were half again as large as in 1937 and roughly 20 percent larger than in 1929 or 1920, previous peak years. The built-up-mica industry was working to capacity toward the end of the year, and the consumption of mica splittings in 1940 was almost 44 percent greater than in 1939 and topped the previous record of 1937 by a wide margin. Consumption of scrap and production of ground mica failed to make new records, but even this branch of the industry was active in 1940.

It is difficult to distinguish civilian from military uses of mica, and many of the ordinary industrial uses of mica in the electrical machinery and communications industries, and even for passenger automobiles and trucks, are essential to the defense program; however, a substantial portion of the greatly increased consumption of high-grade sheet mica and much of that of splittings was for use directly in airplanes, tanks, and other military equipment.

Unmanufactured mica is marketed in a bewildering variety of qualities and sizes that range in price from a fraction of a cent a pound for small or imperfect crystals to $20 or more a pound for large, clear, flat sheets. Mineralogically most of the mica consumed is white mica or muscovite, and the greater part of the remainder is amber mica or phlogopite. Dark-stained muscovite, used for ordinary electrical purposes, is locally called "black mica" in North Carolina, but only insignificant quantities of biotite are used in industry. By far the largest proportion of the tonnage of mica used in the United States is classed as scrap, which is the raw material for making both wet- and dry-ground mica. This category includes byproduct mica recovered in washing kaolin or kyanite, as well as an increasing quantity of mica produced from schists. Although substantial tonnages of scrap mica have been imported, chiefly from British India, such mica is not classed as strategic because ample supplies could be produced domestically at relatively short notice and because many of its uses are not essential to a major military effort. Vermiculite, an altered variety of mica used chiefly for heat insulation, is not included in the Bureau of Mines figures for mica and is discussed in the Minor Nonmetals chapter.

Salient statistics of the mica industry in the United States, 1936–40

[1] Includes mica recovered from kaolin and mica schists, as follows: 1936, 8,258 tons, $127,343; 1937, 10,536 tons, $149,931; 1938, 6,550 tons, $86,602; 1939, 10,011 tons, $108,899; 1940, 9,674 tons, $138,148.
[2] Exclusive of a nominal quantity of splittings produced in the United States and South America.

In respect to mica required for the most essential and strategic uses, the United States is by no means as well-situated as its production and foreign trade statistics may imply. Domestic mines supply almost enough punch and circle sizes (sheet mica under about 2 square inches but over 1 square inch in area, used for making washers and small radio stampings) but seldom as much as one-third of our requirements of larger sizes. In respect to the qualities of mica used for such highly important items as radio-transmitter condensers or high-tension magneto condensers, which are indispensable to the functioning of squadrons of airplanes, tanks, ships, and other mobile mechanical instruments of modern warfare, the United States has depended for its past requirements almost entirely on British India. Only a fraction of the mica produced, even in that country, is of a quality suitable for the most exacting requirement of high-grade condensers, but fortunately South American mica has begun to be accepted for these purposes. It is doubtful whether the United States could produce all its sheet-mica needs, even under the stimulus of greatly increased prices, and there is no doubt that it could not supply its requirements of condenser sheet because its present-day needs of these high qualities are much larger in proportion to its total mica requirements than the normal ratio of such mica to run-of-mine production of sheet mica, even in India. Careful analysis shows that the proportion of punch and small sheet is quite large in domestic mine production.

As regards splittings, the United States depends almost wholly on imports, as domestic production normally supplies less than 2 percent of requirements. British India dominates the field of muscovite splittings, not so much because of its abundant supplies of raw mica as because of its experienced coolie labor, which can produce them at a fraction of their cost elsewhere. Madagascar holds a somewhat similar position in respect to supplies of amber splittings, although these are also produced in Canada; as these can be split mechanically whereas muscovite cannot, they may be produced to an increasing extent in the United States. Muscovite splittings can be produced in this country but only at a cost several times greater than the normal cost of Indian splittings.

Amber mica is not mined in the United States, and known deposits are scarce and seemingly unworkable.

DOMESTIC PRODUCTION

Sheet mica.—Following the slump in 1939 mica mining picked up rapidly during the early months of 1940 and by midsummer began to show symptoms of a boom. In North Carolina many of the small feldspar miners were producing mica, and mica mines that had been inactive for years were being reopened. Interest was revived in prospects and abandoned mines in other States. As would be expected during the early stages of a revival and especially in view of the posting of relatively higher prices on smaller sizes, the main increase in domestic production was of punch and circle mica, the output of which in 1940 was greater than in any preceding year since 1929, and totaled 1,405,305 pounds valued at $116,087 compared with 665,755 pounds valued at only $39,207 during 1939. The output of larger sizes of sheet mica increased sharply to 220,132 pounds valued at $175,598 from 147,953 pounds, $99,756 in 1939 but fell short of the 1937 figures. Total sales of sheet mica by domestic producers were 1,625,437 pounds valued at $291,685 in 1940 compared with 813,708 pounds, $138,963 in 1939 and 1,694,538 pounds, $285,244 in 1937. The value of the 1940 output was greater than that of any other year since 1926.

Production statistics on mica have been published annually since 1880, when American mines produced 81,669 pounds of sheet mica valued at $127,825. After rising to 147,410 pounds valued at $368,525 in 1884 the output declined rapidly as a result of competition from Indian mica, which began to be imported in 1885. The low point was 35,943 pounds valued at $43,793 in 1894, after which the growing demand for electrical uses initiated an upturn that culminated in a volume peak of 2,476,190 pounds in 1910. Value figures for earlier years are not strictly comparable, because values for cut mica and semifinished products formerly were included in the returns of miners who operated their own cutting plants. No segregation of punch and circle from larger sheet mica was made in the statistics before 1924. (See fig. 1.)

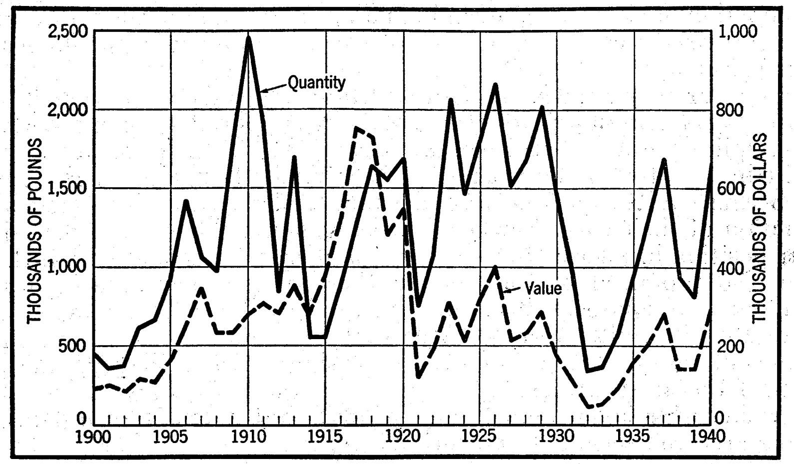

FIGURE 1.—Sheet mica produced and sold by producers in the United States, 1900–1940 (statistical data for 1908–39 tabulated in Minerals Yearbook, 1940, p. 1405, and for 1880–1916 in Mineral Resources of the United States, 1916, part II, p. 292).

[1] Includes small quantities of splittings in certain years.
[2] 1939: Arizona, California, Colorado, Georgia, Maine, New Mexico, New York, South Dakota, Vermont, Virginia, and Wyoming; 1940: Alabama, Arizona, California, Colorado, Georgia, Maine, New Mexico, New York, South Carolina, South Dakota, Vermont, and Virginia; includes also "Uncut mica larger than punch and circle" and scrap for New Hampshire.
[3] "Uncut mica larger than punch and circle" and scrap for New Hampshire included with "Other States."

Scrap.—Production of "scrap mica" from domestic sources declined to 22,386 short tons valued at $314,565 in 1940 compared with 24,672 tons, $311,895 in 1939 and the all-time record of 25,196 tons, $354,737 in 1937, but it exceeded that of any other year. In addition to mine scrap these figures include mica recovered in washing kaolin or kyanite or by milling schist, amounting to 9,674 tons valued at $138,148 in 1940, 10,011 tons, $108,899 in 1939, and 10,536 tons, $149,931 in 1937.

Ground mica.—The output of both dry-ground and wet-ground mica in the United States declined in 1940, totaling 27,984 short tons valued at $1,016,628 compared with 30,924 tons worth $1,156,333 in 1939. The 1940 output of dry-ground mica was somewhat larger than that of any other year except 1939, and that of wet-ground mica was ahead of that of all other years except 1938 and 1939. Of the total decline in 1940 (2,940 tons), approximately 800 tons represented reduction in exports, which comprised 3 percent of sales in 1940 compared with 5 percent in 1939.

The output of ground mica includes the products made from mine scrap, factory scrap, byproduct mica, and schist mica of all kinds.

Ground mica sold by producers in the United States, 1936–40, by methods of grinding

Year	Dry-ground [1]		Wet-ground		Total [1]	
	Short tons	Value	Short tons	Value	Short tons	Value
1936	20,800	$457,042	4,785	$265,374	25,585	$722,416

[1] Includes mica from kaolin and schist.
[2] Includes mica used for molded electric insulation, house insulation, Christmas-tree snow, manufacture of axle greases and oil, annealing, pipe-line enamel, plastic specialties, textiles, coating levee mattresses, and other purposes.

MICA SPLITTINGS

The consumption of splittings increased to 4,918,861 pounds valued at $1,725,522 in 1940 from 3,423,044 pounds, $1,089,683 in 1939. The previous record consumption was 4,347,435 pounds valued at $1,257,645 in 1937 and was followed by a sharp slump in demand for built-up mica, which developed even before the end of the year. In 1940, however, activity was well-maintained throughout the fourth quarter, and early in 1941 the industry's factories were speeded up to operate faster than ever before.

Stocks of splittings at the end of 1940 were larger than in any previous year, aggregating 5,412,801 pounds compared with 3,480,625 pounds at the close of the preceding year and a previous record of 4,744,627 pounds on December 31, 1938.

Owing to the British blockade of Madagascar, deliveries of amber splittings failed toward the end of the year to pace the greatly increased consumption. Relatively small quantities of amber splittings are obtained from Canada. Whereas muscovite splittings have never been produced successfully, except by hand, some Canadian amber mica has been split mechanically. The possibility of expanding such operations may be investigated should it become impracticable to obtain enough Madagascar splittings, and perhaps split Canadian mica may even serve as a substitute for Indian splittings.

Since war tempo rose in May 1940 a good deal of attention has been devoted to producing splittings from domestic and South American mica. Plenty of small block mica is available in the Western Hemisphere, but much of the domestic mica does not seem to split quite as readily as Indian mica, and American workers not only are paid several times as much an hour as coolie labor gets a day but are not temperamentally suited to such work.

Consumption and stocks of mica splittings in the United States, 1936–40, by sources, as reported by the consumers

Year	India		Canada		Madagascar		Total

[1] Exclusive of a nominal quantity of splittings produced in the United States and South America.

BUILT-UP MICA

National defense orders piled upon a broad increase in civilian consumption have boosted the output of built-up mica to an all-time record. Various products used in electrical equipment for airplane, truck, and passenger-automobile engines and for miscellaneous industrial apparatus and household appliances are made from board prepared by pasting together tissue-thin splittings of mica, only about a thousandth of an inch thick.

The total output of built-up mica, as reported by manufacturers to the Bureau of Mines, jumped to 4,413,000 pounds valued at $5,811,000 in 1940 compared with 3,425,395 pounds, $4,730,000 in 1939 and only 1,757,654 pounds, $2,200,000 in 1938. Available figures for earlier years were given in Minerals Yearbook, 1940.

Built-up mica produced in the United States, 1939–40, by kind of product

Product	1939		1940[1]	
	Pounds	Value	Pounds	Value
Molding plate	1,099,066	$1,090,000	1,315,000	$1,410,000
Segment plate	1,135,555	1,610,000	1,510,000	2,024,000
Heater plate	369,677	815,000	561,000	878,000
Flexible (cold)	239,582	290,000	330,000	383,000
All other (tape, etc.)	581,515	925,000	697,000	1,116,000
	3,425,395	4,730,000	4,413,000	5,811,000

[1] Partly estimated.

PRICES

The prices of India mica remained virtually unchanged during 1940, although there was a tendency toward upward revision of condenser splits, because of heavy demand, and of the lower-priced block and splittings, owing to wartime freight and ocean insurance rates. Better acceptance of South American mica by consumers resulted in reducing the discounts and thus increasing the prices paid for high-grade Brazilian mica, and a similar trend in respect to domestic mica was accelerated by the deliberate policy of leading buyers (especially in North Carolina) to stimulate domestic production by paying higher prices. The highest prices were paid during the latter half of the year, and later they were shaded off, with the result that in May 1941 good punch mica was worth about 12 cents a pound compared with a peak of 15 cents in 1940, the pre-war (August 1939) price of 5 to 7 cents, and a depression level of 3 to 5 cents.

Trade-journal quotations and average sales value of domestic uncut sheet mica per pound in 1940

Size	Trade-journal quotations[1]		Average value[2]	
	Dec. 14, 1939	Dec. 12, 1940	Clear	Stained or spotted
Punch	$0.05–$0.06	$0.08–$0.15	$0.087	$0.090
Circle			.109	.100
1½ by 2 inches	.25– .30	.45– .60	.429	.269
2 by 2 inches	.40– .50	.60– .80	.780	.275
2 by 3 inches		.90– 1.20	1.182	.577
3 by 3 inches	1.00– 1.20	1.25– 1.50	1.582	.721
3 by 4 inches	1.30– 1.40	1.50– 1.75	1.925	1.151
3 by 5 inches	1.60– 1.70	1.75– 2.25	2.750	1.443
4 by 6 inches	2.60– 2.70	2.75– 3.50	3.372	1.504
6 by 8 inches	4.00– 4.50	4.25– 4.75	4.817	2.012

[1] Engineering and Mining Journal (Metal and Mineral Markets) quotations for No. 1 or No. 2 quality, f. o. b. North Carolina; stained qualities take 25 to 50 percent discount.

[2] Calculated from reports of 1940 sales by domestic producers to the Bureau of Mines.

FOREIGN TRADE [1]

Imports.—In 1940 the total imports of all kinds of mica increased to 7,688 short tons valued at $2,484,128 from 6,280 tons valued at $1,059,310 in 1939. Compared with the record of 1937—11,339 tons valued at $2,067,599—it is significant that imports of scrap in 1940 were less than half as large but that those of uncut sheet and punch were over 50 percent larger. Compared with the 1939 poundage notable increases occurred in imports of untrimmed phlogopite (210 percent on this small item), untrimmed muscovite (60 percent), thin splittings (191 percent), and condenser and other films over 0.0012 inch thick (38 percent). British India continued to be the largest source of splittings, but South American countries (chiefly Brazil) furnished 88 percent of the cheaper block mica and 48 percent of the better qualities of block mica (worth over 15 cents a pound) imported into the United States in 1940 compared with 6 percent and 43 percent, respectively, from British India.

Imports supply virtually all the splittings, most of the sheet mica larger than punch, and a variable proportion of the small sheet and scrap mica used in this country. Available data on imports for the period 1909–39 were summarized in Minerals Yearbook, 1940 (p. 1413).

[1] In addition, 540 pounds valued at $540 of "All manufactures of which mica is the component material of chief value (duty, 40 percent)" were imported in 1940, and 4,953 pounds valued at $5,155 in 1939.

Exports.—Owing to the elimination of continental European markets after the battle of Flanders and curtailment of shipments to the United Kingdom, exports of mica and its manufactures from the United States were over 50 percent less in quantity during 1940 than during 1939 and smaller than in any other year since 1924. Exports of mica to Canada were greater during 1940 than during 1939 under all categories, and those to many Latin American countries also increased. As usual, ground mica was the chief item, but the aggregate exports of other manufactures of mica greatly surpassed ground mica in value in 1940 and increased in total value compared with the preceding year.

Mica and its manufactures were included with other strategic materials under the first export-control proclamation dated July 2, 1940. The revised schedule specified that none of the following items should be exported unless and until a license was obtained:

Natural raw mica:

- Unprocessed block mica, including thumb-trimmed, knife-trimmed, and sickle-trimmed.
- Processed mica, including splittings of any thickness, condenser films, radio-tube supports, washers, wrappers, and punched or cut patterns or pieces.

Built-up mica and mica products, including sheets, tubes, rods, armature rings, commutator segments, tapes and coil wrappings, washers, and punched or cut patterns or pieces.
Articles in which mica is a component, except articles in which the mica component is incorporated in an electric motor, generator, or transformer, and except kitchen appliances for household use (report mica content in pounds and whether built-up or sheet mica).

The Administrator of Export Control subsequently determined that mica should be included in the list of 24 commodities for which licenses were required, even for individual shipments not exceeding $25 in value.

WORLD PRODUCTION

Tonnage figures afford a progressively less valid measure of the relative importance of different countries as sources of mica, now that other nations than the United States have begun to produce substantial quantities of scrap or waste mica. Even when the output of scrap can be segregated the characteristic differences in size, quality, and degree of preparation of sheet mica itself virtually vitiate any purely statistical comparison. However, the British Empire, principally India, still produces 75 percent or more of the world's high-grade sheet mica, although its position in this field now is based in large part upon the production of splittings. Brazil and other South American countries are becoming increasingly important. Canada is a large potential source of amber mica, but most of the world supply of this variety of mica has recently come from Madagascar. Deposits in that island have been described recently.[2] Promising de-

[2] Lacroix, Alfred, Phlogopite Deposits of South Madagascar: Compt. rend., vol. 210, 1940, pp. 273-276; Chem. Abs., vol. 34, No. 9, May 10, 1940, p. 2744.

posits of mica are reported in the Northern Territory of Australia and on August 28, 1940, the Commonwealth Government virtually commandeered the product.[3] Exports of mica from India were brought under Government control in July 1940.

In Canada phlogopite mica has been produced chiefly from properties in the Hull-Buckingham district of Quebec and the Kingston-Perth area of eastern Ontario. Muscovite has been produced in recent years in both Quebec and Ontario but chiefly as a byproduct of feldspar mining and never in large amounts. Ground mica is produced from mica schist (sericite) in British Columbia.

World production of mica, 1936–40, in metric tons

QUALITY OF DOMESTIC MICA

There is no geologic or mineralogic reason why domestic mica should differ from Indian mica of similar chemical composition and physical appearance, yet the claim has been made that domestic muscovite is so inferior to Bengal ruby in its essential electrical and other physical properties that it cannot be employed for making condensers or for other uses requiring high-grade mica. Much domestic mica has, admittedly, been ill prepared; however, it would be unduly wasteful of a valuable national resource if domestic mica were as closely trimmed as Indian mica, because such trimming would eliminate material that can be utilized as sheet mica. Thorough tests, nevertheless, have

[3] Zapf, L. C. (United States consul, Sydney), Consular Rept., September 19, 1940; abs., Bureau of Mines Mineral Trade Notes: Vol. 11, No. 5, November 22, 1940, p. 29.

indicated that selected mica from American mines is equal in quality to the best imported mica. No notable differences were observed in dielectric strength, change on heating, and power factor; other properties, such as flexibility and hardness, may be duplicated in comparable grades.

Although the results of these tests were published by both the Bureau of Mines [4] and the National Bureau of Standards [5] the prejudice persisted against employing domestic mica for condensers, certain kinds of radio tubes, and even less exacting uses. A somewhat similar prejudice existed against South American mica, which sold at discounts compared with similar grades and sizes of Indian mica; although frequently these discounts were not as heavy as those charged against domestic mica, they were quite substantial a few years ago and have not yet disappeared.

In connection with the present emergency the Geological Survey examined several hundred American mines and later collected samples from more than 150. Through a joint arrangement between the Survey, the Bureau of Mines, and the National Bureau of Standards these samples were tested for power factor. Previous tests had proved beyond reasonable doubt that dielectric strength and heat resistance could be judged by physical appearance, and the additional tests demonstrated that sound domestic mica free from mineral staining was as good as the best Bengal ruby in respect to power factor.

Admitting that the inherent electrical properties of domestic mica were fully as good as those of imported mica, it did not follow that domestic mica could be employed commercially in radio-transmitter or high-tension magneto condensers. From a manufacturing standpoint other factors were involved, such as uniformity, splitting quality, behavior in punching, flexibility, soundness, and freedom from pinholes or waviness. To obtain information on these points the Bureau of Mines obtained the cooperation of a leading supplier who furnished three 10-pound samples of mica from each of two domestic mines. These samples were tested by three leading manufacturers, who made them up into condensers of various types and subjected them to the most rigorous tests. All these manufacturers agreed that these samples of domestic mica were suitable for use in condensers, the only qualification being the observation by one company that the domestic mica did not split as readily as the Indian mica and hence that the losses during splitting were greater.

In view of the successful outcome of these tests of domestic mica in the actual fabrication of condensers a proposed investigation of possible inherent differences in the chemical or structural characteristics of domestic muscovite crystals has been suspended indefinitely. Apparently there is no fundamental difference that cannot be observed by ordinary inspection and routine laboratory tests.

SALT

By A. T. Coons and F. E. Harris

SUMMARY OUTLINE

The total salt output reported to the Bureau of Mines by producers again set a new high record in 1940. Evaporated or manufactured salt, salt in brine for the manufacture of chemicals, and rock salt from 13 States and Puerto Rico aggregated 10,003,448 short tons valued at $26,118,107 in 1940 compared with 9,277,911 tons valued at $24,509,680 in 1939. Of the 83 plants of 66 companies that reported salt production in 1940 compared with (revised figures) 81 plants of 67 companies in 1939, 60 plants produced evaporated salt, 22 plants rock salt, and 10 plants (7 companies) salt in brine. Pressed blocks were made by 19 evaporated-salt plants and 8 rock-salt plants.

Salient statistics of the salt industry in the United States, 1930–34 (average), 1935–39 (average), and 1939–40

	1930–34 (average)	1935–39 (average)	1939	1940

Apparent consumption short tons	7,358,545	8,616,767	9,199,671	9,886,806

[1] Values are f. o. b. mine or refinery and do not include cost of cooperage or containers.

The per capita consumption of salt, most of which is used industrially, continues to increase. Per capita data for 1910–36, with information regarding the distribution of salt consumption, have been summarized in Bureau of Mines Information Circular 7062.[1] In 1938 (including salt or brine) it was about 123 pounds a person; in 1940, according to the latest census of population figures, it averaged about 151 pounds a person.

Salt is being used in many indirect ways for national defense work. About half of the total production is employed in the form of brine in the manufacture of chemicals. The heavy chemicals made from salt are used for processing a wide range of products that now are increasingly necessary for military purposes. The other half of the output is marketed as dry salt; the largest use for it normally is food preparation (including canning, preserving, and the manufacture of flours and similar articles), the importance of which is enhanced by the present emergency. According to the Census of Manufactures, 1939, salt used only in bread, biscuits, crackers, and pretzels in 1939 totaled 94,603 short tons valued at $1,859,337. Displacement of articles formerly imported by synthetic products has had its effect on the size of total output of salt. These synthetics include such items as salt cake,[2] rubberlike materials, and silk substitutes.

Evaporated salt.—Salt is evaporated by several methods—in open pans or grainers, in vacuum pans, and by the sun. Most table salt is evaporated salt because most salt as recovered needs refining.

[1] Included under "Other States."
[2] Includes a quantity of salt contained in brine for chemical use reported as evaporated salt with value as evaporated salt.
[3] 1939: Colorado, Louisiana, New Mexico, and Oklahoma; 1940: Colorado, New Mexico, Oklahoma, Texas, and Utah.

Rock salt.—As in the past, the output of rock salt came mainly from four States, although several others contributed to the total.

Rock salt sold by producers in the United States, 1936–40

Year	Short tons	Value	Year	Short tons	Value
1936	2,009,579	$6,003,054	1939	2,035,157	$6,496,807
1937	2,030,432	6,447,648	1940	2,265,548	7,384,839
1938	1,901,861	6,252,081			

Brine.—The production of salt in brine in 1940, as in 1939, increased the most of the three types of salt, overtopping its previous high record, that for 1937. More common salt is used in the manufacture of chemicals than any other basic material. According to the Federal Reserve Index, production of chemicals in 1940 averaged 115 (1935–39 = 100) compared with 102 in 1939 and 96 in 1938.

Blocks.—Both sodium and chlorine are indispensable to animal life, and common salt meets the requirements most readily. Pressed blocks have been found to be the best way to serve most livestock. In addition to blocks weighing about 50 to 60 pounds and a certain quantity of a smaller size for sheep, some manufacturers now make very small (3-ounce) blocks for small pet animals; these are known as "petlicks." Several producers who market loose crude salt for use by cattle reported a decline in the demand because of the increasing use of blocks of salt; however, this is not apparent to any great extent, as the production of pressed blocks showed only a slight gain in both types of salt consumed.

Pressed-salt blocks sold by original producers of the salt in the United States, 1936–40

Year	From evaporated salt		From rock salt		Total

MARKETING

Prices.—On January 1, 1940, the quoted price for bagged vacuum fine salt in carlots delivered at New York was $15.30 a short ton, which held until March 25, when it advanced to $15.70 a ton. In less than carlots salt of this type was priced within the same range throughout the year—$16.60 to $19.70 a ton. Rock salt in bags, in carlots delivered at New York, was quoted at $13.20 to $13.80 a ton on January 1, 1940, changed to $13.20 to $13.38 a ton in May, and advanced to $13.70 a ton in October. Bagged rock salt in less than carlots was $15 to $15.60 a ton in January 1940 and remained at this price until October 10, when it advanced 50 cents or to a basis of $15.50 to $16.10 a ton.

For the most part the demand was steady throughout the year. Shipments were regular, except in midsummer. In December it was reported that cold weather stimulated the demand for salt for ice control, while other consumers showed good interest.

Salt producers in some sections of the West and South reported that wages and cost of materials had increased but prices had not advanced. None reported strikes in the salt industry, but some said that the industry was affected by strikes in other industries, such as canneries. Certain producers reported exports of salt to Japan for the first time in their experience.

Market grades and packages.—During 1940 the Standing Committee in charge of Simplified Practice Recommendation R70, Salt Packages,[3] completed revision of the standards originally formulated in 1927 and reaffirmed in 1931 and 1933. The National Bureau of Standards reported on March 28, 1941, that the producers of salt had already recorded their approval of the 1940 revision to an extent representing more than 90 percent of the industry's volume.

The standards define the sizes, varieties, types, and grades of salt in blocks and bricks, dry solar fine-milled, dry solar kiln-dried, granulated salt, high-grade salt, packers salt, medium salt, special medium, rock salt, coarse grades, table salt, and Kosher salt. Two concise tables list the kind of salt, the net weight of the contents and the kind of primary container, and the capacity of and kind of shipping container. The first table gives the salt packages for the larger part of the United States, and the other comprises Pacific coast practice (including Washington, northern Idaho, Oregon, California, western Nevada, and Arizona).

It was impracticable to include much of the Pacific coast practice in the original recommendation of 1927 because of differences of packaging growing out of conditions peculiar to that region. The present recommendations have not attempted to reconcile the differences, but they do include Pacific coast practice.

Compared with the previous standards the present recommendation has reduced the number of sizes and capacities. Whereas nine capacities of pockets (trade term for cotton bags of 10 pounds or less capacity) were standard previously, this number has been cut to five; the number of different sizes of bags of either cotton or burlap has been cut from nine to four; square cartons have been reduced from six to four sizes. However, two new packages have been added—one size of round can and a hexagonal package, each of 1⅝-pound capacity.

[3] Composed of 8 members representing as many salt companies, in voluntary cooperation with the Division of Simplified Practice of the National Bureau of Standards.

[4] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

WORLD PRODUCTION

Unsettled world conditions and the inability to obtain official figures in many countries make it impossible to furnish more than fragmentary information on the salt industries abroad; however, because of continued interest in foreign salt fields and salt requirements, as evidenced by inquiries to the Bureau of Mines, such figures and statements as are available are set down here, even though incomplete.

Canada.—Preliminary figures show that 464,714 short tons of salt valued at $2,823,269 were sold in Canada in 1940 compared with 424,500 tons valued at $2,486,632 in 1939. A recent report [5] describes tests that had been made on the use of sodium chloride as a moisture retainer in the stabilization of roads in eastern Canada. Illustrations of roads so treated showed their hardness and smoothness, and the text discusses the advantages of low cost, easy application, good compaction obtained, and small maintenance required. Salt is finding wider use in Canada for stabilizing clay and gravel roads and runways at airports. Another Canadian use for salt is to mix it with sand piled along highways for application on icy surfaces, because the salt has the effect of keeping the sand loose and free-flowing, even in the coldest weather. Some of the railways in Canada have found that by salting their coal piles they can keep them free from lumping and caking in winter. A new plant costing $250,000 was built in a deposit in Alberta that is estimated to have 30,000,000 tons of salt; production is to proceed at the rate of 85 tons a day.

China.—New salt production at the Hanku field during the 1940 season was estimated at 300,000 metric tons, with a similar amount for the fields at Tangku, Hsinho, and Naukai combined, as reported in September 1940 by Consul Frederick W. Hinke of the Tientsin consular district, in which all of these fields occur. The current price of export salt at Hanku is said to have risen more than 70 percent above the 1939 price, owing to the necessity for improving the fields. Prices of industrial salt for local consumption likewise are said to have risen more than 66 percent in the last year.

Japan.—Information available in Tientsin, China, to Consul Frederick W. Hinke in September 1940 regarding purchases by Japan forecast roughly that 400,000 tons of salt would be exported from the Hanku field, China, to Japan in 1940, or about the same as in 1939. It is well-known that Japan has been seeking to supplement its imports of salt for some time past. Former sources of supply (such as northern Africa—Egypt, Eritrea, and Italian Somaliland) have been cut off by the war. Its chemical industry has suffered; the lack of salt also has crippled Japan's textile industries, and production has been cut down considerably. It was reported [6] in New York charter circles late in the summer of 1940 that commitments had been arranged for transportation of salt from New Orleans and West Indies to Japan on a freight rate of $13.50 a ton.

Netherlands Indies.—According to Consul Marcelis C. Parsons, Jr., Batavia, Java, a contract was signed by the Netherlands Indies Salt My. and representatives of Japanese buyers,[7] under whose terms Japan may buy annually 100,000 metric tons of salt over a period of 3 years.

[6] U. S. Dept. of Commerce, World Trade Notes: August 10, 1940, p. 520.
[7] Bureau of Mines Mineral Trade Notes: Vol. 12, No. 2, February 20, 1941, p. 29.

Salt exports from Netherlands Indies to Japan totaled 64,000 metric tons in 1938, 71,000 tons in 1939, and 5,000 tons in the first 10 months of 1940.

West Indies.—Although Turks and Caicos Islands have not exported much salt in recent years—averaging about 35,000 short tons—they are situated conveniently off the Atlantic seaboard of the United States, where salt is not produced. An ordinance approved by the Governor in March 1940, set up a Salt Industry Board with powers to market salt, allot quotas, and regulate and control the exportation of salt, all of which is affecting the salt industry of these islands. Details of the report by Consul General Hugh H. Watson, Kingston, Jamaica, as of June 21, 1940, were published by the Bureau of Mines.[8]

World production of salt, 1936–40, by countries, in metric tons

DIRECTORY OF SALT PRODUCERS IN THE UNITED STATES

Recent changes among producers.—Since the last printed list of salt producers in the United States (Minerals Yearbook, 1936), several additional localities have begun to supply commercial salt. A plant in a newly producing deposit in Colorado is operated by the United States Vanadium Corporation. Deposits have been discovered in the Gulf region of Texas, and production of that State expanded considerably. California, Utah, New Mexico, and Puerto Rico have added or reopened plants, and several States report one new operation each. In 1935, 74 plants representing 60 companies were listed; in 1940, 83 plants representing 66 companies. Otherwise the salt deposits in the United States that supply salt for commercial purposes (except for small deposits used for local supply) are confined to the same definite regions as in 1935. Michigan, New York, and Ohio in the northeastern section of the United States supplied 67 percent of total salt sold or used by producers in 1940. Louisiana and Kansas in the south central section are the next largest producers, and California leads in the western States.

Producers of salt in the United States in 1940

Company name and address	*Plant site*	*Nature of salt*
Carlos M. Ramirez Acosta, Box 12, San German, P. R.	Lajas (Salina Fortuna) Puerto Rico.	Solar-evaporated.
American Salt Co., Mt. Eden, Calif.	Mt. Eden, Alameda County, Calif.	Do.
American Salt Corporation, 630 New York Life Bldg., Kansas City, Mo.	Lyons, Rice County, Kans.	Evaporated salt (open pans or grainers, vacuum pans), pressed blocks from evaporated salt, rock salt, pressed blocks from rock salt.
Barton Salt Co., Hutchinson, Kans.	Hutchinson, Reno County, Kans.	Evaporated salt (open pans or grainers, vacuum pans), pressed blocks from evaporated salt.
California Rock Salt Co., 2436 Hunter St., Los Angeles, Calif.	Amboy (Saltus), San Bernardino County, Calif.	Rock salt.
Carey Salt Co., Hutchinson, Kans.	Hutchinson, Reno County, Kans.	Evaporated salt (open pans or grainers, vacuum pans), pressed blocks from evaporated salt.

MAGNESIUM COMPOUNDS AND MISCELLANEOUS SALINES

By Alvin Schallis and A. T. Coons[1]

SUMMARY OUTLINE

Under the dual stimulus of increased demand generated by the national defense program and of somewhat reduced imports of foreign material, the magnesite industry of the United States greatly expanded its operations during 1940. Magnesite production in California was increased, and construction of a flotation plant at Chewelah, Wash., to be completed by the early summer of 1941, was commenced. Plans were completed for opening Nevada magnesite deposits to supply raw material for both metallic magnesium and refractories, and operations were begun early in 1941. Dolomite was employed for magnesia refractories, and the use of magnesitic dolomite refractories increased substantially in 1940.

Utilization of the sea as a source of raw materials increased rapidly during 1940. Owing to the pressing demands of the national defense program the recovery of bromine and magnesium compounds from sea water or bitterns was accelerated. Large-scale recovery of magnesium compounds for the production of magnesium metal from raw sea water was initiated at Freeport, Tex., by the Dow Chemical Co. during 1940, and capacity at this plant is already being enlarged. Valuable materials are being reclaimed from other natural brines at an increasing rate, and general stock-taking and investigation of plant wastes and of idle resources were under way throughout the country. The American Potash & Chemical Co. added liquid bromine to the list of products that it obtains from the brines of Searles Lake, and the Arizona Chemical Co. began to recover magnesium sulfate as a byproduct of its sodium sulfate operations in Texas. Still unutilized, but by no means ignored, are the large potential supplies of magnesium associated with the potash beds at Carlsbad, N. Mex.

Producers of natural salt cake in the Southwest operated at full capacity, furnishing the southern kraft pulp industry with material formerly supplied largely from European sources. The Desert Chemical Co. built a new plant to recover natural sodium sulfate at Dale Lake, Calif., but no production was recorded during 1940. The manufacture of "synthetic salt cake" on a large scale was begun during 1940 and an appreciable portion of the southern salt-cake market was acquired. Production of most materials, whether or not directly affected by war conditions, shared the general business improvement. Early in 1941 bromine, iodine, and borax were added to the export control list. Fortunately, no immediate shortage of these materials has been threatened in the United States.

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

MAGNESIUM COMPOUNDS

MAGNESITE

Fostered by external conditions similar to those at the time of its creation during the World War of 1914–18, the domestic magnesite industry attained an all-time record production during 1940 (see fig. 1). The estimated output of crude magnesite was 333,166 short tons valued at $2,487,969, representing a 67-percent increase in quantity and a 70-percent increase in value over the 1939 total of 198,980 tons valued at $1,465,190, and a 5-percent increase over the previous maximum quantity of 316,838 tons in 1917. Imports of all types of magnesite fell sharply during 1940 owing to the difficulty of obtaining shipments from German-occupied territories. However, despite the scarcity of ship bottoms, imports of dead-burned magnesite from Manchuria increased to the high level of 25,970 tons valued at $437,863.

Salient statistics of the magnesite industry in the United States, 1936–40

Short tons	89,979	83,204	38,738	86,077	140,668
Value	$1,713,527	$1,598,336	$730,978	$1,699,723	$2,802,537
Average per ton [2]	$19.04	$19.21	$18.87	$19.75	$19.92
Imports for consumption:					
Short tons	42,608	56,020	24,990	44,420	30,951
Value	$662,567	$795,047	$371,669	$800,664	$551,536
Apparent new supply ...short tons	132,587	139,224	63,728	130,497	171,619
Percent domestic	67.9	59.8	60.8	66.0	82.0

[1] Partly estimated; most of the crude is processed by the mining companies, and very little enters open market.
[2] Average receipts f. o. b. mine shipping point.

Sales of domestic dead-burned magnesite increased 63 percent in 1940 to 140,668 short tons valued at $2,802,537 from 86,077 tons valued at $1,699,723 in 1939. Increasing requirements of the steel and other industries for this material, especially toward the end of the year, taxed the ability of the magnesite producers to meet the demand. The situation with regard to supplies of high-grade magnesite and periclase may become critical as the national defense program develops.

The Westvaco Chlorine Products Corporation (405 Lexington Avenue, New York, N. Y.) operated its Patterson (Calif.) plant at capacity during 1940, processing the crude magnesite mined at its Bald Eagle mine near Gustine, Calif., and at its Western mine above Livermore, Calif., as well as some magnesite and brucite obtained from the mine of Basic Ores, Inc., near Luning, Nev. The sea-water plant of the Westvaco Chlorine Products Corporation was enlarged 50 percent during 1940 and was operated at capacity throughout the year. This company, in joint operation with the Permanente Corporation, has leased a large magnesite property in the Luning district of Nevada and is opening this deposit as quickly as possible with the

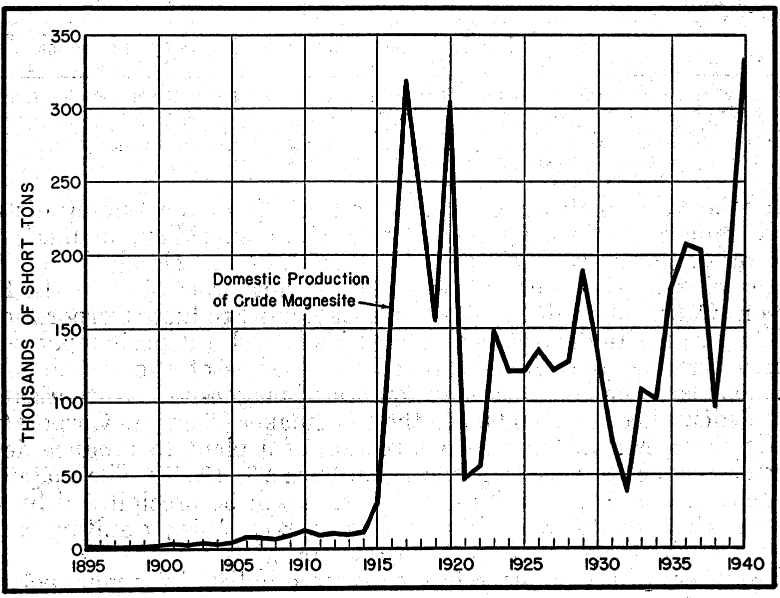

FIGURE 1.—Production of crude magnesite in the United States, 1895—1940.

expectation of producing magnesite from this source before the middle of 1941. Crude magnesite from this deposit will be shipped to Patterson, Calif., and also to Permanente, Calif., where it will be used in the production of magnesium metal by an electrothermal reduction process. The Westvaco Chlorine Products Corporation has also obtained a lease on the Double Eagle magnesite property near Valley, Wash. It is planned to maintain this property as a reserve until additional production of magnesite becomes imperative.

The Northwest Magnesite Co. (Farmers Bank Building, Pittsburgh, Pa.) operated four or five of its six kilns at Chewelah, Wash., for 12 months of 1940; both the Finch and the Allen-Moss quarries supplied the raw magnesite for them. Construction of a 300-ton daily capacity flotation plant to reduce the silica content and to produce a more satisfactory refractory-grade magnesite for brick manufacture from run-of-mine crude magnesite was begun in 1940 by the company, and the plant was expected to be completed by the early summer of 1941.

Magnesite imported for consumption in the United States in 1940, by countries and classes

County	Crude		Caustic-calcined				Dead-burned and grain and periclase	
			Lump		Ground

[1] For statistical purposes trade with the Sudeten area, as far as ascertainable, is included with Germany, while trade with the other Czechoslovak Provinces occupied by Germany, Hungary, and Poland has been included with these countries since March 18 or 19, 1939. After November 16, 1939, trade with Danzig and that part of Poland occupied by Germany has been included with Germany, and trade with that part of Poland occupied by U. S. S. R. has been included with U. S. S. R.

A relatively small quantity of magnesite from the Luning district of Nevada was mined by Basic Ores, Inc., a subsidiary of Basic Refractories, (formerly Basic Dolomite, Inc.), of Cleveland, Ohio. The larger part of this material was shipped for processing to the Patterson (Calif.) plant of the Westvaco Chlorine Products Corporation.

The magnesite deposit near Llano, Tex., and a deposit reported in North Carolina were investigated by the Office of Production Management as possible emergency sources of magnesite. Authorization of a Federal loan of $300,000 to the Rademaker Chemical Corporation of Eastlake, Mich., for the construction of a plant to produce dead-burned magnesite was announced on April 23, 1941. The magnesia content of the natural brines of that area will be precipitated by the lime content of dolomite from Sturgeon Bay, Wis., resulting in recovery of the magnesia from both raw materials.

Producers of magnesite refractories were indicted for monopoly on January 20, 1941. Antitrust charges in connection with the production of magnesite were filed against the Harbison-Walker Refractories Co. and the General Refractories Co. (joint owners of Northwest Magnesite Co.), the American-Austrian Magnesite Co., and four foreign companies. The charges were denied.

Production of caustic-calcined magnesite, reaching its highest level since 1926, increased 60 percent to 16,261 short tons valued at $512,607 in 1940 from 10,157 short tons valued at $310,102 in 1939. This increase may be largely accounted for by the greater use of magnesium oxychloride cement for flooring purposes in defense projects, and of "soluble" magnesium oxide in fertilizers. The use of magnesium oxychloride cement for floors of explosives plants is especially valuable owing to its nonflashing properties. Caustic-calcined magnesite for magnesium oxychloride cement was produced largely from high-purity California magnesite, whereas "soluble" magnesium oxide for fertilizers was made from sea-water magnesia, which is more suitable owing to its small particle size.

Production of magnesite in Chosen may be expected to reach large proportions within a few years. The semiofficial concern, the Chosen Magnesite Development Co., which was organized in 1939, has undertaken to develop reserves of magnesite (estimated at about 3 billion tons) in Tansengun, South Kankyo Province, Chosen. No commercial shipments are expected until 1942 or 1943, however, owing to the necessity of building a railroad connection from the deposits to the Kankyo line of the Government Railway. Plans for developing magnesite deposits in Australia (at Bulong near Kalgoorlie, Western Australia), Kenya Colony, and Italy (in the Dolomite Mountains of northern Italy) were announced during 1940.

Price quotations of the Engineering and Mining Journal remained the same as in 1939, that is, at $22 and $25 a short ton for dead-burned magnesite f. o. b. Chewelah, Wash., and California shipping points, respectively. For other products, its quotations f. o. b.

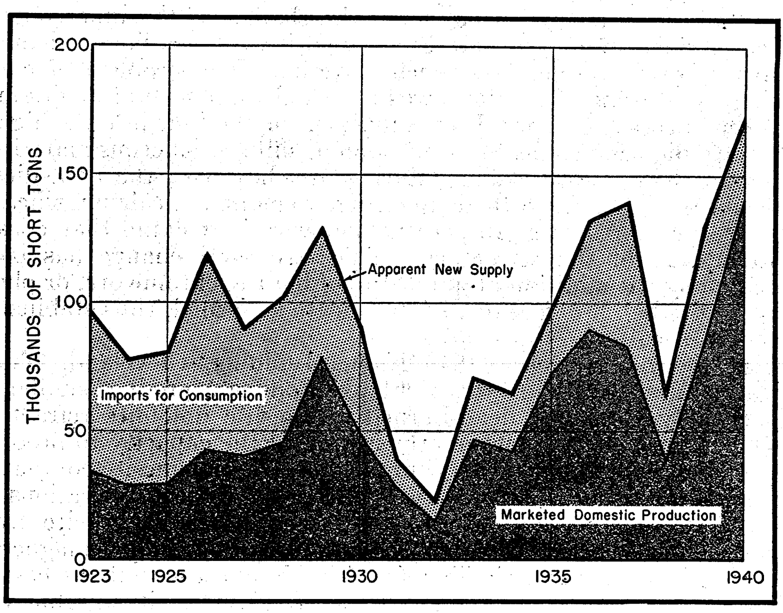

FIGURE 2.—Apparent new supplies of dead-burned magnesite in the United States from domestic and foreign sources, 1923–40.

California remained nominally as follows: Artificial periclase, 94 percent MgO, $65; 90 percent $35; caustic, 95 percent MgO, white color, $40; 85 percent MgO, no color standard, $37.50 a ton.

DOLOMITE

Sales of dead-burned dolomite by domestic producers, reflecting the increased activity of the steel industry, advanced to the record high of 867,909 short tons valued at $6,925,328 in 1940—a 29-percent increase in quantity and 27 percent in value compared with the 1939 production of 671,561 tons valued at $5,447,554. Imports of dead-burned dolomite, reaching the end of their steady and rapid decline from the high level of 13,928 tons in 1936, ceased in 1940.

Dead-burned dolomite sold in and imported into the United States, 1936–40

Year	Sales		Imports [1]		Year	Sales		Imports [1]	
	Short tons	Value	Short tons	Value		Short tons	Value	Short tons	Value
1936	596,751	$4,887,243	13,928	$349,678	1939	671,561	$5,447,554	186	$4,260
1937	617,706	5,217,833	9,083	231,084	1940	867,909	6,925,328		
1938	366,626	3,095,355	2,875	67,340					

[1] Reported as "dead-burned basic refractory material."

War conditions have given impetus to research into and development of dolomite and magnesitic dolomite refractories. This field is particularly attractive owing to the enormous supplies of dolomite located conveniently as regards industries consuming basic refractories. The chief objections to the use of untreated dead-burned dolomite for refractory purposes are the slaking of the lime content during periods of disuse and the low orders of spalling resistance exhibited by the products of such material. The problem of overcoming the slaking of the lime was attacked from several angles and has been successfully solved by conversion of the lime into the highly refractory dicalcium silicate by addition of suitable siliceous materials. Owing to temperature changes during use, however, the beta dicalcium silicate first formed tends to change to gamma dicalcium silicate, with an accompanying 10-percent increase in volume that causes disintegration of the refractory. This structural change has been overcome by the addition of quantities of borate, chrome ore, or phosphate to the batch before dicalcium silicate is formed, thus stabilizing the beta form.

Basic Refractories, Inc. (845 Hanna Building, Cleveland, Ohio), which acquired United States rights to produce a product similar to the specially stabilized dead-burned magnesitic dolomite refractory developed in Canada, has greatly expanded the capacity to produce this product at its plant near Tiffin, Ohio. The magnesite content of the dolomite for this refractory is increased, in the operations of Basic Refractories, Inc., by substantial additions of brucite from Nevada. Consideration was given to the use of byproduct magnesite from the Eastern Magnesia Talc Co. for this purpose, but the cost of refining this material to a point that would make it suitable was prohibitive. The Standard Lime & Stone Co. (First National Bank Building, Baltimore, Md.) has begun to produce a similar magnesian dolomite refractory from dolomite as the only source of magnesia. The slightly soluble lime content of the calcined dolomite is reduced in the process of this company by leaching with large volumes of water. At least two other processes for reducing the lime content of burned dolomite are being investigated in pilot plants. One of these methods, which is under investigation in Pennsylvania, involves slaking of the calcined dolomite, treatment of the calcium hydroxide so formed with hydrogen sulfide to form calcium hydrosulfide, and subsequent extraction of the calcium hydrosulfide to leave a residue of high magnesia content. The hydrogen sulfide is regenerated from the calcium hydrosulfide by treatment of the solution with carbon dioxide to form calcium carbonate. In the other process, which is being developed in Ohio, calcined and slaked dolomite is treated with a sugar solution to form soluble calcium sucrate, which is removed from the residual magnesia afterward by filtration. The sugar solution is regenerated by treatment with carbon dioxide to form calcium carbonate and sugar.

TECHNOLOGIC TRENDS IN MAGNESIA REFRACTORIES

Recent estimates indicate that the 1940 consumption of magnesite by the steel industry per ton of steel produced reached a low level and no further reduction in consumption is expected. The recent decrease in the consumption of magnesite per ton of steel has resulted from at least two causes: (1) Improvement in the magnesite refractories so that replacements and repairs have been less frequent and (2) replacement of much magnesite brick by chrome and chrome-magnesite brick in many applications where magnesite brick formerly were used exclusively. Consumption of magnesite per ton of steel produced, however, is expected to increase somewhat in the near future. This will be caused by several factors, prominent among which are: (1) The operation of all-basic open-hearth furnaces, which has been made possible by improved magnesite and chrome-magnesite brick and changes and improvements in furnace design and (2) an increasing trend toward the replacement of chrome-containing brick by straight magnesite brick in furnaces for treating alloy steels in which contamination by chrome may be objectionable.

During recent years there has been a strong trend toward the use of chrome-magnesite refractories. It is found that for general purposes these refractory materials in combination are vastly superior to either component alone. The combination of chromite and burned magnesite may range from 80 to 20 percent magnesite and from 20 to 80 percent chrome ore, although a ratio of 60 to 75 percent chrome ore to 40 to 25 percent burned magnesite is preferred for general basic refractory purposes. These mixtures show greater refractoriness than straight chrome ore and have better physical and chemical properties than either material alone. The increased refractoriness results from formation of forsteritic materials by combination of the magnesite with the fusible gangue materials in the chrome ore. The volume stability of chrome-magnesite has been ascribed to the reaction between the added magnesium oxide and the gangue material, the solid solution of MgO in chromite, and the replacement of the FeO in the chrome by MgO.

Studies of the internal structure indicate that the relative size of the particles and the distribution of the various components is even more important than the percentage of chrome ore or magnesite. A substantial percentage of all basic refractory brick now being manufactured is formed from properly sized particles under high pressure without the conventional burning in kilns.[1] High resistance to thermal shock usually is obtained by keeping the chrome fraction coarse and the magnesia fraction considerably finer so that it may fill the interstices between the chrome particles. Suitable refractory bonds are added to the mix before molding. The brick so obtained are strong, resilient, and very resistant to spalling, which makes them preferable

[1] Opinion regarding the general merit of unburned brick is not unanimous. It is claimed that some residual shrinkage of the brick although small, remains and that the resistance of these brick to spalling is temporary, being lost after use at high temperature.

to silica in most, if not all, parts of open-hearth furnaces above the floor level.

Owing to their relatively low compressive strength at high temperatures, however, it is not practical to use magnesite or chrome-magnesite brick for arched roofs of large furnaces. However, they may be used to advantage in the construction of suspended roofs having iron plates between the bricks. Because they are more resistant to the action of iron oxide and are more refractory, properly constructed all-basic open-hearth furnaces permit higher working temperatures, reduce shut-down time, lower the slag bulk and the amount of fettling material required, and generally make possible increased production of superior quality metal. It is claimed that these advantages overbalance the additional cost of constructing suspended roofs on large installations and that there will be a definite trend toward all-basic open-hearth furnaces. This trend undoubtedly will be accelerated by the increasing demands for steel caused by the national defense program. Because of the smaller stresses involved, small basic arched roofs give satisfactory service without the need for external support.

Increased working temperatures in many metallurgical furnaces are requiring the replacement of silica brick with higher-melting refractories of the forsterite type for many processes. These are, in many instances, being produced by combination of olivine and talc or serpentine with magnesite. Work done by the Bureau of Mines [2] indicates that excellent refractories can be made from Pacific Northwest olivine by proper control of particle-size distribution and addition of suitable conversion agents, such as chromite and MgO.

OTHER MAGNESIUM COMPOUNDS

The output of magnesium compounds other than magnesite and dolomite produced from natural sources and sold or used in the United States rose to an all-time high of 108,266 tons valued at $2,452,814 during 1940 compared with 85,754 tons valued at $2,159,019 in 1939. The increased production of magnesium chloride, which placed it ahead of magnesium sulfate for the first time, reflected the rapidly growing demand for magnesium metal and the sharply increased use of magnesium oxychloride cement in national defense industries. The increased production of magnesium sulfate resulted partly from the cessation of imports of Epsom salts and calcined kieserite from Germany and partly from the general acceleration of business activity. Recovery of magnesium sulfate was undertaken during 1940 by the Arizona Chemical Co. as a joint product of its sodium sulfate operations in Texas.

The production of brucite from the deposit near Luning, Nev., increased further in 1940, but the Bureau of Mines is not at liberty to publish the figures separately, and the material is included under "Other magnesium compounds." Basic Ores, Inc.—a subsidiary of the principal consumer, Basic Refractories, Inc.—is the only domestic producer. Brucite is used by the parent company mainly to increase the magnesia content of dolomite in preparing stabilized magnesitic dolomite refractories.

[1] Magnesium silicofluoride or fluosilicate included under "Magnesium salts and compounds, n. s. p. f."

Although much larger requirements of metallic magnesium for airplane construction have stimulated research into the production of this metal from sources other than magnesium chloride, the capacity for producing magnesium chloride for use in the existing electrolytic process was considerably increased during 1940. The Dow Chemical Co. erected a large plant to recover magnesium compounds from sea water at Freeport, Tex., and an estimated 6,500 tons of magnesium metal will be produced annually. The output of this amount of magnesium metal involves precipitation of almost 16,000 tons of magnesium hydroxide as the primary form of the recovered material. Although this plant was not completed much before the end of 1940, its capacity is already being increased.

Magnesium oxide was suggested [3] as a water conditioner to remove silica. A product obtained by the calcination of dolomite in such a manner that magnesium oxide is produced and the calcium carbonate is not affected has been employed for several years in Germany to remove carbon dioxide and other acidic materials from water and thus prevent corrosion of pipes and conduits.

CALCIUM CHLORIDE

Production and sales of calcium chloride and mixed calcium-magnesium chloride, basis 75 percent $(Ca, Mg)Cl_2$, obtained directly from natural brines decreased to 94,238 short tons valued at $1,485,784 in 1940 compared with 108,441 tons valued at $1,307,717 in 1939. Sales of calcium chloride obtained as a byproduct of the ammonia-soda process for the production of sodium carbonate are nearly twice as large as those of material from natural brines. However, these sales

[3] Betz, L. D., Noll, C. A., and McGuire, J. J., Removal of Silica from Water by Hot Process: Ind. Eng. Chem., vol. 32, No. 10, October 1940, pp. 1323–1329.

are not included in the foregoing figures because the salt and limestone from which such calcium chloride is produced are reported with those discussed in the Salt and Stone chapters in this volume. Total sales of calcium chloride (both natural and byproduct) during 1940 are estimated at 266,000 short tons—an increase of a little more than 2 percent over 1939.

Calcium (calcium-magnesium) chloride from natural brines sold by producers in the United States, 1936–40

Year	Short tons	Value	Year	Short tons	Value
1936	125,911	$1,909,908	1939	[1] 108,441	$1,307,717
1937	[1] 97,142	1,295,403	1940	[1] 94,238	1,485,784
1938	[1] 96,470	1,218,938			

[1] Calculated to basis of 75 percent $CaCl_2$.

Calcium chloride imported for consumption in and exported from the United States, 1936–40

Year	Imports		Exports	
	Short tons	Value	Short tons	Value
1936	2,128	$25,678	27,831	$503,966
1937	2,205	24,908	21,732	415,309
1938	1,642	21,174	24,118	396,981
1939	996	12,314	19,382	318,199
1940	----------	----------	8,907	194,738

Owing to limited demand barely more than 5 percent of the total calcium chloride produced in the manufacture of sodium carbonate is recovered as a byproduct. Notwithstanding the fact that it is still largely a waste material, calcium chloride has attained considerable economic importance, as indicated by the afore-mentioned sales figures. Its greatest application is for the construction and maintenance of roads, where it is used to lay dust, and to aid in the consolidation and stabilization of dirt and gravel roads, in the curing of concrete, and ice control. Other uses are for dedusting and ice control of coal and coke, for dust control of private grounds, in refrigerating brines, in air-conditioning, and in numerous other smaller outlets. Recent estimates of the proportional utilization of calcium chloride are: Road stabilization, surface consolidation, and dust laying, 40 to 45 percent; highway ice control, about 15 percent; dust- and freeze-proofing of coal and dust-proofing of coke, 10 to 14 percent; refrigeration, 5 percent; concrete acceleration and conditioning, 5 percent; manufacture of other chemicals, 3 percent; and miscellaneous, 17 to 18 percent.

A vigorous campaign by the Solvay Sales Corporation and other manufacturers is under way in an attempt to develop the miscellaneous uses of calcium chloride as well as those that consume large tonnages. One of the more interesting applications is dehumidification of the air of private homes. Low-cost equipment in which flake calcium chloride can be used for this purpose has been placed on the market; and it is claimed that, under proper conditions, the humidity can be reduced sufficiently to prevent condensation of moisture on cold pipes and basement walls during humid weather and even to prevent the sensation of dampness and the formation of mold. A patented dehydrator of air known as Caloride has recently been placed on the market. This material consists of nonporous lumps of 72-percent calcium chloride into which activated carbon is dispersed. It is designed not only to dehydrate the air but also to absorb some odors. Equipment has been developed for applying it to dehydration of air both in residential and in industrial air-conditioning.

BROMINE

After advancing almost steadily since 1926, the production of bromine jumped 56 percent to another all-time high of 29,633 short tons valued at $11,772,515 in 1940, compared with 18,941 short tons valued at $7,611,400 in 1939. Despite the improvement in the quality of base gasolines the use of bromine in the production of tetraethyl lead again rose more rapidly than did the production of gasoline. This resulted, at least in part, from the fact that during the past few years even the so-called regular gasolines have been improved by larger additions of this knock-inhibiting compound.

Bromine and bromine in compounds sold or used by producers in the United States, 1936–40

Year	Pounds	Value	Year	Pounds	Value
1936	20,609,025	$4,038,438	1939	37,882,005	$7,611,400

The present abundant supplies of bromine, available at relatively low cost, have encouraged research into and development of new applications for this element by assuring the user of adequate supplies should large quantities be required. The use of bromine in the shrinkproofing of wool was described by Ericsson.[4] Advantages claimed were: Less chemically determinable damage to the wool fiber, easier control during application, and a reduction of fumes with a newly designed apparatus. A new, although not large, use of bromine compounds as a substitute for tincture of iodine has recently been reported

[4] Ericsson, Ralph L., Textile Chemists Told Army Needs: Oil, Paint, and Drug Reporter, vol. 138, No. 18, October 28, 1940, p. 56.

in Germany. This is a combined bromine preparation, the bacteriocidal power of which is said to be equal to that of tincture of iodine, and it is claimed to be superior to iodine in other respects. The importance of this development rests not so much upon the new outlet for bromine as upon the release of the medical and surgical requirements of relatively large quantities of iodine, of which there is a severe shortage in Germany.

On December 23, 1940, bromine and its compounds were added to the export-control list. The United States is the world's largest producer of bromine and, although figures are not available, exports are considerable. Germany and Palestine also are large producers, and appreciable amounts are produced in Japan, France, Tunisia, Italy, Russia, and the United Kingdom. Plants for recovering bromine from sea water are reported to be operating in France and in England.

Fourteen plants reported production of bromine or bromine compounds from natural sources during 1940. The Ethyl-Dow Co. produced the largest quantity, recovering bromine from raw sea water near Wilmington, N. C. The second largest producer was the Dow Chemical Co., which recovered bromine from natural brines in Michigan. This company has also begun to produce bromine at its Freeport (Tex.) plant where magnesium compounds are recovered from raw sea water. The American Potash & Chemical Corporation—a newcomer into the bromine field—also supplied an important quantity of bromine during 1940, having recovered this element from some of the more concentrated process liquors derived from Searles Lake brines. Equipment for producing bromine compounds as well as liquid bromine was being installed early in 1941, and actual output of these compounds was expected to begin by early summer.

IODINE

Domestic production of iodine during 1940 continued the increase begun in 1937; however, owing to the fact that output was reported by only two companies—the Dow Chemical Co. at its plant at Long Beach, Calif., and the Deepwater Chemical Co. at its plant at Compton, Calif.—the Bureau of Mines is not at liberty to publish the figures. The domestic production of iodine during 1937 (statistics for which are the last published by the Bureau of Mines) was 299,286 pounds valued at $242,422. Imports of iodine in 1940 (all crude) totaled 1,244,146 pounds valued at $1,296,181—a sixfold increase over the imports of iodine during 1939, which totaled 200,000 pounds valued at $168,233.

Crude iodine imported for consumption in the United States, 1936–40

Year	Pounds	Value	Year	Pounds	Value
1936	592,217	$558,326	1939	200,000	$168,238
1937	1,967,148	1,784,491	1940	1,244,146	1,296,181
1938	570,532	464,303			

On April 15, 1941, iodine was added to the export-control list. Supplies of iodine—an essential in medicine and photography—are ample but not overabundant in the United States. The recovery of iodine in this country depends on the market price more than on natural resources of this element. Should suspension of imports cause a sufficient increase in price, profitable recovery of iodine in the United States could be increased to an estimated 500 tons [5] annually, which is about equivalent to annual domestic consumption. Since 1932 the United States sales agency of the Chilean iodine producers has maintained a minimum stock on hand of 1,000 metric tons of iodine; as soon as stocks are depleted to this figure fresh shipments are imported. If imports of iodine should be cut off these stocks, which are equivalent to almost 2 years' normal supply, will be adequate to supply domestic requirements until new equipment for the recovery of iodine can be installed in this country.

The bulk of the world supply of iodine is produced as a byproduct of the nitrate industry in Chile. The greater part of the Chilean output is supplied by the two modern Guggenheim-process nitrate plants, Maria Elena and Pedro de Valdivia. France, the United Kingdom, Ireland, Norway, Japan, Netherlands Indies, and British India also contribute to the world iodine output. Germany depends on foreign sources for all of its iodine requirements; in consequence of a special trade agreement with Chile, net imports expanded markedly in 1935, to 252 short tons from 64 short tons in 1934, then contracted steadily, falling to 140 short tons in 1938 and an estimated 135 short tons in 1939. As a result of the British blockade, therefore, Germany is suffering from an acute shortage of iodine. Various measures have been taken to relieve the situation. Waste iodine from all possible sources is being recovered, one of the most outstanding being the photographic-chemical industry. Fixing baths at photograph-development establishments are an especially advantageous source of reclaimed iodine, inasmuch as they are invariably treated for the recovery of silver. Other sources of reclaimed iodine are residues, solutions, and other iodine-containing industrial wastes of the pharmaceutical industry and plants producing inorganic or organic iodine-bearing preparations. Germany has reduced the consumption of iodine by restricting its use and by developing substitutes. As noted under the foregoing discussion of bromine a new antiseptic agent recently developed in Germany, incorporating oxygen-bromine compounds, a metal salt, and weak acid thiocyanate solutions, has been found an effective substitute for tincture of iodine and is already in general use, having been accepted as standard by the German army. Iodine is now employed in Germany principally for industrial purposes, especially photography; consumption for photographic purposes has been greatly expanded in recent times by the extensive use of military photography. Recently the iodine situation in Germany has been somewhat relieved by supplies originating in France.

SODIUM SULFATES

Sales of natural sodium sulfates continued their upward trend of the last 6 years by jumping 36 percent to 187,233 short tons valued at $1,528,633 in 1940 compared with 137,479 short tons valued at $1,027,876 in 1939, the previous record year. This increase in production was caused (in part at least) by the sharp decrease in imports of salt cake during 1940, which—owing to war conditions—totaled only 73,027 short tons valued at $1,009,694 and represented a 51-percent decrease in quantity and a 28-percent decrease in value from the 1939 imports of 148,794 short tons valued at $1,394,484.

Virginia	901		Duluth and Superior	423	
Gulf ports:					
Florida	50,541	11,940			
Galveston	1,207			148,794	73,027

The Bureau of the Census reports that sales of salt cake from chemical works as well as from natural sources amounted to 224,749 short tons valued at $2,291,944 in 1939 (241,347 tons, $2,367,616 in 1937), sales of anhydrous (refined) sodium sulfate 42,489 tons, $689,599 in 1939 (21,797 tons, $312,285 in 1937), and sales of Glauber's salt 34,493 tons, $539,770 in 1939 (31,934 tons, $490,660 in 1937).

Responding to the demand for domestic salt cake (fig. 3) caused by the reduction of imports in consequence of war conditions, a large plant at Dale Lake, Calif., has been constructed by the Desert Chemical Co. to manufacture salt cake and anhydrous sodium sulfate. Owing to the use of solar evaporation for the recovery of both Glauber's salt and salt cake, operating costs at this plant are said to be very low. It is hoped that these low operating costs will offset the somewhat unfavorable situation of this plant with respect to the consuming areas. "Synthetic salt cake," a sintered mixture of soda ash and sulfur in proportions of about 3 parts of sulfur to 10 of soda ash, has become an important factor in the kraft-paper market for sodium sulfate. This product is not a satisfactory substitute for sodium sulfate in other applications, but the kraft pulp and paper industry is by far the

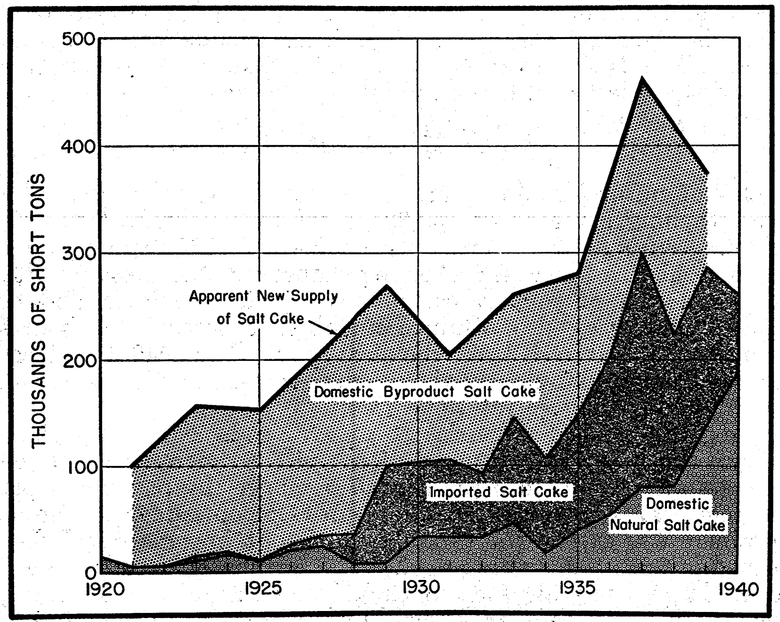

FIGURE 3.—Apparent new supplies of salt cake in the United States from domestic and foreign sources, 1920–40.

largest consumer of sodium sulfate and requires well over 70 percent of the entire output of this chemical. It is reported that the Mathieson Alkali Works at Lake Charles, La., is producing "synthetic salt cake" at the rate of about 400 tons a day, largely replacing the imported salt cake no longer available from Germany.

A number of sulfate-process pulp plants are using a combination of gypsum and sodium carbonate instead of salt cake. Sodium carbonate and gypsum are added to the black ash of the process, and sodium sulfide is obtained after the mass has been burned. Advantages claimed for this process are lower furnace losses and better control of the sulfidity of the digesting liquor.

Natural sodium sulfates and sodium carbonates sold or used by producers in the United States, 1934–40

Year	Sodium sulfates [1]		Sodium carbonates [2]	
	Short tons	Value	Short tons	Value
1934	16, 650	$148, 225	88, 325	$1, 254, 113
1935	38, 706	275, 943	93, 230	1, 173, 003
1936	51, 608	336, 559	102, 866	1, 106, 364
1937	80, 053	599, 266	104, 711	1, 191, 485

[1] Salt cake and Glauber's salt.
[2] Soda ash, bicarbonate, sesquicarbonate, and trona.

The price of imported salt cake, as quoted by the Oil, Paint, and Drug Reporter (assumed to be the price of salt cake on the southern market) rose from its pre-war level of $15 to $16 a ton to $18 a ton in

December 1939 and to $20 a ton in January 1940. The price remained at this latter figure during 1940 until the production of "synthetic salt cake" and the availability of salt cake from other sources reduced the price to $16.50 a ton late in December 1940.

SODIUM CARBONATES

Sales of natural sodium carbonates continued to increase during 1940, reaching a record of 130,034 short tons valued at $1,629,283 compared with 124,743 short tons valued at $1,528,810 in 1939—the previous high. Likewise reflecting improved business conditions, the production of sodium carbonates by the ammonia and other chemical processes also attained an all-time record. Estimates of the output of soda ash from chemical sources for 1940 are placed at 3,025,000 tons manufactured by the soda-ammonia process and 25,000 tons by the electrolytic process.

Owing to technical advances the use of soda ash in the glass industry—the greatest consumer of sodium carbonate—continued to grow despite inroads into the container market by paper and plastic products. It is predicted that difficulties in obtaining tin for metal containers will extend the production of container glass and thereby the use of soda ash in this field. The output of caustic soda—the second largest use for sodium carbonate—was placed at 1,095,000 tons during 1940 compared with 1,025,000 tons during 1939.[6] Of the 1940 production 46 percent was obtained from soda ash by the lime-soda process in 1940 and 52 percent in 1939. This decrease in the production of caustic soda by the lime-soda process in 1940 was caused in great measure by the increased demand for chlorine, which is largely obtained by electrolysis of sodium chloride, with caustic soda as an unavoidable coproduct. Many manufacturers of caustic soda by the lime-soda process also operate electrolytic cells for producing chlorine and sodium hydroxide; consequently they will reduce output of caustic soda by the lime-soda process when necessary to avoid accumulating large stocks of this material.

An interesting new use for sodium carbonate is in the manufacture of "synthetic salt cake," already described. This material is and probably will always be exclusively a product of the sodium carbonate produced by the ammonia-soda process, inasmuch as natural salt cake is economically available in areas where natural soda ash is largely used. The smelting of low-grade iron ores by the so-called acid process has become a newly important use for sodium carbonate in Germany. Owing to the great wartime requirements for steel in that country it has been necessary to resort to extensive use of low-grade iron ores locally available; consequently a new and very large demand for a special fused lump-form soda ash has arisen in that country. Such a product has been employed for some time in the United States for a similar purpose—usually in refining high-grade steels—but the demand for sodium carbonate for this use has never been very great.

Research into the applications of sodium carbonate continues; because of this, it is thought that the present importance of sodium carbonate in industry will continue or may even grow. Investigational work now in progress includes research on sodium carbonate

[6] Chemical and Metallurgical Engineering, Commodity Reviews and Forecasts, Alkalis and Chlorine: Vol. 48, No. 2, February 1941, pp. 92–94.

for improving the manufacture of clay products. Relatively small quantities of sodium carbonate are used, but excellent results are obtained by proper manufacturing control.

BORATES

Owing to extensions of the British blockade of exports from the United States to European countries falling under Axis control, domestic production of borate minerals declined slightly to 243,355 short tons valued at $5,643,390 during 1940 compared with 245,284 short tons valued at $5,689,797 (revised figures) in 1939. Exports dropped sharply to 64,313 short tons valued at $2,456,523 from 91,139 short tons valued at $3,230,304 during the preceding year and a record of 154,052 tons valued at $4,715,691 in 1937. Apparent consumption in the United States increased in 1940 owing to general business improvement rather than to any specific technical advances. Increased sales and lower prices of ovenware expanded somewhat the requirements for boric acid and borates of manufacturers of heat-resisting glass; and increased sales of vitreous enamelware, resulting from improvements in the products and from the scarcity of corrosion-resistant alloys for other than national defense purposes, were another favorable factor. Both industries are important consumers of borax.

Salient statistics of the boron-mineral industry in the United States, 1936–40

	1936	1937	1938	1939	1940

[2] Revised figures.
[3] Also 348 pounds of crude valued at $3.

The use of boron in fertilizer, though not large as yet, is growing steadily and within a period of years may become a major outlet for this element. Active research has developed the fact that there is a different and a relatively narrow range of optimum concentration for each type of plant. Too little boron causes deficiency diseases in plants, and too much may prove toxic. The problem is complicated further by the fact that on some soils the very small quantities of boron compounds that can be employed may be made completely unavailable by other minerals contained in these soils.

Other uses of boron materials are being investigated. The Bureau of Mines has published a report[7] on the electrolytic production of calcium boride—an agent used to some extent in metallurgical work as a source of boron or as a deoxifier or degasifier of molten metals.

[7] Koster, J., Knickerbocker, R. G., and Fox, A. L., An Electrolytic Method for the Production of Calcium Boride: Bureau of Mines Rept. of Investigations 3500, 1940, 20 pp.

Research and development work has also been carried out in an attempt to improve the methods of recovering boron minerals from their ores. Another Bureau of Mines report [8] describes the recovery of a relatively high grade of crude boric acid by treatment of the ground crude ore with sulfur dioxide and water, followed by flotation of the precipitated boric acid. The same report also describes a method of recovering 94- to 95-percent calcium borate from a 70-percent colemanite concentrate by extraction with carbonic acid followed by precipitation of the resulting boric acid solution with lime.

Borax was placed on the export-control list on March 4, 1941. Inasmuch as over 90 percent of the world supply of boron materials is produced in this country this action affords the United States Government a means to ration most of the world supply of this important material.

GEM STONES

By Sidney H. Ball[1]

SUMMARY OUTLINE

The jewelry industry in 1940.—Retail sales of jewelry in 1940 totaled about $416,000,000—a 15-percent increase over sales of $361,564,000 in 1939, as reported by the Bureau of the Census. They were the most satisfactory since 1929, but the quantity sold exceeded that in 1929, as jewelry prices today are below those of that year. In 1939, 14,558 retail jewelry stores were operating in the United States. The Retail Business Census shows that in 1929, $1.11 out of the consumer's $100.00 was spent for jewelry, contrasted with only $0.86 in 1939. As compared to 1939, Michigan, Washington, Oregon, and Texas showed notable advance in retail sales in 1940. The gains were due largely to the increased sale of relatively inexpensive items, and although some high-priced articles were sold a colorless stock market exercised a restricting influence, particularly in New York. The volume of Christmas trade was at least 25 percent above that in 1939. Diamonds and watches were the leading items; sales of the former were augmented by the large number of engagement and wedding rings bought, especially after the passage of the Selective Service Act.

Jewelry manufacturers were unusually busy from May on, and overtime was common. The industry experienced some labor difficulties in 1940, the principal issue being the closed shop.

Retailers evidently believe wholeheartedly in the future of their trade. Tiffany's moved, for the fifth time in the 103 years of the corporation's life, to commodious quarters at 5th Avenue and 57th Street, New York City; two other important Fifth Avenue retailers thoroughly remodeled their stores; and, late in the year, at least two internationally known French jewelry houses opened shops on Fifth Avenue.

Fashions in jewels.—Colorful jewelry in large units characterized the 1940 mode. Gold, often in two or three colors, was more popular than platinum, although the latter was used in the finer diamond mountings. Patriotic, geometric, conventionalized floral, astronomic,

[1] Figures on imports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

animalic (some few attractive), Egyptian, and East Indian motifs were seen. Styles were striking and individual. Jewelry ensembles set with similar stones continued to gain popularity, as did large pieces divisible into several ornaments. An abundance of bracelets and necklaces, hair ornaments (including tiaras), clips, rings, and earrings were worn. Wealthy refugee women wear their jewels, and American women are not to be outdone.

Large diamonds and colored gems set pavé with small diamonds were popular; but in the fall, the high price of small cut (owing to destruction of the cutting industry in the Low Countries) forced new styles requiring fewer melee. The finer gems—including the diamond (including fine yellow and some coffee-colored stones), ruby, and sapphire (not only blue but yellow)—were particularly popular, while the emerald was less so. The less-valuable colored stones—star sapphires, moonstone, and topaz, and, to a smaller extent, aquamarine and amethyst—were likewise much used. The appreciation of and demand for colored stones almost unknown to the earlier generation is evidence of the increasing knowledge of precious stones among the American people. Because of the insistent demand for diamonds, colorless stones were most popular; red, blue, green, and yellow stones followed in order.

Costume jewelry.—No costume is now considered complete without real or imitation jewelry, which is being used more and more. The black gowns so prevalent today form an excellent background for "gold" pins, clips, necklaces, and bracelets. The sales of costume jewelry in 1940 increased substantially, probably to a greater extent than sales of real jewelry. Designs are improving and either follow the lead of jewelry designers or in some instances precede them. Many foreign sources of supply were cut off by the war, but American industry has successfully made up the deficit. Plastics are effectively used, and lucite beads are a fair substitute for satin spar. The manufacture of costume jewelry centers in New York. The value at the factory of costume jewelry produced in 1939 was $33,921,990 (1937, $29,928,567), and over 12,000 people were employed in the industry.

Domestic production.—From the 1909 peak output of gem stones valued at $534,280, the domestic industry dwindled to only $3,000 in 1934. Since then production has increased markedly and in 1940 was valued at $340,000 to $750,000; the first figure is a rough estimate of the amount used in jewelry and the second an estimate of the total, including that treasured by collectors or sold to tourists, collectors, and rock gardeners. The rise is due largely to the growth of lapidary work as a hobby (particularly in the Pacific Northwest and notably in Oregon and Washington). Stones of the agate family comprise about 87 percent of the amount used in jewelry. Gems are produced largely by individuals or partnerships, and as there are no official returns exact figures are not available.

The war has shut off, at least in part, the country's normal sources of supply of colored gems; their place, to some extent, has been taken by gems of American origin.

In the Northwest, especially in Oregon (according to correspondence with H. C. Dake) mineral collectors and lapidaries, both professional and amateur, continue to increase. He estimates the value of the material (largely quartz minerals) collected and cut in 1940 as follows: Oregon (professional lapidaries—$150,000, amateurs—$225,000);

Washington, \$140,000; and Idaho, \$47,000—a total of \$562,000. A new agate-producing district in Harney County, Oreg., an opalized-wood locality in central Washington, nephrite in place in an aplite dike near Split Rock, Fremont County, Wyo., and nephrite boulders about 48 miles southeast of Lander, Wyo., are reported. Miss M. Barrie Berryman states that there are some 50 professional and amateur lapidaries in Utah; she estimates the total value of the rough and cut gems and mineral specimens produced in the State as \$25,000 in 1940 compared with \$8,000 in 1939.

With the exception of quartz gemstones, turquoise leads in total value—about \$20,000; Nevada ranks first in output and Colorado second. The Fox turquoise mine near Cortez, Lander County, Nev., produced 7,928 pounds of rough turquoise; of this the more desirable material was sold for \$11,405. The Tonopah district and mines at Austin, Nev., also produced some turquoise, as did the turquoise mine in the San Luis Valley near Villagrove, Colo. A little is reported to have been produced in New Mexico, and some Arizona turquoise was sold, although little or no mining was done in 1940. Sales of turquoise jewelry in the southwestern curio shops were large.

Arthur L. Crawford reported that three localities in Utah (5 miles west of Fairfield, Utah County; 9½ miles south of Grantsville, Tooele County; and 25 miles north of Lucin, Box Elder County) produced variscite in 1940, and the mineral was also discovered near Promontory Point, Box Elder County.

In 1940 Montana produced about 12,350 troy ounces of sapphires (1,029 pounds) valued at about \$17,000. The principal producers were the American Gem Mines at Philipsburg, owned by Charles H. Carp and J. W. Kaiser, and the Perry-Schroeder Mining Co. of Helena, dredge operators. The stones are used industrially, as few are suitable for jewelry. As difficulty is likely to arise in obtaining synthetic sapphires and rubies from Europe, Montana sapphire mining may well become an important cog in our national defense program, because jewels are essential in many instruments necessary for military purposes.

Austin F. Rogers [2] describes nephrite recently found in the western part of the Santa Lucia Range, southern Monterey County, Calif. It occurs not only in large and small boulders but also in place in serpentine in a region of Franciscan rocks. The nephrite ranges from light greenish gray to black in color, and some of it is suitable for cutting. According to reports, californite (a compact vesuvianite used as a substitute for jade) is being mined by the Curly Jack Mining Corporation on the South Fork of Indian Creek near Happy Camp, Siskiyou County, Calif.

Three operators produced tourmaline, kunzite, beryl, and rock crystal valued at about \$2,400 from the well-known gem-stone deposits of San Diego County, Calif.

In 1940 a number of mineral collectors visited Topaz Mountain in the Thomas Range, Juab County, Utah, according to Miss Berryman. By blasting they collected a quantity of sherry-color topaz, which had been bleached water-white at the surface. When cut this material forms attractive gems readily sold locally.

A considerable amount of moss agate was recovered from the gravels of the Yellowstone River in southeastern Montana. This

[2] Rogers, Austin F., Nephrite Jade from Monterey County, Calif.: Bull. Geol. Soc. America, vol. 51, No. 12, pt. 2, December 1940, p. 1941.

source has long furnished beautiful moss agate for jewelry, but fine material is becoming scarce. The deposit in the Granite Hills near Split Rock, Wyo., also supplied considerable moss agate, and some was produced in other Mountain States.

A few Sioux still dig pipestone at Pipestone, Minn., and cut it into pipes or ornaments for their own use or for sale.

In the fall of 1939 Carl M. Anderson found a deposit of lapis lazuli, some of rather fine quality, at an elevation of 12,500 feet on the slope of Italian Mountain, Gunnison County, Colo. The lapis occurs as three stringers in Paleozoic metamorphic limestone intruded by diorite, which reach a maximum width of 7 or 8 inches and are traceable for about 300 feet. Harold I. Rosencrans, a Longmont jeweler, controls the deposit, cuts the lapis, and sold some in the East and set the remainder in Indian-style silver jewelry for distribution in the West.

Some gem stones were produced as a byproduct of North Carolina feldspar and mica mining; C. C. West operated a ruby property near West Mills, Macon County, and sold the product to the tourist trade. A number of lapidaries also cut for sale to tourists.

A small amount of rose quartz was produced at Scott's mine near Custer, S. Dak. The total recorded production of rose quartz in the Black Hills from 1879 to date has been valued at about $55,000. A small amount was also produced at Albany, Maine, and asteriated rose quartz in North Carolina.

Other gem stones produced in the United States in 1940 included agate (Utah, South Dakota, New Mexico); agatized wood (private lands surrounding Petrified National Monument, Ariz., New Mexico, Utah); alabaster (New Mexico, Utah, Wyoming); amazonstone (Colorado); amethyst (Red Feather Lakes, Larimer County, Colo., Georgia, Maine, North Carolina); aquamarine (Colorado, Maine, North Carolina); azurite (Bingham, Utah); chalcedony (Utah); emerald matrix (North Carolina); garnet (Colorado, New Mexico, North Carolina); golden beryl (North Carolina); jasper (California, New Mexico, North Carolina, Utah); lazulite (Clubbs Mountain, N. C.); malachite (Bingham, Utah); moonstone (North Carolina); rock crystal (Arkansas); iridescent obsidian (California); rhodonite (Utah); rutilated quartz (North Carolina); topaz (Colorado, Maine, North Carolina); pink sapphire (Georgia); and tourmaline (Maine).

Imports.—Imports of precious and imitation stones (exclusive of industrial diamonds) into the United States in 1940 totaled $37,767,705—a 6.7-percent decrease as compared with 1939. Details are shown as follows:

	Carats	Value
Diamonds:		
Rough or uncut (suitable for cutting into gem stones), duty free	227,886	$11,595,703
Cut but unset, suitable for jewelry, dutiable:		
Less than 10 stones per carat	54,005	5,457,151
10 or more stones per carat	267,466	16,544,568
Emeralds:		
Rough or uncut, free	14,364	6,915
Cut but unset, dutiable	16,093	394,104
Pearls and parts, not strung or set, dutiable:		
Natural		224,101
Cultured or cultivated		355,595

	Value
Other precious and semiprecious stones:	
Rough or uncut, free	$153,858
Cut but unset, dutiable	2,191,513
Imitation, except opaque, dutiable:	
Not cut or faceted	4,127
Cut or faceted:	
Synthetic	359,672
Other	423,344
Imitation, opaque, including imitation pearls, dutiable	32,193
Marcasites, dutiable:	
Real	6,790
Imitation	18,071
	37,767,705

As compared with 1939 imports of rough diamonds, other precious and semiprecious stones, cultured and imitation pearls, and synthetic gems increased whereas imports of cut diamonds, uncut emeralds, natural pearls, and marcasites decreased. The number of watch jewels imported in 1940 totaled 98,771,042 valued at $1,831,007 compared with 43,712,840 valued at $913,245 in 1939.

Government regulations.—Owing to the war, Government regulations affecting the jewelry trade were legion in 1940. By Presidential proclamation, effective July 5, 1940, as a result of the Sheppard-May Bill, a license was required to export industrial diamonds and quartz crystals, and on December 20, 1940, the order was amplified to include all products that contain them.

The British embargo on the export of diamonds (to prevent industrial diamonds from reaching the enemy) promulgated at the beginning of the war is effective, except for a major leak of Brazilian stones to Germany. In 1940 the order was amended several times to increase the control of industrial diamonds. As of July 1, 1940, diamonds, precious stones, and jewelry were permitted to be carried out of Great Britain by license only to prevent the export of capital. Customs officials at British ports require the presentation of a license for all jewelry worn by travelers, even wedding rings if they appear to be new. The budget of July 1940 increased the British tax on jewelry to 33⅓ percent of the wholesale value.

Canada has classified industrial diamonds and piezoelectric quartz crystals as of indirect strategic value. To keep cash within the Dominion, in December 1940 Canada prohibited the importation of jewelry and uncut diamonds from the United States and placed a 25-percent excise tax on the sale of luxury articles. Canada was formerly this country's most important foreign market for jewelry. Severe regulations exist regarding the sale of military emblems that might be mistaken for official insignia.

In May the Union of South Africa decreed that all shipments of rough diamonds can thereafter be addressed and delivered only to parties in London.

For the period July-December 1940 New Zealand cut imports of precious stones from the United Kingdom and its Crown colonies by 75 percent. The export of precious stones, unset or in jewelry, from Australia is prohibited, except by consent of the Minister for Trade and Customs.

On June 3, 1940, France decreed that cut precious stones and jewelry could not be exported from the country; previous decrees had covered the export of rough stones.

In May 1940 Germany prohibited the sale in the Reich of gold objects weighing more than 50 grams (1.6 ounces) or of more than 14 carats gold content. Early in 1940 Hebrews in Bohemia and Moravia were required to register with the Government all precious stones and articles made of precious metals. In Occupied France the German military authorities required inspection of all private safety deposit boxes and official listing before January 10, 1941, of the gold and precious stones they contained.

Early in 1940 Japan appealed to its citizens to sell or give their gold jewelry to the Government. In June the sale of watches costing more than $12 and the manufacture and sale of rings and necklaces were prohibited. Stocks of such articles in stores were to be liquidated within 3 months. The export of gold, even that in one's teeth, is reported to be dutiable upon leaving Japan.

On March 24, 1940, French Indochina required all shipments of imitation precious stones imported into the colony to show clearly the country of origin. Many of the zircons cut in Bangkok, Siam, originate in Indochina and are smuggled across the border. To control the trade, the Indochinese Government on June 12, 1940, decreed (1) that only the Kha people could dig the gems; (2) that only licensed buyers could purchase them; and, (3) that buyers and lapidaries must keep an accurate and detailed account of the stones bought and sold.

On July 22, 1940, Switzerland placed the control of industrial diamonds under its War Industries and Labor Office, to regulate sales and insure more equitable distribution of the supply on hand.

On February 8, 1941, President Getulio Vargas of Brazil issued a decree prohibiting the export of 35 minerals (including industrial diamonds and rock crystal) without an export permit, except to American nations. Exports to Japan, either for Japanese consumption or for reexport, were relatively large in 1940.

Industrial gem stones and national defense.—Certain gem stones are essential to the United States armament program. Industrial diamonds are one of the critical [3] minerals being stocked by the Government to insure rapid and efficient motor- and airplane-engine production. Lapidaries should be trained to produce the smaller-gage diamond dies. As of June 30, 1940, the Procurement Division of the United States Treasury had purchased 11,800 pounds of rock crystal for $98,875, and early in 1941 it bought Brazilian industrial diamonds valued at $100,000. Piezoelectric quartz from Brazil is necessary in the manufacture of certain types of radios, telephones, telegraph instruments, and cables. Rock crystal is also essential for the lenses and prisms widely used in optical instruments and when fused is employed in the chemical and electrical trades. Limited quantities of fine fluorspar, also utilized in optical instruments, can be obtained in the Illinois-Kentucky fluorspar district, and a synthetic substitute is said to be satisfactory. Iceland spar is essential for Nicol prisms. A deposit found recently in the Copper Mountain mining district 30 miles southwest of Taos, N. Mex., promises to replace in the American optical industry the spar formerly imported from Helgustadir, Iceland. Tourmaline is used in the tourmaline tongs (a simple form of polariscope) and might have other value in military instruments. Watch

[3] Considered "critical" by the Army and Navy Munitions Board for purposes of procurement under the Reconstruction Finance Corporation.

and instrument jewels, essential for airplane instruments and time bombs, are normally cut in Switzerland from European-made synthetic sapphire. An adequate domestic supply of raw material is available in the Montana sapphire mines, but lapidaries should be trained in this country to cut the jewels.

Effect of war on jewelry trade.—The jewelry industry continues to feel the effects of war. Destruction of the cutting industry in the Low Countries doubled or even quadrupled the price of small-cut diamonds. The price of fine large stones, however, only increased about 20 percent, inasmuch as such goods can be profitably cut in this country, England, and South Africa. For the present prices should be firm, with possible increases in large-cut stones later. The limited supply of small-cut stones in this country will result in fashion changes, and pavé settings will be replaced by "sec" mountings (large stones set with a minimum of small stones).

The British embargo on the export of uncut gem and industrial diamonds has been administered broadly; in consequence, imports into the United States have been unusually large. New York has increased in importance as a diamond center but can scarcely, as some claim, become the locale of the world cutting industry.

The fine-precious-stone industry, with its center—Paris—in the hands of the Germans, has been in chaos; imports into the United States have been more or less normal, and although prices are firm no great increase is expected, as stocks in the United States are adequate. For the duration of the war India will be a more important—and Paris a much less important—center of fine-gem trading.

Most of the less-valuable stones were cut in Germany, Czechoslovakia, and France, and before the war the United States imported synthetic stones from Germany, France, and Switzerland. The stocks of the less-valuable stones were normal when war broke, but since then they have been replenished but meagerly; in consequence, shortages of certain stones already have occurred. Stocks of synthetic stones suitable for jewelry are not large.

An alleged shortage of iridium (used as an alloy in jewelry platinum) caused a marked increase in price in 1940 (from $175 to $275 an ounce), although the price of platinum itself was stable. The war can only increase the cost of most jewelry items.

DIAMOND

Notwithstanding world conditions the diamond industry in 1940 had a relatively satisfactory year. Production increased in total weight but decreased in total value. Total sales of rough stones by the Diamond Trading Co. were about the same as in 1939, but the war has largely limited retail purchases (with the exception of clandestine investment buying) to the American continents, India, and the East Indies. The invasion of the Low Countries disrupted the cutting industry. The Germans have the men, equipment, and plants but little rough stock; Great Britain has the stocks; and Great Britain and powers friendly to it have a few cutters of large stones.

Share dealings.—The shares of diamond-mining companies, virtually all of which are listed on the London Stock Exchange, had a limited and at times a nominal market in 1940. After a short spurt quotations declined until the French debacle in June, by which time they had been reduced almost 50 percent; prices then seesawed for 3 months and afterward rose rather sharply. During the year five representative stocks lost about 8 percent—better performance than that of most British and American stocks. At the end of the year quotations were 29 percent of their high (1927) and 285 percent of their low. Of the 11 leading diamond-mining companies, 8 paid dividends.

Market.—In 1940 the Diamond Trading Co., which controls the sale of about 95 percent of the world output of diamonds, sold rough stones valued at about £6,000,000. For the first 4 months of the year sales were large and reminiscent of the prosperous twenties. But with invasion of the Low Countries trade fell off markedly, and America remained the chief customer. Industrial diamonds were, however, sold in quantity throughout the year.

Sales of polished diamonds were also large until May, and during January and February small cut stones were in marked demand. After May, the United States was practically the only buyer of importance and since then has been building up its stock of small cut stones. Retail sales in the United States increased compared with those in 1939.

Stocks of rough stones held by the Diamond Corporation are large, although they include few fine, large gems. Stocks of rough gem-grade diamonds in the United States are believed to be adequate, but stocks of industrial grades are less so. Stocks of large cut stones are adequate; those of small cut stones are inadequate, and unless the latter can be replenished, jewelry styles must change.

Imports.—Diamond imports into the United States in 1940 by countries were as follows:

Diamonds imported into the United States in 1940, by countries

[Exclusive of industrial diamonds]

Country	Rough or uncut			Cut but not set		
	Carats	Value		Carats	Value	
		Total	Average		Total	Average
Belgium				242, 326	$15, 137, 583	$62. 47
Brazil	3, 436	$322, 773	$93. 94	1, 612	140, 058	86. 88

	227, 886	11, 595, 703	50. 88	321, 471	22, 001, 719	68. 44

Cutting.—The cutting industry was normal for the first 4 months of the year, but when the Germans invaded the Low Countries in May the centers of 90 percent of the industry became wholly disorganized. America, the principal market, must now depend on the 450 cutters in the United States, 300 in South Africa, and 200 in England to supply its needs, as Brazil, Borneo, India, and Palestine cater largely to local and Eastern markets. The cutters in the first three countries are paid such high wages that small stones cannot be cut profitably. Recent increases in America (the minimum weekly wage rose from $75 to $120) must increase prices; however, some observers claim that if the industry is mechanized further the United States can profitably cut small diamonds.

World production.—Owing to the war, actual production figures are not available but the estimates in the following table are believed to be fairly accurate. World production (gem and industrial) in 1940 is estimated to have been 14,140,200 carats (2.828 metric tons) valued at about $31,000,000—an all-time record as to quantity. Compared with 1939 total weight increased 13 percent; value decreased 24 percent. In other words, the production of bort increased markedly and that of gem stones decreased by about 22 percent. Belgian Congo was the leading world producer both in weight (77 percent) and in total value (24 percent). As only one pipe mine was operated—and that for but 8 months—the alluvial mines produced 96 percent of the world total by weight and 91 percent by value. Of the world total the British Empire produced 14 percent by weight and 37 percent by value. Industrials comprised 85 percent by weight of the world total.

The following table shows, as accurately as available statistics permit, world production for the past 5 years:

World production of diamonds, 1936–40, by countries, in metric carats

[Including industrial diamonds]

Country	1936	1937	1938	1939	1940
Africa:					
Angola	577,531	626,424	651,265	690,447	[1] 785,000
Belgian Congo	4,634,266	4,925,228	7,205,620	8,344,765	[1] 10,900,000
French Equatorial Africa	1,550	5,588	19,644	[1] 16,000	[1] 16,000
French West Africa	18,897	57,687	61,928	56,314	[1] 75,000
Gold Coast (exports)	1,414,677	1,577,661	1,296,763	1,087,652	[1] 825,000
Sierra Leone	616,200	913,401	689,621	[1] 600,000	[1] 600,000
South-West Africa	184,917	196,803	154,856	36,010	30,017
Tanganyika	2,704	3,234	3,576	3,445	[1] 2,250
Union of South Africa:					
Mines	339,719	820,284	979,460	[2] 1,089,144	[1] 351,400
Alluvial	284,204	207,359	259,148	160,684	[1] 172,000
Total Union of South Africa	623,923	[3] 1,030,434	1,238,608	[2] 1,249,828	[1] 523,400
Brazil	136,462	192,000	111,257	[1] 350,000	[1] 325,000
British Guiana	41,067	35,958	32,522	32,491	26,764
Other countries [4]	6,000	6,000	34,200	19,000	[1] 31,750
	8,258,200	9,570,400	11,499,900	12,486,000	14,140,200

[1] Estimated.
[2] Includes 1,009 metric carats recovered by debris washers.
[3] Includes 2,791 metric carats recovered from re-treatment of tailings.
[4] 1935: Borneo, India, Nigeria, and Venezuela; 1936: Borneo, India, New South Wales, Rhodesia, United States (California), and Venezuela; 1937: Borneo, India, Liberia, New South Wales, Rhodesia, and Venezuela; 1938–40: Borneo, India, New South Wales, U. S. S. R., and Venezuela.

The Belgian Congo increased its output, particularly from the Beceka mines, which produce mainly bort. Angola also increased its yield about 14 percent. The Gold Coast curtailed production drastically, and the pipe-mine output was about 37 percent of that in 1939. Venezuela—a minor producer— is increasing its output.

Age of African diamond deposits.—The more famous of the African diamond fields (South African kimberlite pipes) are of Cretaceous age. South African alluvial deposits and those of South-West Africa are derived from the break-down of such pipes. The Tanganyika pipes are contemporaneous, as are the noncommercial Belgian Congo pipes; strangely enough, the Arkansas kimberlite intrusives are approximately of the same age.

The Belgian Congo-Angola diamonds are known to be older than the Jura-Triassic and are presumably of pre-Cambrian age. Junner[3] believes that the Gold Coast deposits are also of pre-Cambrian age, and diamonds have been recovered from the clean-up of the Ashanti-Adowsena gold mine, whose ore bodies occur in the Banket series (Tarkwaian quartzites of pre-Cambrian age). An occasional diamond is found in the gold mines on the Witwatersrand, where the gold deposits also occur in pre-Cambrian rocks. The important Sierra Leone deposits and those of the French African colonies are likewise presumably of pre-Cambrian age.

In normal years the value of the production from the Cretaceous and pre-Cambrian deposits is more or less comparable; in 1940, owing to the small amount of activity in pipe mining, the older deposits represented 96 percent by weight and 72 percent by value of that part of the world production that can be allocated to deposits of these two types.

Industrial diamonds.—In 1940 American industries, working under the stress of the defense program, consumed more diamonds than ever, probably in excess of 2,000,000 carats, and in European munition plants the increased use was equally great. In the past 30 years the use of industrial diamonds has increased eightfold, and a decade hence the diamond mines of the world may have difficulty in satisfying the world demand. Industrial diamonds are one of the critical war materials to be stocked by the Procurement Division of the Treasury. During the last 2 years the American trade has accumulated a stock of industrial stones that may be adequate for 1 year's consumption. Naturally such a small stock is wholly inadequate for a highly industrialized country lacking local sources of supply. Features of the trade in 1940 were (1) the further expansion of the use of diamond-impregnated wheels and tools with a powdered-metal bond, (2) the increased use of mechanically set drill bits studded with small stones, and (3) the tendency to replace cleavages by fine crystals in diamond dies.

Throughout 1940 the demand for industrial diamonds was strong because of the high rate of industrial activity in the United States and in Great Britain. Prices were firm, with an upward trend.

Imports of industrial diamonds into the United States during the past 5 years were as follows:

Industrial diamonds (glaziers', engravers', and miners') imported into the United States, 1936–40

Year	Carats	Value		Year	Carats	Value	
		Total	Average			Total	Average
1936	1,166,094	$4,328,603	$3.71	1939	3,568,730	$9,725,683	$2.73
1937	1,885,970	6,542,365	3.47	1940	3,809,071	11,026,563	2.89
1938	1,396,247	4,213,412	3.02				

Imports from Brazil increased markedly and caused an advance of 16 cents a carat in the average value.

[3] Junner, N. R., Origin of Gold Coast Diamonds: Gold Coast Colony Report of Geol. Survey Dept. for financial year 1937–38, p. 6.

RUBY, SAPPHIRE, AND EMERALD

Sales of rubies, sapphires, and emeralds and of less-expensive colored gems were large in 1940. Particolored sapphires were popular, and one New York jeweler combined Montana sapphires and yellow gold attractively.

After the Burma Ruby Mines, Ltd., abandoned operations in 1931 local Burmese miners continued them. The production rose markedly from 1934 to 1937 (21,622 carats of rubies valued at £2,708 and 153 carats of sapphires valued at £25 in 1934 to 157,308 carats £6,841, and 4,392 carats, £228, in 1937, respectively). There was a further increase in 1938. A few spinels are a byproduct.

In 1939 the Anakie (Queensland) industry sold sapphires valued at £326; production was somewhat greater, as appreciable quantities of fancy stones and industrial corundum were exported but not sold.

The Kashmir sapphire output was nominally 18,344 carats valued at £41 in 1937 and 4,892 carats, £11 in 1938. Owing to its high altitude this deposit (at Soomjam in the Pedar district) can be worked only when the weather is favorable.

After 25 years of Indochinese sovereignty the sapphire deposits of Pailin were reincorporated into Thailand (Siam) toward the close of 1940.

In 1940 the United States imported 16,093 carats of cut emeralds valued at $394,104 (United Kingdom 58 percent, Russia 20 percent, Colombia 13 percent, France 2 percent, and Belgium 1 percent) and 14,364 carats of rough emeralds valued at $6,915. The Chivor Emerald Mines, Ltd., Colombia, was operated under lease in 1940, and some good material is reported to have been found. Dr. Thomas Clements (see following bibliography) considers that the Muzo (Colombia) emeralds were deposited by magmatic waters at relatively low temperatures. Although the mine has been closed since January 1, 1939, Dr. Clements states that the deposit is not exhausted, and he believes that there may be other deposits in the vicinity. Government reports indicate that emerald stocks valued at about $400,000 are in the Banco de la República. Brazil exports a few light-color emeralds obtained in the States of Minas Gerais and Bahia.

LESSER GEMS

A little opal was produced at Sheep Creek Station, Queensland, in 1939, but operations at Duck Creek were at a standstill.

Burma produced 1,303 hundredweight of jadeite valued at £4,320 in 1938 and 2,952 hundredweight valued at £13,030 in 1937; the cause of the decrease was attributed to the war in China.

Production of amber in Palmnicken, Prussia, increased consistently from 1936 to 1939 (estimated exports for 1939 were 26,860 kilograms valued at 138,000 reichsmarks); most of this output was shipped to Danzig for processing and re-export. The Myitkynia district produced 38.7 hundredweight of amber valued at £668 in 1937, but no production was recorded in 1938.

A rock crystal weighing 4,400 pounds and valued at $25,000 was found at Itamarandiba, Brazil, in 1940. The Swedish Geological Survey reports the discovery of rock crystal in the Province of Jamtland, northern Sweden. Preliminary tests suggest that this find may supply Sweden's small demand for piezoelectric rock crystal formerly obtained from Brazil.

Kornerupine of gem quality is reported to have been identified in concentrate from gem pits at Ratnapura, Ceylon.

Dr. A. L. Parsons reports that a little iolite was produced from the Great Slave Lake region, Canada. Some attractive gems have been cut from the material.

Agalmatolite is exploited on a small scale at the large deposit near Para de Minas, Minas Gerais, Brazil; it is used for church construction, ornamental purposes, and sculpture.

In 1939 Turkey produced less meerschaum than in 1938 (335 cases compared with 385 in 1938).

In the first half of 1940 Brazil exported 1,754,745 carats of gem stones—virtually all to the United States. Bahia and Rio de Janeiro were the principal shipping points.

MINOR NONMETALS

By Paul M. Tyler and Leo J. O'Neill [1]

SUMMARY OUTLINE

CARBON DIOXIDE

According to preliminary figures of the Bureau of the Census, the production of dry ice in 1939 (the latest data available) amounted to 178,447 short tons valued at $5,532,315, and the output of liquid or gaseous CO_2 (including 15,000,000 pounds piped to dry-ice plants) was 51,104 short tons valued at $4,657,037. In 1937, the previous year for which statistics are available, the dry-ice output was 156,609 short tons valued at $4,618,937, and the production of liquid or gaseous CO_2 totaled 50,358 tons worth $4,939,508. The number of plants producing solid carbon dioxide increased from 42 in 1937 to 44 in 1939, whereas the number of plants producing liquid or gaseous CO_2 decreased from 61 in 1937 to 55 in 1939. The principal outlets for dry ice are in the ice-cream industry and for food refrigeration. Liquid CO_2 is used mainly in carbonating beverages. Imports of carbon dioxide for 1940, all of which came from the United Kingdom, amounted to 350 pounds (including weight of containers) and had a foreign market value of $197.

GRAPHITE

Although listed as a "critical" rather than a "strategic" material, graphite assumed considerable importance in plans for national defense and aid to Britain in 1940. Graphite crucibles are no longer used in making ingot steel and have been superseded in large part for melting steel and nonferrous metals in general foundry work. Nevertheless, they are still a wartime necessity, being employed for special castings and more especially in recent months in the manufacture of bronze and other copper-alloy castings for shipyards building naval as well as merchant vessels. Retorts for recovery of secondary zinc also are made from crucible-grade graphite admixed with clay and stoppers for ladles used in steel works from somewhat similar mixtures. Modern crucibles, which usually contain about 50 percent graphite,

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

withstand at least twice as many heats as those manufactured in 1914–18. With less melting to be done in crucibles and with more service obtainable from each crucible, the quantity demand pattern of the World War of 1914–18 has not been repeated. During the last war, moreover, crucible makers insisted on having Ceylon plumbago, whereas in recent years they have been just as insistent that Madagascar flake graphite is the only material that they can use, although several use admixtures of Ceylon graphite for certain products. One company utilizes a small quantity of Alabama flake for a special type of crucible.

Procurement of Madagascar flake afforded some difficulty even before the fall of France, and at the close of 1939 stocks were somewhat depleted. Madagascar recognized the Vichy Government, and although the French authorities were willing to do business with the United States the British blockade of the island effectively prevented shipments, except after major diplomatic maneuvers. Actual imports during 1940, including a small purchase for a Government stock pile, aggregated roughly three times the average quantities imported annually during the last 5 years, but estimated requirements were stepped up to at least 350 to 400 tons a month, or more than twice normal needs.

Graphite imported for consumption in the United States, 1936–40, by kinds

Year	Amorphous				Crystalline					
	Natural		Artificial		Lump and chip		Dust		Flake	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value
1936	20,160	$344,499	1,635	$63,804	251	$18,107	68	$4,090	2,057	$136,162
1937	25,354	512,162	802	31,562	482	41,499	321	17,600	2,634	149,492
1938	14,676	247,789	500	19,870	41	3,074	168	10,643	1,620	90,663
1939	18,675	269,046	413	15,383	(1)	(1)	[1] 602	[1] 30,421	2,260	110,476
1940	23,766	487,675	260	9,187	(1)	(1)	[1] 752	[1] 54,027	6,551	340,396

[1] Lump and chip included with dust.

Natural graphite exported from the United States, 1936–40

Year	Short tons	Value	Year	Short tons	Value
1936	816	$114,847	1939	976	$109,715
1937	1,514	163,331	1940	1,632	148,639
1938	983	112,443			

Prices of graphite in Madagascar were virtually unchanged during the year, and early in 1941 a cargo of several thousand tons was made up of various lots ranging in price (according to screen analysis and carbon content) from a minimum of $58 to a maximum of about $82 a metric ton, averaging $70 f. o. b. Tamatave. Freight rates, which for some time had remained unchanged at 90s. (say $18) a ton, were advanced to $25 a ton in November and later to $36. Import duty (30 percent or about $21) raised the total cost of the material to around $130 a metric ton or about 5⅞ cents a pound, delivered in New York, duty paid, in May 1941. Prices of amorphous graphite remained virtually the same as in 1939. In fact, almost the only substantial change in graphite quotations, apart from the advances due to increased ocean freight, was in Ceylon crucible grades, which were jumped to around 10 cents a pound f. o. b. mines compared with 5 or 6 cents a year earlier.

Notwithstanding the increase in imports a little more interest was evidenced in domestic graphite mining. The Long Valley Ore Co. mine at Pope Mills and the milling plant at Morristown, St. Lawrence County, N. Y., changed hands late in 1940 and were closed for extensive alterations which are expected to improve quality of the concentrate and to maintain a steady production rate of around 12 tons a day. The ore contains fine flake graphite disseminated in a sheared, thick-bedded quartzite or quartzose schist. Reserves are considered to be more than ample for several years' operations at least and may prove fairly large. Abandoned mines in the eastern and southeastern Adirondacks, previously described by Alling,[2] were examined by the Federal Geological Survey, which reports by letter that some of them may warrant further investigation, in the light of modern milling practice. A virgin prospect near Suffern, N. Y., yielded promising samples and was being investigated during the late fall in the hope that graded crushing and proper beneficiation might yield larger flake than hitherto has been obtainable commercially from domestic deposits.

The Alabama graphite industry was revived after 10 years of virtual inactivity. The Ceylon Graphite Co. near Goodwater, Coosa County, which rebuilt its mill late in 1939, began producing flotation concentrates comprising about 75 percent No. 1 flake, 20 percent No. 2 flake, and 5 percent dust. A small tonnage of amorphous graphite for paint was mined at Carson City, Nev., by the Carson Black Lead Co. Efforts were made to revive production of graphite in California, Georgia, Montana, Texas, Virginia, and perhaps other States, but the Bureau of Mines has no knowledge of any substantial production of natural graphite in 1940 except by the three companies mentioned. Artificial graphite was manufactured and sold by the Acheson Graphite Co. (30 East 42d Street, New York, N. Y.) at Niagara Falls and by the Exolon Co. at Blasdell, N. Y.

World production.—Owing to the absence of figures for the Soviet output, which in 1935 approximated 84,000 metric tons, world production statistics for graphite are incomplete. With the possible exception of the U. S. S. R. the largest producing area in recent years has comprised Bavaria, Moravia, and Austria, which produces mostly low-grade material suitable only for local consumption. The movement of this material in international trade has been confined virtually to transactions across the central European frontiers established by the Versailles treaty and wiped out by the expansion of Germany under Hitler. The principal source of overseas shipments is Chosen, which in recent years has become a large exporter of amorphous graphite and a by no means insignificant source of flake graphite. Next in order as regards tonnage but far more important as regards value of product is Ceylon. Although in recent years a substantial portion of Ceylon's exports, especially those to the United States, has been classified as "amorphous," the average price per ton f. o. b.

[2] Alling, H. L., The Adirondack Graphite Deposits: New York State Mus. Bull. 199, Albany, 1918.

mines is many times greater than that of material mined in any other important producing country, including even Madagascar, which is the only other large source of crystalline graphite worth more than about $50 a ton f. o. b. mines. Mexico, the only other country furnishing as much as 10,000 tons a year, produces amorphous graphite, all of which is exported to the United States and worth about $10 a ton, or roughly the same as the Chosen graphite f. o. b. mines.

Brazil.[3]—Graphite schists occur in the basal complex of Minas Geraes but usually are low-grade, although workable graphite (87 percent) is reported at Itabira. The best deposits—at Fortaleza, Arassuai, and Jequitinhonha—are veins in gneiss. Most important is that at Arassuai, which yielded only 8 metric tons from 1930 to 1937.

World production of natural graphite, 1915–34 (5-year averages), 1935–37 (3-year average), 1938, and 1939, in metric tons

3 Leonardos, O. H. (Graphite in Minas Geraes): Service fomento produccao mineral, Brasil, Avulso 26, 1938; Chem. Abs., vol. 34, No. 12, June 20, 1940, p. 4024.

Ceylon.—Japan continued to be the principal buyer of Ceylon graphite throughout 1940, and it was not until after the close of the year that the British Government placed an embargo on shipments to that country. A joint marketing scheme for Madagascar and Ceylon graphite was projected in April, presumably to gain political control of world supplies of high-grade graphite, but this plan was not popular in Ceylon and collapsed after the Battle of Flanders.

The total graphite shipped from Ceylon in 1940, according to preliminary reports, was 24,028 long tons valued at 5,750,144 rupees compared with 22,396 tons valued at 3,407,135 rupees in 1939 (Rs. 1 equaled $0.3003 in January 1941). Of the 1940 exports the United Kingdom purchased about 11,000 tons, and the United States and Japan about 6,000 tons each; smaller quantities were shipped to other countries. Whereas exports to the United States consist principally of relatively low priced amorphous or crystalline dust, Japan's purchases have been principally of high-grade crystalline.

According to Consul George M. Graves (Colombo):[4]

Increased orders for graphite have caused prices to rise. In fact, as one mine owner explained it to the Consulate, prices are rising with demand. There is, of course, another explanation of rising prices in that mining equipment has more than doubled in price and both freight and insurance rates are up.

Presumably the United Kingdom is cut off from the Madagascar market and therefore looks more to Ceylon for its requirements. Supplies on hand, particularly of the crystalline grades, are small. However, normal demand of the United States trade for amorphous grade should be met easily in 1941. Whether the United States will be able to obtain all its needs of crystalline graphite from Ceylon will depend on orders received from the United Kingdom, willingness of American importers to pay prevailing prices, and restrictions placed upon the shipment of graphite to Japan.

Crystalline graphite is relatively scarce, and neither mine owners nor shippers will enter into long-term future contracts for crystalline grades. One important producer of amorphous graphite informed the Consulate that no large mines in Ceylon are producing the crystalline grade, and that shippers of the commodity therefore are dependent on small mine owners, from whom they purchase stocks in 3- to 5-ton lots. Except at the few large mines, which produce chiefly amorphous grades, the mineral is mined by old-fashioned methods.

The Consulate has been supplied with the following current prices per long ton c. a. f., New York, of various grades of Ceylon graphite:

Percent	Grade	Price per long ton
88	"XB" flaky crucible O. L	$257.00
85	"B" flaky crucible O. L	234.00
98	Hard large lumps	193.00
97	Carbon ordinary lumps	178 00

65	do	99.00
60	do	90.00
55	do	83.00

[4] Graves, George M., Bureau of Mines Mineral Trade Notes: Vol. 12, No. 4, April 19, 1941, pp. 25–26.

The Administration Report of the Government mineralogist for 1939 (published May 1940) contains the following optimistic statement regarding possible extensions of graphite deposits:

Geological examination of the country north and northeast of Kurunegala and extending roughly in the quadrangle of territory enclosed between the lines Nikaweratiya to Vavuniya and Dambulla to Horowpotuna has proved a strike continuation of rocks belonging to the series that may be regarded as the carrier of the valuable graphite deposits of Ceylon. A fairly promising lode of graphite in the form of intersecting veins of graphite in the acid granulites and quartzleptynites, with charnockite dikes and sills, which was examined near Horowpotuna, reveals the possibilities of a large area of similar petrological composition and structural relations. Since then crystalline graphite has been observed as a rock constituent at several intermediate localities along the strike of rocks to south of Anuradhapura.

The chief mining areas for plumbago are centered in the southwestern half of the Island, to which alone prospecting has been directed hitherto. So far very little attention has been given to parts of similar composition and structure lying outside this area, where the country rocks are concealed under superficial deposits, soils, etc., for wide stretches. Detailed prospecting in this ground by private agencies is strongly recommended and is likely to reveal workable areas with promising contents of graphite.

Chosen.—Official statistics on exports of graphite from Chosen were discontinued after March 1940, but production of both flake and amorphous varieties undoubtedly increased, although shipments to non-yen-bloc countries declined. According to advices from Vice Consul Arthur B. Emmons, 3d, at Keijo, flake graphite prices, in terms of United States currency, ranged during the third quarter from \$21.09 a long ton for crude Grade C, No. 2, to \$107.81 for Grade A, while those of crude amorphous fluctuated between \$7.93 (Yen 30) and \$9.38 (Yen 40) a ton.

The local press announced on January 25, 1941, that the Government General of Chosen would publish new control regulations for the graphite industry in February. According to these regulations as reported, the Chosen Mining Development Co. (Chosen Kogyo Shinko Kaisha) will be designated a sole controlling agency, will purchase all graphite produced, and, in turn, will supply it to consumers. This monopoly company will fix prices and exercise arbitrary control over all phases of the graphite industry.

Madagascar.—According to a recent report,[5] the average yield at the oldest works in Madagascar, operated at Tsarazafy by Société Génerale des Graphites, is 1 ton of rough concentrates ("débourbé," about 50 percent carbon) to 3 tons of ore; 4½ tons of rough concentrates yield 1 ton of standard flake graphite containing 90 percent carbon and 1 ton of dust containing 80 to 86 percent carbon. Thus almost 7 tons of crude ore are treated for each ton of salable product, half of which is dust.

Production in Madagascar reached an all-time peak of 27,000 metric tons in 1917. Exports declined in 1932 to only 2,146 tons and jumped to 13,433 tons in 1938 under the stimulus of rearmament in Europe. Elimination of German purchases doubtless reduced shipments to some extent in 1939 and drastically later. At the end of 1940 considerable stocks had accumulated on the docks at Tamatave, the only port of shipment. Normally, however, production does not keep much ahead of shipments, and frequently partial payments on orders have to be made to finance mining and treatment, as many operators cannot finance themselves.

---

Mexico.—Exports of graphite from Sonora to the United States, as reported by Vice Consul Henry T. Dwyer at Guaymas, jumped to 14,551 short tons valued at $140,590, which represents a 60-percent increase over the 1939 shipments of 9,070 tons valued at $92,181, and prices for the 80- to 82-percent product were advanced from $10 to $10.60 (United States currency) f. o. b. Mexican shipping point.

A general review of the Mexican graphite industry was prepared by Assistant Trade Commissioner John Bankhead.[6]

GREENSAND

In recent years the only commercial production of greensand has been in New Jersey, and this has been consumed almost exclusively in water-softening compounds. A brief survey of the industry was published in Bureau of Mines Mineral Trade Notes (vol. 9, No. 5, November 20, 1939, pp. 14–17). Shipments of refined greensand in 1940 totaled about 6,481 short tons valued at about $209,938 compared with 6,466 tons worth $150,500 in 1939 and an annual average of 12,715 tons valued at $197,200 for the 1925–29 period. Valuation figures are partly estimated.

Refined greensand produced in New Jersey, 1936–40

Year	Short tons	Value	Year	Short tons	Value
1936	8,368	$177,835	1939	6,466	$150,500
1937	9,734	210,974	1940	[1] 6,481	[1] 209,938
1938	6,576	152,000			

[1] Estimated.

ICELAND SPAR

By far the most important use for perfectly crystallized, waterclear, flawless calcite of optical grade is for the manufacture of Nicol prisms, which are an essential part of every polarizing microscope and of saccharimeters, dichroscopes, photometers, colorimeters, and polariscopes.[7] For many years this material was produced extensively in Iceland from deposits now apparently exhausted; later it came in meager amounts from South Africa and Spain. Domestic production has been negligible until about a year ago, when Ed. M. Stanton and associates of Santa Fe opened up a new deposit about 30 miles southwest of Taos, N. Mex. Users of this material report that it is of satisfactory quality, and high-grade rhombs up to 17 pounds in weight have been obtained.

KYANITE, ANDALUSITE, AND DUMORTIERITE

The increased use of kyanite for refractories is revealed by record domestic shipments for 1940 of 4,241 short tons valued at slightly less than $94,000 f. o. b. mines compared with 2,950 short tons valued at $69,000 f. o. b. mines in 1939. California and Virginia are the leading producing States. Imports of kyanite, all from British India, jumped

[6] Bankhead, John, Bureau of Mines Mineral Trade Notes: Vol. 12, No. 1, January 20, 1941, pp. 16–18.
[7] Hughes, H. H., Iceland Spar and Optical Fluorite: Bureau of Mines Inf. Circ. 6468R, 1941, 19 pp.

to 7,658 short tons having a foreign market value of $92,159 compared with 3,381 tons (revised) valued at $38,137 in 1939 and 3,964 tons valued at $32,458 in 1938.

The average price of all domestic kyanite sales as reported to the Bureau of Mines by producers was $22.10 a short ton f. o. b. mines. One of the largest producers, Kyanite Products Corporation, quotes raw 94-percent flotation concentrates (35-mesh) at $15 a ton in bulk and $17.50 in bags. Grinding through 100-mesh adds an extra $2 a ton, and calcining adds $5 a ton. Extra-low-iron grades carry a substantial premium, and a special product (under 0.1 percent Fe_2O_3, 98 percent kyanite) calcined and ground to 325-mesh has been offered by Celo Mines at $78 a ton f. o. b. Burnsville, N. C. Freight rates to northern and midwestern consuming points average $5 to $6 a ton on carload shipments.

The Phosphate Recovery Corporation remodeled and added calcining equipment to its plant at Darlington Heights in Prince Edward County near Pamplin, Va. This operation was taken over in September 1940 by the Kyanite Products Corporation, which also acquired the lease on the Knob Hill (S. C.) property. No production was reported at the latter property during the year, but plans were announced to drill the deposit in 1941. At Clarkesville, Ga., kyanite was produced by the A. P. Greene Fire Brick Co. and at the No. 3 plant of the Southern Mining & Milling Co. Celo Mines, Inc., Burnsville, N. C., produced kyanite and byproduct garnet. The kyanite deposit owned by the Vitrefrax Corporation at Ogilby, Imperial County, Calif., was operated by the Western Nonmetallic Co., which also does the milling. The product is used principally for making mullite grain.

Domestic production of andalusite and dumortierite has ranged from 400 to 2,000 tons per year; it is used mainly in the manufacture of spark plugs. The Tillotson Clay Products Co. has mines in California and Nevada but produced andalusite at the Nevada property only. Champion Sillimanite, Inc., produced dumortierite at Oreana, Nev., all of which was shipped for use by the parent company in the manufacture of spark-plug cores. The andalusite mine at Laws, Calif., owned by the company was not operated during 1940.

According to Boyd,[8] several useful minerals may be recovered from a north Georgia kyanite schist, which contains 4 to 8 percent kyanite, about 25 percent commercial mica, small quantities of commercial graphite, and impurities of silica, iron minerals, and slimes. The kyanite is separated from the gangue by mulling in patented mullers, screening, and jigging. The mica is recovered by settling, screening, and tabling and the graphite by flotation.

Tests of North Carolina kyanite showed that the rate of inversion to mullite and silica varies with the degree of shattering of the grains. Grains passing 325-mesh decomposed about twice as rapidly as coarser grains at certain temperatures, but above 1,500° C. all samples decomposed rapidly.[9]

Kyanite is mentioned as a cheap source of alumina for commercial glasses.[10] Finely powdered material containing less than 0.1 percent Fe_2O_3 can be produced upon a commercial basis and may afford a cheap and efficient source of alumina for improving the strength, vis-

[8] Boyd, Walter B.: Bull. Am. Ceram. Soc., vol. 19, No. 12, December 1940, pp. 461-463.
[9] Bartlett, Helen B., Rate of Decomposition of Kyanite at Various Temperatures: Jour. Am. Ceram. Soc., vol. 23, No. 9, September 1940, pp. 249-256.
[10] Scholes, Samuel R.: Ceram. Abs., vol. 19, No. 3, March 3, 1940, p. 64.

cosity, chemical durability, and thermal endurance of the glass. Inasmuch as kyanite contains approximately three times as much alumina as feldspar the tolerable content of iron oxide might be three times as great.

Consideration is being given to proposals to erect a plant in Sweden to produce aluminum from andalusite, which is reported to contain 35 to 40 percent Al_2O_3. Before the war, bauxite for the Swedish aluminum industry was imported from Norway.[11]

LITHIUM MINERALS

Shipments of lithium minerals and compounds by producers decreased to 1,961 short tons valued at $79,679 in 1940 as against 1,990 tons worth $97,000 in 1939 but compared favorably with the record of any previous year for which figures can be published. The decline in tonnage resulted from a drop in lithium compound shipped from the brine-refining operations at Searles Lake, Calif., which more than offset a slight increase in mine production. Consumption, on the other hand, continued to increase, causing stocks to be lower than for several years.

Although the quantities of lithium compounds consumed directly for war purposes are rather small, lithium is considered essential for certain uses by the American and British Governments. Increasingly large quantities of lepidolite were shipped to glassmakers in 1940, and the consumption of spodumene in ceramic work continued to grow. In enamels the addition of spodumene, a powerful fluxing agent, lowers the maturing temperature, thus reducing wear and tear on refractories. Small quantities of lithium chloride and lithium fluoride are used in welding-rod coatings and are said to give an exceptionally fine finish to the weld. Lithium-calcium alloys are effective in removing the nitrogen and oxygen gas from molten copper, thereby increasing its conductivity. The amount of lithium required in this process is only 0.001 percent. Small quantities of lithium hydroxide are used in Edison batteries, which are employed mainly in mine locomotives.

Spodumene was shipped by the Tennessee Mineral Products Corporation, Spruce Pine, N. C.; Lawrence Judson, Keystone, S. Dak., who leased the Ralph A. Smith property; and the Maywood Chemical Works from its Etta mine at Keystone, S. Dak. Amblygonite also was shipped from the Ralph A. Smith property. Only lepidolite was shipped from the Ingersoll mine of the Black Hills Keystone Corporation, although amblygonite and spodumene were also produced. The Black Hills Tin Co. produced spodumene from its recently installed flotation unit; the product is scheduled for shipment early in 1941. The mine at Hill City, S. Dak., formerly operated by H. Taylor, was idle in 1940 but shipped a small tonnage of spodumene mined the previous year.

Lithium compounds shipped from mines in the United States, 1936–40

Year	Producers	Short tons	Value	Year	Producers	Short tons	Value
1936	6	1,241	$34,273	1939	4	1,990	$97,000

1938	4	892	47,088				

[11] Bureau of Foreign and Domestic Commerce, Foreign Commerce Weekly: Vol. 1, No. 6, November 9, 1940, p. 278.

MEERSCHAUM

No meerschaum has been produced in the United States since about 1914. World supplies of the mineral, which is used almost exclusively in pipes and other smokers' articles, come from Eskishehir, Turkey. Imports into the United States in 1940 exceeded the total for the preceding 3 years, amounting to 18,431 pounds valued at $18,804. The average import value dropped to a new low of $1.02, the previous minimum being $1.36 in 1924.

MINERAL WOOL

The Bureau of Mines does not collect statistics on mineral wool, and those obtained by the Bureau of the Census are upon a biennial basis. In 1939, according to the latter Bureau, 58 plants produced mineral wool, vermiculite, and certain allied products valued at $8,237,553, a 10.4-percent increase over the value of products of 32 establishments reporting in 1937. Production of rock wool, shaped or in bulk, was reported as 139,455 short tons valued at $3,771,110 (141,262 tons, $5,525,628) and that of slag wool as 163,135 tons valued at $4,758,910 (55,180 tons, $2,514,854) in 1939 (revised figures for 1937 in parentheses). Under the sponsorship of the National Mineral Wool Association (Wharton Clay, secretary, 1270 Sixth Avenue, New York, N. Y.) the mineral-wool industry held a centennial celebration in Chicago on May 16, 1940. Most of the growth in the industry, however, has occurred during the last 10 years; it was not used extensively for home insulation until 1927, and the pneumatic method of installing it in dwellings already built was not perfected until 1930. Recent trends are toward full, thick insulation and increased use of batts and strips rather than loose wool. During 1940 the latter trend offset a substantial price reduction, with the result that compared with 1939 figures the total value of sales increased somewhat more than the increase of about 25 percent in tonnage sold.

MONAZITE

Monazite is a monoclinic phosphate of cerium metals, essentially $(Ce,La,Di)PO_4$, but it contains 0 to 18 percent thoria (ThO_2). Formerly monazite was valued principally for its thoria content, and even though the demand at present seems to be principally for the ceria, quotations are still based upon a minimum thoria content of 8 percent. The 1940 price—$60 to $65 a short ton—compares with $60 to $70 or $75 quoted in 1939 and earlier years.

After electricity supplanted gas for general lighting in this country, the consumption of monazite decreased sharply. As world production dwindled to about 23 tons in 1925, monazite seemed destined to be dropped from the list of useful minerals. However, the downward trend was reversed, and since 1932 production and consumption have increased owing to the increased use of pyrophoric alloys; of ceria and other rare earths in glass; of cerium fluoride and oxide in cores of searchlight, motion-picture, and therapy-lamp carbons; and (relatively new) of cerium acetate as a water- and mildew-proofing compound. Thoria is now considered a byproduct. Formerly gas-mantle manufacturers accumulated great quantities of residues carrying cerium, lanthanum, and other rare earths, but a processor of monazite stated in a recent interview that he could not fill the demand for cerium, whereas the demand for thorium was so small relatively that thoria was being stock-piled. Domestic manufacturers of incandescent mantles, however, continue to do a good export business; and fairly large quantities of thorium nitrate, although subject to export control, are exported to Japan and China.

Monazite was mined in the United States from 1893 to 1910 and again in the war years 1915–17. About 1 ton was produced in Florida in 1925. At the present price for imported monazite containing 8 percent thoria, domestic mines cannot operate at a profit. Even after concentration most domestic monazite contains less than 6 percent thoria and thus falls below commercial grade under present specifications. Hess [12] has stated that 15 cents a pound seemed to be about the minimum price at which domestic monazite could be mined in the Carolinas. The dominant position of British India as a producer of monazite is due chiefly to the high-grade beach sands of the State of Travancore, where some of the deposits contain as much as 50 percent monazite and yield after concentration a product containing 95 percent. In both Brazil and India monazite may be considered a byproduct from the mining of beach deposits for their ilmenite, rutile, and zircon content. Domestic deposits in the Carolinas do not contain similar associated minerals. Florida beach sands, on the other hand, do yield ilmenite, rutile, and zircon as joint products with monazite, and in 1940 mining of these sands was resumed. No figures as to the output of monazite (probably small) are available for publication.

OLIVINE

North Carolina olivine mines were operated intermittently, and shipments and consumption in 1940 probably did not exceed those of earlier years. Although commercial developments appear to be marking time, research is active, particularly at Norris and Knoxville, Tenn. At its Norris Electrotechnical Laboratory the Bureau of Mines has removed detrimental iron (from fayalite) as ferrosilicon in laboratory electric furnaces, the purified magnesium-silicate melt being either cast directly into blocks or granulated and then molded into refractory products. Various processes are proposed for obtaining magnesium salts and other compounds from this material, which contains more magnesium than any other common mineral except brucite. A preliminary report of studies of Pacific Northwest olivine was issued by the Bureau of Mines.[13]

QUARTZ CRYSTAL

Quartz crystal is a mineral of great strategic importance, as it is essential to radio communication and other military purposes. Japan, the United Kingdom, Germany, and the United States consume over 95 percent of the world total, which amounted in 1940 to about 1,000 short tons valued at $1,115,000 and which is supplied almost entirely by Brazil. No mineral is more abundant in nature than quartz, and hundreds of millions of tons of quartz worth only 50 cents to a maximum of about $2 a ton are produced annually in the United States and sold as sand, gravel, or stone. Even quartz crystal is so abundant that many hundreds of tons a year are thrown away as waste at feld-

[12] Hess, F. L., Monazite (chapter): Am. Inst. Min. and Met. Eng., Ind. Minerals and Rocks, New York, 1937, pp. 523–526.

spar quarries. It seems amazing, therefore, that the world must needs turn to only one country for its supply of crystals of the quality that can be used in radio work and that the price of these crystals should range from $2 to $20 or more a pound, or several times as much as ordinary quartz crystals are worth a ton.

In midsummer 1940 the Bureau of Mines surveyed stocks of quartz crystal suitable for radio-frequency control and found that stocks in private hands were adequate to supply immediate needs but that these should be supplemented by a Government stock pile that has been accumulating gradually in consequence of purchases by the Procurement Division of the United States Treasury Department. Japan was currently buying about 40 percent of all crystal produced in Brazil, and England's purchases have been expanded so that they virtually equaled the quantity bought by Japan and probably comprised a larger quantity of strategic quartz. United States purchases in recent years have represented about 5 percent of the quantity and about 15 percent of the value of exports from Brazil.

Before 1939 only a minor portion of Brazilian quartz, probably not over one-fourth, was usable for radio work. Quartz crystals vary greatly in perfection and size. For cutting into commercial piezo-electrical plates, resonators, or oscillators certain large users prefer crystals weighing 3 to 8 pounds and having at least two crystal faces. Such crystals cost $5 to $15 a pound delivered in New York and are difficult to get in quantity, so a considerable portion of the finished plates is made in relatively small shops where individual craftsmen can use economically crystals weighing only a half-pound or less, provided they are reasonably free from twinning, cracks, ghosts, veils, phantoms, needles, and bubbles. Most of these imperfections can be seen with the naked eye except twinning, which is one of the commonest and most serious defects.

Up to 1925 quartz crystals were used principally for ornamental purposes and to a minor extent for lenses and prisms for optical instruments or for making clear fused quartz. Their wide use for radio-frequency control is of relatively recent date, and not until 1937 were they employed extensively in telephony. Miscellaneous uses of strategic interest are in range finders, in instruments used for measuring pressures or detonation in gun barrels or airplane engines, in depth-sounding and direction-finding apparatus, and for sundry precision instruments, including chronometers, seismographs, periscopes, gun sights, and polariscopes.

Quartz crystal (Brazilian pebble) imported for consumption in the United States, 1932–40

Year	Quantity	Value	Value a pound	Year	Quantity	Value	Value a pound
	Pounds				*Pounds*		
1932	374	$86	$0.23	1937	32,821	$62,076	$1.89

1935	7,155	1,722	.24	1940	126,521	264,436	2.09
1936	22,766	9,645	.42				

SERPENTINE

Attention has been drawn to the possibility of utilizing the serpentine resources of Georgia as a source of magnesium and its salts.[14] A large deposit in Columbia County, Ga., is shown upon the new (1939) geologic map of the State. Analyses of several samples indicate a content of 36 to 38 percent MgO. Sulfuric acid for extracting the magnesium could be produced from the large pyrite deposits of Paulding and Lumpkin Counties, some of which were operated during the last war. The serpentine contains 2 to 5 percent chrome ore, which (it is reported) would be readily separable.

STRONTIUM MINERALS

Important changes characterized the strontium industry in 1940. Imports from Germany, the sole source of strontium salts in past years, were completely cut off, domestic mines resumed production on a small scale, and in December 1940 strontium metal and salts were added to the list of commodities that may not be exported except under license. The Mudrite Products Co. of Houston, Tex., has produced a small tonnage of impure celestite for several years; but this was ground for use as an oil-well drilling-mud admix, and no domestic production of minerals for their strontium content has been previously reported since 1918. Domestic requirements for strontium minerals and salts have hitherto been met by imports, principally from England and Germany; the former supplied virtually all requirements for strontium minerals.

The minerals celestite and strontianite are employed principally in the manufacture of strontium chemicals; however, ground celestite is used in fairly large quantities for purifying caustic soda for the rayon industry and strontianite on a semicommercial scale in Europe for desulfurizing and dephosphorizing steel. Although a few tons of strontianite mined in the United States in 1940 were shipped to a manufacturer of ferrous alloys, employment of strontium in steel making affords less promise in the United States than in Europe owing to the higher quality of domestic iron ores. Strontium nitrate is used in peace time in railroad flares and signals and is considered essential for military flares and rockets. Other strontium compounds are necessary constituents of tracer bullets and shells. In the past the greatest demand for strontium minerals has been from the German beet-sugar industry, where strontium hydrate is used in desaccharizing beet-sugar molasses. The use of strontium chloride in gas refrigeration, which appeared to promise wide application a few years ago, has failed to develop.

Excluding a considerable tonnage of celestite ground for use in oil-well drilling fluid as a weighting agent (displacing barite), domestic production, as reported by a total of six producers in California, Ohio, Texas, and Washington, was less than 350 tons in 1940. Imports of strontium minerals in 1940 amounted to 5,502,029 pounds and were mostly celestite from England, although 44,800 pounds of strontianite originated in Tunisia. Imports of strontium nitrate and the precipitated carbonate, previously supplied by Germany, ceased in 1940. Apparently the decrease in imports was more than compensated for by domestic production. A deposit of high-grade celestite in Mexico

[14] Fulcron, A. S. Magnesium and Magnesium Salts in Columbia County, Ga. Manufacturers Record, vol. 110, No. 2, February 1941, p. 19.

was developed in 1940, and exports of the material to the United States began in January 1941.

Quotations for finely powdered celestite containing 90 percent strontium sulfate remained unchanged at $37 a short ton from August 1939 to September 1940, when they were nominally advanced to $45 a ton concurrent with an advance in specifications to 92 percent minimum $SrSO_4$. The nominal quotation for powdered strontium carbonate remained unchanged at $55 a ton for material containing 84 to 86 percent $SrCO_3$. The price of technical carbonate was advanced 2 cents to 25 cents a pound in November, and supplies were reported limited. Mineral prices, however, are upon a basis of negotiation between buyer and seller, and the price for crude domestic material ranged between $15 and $20 a ton, f. o. b. mines.

The manufacture of strontium nitrate and strontium chloride from celestite is described in Research Series 67, Purdue University Engineering Experiment Station.

An important new source of strontium, discovered during the year at Utatur, is the first known commercial deposit of strontium minerals in South India.[15]

A discovery of strontianite associated with barytes in Newfoundland has been reported by A. O. Hayes and H. Johnson in a special bulletin referred to by A. K. Snelgrove in Information Circular 4 (1938, p. 126) issued by the Newfoundland Geological Survey.

Strontium minerals and chemicals imported for consumption in the United States, 1936–40

Year	Minerals		Nitrate		Carbonate and oxide	
	Pounds	Value	Pounds	Value	Pounds	Value

1940	5,502,029	28,686				

VERMICULITE

Sales of vermiculite increased in 1940 to 22,209 short tons valued at $148,723 compared with 21,174 tons worth $174,587 in 1939 and exceeded the quantity sold in any previous year except 1937, when total shipments of 26,556 tons having the high value of $260,664 were reported by producers. By far the bulk of the 1940 output was mined by the Universal Zonolite Insulation Co. of America (2601 West 107th Street, Chicago, Ill.) at Libby, Mont. However, there were at least four producers in North Carolina and one each in Colorado and Wyoming. Recent developments have been reported elsewhere.[16] Annual sales since the beginning of the industry in 1924 were tabulated in Minerals Yearbook 1940 (p. 1480).

PART IV. MINE SAFETY

EMPLOYMENT AND ACCIDENTS IN THE MINERAL INDUSTRIES

By W. W. Adams

SUMMARY OUTLINE

Increased employment and a more favorable accident-frequency rate in proportion to the number of man-hours of work performed were the outstanding facts revealed by reports from operators in the various mineral industries of the United States for 1940. Although data covering many operations had not been received when this was written, those available so far show upward trends in the number of employees, the number of man-days and man-hours worked, and the average number of workdays and workhours per employee during the year. Injuries, both fatal and nonfatal, caused by accidents to the employees, were more numerous in 1940 than in 1939, but the increase was proportionately smaller than the gain in man-hours worked, so that from the viewpoint of number of accidents among any given number of workers, the year's record as a whole was favorable. Virtually no change appears to have been made in the fatality rate, which was 1.14 per million man-hours worked in 1939 and continued at about the same level throughout 1940, as far as may be judged from the incomplete reports now available. On the other hand, the nonfatal-injury rate of 64.56 per million man-hours worked in 1939 apparently was lowered to 60.28 in 1940.

During the decade ended in 1940 employment in the mineral industries attained a maximum in number of workers in 1937, having increased by 188,608 men over the low point reached in the depression year 1932. The estimate of 812,000 employees for 1940 is within 6 percent of the peak year 1937. The highest accident-frequency rate (fatal plus nonfatal) was for 1931—the first year of the decade; since that time the trend of the yearly rates has been downward, apparently reaching its most favorable level in 1940, according to information now available.

Number of men employed in the mineral industries of the United States, 1938–40

	1938	1939	1940[1]
Coal mines:			
Bituminous	445,246	445,044	450,000
Pennsylvania anthracite	96,282	94,331	93,200
	541,528	539,375	543,200

[1] Subject to revision.

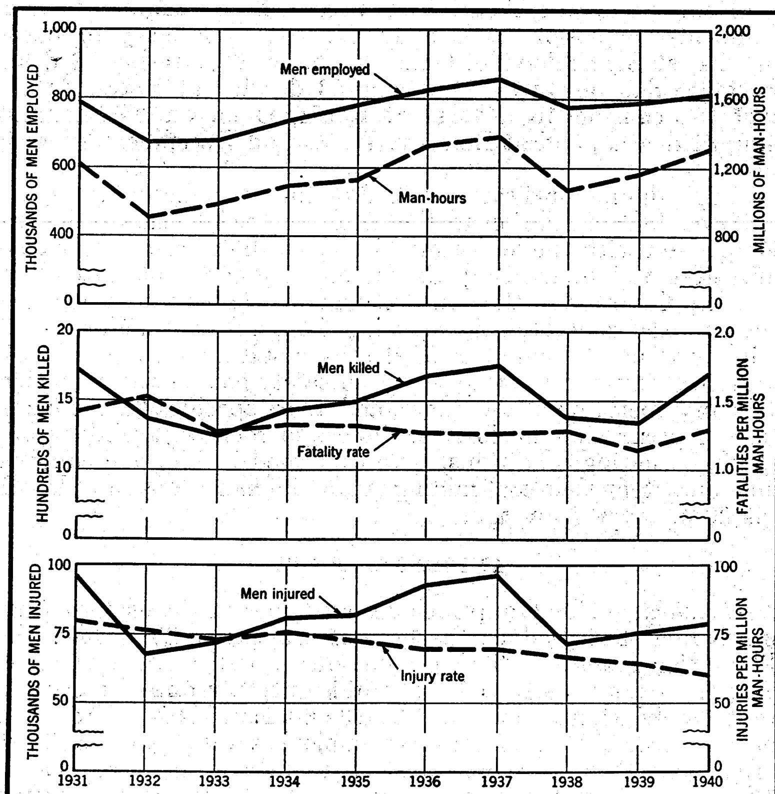

FIGURE 1.—Trend of employment and fatal and nonfatal accidents in the mineral industries of the United States, 1931–40.

EMPLOYMENT AND ACCIDENTS

BITUMINOUS-COAL MINES

Employment.—About 630 million man-hours of work were required to supply the United States with bituminous coal in 1940. This amount of labor, performed by approximately 450,000 employees in and about the mines, represented an increase of about 14 percent over 1939. According to present estimates, the output in 1940 was 453,200,000 tons—an increase of 57 million tons over 1939. The average employee was employed about 19 more days than in 1939.

Accidents.—Although accidents increased in number in 1940, along with the increase in the number of hours worked, the greater volume of employment or exposure to occupational hazards did not cause a rise in the accident-frequency rate per million man-hours of exposure; in fact, the accident rate apparently declined, as it was estimated at 69.81 compared with a rate of 71.01 in 1939 shown by final reports from the operating companies. This estimated accident-frequency rate for 1940 included a fatality rate of 1.93 compared with 1.56 for the previous year; the unfavorable showing for 1940 was due chiefly and almost entirely to the occurrence of six major disasters, with a total of 276 deaths in 1940, whereas only one major disaster, with a total of only 28 deaths, occurred in 1939. The six major disasters in 1940 included explosions at Bartley, W. Va., on January 10, causing 91 deaths; at St. Clairsville, Ohio, on March 16, causing 72 deaths; at Portage, Pa., on July 15, causing 63 deaths; at Bates, Ark., on August 27, causing 10 deaths; at Cadiz, Ohio, on November 29, causing 31 deaths; and at Beckley, W. Va., on December 17, causing 9 deaths.

Although the major-disaster record of 1940 was distinctly unfavorable, it was bad in relation to that of other recent years rather than in comparison with the long-time history of the industry. Even the six disasters and their heavy death toll in 1940 should not obscure the creditable progress that the bituminous-coal industry has made during the past generation in reducing the number of major disasters and in lowering the number of deaths resulting from them. The general awakening to the importance of safety as a factor in efficiency in the daily operation of the mines, and, more specifically, the increasing use of permissible explosives, the use of rock dust, and improvement in ventilating conditions, have combined to improve conditions to such an extent that coal mining is not the hazardous industry that it was 30 or more years ago.

ANTHRACITE MINES

Employment.—This group includes all mines in the eastern part of Pennsylvania that produce the type of coal generally termed "hard coal" or "anthracite." The production of anthracite during 1940 amounted to about 50,100,000 tons; this output required the work of approximately 93,200 men for 122,493,000 man-hours. Preliminary reports indicate that the number of employees was slightly under that for 1939 and that there was also apparently a slight reduction in man-hours worked during the year. No material change occurred in the total number of work days or work hours of the average employee during 1940.

Accidents.—Accidents to the men working in and about the Pennsylvania anthracite mines caused 184 deaths. In addition, 13,156 (estimated) men received injuries that resulted in at least 1 day of disability. Reports available thus far suggest that final records for 1940 will show a fatality rate of 1.50 and an injury rate of 107.40 per million man-hours worked; both of these rates were more favorable than the corresponding rates for the previous year.

Since June 2, 1938, when 10 men were killed in a mine explosion in Luzerne County, the anthracite-mining industry of Pennsylvania has been operated without an accident in which as many as 5 lives were lost.

IRON-ORE MINES

Employment.—Substantial gains in employment in iron-ore mining in 1940 were indicated by reports from the mining companies to the Bureau of Mines. Increases in number of employees amounted to approximately 12 percent, in man-days worked to 19 percent, and in man-hours worked to 21 percent. Incomplete returns indicate that employees at all iron-ore mines in 1940 totaled 22,100 and the man-hours worked 43,200,000. The average employee appears to have worked a little longer each day than he did in 1939, although the increase was only a fraction of an hour a man. The number of workdays per employee also increased in 1940.

Accidents.—For some years the iron-mining industry has conducted its operations with a greater measure of safety than most other branches of the mineral industry. This condition was maintained throughout 1940, although the accident-frequency rate for that year was not as favorable as for 1939. According to available reports from the operators of the mines the accident-frequency rate per million man-hours worked was 18.75 compared with the 17.51 shown by final reports for 1939.

COPPER MINES

Employment.—This group of mines covers all those operated chiefly for the copper content of their ores, although one or more metals other than copper may have been contained therein. Reports from operators of the mines showed that approximately 19,300 men were employed in 1940—a gain of between 4 and 5 percent over the 18,436 men who worked in 1939. A larger increase, amounting to about 16 percent, was made in the total man-hours of work performed, which was estimated at 48,800,000. Reports from the companies also showed that the period of employment per worker was substantially greater than in 1939, when the average employee had 285 days of work.

Accidents.—The accident situation at copper mines improved. Accidents occurred at the rate of 53.38 per million man-hours worked, which represented progress in accident prevention compared with the previous year's rate of 59.83. These figures included a fatality rate of 0.90 for 1939 and an estimated fatality rate of 1.00 for 1940.

LEAD AND ZINC MINES (MISSISSIPPI VALLEY STATES)

Employment.—This group includes all lead- and zinc-producing mines in the Mississippi Valley States, chiefly Oklahoma, Missouri, and Kansas; it also includes mines in Illinois and Kentucky producing fluorspar. Fluorspar mines in the two States mentioned are included for two reasons—because it is desirable to maintain unbroken a statistical series in the Bureau of Mines accident records that extends back to 1911 and because natural conditions regarding safety are not materially dissimilar in the two classes of mines in the States named and therefore permit separate figures to be published for Illinois and Kentucky. With this explanation as to the coverage of the figures, it may be stated that mines in the Mississippi Valley States employed about 7,800 men in 1940—an increase of more than 500 over the previous year. Man-hours of work totaled nearly 14 million—a gain of approximately 12 percent over 1939. The average employee gained about 10 workdays over the preceding year, when the average was 216 days of employment per man.

Accidents.—From reports now available the accident-frequency rate in 1940 seems to have been 59.29 per million man-hours worked. This rate was almost the same as that of 59.52 for 1939; however, the fatality rate, which is included in the frequency rate, appears to have been reduced somewhat from that for 1939—1.20 per million man-hours worked.

GOLD AND SILVER MINES

Employment.—This group includes gold and silver lode and placer mines in all States, lead and zinc mines elsewhere than in the Mississippi Valley region, and mines that produced some copper but that were operated chiefly because the ore contained metal other than copper.

The group as a whole employed about 56,200 men in 1940; 40,800 represented the number of employees at lode mines and 15,400 those at placer operations. Employment at each of the two classes of mines gained in 1940. Lode mines were in operation nearly 77 million man-hours, and placers were active about 21 million man-hours. The number of workdays of the average employee in 1940 apparently increased slightly at placer mines, but there appears to have been no change at lode mines.

Accidents.—As estimated for 1940, the accident-frequency rate was slightly more favorable than that revealed by final figures for 1939. This comparison applies both to lode and placer mines. The improvement was not great, and final reports from the operators may indicate that the rate was virtually the same in 1940 as in 1939. The tentative rate for lode mines for 1940, covering fatal and nonfatal injuries, was 106.44 per million man-hours worked, compared with a final rate of 110.51 for 1939; the rate for placer mines was 33.71, compared with 35.31 for 1939.

MISCELLANEOUS METAL MINES

Employment.—This group covers all operations that mine any kind of metallic ores except those produced chiefly for their gold, silver, copper, lead, zinc, or iron; therefore it includes mines that produce certain strategic minerals, such as tungsten, mercury, manganese, bauxite, and molybdenum. According to tentative figures now available, reflecting the intense demand for these strategic metals occasioned by national defense preparations, the number of employees in 1940 rose to approximately 5,200—a relative increase of 44 percent over the 3,623 employed in 1939. The man-hours of employment rose from 6.6 million in 1939 to 11.5 million in 1940—a relative increase of approximately 74 percent.

Accidents.—The safety record for miscellaneous metal mines was less favorable than in 1939. The accident-frequency rate per million man-hours of employment was approximately 80.18, compared with 76.19 in 1939.

NONMETALLIC-MINERAL MINES

Employment.—This group covers mines that yield all kinds of nonmetallics except stone, sand, gravel, and clay; therefore it includes those that produce phosphate rock, rock salt, sulfur, gypsum, and many other minerals. About 10,600 men were employed in 1940—a 10-percent increase, compared with the average working force of 9,630 men in 1939. During 1940, 21.2 million man-hours of work were performed; the corresponding figure for 1939 was 17.3 million.

Accidents.—From reports received so far the nonmetallic-mineral mines had an accident-frequency rate of 36.84 per million man-hours worked, which compares favorably with the rate of 42.19 shown by final reports for 1939.

CEMENT MILLS AND QUARRIES

Employment.—A gain in employment was reported for cement quarries and mills in 1940, compared with 1939; the number of men working increased 3 percent and the total number of man-hours 6 percent. The total estimated number of workers was 26,700 and man-hours worked 55.2 million. Reports for 1940 also showed an average increase of about 6 workdays in the period of employment per man.

Accidents.—The number of accidents in the cement industry increased in 1940, along with an increase in the number of workers and in man-hours of employment. Five hundred and thirty-six men were killed or injured in 1940. These figures represent a fatality rate of 0.27 and an injury rate of 9.44 per million man-hours of employment in the cement industry, compared with 0.23 for fatalities and 8.79 for injuries in 1939; thus the injury rate for 1940 was less favorable.

MARBLE QUARRIES

Employment.—Fewer men were employed and fewer man-hours of employment reported for marble quarries in 1940 than in 1939. The average number of men working at quarries and finishing plants was estimated at 3,200, and the total man-hours worked during the year was 6 million—a 13-percent decrease in the number of men employed and a 16-percent decrease in the number of man-hours of employment.

Accidents.—A far greater proportionate decrease occurred in 1940 in the number of men injured than in the volume of employment. All told, 239 men were injured, 3 fatally, compared with no fatalities and 429 nonfatal injuries in 1939, resulting in a 33-percent decrease in the accident rate in 1940, compared with 1939. The combined rate for 1940 was 40.58 per million man-hours worked; for 1939 it was 60.91.

SLATE QUARRIES

Employment.—The number of men working in the slate-quarrying industry was almost identical with that in 1939, although the man-hours worked decreased 6.1 percent. Final figures for 1940 show 2,800 employees and 5.0 million man-hours of employment, as well as a slight loss in the average amount of employment per worker.

Accidents.—Three hundred and fifty-six men were injured by accidents at slate quarries during 1940; 1 injury resulted fatally. The rate for 1940 was 71.03 injuries and fatalities per million man-hours worked compared with 70.98 for 1939.

TRAPROCK QUARRIES

Employment.—Reports from traprock quarries in 1940 indicated a gain in employment over 1939, when 2,771 men were reported employed. The total number of man-hours worked is estimated at 4.5 million for all operations, representing a gain of about 7 percent over the 4.2 million man-hours worked in 1939.

Accidents.—Although final figures are not available injuries during 1940 totaled 280 and included 3 fatal injuries. The frequency rate, covering both fatal and nonfatal injuries, was 62.09 compared with 65.95 in 1939.

GRANITE QUARRIES

Employment.—Fewer men were employed in and about granite quarries in 1940 than in 1939—approximately 8,000 compared to 8,390. The aggregate number of man-hours worked in the industry as a whole decreased about 8 percent. The period of employment averaged somewhat less than the 222 workdays per man shown by final reports for 1939.

Accidents.—Preliminary data indicate that the accident-frequency rate in 1940 was 44.77 per million man-hours of exposure to risk. The rate for 1939 was 42.98. The fatality rate was somewhat higher in 1940 than in 1939.

SANDSTONE QUARRIES

Employment.—About 3,400 men were employed at sandstone quarries—an increase over the 3,113 employed in 1939. Approximately 5.6 million man-hours of work were performed compared with 4.8 million in 1939—an advance of about 17 percent.

Accidents.—The number of accidents increased in 1940; fatal and nonfatal injuries are estimated at 355, representing an accident-frequency rate of 63.39—a tentative figure that compares with a final rate of 65.31 for 1939. No fatal accidents occurred in 1939, but preliminary reports indicate that 5 men were killed in 1940.

LIMESTONE QUARRIES

Employment.—Limestone quarries (not including those whose product was used chiefly for the manufacture of lime or cement) in the United States employed approximately 23,200 men in 1940—a slight gain over the 22,968 employed in 1939. The man-hours of employment also increased—from 35.7 million in 1939 to an estimated 37.2 million in 1940; moreover, a slight gain was also made in the number of workdays per employee in 1940.

Accidents.—A decrease in accidents, both in number and in relation to man-hours of employment, was shown by operators' reports for 1940. Tentative figures indicate a reduction in the accident-frequency rate from 49.16 in 1939 to 45.71 in 1940.

LIMEKILNS AND QUARRIES

Employment.—Gains in the number of workers and man-hours worked in 1940 compared with 1939 were reported by the lime industry. Tentative figures showed that 10,400 men were employed compared with 9,632 in the previous year; they also showed 22.7 millions of man-hours worked—an increase of 12 percent. The average employee also had more days of work than he had in 1939.

Accidents.—Tentative figures show an accident-frequency rate of 44.95 per million man-hours worked in 1940 compared with 49.59 for 1939.

BYPRODUCT COKE OVENS

Employment.—Increased employment in 1940 raised the total number of employees at byproduct coke ovens to 17,500—an 18-percent gain over 1939. The volume of employment was the equivalent of 50.4 million man-hours compared with 42.2 million in 1939—a 19-percent gain.

Accidents.—Complete reports for 1940 show that 415 fatal and nonfatal injuries occurred. The combined accident-frequency rate covering fatal and nonfatal injuries was 8.24 compared with 8.15 in 1939—a slight advantage in favor of 1939.

BEEHIVE COKE OVENS

Employment.—Although the number of men working at beehive coke ovens in the United States has been small in recent years it increased greatly in 1939 and again in 1940. It is estimated that 2,000 men worked at the ovens in 1940—a gain of nearly 14 percent over 1939, when 1,757 were employed. Man-hours of work also increased, being 2.8 million in 1940 and 1.5 million in 1939—an increase of 79 percent.

Accidents.—Operators' reports showed no fatal accidents in 1940 but revealed that the nonfatal injuries resulted in an accident-frequency rate of 48.29 per million man-hours worked; this rate did not compare favorably with the safety record of 1939, which was represented by a frequency of 40.25.

ORE-DRESSING PLANTS

Employment.—Ore dressing and beneficiating plants or mills employed approximately 13,200 men in 1940 compared with 12,476 in the previous year and were in operation 29.9 million man-hours; the latter figure revealed a 9-percent gain over the 27.5 million man-hours worked in 1939.

Accidents.—Accidents to men employed at the mills occurred at the rate of 28.56 per million man-hours worked in 1940. When compared with a frequency rate of 31.87 in 1939 the safety record for 1940 is seen to have been favorable.

SMELTERS

Employment.—As classified herein, the smelting industry covers the smelting and refining of all metallic ores except iron ore. Accident and employment statistics covering the smelting of iron ore and the manufacture of steel are not included in Bureau of Mines figures because such statistics are collected and compiled by the United States Department of Labor. The smelter industry employed approximately 20,000 men in 1940—a 26-percent increase over the 15,905 men employed in 1939. The man-hours of employment in 1940 reached 46.5 million compared to 37.7 million in 1939—a 23-percent increase.

Accidents.—In face of the intense production effort, accident prevention suffered a set-back in 1940. The accident-frequency rate increased from 16.35 in 1939 to 19.90 in 1940.

AUXILIARY WORKS AT ORE-DRESSING PLANTS AND SMELTERS

Employment.—Auxiliary works cover all operations at mills and smelters not directly connected with milling and smelting processes.

311436—41——91

About 14,400 men were so employed in 1940, indicating a material gain over the 13,202 men working in 1939. Man-hours worked likewise increased in 1940, as the estimated number totaled 35.6 million, a 13-percent increase over the 31.5 million man-hours worked in 1939.

Accidents.—Preliminary figures indicate an accident-frequency rate of 18.93 per million man-hours worked—a gratifying improvement over that of 22.28 for the previous year.

SUMMARY, 1931–40

Accident and employment data of the Bureau of Mines, except those covering nonfatal injuries at coal mines, first became available for 1911; these figures covered the mining and quarrying industries only. Beginning with 1913 statistics also became available for coke ovens and for ore-dressing plants and smelters, although the early records did not show the number of man-hours worked. After a few years some companies operating metal mines and stone quarries supplied special information, including man-hours worked, and tables based upon these data were prepared from time to time. Nationwide coverage of accidents and employment, including the number of man-hours worked, first became available for coal mines in 1930 and for quarries, coke ovens, metallurgical plants, and all other mines in 1931. Beginning with 1931, therefore, the yearly records of the Bureau of Mines are complete as to fatal and nonfatal injuries, men employed, and man-days and man-hours worked.

As this review of accidents and employment in the mineral industries of the United States for 1940 was necessarily prepared before many operating companies had sent their reports to the Bureau of Mines, it has not been practicable, in some of the brief reviews of each of the separate mineral-commodity groups, to state the actual number of deaths that occurred during 1940, although the combined number of deaths and injuries has been given, either specifically or by indicating the accident-frequency rate per million man-hours worked. Except in the larger groups or in groups for which nearly complete returns have been received, the number of deaths is usually too small to be estimated accurately.

When the record covering all branches of the mineral industries covered by the Bureau of Mines accident reports is reviewed, preliminary reports indicate that final reports for 1940 probably will show approximately 1,690 men killed and 78,550 injured. Should final reports from operating companies confirm this statement, 1940 will have been the best year, from the standpoint of the employees exposed to occupational risk, of any during the decade that began with 1931; that is to say the accident-frequency rate, estimated at 61.58, was lower than in any previous year of the period from 1931 to 1940. The estimated rate for nonfatal injuries was 60.28, which is lower than that for other years of the decade and compares most favorably with the rate of 79.73 for 1931. The estimated fatality rate for 1940—1.30—was lower than the corresponding rates that prevailed during most of the early years of the decade but did not compare favorably with the latter part of that period.

Employment figures for 1940 showed that the number of employees probably increased at 17 out of the 21 groups of mineral operations for which separate figures were compiled. A similar comparison was revealed for the number of man-hours worked. The number of accidents increased in only 14 of the 21 groups, explaining in large measure why the over-all accident-frequency rate for all 21 groups was more favorable in 1940 than in 1939 and, in fact, than in any other year of the decade 1931–40.
