COMMODITY REVIEW

METALS

Iron and Steel.—Production of iron ore and concentrate in 1976 was around 9.5 million tons. About 54% of total production was from the Musan mine, which reportedly has an annual output capacity of 6.5 million tons per year. The bulk of the remainder was from Chaeryŏng, Hasŏng, Kaech'ŏn, Kŏmdŏk, Songhŭng, Sŏngnam, Tŏkhyŏn, Unyul, and Yŏngwŏn. Newly developed mines at Sŏhae-ri and Tŏksŭng produced lesser quantities of iron ore. The mines at Chaeryŏng, Hasŏng, Kŏmdŏk, Songhŭng, Tŏkhyŏn, Tŏksŭng, and Unyul reportedly had completed their expansion programs to increase annual output.

Pig iron production during 1976 was estimated at 3.0 million tons and was by the Ch'ŏngjin steel plant, the Hwanghae iron and steel complex, the Kangsŏn steel complex, and the Kimch'aek iron and steel works, the largest in North Korea. The country's combined annual steel capacity was around 4 million tons. The steel complexes at Hwanghae, Kangsŏn, and Kimch'aek were recently modernized. A new iron and steel complex was being established at Namp'o, designed to have an initial capacity of 1 million tons per year, later to be expanded to 3 million tons per year. Under the fifth economic development plan, crude steel production is to reach 12 million tons in 1980.

Output of steel semimanufactures was estimated at 2.8 million tons. Although most of the production was domestically consumed, about 4% of the output was exported, mainly to the U.S.S.R. North

Korea planned to increase exports of steel products during 1977.

Nonferrous Metals.—Lead and zinc continued to be the principal nonferrous metals produced in North Korea. During 1976, estimated output of lead and zinc was 120,000 tons and 168,000 tons, respectively. The country's lead-zinc smelters are located at Haeju, Namp'o, and Munp'yŏng. A new smelter was reportedly being constructed on the east coast in the Tanch'ŏn area. The bulk of domestic output of lead-zinc ore was from mines at Sŏngch'ŏn and Kŏmdŏk.

About 13,000 tons of refined copper is produced annually from indigenous ore. North Korea also imports around 50,000 tons of 30%-grade copper concentrate from Peru. Small aluminum remelt facilities are located at Chinampo, Hŭngnam, and Tasado. Domestic requirements for aluminum, however, are met by imports, largely from Japan. A primary aluminum smelter of 20,000-ton-per-year capacity was near completion. Metal content of tungsten mine output was around 2,150 tons, about 5.2% of the total world production. North Korea also produces small quantities of cadmium, gold, nickel, and silver.

NONMETALS

Cement.—Production of cement totaled around 6 million tons in 1976. About half of the output was from the Sunch'ŏn cement works; the bulk of the remainder was from plants located at Haeju, Komusan, Kusŏng, Majŏng, Pongsan, and Sŭnghori. The Sunch'ŏn works was nearing completion of an expansion program to double its capacity to 6 million tons per year. Installation of additional kilns at the Haeju cement works reportedly was completed, boosting its capacity to 3 million tons per year. A 5-million-ton-per-year cement plant at Ch'ŏnnae was still under construction. By 1978–79, North Korea's annual cement capacity was expected to be around 15 million tons. Under the fifth economic development plan, the target for cement production in 1980 was set at 20 million tons.

Magnesite.—North Korea continued to be one of the world's largest producers of magnesite. Mine output in 1976 was estimated at 1.5 million tons from mines in South Hamgyŏng and Kangwŏn Provinces. Crude magnesite was beneficiated and sintered at plants at Tanch'ŏn, Songjin, and Ch'ŏngjin for production of dead-burned and caustic calcined grades of magnesium oxide.

Other Nonmetals.—North Korea continued to be one of the world's largest producers of graphite. Output in 1976 was about 75,000 tons, comprising mostly low-grade amorphous material. Production of barite was around 120,000 tons. Much of this material was shipped to the U.S.S.R. under a long-term barter agreement. North Korea also produces significant quantities of fluorspar, pyrite, salt, and talc. Output of natural phosphate for fertilizers was estimated at 450,000 tons. Small- to medium-scale phosphate fertilizer plants are located in almost all of the provinces. Production of chemical fertilizers in 1976 was around 2.8 million tons, of which about 50% was produced at the Hŭngnam fertilizer complex and most of the remainder at the Ch'ŏngsu chemical plant and the Such'on Nitrolime Fertilizer Factory.

MINERAL FUELS

Coal.—North Korea's major mineral commodity and domestically produced fuel source is coal. Output in 1976 was estimated at 41 million tons, below the target set for the fourth economic development plan ending in 1976. About 80% of total output was anthracite consumed locally for space heating. The remainder was bituminous coal that was reportedly of good metallurgical grade. The Chollima Sinch'ang coal mine is the nation's largest producer. Additionally, there are large open cast workings at Yonghŭng. The mines at Kukdong and Yangjŏng were newly opened and were producing more than 1 million tons of coking coal. The mines at Aoji and Kogŏnwŏn were claimed to have produced large quantities of high-grade metallurgical coal. New coal mines were being developed at Tŏkch'ŏn, Kangdon, Kangsŏ, Kowŏn, and other places in South P'yŏngyang Province. Additional coal production came from existing mines at Chiktong, Ch'ŏnsŏng, Huknyŏng, Kaech'ŏn, Kŏmdŏk, Musan, Taedae-ri, Tŏksŏng, Yongdae, and Yongmun.

Petroleum.—There are no known commercial occurrences of oil and natural gas in North Korea. Domestic demand for

petroleum has been met through imports, principally from the People's Republic of China and the U.S.S.R. A pipeline was completed in late 1975 to bring Taching oil from the People's Republic of China to North Korea. Moreover, an oil refinery was being built in the west to process Chinese crude oil and provide naphtha feedstock for a recently constructed petrochemical plant. The oil refinery on the east coast, which reportedly came onstream in 1974–75, presumably handles imports of crude oil from the U.S.S.R.

The Mineral Industry of the Republic of Korea

By E. Chin [1]

During the third 5-year economic development plan, the economy of the Republic of Korea was projected to grow at an average annual rate of 8.6% between 1972 and 1976; in actuality, the economy attained a real annual growth rate of 11.2%. In terms of 1970 market prices, the gross national product (GNP) in 1976 reached 4,758 billion won. At current market prices, the GNP was 12,109 billion won (U.S. $25.0 billion).[2] By sectors, mining and quarrying accounted for only 1% of the GNP in 1976, compared with 30% for manufacturing, 25% for agriculture, forestry, and fishery, 16% for wholesale and retail trade, and 28% for other goods and services.

The mining and quarrying sector grew by 13.5% in current prices over the 1975 level to $273 million in 1976. During the year, the principal sectors reporting increased output were iron ore, tungsten, gold, silver, lead, zinc, talc, cement, petroleum products, iron and steel, and nonferrous smelter products. Decreased mine output was reported for anthracite, copper ore, and fluorite.

Production indexes (1970=100) for the major components of the mining, mineral processing, and metals sector for the last 5 years follow: [3]

	1972	1973	1974	1975	1976
Mining:					
Coal, anthracite	100	110	123	142	133
Metallic ores	90	102	106	112	125
Nonmetallic ores	104	140	149	166	186
Primary metals:					
Iron and steel	130	207	402	429	621
Nonferrous metals	127	151	178	262	378
Industrial chemicals	110	135	152	199	291
Petroleum products	118	139	138	152	171

Inflation continued upward in 1976. Wholesale prices rose 8.9% in 1976, compared with 20.2% in 1975. The curtailment of the escalation in wholesale prices was ascribed to stabilized prices for major imported raw materials, to bumper harvests of major food grains, and to the implementation of the Price Stabilization and Fair Transactions Law during 1976. Consumer prices rose 11.4% in 1976, compared with 25.4% in 1975. The increase in consumer prices was attributed largely to higher costs of foodstuffs. Prices of imported goods were up 7.7%. The increase in wholesale prices of imported goods ranged from 1.8% for fuels, through 11.6% for metals and metallic products, to 51.6% for fibers and fiber products.

During 1976, expansion of construction activities remained generally stagnant owing to a decrease in Government-initiated projects. The Government issued permits for new construction projects totaling 17,985,000 square meters for 111,580 structural units, distributed as follows in square meters: New housing units, 9,494,000; commercial and service structures, 3,240,000; industrial structures, 3,494,000; and educational and other structures, 1,757,000. Included in the industrial structures were plant construction for an 80,000-ton copper refinery, a 50,000-ton zinc refinery, a 10,000-ton methanol plant, a 350,000-ton ethylene plant, and a 230,000-ton polyethylene plant.

[2] Where necessary, values have been converted from Korean won (W) to U.S. dollars at the rate of W484=US$1.00 for 1976.

[3] The Bank of Korea (Seoul). Economic Statistics Yearbook 1977. June 10, 1977, 325 pp.

In midyear, construction began on an 845-kilometer expressway to link Taegu and Masan, scheduled for completion at yearend 1977. Additionally, the Government undertook road pavement projects covering 1,111 kilometers. During the year, pavement of roads totaling 126 kilometers was completed, bringing the total length of the Nation's paved roads to 3,746 kilometers.

In 1976, ground was broken for the construction of a dam at Taechong, to be completed in 1979. On October 28, 1976, a multipurpose dam at Andong, North Kyonsang Province, was dedicated. By yearend, 28 industrial estates were in existence or being constructed in Korea. Included in these were 2 free export zones (Masan and Iri), 6 export industrial estates, 1 special export industrial estate, 1 special electronics export estate (Kumi), 11 provincial industrial estates, and 4 special industrial estates.

During 1976, overseas construction and engineering contracts totaling $2.5 billion were awarded to Korean firms and were geographically distributed as follows: Middle East, $2.4 billion; Southeast Asia, $24 million; other Pacific areas, $17 million; Africa, $16 million; and Latin America, $14 million. At yearend, 53 domestic firms were engaged in overseas construction projects.

Under an energy development plan (1977–81) drafted in 1976, Korea's total energy demand in terms of coal was projected to increase from 66,585,000 tons in 1977 to 93,135,000 tons in 1981. Domestic demand for coal was projected to increase from 21,760,000 tons in 1977 to 30,291,000 tons in 1981. Demand for oil products was to increase from 37,700,000 tons to 54,694,000 tons. Demand for energy generated from hydropower and atomic sources was to increase from 1,013,000 tons in terms of coal to 2,907,000 tons in 1981, whereas the demand for charcoal would be 6,112,000 tons in 1977 and decrease to 5,243,000 tons in 1981.

Total electric power generation in 1976 was 23.1 billion kilowatt-hours of which 1.8 billion kilowatt hours was from hydrosources and 21.3 billion kilowatt hours was from thermal plants. During the year, 568.7 million kilowatt hours was consumed by 362 mining and quarrying operations, 2.6 billion kilowatt hours by 4,859 chemical firms, 1.8 billion kilowatt hours by 1,273 nonmetal manufacturers, and 2.4 billion kilowatt hours by 8,598 firms fabricating metal products.

In 1976, the total scale of government expenditures for investments and loans was $1.9 billion, of which $40 million was allocated to the mining sector, up 14.1% from the 1975 budget. The manufacturing sector received $206 million; expansion of power generating facilities, $193 million; transportation, $444 million; and other, $1,017 million. On March 30, 1976, Korea drew 55.4 million Special Drawing Rights (SDR's) from the International Monetary Fund (IMF) Oil Facility, which had remained unused from the 1975 ceiling. Korea's aggregate drawings from the IMF Oil Facility totaled 252.7 million SDR's at yearend. During the year, the International Finance Corp. extended a total of $52.7 million in investments and loans to Korea, of which Korea Zinc Co. received $19 million for the construction of a zinc refinery. On March 30, 1976, the State-run Dai Han Coal Corporation concluded a loan agreement for $12 million with the Asian Development Bank for the development of coal mines.

In 1976, Korea had a total of $1.6 billion in foreign loans and investments, distributed as follows: Foreign public loans, $695 million; foreign commercial loans, $852; and foreign investments, $86 million. Out of these totals, extensions to the metal industry by foreign public loans were $2.7 million; foreign commercial loans for the metal industry, $145 million; and foreign investments for mining, $0.3 million.

In May 1976, the Korea Research Institute of Geoscience and Mineral Resources (KIGAM) was founded. The Institute was established to assist the country and its industries in a balanced development of indigenous resources by means of geological research and exploration for minerals, energy, and water resources on land and in adjacent offshore areas. Prime research projects of KIGAM included radioactive mineral exploration for nuclear raw materials, geophysical exploration and experimental drilling for petroleum and natural gas, exploration and delineation of metal and nonmetal mineral resources, a reconnaissance survey for coal, geological mapping, engineering geology, marine mineral development, and fundamental studies and services to support the Institute's prime research projects.

PRODUCTION

The index for mining production in 1976 was 142.6 (1970=100), an increase of 1.7% over the 1975 index. The decline in production levels for coal, copper ore, kaolin, fluorite, and agalmatolite was offset by increased output of iron ore, tungsten, gold and silver, lead and zinc ore, and talc. In terms of value, the mining of anthracite dominated the mineral economy of the Republic of Korea. In 1976, 16.4 million tons of anthracite, valued at $326 million, was produced. Production of limestone was 19.1 million tons and was used primarily in cement manufacture. Total output of cement during the year was 11.9 million tons. Mine production of zinc ore was 118,271 tons, and output of lead ore was 29,066 tons. Production of tungsten ore was 4,660 tons (gross weight) and constituted around 8% of the world's output. The Republic of Korea continued to be one of the world's leading producers of graphite. However, production of amorphous graphite decreased 15% to 38,277 tons in 1976.

Production of primary aluminum metal, all from imported alumina, totaled 17,605 tons. Smelter output of copper, mostly from imported material, was 29,741 tons. Production levels of lead and zinc and other nonferrous metals were generally higher in 1976.

There was no domestic production of oil and natural gas. Total petroleum refinery input in 1976 was 132.4 million barrels. Output from refining operations increased over production during 1972–75. Production of residual fuel oil increased 10%, and production of distillate fuel oil increased 23%. Refinery outputs of jet fuel, kerosine, and gasoline were above the 1975 yield.

TRADE

Overall trade for the Republic of Korea in 1976 was close to $16.5 billion; imports were about $8.8 billion, compared with exports of $7.7 billion. By area, shipments between other Asian countries constituted close to 40% of the total value of the Republic of Korea's trade, followed by North America, the Middle East, Europe, and other. Japan and the United States, in that order, remained the top trading partners in 1976.

By major commodity groups, exports in 1976 was constituted as follows, in million dollars: Food and animal stock, 510; beverages and tobacco, 78; inedible crude materials, 196; mineral fuels and related materials, 144; chemicals, 119; manufactured goods, 5,365; machinery and transport equipment, 1,280; and other, 23. Imports during 1976 were distributed as follows in million dollars: Foodstuffs, 690; beverages, 30; inedible crude materials, 1,565; fuels, 1,747; chemicals, 847; manufactures, 1,479; machinery, 2,387; and other, 10.

Imports of crude petroleum totaled about 135 million barrels, valued at $1.6 billion. Domestic receipts of mineral products in 1976 were about $91.4 million. Exports of major mineral items in 1976 were as follows, in million dollars: Tungsten, 42.6; zinc ore, 8.2; talc, 5.5; kaolin, 5.1; agalmatolite, 3.6; silica, 3.2; silver concentrate, 3.1; lead ore, 2.5; graphite, 1.9; bismuth concentrate, 1.3; and gypsum, 1.2.

COMMODITY REVIEW

METALS

Aluminum.—Production of primary aluminum metal in 1976 was 17,605 tons, valued at $19.1 million. Total metal output was by Aluminum of Korea, Ltd. (Koralu) at its Ulsan smelter, using alumina imported from Japan. Koralu, a 50–50 joint venture of the Korean Industrial Bank and Péchiney Ugine Kuhlmann (France), has an annual production capacity of 18,000 tons of aluminum metal. The company was planning to expand its smelter capacity in two stages: 38,000 tons by 1977–78, and 72,000 tons by 1979. However, the Government has not given approval for the expansion program owing to power cost subsidies. Korea's demand for aluminum metal is currently close to 60,000 tons per year.

Copper.—Production of copper concentrate in 1976 was 15,030 tons, averaging 15% copper. The Kumpuk copper mine at Kyunsang Nando accounted for the bulk of the Nation's copper ore output. During the year, total production of electrolytic copper was 29,741 tons. The Changhang smelter, owned by Korea Mining & Smelting Co., Ltd., produced 22,135 tons of copper metal. The capacity of the Changhang smelter was being expanded to 37,700 tons per year of copper metal. The current annual demand for copper metal was estimated at 45,000 tons. Imports supplied about 20% of Korea's copper requirements and Korea Mining imported 67,599 tons of copper concentrate during 1976.

In September 1976, a contract was awarded to a European consoritum composed of Davy Power Gas, Ltd. (United Kingdom), Outokumpu Oy (Finland), and Sybetra S.A. (Belgium) for the construction of an 80,000-ton-per-year copper smelter-refinery at the nonferrous metals industrial complex being developed at Onsan. Construction began on the copper facility late in the year and was expected to be completed by March 1979.

Iron and Steel.—Mine production of iron ore was around 755,000 tons in 1976, compared with 644,000 tons 1975. Nearly half of the domestic mine output was from the Yangyang mine in Kangwon Province operated by the Dai Han Iron Mining Co., Ltd. Total domestic production constituted about 30% of Korea's requirements for iron ore.

Production of pig iron in 1976 totaled 1.9 million tons, compared with 1.2 million tons in 1975. Close to 90% of the pig iron output was by Pohang Iron and Steel Co., Ltd. (POSCO); the remainder was by Dongkuk Steel Mill Co. (Dongkuk) and Inchon Iron Works Co. Crude steel production in 1976 was 2.7 million tons, compared with 2.0 million tons in 1975. POSCO produced about two-thirds of the crude steel output; Pusan Iron and Steel Co., Dongkuk, and Kuck Dong Steel Co. accounted for the remainder.

In May 1976, POSCO completed the second-stage expansion of its integrated iron and steel facility at the Pohang Industrial Estate in Yeong-il County, Gyeongbug Province. The capacity to produce crude steel was increased to 2.6 million tons from 1.03 million tons. In October 1976, ground was broken for construction of blast furnace No. 3. When the furnace is completed in 1979, POSCO's capacity will be 5.5 million tons of steel per year.

Lead.—Production of lead concentrate during the year totaled 29,066 tons, grading 50% lead. Young Poong Mining Co., Ltd., accounted for virtually all of the country's mine lead output from mines at Yeonhua, Boonpyong, and Ulgen. Production from the No. 1 and No. 2 mines at Yeonhua accounted for 17,531 tons of lead concentrate, or about 60% of the total domestic output. Young Poong Mining was expanding the mill capacity at Yeonhua whereby its annual capacity to produce lead concentrate would be increased by about 25%.

The Changhang smelter of the Korea Mining & Smelting Co., the sole producer of lead metal in Korea, produced 7,762 tons of pig lead. Young Poong Mining was planning a 50,000-ton-per-year smelter at the nonferrous metals industrial estate at Onshan. Construction was expected to begin in 1978.

Tungsten.—Total production of tungsten concentrate, averaging 70% WO_3, was 4,660 tons. The Sangdong mine of Korea Tungsten Mining Co., Ltd., produced the bulk of the country's tungsten output. The remainder was distributed as follows, in tons: Chungyang Co., 145; San-Nae, 78; Okbang Mining Co., Ltd., 64; Wol-Ak, 53; Sam

Yang, 37; Ssangjon, 26; Daewha, 22; Sudo, 11; and other, 34. The mill at Sangdong can process 2,000 tons of ore per day; the concentrate produced is shipped to Korea Tungsten's plant at Taegu where it is processed to produce tungsten powder, carbide, and ammonium paratungstate. Data on the production of metal, powder, carbide, and ammonium paratungstate were not reported. However, the value of exports of tungsten carbide and powder during 1976 was $1.6 million and $4.8 million, respectively. The total value of exports of all forms of tungsten was reportedly around $42.6 million. Korea's production of tungsten constitutes about 8% of total world output.

Zinc.—Production of zinc concentrate containing 50% zinc, wholly by the three mines of Young Poong Mining Co., Ltd., was 118,271 tons in 1976. Output from the Yeonhua mines accounted for about 77% of the zinc mined during the year. Production of zinc metal increased 30% in 1976 to 27,222 tons.

Construction continued on the 80,000-ton-per year Bonghwa zinc smelter of Korea Zinc Co. at Onsan. This project is a joint venture between Young Poong Mining and Toho Zinc Co., Ltd. The Bonghwa facility was expected to be onstream in late 1978. On November 13, 1976, the International Bank for Reconstruction extended to Korea Zinc $19 million, repayable in 8 years at an interest rate of 10.75%. Total cost of the project was estimated at $71.3 million, of which $39 million was to be financed by foreign capital and the remainder by domestic funds.

Other Metals.—During 1976, 174 tons of bismuth metal was produced as a by-product of tungsten processing by Korea Tungsten Mining Co., Ltd. Production of silver metal totaled 1.9 million troy ounces. The bulk of the output was by the Changhang smelter of Korea Mining & Smelting, 963,212 troy ounces, and the Boonpyong operations of Young Poong Mining, 771,624 troy ounces. The country's output of gold was 18,744 troy ounces. Close to 65% of the total production was from Korea Mining's Changhang smelter. Output of 40% manganese ore was 1,383 tons, and molybdenite output was 120 tons. Mine production of other metal ores during the year included minor amounts of antimony, arsenic, and tin.

NONMETALS

Cement.—Cement production by 10 plants of 7 companies totaled 11.9 million tons. During 1976, Asia Cement Manufacturing Co., Ltd., and the Hanil Cement Manufacturing Co., Ltd., completed expansion of their plants at Jecheon and Danyang. Tong Yang Cement Manufacturing Co., Ltd., expanded production at its Samch'ok plant from 1.0 million tons to 2.6 million tons per year at a cost of $22.8 million. The Export-Import Bank of the United States and the Republic of Korea provided financing for the project. All the equipment and machinery was supplied by Fuller Co. Part of the added plant output was to be stockpiled for export to certain member nations of the Organization of Petroleum Exporting Countries, with which cement clinker would be traded for oil.

Total cement manufacturing capacity was 14.9 million tons at yearend 1976, compared with 11.9 million tons at yearend 1975, and was distributed as follows, in thousand tons:

Company and plant location	Capacity
Asia Cement Manufacturing Co., Ltd., Chen'on	1,885
Hanil Cement Manufacturing Co., Ltd., Tanyang	2,485
Hyundai Cement Co., Tanyang (2 plants)	1,200
Korea Cement Co.:	
Changsong	660
Mun-gyong	480
Ssangyong Cement Industries Co., Ltd.:	
Tonghae	2,900
Yeongweol	1,700
Sungsin Cement Co., Tanyang	1,000
Tong Yang Cement Co., Samch'ok	2,600
Total	14,910

Ssangyong Cement awarded a European consortium a contract for expanding its Tonghae plant from 2.9 million tons to 5.6 million tons per year, making the operation one of the largest production facilities in the world when completed in mid-1979. The contract calls for planning, delivering, and installing equipment valued at $125 million. An option for a further expansion phase valued at $65 million was also included. Because of the good transportation network and distribution terminals at Ulsam, Pusan, and Masan, the Tonghae plant will supply the demand on the east coast and interior of South Korea as well as provide cement for export markets.

During the fourth 5-year plan, cement production was expected to reach 23 million tons per year by 1978–80. Domestic consumption was estimated to range between 13 million to 16 million tons per year. The surplus production would be available for export.

Fertilizer Materials.—Production of urea was 845,540 tons in 1976, compared with 924,666 tons in 1975. Chinhae Chemical Co., Ltd., Hankook Fertilizer Co., Ltd., Yong-Nam Chemical Co., Ltd., and Korea General Corp. produced urea fertilizers. Production of compound fertilizers totaled 774,001 tons and was by Chinhae Chemical Co., Ltd. and Yong Nam Chemical. Kyunki Chemical Co., Ltd., and Pungnong Chemical Co., Ltd., produced 147,622 tons of fused magnesium phosphate. Ammonium sulfate was produced by Han Kook Caprolactam Corporation and by POSCO.

Namhai Chemical Co., a subsidiary of the Korea General Chemical Corporation, was constructing a large-scale compound fertilizer plant at Yeocheon, Jeonnam Province. This facility, which will have an annual production capacity of 635,000 tons of urea and 330,000 tons of compound fertilizers, was scheduled for completion in 1978.

Other Nonmetals.—Due to greater demand for cement, limestone production increased 13% to 19.1 million tons in 1976. Output of silica sand and silica stone was 261,952 tons and 265,468 tons, respectively. Production of kaolin clay decreased 16% to 249,600. Production of talc and pyrophyllite was 147,774 tons and 348,694 tons, respectively. Production of other nonmetallic minerals during 1976 follows, in tons: Marine salt 691,000; amorphous graphite, 38,277; crystalline graphite, 3,413; feldspar, 26,208; fluorite, 20,270; diatomaceous earth, 13,483; asbestos, 4,762; barite, 4,174; and andalusite, 520.

MINERAL FUELS

Coal.— *Anthracite.*—Mine production of anthracite in 1976 was 16.4 million tons, valued at $326 million. Virtually all of the production was domestically consumed, primarily for space heating. The Government-owned Dai Han Coal Corporation produced 28% of the country's anthracite output. The remainder of the production was by private companies. The largest private producer is San Chang Coal Co., Ltd., which operates the Samchuk mine.

During the year, the Government released a total of $7.6 million from its facility fund for coal mine development. On March 30, 1976, the Asian Development Bank, approved a $12 million loan to the Dai Han Coal Corporation for 15 years at 8.75% interest. During the year, Dai Han imported the following equipment needed for the modernization of its coal mines: Machine tools and safety devices, $7.04 million; miscellaneous mining equipment, $1.90 million; and test drilling equipment, $0.55 million.

Petroleum.—The Republic of Korea imports all of its oil requirements, mostly in the form of crude petroleum. In 1976, 18.3 million tons of crude oil was imported, valued at $1.6 billion. In 1976, the domestic demand for oil products was estimated at 130 million barrels. Consumption by product type follows, in million barrels: Gasoline, 5.0; kerosine, 4.5; light oil, 25.6; bunker "C" oil, 66.7; heavy oil, 2.1; jet fuel, 4.4; naphtha, 14.8; solvents, 0.4; liquid propane gas, 0.8; and asphalt, 0.9.

Three refineries account for Korea's daily capacity of 435,000 barrels per day: Korea Oil Corp. at the Ulsan petrochemical complex, 215,000 barrels per day; Kyong-In Energy Company at Inchon, 60,000 barrels per day; and Honam Oil Co. at Yosu, 160,000 barrels per day. Kyong-In Energy proposed plans to double the capacity of its refinery at Inchon. Iranian Oil Co. and a local group composed of Ssangyang business interests were planning a 100,000 barrels-per-day refinery at Onsan in Kyongsang Province. Another group, composed of Saudi Arabian and Japanese interests, proposed a new refinery at Ulsan, with a capacity of 150,000 barrels per day.

The oil discovery at Pohang about 200 miles southeast of Seoul stirred a great deal of interest in early 1976, but the commerciality of the discovery was not revealed. Oil exploration offshore was virtually at a standstill, because all concession holders have drilled only dry holes and because of disputed territorial claims.

The Mineral Industry of Kuwait

By David E. Morse [1]

The economy of Kuwait, a small nation of 1 million people at the northwest end of the Persian Gulf, was based on income derived from the sale of crude oil and refined petroleum products. Crude oil production was controlled by the State-owned Kuwait Oil Co., Ltd. (KOC). The KOC oil refinery at Mina Al Ahmadi and the Shuaiba oil refinery operated by the Kuwait National Petroleum Co. (KNPC), also Government-owned, represented 75% of the nation's total petroleum-refining capacity. Kuwait's fiscal year had been a 12-month period beginning April 1 and ending March 31 until fiscal year 1975–76, a 15-month transition fiscal year that ended June 30, 1976. Succeeding fiscal years were to begin July 1 and end June 30. During the 15-month fiscal year 1975–76, revenues from oil were $12.17 billion,[2] or 89% of all Government revenues.

During calendar year 1976, oil receipts were $9.3 billion. Government revenues in recent years have increased dramatically; revenue for the first quarter of 1976 exceeded total revenues for fiscal year 1973–74, owing to the Government's full acquisition in 1975 of KOC and the higher crude oil prices instituted by the Organization of Petroleum Exporting Countries (OPEC). In addition, investment revenue during 1976 increased to $1.1 billion. Government expenditures were $3.2 billion, and Government revenues exceeded expenditures by $7.6 billion during the year.[3]

The high level of income has allowed the Government to undertake a wide range of domestic and foreign economic programs. The Government planned to spend several hundred million dollars to double electricity generation capacity to 2,618 megawatts and increase water desalinization output to 110 million gallons per day. Major public works projects included port expansion at Shuaiba and Shuwikh, highway modernization and extension, four new hospitals, new public housing, greater distribution of fresh water, a new State mosque, and a zoo. Domestic projects devoted to petroleum-related industries included the Kuwait Gas Utilization Project, expansion of ammonia and urea facilities, plants to produce aromatic hydrocarbons, petroleum refinery expansion, and a melamine plant. Kuwait's economic boom has had some negative effects, such as port congestion, increased pollution owing to expanded industry, and labor shortages. The Government continued to assess the viability of industrial projects, especially in the petrochemical field, owing to the building of large plants by other oil-producing nations in the Persian Gulf area.

Kuwait continued to invest considerable sums outside the country and had foreign assets of approximately $17 billion in 1976. The Government provided important economic assistance to Egypt, Jordan, and Syria. Kuwaiti firms increased activities outside the developed nations and invested in joint ventures in Malaysia, Mauritania, Peru, Sudan, Venezuela, and the Yemen Arab Republic. The Governments of Kuwait and Romania began negotiations on a $1 billion joint venture petrochemical complex to be built near Navordari on the Black Sea. Kuwait was to have a 49% share in the venture and supply 160,000 barrels of crude oil per day to Romanian refineries.

The former Kuwait-Saudi Arabia Neutral Zone has been partitioned since 1969. The northern half is administered by Kuwait and the southern half by Saudi Arabia. However, the petroleum concessions in the former Neutral Zone were not affected by the partition agreement. During 1976 in the partitioned Neutral Zone, Arabian Oil Co., Ltd. (AOC) was the offshore concessionaire for both Kuwait and Saudi Arabia, American Independent Oil Co. (Aminoil) was the onshore concessionaire for Kuwait, and Getty Oil Co. was the onshore concessionaire for Saudi Arabia. Petroleum has been the only mineral product obtained both onshore and offshore in the partitioned Neutral Zone, and the two countries have shared the revenue from the production of crude oil.

PRODUCTION

During 1976, Kuwait's crude oil production capacity was greater than 4 million barrels per day; total crude oil output averaged 2.15 million barrels per day, including Kuwait's share of production from the partitioned Neutral Zone. KOC increased output 4.3%, but Kuwait's share of production from AOC's and Aminoil's fields in the partitioned Neutral Zone decreased 5.4%. Crude oil production ranged from 1.4 million barrels per day in April to over 3 million barrels per day in December. Output for the fourth quarter averaged 2.9 million barrels per day because importing nations stockpiled crude oil in anticipation of a January 1977 price increase. Kuwait's oil output had declined steadily since its peak in 1972 because of the Government's policy of maintaining oil prices and controlling the rate of production (1976 planned output was to average 2 million barrels per day), but the 1976 output had an overall increase of 3.1% owing to the large fourth quarter demand of the international market.

In the partitioned Neutral Zone, AOC produced an average of 307,800 barrels per day from the offshore Khafji and Hout Fields, and Aminoil produced an average of 80,000 barrels per day from onshore fields.

During 1976, associated natural gas production in Kuwait averaged 1,083 million cubic feet per day, an increase of 3.4% over 1975 output. Over 61% of the natural gas output was utilized domestically, the highest percentage in the Middle East.

Output of urea fell 4% below 1975 production, and ammonium sulfate production was discontinued owing to slumping prices. In 1976, sales of sand-lime brick, cement, and cement products increased 41% in value.

[2] Includes Kuwait's share of refinery output by its concessionaires in the former Kuwait-Saudi Arabia Neutral Zone.

TRADE

Kuwait's exports were dominated by the activities of the petroleum industry. During 1976, Kuwait exported 656 million barrels of crude oil and 147 million barrels of refined petroleum products, including liquefied petroleum gas. Petroleum exports maintained their 93% share of the export market, although the value of all exports increased 14% and the value of nonpetroleum exports increased 25% over 1975 values. Crude oil was exported mainly to the Far East (46%) and Europe (41%); Japan and the United Kingdom were the largest customers. In 1976, Brazil was the largest importer of Kuwaiti crude oil in the Western Hemisphere (4.4%). The value of nonpetroleum exports and reexports was overshadowed by the magnitude of the value received from petroleum, but has become substantial; chemical fertilizers, manufactured from domestic raw materials, were a significant portion of the nonpetroleum exports. The value of all exports during the year was approximately $10.2 billion.

At $3.3 billion, 1976 imports increased 38% over the 1975 value. Main imports were transport equipment, machinery, food and live animals, and manufactured goods. Kuwait's prime sources of imports were Japan, the United States, the Federal Republic of Germany, the United Kingdom, and France.

COMMODITY REVIEW

NONMETALS

Cement.—The Kuwait Cement Co. (KCC) produced cement from gypsum and clinker imported from Iraq. During 1976, KCC increased capacity to 300,000 tons per year and increased sales $7 million. The company planned to install new facilities to increase production capacity to 1 million tons per year in 1978 and to 1.3 million tons by 1980. KCC reached a preliminary agreement to produce cement and clinker in Oman and signed an agreement to set up a 3-million-ton-per-year plant in Saudi Arabia. Kuwait was to take 1,000 tons per day of cement and 4,000 tons per day of clinker from the Saudi project.

Construction Materials.—National Industries Co. (NIC) was the primary domestic manufacturer of building materials in Kuwait. In 1976, the company expanded the capacity of its sand-lime brick facilities from 60 million to 150 million brick per year. A new 156-million-brick-per-year sand-lime brick plant in southern Kuwait was to be in full production by the end of 1977. Two asbestos plants were to be built in the Mina Abd Allah area to expand asbestos products production by 35,000 tons per year. In 1976, NIC sales increased 43% in value.

Fertilizer Materials.—Petro Chemical Industries Co., owned by the Government, produced ammonia, urea fertilizer, and sulfuric acid, and halted ammonium sulfate production during 1976. Petro Chemical's urea output declined 4.3% in 1976 owing to slackened world demand for fertilizers and a temporary shutdown caused by severe weather and sandstorms in April. Production of ammonium sulfate at the 160,000-ton-per-year facility was discontinued because of low demand and the poor price in the world market. Most of NIC's fertilizer output was exported to Persian Gulf States and to Eastern Asia.

MINERAL FUELS

Natural Gas.—Kuwait produced natural gas only in association with crude oil, and output was dependent on the rate of crude oil production. The Dorra gasfield offshore in the partitioned Neutral Zone, the only known field of nonassociated natural gas, had not been developed for commercial use. AOC completed one well during 1976 and was drilling another at yearend in the Dorra gasfield. Estimated natural gas reserves in Kuwait were 37 trillion cubic feet at yearend 1976, a 2.1% decrease from those of yearend 1975. Natural gas was used for reinjection into oilfields, electric power generation, water distillation, fertilizer raw material, and general use. Total estimated natural gas reserves in the partitioned Neutral Zone were 19 trillion cubic feet at yearend 1976, a 3.8% decrease from that of yearend 1975. Most of the natural gas produced in the partitioned Neutral Zone during the year was flared.

Kuwait utilized 61.6% of its 1976 natural gas output and embarked on a course to make use of all natural gas production. The Kuwait Gas Utilization Project was to come to fruition in 1978 and produce 5.5 million tons per year based on a crude oil output of 3 million barrels per day, or 3.6 million tons per year if crude oil output is restricted to 2 million barrels per day. KOC was entrusted with overseeing the $875 million project and plans to test the Permian Kuff formation, which produces nonassociated natural gas in the partitioned Neutral Zone, Saudi Arabia, and Bahrain. A 20,000-foot test well in the Burgan Field was scheduled for 1977, and the Kuff was expected to be tapped near 16,000 feet. A source of nonassociated natural gas was desired to reduce the project's dependence on inconsistent crude oil production. Kuwait Oil Tanker Co. ordered four gas tankers with a capacity of 71,650 cubic meters each that are to be put in the service of the project. Delivery of the gas tankers was expected in 1978 and 1979.

Petroleum.—Seven wells were completed in Kuwait during 1976. KOC completed five oil wells during the year, although no drilling was reported during 1975. KOC's 1976 output came from 587 flowing wells; the bulk of production was from the Burgan-Magwa-Ahmadi complex. Kuwait Spanish Petroleum Co., a joint effort of KNPC and Hispanoil (Spain), completed two wildcat wells in 1976, the last of a seven-well $20 million exploratory program. All wells were dry, and Hispanoil

relinquished its concession rights in October 1976. Offshore in the partitioned Neutral Zone, AOC completed four oil wells in the Khafji Field and one oil well in the Hout oilfield, and was drilling another well in the Khafji Field at yearend. AOC drilled 12 wells in 1975 and 20 wells in 1974. AOC's 1976 output came from 123 wells in the Khafji Field and 25 in the Hout Field; most of the output was from the high-sulfur Khafji Field. Offshore production capacity was 350,000 barrels per day in 1976. Onshore in the partitioned Neutral Zone, Aminoil/Getty did not report any drilling activity and production came from 10 flowing and 298 artificially lifted wells in the Wafra, South Fawares, and South Umm Gudair Fields. Onshore production capacity was 200,000 barrels per day in 1976.

Crude oil reserves were estimated at 69,500 million barrels in Kuwait and 6,500 million barrels in onshore and offshore fields in the partitioned Neutral Zone.

Kuwait's production of refined petroleum products was exported except for approximately 17,000 barrels per day consumed by the domestic market. Kuwait was served by three petroleum refineries with a combined daily throughput capacity of 645,000 barrels. The Shuaiba oil refinery (KNPC) operated at 90% of capacity and provided petroleum products for domestic and foreign customers during the year. The export-oriented refinery at Mina Al Ahmadi (KOC) operated at 35% of rated capacity, an increase of 22,000 barrels per day over 1975 production. The Aminoil oil refinery at Mina Abd Allah continued to operate at approximately 58% of capacity in 1976 despite a December 1975 fire that caused extensive damage to the refinery's desulfurization unit. KNPC installed a new 42,000-barrel-per-day hydrocracking vessel at the Shuaiba oil refinery late in 1976. The new unit and hydrogen production facilities were scheduled to come onstream in September 1977. KNPC awarded an $8 million contract to Shell Oil Co. and a local contractor to build a 28,000-ton-per-year lubricating-oil blending plant at Shuaiba. Foster Wheeler Italiana received a $12 million contract from KOC to build a 200,000-ton-per-year asphalt plant, to be completed in 1977.

The Mineral Industry of Liberia

By Janice L. W. Jolly [1]

The mineral industry of Liberia in 1976 consisted primarily of the production of iron ore and diamond. Some gold, cement, and refined petroleum products were also produced. Iron ore production was cut back during the first half of 1976 when the declining demand of 1975 continued. The sluggish demand had led to a stockpile of nearly 5 million tons at the ports of Buchanan and Monrovia by yearend 1975. By yearend 1976, however, demand had improved so that an overall 13% gain over the 1975 volume of iron ore exports was achieved. Industrial diamond production declined 7.0% from that of 1975. Despite the drop in revenues derived from these principal income earners, Liberia achieved a foreign trade surplus of $61 million,[2] and its foreign exchange position was measurably improved. The gross domestic product (GDP) for 1976 was estimated at $863 million, up 9.7% from that of 1975 at current prices and representing a 2.5% growth in real terms.

The 1976 budget provided for expenditures and revenues of $129.9 million, representing an increase of $12.9 million over the 1975 budget. The Government changed to a fiscal year beginning July 1 and implemented a new 4-year development plan on July 1, 1976. Emphasis was to be on rural development with most expenditures on infrastructure improvement. In the first year, development projects costing $73.1 million were to be started. Total costs for the 4 years were estimated at $415 million. Liberia was to finance 38% of the plan, while foreign donors were to provide 62%. Road construction was to receive $126 million. A cement factory was also included in the plans.[3]

Liberia and Sierra Leone were well on their way to fusing their economic systems in a full common market.[4] After months of negotiations, the two countries agreed to harmonize all customs duties. The Mano River Union Secretariat, the body charged with integrating the economies, was approved in 1973 by the joint Council of Ministers. All that remained was approval by the Liberian Legislature and assent by the respective heads of state. The new tariff was to come into effect by April 1, 1977. The Economic Community of West African States (ECOWAS) reached agreement on several items dealing with financial contributions from the 11 member States and how they should be operated and managed. Location of headquarters and selection of the secretary general were yet to be decided.

Thirty or forty foreign firms expressed an interest in establishing manufacturing facilities in Monrovia's Industrial Free Zone (IFZ). Work on the IFZ's infrastructure was to start in 1977. To protect their investments and to obtain favorable treatment, most investors were to have some Liberians as shareholders. Corporations were required to be incorporated in Liberia.

Terms of mineral concessions were usually negotiated on a case-by-case basis. Each application for a mineral concession was to be made in writing to the Ministry of Lands and Mines. If the ministry was satisfied with technical aspects of the proposal and with the applicant, the applica-

tion was forwarded to the concession secretariat in the Ministry of Finance for further evaluation. The secretariat then made its recommendation to the Concession and Investment Commission, which forwarded the application to the President, who then sent it to the Legislature for approval. The entire process took as little as 3 weeks. The mining concessions were to comply with the Investment Incentive Code as amended in 1974. The Code was originally set by a law enacted in 1966.

Electrical production in 1975 was 860 million kilowatt-hours, resulting in an average annual increase from 1970 to 1975 of 6.4%. Energy consumption per capita was 432 kilograms in coal-equivalent kilograms. Steel consumption was 27,000 tons.[5]

PRODUCTION AND TRADE

Iron ore production in the first half of 1976 was 11.0 million tons, a 23% drop from that of the last 6 months of 1975. Bong Mining Co., Ltd. (BMC), was the largest producer for the second consecutive 6-month reporting period with 4,425,159 tons in the first half of 1976. Liberian American-Swedish Minerals Co.-Joint Venture (LAMCO–JV) produced 4,264,030 tons; National Iron Ore Co., Ltd. (NIOC), 1,390,938 tons; and Liberia Mining Co., Ltd. (LMC), 876,842 tons in the first half of 1976.

Liberia's total export earnings for 1976 were $460 million, up 13.4% from the amount earned in 1975. Iron ore exports for 1976 were 20.5 million tons, valued at $331.6 million, up 12.9% in value from the $293.6 million earned in 1975 for 18.1 million tons exported. The volume of iron ore exports fell during the last half of 1975 and the first half of 1976 as sales and demand declined. The volume of iron ore exports increased nearly 8% in the third quarter of 1976, however, as demand began to pick up at yearend. The average price per ton had increased over 115% since 1973 to about $16.20 in 1976. Diamond exports in 1976, valued at $16.6 million for 320,000 carats shipped, were down 9.8% in value from the $18.4 million received in 1975 for 420,014 carats. Iron ore and diamonds together made up 76% of the total export value in 1976. At the time of this report, no figures were available on the value of gold exported. Total imports (c.i.f.) in 1976 were valued at $399.2 million, up 20.5% from the 1975 import value of $331.2 million.[6]

During the first half of 1976, 2,136,049 barrels of crude oil were imported from Saudi Arabia by the Liberia Refining Co. (LRC). In the same period, 4,622 barrels of motor gasoline and 68,983 barrels of petroleum distillate were imported. Mobil Oil (Liberia) Inc. was the sole importer of aviation gasoline, which amounted to 4,895 barrels imported from the United States. Total petroleum imports for 1975 were valued at $40.7 million. Liberia exported 16,036 barrels of motor gasoline to Guinea and 2,943 barrels of liquefied petroleum gases to Sierra Leone in the first 6 months of 1976.

COMMODITY REVIEW

METALS

Gold.—Several U.S. companies were interested in gold exploration in Liberia and had applied for concessions near Zwedru. Azuza Mining Corp., Afro-American Mining Corp., and the Liberia Gold and Diamond Corp. were continuing their exploration efforts in southern Liberia.

Iron Ore.—The Liberian Iron and Steel Corp. (LISCO), American Metals Climax (AMAX), and a group of Japanese companies, including Kawasaki Steel Corp., C. Itoh & Co., Ltd., Nissho-Iwai Co., Ltd., Marubeni Corp., and Toyo Menka Kaisha, Ltd., were to sign a supplementary agreement with the Liberian Government for the Wologisi iron ore project by early 1977. The new agreement was to stipulate a royalty of 1% on sales for the first 10 years and a royalty of 2% thereafter.[7] Royalty payments were not to be credited toward meeting income tax obligations. Twenty percent of the Wologisi project shares were being reserved for Liberian investors. The remaining problems of financing and finding markets for the ore were yet to be solved. The project was scheduled to start in 1983. AMAX was to arrange iron ore delivery contracts. Estimates for financing had been raised to $1.6 billion. Annual production of 10 million tons of iron oxide pellets was to be transported by a 137-mile slurry pipeline to a new port to be constructed 9 miles southeast of Robertsport. Technical studies by the Bechtel Corp. on the Wologisi iron ore deposit, scheduled for completion in 1975, had not been completed by yearend 1976.

Negotiations were in progress on the Guinean Iron Mining Co. (MIFERGUI) project that was set up in 1973 to mine the iron deposits located on the Guinean–Liberian border. Liberia had already signed an agreement for its participation in the MIFERGUI–Nimba joint venture and paid $50,000 for a 5% equity participation. Liberia had also approved transit of the Guinean ore through Liberia. However, it was expected that Guinea would

[7] Financial Times (London). Liberia Signs Big Iron Deal. Feb. 10, 1977, p. 28.

have to invest about $100 million in the rail extension from Nimba to Guinea, double tracking of 90% of the railroad track, and expansion of the port facilities at Buchanan, which were considered inadequate to handle the additional tonnage. The Nigerian Government was the largest foreign shareholder in MIFERGUI–Nimba with 13.5%.

Liberian Iron Ore Ltd. (LIO) reported that its net income for the first 9 months of 1976 fell 37.1% to $13,770,000 from $21,900,000 earned for the same period in 1975 on equity in earnings by its 50%-owned LAMCO. LAMCO's net profits for this period were down 38.4% from $42 million in 1975. The reduction in profits was due to substantially increased operating costs as well as to a 1.3% drop in sales. LAMCO–JV was operating at 60% capacity owing to slackening demand in the first half of 1976, but had resumed full production by January 1977 as a result of renewed demand. LAMCO decided to defer implementation of its large Tokadeh project. It was proceeding, however, with installation of additional crushing facilities at Buchanan to meet increased world market demand for fines.

BMC was the largest producer of iron ore in the last half of 1975 and the first half of 1976, although the company had curtailed production to respond to reduced demand and the subsequent large stockpile.[8] The West Germany-based European Coal-Steel Co. was to loan Liberia $35 million to boost production at the Bong mine.[9] Construction was in progress on a second pelletizing facility and improvements to the beneficiating plant at BMC, where an 11th concentrating line was being added. The new installations were to start up in mid-1977. BMC's projected capacity was 7.5 million tons, consisting of 4.8 million tons of pellets and 2.7 million tons of concentrates. In the first half of 1976, BMC produced 4,425,159 tons.

In 1976, LMC produced 1,547,267 tons of iron products from its Bomi Hills mines.[10] The Bomi Hills operation was to close on March 31, 1977, with all shipments completed during the year. Exports totaled 1,921,776 tons in 1976, comprising 790,235 tons of blast furnace ore, 579,556 tons of concentrates, and 551,985 tons of fines. LMC and NIOC had begun negotiations for the Bie Mountain iron ore mining concession.

NIOC solved the problems at its Mano River II mine, and production increased to 1,390,938 tons for the first half of 1976. A Ralph M. Parsons Co. subsidiary was sued for $50 million plus interest and recovery of $725,000 in payments by NIOC. The suit charged Parsons-Jurden Corp. with errors in performance in the engineering contract for their ore-processing facility.

Liberia became the 11th member of the Association of Iron Ore Exporting Countries in 1976. There were no new developments on the Putu iron ore project in Grand Gedeh County, where a Japanese-West German consortium was doing technical studies.

MINERAL FUELS

Petroleum.—The LRC refinery (owned 67% by Sun Oil Co.) was closed for repairs for 3 to 4 months after a fire caused by bursting pipes resulted in damage to the crude-processing unit in December 1976. The furnace was to be replaced.

The Mineral Industry of Libya

By Candice Stevens [1]

The oil industry continued to dominate the Libyan economy, accounting for more than 50% of the 1976 gross domestic product (GDP) of $14.5 billion.[2] Increased Governmental participation in the petroleum sector owing to past nationalization measures resulted in a growth in Government oil revenues to nearly $8 billion in 1976. The Libyan oil policy had as its goals maximizing the income per barrel by increasing prices and tax rates; expanding the activities of the State-owned National Oil Corporation (NOC); utilizing oil and gas revenues to develop other sectors of the economy; and developing the national oil sector (exploration, production, refining, petrochemicals, and gas exploitation).

By law, 15% of Libya's oil revenues were to be set aside as Government reserves each year, 15% were designated for the general budget, and 70% were to be devoted to development projects. The current 5-year plan (1976–80) envisaged a total expenditure of about $24 billion. The emphasis was on economic diversification, particularly the development of transportation, electrification, and industrial projects outside of the oil sector. An aluminum smelter and a large iron and steel complex utilizing domestic iron ore resources were to be financed with the aid of Yugoslavia. Cement production capacity was to undergo a major increase, and two new facilities were to make Libya self-sufficient in ammonia fertilizers.

Installed electrical power in Libya increased from 276 megawatts in 1970 to 2,380 megawatts in 1976, and was to undergo further expansion. Two new desalination and electrical powerplants to come onstream at Tripoli and Tobruk were part of a $675 million plan to build similar plants throughout the country. In 1975, the U.S.S.R. agreed to build a 440-megawatt nuclear powerplant in Libya; in March 1976, Libya signed an agreement with France for the supply of a 600-megawatt nuclear powerplant.

The petroleum sector had low priority in Libya's development plans, receiving less than 10% of the allocations of the current 5-year plan. Nevertheless, new projects were undertaken with the assistance of foreign companies on which Libya remained dependent for exploration, marketing, and management of existing fields and installations. Oil production was to be expanded, refining capacity was to be doubled by the construction of five new facilities, and the petrochemical industry was to be supplemented by plants for the production of methanol and ethylene.

PRODUCTION

Libya's petroleum production was again on the upswing in 1976, increasing 31.0% from 540 million barrels in 1975 to 707 million barrels. The upsurge in oil production narrowed the gap between the outputs of Libya and Africa's largest producer, Nigeria. Libya's natural gas production rose substantially over that of 1975, and output of refined petroleum products increased owing to the addition of the new Zāwiyah refinery. Production in the cement industry almost doubled. Libya produced

[1] Economist, International Data and Analysis.
[2] Where necessary, values have been converted from Libyan pound-dinars (Lpd) to U.S. dollars at the rate of Lpd1 = US$3.38.

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the commodities listed, construction materials such as sand and gravel, crushed stone, brick, and tile are also produced, but available information is inadequate to make reliable estimates of output levels. Natural gas liquids are also produced, but are blended with crude oil and are reported as part of that total.

[2] Includes gas reinjected to reserves, if any.

small quantities of gypsum, lime, and other materials for use in the construction industry. Libya's production of mineral commodities in 1976 is given in table 1.

TRADE

Libya's mineral trade was dominated by crude oil and natural gas exports. Libya exported approximately 676 million barrels of crude in 1976, earning over $7 billion in foreign exchange. The United States replaced Italy, the United Kingdom, and West Germany as Libya's top oil market in 1976. An agreement was concluded with the U.S.S.R. for the export of nearly 15 million barrels of petroleum in 1977. During 1976, the Government proposed the nationalization of foreign trade and the establishment of a central Government agency to define import needs and to regulate supplies, although no final action was taken.

A major expansion program was to ease congestion at Libya's main ports. The Tripoli port was undergoing an increase in handling capacity to 12.5 million tons per year. A Japanese consortium led by Japan Industrial Development Co., Ltd., was engineering the second stage of construction which included new breakwaters, quay walls, container berths, and storage facilities. The capacity of the Benghazi port was to be increased from 1 million tons to 4.2 million tons per year by the year 2000. The Turkish firm Mudurgolu was contracted for the $83 million project to add 16 new berths as well as a new deepwater container berth. The Italian engineering firm Lodigiani signed a contract to build a $37.8 million harbor at Marsa el Brega. The Qaṣr Aḥmad harbor in Misurata was to undergo an expansion in port facilities to 500,000 tons per year, and the Derna port capacity was to be brought up to 400,000 tons per year.

Tonnage of the Libyan tanker fleet, operated by National Libyan Maritime Transport Co., was to be increased 50% by 1977 to 12 vessels from the present 8 totaling 686,500 tons. An additional tanker was on order for a later date.

Data on trade in 1975 were not available.

COMMODITY REVIEW

METALS

Aluminum.—Plans were finalized during the year by Libya and Yugoslavia for the establishment of an aluminum smelter in Libya that will use Yugoslav raw materials and Libyan natural gas. The $1.9 billion complex was to be completed in 1980 in northwestern Libya near the Tunisian border. Construction was to be by a Yugoslav consortium consisting of Energoinvest-Sarajevo, Titograd Aluminum Combine, Progresinvest of Belgrade, and Jadral of Obrovac. Yugoslavia was planning an expansion of its domestic bauxite operations and alumina refining capacity to supply the Libyan unit.

Iron and Steel.—Feasibility studies were in progress on the exploitation of iron ore deposits at Wadi Shati, situated nearly 600 kilometers from the coast near the town of Sebha. Reserves were estimated at nearly 2 billion tons of relatively low-grade ore. The three most promising areas were South Taroot, with 475 million tons averaging 50% iron; Askkeda, with 640 million tons averaging 51% iron; and Duésa, with 700 million tons averaging 45% iron. The construction of necessary infrastructure, particularly a railroad link with the coast, would be a major cost factor of the project.

At yearend 1975, Société Nationale de Sidérurgie (SNS) signed a $12.7 million contract with the Indian engineering firm, Dastur International, to provide consultative services for the execution of the first stage of an integrated iron and steel complex at Misurata, 200 kilometers east of Tripoli. The first stage of the plant was scheduled for completion in 1980 at an initial capacity of 1 million tons per year. The second stage, planned for 1986, would include a 5-million-ton-per-year blast furnace to process ore from reserves at Wadi Shati. The U.S.S.R. was to construct a pipeline to supply natural gas to the Misurata complex.

A ministeelworks was also under construction at Tripoli. In April 1976, a scrap iron smelting plant was inaugurated. The $8 million plant financed by Yugoslavia was to produce 20,000 tons per year of reinforcing bars. In July 1976, a longitudinal welding pipe factory was commissioned at the same location. The 22,000-ton-per-year plant was constructed by a Spanish firm.

NONMETALS

Cement.—Libya planned a major increase in cement production capacity to meet rising domestic demand. Cement production in 1976 totaled 1.5 million tons from two plants—the National Cement Co. plant near Homs with an annual capacity of 500,000 tons and the Libyan Cement Co. plant at Benghazi with an annual capacity of 1 million tons.

Five additional cement plants were in various stages of planning or construction. Compagnie Générale des Ciments de Sūk el Khamīs was established during 1976 to operate the new $114 million plant at Sūk el Khamīs, located south of Tripoli in the Tripolitania Region. The 1-million-ton-per-year plant, constructed by the West German firm Humboldt Mining Co., was scheduled to open in mid-1977. Humboldt and Welfenger (West Germany) were awarded a $110 million contract for the construction of a second cement plant at Benghazi to be opened in 1978. The contract for the Benghazi plant, which would have a capacity of 1 million tons per year, also provided for technical assistance in operating the plant for a 2-year period and training of Libyan personnel. National Cement Co. awarded the French firm Fives Cail Babcock S.A. a $150 million contract for construction of a 1-million-ton-per-year plant at Homs, due for completion in 1979. A fourth cement plant under construction at al Hawaari, located in southeastern Libya near al Jawf, was to have a 1-million-ton-per-year capacity. A smaller cement plant with a capacity of 500,000 tons per year was planned for Sebha in the central part of the country.

Also under construction in 1976 were a 60,000-ton-per-year brick factory at Benghazi, to be opened in 1977; a 200,000-ton-per-year brick factory at Tripoli, to be opened in 1978; and a 10,000-ton-per-year tile plant at Tripoli.

Fertilizer Materials.—In furtherance of its plans to develop a domestic fertilizer industry, Libya contracted British Sulphur Corp. Ltd. to conduct feasibility studies on establishing facilities for production of

phosphatic and ammonia fertilizers. Previous surveys confirmed the existence of commercial phosphate deposits in southwestern Libya at Jabal al Gharbī, al Ḥamādah al Ḥamrā', Masra, and Mrada.

Construction continued on the 1,000-ton-per-day ammonia plant at Marsa el Brega on the Mediterranean coast. Friedrich Uhde GmbH (West Germany) was the main contractor for the plant, scheduled for startup in 1977. During the year, Coppas International (U.K.) Ltd. received a $14 million contract for operation and maintenance of the plant and training of Libyan personnel.

In 1976, Foster Wheeler Italiana was awarded a $100 million contract for the installation of a urea plant at Marsa el Brega. The contract also provided for project offsites, including steam generation, power production, and desalination facilities, as well as basic designs for a town complex to be located in the area. Upon completion in 1979, the plant was expected to make Libya self-sufficient in ammonia-based fertilizer.

Gypsum.—Libya produced approximately 60,000 tons of gypsum in 1976 for use in cement manufacture. The two major quarries were located at the Jefren gypsum-anhydrite deposit south of Tripoli and the er-Régima deposit east of Benghazi.

Lime.—Lime production totaled 325,000 tons in 1976 from deposits near Tripoli and Benghazi. The Tripoli lime plant was supplemented by a new facility at Benghazi that started production in 1975 with an annual capacity of 37,500 tons of slaked lime. In addition, a new lime plant at Sūk el Khamīs was opened in June 1976. Annual production capacity was 70,000 tons of quick lime and 100,000 tons of slaked lime.

Salt.—The Libyan Government operated several small salt plants capable of producing about 10,000 tons per year of salt from seawater. During the year, a West German firm continued construction of a new salt plant at Tripoli, scheduled to produce 22,000 cubic meters of salt per day. Société Internationale de Dessalement de l'Eau de Mer (SIDEM) was contracted to build another salt factory at Tobruk. The plant was to be commissioned in 1977 with a capacity of 24,000 cubic meters per day.

Raw materials available in Libya's seawater and the large salt beds around Abū Kammāsh were to provide the basis for a large chemical complex that will begin production in 1980. A $514 million contract was awarded in 1976 to a West German consortium led by Salzgitter Industriebau GmbH. Other participants were Friedrich Uhde GmbH for plant installation, Philipp Holzmann A.G. for civil engineering, Klöckner Industrieanlagen GmbH for equipment, and Industriet-Montage (Indumont) for electrical engineering. The complex was to include four independent chemical units, a water desalination and power plant, and a separate tanker terminal. Annual production was to consist of 120,000 tons of salt, 50,000 tons of caustic soda, 60,000 tons of polyvinyl chloride, 8,000 tons of hydrochloric acid, 7,000 tons of sodium hydrochloride, and 5,000 tons of liquid chlorine.

MINERAL FUELS

Natural Gas.—Libya's natural gas production in 1976 was 634 billion cubic feet, 20% of which was flared. Reserves were estimated at 28,500 billion cubic feet at yearend 1976.

Esso Standard Libya Inc.'s liquefied natural gas (LNG) plant at Marsa el Brega was back in full production after the shutdown in late 1974 owing to a price dispute with its Italian and Spanish customers. The plant achieved record highs in average production in 1976 of 297 million cubic feet per day of LNG and 21,000 barrels per day of naphtha. The Nasser Field was the main source of associated gas production, supplying 345 million cubic feet daily. Esso Standard initiated a major project to develop the Hatéiba gasfield some 80 kilometers south of Marsa el Brega, with completion scheduled for yearend 1977.

Occidental of Libya, Inc. (Oxylibya) produced approximately 2 million barrels of gas liquids—naphtha, butane, and propane—at its liquefied petroleum gas (LPG) plant in 1976.

Petroleum.—*Exploration.*—Exploration activity increased in Libya in recent years owing to the conclusion of a number of production-sharing agreements with foreign companies. During 1976, nearly 455,000 square kilometers of territory was

held under contract by 20 companies. The agreements provided for the foreign companies to assume all exploration risk costs, giving the Government about $600 million in exploration commitments. In the event of a commercial discovery, the Government was to receive between 81% and 85% of production. Libya was to pay the majority of development costs but would be reimbursed with interest over the long term if production reached a certain undisclosed amount. The major exploration agreements are outlined in table 2.

Oxylibya, which held exploration blocks covering 45,000 square kilometers, had three discoveries in the past year. In the northwestern Sirte Basin, two wells tested 882 barrels and 2,045 barrels per day, respectively, from about 3,900 feet. Development drilling began immediately and Oxylibya scheduled one of the fields for production in 1977. Negotiations were underway with Oasis Oil Co. of Libya, Inc., to conclude a throughput arrangement with the Oasis pipeline to es-Sider. A third discovery, 113 kilometers southwest of es-Sider, tested 2,400 barrels per day of 52.5° API gravity crude.

A consortium led by Elf-Aquitaine, which held both onshore and offshore tracts, reported a large oil discovery about 100 kilometers north of Zurara near the Tunisian border. Further drilling to delineate reserves was undertaken. Shares in the consortium were divided among Elf-Aquitaine (50%), Elf Libye (25%), Österreichische Mineralölverwaltung A.G. (OMV) of Austria (15%), and Wintershall A.G. of West Germany (10%).

A well drilled by NOC during 1976 tested 4,000 barrels per day at 6,000 feet. The discovery was in the al Ḥamādah al Ḥamrā' region of western Libya, where the company has been drilling for more than 2 years. Umm al-Gawabi Co., a wholly-owned subsidiary of NOC, struck an estimated 100-million-barrel deposit near Beda Field and another deposit of an estimated 50 million barrels near Nafoora Field. Commercial production from both fields was planned for 1977.

Total conducted a 10,000-square-kilometer aeromagnetic survey of its Mizrāq concession area in southwestern Libya. Exxon completed seismic surveys on 10,000 square kilometers in the Mediterranean offshore and onshore area. Exxon was to begin drilling offshore in early 1977. Mobil Oil Libya Ltd. surrendered the offshore portion of its acreage in 1976 but was to be assigned additional areas onshore.

The dispute between Libya and Tunisia continued in 1976 over rights to explore for oil in an area of the Mediterranean bordering both nations. During the year, the two countries agreed to submit the case to the International Court of Justice at The Hague for settlement.

Table 2.—Libya: Exploration concessions in 1976

Company	Location	Date of agreement	Acreage (square kilometers)	Exploration commitments		Production sharing [1] (percent)
				Value (millions)	Years	
Oxylibya	Sirte Basin onshore	1974	45,000	$90	5	81–19
Elf-Aquitaine	Sirte Basin onshore	1974	20,000	45	4	85–15
	Zuara offshore					81–19
Exxon	Sirte Basin onshore	1974	14,000	90	5	85–15

[3] Compagnie Française des Pétroles.

Production.—Following the phenomenal growth between 1961 and 1970, oil production in Libya started to decline owing to a conservation policy instituted by the Government. In 1976, however, the Government urged production increases and output reached 1.9 million barrels per day, compared with 1.5 million barrels per day in 1975. Libya planned to attain the 2.4-million-barrel-per-day mark by 1977. At yearend 1976, Libya's crude oil reserves were estimated at 25.5 billion barrels.

As a result of the participation and nationalization measures initiated in 1973, Libya acquired ownership of over two-thirds of its oil production. The Government held a majority interest in all but two of the eight foreign operating companies (see table 3). The companies accepted compensation based on the net book value of their assets and the right to buy back 51% of their former production. During 1976, Libya raised the price of light crude from $12.13 to $12.62 per barrel in accordance with a decision by the Organization of Petroleum Exporting Countries (OPEC) to allow members to adjust their rates to suit market conditions.

The greatest potential for production increase was that of the two subsidiaries of the State-owned NOC—Arabian Gulf Exploration Co. (AGECO) and Umm al-Gawabi. AGECO, created in 1971 to assume the interests of BP Exploration Company (Libya) Ltd. and Nelson Bunker Hunt, operated the Sarīr Field, which averaged 270,000 barrels per day in 1976. Production capacity at Sarīr, Libya's largest field, was about 400,000 barrels per day, to be increased to 600,000 barrels per day by 1980. Umm al-Gawabi was formed in 1974 to take over the interests of American Overseas Petroleum Ltd. (Amoseas), a joint venture of Texaco Inc. and Standard Oil Co. of California. In 1976, the International Court of Justice ruled that this nationalization was illegal and ordered the Libyan Government to pay just compensation by June 30, 1977. Umm al-Gawabi produced approximately 110,000 barrels per day from several fields.

Oasis, which included Continental Oil Company of Libya (Conoco), Marathon Petroleum Libya Ltd., and Amerada Hess Corp., was the country's largest producer with an average of nearly 700,000 barrels per day in 1976. Oxylibya averaged 350,000 barrels per day from eight fields. Agip, a subsidiary of Italy's State-owned Ente Nazionale Idrocarburi (ENI), produced 147,000 barrels per day from its single Abu Tiffel Field. Esso Sirte, a collaboration of Esso and Grace Petroleum Corp., produced 65,000 barrels per day at its Raguba Field. The Nasser, Jabal, and Ralah Fields, operated by Esso Standard, produced at a combined rate of 190,000 barrels per day, with the Nasser Field contributing 88% of the total. Libya's oil production in 1976 is detailed in table 4.

Amoco	Sahābī	1961	6

Refining.—Libya had a total crude oil processing capacity of about 78,800 barrels per day, distributed among the following refineries:

Refinery	Operator	Capacity (barrels per day)
Zāwiyah	NOC	60,000
Nafoora	Amoseas	1,800
Marsa el Brega	Esso Standard	8,000
Amal	Mobil	1,800
Intiṣār	NOC	1,800
Zuetina	do	3,000
Dahra	Oasis	2,400

In an effort to raise refining capacity above 1 million barrels per day, several projects were initiated. The Zāwiyah refinery, the country's largest, was to double its capacity in 1977. SNAM Progetti S.p.A. (Italy) was awarded a $53 million contract to expand the refinery, situated 45 kilometers west of Tripoli. In December 1976, the Dutch firm Protech International B.V. was contracted to construct a 370-kilometer pipeline from the Hamada region to the Zāwiyah refinery.

SNAM Progetti was also charged with studies for and supervision of construction of a 220,000-barrel-per-day refinery at Tobruk. The actual construction of the $338 million refinery, scheduled for completion in 1978, was to be by Italy's Foster Wheeler Italiana. Plans for three other refineries were also announced: A 300,000-barrel-per-day refinery at Marsa el Brega; a 400,000-barrel-per-day refinery at Zuetina, located 125 kilometers south of Benghazi; and a 220,000-barrel-per-day refinery at Misurata, located east of Tripoli.

The methanol unit at the large petrochemical complex under construction at Marsa el Brega was to be commissioned in early 1977. Constructed by Friedrich Uhde GmbH, the $88 million plant was to have a capacity of 1,000 tons of methanol per day. The plant was to be under the supervision of National Methanol Co., equally owned by NOC and Oxylibya. A unit for the production of 1,000 tons of ethylene per day was to be completed in 1978. The $203 million ethylene plant was under construction by Stone & Webster Engineering Ltd. (United Kingdom).

The Mineral Industry of Madagascar

By David E. Morse [1]

One of the outstanding features of Madagascar is its varied mineralization fairly well distributed throughout the country. The island contains large resources of chromite, iron ore, lateritic nickel, limestone, mica, quartz, and zircon. The primary minerals produced in 1976 were chromite, graphite, and phlogopite mica. Chromite production increased 14% over that of 1975 to 221,000 tons; graphite output declined 362 tons to 17,412 tons; and mica production decreased from 544 tons in 1975 to 81 tons in 1976. Madagascar's small-scale mines produced a wide variety of semiprecious and ornamental stones, including agate, beryl, celestite, jasper, rhodenite, rose and smoky quartz, opal, tourmaline, and zircon. The mineral sector of the economy continued to be a small contributor to the gross domestic product (GDP) but a significant source of foreign exchange during 1976. No petroleum exploration activity was conducted in Madagascar during the year although Total Chimie of France and Agip S.p.A. of Italy maintained concessions for areas along the west coast.

The Democratic Republic of Madagascar came into being on December 30, 1975. The island nation had been called the Malagasy Republic since its independence in 1960.

In keeping with its expressed goal of State ownership of all basic means of production, the Government nationalized the petroleum sector of the economy in July. The companies most affected were the joint shareholders of the country's only petroleum refinery. The State had previously held a 51% share in the refinery, and Total Petroleum Ltd., Esso Co., Caltex Petroleum Corp., and Shell Oil Co. had controlled the remaining 49%. The State assumed full control of importing, refining, storing, and marketing petroleum and petroleum products.

The Government stated that it would require 51% or greater ownership in any new mining venture and that the majority of the profits should be kept in the country to minimize the loss of foreign exchange and to aid development.

Initial site preparations began during the year on the Namorona River hydroelectric complex. The bulk of the electricity produced was to go to planned aluminum smelters. The planned $100 million Rogez hydroelectric complex on the Vohitra River in east-central Madagascar neared construction. The output of the Rogez project was to be used to exploit the Ambotavy nickel deposit and to power a planned ferrochrome plant.

The Government continued its efforts to improve the island's road system. Work began on improvements to the central-south axis road and the Arivonimamo-to-Analavory link. The construction of a 370-kilometer vehicle track between Tsiroanomandidy and Maintirano was funded by an Arab Development Bank loan. Most mineral exports were carried by rail from Antananarivo (formerly Tananarive) to the port of Tamatave for transport to world markets.

---

[1] Physical scientist, International Data and Analysis.

PRODUCTION AND TRADE

Production data is shown in table 1.

The value of mineral exports in 1976 was $29.0 million,[2] a 58% increase over the $18.4 million in 1975. Exports of chromite concentrate of 218,000 tons were valued at $22.4 million, a per-ton increase of 26%, reflecting higher world chromite prices. Compared with those of 1975, graphite exports in 1976 increased 5% to 17,900 tons and increased 20% in value to about $5.3 million. Phlogopite mica exports rebounded to 930 tons in 1976 from 137 tons in 1975 and were valued at $750,000. The export value of gem, semiprecious, and ornamental stones was almost triple that of 1975 at nearly $550,000. In 1976, crude oil imports were about 4.1 million barrels, a 29% decrease from those of 1975.

Because of the Government's tight control on imports and the increased value of agricultural exports, Madagascar almost achieved parity between imports and exports in 1976, compared with the 1975 deficit of $36.5 million.

[2] Where necessary, values have been converted from Malagasy francs (FMG) to U.S. dollars at the rate of FMG241 = US$1.00.

COMMODITY REVIEW

METALS

Bauxite.—A French consortium was to develop the 165-million-ton Manantenina bauxite deposit. Planned output was 5 million tons per year. Neither the timetable for mine development nor the status of the proposed aluminum smelter was known. The smelter was to use power from the hydroelectric complex under construction on the Namorona River.

Chromite.—Madagascar Chrome Resources Development Co. conducted geologic surveys and diamond drilling on its 8,000-square-kilometer concession area between Andriamena and Tsaratanana northwest of Lake Alaotra. Mining operations were to begin in 1979 with most of the output to be exported to Japan.

Kraomita Malagasy, formerly Compagnie Minière d'Andriamena (Comina), operated the country's only chromite mines located at Andriamena and Befandriana Nord. Chromite output averaged over 17,000 tons per month of dry concentrate containing 50% to 52% Cr_2O_3 from Madagascar's Government-owned mines. Over 80% of the output came from the Andriamena mine that had reserves of about 5 million tons. A 40,000-ton-per-year ferrochrome plant was planned to come onstream in 1980 and use power from the Rogez hydroelectric complex.

Iron Ore.—Iron ore deposits have been studied at Ambotavy near Moramanga in east-central Madagascar, at Ambonimahavony near Ansirabe, at Soalala on the west coast south of Majunga, between Bekisopa and Fasentsara in south-central Madagascar, and in the Ambohipaky coastal region. The relatively low iron content and general lack of good surface

transportatiton have deterred development of the deposits.

Nickel.—A detailed study has been made of the 120-million-ton 1% to 2% lateritic nickel deposit at Ambotavy. It was to be exploited using power generated at the planned Rogez hydroelectric power project. No progress toward development of this deposit was reported during 1976.

Other Metals.—A pilot plant was operated by Montedison S.p.A. of Italy to extract ilmenite and zircon from the beachsands of the east coast near Tamatave. United States Steel Corp. and Bureau de Recherches Géologiques et Minières (BRGM) of France began pilot plant operations on beachsand deposits in the Fort-Dauphin area during 1976. These deposits along the southeast coast contained several million tons of ilmenite with lesser amounts of zircon and monazite.

NONMETALS

Cement.—The country's only cement plant at Amoania operated at full capacity during 1976. An accord was signed with the U.S.S.R. for the construction of a new cement plant in the Antananarivo area. Details of the agreement were not available.

Graphite.—Production of quality flake graphite in 1976 was nearly double the 1975 output. Total graphite production remained at about the same level it had been for the previous 2 years. World demand for graphite remained high but the island's principal operators were reluctant to make commitments to expand output because of the Government's recent (1975) nationalizatiton of other mining operations.

Mica.—Production of phlogopite mica from mines in southeastern Madagascar dropped to 81 tons in 1976, a decrease of 85% from that of 1975. Mica production has been affected by synthetic products in some electronic uses and by a low-cost substitute made in India from mica scrap. The quality of Madagascar's mica has been decreasing, and mica mining companies closed down industrial operations early in the year owing to lack of demand for blocks and splittings.[3] The 1976 exports of 936 tons consisted mostly of scrap coming from previous years' stockpiles.

MINERAL FUELS

Coal.—The Sakoa formation in southeastern Madagascar, 160 kilometers east of Tulear, contains over 60 million tons of bituminous coal with a 17% ash content. Total Sakoa resources were estimated to be nearly 1 billion tons of high-ash noncoking coal. Experimental mining operations were conducted at Andranomanintsy during the 1950's by the Bureau Minière de La France. Total coal output between 1950 and 1960 was 22,800 tons. Little activity has taken place since 1960 although Utah Development Co. has maintained a coal prospecting permit in the area since 1974. Significant infrastructure investment would be needed for development because of the remoteness of the deposits and lack of good transportation facilities.

Petroleum.—No petroleum exploration activity was conducted in Madagascar during 1976. The Government nationalized the country's oil companies in July 1976. The State assumed control of the only oil refinery and all storage, transport, and marketing facilities in a negotiated settlement. The petroleum refinery at Tamatave had an input of 4.32 million barrels during the year, a 24% decrease from that of 1975. The decrease was in response to the Government's policy of restricting imports to achieve balance between imports and exports.

[3] U.S. Embassy, Antananarivo, Madagascar. State Department Telegram 1337, July 21, 1977.

The Mineral Industry of Malaysia

By E. Chin [1]

The Malaysian gross national product (GNP) in 1976 was $10.8 billion [2] in current dollars compared with $8.7 billion in 1975. In terms of constant 1970 dollars, the GNP in 1976 was $7.6 billion, a real growth of 11.5% over that of 1975. The gross domestic product (GDP) in 1976 was $6.9 billion in 1970 dollars and was distributed by sector as follows, in million dollars: Agriculture, forestry, and fishing, 2,084; manufacturing, 1,037; wholesale and retail trade, 909; transport and communications, 475; mining and quarrying, 324; construction, 304; electricity and water, 176; and other, 1,551. The value of production by the mining and quarrying sector increased 27% over that of 1975. The increase in oil production offset the decline in quantity of bauxite and tin-in-concentrate produced in 1976. The capacity to produce crude oil averaged 165,400 barrels per day in 1976, an increase of 69% over the daily output in 1975.

Malaysia's proven reserves of oil were estimated at around 1 billion barrels. In regard to the status of its oil reserves, the Government was seeking an optimum balance between financing economic growth in light of higher oil revenues and conserving this depleting, nonrenewable resource. Petroleum Nasional Berhad (Petronas), the agency charged with coordinating the exportation of petroleum in the country, concluded the transfer of petroleum rights from the 13 State governments to the Federal Government. Also, since April 1975, foreign oil companies operating in Malaysia were under an interim arrangement in their oil exploration and production activities. Because of protracted negotiations on production-sharing arrangements, the Government gave notice on July 29, 1976, to the oil companies with exploration rights in Malaysia to conclude their agreements with Petronas by November 15, 1976.

Sarawak Shell Berhad and Sabah Shell Petroleum Co. Ltd., and their partner, Picten Malaysia Co., concluded production-sharing agreements with the Government on November 30, 1976, and Exxon Production Malaysia, Inc., on December 6, 1976. Provisions of the three agreements included the following: A maximum cost recovery by the oil companies equivalent to 20% of the oil and 25% of the gas produced as well as 10% royalty to the Government; a 70–30 after-cost-profit split before taxes of the remainder in favor of Petronas; payment of income taxes (45% on oil) by both contractor and Petronas; and a refund of 70% of profit oil proceeds when the price of oil exceeds the base price of $12.72 per barrel during the first year (the base price increases 5% each year). Petronas will receive a bonus for each commercial discovery and a production bonus from each contractor whose average quarterly production exceeds 725,000 kiloliters. The agreements were for a period of 20 years effective April 1, 1975. Provisions for various extensions to be granted on application include: Exploration period of 3 years plus 2 years' extension on application; 2 years for development with an extension to 4 years; and production life of 15 years for oil and gas which can be extended to 20 years in the case of gas.

Production of tin-in-concentrate in Malaysia has declined during 1973–76 at

[1] Physical scientist, International Data and Analysis.

[2] Where necessary, values have been converted from Malaysian dollars (M$) to U.S. dollars at the rate of M$2.50=US$1.00.

an average rate of 4.5% per year. Moreover, the domestic tin industry claimed it was assessed a heavier tax burden (export duty and surcharge, tin profits tax, and income tax), which caused a higher cost for production. The Malaysian Chamber of Mines estimated that 70% of the gross profits from the sales of tin was consumed by various taxes imposed by the Government and that about 30% of the total tax on tin was for export duty and surcharge alone.

To encourage investment in the industry, the Government was reviewing the tax structure of the tin industry. Reduced duties on import items required by tin operators in Malaysia, such as diesel engines and water pumps, were being considered. The Government was also proposing to introduce a new national mining code that would standardize and streamline procedures governing prospecting, alienation, issue and renewal of leases, conversion, and other provisions to stimulate production. The floor price for tin under the International Tin Agreement is regarded as a minimum guaranteed price. At the beginning of 1976, the floor price for tin was M$900 per picul; three price increases during the year brought the yearend price to M$1,075 per picul. The International Tin Council then revised the floor price under the Fifth International Tin Agreement to M$1,200 per picul, effective July 15, 1977. It was believed that the higher floor price would be an inducement for tin producers to increase output. However, the administrative and fiscal problems facing the tin industry in Malaysia continued to inhibit increased investment by miners.

The Government was attempting to establish a tin exchange in Kuala Lumpur, which would be part of a program to set up a multicommodity exchange to deal with exports of the country's major primary commodities such as rubber, tin, and palm oil. The Ministry of Primary Industries was conducting a study on the practicability and feasibility of developing Kuala Lumpur as a terminal market. Assistance was being sought to engage consultants to undertake a feasibility study and prepare a report.

PRODUCTION

Crude petroleum became Malaysia's largest mineral foreign exchange earner. During the year, total production of crude oil was 60.5 million 42-gallon barrels, all from eight fields in East Malaysia. At yearend, production rates per day for the three operating companies were as follows, in barrels: Exxon, 11,336; Sabah Shell, 64,305; and Sarawak Shell, 116,213. The bulk of the production of crude oil is exported; only about 20% is consumed locally by three refineries.

Production of tin-in-concentrate was 63,401 tons; output by dredging and gravel pumping operations accounted for about 86% of the total output. Production of tin metal by three local smelters totaled 78,018 tons. Columbite, gold, scheelite, ilmenite, monazite, xenotime, and zircon were produced as byproducts of tin mining operations. Output of bauxite and iron ore continued to decline owing to the lower tenor of ore and gradual depletion of deposits as well as reduced demand by foreign markets.

Table 1.—Malaysia: Production of mineral commodities [1]

(Metric tons unless otherwise specified)

Commodity [2]	1974	1975	1976 [p]

Total ---do	33,361	29,056	34,540

[e] Estimate. [p] Preliminary. [r] Revised.

[1] All production is from West Malaysia unless otherwise indicated.

[2] In addition to the commodities listed, a variety of crude construction materials (clays, sand and gravel, and stone), salt, and fertilizer are produced, but production is not reported and available information is inadequate for the formulation of reliable estimates of output levels.

[3] Estimates based on exports of copper concentrates.

[4] Based on export figures. May differ from data shown elsewhere in this chapter because of difference in source.

[5] Includes small production of tin from a smelter in Singapore.

[6] Includes production from Sarawak and West Malaysia.

TRADE

Total trade value in 1976 was estimated at $9.3 billion; exports were valued at $5.4 billion and imports at $3.9 billion. By standard industrial trade classification, Malaysia was a net importer of food, beverages, and tobacco, and machinery and transport equipment; it was a net exporter of inedible crude materials, mineral fuels, animal and vegetable oils and fats, chemicals, and manufactured goods and articles.

By value, Malaysia's export markets in 1976 were as follows, in billion dollars: Western Europe, 1.2; Association of Southeast Asian Nations (ASEAN), 1.2 (Singapore alone, 1.0); Japan, 1.1; the United States, 0.8; and other, 1.1. Imports were from Japan, the United States, Singapore,

the United Kingdom, Australia, the People's Republic of China, and others, in that order. Malaysia's leading export commodity was rubber (valued at $1,247 million), followed by timber materials ($930 million), crude petroleum ($620 million), and tin and tin-in-concentrates ($611 million). Exports of other mineral-related materials included partly-refined and refined petroleum products ($207 million), chemicals and chemical products ($28 million), nonmetallic mineral products ($28 million), and manufactures of iron and steel ($25 million).

Malaysia currently supplies about one-fourth of the world's production of tin. Excluding petroleum, tin accounts for about 90% of the value of all Malaysian mineral exports. The United States, Japan, and the European Economic Community were the major markets for Malaysian tin, consuming collectively about 80% of total Malaysian tin exports. Most of the remainder of Malaysia's mineral exports were bauxite, iron ore, ilmenite, and copper concentrate. The bulk of these exports was to Japan.

COMMODITY REVIEW

METALS

Aluminum.—Bauxite was mined at two sites at Telok Ramunia in Johore State (West Malaysia) by Southeast Asia Bauxites Sdn. Bhd. (a subsidiary of Alcan). Mine output, down 6% from that of 1975, totaled 660,235 tons in 1976. Ore reserves at Telok Ramunia were estimated to be about 10 million tons, which represents a 17-year life for this operation at the current mining rate. Moreover, mine production has been diminishing annually owing to lower grade ore rather than decreased export demand. Because Malaysia lacks smelter facilities, its bauxite production was exported, and as in previous years, mostly to Japan. In 1976, exports to Japan totaled 512,474 tons valued at $9.2 million.

The Sabah and Sarawak State governments approached Reynolds Metals Co. to study the feasibility of constructing smelter facilities at Labuan and Bentulu, respectively. Initial plans called for site examination for a 100,000-ton-per-year smelter and port facility and a construction schedule.

Copper.—Production from the Mamut porphyry copper mine managed by Overseas Mineral Resources Development (OMRD) Sabah Bhd. began in May 1975. OMRD Sabah is a joint venture between seven Japanese companies and Malaysian interests. Mine ore output capacity per day was estimated at 16,000 tons, grading 0.59% copper and 0.02 troy ounce per ton gold. Total production of copper concentrate grading 28% copper in 1976 was close to 78,000 tons compared with the planned annual capacity of 120,000 tons. A shipping port constructed at Usukan Bay, 115 kilometers northwest of the mine, consists of a 9,000-ton-capacity stockyard, a 400-meter-long jetty with 30-inch belt conveyors, and a platform with shiploader. At full capacity, sixty 8-ton dump trucks will be used to transport the copper concentrate from the mine site to the port. In 1976, 73,941 tons of copper concentrate, valued at $25.8 million, was shipped to Japan for smelting and refining.

Iron Ore.—Since the Bukit Ibam mine was closed at Rompin in 1970, mine production of iron ore has declined annually. Total output in 1976 was 308,184 tons, a decrease of 11% from that of 1975. Iron ore was mined from relatively small deposits in Pahang, Johore, Perak, and Kedah States, with Pahang accounting for about one-half of the total output. Although deposits of high-grade ore are known to exist in Malaysia, none contain sufficient reserves to support profitable mining.

Iron and Steel.—Malayawata Steel Berhad was the only steel producer in the country. Because of increased demand for steel products, the Sabah State government proposed plans to build a steelmill at the Likas industrial estate near Kota Kinabalu. A feasibility study was undertaken by the government, and a license was reserved for the State Economic Development Corp. to build a 40,000-ton-per-year steelmill, which will initially produce mild steel round bars for the construction industry. Austromineral of Austria was preparing a feasibility study on the construction of a 500,000-ton-per-year integrated iron and steel mill near Kuantan on the east coast where port facilities were under construction.

Tin.—Output of tin-in-concentrate totaled 63,401 tons in 1976, representing a decline for the fourth consecutive year. Production of tin metal by the Butterworth and Penang smelters was 77,297 tons in 1976 compared with a peak production during the past decade of 91,496 tons in 1970. However, Malaysia remained the world's largest producer of tin-in-concentrate and refined metal, as well as the world's largest exporter of tin. The decline in output was credtied to Government export assessments. Government revenues collected on tin exports were $82.9 million for the export duty levied, $33.4 million for the export surcharge, and $610.6 million in foreign exchange for tin sales.

Production of tin-in-concentrate was as follows, by type of operation: Gravel pump 49.9%, dredging 36.4%, dulang 4.8%, open casting 3.6%, underground 2.9%, and re-treatment and other 2.4%. Output by gravel pumping operations was down 5% from that of 1975 while production from dredging was up 4%. During 1976, 99 mines were closed down and, at yearend, 811 mines remained in operation. The breakdown of active mines at yearend was as follows, by type of opera-

tion (yearend 1975 data in parentheses): Gravel pump, 724 (810); dredges, 51 (55); open cast, 11 (12); and other, 25 (33). Concomitant to the decrease in mine production and the number of active mines, the labor force in the tin industry decreased from 54,800 in 1,137 mines during 1966 to 36,828 by yearend 1976 (39,736 at yearend 1975).

Malaysian imports of 73%-grade tin concentrate in 1976 totaled 12,757 tons. Receipts from Australia were 6,119 tons; Burma, 2,298 tons; Indonesia, 1,866 tons; Laos, 1,159 tons; and other, 1,315 tons. Exports of tin metal reached 82,162 tons in 1976 (77,999 tons in 1975). Shipments to the United States constituted 36% of total exports, followed by Japan 22%, the Netherlands 18%, and other countries 24%.

During 1976, Perbadanan Nasional Bhd. (Pernas), a public limited company of which the Government of Malaysia owns approximately 95% of the equity, purchased the controlling interest in London Tin Corporation Ltd., the world's largest privately-owned tin investment group and the largest holder of Malaysian tin mines. Pernas then reached an agreement with Charter Consolidated Ltd. to form a 50–50 joint venture that would consolidate each party's resources and dredging facilities under a new company, Pernas Charter Management. The tin concessions of Charter Consolidated were second only to those of London Tin. Through these acquisitions by Pernas, the Government of Malaysia controlled 36 of the 51 dredges in Malaysia as well as 24.1% of the tin industry in Malaysia.

Government taxes on the Malaysian tin industry, which were reportedly the highest in the world, were a major concern for the operating companies. In some instances, the export tax and the export surcharge on tin accounted for about 70% of the total profit of an operating company. In addition to the aspect of profitability, there was little new investment in the domestic tin industry owing to the Government's delay in issuing renewal of existing leases and not granting new mining leases to non-Malay firms. Another deterrent to non-Malay investment was that many known occurrences of tin lie in Malay Reserve Lands on which exploitation is limited to Malays or Malay-controlled entities. Under the New Economic Policy, a Government program for economic development, ownership in the industry was to be redistributed by limiting new land leases to Malays. As a result, ownership in the domestic tin industry would be held 30% by Malays, 40% by non-Malay Malaysians, and the remainder by foreigners.

In addition to London Tin and Charter Consolidated, major producers of tin concentrates in Malaysia included the following:

Producer	Location	Activity	Number of operations
Ayer Hitam Tin Dredging Malaysia Bhd.	south of Selangor	dredging	3
Berjuntai Tin Dredging Bhd	Kuala Selangor	do	7
Gopeng Consolidated Limited	Ipoh	open cast	1

Tronoh Mines Malaysia Bhd	Perak	do	2

The tin ore reserves of Pahang's Bakak mine were estimated at 619,771 tons, with an average grade of 1.3% cassiterite.

Titanium.—The major mineral obtained from alluvial tin mining is ilmenite, an iron-titanium oxide. Malaysian ilmenite assays about 53% TiO_2, but higher grades (up to 65% TiO_2) have been recovered at Sungkai in Perak and at Petaling in Selangor. Production of ilmenite, all from West Malaysia, totaled 180,004 tons in 1976. During the year, Malaysian Titanium Corporation Sdn. Bhd., a joint venture of Pernas (40%), Empat Nombor Ekor Bhd. (30%), and Malayan Tin Smelting and Finance Co. Sdn. Bhd. (a subsidiary of Straits Trading Co. Ltd.), completed the construction of a titania plant at Lahat to utilize local ilmenite as a raw material. The company was licensed to use the Benelite process, an acid-leach process to convert ilmenite into a synthetic rutile (titanium oxide). By using the Woodhall-Duckham acid-regeneration process, 95% of the hydrochloric acid used in the leach circuit could be recovered and regenerated. The plant was to initially process 17,000 tons of ilmenite in 1976, 50,000 tons in 1977, 55,000 tons in 1978, and 60,000 tons in 1979. Adverse factors facing the company were startup technical difficulties, the sharp decrease in price of Australian rutile, and decreased demand for titanium.

Other Metals.—Recovery of other metallic minerals from tailings of dredging operations was as follows, in tons: Columbite, 46; scheelite, 16; zircon, 3,129; and the rare-earth minerals monazite, 1,879, and xenotime, 139. In addition to small quantities of wolframite concentrate produced as a byproduct of alluvial tin operations, the major source of tungsten production is a wolframite lode in Pahang. Gold production in 1976 totaled 4,538 troy ounces. Gold was recovered as a byproduct of tin dredging operations at Batang Padang and Kuala Lumpur and from small-scale mining operations in the Raub area and the Bau District in Sarawak.

NONMETALS

Cement.—Malaysia's value-added in the construction sector increased 7% in 1976 and was expected to accelerate in 1977 because of increased residential construction and public sector building projects. Domestic resources of limestone, granite, and sand and gravel are abundant and assure a readily available supply for the construction industry. Cement production, however, increased 17% in 1976 to about 2.1 million tons. The bulk of the production was by companies in West Malaysia. The price of cement remained stable inasmuch as price increases were subject to approval by the Ministry of Trade. Moreover, the total supply of cement on a countrywide basis was adequate to meet the domestic demand.

During 1976, Tasek Cement Bhd. in Ipoh was completing an expansion program to double its production capacity to 1,040,000 tons per year at a cost of $24 million. When completed in early 1977, Tasek Cement would be the largest producer in Malaysia and one of the most advanced in Southeast Asia because of the installation of X-ray analyzing equipment, computerized process controls, and other technical innovations for energy conservation and environmental protection. Other cement production was as follows, in thousand tons per year: Associated Pan Malaysian Cement Sdn. Berhad, 750; Cement Industries of Malaysia Sdn. Berhad, 400; and Malaysia Industrial and Mining Corp. Berhad, 60. The Government approved two additional cement projects, Siemen Perak Sdn. Bhd. and Phang Cement Sdn. Bhd.

Fertilizer Materials.—During 1976, domestic production of nitrogenous, phosphatic, and potash fertilizers totaled 272,000 tons. Three of the more than twenty companies accounted for about 35% of the total production. In order to meet the domestic demand for fertilizers, about 400,000 tons of fertilizers was imported in 1976, consisting mainly of potassic fertilizers (45%), urea (21%), and composite, complex, and compound fertilizers (19%). The major suppliers of fertilizer materials were Christmas Island, Canada, the Federal Republic of Germany, Japan, and the United States.

To maintain reasonable prices for fertilizers, the Government introduced subsidy schemes and also included fertilizers in the essential commodities list under the Control of Supplies Regulations. Moreover, import duty exemptions were granted on all types of imported fertilizers except those produced locally; on these, a

protective import duty of about $18 per ton was levied.

Domestic demand for fertilizers was expected to increase at an annual rate of 3%. Domestic production was projected to increase 9% per year to 1978. During September 1976, Petronas initiated a feasibility study on establishing a urea project in Malaysia under the sponsorship of ASEAN's regional industrialization scheme. The study, to be completed in late 1977, centered on building a nitrogen fertilizer complex at Port Dickson that would have a capacity of 330,000 tons per year of nitrogen in ammonia and 304,000 tons per year of nitrogen in urea. Proposals to include production capacity for ammonium sulfate and nitrogen-phosphorus-potassium fertilizers were also included.

Other Nonmetals.—Production of crushed rock was about 11.3 million tons in 1976. The major producing States were Selangor, Johore, Pahang, and Perak. Crushed granite, most of which was used for road metal and concrete aggregate, constituted 68% of total production. The remainder was predominantly limestone, of which about 50% was used for road metal and concrete aggregate, 40% for cement manufacture, and 10% for various specialty uses. During the year, there were 100 granite quarries, 68 limestone quarries, and 21 unspecified quarries being worked in 11 States.

Sand and gravel production by 322 operations in 10 States totaled nearly 1.9 million tons in 1976. Almost all of the output was used as concrete aggregate. Perak, Johore, Penang, and Pahang, in that order, were the major producing States.

Kaolin production in 1976 was about 30,000 tons. Part of the output was consumed locally by the ceramic, paint, rubber, plastics, and pesticide industries; the remainder was exported to Japan and Singapore. Production of ball clay and common clay was not reported. However, domestic ball clay, obtained mostly from alluvial tin operations, was used with kaolin for manufacturing wall, floor, and mosaic tiles, and sanitary- and tableware. Common clay was used primarily in drainage and sewer pipes, flower pots, and similar uses.

Output of quartz sand and powder, primarily from sand deposits in Johore and from tin tailings operations, was 56,100 tons and 8,160 tons, respectively. Most of the quartz was used locally by the glass and ceramic industries, and some quartz sand was exported to Singapore. Barite production in 1976 was 6,096 tons, all from the Tasek Chini deposit in Pahang, which was estimated to contain 508,000 tons of barite. One plant in Selangor extracted feldspar from granite for use as a flux in the production of sheet glass.

MINERAL FUELS

Natural Gas.—As a result of the increase in crude petroleum production, output of associated natural gas averaged about 355 million standard cubic feet per day by August 1976. There is no commercial utilization of associated natural gas in Malaysia. Only about 20% was collected and used (15% consumed as fuel in exploration and production activities and 5% sold to Sarawak Electricity Supply Co. and to brick manufacturers in Miri, Sarawak). The remainder was simply flared.

Nonassociated natural gas fields occur offshore Sarawak and West Malaysia. Currently there is no commercial production from these fields. Petronas continued negotiations with Shell Oil Co. and Mitsubishi Corporation of Japan for construction and operation of a natural gas liquefaction plant to utilize gas from the Central Luconia Fields in Sarawak. If an agreement is reached, the $1 billion proposed plant would have an annual capacity of about 6 million tons of liquefied natural gas.

Petroleum.—Although 19 oilfields of commercial value have been discovered in the offshore areas of Sabah, Sarawak, and West Malaysia, only 8 were in production in 1976, producing a total of 60.5 million barrels during the year. Sarawak Shell operated six fields in Sarawak with a combined production rate of about 116,213 barrels per day in 1976 from West Lutong, Baram, Baronia, Tukau, Bakau, and Fairley Baram. The second largest producer, Sabah Shell, operating its only field at Samarang, was expected to increase its output from 27,500 barrels to 64,300 barrels per day by yearend 1976. Similarly, Exxon was expected to maintain the production rate at its Tembungo

Field of 11,300 barrels per day in 1977.

Exxon discovered promising oilfields in Pulai, Tapis, Bekok, and Siligi off the east coast of West Malaysia in the South China Sea, contracted the area, and signed a production-sharing agreement with Petronas in December 1976. Production from Exxon's new oilfields off the Trengganu coast was expected to come onstream in mid-1978 at an initial rate of 5,000 barrels per day.

Promising oil sites discovered by Continental Oil Company of Malaysia (Conoco) were at Sotong, Anding, and Duyong, which are situated a few miles to the south of Exxon's exploration areas. Duyong is the only natural gas field found to date off West Malaysia. Conoco has not contracted for a production-sharing agreement as yet, citing a need for further detailed study. Neither Conoco nor Exxon reported any operations in West Malaysia in 1976.

During the year, 10 exploratory wells and 41 development wells were drilled compared with 27 and 42, respectively, in 1975. Sarawak Shell drilled 5 exploratory wells and 23 development wells in East Malaysia, mainly in the Baronia and Tukau Fields. The company also conducted seismic surveys on land and offshore. On November 30, 1976, Sarawak Shell relinquished 37,036 square kilometers of onshore and offshore acreage.

Sabah Shell conducted a seismic survey and drilled five exploratory and appraisal wells offshore Sabah. The company also drilled 18 development wells in the Samarang Field. On November 30, 1976, Sabah Shell relinquished a small part of its acreage, the islands of Labuan and Gaya and their territorial waters.

Oceanic Group, Sabah Teiseki Oil Co., and Aquitaine Petroleum Co. (South East Asia) reported no activities in 1976; Aquitaine relinquished its acreage on August 11, 1976. With the prospect that Exxon's Pulai and Tapis Fields in West Malaysia would come into production by mid-1978 and the possibility of production from Sabah Shell's fields at Erb West in offshore Sabah, crude oil production in Malaysia was projected to reach 76.7 million barrels per year by yearend 1978.

The intake of crude oil by the three refineries in Malaysia (the Shell and Exxon refineries at Port Dickson and the Shell refinery at Lutong, Sarawak) averaged about 98,740 barrels per day. About 20% of the domestic production of crude oil was consumed locally for refining. The refinery at Lutong uses only local crude oil; the Port Dickson refineries were designed to refine feedstock in the ratio of 70% imported heavy crude oil to 30% locally produced crude oil. Moreover, the product mix of the output at the Port Dickson refineries meet more of Malaysia's demand, 45% of which was for middle distillates such as diesel fuel and kerosine. Additionally, Malaysia benefits from the export of local crude since this lighter grade commands a higher unit price. In view of the projected increase in domestic consumption of petroleum products, the Government planned to establish another refinery at the end of the Third Malaysia Plan.

The Mineral Industry of Malta

By Roman V. Sondermayer [1]

The mineral industry of Malta, a small country situated south of Sicily covering 122 square miles of islands, the largest of which are Malta and Gozo, consisted primarily of salt and limestone production during 1976. Its modest demand for fuels, construction materials, fertilizers, diamond, and metals was met through imports. The country's gross national product (GNP) for 1976, according to preliminary estimates, was $450 million. The value of output and employment in the extractive industry were not available. Unemployment was 4% and inflation was about 10% during 1976.

PRODUCTION AND TRADE

The 1974–76 trends in production of minerals in Malta are shown in table 1.

The value of mineral exports, mostly reexports of fuels for bunkering, was 15% of Malta's total exports. Domestic output of limestone and salt was significant only to the local economy. The value of mineral imports, mostly fuels, was 13% of the country's total imports, with Italy as the major supplier. The size of the country and its manufacturing industry limited demand for imported mineral products. Malta imports modest quantities of a variety of mineral commodities, mainly fuels for transportation and household use. Minor quantities of metals and nonmetals were imported to meet the demand of craft shops and the construction industry. The value of trade in mineral commodities in 1975 is shown in table 2.

[1] Physical scientist, International Data and Analysis.

COMMODITY REVIEW

Metals.—Small quantities of imported steel nonferrous metals were consumed by Malta's modest manufacturing industry. In addition, precious metals were consumed by jewelers, and several diamond cutters operated modest facilities.

Nonmetals.—*Stone.*—Limestone was produced in various locations on Malta and Gozo. The largest quarries were situated near the capital city of Valletta. Debono Enterprises Ltd., at St. Paul's Bay, was among the major quarry owners and operators. In addition to its use for construction, stone from Malta was used by skilled craftsmen for ornamentation because it is easily carved. Balustrades, stone carvings, and stone-turned objects were produced and sold as souvenirs. Calcite stone, after polishing, was used for lampstands and other household accessories.

Other.—Salt was produced in Salina Bay on the island of Malta. The possibility of building a cement plant was virtually abandoned during 1976 largely for environmental reasons. Lime was in short supply, and during the year a feasibility study for a lime plant, using local limestone, was underway to determine the economic aspects of such a venture. Where the plant would be located and results of the study had not been made public by yearend.

Mineral Fuels.—All fuels, both liquid and gaseous hydrocarbons, were imported. Liquid hydrocarbons, mostly petroleum refinery products, were used by the transportation sector, in the production of electricity, and in households. Two fuel oil-operated power stations, with a combined capacity of 115 megawatts, supplied electric power to the islands. Besides the electricity-generating facilities, the power station complex included four 1-million-gallon-per-day seawater distillers; the fresh water produced is pumped to the Luga and Ta' Qali water reservoirs. The powerplants and seawater distillers were operated by the Malta Electricity Board, a public corporation.

Liquefied petroleum gas (LPG) was also imported, and the Malta Gas Board operated an LPG bottling plant at B'Bugia, on Malta, with storage capacity for 800 tons of LPG. Plans were made to increase that capacity to 1,100 tons. The Board distributes gas cylinders by truck to individual households. For bulk deliveries of LPG, the Board has large truck tankers.

The idea of constructing a petroleum refinery was abandoned on the grounds of the adverse environmental impact of refinery operation on a small island. During 1976, no offshore wells were drilled; sea boundaries between Malta and other countries were not yet determined.

The Mineral Industry of Mexico

By Roland W. Merwin [1]

Mexico's gross domestic product (GDP) at current prices was $78,637 million,[2] compared with the revised GDP of $79,016 million in 1975. The mining sector contributed 0.9% in 1976, the same as the revised 0.9% in 1975, while the petroleum sector accounted for 5.1% compared with 4.8% in 1975.

Mexico's foreign exchange rate, which had been maintained at 12.50 pesos to the U.S. dollar since 1954, was allowed to float through September 1976. By yearend it had dropped to approximately 20 pesos to the dollar. During 1976 it averaged 15.45 pesos to the dollar. There was an inflation rate of approximately 20% in 1976.

Government Policies and Programs.—The trend toward greater Governmental control and ownership of the mineral industry continued. The rationale for this was the belief in Government circles that such a policy was necessary owing to the lack of private Mexican equity capital for developing the mineral industries, and to the disinclination of the Government to allow the entry of foreign equity capital, except on a minority basis, into Government-owned or -controlled corporations.

The new policies were outlined in the Mining Law of 1975 which fundamentally changed the Mining Law of 1961 as related to nonfuel minerals. Provisions of the new law were enumerated in the 1975 edition of this chapter. Most of the provisions encountered strong opposition from the private mining sector in Mexico, as represented by the Camara Minera de Mexico (CMM).

Following prolonged negotiations between the Government and CMM, the official regulations implementing the Mining Law of 1975 were issued in late November 1976. The regulations appeared to represent a compromise between the widely varying positions of the Government and CMM. However, it was thought that the method and degree of strictness of their enforcement would be much more important than the content of the law and its regulations. If the Government was intent on expanding its share of the mining industry, it would be able to virtually freeze the private sector out of future expansion.

A major policy decision facing the Government at yearend 1976 was the position to be taken on expansion of Mexico's petroleum industry. Petróleos Mexicanos, S.A. (PEMEX), the autonomous Government-owned organization having exclusive control over the Mexican petroleum industry from exploration through marketing, was in the process of developing very large reserves of crude petroleum and associated natural gas in the southern States of Chiapas and Tabasco, commonly referred to as the "Reforma trend." Informed authorities in Mexico have speculated that such petroleum reserves could exceed 30 billion barrels and could support exports of about 1 million barrels per day of crude oil, in contrast to current exports of approximately 150,000 barrels per day. Additionally, it was believed that the associated natural gas production would be large enough to support large exports of natural gas to the U.S. market.

At yearend 1976, it was becoming increasingly apparent that high levels of exports of crude petroleum, refined products, and natural gas would largely solve Mex-

[1] Supervisory physical scientist, International Data and Analysis.

[2] Where necessary, values have been converted from Mexican pesos (Mex$) to U.S. dollars at the rate of Mex$12.50=US$1.00 for 1975 and Mex$15.45=US$1.00 for 1976.

ico's pressing financial problems. PEMEX, on the other hand, stated in 1976 that the high reserve figure was not yet fully proved. Additionally, PEMEX would prefer to develop the region more slowly and, in effect, retain the prospective petroleum reserves for the nation's future industrial needs, rather than export a nonrenewable national resource for immediate financial gain. This is a basic philosophical difference that has long prevailed in Mexican Government circles as related to other minerals, and it appeared that it could only be resolved at very high Government levels.

PRODUCTION

Mexico's mining industry, exclusive of construction materials, has been largely based on the production of lead, zinc, silver, fluorspar, and sulfur. Lead, zinc, and silver mine output increased substantially over that of 1975. However, the production of fluorspar decreased substantially and there was virtually no change in the production of sulfur compared with that of 1975.

On the basis of preliminary data covering 18 metallic and 21 nonmetallic minerals, it was estimated that the production value of Mexico's mining industry decreased 6% from a revised $1,050 million in 1975 to $982 million in 1976. The apparent decline in mineral production value was accounted for by the devaluation of the Mexican peso. When stated in pesos the production value increased 15% over that of 1975.

Mexico's crude petroleum production rose to 267 million barrels in 1976 from 262 million barrels in 1975, an increase of 2%. The sales value of marketable products, including exports, decreased 7% from a revised $2,745 million in 1975 to $2,564 million in 1976. Again, the apparent decline in sales value was owing to the devaluation of the Mexican peso; in terms of local currency the sales value increased 17%.

Data on mineral production are shown in table 1.

Table 1.—Mexico: Production of mineral commodities

Table 1.—Mexico: Production of mineral commodities—Continued
(Metric tons unless otherwise specified)

Commodity [1]		1974	1975	1976 [p]
NONMETALS—Continued				
Stone, sand and gravel—Continued				
Quartz, quartzite, glass sand		513,984	518,973	509,029
Cobblestone		5,081	3,477	NA
Strontium minerals		29,545	14,722	22,157
Sulfur, elemental:				
Frasch process	thousand tons	2,257	2,074	2,054
Byproduct from natural gas	do	65	90	96
Total	do	2,322	2,164	2,150
Sulfates, natural sodium		148,271	300,121	228,025
Talc		2,649	1,480	192
Wollastonite		1,984	543	1,414
MINERAL FUELS AND RELATED MATERIALS				
Carbon black [e]		34,000	36,000	41,000
Coal, bituminous	thousand tons	5,166	5,193	5,650
Coke:				
Metallurgical	do	2,034	2,058	2,152
Imperial	do	17	12	21
Breeze	do	20	18	16
Total	do	2,071	2,088	2,189
Gas:				
Manufactured, all types		211,751	[e] 212,000	NA
Natural:				
Gross production	million cubic feet	744,673	786,469	771,785
Marketable production	do	560,911	583,885	577,934
Natural gas liquids:				
Field condensate	thousand 42-gallon barrels	29	50	[e] 50
Other	do	28,416	32,665	34,154
Petroleum:				
Crude	do	209,826	261,540	267,320
Refinery products:				
Aviation gasoline	do	409	522	565
Other gasoline	do	64,922	66,504	76,366
Jet fuel	do	5,734	5,275	6,179
Kerosine	do	12,882	12,956	13,444
Distillate fuel oil	do	50,226	55,376	59,075
Residual fuel oil	do	62,296	65,441	78,217
Lubricants	do	2,759	3,024	3,103
Other:				
Liquefied petroleum gas	do	18,439	18,819	20,278
Asphalt	do	4,725	4,115	3,690
Unspecified	do	4,653	4,555	1,471
Refinery fuel and losses	do	13,411	11,380	11,405
Total	do	240,456	247,977	273,793

[e] Estimate. [p] Preliminary. NA Not available.
[1] In addition to the commodities listed, lime, pumice, and additional types of crude construction materials were also produced, but output is not reported and available information is inadequate to make reliable estimates of output levels.
[2] Calculated white arsenic equivalent of metallic arsenic content of products reported.
[3] Calculated from reported metal content on the basis of ore containing 66.67% iron.
[4] Calculated from reported metal content on the basis of ore containing 36% manganese.
[5] Estimate by the International Tin Council.
[6] Excluding that for cement production.

TRADE

Mexican exports were valued at $2,992 million in 1976, compared with $2,715 million in 1975, an increase of 10%. In 1976, nonfuel mineral exports were valued at $340 million, or 11% of total exports. The principal contributers to this sector were zinc, lead, sulfur, and fluorspar minerals and products valued at $243 million. Exports of petroleum and petroleum products were valued at $557 million in 1976, or 19% of total exports.

Mexican imports were valued at $6,032 million in 1976, compared with $6,058 million in 1975. Mineral imports were valued at $893 million in 1976, or 15% of total imports. The principal mineral import items in 1976 were iron and steel scrap and castings valued at $393 million and petroleum products valued at $318 million.

Available data on mineral exports and imports are shown in tables 2 and 3, respectively.

Table 2.—Mexico: Exports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1974	1975 [1]	Principal destinations, 1975
METALS			
Aluminum:			
Oxide (alumina)	6	NA	
Metal including alloys, all forms	1,378	NA	
Antimony:			
Ore and concentrate, gross weight	6,587	8,288	United States 8,210.
Metal including alloys, all forms	98	275	United States 225; Italy 29.
Arsenic:			
Oxide, gross weight:			
White	5,328	3,255	United States 3,088; Brazil 109.
Black	(2)		
Speiss and similar materials, oxide content	72	NA	
Bismuth metal including alloys, all forms	838	405	United States 180; United Kingdom 106; Netherlands 51.
Cadmium:			
Concentrate and speiss, gross weight	660	NA	
Flue dust, metal content	462	369	All to United States.
Metal	441	444	United States 231; Brazil 96.
Copper:			
Ore and concentrate, gross weight	4,774	8,387	United States 4,829; Belgium-Luxembourg 3,558.
Copper sulfate	1,343	425	Brazil 338; United States 46.
Metal including alloys:			
Scrap	--	6	All to West Germany.
Unwrought and semimanufactures	14,551	12,137	United States 7,898; Japan 1,997; France 998.
Iron and steel:			
Ore and concentrate, gross weight	4	13,843	United States 13,501.
Metal including alloys:			
Scrap	327	2,500	All to United States.
Primary forms	--	316	Do.
Ferroalloys:			
Ferrosilicomanganese	--	182	NA.
Other	1,777		
Steel, primary forms	2	2,339	NA.
Semimanufactures	106,358	75,807	NA.
Lead:			
Ore and concentrate, gross weight	17,263	454	All to United States.
Oxides:			
Litharge	40,819	24,643	United States 11,558; Venezuela 4,004; Italy 1,813.
Red lead	3,377	1,503	United States 404; Brazil 288; West Germany 182.
Metal including alloys:			
Scrap	--	131	United Kingdom 55; United States 27; Canada 23.
Unwrought:			
Antimonial and other bars	5,348	3,352	United States 1,500; Netherlands 1,145; Venezuela 522.
Refined	108,104	97,955	Italy 30,377; United States 16,541; Brazil 13,165.
Semimanufactures	75	NA	
Manganese ore and concentrate, gross weight	264,695	194,091	Japan 151,001; United States 36,661.
Mercury ----76-pound flasks--	29,342	11,504	United States 6,289; Brazil 2,488; Argentina 1,120.
Nickel metal including alloys, all forms	6	NA	
Selenium:			
Elemental	20	42	United Kingdom 20; United States 18.
Matte, speiss, anode slimes, smelter residues	50	NA	
Silver:			
Ore and concentrate	18,922	32,140	NA.
Metal ----thousand troy ounces--	24,137	28,657	NA.
Tin:			
Ore and concentrate	--	5,550	All to United States.
Metal including alloys, all forms	17	(2)	All to Nicaragua.
Titanium oxide	--	71	Colombia 50; Ecuador 20.
Tungsten ore and concentrate, gross weight	349	3,053	United States 2,961.
Zinc:			
Ore and concentrate, gross weight	292,092	103,257	Netherlands 29,555; United States 28,544; Belgium-Luxembourg 13,624.
Oxide, white	11,606	6,908	United States 6,437.
Sulfate	7,351	3,060	United States 2,790; Canada 234.

See footnotes at end of table.

Table 2.—Mexico: Exports of mineral commodities—Continued

(Metric tons unless otherwise specified)

METALS—Continued			
Zinc—Continued			
Metal including alloys:			
Scrap	--	4,813	Japan 4,398; United States 414.
Powder	2,105	8,645	All to United States.
Unwrought	73,711	86,471	United States 33,636; Brazil 16,235.
Semimanufactures	348	NA	
Other nonferrous base metals:			
Ores, concentrates, and metallurgical residues, except scrap	3,489	73	United States 69.
Metals, all forms	83	310	United States 130.
NONMETALS			
Abrasives, natural, n.e.s.:			
Emery	2	1	Mainly to Ecuador and Costa Rica.
Pumice	20	55	All to United States.
Asbestos	7	2	All to Nicaragua.
Barite and witherite	148,351	113,675	United States 113,236.
Cement	187,679	NA	
Clays and clay products:			
Crude:			
Bentonite	43	56	United States 50; Honduras 5.
Fuller's earth and other earth	28,039	11,011	Peru 3,546; Brazil 3,170; Colombia 842.
Kaolin (china clay)	5	31	All to Colombia.
Other	263	335	Guatemala 197; Peru 68; Ecuador 35.
Products:			
Refractory	302	NA	
Nonrefractory	161,955	NA	
Diamond, industrial—carats	30,000	140,000	All to Switzerland.
Diatomite and other infusorial earth	15,505	3,364	Argentina 1,615; Brazil 526; West Germany 305.
Feldspar	709	40	All to Venezuela.
Fertilizer materials:			
Crude, phosphatic	5,239	257	All to United States.
Manufactured:			
Nitrogenous, including urea	31,076	NA	
Phosphatic	65,248		
Potassic	943		
Other, including mixed	729		
Ammonia	4,525		
Fluorspar:			
Acid grade	546,097	360,765	United States 307,051; Canada 53,327.
Metallurgical grade	531,049	478,204	United States 400,006; Canada 75,979.
Graphite, natural	58,429	46,657	United States 46,627.
Gypsum:			
Crude—thousand tons	1,227	585	All to United States.
Calcined—do	11	16	All to Belgium-Luxembourg.
Lime	591	1,389	All to United States.
Mica	--	51	Do.
Perlite	2,614	2,282	Cuba 509; Venezuela 482; Brazil 477.
Precious and semiprecious stones, except diamond—kilograms	358	4,728	Japan 4,657.
Salt—thousand tons	4,470	3,653	Japan 3,151; United States 376; Canada 125.
Sodium and potassium compounds:			
Sodium compounds:			
Sodium carbonate	599	NA	
Sodium hydroxide	5,949	4,466	Argentina 3,880; Brazil 349.
Sodium sulfate	85,946	117,273	Brazil 82,291; Venezuela 18,854.
Potassium compounds	5	NA	
Stone, sand and gravel:			
Dimension stone	10,236	NA	
Crushed rock	18,805	NA	
Limestone, dolomite, calcite	1,967	NA	
Quartz and quartzite	4,407	3,339	All to United States.
Sand:			
Construction	3,546	NA	
Glass	23,979	10,978	Guatemala 10,897.
Strontium minerals	27,164	15,028	United States 14,972.

See footnotes at end of table.

COMMODITY REVIEW

METALS

Aluminum.—Alúmino S.A. de C.V., with a smelter near Veracruz, was Mexico's only primary aluminum producer in 1976. Using imported alumina, the smelter had a rated capacity of 45,000 tons of aluminum metal per year, and was capable of producing approximately 40% of Mexico's domestic requirements. Previously announced plans to double the capacity of the smelter had not progressed past the planning stage at yearend 1976.

During the year virtually no progress was made on the Government's plans to establish a 120,000-ton-per-year aluminum smelter at Coatzacoalcos, Veracruz. As planned, the smelter would be a joint venture of the Mexican and Jamaican Governments with Kaiser Aluminum & Chemical Corp. providing technical assistance.

Copper.—The Government gave priority attention, including strong financial support, to the development of a major copper industry in Mexico during 1976. If all of Mexico's projected new copper capacity were to come onstream as scheduled, Mexico's copper production would rise from 90,000 tons in 1976 to 500,000 tons in 1982, making Mexico one of the world's leading producers of copper.

Cía. Minera de Cananea S.A. de C.V., the nation's largest producer, completed an expansion program during 1976 which raised its capacity from the previous 40,000 tons of copper per year to 70,000 tons per year, and was planning to increase its capacity to 140,000 tons per year by 1982.

At yearend 1976, the Government-controlled Cía. Mexicana de Cobre, S.A., in which Industrial Minera Mexico S.A. (IMM) has a substantial minority interest, was well advanced on its programs of mine stripping and concentrator construction at its La Caridad mine at Nacozari, Sonora. Initial mining and milling operations at the rate of 140,000 tons of copper per year are scheduled for the spring of 1978. The ultimate capacity will be 250,000 tons of copper per year. La Caridad's copper-smelting and electrolytic-refining facilities at Empalme on the Gulf of California are scheduled for initial operations in early 1979.

In a closely related development, IMM was engaged in feasibility studies leading toward the development of the El Arco mine located near Guerrero Negro in Baja California across the Gulf of California from Empalme. In anticipation of the development of what appeared to be a major copper deposit at El Arco, the La Caridad smelter at Empalme was being built of sufficient size to treat concentrates from both La Caridad and El Arco.

Iron and Steel.—The year 1976 was a disappointing one for Mexico's iron and steel industry. At yearend, the installed steel ingot capacity was 9.9 million tons, whereas steel ingot production in 1976 remained virtually unchanged from that of 1975 at 5.3 million tons. As a result, most of the ambitious plans for expansion of the Mexican steel industry were deferred until conditions improved.

The Government-owned Cía. Siderúrgica Lázaro Cárdenas-las Truchas, S.A. (SICARTSA) in the State of Michoacán on the Pacific coast completed the first stage of construction, giving the firm an initial production capacity of 1.3 million tons per year of steel ingot. Construction continued on the second stage of the project which is designed to raise capacity to 3.65 million tons per year by 1980.

Lead and Zinc.—Industrias Peñoles, S.A., completed construction of a new lead smelter and refinery at Torreón, Coahuila, which had a capacity of 190,000 tons of lead per year. It will also produce gold and silver as byproducts.

IMM completed expansion and modernization programs at three of its major mines in Mexico. At the San Martin, Zacatecas, zinc-copper mine, production capacity increased 85%, and at the Charcas, San Luis Potosí, mine, lead and zinc capacity was increased 30%. The first phase of the expansion program at the Santa Barbara lead-zinc mine in Chihuahua was completed at yearend 1976, increasing ore production 25%.

Lead and zinc smelting and refining charges, which are set by the Government, were being reviewed to determine what new rates should apply in view of the devaluation of the peso, sharply increased electricity costs, and other cost increases. The study is expected to be completed in mid-1977.

Manganese.—Cía. Minera Autlan, S.A. de

C.V., completed construction work on its new high-carbon ferromanganese alloy plant at Tomas, Veracruz, reported to be one of the largest plants of its type in the world. In addition, it proceeded with a large-scale expansion program at its mine in Molango, Hidalgo.

Silver.—Although total silver production was below the projected goal, Mexico ranked as the world's leading silver producer in 1976. Industrias Peñoles, from its various holdings, accounted for most of the 42.6 million troy ounces produced.

Cía. Minera Las Torres began milling output from the Las Torres group of mines at Guanajuato, 400 kilometers northwest of Mexico City. This mining operation is owned by Industrias Peñoles (33%), Cía. Minera Fresnillo S.A. (37%), and Lacana Mining Corp. (30%). In 1976, mine output was 4 million troy ounces of silver and 40,000 troy ounces of gold. There are an estimated 4.3 million tons of proven and probable ore reserves grading 11.2 troy ounces of silver and 0.07 troy ounce of gold per ton.

A flotation plant of 1,200-ton-per-day capacity at Lacana's and Industrias Peñoles' Encantado mine at Coahuila should be operational in 1977. The Encantado mine has estimated proven and probable ore reserves of 3.2 million tons grading 13.2 troy ounces of silver and 7.6% lead per ton.

NONMETALS

Cement.—Despite the almost complete lack of growth in the construction industry, 1976 was a satisfactory period for Mexico's cement industry, largely because intensified export promotion efforts met with considerable success. Installed capacity at yearend 1976 was 13.6 million tons per year compared with 13.5 million tons at yearend 1975. Production during 1976 was approximately 92% of rated capacity. Almost all major plants within the industry were involved with additional capacity projects in 1976, even though the cost of these projects has been increased sharply by much higher prices for foreign-produced machinery following the devaluation of the peso.

Fertilizer Materials.—*Phosphate Rock.*—The Government-owned Roca Fosfórica Mexicana, S.A., in close cooperation with Consejo de Recursos Minerales, continued to make good progress in its programs to develop promising phosphate rock deposits in Baja California. Drilling has delineated deposits containing an estimated 600 million tons of ore with a geologic probability of additional tonnage in the immediate area. As much of the ore lies underground, a variety of underground mining methods were being experimented with to determine the best methods to be utilized. Investigations continued on the metallurgical treatment of the ore, with a small pilot-plant being installed in the latter part of 1976.

Fluorspar.—Mexico maintained its position as the world's largest producer of fluorspar and the major source of supply to the U.S. market. However, both production and exports declined sharply from those of 1975, because of reduced demand in the U.S. market.

The leading producers in 1976 were IMM, Industrias Peñoles, Minera Frisco S.A., La Dominica S.A. de C.V., and Minera Continental, S.A., all of which were private enterprises with foreign capital participation on a minority basis. Together they accounted for approximately 83% of the output in 1976. Despite the slowdown in demand, they were all proceeding with long-range plans for expansion. A large number of small miners accounted for the remaining 17% of the output in 1976.

The Instituto Mexicano de la Fluorita (IMF), in cooperation with the Government, was engaged in programs to improve the position of the fluorspar industry. Under one program, technical and financial assistance were being provided to smaller producers. Under a program to improve customer acceptance, considerable attention was being given to the briquetting and/or pelletizing of fluorspar products as the most acceptable form for steelmaking operations in the U.S. market.

Sulfur.—Production at Frasch-type operations did not vary greatly from that of 1975. However, sulfur exports dropped about 25% to 1 million tons in 1976 as a result of a sharp decline in world demand.

MINERAL FUELS

Coal.—Consejo de Recursos Minerales initiated a program of geologic mapping and drilling designed to delineate and characterize Mexico's extensive coal resources in the State of Coahuila in north-

ern Mexico. The main purpose of the study was to develop coal reserves that could be used for power generation by the Comisión Federál de Electricidád, the Government agency responsible for all electric power generation in Mexico.

Petroleum.—PEMEX had a very successful year. Not only did production increase substantially over that of 1975, but officially announced proven reserves increased from 5.3 billion barrels at yearend 1975 to 11.2 billion barrels at yearend 1976.

The improvement in the position of the Mexican petroleum industry continued to be largely based on the development of the Reforma trend region in southern Mexico. First brought into production in 1972, the Reforma trend is now recognized as one of the large petroleum provinces of the world, the extent of which had not yet been fully delineated. Including new fields discovered in 1976, the proved onshore producing area in the Reforma trend now stretches some 50 miles from south to northeast and 35 miles from east to west at the widest point. Additionally, an offshore development in late 1976 appeared to indicate that the Reforma trend would extend into the Gulf of Campeche.

At yearend 1976, approximately 100 producing wells in four fields in the Reforma trend were producing at the rate of 515,000 barrels per day. Of these fields, only one had been completely developed to the full production stage, while the other three were in the process of being fully developed. Thirteen other proven structures had only the discovery well and no production handling infrastructures.

Although the major portion of PEMEX's exploration and development efforts were related to the development of the Reforma trend region, other areas in Mexico continued to receive considerable attention. In one development of considerable interest, the drilling of a producing gas well in Baja California identified a new hydrocarbon zone in this area.

PEMEX completed 79 exploration wells in 1976 compared with 87 wells in 1975. Of these wells, 14 produced oil, 11 produced gas, and 54 were dry. PEMEX drilled 257 development wells in 1976 compared with 226 wells in 1975. Of these, 157 produced oil, 43 produced gas, and 57 were dry. Of the total development wells, 112 were in the Reforma trend area and were completed to an average depth of 10,500 feet.

PEMEX's installed primary refining capacity at yearend 1976 was 865,000 barrels per day compared with 785,000 barrels per day at yearend 1975. The primary refinery throughput averaged 737,500 barrels per day in 1976, an increase of 12% over that of 1975. At yearend 1976, plant additions and refinery construction were in progress to raise Mexico's primary refining capacity to approximately 1.5 million barrels per day.

The Mineral Industry of Morocco

By Janice L. W. Jolly [1]

The mineral industry of Morocco contributed about 4.4% to the gross domestic product (GDP) of 1976. Valued at $4.3 billion [2] in current prices, the GDP showed a real growth of 10% over that of 1975. Agriculture, Government investment, industry, and commerce were responsible for this growth, the largest since 1971. Revenues from phosphate and other minerals were down, with general mineral output stagnant. Morocco's ambitious investment plans, combined with rapidly expanding contract authorizations for future projects, continued to offer opportunities for foreign business. The Moroccan Investment Code continued to offer inducements to firms willing to accord local partners at least half ownership plus board chairmanship. In priority sectors such as mining and export industries, 100% foreign ownership was authorized.[3]

A significant event during the year was the acquisition of the Bu Craa phosphate deposits in Spanish Sahara. Following publication of an ambiguous advisory opinion on Spanish Sahara by the International Court of Justice in October 1975, the "Green March" of 350,000 unarmed Moroccan civilians took place into the Spanish colony. Spurred on by this development, the Spanish, Moroccan, and Mauritanian Governments signed an agreement on November 14, 1975, creating a tripartite administration for Spanish Sahara with final Spanish withdrawal slated for February 28, 1976. On April 14, 1976, the two remaining administrators implemented their claims to sovereignty over the area by dividing the territory between them. The northern two-thirds, which included the Bu Craa deposits, went to Morocco. The division was being actively contested by the Polisario Front and its political arm, the Saharan Democratic Arab Republic, with Algerian support. The ensuing conflict effectively stopped Bu Craa phosphate exports, although some mining continued.

The year 1976 was the 4th year of the current 5-year plan and many projects inaugurated as part of this plan were completed or nearing completion. Virtually all of them augmented infrastructure and represented potential for improving commerce. Important current projects included a steelmill complex at Nador, a petrochemical complex at Mohammedia, a chemical complex at Safi, and the extension of the oil refinery at Mohammedia. Construction of new ports at Nador and El Jorf Lasfar were underway. Construction of three powerplants and installation of six gas turbines and four power units began in 1976. A study was being made for a new railway to the south, linking Marrakech with Agadir and El Ayoun.

The Moroccan agency Direction des Mines et de la Geologie et de l'Energie and Hunting Geology and Geophysics Ltd. signed a contract for airborne and ground geophysical surveys over southern Morocco. The survey area included the western High Atlas, the Anti-Atlas, Jebel Sarhro, and Jebel Siroua. The project area covered about 165,000 square kilometers and would require a total of approximately 80,000 line-kilometers of flying. Of this, approximately 54,000 line-kilometers were to be flown with a high-sensitivity Geometrics G 803 proton magnetometer, and

[1] Physical scientist, International Data and Analysis.

[2] Where necessary, values have been converted from Moroccan dirhams (DH) to U.S. dollars at the rate of DH4.40=US$1.00.

[3] U.S. Embassy, Rabat, Morocco. State Department Airgram A-10, Jan. 24, 1977, 8 pp.

the remaining 26,000 line-kilometers were to be flown with both high-precision magnetometry and gamma ray spectrometry. All the data resulting from the surveys were to be compiled and interpreted by Hunting. A Japanese group was working in the Anti-Atlas, and the United Nations Development Program (UNDP) completed a survey program. Particular attention was being paid in these surveys to stratiform copper mineralization and lead-zinc deposits. Other projects contemplated for the near future were preparation of mineral maps at a scale of 1:500,000 and metallogenic maps at a scale of 1:1,000,000; a study of apogranitics and associated mineralization; and geologic and metallogenic studies of the Upper Moulouya Valley, the southern border of the Middle Atlas, the Oriental Rif, the Horst Region, and the Jebilet. High priority was being given to research for new sources of energy such as oil shale, lignite, geothermal, and uranium.[4] The Bureau de Recherches et de Participations Minières (BRPM) was also exploring for mercury and magnesium minerals in the "pre-Rif" area.

PRODUCTION AND TRADE

Mineral production, excluding petroleum, natural gas, and cement, was valued at $611.4 million in 1976. Phosphate rock accounted for 87% of the total value received, lead concentrate 3.3%, anthracite 2.4%, manganese ore (chemical grade) 1.5%, iron ore 1.1%, cobalt concentrate 0.8%, and zinc concentrate 0.7%. Petroleum production was down from the 1975 level, with 8,900 tons (approximately 62,300 barrels) produced in 1976.[5]

The principal exports were phosphates and lead, and the main imports were crude petroleum, industrial machinery and equipment, and iron and steel products. The trade deficit for 1976 was estimated at $1.4 billion, about 34.6% higher than that recorded for 1975. The principal cause of the deficit was the continued low receipts for phosphate exports. Imports were valued at $2.6 billion in 1976 and exports were valued at $1.2 billion. As during most of the preceding years, the United States continued as the second largest supplier to Morocco after France, closely followed by West Germany. In 1976, with $297 million of exports to Morocco, the United States accounted for 11.4% of Moroccan imports. Morocco exported manganese to the United States.

Although phosphate fertilizer markets remained relatively depressed throughout 1976, there was a marked improvement over those of 1975 as both phosphate rock and triple superphosphate exports increased and fertilizer consumption returned to its 1974 level. The massive 1974 escalation in phosphate rock prices by north African producers to about $65 to $70 per ton had an immediate and dramatic effect on world consumption. Most European countries cut usage about 20%, as did India and other developing countries. Market forces soon prevailed, however, and the prices were down to about $36 to $40 per ton f.o.b. Casablanca by 1976. During this period, as U.S. sources became available at lower prices, the European market became dislocated as plants closed down, and there was a shift from a position of net exporter to net importer of fertilizers. By 1976, as prices were forced down, European buyers were also increasing Moroccan imports. Even so, substantial surpluses of phosphoric acid, phosphate rock, and sulfur were being forecast up until 1981 and beyond.[6]

Although phosphate rock exports for the first half of 1976 were below those of 1975, the total for 1976 was 15.6 million tons, an improvement of 5% over 1975 phosphate rock exports. Revenues, however, were still below those of the peak 1974 year. The major proportion of the year's export sales were of Khouribga 70% to 72% tricalcium phosphate ($Ca_3(Po_4)_2$ or BPL) rock, followed by Khouribga 75% BPL. Bu Craa was among the major producers in 1975, with export sales reaching 2.7 million tons. However, Bu Craa phosphate rock exports fell drastically to 277,000 tons in 1976 and were derived mostly from production stocked at El Aaiún. Japan was a major customer for

[4] U.S. Embassy, Rabat, Morocco. State Department Airgram A-14, Feb. 7, 1977, 6 pp.
[5] Bulletin Mensuel (Morocco). Mineral Production. Nouvelle Serie No. 89, May 1977, p. 3.
[6] European Chemical News (London). Supply Glut Overhangs Phosphate Industry Despite Market Upturn. V. 30, No. 791, June 17, 1977, pp. 6, 29.

Moroccan phosphate rock as were Brazil and Mexico. European customers, however, were the heaviest buyers and included Belgium, France, Italy, Spain, the United Kingdom, Romania, Yugoslavia, West Germany, and the Netherlands.[7]

Moroccan triple superphosphate exports increased 86% in 1976 over those of 1975. The improvement was attributed to the contributions of the new sulfuric and phosphoric acid facilities at Maroc Chimie II. West Germany was the single largest European buyer with 27,100 tons out of a total of 49,500 tons exported to Europe. Burma was also a large customer with 28,200 tons, as was Brazil with 21,000 tons. Other important buyers included Hungary, Yugoslavia, Bangladesh, Japan, and Australia.

About 75% of the aggregate phosphate rock exports was shipped from Casablanca where the terminal had a storage capacity of 400,000 tons with compartments for four grades of rock: Khouribga 70% to 72% BPL, calcined, 80% to 82% BPL, and 75% to 77% BPL. A modernization and expansion program was continued, making it possible to allow all grades to be loaded simultaneously on vessels. Products associated with the Maroc Chimie fertilizer complex and Youssoufia phosphate mining moved through the port at Safi where work was proceeding on storage and handling facilities for two grades of phosphate rock —the 70% to 72% BPL and the 73% to 75% BPL calcined material. Activity was expected to grow at Safi accompanying increased production from Youssoufia, expansion of the Maroc Chimie fertilizer complex, and construction at Safi of two phosphoric acid/monammonium phosphate (MAP) plants (Maroc Phosphore I and II), the output of which was to be almost entirely exported. The loading capacity of the terminal was to be increased to 10 million tons per year. Construction of a third phosphate shipping terminal in the Doukkala region was also planned.

Fuel briquets [e]	6,000	6,000	6,000
Gas, natural:			
Gross production ——million cubic feet	[r] 2,841	2,501	1,730
Marketed ——do	[r] 2,084	[r e] 2,000	[e] 1,500
Petroleum:			
Crude oil ——thousand 42-gallon barrels	191	171	62
Refinery products:			
Gasoline ——do	2,932	3,123	3,177
Jet fuel ——do	934	983	594
Kerosine ——do	574	754	1,050
Distillate fuel oil ——do	4,884	4,875	5,506
Residual fuel oil ——do	6,214	7,114	7,524
Other ——do	[r] 1,726	1,267	1,499
Refinery fuel and losses ——do	[r] 988	1,157	1,331
Total ——do	[r] 18,252	19,273	20,681

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the commodities listed, Morocco also produces manufactured phosphate fertilizers and a variety of crude construction materials, but available information is inadequate to make reliable estimates of output levels.

[2] Estimate by International Tin Council.

Table 2.—Morocco: Exports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1974	1975	Principal destinations, 1975
METALS			
Aluminum metal including alloys, all forms	566	458	Senegal 127; Mali 104; Netherlands 101.
Antimony ore and concentrate	4,084	3,102	Yugoslavia 1,248; United Kingdom 1,013.
Cobalt ore and concentrate	14,547	13,144	France 9,144; People's Republic of China 4,000.
Copper:			
Ore and concentrate	17,586	8,511	Belgium-Luxembourg 4,317; West Germany 2,194.
Metal including alloys, all forms	1,433	354	Spain 191; Netherlands 60; West Germany 26.
Gold waste and sweepings—troy ounces	--	64,301	All to United Kingdom.
Iron and steel:			
Ore and concentrate	10,200	213,920	Poland 55,900; Switzerland 50,330; Czechoslovakia 22,000.
Roasted pyrite	530,297	79,745	East Germany 28,970; West Germany 20,375; Switzerland 15,000.
Metal:			
Scrap	79,800	28,972	Spain 23,968; Italy 3,598.
Ferroalloys	661	297	All to West Germany.
Semimanufactures	1,077	59	Mainly to Senegal.
Lead ore and concentrate	125,905	74,762	West Germany 15,999; Spain 13,321; Belgium-Luxembourg 11,494.
Manganese ore and concentrate	164,940	110,960	United States 24,304; France 22,951; West Germany 14,398.
Silver metal including alloys value, thousands	$82	$278	Switzerland $128; United Kingdom $80; Belgium-Luxembourg $70.
Zinc:			
Ore and concentrate	26,449	26,499	France 12,042; Netherlands 6,817; United Kingdom 2,695.
Oxide	10,293	4,132	All to France.
Metal including alloys, all forms	50	24	Do.
Other:			
Ores and concentrates	31,856	1,290	Mainly to France.
Ash and residue containing nonferrous metals	430	511	All to France.
Oxides, hydroxides, peroxides of metals, n.e.s	8	10	Algeria 5; Libya 4.
NONMETALS			
Barite and witherite	81,686	122,170	United States 76,850; United Kingdom 11,001.
Clays and clay products (including all refractory brick):			
Crude clay, n.e.s.:			
Bentonite	--	1,000	All to Nigeria.
Fire clay	7,472	3,761	NA.
Fuller's earth	22,142	23,216	Spain 17,646; Tunisia 4,373.
Other	(1)	--	
Products:			
Refractory (including nonclay bricks)	5,624	6,168	Iraq 1,983; Lebanon 842; Portugal 745.
Nonrefractory [2]	462	188	NA.
Fertilizer materials:			
Crude phosphatic—thousand tons	18,700	13,110	Poland 1,662; Italy 1,258; Belgium-Luxembourg 1,254.
Manufactured:			
Nitrogenous	--	262	All to Mauritania.
Phosphatic	131,673	87,045	Indonesia 35,125; Hungary 20,000; Brazil 10,500.
Fluorspar	5,500	29,295	Mainly to France.
Gypsum and plasters	181,240	197,956	Nigeria 69,734; Ivory Coast 30,852; Portugal 23,800.
Lime	225	47	Mauritania 20; Gibraltar 10.
Pigments, mineral, including processed iron oxide	1,704	(1)	All to France.
Precious and semiprecious stones, natural and manufactured—value, thousands	$2	$3	France $2.

See footnotes at end of table.

COMMODITY REVIEW

METALS

Cobalt.—Production came from the Bou Azzer mine in southern Morocco, owned 55.25% by the French firm Omnium Nord Africain, 35% by the BRPM, 5.5% by the Omnimines group and 4.25% by others. Ore reserves were estimated at 28 million pounds of cobalt metal and total identified resources, at 30 million pounds. In 1976, 7,185 tons of cobalt concentrate was produced, compared with 14,007 tons in 1975.

Copper.—World market prices were barely sufficient to cover production costs at the seven operating copper mines that included the Bou Skour, Ouansimi, and Tazalaght copper mines. New equipment and development plans were being delayed. Copper production fell from 17,970 tons of concentrate in 1975 to 16,380 tons of concentrate in 1976. The production of high copper ore at Assif Imider was planned for 1977, and development of the Bleïda area near Zagora was in progress. The Oumejrane mine, located near Ouarzazate, was expected to produce 1,800 tons per year of cement copper (80% copper) by yearend 1977. Reserves at Oumejrane were estimated at 180,000 tons of 1.8% copper.

Iron Ore.—Production of iron ore by the Société d'Exploitation des Mines de Fer du Rif (SEFERIF) from the mine near Nador decreased significantly to 342,763 tons in 1976, compared with 554,000 tons produced in 1975. Approximately 1,500 workers were employed at the mine. In early 1976, the Société Nationale de Sidérurgie (SONASID) was created and first bids for the steel compex at Nador were issued. The first awards were expected in 1977. Plans called for the plant to begin operation in 1980 or 1981. Plans to establish a $9.3 million iron plant at El Jadida, designed to produce from 100,000 to 120,000 tons per year, were also being made.[8]

Lead and Silver.—The lead smelter at Oued El Heïmer was opened and in 1976 produced 26,379 tons of lead metal and 12,950 kilograms of silver as a byproduct. Consideration was being given to the construction of a new foundry in Meknès with expected production of 65,000 tons per year of lead. Compagnie Minière de Touissit was expected to expand the capacity of its two mines (Beddiane and Oued Mekta) in the Oujda region starting in 1977. The capacity was to be raised from 600 tons to 900 tons per day. Production facilities of the lead-zinc mine at Dra-Sfar near Marrakech were improved in early 1976. Two new veins of major importance were reported in Tétouan Province, and new lead and zinc reserves were also being reported at the Bou Azzer, Touissit, Bou Skour, and Zeïda mines. Exploration was being conducted by the BRPM near Debdou (northeast and south of Oujda), at Tizert, Tirzi, Allous, Assif, Imider, and Naour.

Manganese.—Chemical-grade manganese production for 1976 was 117,304 tons, compared with 131,000 tons for 1975. Production of metallurgical-grade manganese had stopped completely. Most production was derived from the Imini mine operated by the BRPM and Société Anonyme Chérifienne d'Études Minière (SACEM).

Pyrrhotite.—Pyrrhotite was still being produced from the Kettara mine located near Marrakech, but production fell sharply from the 203,789 tons produced in 1975 to 76,242 tons in 1976. The mineral was used as a source of sulfur for the Safi chemical complex.

Uranium.—Three U.S. companies, Gulf Oil Corp., Westinghouse Electric Corp., and the Uranium Recovery Corp., were inquiring into possibilities of uranium recovery from Moroccan phosphate rock. Uranium reserves contained in Moroccan phosphate had been estimated at 18 million tons.[9] Increasing uranium prices of over $40 per pound were offering the phosphate industry a more attractive opportunity to recover uranium as a byproduct of fertilizer manufacture. An independent research organization recently estimated the cost of recovering uranium from phosphoric acid at about $15 per pound by one of two solvent extraction processes. Developed by the Oak Ridge National Laboratory in Oak Ridge, Tenn., these processes both conserve a fuel resource and remove a radioactive fertilizer contaminant.[10] Uranium exploration was also being carried out by the BRPM.

[10] Chemical Engineering. Recovering Uranium From Wet-Process Phosphoric Acid. V. 84, No. 1, Jan. 3, 1977, pp. 56–57.

Morocco announced its desire to build a nuclear powerplant in order to meet its needs for electric power. Such a project was considered all the more necessary by the Government since a sufficient supply of uranium at a low cost was now being speculated from phosphates.

Zinc.—Zinc oxide production increased at the Zellidja mine in eastern Morocco as a result of a new tailing flotation plant, built by Société des Mines de Zellidja. Tailing retreatment began in early 1976. A Marconaflo system was selected for remining of the tailing pond. A static, or bridge-mounted, caisson was chosen to remine the slimes, which were too soft to support vehicles, and two skid-mounted caissons were used to remine the sand portion. During the first 40 days of operation, each of the skid caissons remined and pumped 65,000 tons of tailing. At the mill, after desliming at 11 microns, about 65% sand and 35% slime were mixed to make a 35% to 38% weight flotation feed.[11] An agreement between Zellidja and a miners cooperative, CADET, was being studied for the construction of a transformation plant for calamine and manufacture of zinc oxide. An agreement was signed in February 1976 between the BRPM and Zellidja for the joint operation of the lead-zinc-gold-pyrite mine at Bou Maadene, as well as for the beneficiation of precious metals at Ksar es Souk and for the recovery of barite at the lead mine in Zeïda.

NONMETALS

Cement.—A $4.1 million contract was signed with the Blue Circle Group of the United Kingdom for supervisory services in connection with building the cement plant at Mediouna, south of Casablanca. The plant was to take 4 years to build and was to have a 1-million-ton-per-year capacity. Construction contracts were to be awarded in 1977. Blue Circle was also involved in work on a similar plant at Oujda. Total cost for plant hardware was estimated at $100 million. Despite a 6% increase in cement production between 1974 and 1975, imports of about 400,000 tons of cement were still needed in the first half of 1976.

In August 1976, a new cement factory in Marrakech owned by Ste. des Ciments de Marrakech S.A. began operation and was expected to produce 500,000 tons annually by 1978. A $66.6 million cement plant was also being built by Blue Circle (Cimenterie de l'Oriental) near Oujda with a 1-million-ton-per-year capacity, and another was planned to be built near Rabat with a 625,000-ton-per-year capacity.

Together with other projected plants, these should cover Morocco's cement needs by 1985. By that date it was projected that Morocco's domestic needs would be 10 million tons of cement annually. Morocco hoped to build a total of 12 more cement plants by 1985. Asmet de Temara S.A., the plant planned for Temara, located south of Rabat, purchased about $26 million in equipment from the United States. A new society, the Société Nationale des Materiaux de Construction (SNMC), was organized during 1976 to work with the private sector in developing a national cement plan.[12]

Fluorspar.—The fluorite mine at El Hammam near Meknès, operated by Société Anonyme d'Entreprises Minières (SAMINE), further increased its production to 51,450 tons, an increase of 8.5% over the 1975 output. Reserves were estimated in 1974 at 5 million tons of 50% CaF_2 ore.

Ore reserves of 665,000 tons were established for the Zrahina fluorite-barite deposit and for the newly discovered Rouif vein by the West German geological mission from the Federal Institute for Geosciences and Natural Resources. The ore contains 34.8% fluorite, 14.1% barite, 1.9% lead, and 60 grams of silver per ton. The BRPM was starting preparations for mining.[13]

Nitrates.—An agreement was concluded between the Moroccan Office for Industrial Development and the consulting Agency for Production and Energy to provide the Office with consultancy services to set up the first ammonium nitrate project in Morocco. The industrial complex will include nitric acid and ammonium nitrate units to manufacture fertilizers and explosives. Operations were expected to start up by 1980.

[13] Federal Institute for Geosciences and Natural Resources. Activity Report 1975/1976 (Hannover, West Germany). Morocco. April 1977, p. 49.

Phosphates.—Of the 15.7 million tons of phosphate rock produced in 1976, 8 million tons came from Khouribga strip mining, 4 million tons from underground workings near Khouribga, and 4 million tons from the mining operations at Youssoufia. About 1.5 million tons went into local production of phosphatic chemicals for export.

The three principal phosphate bearing regions of Morocco are the Oulad Abdoun Plateau, the Gantour Plateau, and the Meskala region, which together have reserves estimated at more than 40,000 million tons of crude phosphatic rock.

The Oulad Abdoun Plateau is divided into three sections: Khouribga-Oued Zem, presently under exploitation; Sidi Hajjaj, to the west, where mining will start in 1985; and Sidi Chenane and Kasba Tadla, extending northward along the Atlantic coastline. The Gantour deposits comprise the following sections extending eastward from Youssoufia: Youssoufia, presently exploited; Benguerir, where production was scheduled for 1977; Djenane El Kheil-Ouata; Nzalet El Harareha; and Tassaout. Meskala is located south of Youssoufia between Essaouira and Marrakech and was under study for future exploitation. Production at Meskala was scheduled to start in 1986. A sizable deposit is also located south of the High Atlas range which did not appear to be economically viable at the present time.

The Khouribga deposit extends over 4,000 square kilometers and consists of four individual phosphate beds. Until 1970, mining was limited to Bed I, occurring at depths up to 40 meters; work on Bed II started at the end of that year near Oued Zem. The possibility of exploiting Beds 0 and III were under consideration. Both underground and opencast mining operations were used. There were four underground mines: Recette II, Recette VII, Recette VIII, and Recette IX. Recette IX production was being phased out. The two principal open pit mines were Sidi Daoui and Mera al Arech. A new open pit was located at Recette IV, between Sidi Daoui and Mera al Arech. Beneficiation was carried out at the following facilities: Drying plants at Beni Idir, Khouribga, and Oued Zem; a washing plant at Kerkour Rih; a washing plant for the beneficiation of Bed II ore from Sidi Daoui; and two pilot plants consisting of a calcining unit and a dry-separation unit, each with 400,000-ton-per-year capacity. A new drying plant was under construction at Oued Zem.

At Khouribga, the "Grand Daoui" project was aimed at bringing the aggregate capacity of opencast operations to 10 million tons per year. Construction of a complete handling and storage system was planned. A screening unit and a 15-kilometer conveyor belt system were to bring Sidi Daoui rock to the beneficiation plant at Beni Idir. A 3-million-ton-per-year washing plant and facilities for handling and storage were planned, along with expansion of the Beni Idir complex to 10-million-ton-per-year capacity and a new mining site where an underground operation (Block 8) was to be opened, replacing Block 6.

The Youssoufia deposit, located 70 kilometers east of Safi, was initially brought into production in 1931. Development of the extensive dark phosphate reserves was recently initiated. The project involved a 65-million-ton portion of these reserves which lies beneath the water table. About 70% of the ore mined at Youssoufia was from underground mines. Plans for improvement at Youssoufia during the Office Chérifien des Phosphates (OCP) 1973–77 plan included construction of a new mining site at Recette V, construction of a 10-kilometer conveyor belt line and erection of a handling and storage facility adjoining the drying plant. Development of large-scale projects such as the new mining operations at Benguerir and Sidi Hajjaj were expected to start showing results during the 1978–82 plan. Present Government plans estimate a startup date for Sidi Hajjaj of 1985 with 3 million tons per year, but Benguerir would come onstream first with 8 million tons per year. Plans for Sidi Hajjaj included shipping to the port for processing there. A new port must be built at El Jorf Lasfar as well as a railroad to the port. The ore was to be first processed in saltwater and afterward washed in fresh water.

A new phase of activity was started with OCP's 1973–77 expansion of production at the Safi fertilizer complex from 345,000 tons to 900,000 tons per year. The fertilizer complex at Safi was first brought into production by Maroc Chimie I in June 1965. The production expan-

sion was to be achieved through three main developments, progressing as follows: (1) Addition of the new PK–NPK fertilizer plant Maroc Chimie II, which was commissioned in April 1974 and progressed to 100% installed capacity by 1976; (2) improvement of existing facilities, with production of phosphoric acid increased to 155,000 tons per year and sulfuric acid to 450,000 tons per year; and (3) construction of new facilities, including sulfuric acid, phosphoric acid, and triple superphosphate units. These three new units were scheduled for startup in 1976 with 100% of annual capacity planned for 1978. Maroc Chimie II became operational in early 1976 and was built by the French contractor Spie Batignolles. For Maroc Chimie II, Spie Batignolles built two 1,000-ton-per-day sulfuric acid plants and a 500-ton-per-day phosphoric acid plant. The sulfuric acid plants were using imported brimstone rather than local pyrrhotite.

Consistent with moving toward end-value phosphate rock processing, OCP had also started several large-scale projects involving the erection of a number of phosphoric acid/MAP units in the Maroc Phosphore series. The first unit, Maroc Phosphore I, was located about 10 kilometers from Safi near the Maroc Chimie complex. The plant included a 4,500-ton-per-day sulfuric acid unit, a 1,500-ton-per-day phosphoric acid unit, and a MAP unit with an annual 415,000-ton product capacity. Startup of the first stage was scheduled for 1975, with the second stage to be brought into production by late 1976. Maroc Phosphore I was built by a consortium of Uhde France, Polimex of Poland, and Siemens A.G. of West Germany, with Nissan technology, and was scheduled to process 1.65 million tons of phosphates supplied from Youssoufia. About 33% of the phosphoric acid was used for MAP production, with the remainder going for export. Heurtey Industries and Uhde France were to build the Maroc Phosphore II phosphoric acid complex planned for Safi, including three 1,700-ton-per-day sulfuric acid plants with offsite storage facilities and three 500-ton-per-day phosphoric acid plants.

Morocco further improved its potential as a world producer with acquisition of 65% of Spanish Sahara's Bu Craa deposits in 1976. Spain's Government-owned holding company Instituto Nacional de Industria (INI) retained the remaining 35%. Spain withdrew from the Sahara on February 28, 1976, and Morocco and Mauritania were assigned administration of the territory under a bilateral agreement that was signed in April. Under the terms of the agreement, the area was split geographically, giving Morocco administration of the Bu Craa mines, but adding the provision that Mauritania should also benefit from the phosphate sales. With acquisition of a majority holding in Fosfatos de Bu Craa (Fosbucraa), the company headquarters was transferred to Rabat and the sales organization was linked to the OCP. A consortium of small banks was loaning $20 million to Fosbucraa to cover costs of repair to damaged facilities and get the mine back into full operation.

Production of phosphate rock from Bu Craa was at a standstill for much of the year. Rock transportation by conveyor belt to port El Aaiún was paralyzed much of the time. The conveyor belt, extending in sections over 100 kilometers, has often been called the world's longest conveyor.[14] At yearend, both the calcination plant and powerplant were closed. Plans were being discussed for rock transport by trucks under military guard. Over 300 workers employed at Bu Craa were laid off, and in an effort to alleviate excessive unrest, the OCP offered work at its facilities in Morocco.

Potash.—In early 1976, studies were conducted on the Khemisset potash deposits with respect to possible production of potassium chloride and potassium sulfate.

Salt.—New reserve estimates indicate 3 billion tons of rock salt in the deposits located near Mohammedia. Equipment was installed during 1976 for the expected initial production of 900,000 tons annually in 1978.[15] Plans were also underway to use the cavities left by salt extraction for the storage of imported crude oil. A chemical complex was planned to be developed concurrently that would allow production of chlorine, caustic soda, polyvinyl chloride, and soda ash.

[15] To the Point International (Brussels). Bigger Salt Yield. V. 4, No. 19, May 2, 1977, p. 35.

MINERAL FUELS

Coal.—A new open pit coal mine was opened at Jerada, where the BRPM was studying the possibility of coking anthracite coal. The only sizable increase in mineral production recorded for 1976 was in anthracite mining at Jerada by the Moroccan Government. Output increased from 652,000 tons in 1975 to 701,756 tons in 1976.

Oil Shale.—The West German firm Kloeckner was evaluating oil shale deposits at Timhadit in the Middle Atlas. The BRPM was also conducting research on bituminous shale at Timhadit and Tarfaya in conjunction with the Oil Shale Corp. (OSCO) and Union Oil Co. of the United States. The existence of several billion tons of proved reserves was verified by drilling. Reserves of 1,800 million tons of shale with a potential oil yield of 10% were indicated at Timhadit from the initial drilling program.[16] Recent oil shale studies released by OSCO, however, revealed reserves estimated at 10 billion tons at Timhadit, with an oil content of 74 liters per ton. Oil content at Tarfaya proved to be variable, from 8 to 72 liters per ton, with reserves as yet undetermined. The U.S.S.R. was also performing tests and reportedly established that the shales can be burned directly as a low-yield fuel, as with Baltic deposits.[17]

Petroleum.—The OCP and Abu Dhabi National Oil Company commissioned Badger Co. Inc. of the United States to make a feasibility study for a joint fertilizer and oil refining complex to be located at El Jorf Lasfar, near El Jadida.

Phillips Petroleum Co. (operator), Getty Oil Co., and Agip S.p.A. (Italy) took equal shares in two offshore exploration areas that covered 10,000 square kilometers between Agadir and Essaouira. The blocks extend from about 20 to 120 kilometers off the coast in depths up to 2,000 meters. Title to the blocks, which were known as Cap Sim Profond and Cap Tafelney Profond, was held by the BRPM.[18]

An accord was signed between Phillips Petroleum, British Petroleum Co. Ltd., and the BRPM for exploration and exploitation of oil in an area covering about 35,000 square kilometers in the Saharan Province of Boujdour.[19]

The BRPM completed Toukimt 1, an oil and gas discovery at 11,483 feet. Toukimt 2 and Toukimt 3 were also started, but no results were reported. Sun Oil Co. abandoned the offshore Ifni Marine 1 at 6,500 feet. In total, seven wells were drilled in 1976; six were dry, but two of the seven were still drilling at yearend. A total of 78,000 feet were drilled, compared with 52,993 feet for 1975.

Exxon Corp., Phillips Petroleum, and the BRPM did geophysical surveys, with 1,100 line-miles shot by the BRPM onshore, 300 line-miles shot by Exxon offshore, and 1,260 line-miles shot by Phillips offshore. Exxon relinquished three shelf permits and six deepwater permits.

Morocco's crude oil production was derived from seven small fields that were discovered between 1957 and 1961, plus Sidi Rhalem, discovered in 1961. Gas production increased from 6.6 billion cubic feet per day in 1975 to 7.5 billion cubic feet per day in 1976. The increase was derived from the Ksiri gasfield that began producing in 1976.[20]

The Mineral Industry of Mozambique

By David E. Morse [1]

The mineral industry of Mozambique was a minor contributor to the economy of the young nation in 1976. Mineral production as well as activity in most sectors of the economy declined during the year. In March, the Government closed the border with Southern Rhodesia which had a pernicious effect on the already struggling economy. Mozambique had previously earned significant revenues from the transport of goods to and from Rhodesia because 40% of Rhodesian imports and exports had been shipped through the ports of Maputo and Beira, Mozambique. In addition, Mozambique experienced a loss in transient revenues derived from goods destined for Botswana and Zambia by way of Rhodesia. An estimated 75,000 Mozambique nationals were isolated in Rhodesia at the time of the border closure, resulting in an attendant loss of remittance revenue. Other important factors in the country's economic decline were the continued exodus of European managers and technically skilled personnel, the restructuring of the society to meet the new framework of national goals, and the low labor productivity. The Government planned to return to the 1973 production levels by 1980.

Throughout 1976, Mozambique continued to supply a large force of laborers to South African mines, although at a much reduced rate from that of 1975 when 115,000 workers were recruited. The return of some 90,000 workers from the Republic of South Africa and the smaller number of recruits caused the Mozambique workforce employed in the Republic of South Africa to drop to an estimated 65,000 laborers. The work force reduction resulted in a 34% decrease in remittances to the Mozambique Government from the Republic of South Africa, which further reduced foreign exchange earnings during 1976.

The 1976 balance of trade deficit swelled by $75 million[2] to an estimated $275 million despite significant efforts by the Government to restrict imports. The increased cost of imported manufactured goods, crude oil, and petroleum products and the decline in agricultural exports were the prime contributors to the larger trade deficit.

The Cabora-Bassa Gorge hydroelectric project neared maturity in 1976. The 163-meter-high dam created a 250-kilometer-long, 30-kilometer-wide lake in the Zambezi Valley of the Tete District. The third 450-megawatt generator in the south power station came online in 1976. A 1,400-kilometer, dual 530-kilovolt direct current transmission line from Songo, Tete District, to Irene near Pretoria, Republic of South Africa, was completed during the year. Two additional 450-megawatt generators were to be in operation in the south power station by yearend 1979.

During 1976, the U.S.S.R. sent a team of geologists and mining experts to Mozambique to engage in mineral prospecting for bauxite, iron ore, and manganese. The Government stated its willingness to receive foreign investment in mineral activities, but has not promulgated information on its mineral policies.

COMMODITY REVIEW

METALS

Bauxite.—The Alumen mine near Manica was the only operating bauxite mine in Mozambique during 1976. Electric power had been supplied to this area from Southern Rhodesia, and the effect of the border closure on mine output was not known. Reserves at the mine were estimated at 60 million tons of bauxite averaging 44% Al_2O_3.

Copper.—The only copper mine in Mozambique was the Edmundian mine between Manica and the Rhodesian border. The mine had been controlled by a Rhodesian firm but its fate was unknown following the closure of the border. The Chidua copper deposit in the Tete District has been studied and was considered for economic development.

Iron.—There were numerous iron ore deposits in Mozambique but they were not being exploited in 1976. None of the known deposits have reserves in excess of 20 million tons of ore.

Mineral Sands.—Titanium mineral and zircon bearing sands were contained in coastal beach dunes and in offshore deposits between Maganja da Costa and Moma along the north-central coast of Mozambique. Underwater deposits near Pebane containing 30 million tons of ilmenite, 3 million tons of zircon, and 2 million tons of rutile have been investigated by the Preussag A.G. exploration group of West Germany.

NONMETALS

Asbestos.—In 1976, Minas Gerais de Mozambique Lda. was scheduled to begin anthophyllite (grades 3 to 7) production at Mavita, 50 kilometers southwest of Vila Pery. Proven ore reserves were 250,000 tons and 1 million tons was listed as probable ore.

Cement.—The aggregate capacity of Mozambique's cement plants at Matola, Dondo, and Nacala was 990,000 tons in 1976. The civil construction industry, which was nearly paralyzed by the exodus of Portuguese settlers, was severely influenced by the nationalization of all rental property in early 1976. This action had a concomitant effect on the cement industry. Cement output was also constricted by decreased worker productivity and the lack of spare parts caused by the import restrictions.

Fluorspar.—Fluorite deposits have been reported at Djanguire and Lupata in Tete and at Canxixe and Dejalire in Vila Pery. The Djanguire deposit contained an estimated 600,000 tons of ore averaging 62% fluorite and 60 million tons averaging 20% fluorite. None of the known fluorite deposits were being exploited during 1976.

Other Nonmetals.—Small-scale mines extracted a variety of semiprecious stones and columbite-tantalite ore from the pegmatites of the Moçambique, Niassa, and Zambézia Districts. Quality garnets were mined near Nova Freixo, Niassa District.

MINERAL FUELS

Coal.—Companhia Carbonifera de Moçambique S.A.R.L. (CCM) continued to operate the largest mining operation in Mozambique. CCM produced coal from the Moatize mine 30 kilometers east of Tete, Tete District. Proven reserves in the company's 31-square-kilometer concession area were 400 million tons. In September a methane gas/coal dust explosion caused the death of 95 persons and it was subsequently decided to seal the No. 6 shaft. Production was not severely curtailed as the company continued underground operations through two other portals. Two West German companies contracted to complete a feasibility study to determine the viability of establishing a 2-million-ton-per-year open cast operation in a section of CCM's coal concessions. The results of the study were expected in early 1977. Other coal deposits in the Tete District near Chicoa and Mucanha were studied and were to be exploited to produce coal for exports.

Natural Gas.—Natural gas was discovered at Temane and Pande in eastern Inhambane and at Búzi in the Beira District. Total reserves were estimated at 121 billion cubic meters of natural gas by the Geologic Survey in 1974. The natural gasfields of eastern Mozambique remained unexploited throughout 1976.

Petroleum.—No petroleum exploration activity took place in Mozambique during 1976. The petroleum refinery near Maputo continued to operate well below rated capacity because of import restrictions. In July, Iraq agreed to donate crude oil valued at $1 million to Mozambique.

The Mineral Industry of the Netherlands

By William F. Keyes [1]

The Dutch economy made a hesitant recovery in 1976 from the previous year's recession, particularly toward the end of the year. A real growth of 4% brought the gross national product (GNP) to $89.6 billion,[2] and the index of industrial production (1970=100) increased from 115 in 1975 to 124 in 1976. Unemployment declined from 6.0% in 1975 to 5.7% in 1976.[3] Inflation continued at about 8%, but a good performance in international markets, led by higher gas sales, induced an appreciation in the value of the guilder.

Steel production rose about 8% to 5.2 million tons, but remained well below the capacity of 7.3 million tons. Natural gas production, the largest extractive industry, increased 7% largely in response to increased export demand, but reserves declined, leading to concern for the future. The petroleum-refining industry improved somewhat in 1976, but still operated well below capacity. Operations in the other two primary minerals industries, production of aluminum and zinc, were close to normal. Other minerals-related events during the year were the completion of a third basic oxygen furnace by the major steel producer and development of knowledge of a new oil discovery in the North Sea.

Notwithstanding, concern over structural unemployment, low profitability, low capital investment, and continuing inflation led the Government to announce a "one-percent" policy, under which a ceiling of one percentage point per year would be imposed on the growth of the collective burden borne by the economy (taxes, social insurance, and nontax revenue). Export sales of natural gas were excluded from this policy since the Government was determined that long term contracts entered into when energy problems were of less concern should be revised to reflect the greater value of the product compared with imported petroleum.

PRODUCTION

Production of metals and minerals showed little change in 1976 over that of the previous year, with both gains and losses being recorded, although most industries still worked below capacity. The only industry with a sizable increase in production was natural gas, with an increase of 7%. However, there was doubt as to whether the country's reserves could continue to support this growth in production.

Major producers of minerals and metals in the Netherlands are listed in the following tabulation:

[1] Supervisory physical scientist, International Data and Analysis.

[2] Where necessary, values have been converted from Netherlands guilders (Hfl) to U.S. dollars at the rate of Hfl2.60=US$1.00.

[3] The method of calculating unemployment was revised in February 1976.

[1] In addition to the commodities listed, the Netherlands presumably produces a variety of crude construction materials (clays, stone, and gravel), but production is not reported and available information is inadequate to make reliable estimates of output levels.

[2] Coke oven and blast furnace gas only.

TRADE

The Netherlands imported crude petroleum largely from Iran and Nigeria, along with lesser amounts of refined products. Exports of crude petroleum were nominal, but the Rotterdam refining industry sold products to neighboring countries and for ships' bunkers. The chief metallic ores and concentrates imported were alumina from Surinam and France for the Delfzijl and Vlissingen smelters, and zinc concentrates, mostly from Australia and West Germany, for the Budel smelter. Much of these imports was used in the Dutch metal industries, but there were important exports of aluminum to France and of zinc to the United Kingdom.

The value of the chief mineral products traded by the Netherlands in 1975 is given in the following tabulation:

Commodity	Value (millions)			
	Imports	Percent	Exports	Percent
Petroleum and petroleum products	$5,660	18.7	$3,843	12.7
Iron and steel	1,298	4.3	1,051	3.5
Nonferrous metals	613	2.0	570	1.9
Metal ores and scrap	386	1.3	--	--
Natural fertilizers and crude minerals	355	1.2	460	1.5
Natural and manufactured gas	--	--	1,271	4.2
Total trade	30,240	100.0	30,188	100.0

Table 2.—Netherlands: Exports of mineral commodities

Talc and steatite	740	1,556	Belgium-Luxembourg 643; West Germany 384.
Other nonmetals, n.e.s.:			
Oxides and hydroxides of magnesium, strontium, barium	326	205	West Germany 73; United Kingdom 67.
Slag, dross, and similar waste, not metal bearing:			
From iron and steel manufacture thousand tons	51	65	West Germany 47.
Other do	73	84	Belgium-Luxembourg 51; United Kingdom 20.
Unspecified do	197	210	West Germany 87; France 58; Belgium-Luxembourg 54.
MINERAL FUELS AND RELATED MATERIALS			
Asphalt and bitumen, natural	1,037	5	NA.
Carbon black	79,347	67,807	France 33,654; West Germany 13,055.
Coal and briquets:			
Anthracite and bituminous coal thousand tons	1,022	287	West Germany 211; Belgium-Luxembourg 50.
Briquets of anthracite and bituminous coal do	23	NA	
Coke and semicoke do	726	653	France 337; Belgium-Luxembourg 175; West Germany 76.
Gas:			
Manufactured do	145	NA	
Natural billion cubic feet	1,691	1,821	West Germany 904; Belgium-Luxembourg 398; France 344.
Hydrogen, helium, rare gases	14,288	15,449	West Germany 7,246; Belgium-Luxembourg 7,184.
Peat and peat briquets thousand tons	NA	58	Belgium-Luxembourg 43; France 9.
Petroleum:[4]			
Crude thousand 42-gallon barrels	4,343	5,439	United Kingdom 2,443; Belgium-Luxembourg 1,533; Italy 1,078.
Refinery products:			
Gasoline do	61,923	60,843	West Germany 34,910; United Kingdom 12,334; Belgium-Luxembourg 5,491.
Kerosine and jet fuel do	20,507	19,274	West Germany 6,076; United Kingdom 5,720; Denmark 1,496.
Distillate fuel oil do	96,473	102,292	West Germany 61,455; Belgium-Luxembourg 8,601; United Kingdom 5,975.
Residual fuel oil do	133,979	122,411	West Germany 14,033; United Kingdom 10,476; Belgium-Luxembourg 10,250.
Lubricants do	4,005	3,057	Belgium-Luxembourg 453; United Kingdom 393.
Other:			
Liquefied petroleum gas do	4,483	5,290	Belgium-Luxembourg 2,598; Portugal 1,079.
Mineral jelly and wax do	810	504	West Germany 150; Morocco 110; United Kingdom 87.
Bituminous mixtures do	283	242	France 204.
Unspecified do	4,209	4,200	West Germany 1,379; Denmark 686; Norway 490.
Total do	326,672	318,113	
Mineral tar and coal-, petroleum-, or gas-derived crude chemicals thousand tons	545	459	West Germany 193; United Kingdom 128; Belgium-Luxembourg 47.

r Revised. NA Not available.

[1] Excludes monetary gold.

[2] Includes sponge iron, shot, grit, pellets, powder, spiegeleisen, and ferromanganese.

[3] Exports of ash and residue containing aluminum to Belgium-Luxembourg are included in "Ash and residue, other."

[4] Includes bunkers.

[2] Includes spiegeleisen, sponge iron, shot, grit, and pellets.
[3] Imports of bentonite from Belgium-Luxembourg are included in other clays.
[4] Includes bunkers.

COMMODITY REVIEW

METALS

Aluminum.—The Netherlands has no domestic source of bauxite. The two aluminum smelters, which operated at near capacity, were affected only by a temporary shortage of electrical energy. The smelter at Delfzijl, operated by Aluminium Delfzijl N.V. (Billiton-Shell-ESTEL), had a capacity of 106,000 tons of ingots per year, and the Péchiney-Nederland N.V. (Péchiney Ugine Kuhlmann) smelter at Vlissingen had a capacity of 187,000 tons per year.

Iron and Steel.—In the face of an increasingly bleak outlook for steel, Hoogovens IJmuiden B.V. completed its third basic oxygen furnace in March, bringing crude steel capacity to 7.3 million tons per year, compared with 6.0 million tons in 1974 when an $80 million expansion was approved. Capacity should reach 8 million tons per year by 1980. During 1976, approval was granted for expansion to 11 million-tons-per-year capacity by 1985.

Plans by the West German consortium Thyssen-Krupp-Mannesmann to build an ore-pelletizing plant in the Rotterdam harbor area were rejected on environmental grounds by the provincial authorities of South Holland Province. The consortium was reluctant to proceed with an appeal in view of the extended effort that would be required and the consequent escalation of costs.

The Netherlands has no domestic source of iron ore, importing supplies from major world sources such as Sweden, Brazil, and Liberia. Hoogovens, a subsidiary of the Dutch-West German corporation ESTEL N.V., which in turn is a subsidiary of Hoesch AG and Koninklijke Nederlandsche Hoogovens en Staalfabrieken N.V., produced 93% of the 5.2 million tons of steel output in 1976; the remainder was produced by NKF-Staal B.V. at Alblasserdam (near Rotterdam), and Staalgietwerk SMDK N.V. (formerly Royal Demka Steelworks) at Utrecht.

Zinc.—Ore from the Nanisivik mine in Canada did not start arriving in 1976 as originally scheduled, forcing the zinc smelter at Budel to operate below capacity with concentrate largely from Australia. The smelter, the sole producer of primary zinc in the Netherlands, was operated by N.V. Kempensche Zink-Maatschappij and Australian Mining and Smelting Europe. Plant capacity was 150,000 tons per year of electrolytic zinc.

NONMETALS

Nitrogen.—The possibility of building an ammonia plant with a capacity of at least 1,000 tons per day at Eemshaven, north of Delfzijl in the northeast, was being considered by Windmill Holland B.V. Feedstock would be natural gas from either the nearby Groningen Field or the Dutch sector of the North Sea. This site was chosen over a site near the company's fertilizer plant at Vlaardingen because of lower gas prices, a 25% investment premium for that area, the deepwater port, and ample space for construction.

Three companies reportedly produced ammonia, but data on output were not published: Unie van Kunstmestfabrieken B.V., a subsidiary of Dutch State Mines, with a capacity of about 1.2 million tons of ammonia per year at Geleen, Pernis (Rotterdam) and IJmuiden; Nederlandse Stikstof Maatschappij N.V. with a capacity of about 600,000 tons per year at Sluiskil, southwest Netherlands; and Esso Chemie N.V. with a capacity of about 400,000 tons in the Europoort area of Rotterdam.

MINERAL FUELS

Energy.—The Netherlands was again a net energy exporter in 1975 because of its growing natural gas exports, but there was a decline in absolute quantity as petroleum trade decreased. Coal mining ceased in 1974, and as yet petroleum has not been discovered in major quantities.

The Government, in its annual budget message, announced that certain measures would be taken to limit the growth ratio of energy use to GNP to just over 1 to 1; this growth ratio was 1.8 to 1 prior to 1973 and had dropped to 1.5 to 1 by 1976. It was believed that the ratio would drop to 1.3 to 1 in the natural course, resulting in an energy demand of 99.9 million tons of oil equivalent[4] by 1985 compared with 62.3 million tons[5] in 1975. However, special measures, including conservation, insulation, and more efficient use, were expected to bring about the lower ratio. By 1985 the share of natural gas in total energy supply was also expected to decline to 38% from 58% in 1975.[6] Imported oil and some imported coal were to fill the gap. The Netherlands expected to again import 20% of its energy requirements in 1985. The energy balances for years 1974 and 1975 are shown in table 4.

[4] One ton oil equivalent equals 1.47 tons standard coal equivalent.
[5] Calculated on a more restricted basis than that of table 4.
[6] Calculated on a more restricted basis than that of table 4.

Table 4.—Netherlands: Supply and apparent consumption of fuels and power for 1974 and 1975
(Million tons of standard coal equivalent [1])

	Total energy	Coal and coke	Petroleum and refinery products	Natural gas	Nuclear power
1974:					
Production	114.9	0.8	2.2	111.5	0.4
Imports	107.4	5.0	102.4	--	--
Exports	123.4	1.7	63.5	58.0	.2
Apparent consumption	[2] 98.9	4.1	[2] 41.1	53.5	.2
1975:					
Production	111.8	--	2.2	109.1	.5
Imports	97.1	4.7	92.4	--	--
Exports	107.4	.9	47.3	59.2	--
Apparent consumption	101.5	3.8	47.3	49.9	.5

[1] 1 ton standard coal equivalent (SCE) = 7,000,000 kilocalories.
[2] Includes refinery fuel, losses, and nonenergy uses.

Natural Gas. —Total reserves, proven and probable, of natural gas in the Netherlands declined 5.3% during 1976, as shown in the following tabulation, in billion cubic meters at 15° C:

	End of 1976		End of 1975	
	Proven	Probable	Proven	Probable
Groningen Field	1,567.1	203.8	1,649.7	200.8
Other onshore fields	85.5	123.1	99.7	187.0
Continental Shelf	106.5	260.9	98.8	241.3
Total	1,759.1	587.8	1,848.2	629.1

Source: Ministerie van Economische Zaken. "Aardgas en Aardolie in Nederland en op de Noordzee." 1975 and 1976.

This was the first significant decline since 1968, and, according to the Minister of Economic Affairs, it was largely attributable to the constant growth in production.

The decline was viewed with some concern because of the limited volume of new deposits discovered in areas of most promise. The State Geological Service pointed out that exploration at greater, presently unjustifiable depths will ultimately be important to long term supplies; strong Government stimulation to obtain a reliable picture of the energy potential in the ground was recommended.

Production of natural gas increased about 7% to 97 billion cubic meters. The Netherlands continued to be the largest exporter among the market economy countries, exporting more than half of its production. Natural gas was marketed within the country and in neighboring countries (chiefly West Germany, Belgium, and France) solely by N.V. Nederlandse Gasunie. The largest producer was Nederlandse Aardolie Maatschappij B.V. (NAM), owned by Royal Dutch/Shell and Exxon. NAM controlled the Groningen gasfield as well as the principal oilfields, Schoonebeek and Rijswijk.

Under a decree that took affect on April 23, the Netherlands Government increased its participation from 40% to 50% and profit sharing from 50% to 70% in the exploitation of oil and gas offshore in the North Sea. The new decree applied only to 9,000 square kilometers not yet allocated and 13,500 square kilometers for which exploration permits had been granted but which would revert to the State. Permits granted prior to April 23 would not be affected. Terms of exploration licenses were also reduced from 15 years to 10 years, fees were increased, minimum exploitation spending was increased from $2,200 to $5,500 per square

kilometer, and the term for surrender of half the concession was reduced from 10 years to 6 years. The new regulations reflected public criticism of the unusually high profits made by petroleum companies when the price of oil was raised in 1973, but they were apparently less severe than corresponding British and Norwegian regulations. However, oil companies operating in the Netherlands indicated that the new conditions might lead to some offshore gasfields not being developed.

Petroleum.—After a quarter of a century of robust expansion, in which the Netherlands and particularly the city of Rotterdam became one of the world petroleum industry's leading refining centers, the industry was severely affected by the events of the seventies. In 1975 refineries operated at about 50% to 60% of capacity, and the figure improved to only about 65% in 1976, corresponding to a production of about 490 million barrels (65 million tons). Both exports, which take about 60% of the output, and domestic consumption were below the previous normal level, and a slow growth was forecast. There was an anomalous rise in domestic consumption of motor gasoline, however, and both British Petroleum (BP) and Shell announced plans that would shift output toward the lighter end of the barrel.

BP's plans, costing $240 million, included a vacuum distillation plant, installation of a catalytic cracker, an alkylizing plant, and a viscosity breaker unit. Consequently, production of fuel oil will decline 50%. Royal Dutch/Shell's investments included $80 million for construction of a new naphtha-hydrocracker. Identical plans by Esso to increase output of lighter petroleum fractions were under study.

In July the Dutch Cabinet suspended the fee on new investment in the Rijnmond area west of Rotterdam that was designed to prevent excessive industrial concentration there, in order to boost the economy. Oil-related activities in the area would benefit.

Total capacity of the eight Dutch oil refineries remained at about 100 million tons per year or roughly 2 million barrels per day; five of the refineries, with over 85% of the capacity, were in the Rotterdam area.

Reserves of petroleum in the Netherlands amounted to 40.4 million cubic meters (337 million barrels) in the Schoonebeek concession near the West German border at the end of 1976, of which 8.3 million cubic meters (70 million barrels) were proven; in the Rijswijk concession near The Hague, total reserves were 8.8 million cubic meters (73 million barrels), of which 4.7 million cubic meters (39 million barrels) were proven. A promising oilfield of unknown size was discovered by NAM in 1975 in block F–3 in the northeast portion of the Dutch Continental Shelf; in 1976 oil was found by the Union Oil Co. of the Netherlands in the adjacent block F–2.

The Mineral Industry of New Zealand

By Walter C. Woodmansee [1]

The most significant developments in New Zealand's mineral industry in 1976 were in the mineral fuels sector, where construction of production facilities was started at the offshore Kaui gasfield and neared completion at the onshore Kapuni gasfield. The Department of Mines initiated a new coal resource assessment program to define coal reserves more completely and accurately. Plans called for substantial increases in coal production for fueling new electric powerplants. Oil exploration, which was mainly offshore, was at a low level owing mainly to uncertainty concerning a new Government policy on petroleum exploration and development.

Production of iron sands for New Zealand's only direct-reduction plant and steelworks and for export to Japan reached a new high. Both iron sand-producing companies—New Zealand Steel Ltd. and Waipipi Iron Sands Ltd.—planned to increase iron sand production and exports, and New Zealand Steel planned to develop new sponge iron and steelmaking capacity as part of a multiyear development program.

In the nonmetals sector, a new sulfur-processing plant was under construction. Quarry and pit activity was high for sand and gravel, stone, and clay, New Zealand's most widespread exploration and mining operations.

The mineral exploration programs of a number of companies gained momentum on both the North and South Islands during the year. Principal metals sought were copper, gold, lead, and zinc. Applications for prospecting licenses continued to attract opposition from environmentalists. The Government believed that it provided adequate safeguards for environmental protection and enhancement in exploration and mining operations. Amendments to the Mining Act which would provide greater environmental protection in national parks were under consideration at yearend.

In October, the Minister of Energy Resources announced a new energy policy, effective in 1977. Coal prices were to be increased 25% (to average about two-thirds of the fuel oil market price); natural gas, 40% (to average about 15% below the fuel oil price); manufactured gas, 25% to 30%; and electricity rates, 40%. In addition, energy resource taxes were to be introduced to finance energy exploration, development, marketing, research, and conservation programs. The levy on coal was set at $2 per ton; natural gas, $0.0475 per therm; and petroleum liquids, $3 per barrel.[2] The former regulation, which provided for 40% Government participation in oil exploration and development costs in return for 51% of any future return, was dropped. The Government added an excise tax of 10% to 15% on profits from future petroleum production.

The energy strategy was to reduce dependence on imported energy, currently

[1] Supervisory physical scientist, International Data and Analysis.

[2] The New Zealand dollar ($NZ) and U.S. dollar were near parity during most of 1976, and no currency conversions were made for this chapter. In December, the New Zealand dollar was devaluated 17.5% against all currencies except the Australian dollar, and, at yearend, the conversion rate was $NZ1.099=US$1.00.

60%, to 30% of total primary energy requirements by 1985. The Committee to Review Power Requirements, organized in 1975, projected generation of electricity at 39,800 gigawatts in 1984–85. The 1974–75 rate was 18,300 gigawatts. Energy sources for 1981 were forecast as follows: Petroleum 49%, electricity 29%, coal 14%, natural gas 7%, and manufactured gas 1%. The 1976 Power Plan provided for decisions on nuclear power development probably in 1978 and possible installation of the first nuclear facility after 1990.

In order to reduce the need for petroleum imports, the policy was to develop and utilize more coal, natural gas, and hydroelectric resources, and to reduce overall energy demand by conservation practices. Although initial natural gas produced at the Kapuni and Kaui gasfields will fuel electric power stations, this practice is to be phased out, with coal replacing gas as fuel. Potential development of geothermal energy was considered limited because the main geothermal resources were in tourist areas.

PRODUCTION

Production levels for New Zealand's most important mineral commodities—natural gas, sand and gravel, coal, and iron sands—were similar to or higher than those of 1975. The most marked increase was in output of natural gas and condensate. Sand and gravel output was down slightly, but output of coal and iron sands was slightly higher.

Output values of some of the principal nonmetallic mineral commodities were as follows:

	Value (thousands)
Sand and gravel	$44,555
Stone:	
Limestone (for agriculture, roads, industry, cement)	9,631
Dolomite	405
Dimension stone	341
Greenstone	60
Clays:	
Fire clay	772
Ceramic clay	543
Bentonite	42
Serpentine	538
Salt	516
Sand, glass	484
Pumice	130
Other nonmetals	89

Output of gold was valued at $425,000. Value data were not available for other major mineral and metal products, such as natural gas, iron sands, aluminum metal, and cement. On the basis of a price of $11.50 per ton, coal production was valued at approximately $28.6 million.

Total ---do---	27,898	23,416	27,393

e Estimate. p Preliminary. r Revised. NA Not available.

[1] Average 60% iron.

[2] Includes crushed rock for building aggregate, roads, and ballast.

[3] Excludes carbon dioxide component of natural gas, which is reported separately.

[4] Includes crude oil and field condensate.

TRADE

New Zealand's worsening trade deficit was attributed to reduced export demand for agricultural products, which, with forestry products, have accounted for 85% of total export value, and to higher prices for imported crude petroleum, petroleum refinery products, and manufactured goods. Petroleum imports were valued at $430 million for the year ending June 1976 and were expected to be higher in 1977. Approximately one-half of the national energy demand was derived from imported sources.

According to the Department of Statistics, principal mineral commodity exports (provisional) in 1976 were iron sand concentrates (2,146,625 tons) and aluminum and its alloys (98,369 tons). Principal mineral commodity imports in 1976 are given in table 4.

[p] Preliminary.

COMMODITY REVIEW

METALS

Gold.—Mine output was substantially higher than that of 1975. Kanieri Gold Dredging Ltd., using an 18-cubic-foot dredge, accounted for most of the production at its operation along the lower Taramakau River, west coast, South Island. During the first 7 months of the year, Kanieri worked 1,487,000 cubic meters of old tailings at the lower end of its dredging claim. During the remainder of the year, Kanieri dredged previously unworked ground in the lower end of its claim area, and recovered 2,431 troy ounces from 1,458,000 cubic meters of dredged placer material. Dredging was at an average depth of 23.5 meters. The Minister of Mines granted a dredging license to Kanieri for a new area downriver from the existing claim area.

Prospecting and exploration activity for gold was underway elsewhere on the South Island and also on the North Island. Pennzoil of Australia Ltd. conducted a detailed sampling program in the Collingwood area, west coast, South Island, with negative results. Other smaller-scale operations were seasonal. Ryan Mining Ltd. completed a 3-year evaluation program along the Shotover River.

Gold Mines of New Zealand Ltd., a subsidiary of Australian Anglo American Ltd., conducted a regional exploration program for gold in the North Cape and Raukumara Range-East Cape areas, North Island, and the Kaikouri Range, South Island.

Mineral Resources (New Zealand) Ltd. collected bulk samples of quartz vein in a westward extension of old surface workings at the Martha Mine, Waihi, North Island. Upper levels of the mine were also tested. The existing mill was modified to handle increased production, and a crusher was brought in from another mine. Trial treatment indicated that the gold was associated with extremely fine pyrite in the ore.

Iron Sands.—Output of iron sand concentrate at three locations on the west coast, North Island, reached a new high

of nearly 2.5 million tons. Exports to Japan totaled 2.1 million tons, compared with 2.3 million tons in 1975. New Zealand Steel Mining Ltd., a wholly-owned subsidiary of New Zealand Steel Ltd., planned to double capacity at Taharoa, between Auckland and New Plymouth, including installation of a second submarine pipeline to its deepwater, bulk-loading facility. The company had a sales agreement to export 11.8 million tons of iron sands to Japanese iron and steel firms.

Waipipi Iron Sands Ltd., a joint venture of Marcona Corp. (United States) and Viking Mining Corp. Ltd., commissioned a second dredge as part of its program to expand exports to 2 million tons per year to markets in Japan. The company had sales agreements with six Japanese iron and steel companies for delivery of 11 million tons of the iron sand concentrate.[3]

Iron and Steel.—For the year ending March 31, 1976, New Zealand Steel reported production of 113,135 tons of sponge iron at its direct-reduction kiln at Glenbrook, 58 kilometers south of Auckland. Iron sand concentrate from Waikato North Heads was the feed material. New Zealand Steel planned to install a new multiple-hearth furnace to boost sponge iron output 25%.

Production of ingots, billets, flat and corrugated galvanized sheet, pipe, and sections increased over 1975 rates. New Zealand Steel was studying a 10- to 15-year, $400 million development plan, which would increase annual capacity to 450,000 tons and add a 1-million-ton-per-year hot- and cold-rolling strip mill to avoid dependence on imports.[4]

Imports of iron and steel semimanufactures, mainly universals, plate, and sheet, were reduced to 433,076 tons from 468,944 tons in 1975.

Other Metals.—Prospecting was in progress for copper on Coromandel Peninsula, North Island, and on D'Urville Island, west coast, South Island, where soil sampling and a magnetic survey were conducted in a zone of alteration. Also in the west coast area, South Island, drilling was completed on a copper-lead-zinc prospect near the Baton River and on a copper-nickel prospect in the Riwaka complex.

Amoco Minerals New Zealand Ltd. applied for an exploration license to the Roaring Lion molybdenum prospect in the northwest Nelson District, South Island. Carpentaria Exploration Co. Pty. Ltd., the exploration company for Mount Isa Mines Ltd., Australia, terminated its long-term exploration project in the ilmenite sand areas, west coast, South Island.

A few tons of scheelite concentrate was recovered at the Glenorchy workings in the southern part of the South Island.

NONMETALS

Asbestos.—Asarco Exploration Co. of Canada Ltd. and associates carried out geological and sampling work at the Pyke prospect, northwest Otago, southern South Island. Late in the year, a drilling program was started.

Clays.—Bentonite was mined at Coalgate in Canterbury, South Island, and Porangahau in Hawke's Bay. Drilling grade bentonite was used in oil exploration in the Taranaki area. Bentonite was also exported for use in iron ore pelletizing in Tasmania, Japan, and Taiwan. Another clay, halloysite, was mined in the northern North Island for use in ceramics and as a filler in the paper industry.

Mineral Wax.—Wax with a high melting point was derived from peat deposits on the Chatham Islands. These deposits and lignites in central Otago and Southland continued under investigation by the Department of Scientific and Industrial Research.

Sulfur.—Taupo Quarries Ltd. started construction of a treatment plant and ancillary facilities at the 6-million-ton Rotokawa deposit, Taupo area, North Island. Development work continued on a process to separate the sulfur from the pumiceous ore. A small quantity of sulfur was produced at a pilotplant operation in 1976. Four vertical extraction towers were erected at the new processing plant.

Other Nonmetals.—Small tonnages of serpentine were produced at Piopio and the North Cape, North Island, and at Lee Valley, Collins Valley, and Mossburn, South Island.

Quarry activity for sand and gravel and various types of stone was high, particularly near cities. Quarrying included both seasonal and full-time operations. Prospecting continued for good-quality materials. Winstone Ltd. reached full production at its Greywacke quarry near Hunua, North Island.

MINERAL FUELS

Coal.—Total output of bituminous coal, subbituminous coal, and lignite was slightly higher than that of 1975. There were 70 producing mines, 3 more than in 1975; 37 mines were underground operations (29% of output), and 33 mines were open pit operations (71% of output). About 78% of the total output was from State-owned mines. The trend continued toward greater mine mechanization, which resulted in better productivity and extraction percentage and fewer accidents. Hydromining was tested at the Escarpment mine, Buller District, South Island.

Demand was estimated at 3 million tons, distributed as follows: Electricity generation 40%, cement and lime industries 10%, household 7%, iron and steel industry 7%, and miscellaneous commercial-industrial heating and fueling 36%. The use of coal in thermal electric power stations was expected to expand as exploration and development continued for new deposits for this purpose. Three new mines at Huntly, under development for the new power station that was scheduled for completion in 1978, will produce more than 2 million tons per year when in full production. Output at the new, fully-mechanized Huntly West No. 1 mine, managed by Bechtel Pacific Corp. for the Department of Mines, was scheduled for 1.2 million tons per year and a 30-year life.[5]

Research on coal utilization, conducted by the New Zealand Coal Research Association (CRA), was financed by a tax of $0.075 per ton of coal produced and by Government grant. The Department of Mines and CRA advised consumers on efficient coal use.

The Department of Mines embarked on a 5-year exploration program to define coal resources more accurately. The program will include geological and topographic surveys, studies on coal chemistry, exploratory cuts and pits, shallow auger drilling, and deep core drilling. Initial work will be in Mataura District, southern South Island. Exploration continued in Buller and Greymouth Districts, South Island, and Waikato District, North Is-

land, to establish reserves sufficient for fueling new electric powerplants.

At yearend, reserves totaled 940 million tons, up 105 million tons as a result of resource assessment work during the year. These reserves were in 7 bituminous areas, 13 subbituminous areas, and 6 lignite areas. The principal districts were Waikato, with 379 million tons (measured, indicated, and inferred) of subbituminous coal of low to moderate ash and low sulfur; Buller, with 52 million tons of bituminous coal of low to moderate ash and low to high sulfur; Ohai (lower South Island), with more than 100 million tons (mostly inferred) of Waikato-type coal; and Mataura, with an undetermined but large resource of moderate-ash, low-sulfur coal exploitable by open pit.

Natural Gas.—Production increased sharply from the Kapuni gasfield, North Island, where development neared completion. Three new producing wells were completed, and others were in progress. A third processing train went onstream at the natural gas liquids plant of the National Gas Corp.

The Shell BP & Todd Oil Services Ltd. consortium continued development of the large Maui gasfield, 37 kilometers offshore from Kapuni in water 110 meters deep. The first development stage, for 600 million cubic feet per day, included production Platform A with 12 wells, an underwater gas and condensate pipeline, processing facilities at Oaonui, and more than 300 kilometers of onshore pipeline to two power stations. Construction work was delayed by adverse weather and sea conditions. The target date for first-stage completion remained late 1978 despite these delays.

Late in 1975, the Government's Offshore Mining Co. Ltd. announced receipt of a $200 million multicurrency loan to finance its 50% share in the project.

The second development stage, for 300 million cubic feet per day, scheduled for completion in 1983, included Platform B, additional underwater pipeline, and expanded processing facilities.

Petroleum.—Production of condensate from Kapuni gas more than doubled that of 1975.

Petroleum exploration was at a relatively low level, mainly owing to the new Government policy on taxing petroleum production. At yearend, there were 34 active exploration licenses covering 615,495 kilometers, both onshore and offshore. Offshore geophysical and geological surveys continued. The *Glomar Tasman* completed three wells, and *Penrod-74* completed two wells and was drilling a third at yearend. No significant discoveries were reported. The *Glomar Tasman* was drilling for a Shell BP & Aquitaine & Todd Petroleum Development Ltd. group and New Zealand Aquitaine Petroleum Ltd. alone. The *Penrod-74* was drilling for a Shell BP & Todd group and for Hunt International Petroleum Co. (of New Zealand).

New Zealand Petroleum Co. Ltd. was granted an exploration license to a 6,455-kilometer tract offshore from the west coast, South Island. Drilling was scheduled for 1977.

Hunt International suspended *Penrod-74* drilling operations following announcement of a $3-per-barrel tax levy on future oil production. This tax was abandoned in November because it was a disincentive to exploration. The Government planned to discuss a possible future tax on oil profits with the exploration companies.

The new petroleum policy, announced by the Minister of Mines in May, was also unfavorably received by the operating companies. This policy provided for no Government contribution to exploration costs (formerly 40%), continuation of a Government option for a 51% interest in any production program, a 10% royalty rate offshore, and a 15% royalty rate onshore.

The Mineral Industry of Nigeria

By Janice L. W. Jolly [1]

Oil exports valued at $10.2 billion[2] contributed 37.5% to the 1976 gross domestic product (GDP), estimated at $27.2 billion at current prices. Nigeria's industrial expansion continued unabated, fueled by petroleum revenues. Inflation also continued at an annual rate of more than 30%. Distribution bottlenecks, shortages, and other problems were defying short-run control. Strong Government measures had reduced the severe port congestion of 1975, but the problem was expected to continue until additional facilities could be completed. Constrictive Government policies were having the unintended effect of discouraging foreign investment, which is still deemed vital for balanced growth and technology transfer. Oil companies were awaiting improved investment incentives to be announced in 1977.

Six months after the new indigenization policy was first announced, the Nigerian Enterprises Promotion Decree was published in January 1977. The three-schedule decree superseded all previous measures and was to be implemented by December 31, 1978. Mining was included in schedule 2, and thus was to have at least 60% equity participation by Nigerians, both Government and private. Many of the industries in schedule 2 had formerly been required to be a minimum of 40% Nigerian owned, in compliance with the 1972 policy. In October 1976, the Nigerian Government acquired 60% controlling shares in foreign-owned banks. The compulsory acquisition was announced in June as the second phase of the 1972 indigenization program.

In early 1976, it was announced that a number of new States were to be created, resulting in a total of 19 smaller, more manageable units. The North Eastern State was split into the new States of Borno, Gongola, and Bauchi; and the densely populated Western State was divided into Oyo, Ogun, and Ondon. The Northwestern State was divided into Niger and Sokoto, Benue Plateau became Benue and Plateau, and Eastern became Anambra and Imo. Midwest State was renamed Bendel State, North Central was renamed Kaduna State, and South East was renamed Cross River State. Kwara, Kano, Rivers, and Lagos States remained unchanged.

Decree No. 46 of August 24, 1976, established the Nigerian Atomic Energy Commission. Under this decree, the commission was charged with prospecting and mining of radioactive minerals; constructing and maintaining nuclear installations for electricity; conducting research connected with atomic energy uses, and the manufacture or other production, purchase or other acquisition, treatment, storage, transportation, and disposal of any radioactive substances. Nigeria was to buy a nuclear powerplant from the Federal Republic of Germany.[3] Nigeria was a signatory to the nonproliferation treaty.

The Nigerian Government announced plans to carry out a geological survey of the entire country, expected to cost $650 million, as part of the national development plan. The Government-owned Nigerian Mining Corp. (NMC) announced that it would consider entering into partnership with any private company interested in mineral development during the ex-

ploration program. The Government indicated that it may reintroduce a loan scheme for domestic mining companies. An $8 million mineral and metallurgical laboratory was to be established at Jos by the Mathews Ortech Co. for the Government. The French Bureau de Recherches Géologiques et Minières (BRGM) formed a new mineral research company (BRGM, Nigeria Ltd.) in which it held 51% of the equity.

PRODUCTION AND TRADE

Crude oil production returned to an upward trend in the last 3 months of 1976 and totaled 756.1 million barrels for the year, a 16% increase compared with 651.9 million barrels in 1975. Oil exports increased in the fourth quarter to 181.1 million barrels; total 1976 oil exports were 720 million barrels, a 19% increase compared with 1975. Earnings from oil exports increased 37% to $10.2 billion in 1976, and prospects were good that this trend would be maintained.

Nigerian tin production continued its downward trend. Operating at about one-third capacity, the Makeri smelter produced 3,667 tons of tin metal in 1976, compared with 4,677 tons in 1975. About 80 tons of tin was sold locally in Nigeria, the rest was exported and sold through the London Metal Exchange (LME). Rising costs of production and export controls have contributed to lower levels of recent years. Higher world prices in 1976, however, were hopefully paving the way for a reversal in Nigerian tin production and in the first months of 1977, production had begun to improve. The Fifth International Tin Agreement whose membership included Nigeria, came into effect July 1, 1976. Production of columbium as a coproduct of tin mining, and coal, suffering from a soft market have also declined in recent years.

The Nigerian trade surplus reached $2.54 billion in 1976, compared with $1.94 billion in 1975, an increase of 31%. Total exports for 1976 were estimated at $10.9 billion and imports, at $8.33 billion. Imports increased 38% in 1976 compared with that of 1975.

Nigeria signed a protocol with Togo on October 19, 1976, agreeing to supply 400,000 tons per year of blended light crude oil to Togo. The agreement provided an option for resale of excess refinery products to Nigeria and for supply of additional quantities of crude oil. The quantity specified was about 40% of the capacity of the new Togo refinery. Sierra Leone was already purchasing 201,000 tons of crude oil equivalent to 4,100 barrels per day. Supplies to Senegal, Togo, and Sierra Leone total 82,000 barrels per day, representing about 7% of Nigeria's 55% share of current production. In 1976, the United States imported an estimated 40% of Nigeria's total production.

COMMODITY REVIEW

METALS

Columbium and Tantalum.—The principal producers of columbite–tantalum minerals were Bisichi-Jantar (334 tons), Vectis Mines (234 tons) and Amalgamated Tin Mines of Nigeria Ltd. (ATMN) (156 tons). ATMN's one small primary columbite mine was closed down, but the possibility of its redevelopment on a larger scale was being kept under review, depending upon whether the price of columbite continued to improve and upon availablity of mining equipment.[4] Columbium production has declined in recent years owing to higher operating costs and delays in delivery of mining machinery and spare parts caused by the congestion of Port Lagos. Tin slag from the Makeri smelter was also a source of tantalum. Tantalum concentrates produced in Nigeria were estimated to contain 85 tons of tantalum pentoxide from all sources, excluding by-product tantalum from tin slag.

Iron and Steel.—At the end of February, the discovery of an iron ore deposit was announced with resources estimated at 400 million tons, and located in the region of Okene, 320 kilometers north of Lagos. The Nigerian Steel Development Authority (NSDA) continued with overall project management for the planned iron and steel industry expansion. The first stage of expansion was a rolling mill, using imported ingots, that will be in operation by 1981. A Nigerian company was to clear the site, and a British firm was to design a quarry-stone-crushing plant. The objective continued to be the establishment of a completely integrated steel mill capable of carrying out the entire steelmaking process, from receiving ore to producing rolled structural sections, with an ultimate goal of 5.2 million tons of steel produced per year. The U.S.S.R. was to undertake geological surveys, various plant designs, technical assistance and training, and startup of the mill.

Lead.—Nigeria's only active mine produced about 276 tons of lead used domestically for soldering. The Makeri smelter had started a program for recovering lead from old batteries, to be used for making solder. NMC was studying the lead-zinc mine, now inactive, at Ishiaja, south of Abakaliki in Arambra State with hopes of restoring activity.

Tin.—In 1976, the principal tin-producing companies on the Jos Plateau were ATMN, Bisichi-Jantar, Exlands, Gold & Base Metal Mines of Nigeria Ltd. (GBMM), Kaduna Syndicate, Tin and Associated Minerals, United Tin Areas, Vectis Tin Mines, and NMC. Tin concentrate production in 1976 was estimated to be about 5,050 tons. There had been a persistent fall in production since the peak reached in 1968 of 13,240 tons.

The Jos Plateau was plagued with numerous shortages during 1976, including shortages of gasoline, foodstuffs, and frequent power cuts. An increase of 25% in the cost of electricity supplies came into effect in October 1976. The cost of living for all mining company employees continued to rise as a result of the high level of inflation. This contributed to the industrial unrest during January 1976, when demands for full implementation of the Udoji Public Service Review Commission's recommendations were made by the unions. The resulting 40% wage increase imposed a heavy burden on the industry. An appeal was made by the Chamber of Mines and the Association of African Miners for a reduction in the royalty rate. In addition, the industry was suffering from a shortage of trained manpower. Now down to 19 expatriate employees, ATMN once had 180 and was finding recruiting difficult.

A water supply dam, proposed by the Government, was to be built at a locality that would flood acres of good tin mining. It was estimated that approximately 60,000 tons of tin reserves would be lost if the dam is constructed.

Alluvial mine area restoration conditions have been in effect since 1946. At present the company must make the surface flat after the ore is mined out; an 80% restoration is required. It was found that hydraulicking the soil back into position would many times allow trees and grasses to grow better than before. The companies pay compensation rates to farmers (owners) based on the type of ground; for example, in a congested area

[4] Mining Annual Review—1977. Columbium/Tantalum. Pp. 84–85.

the rates would be $89 per acre and $16 per tree.

During 1976, NMC acquired 40% of ATMN and was seeking an additional 14% in accordance with recent Government requirements. The Federal Government has recommended that Government-sponsored institutions and private Nigerian citizens should, by yearend 1978, have not less than a 60% equity interest in the mining industry. Another 6% of ATMN was to be reserved for employees. The Makeri smelter was also 40% Government-owned. The small tin company Exlands was contacted in April by NMC regarding greater Government participation, but GBMM and United Tin had not yet been approached.[5]

The tin royalty rate was 16%, based on the LME posted price, but because the LME price was higher than the actual price received by the companies, the royalty was an effective 17%. There was also a 45% profit tax, and restrictions were introduced on June 29, 1976, limiting the amount of dividends payable. A company cannot pay dividends in excess of 30% of the company's share in gross capital investment.

For the fiscal year ending March 31, 1976, ATMN produced 2,658 tons of tin concentrate and 184 tons of columbite.[6] The company's schedules of expenditures and profits for 1976 indicated that the total revenue received was $7,961 per ton. After deducting a royalty of $1,362, smelter charges of $382, production costs of $5,237 and a 45% profits tax, there was approximately $539 earned for each ton produced. Amalgamated Tin's net profits for the year to March 31, 1976 were down 70% compared with those of fiscal year 1974–75. The drop in profits was caused partly to the devaluation of the pound sterling against the Nigerian naria, and partly to the more than 30% inflation in Nigeria and its effect on operating costs.

Mining depth was beginning to pose a problem. The average depth mined in the past was 60 feet, but ATMN was planning to go eventually to 140 feet. The depth to bedrock in the active pit was 80 feet, and at the new pit site being developed, was 100 feet. An Anderson Manor conveyor belt system was to be used to remove overburden, along with two new bucket-wheel excavators and draglines.

Preparatory underground development and additional exploration continued at the Ririwai (Liruen) tin-zinc project located in Kano State about 120 miles north of Jos on the new Jos-Kano road. NMC was majority shareholder in the project and GBMM held 20% interest. Work completed at yearend on the joint-venture indicated that the deposit extended over a distance of 4.5 kilometers and contained more than 5 million tons of measured and inferred ore reserves. McKaye and Schnelling were consultants for the new mine and did the original survey. The tin-bearing veins at this mine were expected to be lower grade than the alluvial ores. When the new mining is started, the added production will double smelter needs. The smelter was also expected to modify its system to handle the high lead content from Liruen when production starts. The new mine also has an expected potential of an estimated 7,000 tons of zinc concentrates, some chalcopyrite, and significant amounts of silver-lead minerals. There was one wide vein of economic significance with considerable sphalerite and several smaller veins of lesser significance.

NONMETALS

Cement.—Two new cement plants were being constructed, one near Glsoko, to be finished in 1978, and one at Ashaka, to be finished by 1979–80. Producing plants were located at Nkalagu in Anambra State, Ukpilla in Bendel State, Calabar in Cross River State, Sokoto in Sokoto State, and Ewekoro in Ogun State. All facilities utilized local Cretaceous limestone. Cement was selling locally for $3.24 per bag, or $64.80 per ton. Cutler Hammer Europa won a contract to supply a 415-volt electrical control gear to the new cement works at Shagamu.

A $50 million expansion program was being carried out by Niger Cement Co. (NIGERCEM) at its Nkalagu factory in Anambra State and would enable the company to raise its annual production level 50% to 720,000 tons. A new cement plant was planned for Ondo State with its tentative location to be near Iti near Owo,

[5] Industries et Travaux D'Outremer (Paris). Nigeria. V. 24, No. 275, October 1976, p. 732.
[6] The Financial Times (London). Amalgamated Tin Mines of Nigeria (Holdings) Limited. Nov. 8, 1976, p. 15.

but no feasibility study has been made. The firm of Turner and Newall of Manchester, England, was also investing in the cement industry of Nigeria as Turners Asbestos Cement (Nigeria) at Enugu and as Turner Asbestos Cement at Kaduna.

The temporary ban placed on imports of cement in 1975 was lifted. At the time the ban was imposed, it was estimated that up to a 12-month supply of cement was on ships waiting to be unloaded. The massive importation of cement was due to increasing construction, which continued unabated. In spite of this pressure, domestic cement output contributed a relatively low percentage to the needed supply, but production was expected to increase steadily. Importers are now required to obtain clearance from the Ministry of Transport for deliveries, to prevent excessive imports at any one time.

Glass Sands, Quartzite.—A geological survey by the University of Ife determined that the sand at Igbokoda was suitable for the manufacture of sheet glass. Asahi Glass Co., Ltd. expressed interest in this project, located in Ondo State. Tokyo Glass Engineering and Planners Co., Ltd., signed a $4 million contract to reactivate a glass factory project that was closed down during the recent civil war. Discovery of quartzite reserves in Kano State resulted in the establishment of a glass industry there as a joint effort between the Government (85%) and a Hungarian company.[7]

MINERAL FUELS

Coal.—Nigeria's third development plan (1975–80) envisaged $116 million to be spent on construction of a coal carbonization plant and expansion of the Enugu coal mines. The National Coal Corp. (NCC) was expecting to upgrade its staff in order to undertake the expansion, and professionals were being recruited from Europe. The Polish company Katowic Arebowa was assisting with underground coal operations at Enugu. The NCC coal-crushing plant can handle 250 tons per hour, or 2,000 tons per day. There were four active coal mines—Okpara, Anyeama, Ribadu, and Okaba. The local coal market is very limited. The railroad and the National Electric Power Authority (NEPA) each used one-third of the coal production. NEPA used coal for a power station that was being phased out as new hydroelectric and thermal power stations were coming onstream. The coal station had a 15-megawatt capacity. NIGERCEM at Nkalagu takes the rest of the coal for cement production.

The NSDA, with Soviet assistance, was investigating coal in Lafia, where coking-type coal had been reported. The geological structure, however, may make mining difficult.

Natural Gas.—Gas production totaled about 670 billion cubic feet; of this, about 2.4% was sold to utilities and industrial consumers. The balance was flared. Although there was no liquefied natural gas (LNG) production, plans were being made for the construction of several plants. As raw input for an LNG plant, flared gas would be worth $93 million at an estimated value of 15 cents per 1,000 cubic feet. Gas reserves on January 1, 1977, were estimated to be 1,245 billion cubic meters, or 1.9% of the world's total.[8]

The Nigerian Federal Government signed an agreement on October 4, 1976, with Shell International Petroleum Co. Ltd. and British Petroleum for the construction of a $2.5 billion LNG plant at Bonny River. The plant was to have a capacity of 800 million cubic feet per day. The Government was to hold 60% of the equity, and Shell and BP were to hold 20% each. The project was to be executed in three stages and geared to meet U.S. market demands. A similar plant, to be located at Peterside, also in Rivers State, was to be jointly owned by the Government (60%), Phillips Petroleum (15%), Nigerian AGIP Oil Company Limited (15%), and Essence et Lubrificant de France (ELF) (10%).

Petroleum.— *General.*—On May 27, 1976, it was announced that the Ministry of Petroleum and Energy would henceforth be known as the Ministry of Petroleum Resources. The Nigerian Government was dedicated to major expansion of petroleum transportation and processing in the next 10 years. Expansion plans included gas-gathering and processing facilities, improved transportation and storage of crude oil for national security, expansion of the

[7] Standard Bank Review (London). Nigeria. March 1974, p. 16.

[8] Petroleum Economist (London). Nigeria, World Estimated Commercial Production of Natural and Proved Reserves. V. 44, No. 7, July 1977, p. 262.

country's refining capacity by 240,000 barrels per day, and creation of a petrochemical industry.

A combination of Government price increases and decreased pumping allowances cut company profits more than 36% per barrel in the first quarter of the year. Nigerian National Oil Co. (NNOC) boosted the price of its participation crude oil to local producers to $12.75 per barrel for the first quarter of 1976, the highest price for the grade set by any member of the Organization of Petroleum Exporting Countries (OPEC). On July 3, 1976, NNOC offered to sell in the third quarter of 1976 at $13.01 per barrel. However, a revision of gravity differentials was announced in July, backdated to Jan. 1, 1976, that reduced prices of heavier grades of Nigerian crude oil 7.5 cents per barrel, to $12.48. The reduction in the posted price led to a 6.6-cent-per-barrel cut in cost of equity oil to producers to $11.96 per barrel. High prices had resulted in a depressed demand for Nigerian oil although the light crude continued to be desirable because of its good refining characteristics. In addition to stimulating demand for heavier crudes, the Government hoped that the revised differentials would answer company criticism that profit levels were too low to justify new investment.[9]

Oil production in November was the highest level achieved in 2 years. Texaco Overseas (Nigeria) Petroleum Co.'s crude oil production returned to a normal level after the loading facilities were repaired in mid-October; Texaco had virtually shut down completely for the month of September while repairing a hose at its loading terminal. Completion of several new wells resulted in increased production from Nigerian AGIP Oil Company Limited, Phillips Oil Company (Nigeria) Ltd., and ELF. After repair of a broken pipeline at Bonny Terminal, Shell-BP Development Co. of Nigeria's (Shell-BP) output was also nearly back to normal by yearend.

Pan Ocean Oil Corp.'s onshore Ogharefe oilfield was brought onstream in July at a production rate of more than 12,000 barrels per day. Production was from 10 wells on a 445-square-mile tract, located about 50 miles inland and 20 miles south of Bénin City. The oilfield was linked to Shell-BP's Amukpe terminal by pipeline. Pan Ocean held a 100% working interest in the field. Beginning production in July, the field produces from Tertiary sands which are 9,500 to 11,000 feet deep.

Production from Ashland Oil (Nigeria) Co.'s Ossu Field was expected to start in 1977 and was to increase the company's output from 10,000 to 13,000 barrels per day. A pipeline between Ashland's Izombe Field and Brass River terminal was under construction.

In February, the Government was demanding the right, starting in July 1977, to provide tanker transportation for up to 50% of the volume of crude oil that it sells, to specify the currency in which payment is to be made, and to require buyers to give performance guarantee bonds. Each of these demands was expected to cause an increase in oil company costs. The country's first oil tanker, the 270,000-deadweight-ton *Oloibiri,* was launched. The tanker was built at a cost of $44.5 million at a Yugoslavian yard, and, reportedly, was to be managed by a British company.[10]

All shares of the Exxon marketing company, Esso Standard (Nigeria), were acquired by the Government in accordance with an agreement made in November 1976. The company was renamed Unipetrol (Nigeria). Exxon's involvement was purely marketing and all products sold were imported. Up to this point, Government participation in petroleum marketing was confined to 60% of Shell Nigeria's marketing unit, renamed the National Oil Marketing Co., which was acquired in April 1975. Mobil Oil Nigerian Ltd. and AGIP–Phillips marketing units were still owned 100% by their parent organizations.

Exploration.—A combination of Government price increases and decreased pumping allowances continued to have the effect of decreased investment in new exploration. The decline started in 1974 when the Federal Government first took majority ownership in the producing companies and drastically reduced allowable production levels. In 1975, taxes and royalties were increased, reducing profit margins; the posted price increases of 1976 cut profits even further. Major producing companies were slashing investment plans, selling off

[9] Petroleum Economist (London). Nigeria. V. 43, No. 7, July 1976, p. 277.
[10] Africa Report. Business Briefs. September–October 1976, p. 35.

equipment, and giving up exploration concessions. The number of drilling rigs operating in Nigeria declined from 29 in 1974 to 18 in 1975 and 15 in 1976. Although production had increased toward yearend 1976, there was widespread concern that exploration activity had been insufficient to safeguard production in future years. New financial incentives, expected to be announced at the beginning of 1977, would affect the petroleum profits tax (now 85%), royalty rates (now 20%), amortization and investment tax credits, and would promote increased investment.

A total of 21 exploratory wells were completed in 1976. The Shell BP consortium drilled eight exploratory wells four of which (Nembe Creek 6, Onite 1, Obigbo N–25, and Nembe Creek 17) were all shut in after oil was found. Alo 1 tested gas but was also shut in, and the other three holes were dry. NNOC embarked on its first wildcat drilling operation in August. Petty Ray and United Geophysical were hired by NNOC in October 1976 to do basic seismic studies in offshore areas held in national reserve. Gulf Oil Company (Nigeria) Ltd., Japan Petroleum Co. (Nigeria) Ltd., ELF, Phillips Petroleum, and NNOC made discoveries in 1976. A well that produced at a rate of 7,000 barrels per day was discovered in the Niger Delta by Nigerian AGIP Oil Co., a subsidiary of Italy's State-owned Ente Nazionale Idrocarburi (ENI) and operator for the Phillips Petroleum group. Called the Clough Creek No. 1, the well derived oil from four producing zones. Important reserves of gas were also discovered. NNOC was also a member of the AGIP–Phillips consortium.

Occidental Petroleum Nigeria relinquished its last prospecting license in Nigeria and wrote off a total investment of $33 million. Two offshore discoveries were made by the company, but neither was developed.

Refining.—The Government and Snam Progetti, part of the ENI group, signed a formal agreement for the design and construction of Nigeria's second oil refinery. Valued at $630 million, the refinery was to be built at Warri in Bendel State and was to have a 5-million-ton-per-year capacity. Engineering design work in Italy and site work at Warri were started, and the plant was scheduled to come onstream in 1978. Whessoe Ltd. signed a $5 million contract to build 39 steel storage tanks at the Warri refinery. Plans for the 5-million-ton-per-year refinery to be built at Kaduna were also firming up with selection of the King-Wilkinson Co. to provide project management and consultation services. The National Ports Authority was building a new oil jetty at Okirika, Rivers State, to facilitate the shipment of petroleum products from Port Harcourt refinery. The $21 million jetty was to replace the existing one damaged in 1975. Williams Brothers International Corp. won a contract to construct a 206-kilometer, 12-inch products pipeline from Port Harcourt via Aba to Enugu, and a 175-kilometer, 6-inch products line from Enugu to Makurdi, for completion in 1978. Construction was scheduled to begin by mid-1977.

The Mineral Industry of Norway

By Joseph B. Huvos [1]

In 1976, Norway was one of the world's major producers of aluminum, magnesium, and ferroalloys, thanks to its sizable hydroelectric resources. Development of North Sea oil made the country West Europe's largest oil producer. Norway's most important mineral products and approximate percentages of world output were as follows: Magnesium (30%), ilmenite (14%), aluminum (4.9%), nickel (4.5%), cobalt (2%), and zinc (1.2%). Production of other metals, minerals, and fuels, important only to the national economy, included copper, pig iron, steel, lead, vanadium, sand and gravel, cement, feldspar, fertilizer materials, nepheline syenite, quartzite, sulfuric acid, coal, and peat.

In 1976, Norway's gross national product (GNP) was about $33 billion.[2] Of this total the oil and coal industries contributed an estimated 4%, iron and steel 3%, nonferrous metals 4%, and nonmetallic minerals 2%. Out of a total industrial employment of 410,000 in 1976, mining employed about 12,000, including about 20% in oil and coal, the rest in ore mining. In the processing sector, oil and coal processing employed an estimated 2,500, mineral products 13,000, and metals 30,000.

Low product prices continued to prevail for most ores and minerals mined in Norway owing to weak demand in 1976. Aluminum was the only major metal that performed well in 1976.

There were a number of significant developments during the year. New aluminum reduction capacity came onstream at the Mosal Aluminium A/S reduction plant at Lista. New capacity came onstream also at the Titania A/S titanium dioxide plant at Kristiansand. Construction started for rebuilding two potlines at the Årdal reduction plant of Årdal og Sunndal Verk A/S (ASV). Construction continued at the magnesium chloride plant of Norsk Hydro A/S at Herøya; construction continued also at nine hydroelectric powerplant projects. Development continued at the Ekofisk, Statfjord, and Frigg oilfields in the North Sea where six new platforms were installed and two significant oil discoveries were made.

Plans were prepared to build a second ferrosilicon furnace at Orkla Industrier's Thamshamn plant.

Among government measures related to the mineral industry was the decision to continue government loans in support of the copper mining industry.

Where necessary, values in Norwegian kroner (NKr) were converted to U.S. dollars at the rate of NKr 5.4565=US$1.00 for 1976 and NKr 5.2269=US$1.00 for 1975. Source for conversion rate was the International Monetary Fund.

PRODUCTION

The following tabulation shows production indices for various sectors of the mineral industry:

Industry sector	(1970=100) 1975	1976
Mining and quarrying:		
Coal mining	84	111
Metal mining	110	120
Other mining and quarrying [1]	114	112
Manufacturing:		
Iron, steel, ferroalloys	120	112
Nonferrous metals	110	122
Ceramics, glass, glasswares	105	112
Chemical raw materials	108	110
Refining of petroleum and coal	128	142
Electric power	135	142

[1] Includes production of crude oil and natural gas.

Production of mineral commodities is shown in table 1. The tabulation below shows the major producers of commodities:

Commodity	Major companies, principal facilities, and ownership	Percent of domestic output
Aluminum	A/S Årdal og Sunndal Verk—smelters at Årdal, Sunndalsøra; government 75%, Alcan 25%	40
Do	Mosal Aluminium A/S—smelter at Mosjöen; Elkem-Spigerverket A/S 55%, Alcoa 45%	21
Do	Norsk Hydro A/S—smelter at Karmøy; government 51%	17
Coal	Store Norske Spitzbergen Kullkompani A/S—mines at Longyearbyen and Svea; government	100
Copper ore	A/S Sulitjelma Gruber—mine at Sulitjelma; Elkem-Spigerverket A/S–ESV	15
	Folldal Verk A/S—mines at Dovre and Kvalsund	14
	Grong Gruber A/S—mine at Røyrvik	14
Copper, refined	A/S Sulitjelma Gruber—smelter at Sulitjelma; Elkem-Spigerverket A/S	100
Ferroalloys	Elkem-Spigerverket A/S—plants at Svelgen, Kristiansand, Porksgrunn, Salten	30
Do	Electric Furnace Products Co. Ltd.—plant at Sauda; Union Carbide, United States	26
Do	Tinfos Järnverk A/S—plants at Notodden, Kvinesdal	25
Ilmenite	A/S Titania—mine at Telnes; NL Industries, United States	99
Iron ore	A/S Sydvaranger—mine at Sør-Varanger; government 51%	61
Do	Rana Gruber—mine at Rana; government 51%	33
Iron and steel	A/S Norsk Jernwerk—plant at Mo i Rana; government 51%	80
Lead and zinc ore	Bleikvassli Gruber A/S—mine at Hemnes; Frangel and Co. A/S	13
	Folldal Verk A/S—mine at Dovre	12
	Bergverkselskapet Nord Norge A/S—mine at Rana	12
Magnesium	Norsk Hydro A/S—smelter at Oslo; government 51%	100
Nickel and cobalt	Falconbridge Nikkelverk A/S—smelter at Kristiansand; Falconbridge Nickel Co., Ltd., Canada	100
Petroleum	Phillips Norway Group—North Sea Field at Ekofisk; Phillips Petroleum Co. of Norway 40%	100
Petroleum products	Norske Esso A/S—refinery at Slagen, Valloy; Standard Oil Co. of N.J	44
Do	Rafinor A/S & Co.—refinery at Mongstad; Norsk Hydro 30%, government 70%	32
Do	Norske Shell A/S—refineries at Sola and Valloy; Bataafse Petroleum, Netherlands	23
Pyrite	Folldal Verk A/S—mine at Dovre	43
Do	Elkem-Spigerverket A/S—mine at Skorovas Gruber, Namsskogan	25
Do	A/S Sulitjelma Gruber—mine at Fauske	20
Zinc, electrolytic	Det Norske Zinkompani A/S—smelter at Odda; Boliden AB, Sweden	100

Total ——do	45,553	56,231	63,536

e Estimate. p Preliminary. r Revised. NA Not available.

[1] Excludes nepheline syenite.

[2] Excludes a quantity of stone only reported volumetrically as: 1974—4,525,996 cubic meters; 1975—5,309,437 cubic meters; 1976—NA.

TRADE

The trade deficit of more than $3 billion in 1976 was mainly due to large investments in North Sea petroleum extraction and shipping and lagging foreign demand for major Norwegian products.

Metals (mainly aluminum, magnesium, and nickel), ferroalloys, rolled steel, and liquid fuels were again major export items in 1976, accounting for about half of the total value of all mineral commodity exports. Imports of liquid fuels, iron and steel, basic chemicals (mainly alumina and aluminum hydrate), and metallic ores (mainly nickel-copper matte) accounted for slightly more than one-quarter of all commodity imports in 1976.

Trade in mineral commodities in 1974 and 1975 is detailed in tables 2 and 3.

Table 2.—Norway: Exports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1974	1975	Principal destinations, 1975
METALS			
Aluminum:			
Alumina	9	2	NA.
Metals including alloys:			
Scrap	12,805	8,472	West Germany 4,865; Sweden 1,854.
Unwrought	554,513	451,500	West Germany 131,547; United Kingdom 80,362; People's Republic of China 50,157.
Semimanufactures	40,688	37,143	United Kingdom 10,522; Sweden 9,548; Denmark 4,313.
Antimony	NA	NA	
Arsenic	NA	NA	
Cadmium	59	61	NA.
Chromium oxide and hydroxide	1	NA	
Cobalt	1,172	601	NA.
Copper:			
Ore and concentrate	52,964	83,270	West Germany 52,151; Sweden 28,520.
Oxide and hydroxide	2,173	2,154	Portugal 21; Nigeria 15; Taiwan 14.
Copper sulfate	NA	NA	
Metal including alloys:			
Scrap	2,152	1,360	Belgium-Luxembourg 550; West Germany 532.
Unwrought:			
Unrefined	6,290	6,969	All to West Germany.
Refined	25,777	18,363	United Kingdom 4,875; France 4,800; West Germany 2,578; Netherlands 1,989.
Semimanufactures	1,955	1,837	Sweden 1,273; Denmark 183.
Gold metal, unworked or partly worked troy ounces	2,154	2,025	West Germany 868; United Kingdom 482.
Iron and steel:			
Ore and concentrate, except roasted pyrite thousand tons	2,657	3,154	West Germany 1,187; United Kingdom 1,085; Poland 496.
Roasted pyrite	152,508	113,194	Mainly to West Germany.
Metal:			
Scrap	34,446	19,536	Sweden 8,215; West Germany 7,794; Spain 3,505.
Pig iron including cast iron	121,301	100,863	United Kingdom 26,552; West Germany 19,934; Sweden 14,728.
Ferroalloys:			
Ferromanganese	309,365	256,639	United Kingdom 54,503; West Germany 51,603.
Other	527,408	385,969	United Kingdom 114,049; West Germany 104,801; United States 41,075.
Steel, primary forms	212,460	185,319	Netherlands 135,822; Denmark 17,281.
Semimanufactures:			
Bars, rods, angles, shapes, sections	193,475	217,809	United Kingdom 50,076; Sweden 39,150; Finland 28,335; West Germany 25,817.
Universals, plates, sheets	129,461	129,073	Sweden 50,095; United Kingdom 24,831; Denmark 15,991.
Hoop and strip	8,463	13,422	Sweden 10,806; Denmark 1,566.
Rails and accessories	975	877	Austria 274; West Germany 253; Sweden 161; Finland 139.
Wire	8,769	4,772	Portugal 705; United States 522; Switzerland 425.
Tubes, pipes, fittings	33,244	36,494	Sweden 15,212; Denmark 7,622; United Kingdom 5,441.
Castings and forgings, rough	14,002	12,822	Sweden 10,348.
Total	388,389	415,269	
Lead:			
Ore and concentrate	6,015	4,100	Netherlands 2,236; West Germany 1,864.
Oxides	26	14	Thailand 9.
Metal, including alloys:			
Scrap	4,748	4,744	Denmark 2,521; Sweden 1,938.
Unwrought	366	575	West Germany 289; Sweden 205.
Semimanufactures	164	6	Sweden 1.

Table 2.—Norway: Exports of mineral commodities—Continued

(Metric tons unless otherwise specified)

Commodity	1974	1975	Principal destinations, 1975
METALS—Continued			
Magnesium metal including alloys:			
Unwrought ----------value, thousands--	$45,311	$40,805	NA.
Wrought ----------	260	241	Netherlands 172; Sweden 57.
Manganese ore and concentrate ----------	1,831	2,730	United Kingdom 1,500; Sweden 1,230.
Mercury ----------76-pound flasks--	58	NA	
Molybdenum:			
Ore and concentrate ----------	NA	NA	
Metal including alloys, all forms --------	1	NA	
Nickel:			
Ore and concentrate ----------	13,515	6,885	All to Finland.
Matte, speiss and similar materials -----	NA	NA	
Metal including alloys:			
Scrap ----------	309	354	West Germany 274; Sweden 54.
Unwrought ----------	43,180	29,489	United States 13,091; West Germany 6,410.
Semimanufactures ----------	13	26	Sweden 15; Denmark 6.
Platinum-group metals and silver:			
Waste and sweepings --------kilograms--	57,051	48,652	West Germany 41,423; United Kingdom 6,797.
Metal including alloys:			
Platinum-group metals -troy ounces--	30,833	46,779	United States 25,142; Netherlands 8,809; West Germany 7,073.
Silver ----------do----	862,443	959,795	Sweden 851,994.
Rare-earth metals:			
Oxides ----------	8	10	United States 7; Japan 2.
Metal including alloys, all forms -value--	NA	NA	
Silicon, elemental ----------	63,931	49,748	U.S.S.R. 20,198; West Germany 10,825.
Tin metal including alloys:			
Scrap ----------	54	21	United Kingdom 13; Denmark 8.
Unwrought ----------	284	42	Sweden 17; Finland 12; United Kingdom 7; Denmark 6.
Semimanufactures ----------	8	9	All to Sweden.
Titanium:			
Ore and concentrate (ilmenite) ---------	776,814	534,606	NA.
Oxides ----------	900	962	Sweden 693; Denmark 140.
Tungsten metal including alloys, all forms value--	$3,339	$4,000	NA.
Uranium and thorium metal including alloys, all forms ----------do----	$28,882	$17,000	All to Denmark.
Zinc:			
Ore and concentrate ----------	20,488	14,765	Poland 7,510; Netherlands 7,255.
Oxide ----------	560	344	Sweden 225; Denmark 69; Malaysia 36.
Metal including alloys:			
Scrap ----------	371	114	Sweden 41; United Kingdom 37; Denmark 19; West Germany 17.
Blue powder ----------	459	2,838	NA.
Unwrought ----------	55,238	41,838	Sweden 21,879; United Kingdom 9,746; West Germany 6,084.
Semimanufactures ----------	873	388	Mainly to Sweden.
Other:			
Ash and residue containing nonferrous metals ----------	22,932	47,149	West Germany 24,940; United States 12,508.
Oxides, hydroxides and peroxides of metals, n.e.s ----------	2	1	NA.
Metal including alloys:			
Metalloids, n.e.s ----------	10	22	Netherlands 8; United States 8; Belgium-Luxembourg 2.
Pyrophoric alloys --value, thousands--	$3	$9	Mainly to Finland.
Base metals including alloys, all forms, n.e.s ----------	23	1	All to West Germany.
NONMETALS			
Abrasives, natural, n.e.s., grinding and polishing wheels and stones ----------	1,140	838	Sweden 230; Finland 166; Poland 147.
Asbestos ----------	73	5	NA.
Barite and witherite ----------	75	2,979	United Kingdom 2,450.
Boric oxide and acid ----------	NA	NA	
Cement, hydraulic ----------thousand tons--	876	981	Ghana 574; United States 311.
Chalk ----------	2	47	NA.

See footnotes at end of table.

Table 2.—Norway: Exports of mineral commodities—Continued

(Metric tons unless otherwise specified)

Commodity	1974	1975	Principal destinations, 1975
NONMETALS—Continued			
Clays and clay products (including all refractory brick):			
Crude clays, n.e.s	302	160	Egypt 49; Sweden 31.
Products:			
Refractory (including nonclay brick)	8,560	6,824	West Germany 4,163; Sweden 1,284.
Nonrefractory ---thousand tons	1,389	3,956	West Germany 3,473; France 330.
Diamond, gem, not set or strung value, thousands	$6	$8	NA.
Diatomite and other infusorial earth	15	16	NA.
Feldspar and related materials	325,683	300,773	West Germany 73,607; United Kingdom 57,103; Netherlands 53,444.
Fertilizer materials:			
Manufactured:			
Nitrogenous	811,049	874,002	Mainly to West Germany.
Phosphatic	25	3	NA.
Potassic	12	2	NA.
Other	788,552	[1] 101,456	NA.
Ammonia ---value, thousands	$12,350	$12,599	NA.
Graphite, natural	9,570	8,395	NA.
Gypsum and plasters	13,368	20,378	Ghana 19,289.
Lime	NA	100	All to Ivory Coast.
Mica crude including splittings and waste	4,158	3,577	West Germany 953; Netherlands 364.
Pigments, mineral, processed iron oxide	49	61	West Germany 22; Libya 20; Thailand 9.
Precious and semiprecious stones except diamond ---value, thousands	$7	$5	NA.
Pyrite, gross weight	410,573	231,251	West Germany 109,425; Sweden 82,874; France 26,766.
Salt	3,430	2,732	Iceland 1,050; Sweden 1,021; Canada 462.
Sodium and potassium compounds, n.e.s. value, thousands	$453	$335	NA.
Stone, sand and gravel:			
Dimension stone:			
Crude and partly worked:			
Marble and other calcareous	3,697	1,589	West Germany 695; Italy 448.
Slate	45,876	44,018	Netherlands 21,589; West Germany 8,216; Denmark 5,762.
Other	100,557	84,989	France 27,269; West Germany 24,757; Italy 19,512.
Worked, all types	22	308	Sweden 253.
Dolomite	16	81,213	NA.
Gravel and crushed rock -thousand tons	1,180	1,129	West Germany 793; United Kingdom 127; Sweden 100.
Limestone (except dimension)	32,800	140,174	West Germany 101,178; Denmark 32,445.
Quartz and quartzite	4,548	3,641	West Germany 2,426; Denmark 777.
Sand, excluding metal bearing	3,007	2,858	Ivory Coast 351.
Sulfur:			
Elemental	68	22	NA.
Sulfur dioxide	777	1,377	Mainly to Sweden.
Sulfuric acid ---value, thousands	$2,532	$2,572	NA.
Talc, steatite, soapstone, pyrophyllite	66,883	55,318	Sweden 13,649; United Kingdom 10,737; West Germany 9,077.
Other nonmetals, n.e.s.:			
Crude	131	NA	
Slag, dross and similar waste, not metal bearing	2,842	12,800	Mainly to United States.
Oxides and hydroxides of magnesium, strontium and barium	NA	NA	
Building materials of asphalt, asbestos, and fiber cement, and unfired nonmetals, n.e.s	2,235	6,461	Denmark 5,864.
MINERAL FUELS AND RELATED MATERIALS			
Asphalt and bitumen, natural	652	45	NA.
Carbon black	6	8	NA.
Coal and coke, including briquets:			
Anthracite and bituminous coal	54,042	31,120	West Germany 25,641.
Coke and semicoke	70,840	14,940	Romania 12,560; Sweden 2,341.
Peat including peat briquets and litter	5	6	NA.

See footnotes at end of table.

COMMODITY REVIEW

METALS

Aluminum.—The recovery of the international aluminum market in 1976 resulted in increased exports, increased domestic consumption, and lower stocks, although the price of aluminum was still somewhat depressed.

In 1976, Mosal Aluminium A/S, commissioned the new (No. 3) 27,000-ton-per-year potroom at its Lista Island, Vest Agder Province, reduction plant, bringing the plant's capacity to 82,000 tons per year. ASV started rebuilding two potlines at its Årdal, Sognefjord, reduction plant, to add 32,000 tons per year to its present capacity. The State-owned Norsk Hydro, has taken over the majority of Norwegian interests (19.4%) in Sør Norge Aluminium A/S, Husnes, leaving 75% to Schweizerische Aluminium AG (Alusuisse), Switzerland.[3] Norsk Hydro decided to proceed with a 75,000-ton-per-year expansion of its Karmøy, Rogaland Province, reduction plant.

ASV decided to proceed with a feasibility study of a partnership in an alumina project in Hamburg, West Germany. Involved is a $180 million; 450,000-ton-per-year extension of an existing 600,000-ton-per-year plant jointly owned by Reynolds Metals, (United States) and Vereinigte Aluminium Werke (West Germany).

Anortal, a company jointly owned by ASV and Elkem-Spigerverket A/S, operated a pilot plant for processing anorthosite with 30% Al_2O_3 into alumina, and had rights to exploit deposits in Aurland and Voss municipalities in West Norway.

Five companies operating eight primary aluminum plants in 1976, with a total capacity of about 725,000 tons per year, are shown in table 4.

Norwegian companies give high priority to securing raw materials needed for industry. ASV and Norsk Hydro each have 5% interest in the Trombetas, Brasil, bauxite mine of Mineraçao Rio do Norte S.A., and have a contract for the delivery of 350,000 tons per year of bauxite.

Copper, Lead, and Zinc.—For the second consecutive year, the Government extended loans up to $9.5 million to the copper mining industry to ease financial difficulties caused by the depressed copper market. The interest-free loans are to be repaid over a period of 3 years, starting in 1981.

Orkla Industrier A/S decided to separate its Løkken copper mine, east of Trondheim, from its other operations and to incorporate it into a new company jointly owned by Orkla and Sydvaranger A/S. Up to $58

Årdal, Sognefjord	175	Government (75%), Alcan Aluminium Ltd., Canada (25%).
Sunndalsøra, Tingvollfjord	120	
Høyanger, Sognefjord	30	
Mosal Aluminium A/S, Oslo:		
Mosjøen, Vejsnafjord	100	Elkem-Spigerverket A/S, Oslo (55%), Aluminum Co. of America (Alcoa), United States (45%).
Lista Island	80	
Norsk Hydro A/S, Oslo:		
Karmøy Island	120	Government (51%).
Sør Norge Aluminium A/S:		
Husnes, Hardangerfjord	75	Alusuisse (75%).
DNN Aluminium A/S:		
Tyssedal, Sørfjord, Odda	25	Alcoa (50%), British Aluminium Ltd., United Kingdom (50%).

million is to be invested, part of it into the Løkken mine.

A/S Sulitjelma Gruber plans to increase production at its Fauske mines from about 8,000 tons of copper in 1976 to 10,000 tons in 1978. In the meantime, the capacity of the company's Sulitjelma smelter is to be raised to 25,000 tons of blister copper per year.[4] At present, some blister is refined at the Falconbridge Nikkelverk A/S, Kristiansand electrolytic refinery. Surplus Norwegian copper concentrates and all lead concentrates are exported because there is limited copper smelter capacity and no lead smelter in the country.

Det Norske Zinkkompani published plans to invest $86 million over a period of 5 years to raise electrolytic zinc capacity at its Odda plant, southeast of Bergen, from 80,000 tons to 130,000 tons per year.[5] About two-thirds of the zinc concentrates used at the plant were imported. Norway's 12 small complex sulfide ore mines were operated by 10 independent companies. The sulfide ores contained mostly copper, lead, zinc, and pyrites. The more important copper mines of the country were A/S Sulitjelma Gruber's Fauske mine east of Bodö, which produced also lead and pyrite concentrates; Folldal Verk A/S's Dovre and Kvalsund mines, producing zinc and pyrite concentrates; Grong Gruber A/S's Røyrvik mine near the Swedish border northeast of Grong, which produced zinc concentrates; and Orkla Industrier A/S's Meldal mine at Løkken south of Trondheim, producing zinc and pyrite concentrates.

Iron Ore.—Continued weakness in foreign markets affected iron pellet and concentrate exports, and production.

Of five Norwegian iron ore mines three were Government-owned, the others belonged to Elkem-Spigerverket A/S.

1. Government-owned A/S Sydvaranger, Oslo, mined a taconite deposit 8 kilometers from Kirkenes by open pit methods. Concentrates were pelletized in a 3-million-ton-per-year pelletizing plant.

2. The Government-owned A/S Norsk Jernwerk's Rana Gruber located at Rana, near Mo, produced magnetite-hematite ore from an open-cast mine. About 10 million tons of 35% ore was processed into a 65% concentrate making Norsk Jernwerk self-sufficient in iron ore.

3. Government-owned Fosdalen Bergwerks A/S mined iron ore from which about 500,000 tons of magnetite concentrate and some pyrite and chalcocite concentrates was produced.

4. Elkem-Spigerverket's Rødsand Gruber A/S produced raw ores at Nesset, containing 0.31% V_2O_5 and 30% iron, which were processed into about 100,000 tons of magnetite concentrate with 64% Fe. The company's Swelgen, Bremanger, smelter on Norway's west coast produced ferro-vanadium and vanadium-titanium pig iron.

5. Elkem-Spigerverket's Titania A/S produced about 50,000 tons of byproduct iron concentrates, mostly magnetite, at its Sokndal mine in south Norway.

Iron, Steel, and Ferroalloys.—As part of a $50 million investment plan, a second ferrosilicon furnace is to be built at Orkla Industrier's Thamshamn plant near Trond-

[4] International Wrought Copper Council. Survey of Planned Increases in World Copper Mine, Smelter and Refining Capacities 1974–1980. London, 1976, p. 33.

[5] Glückauf. Mar. 18, 1976, p. 275.

heim, bringing ferrosilicon capacity from 22,000 to 60,000 tons per year. The plant, together with a nearby mine, is to be separated from Orkla and run independently under the joint ownership of Orkla and Elkem-Spigerverket.

Norwegian iron ore and natural gas are to be used at a 1.2-million-ton-per-year three-unit Midrex plant to be built at the Emden, West Germany, terminal of the Ekofisk natural gas pipeline. A/S Sydvaranger signed a preliminary agreement with Korf Stahl AG, Baden-Baden, to form a new jointly owned company, Norddeutsche Ferrowerke GmbH, to operate the new plant.

Norway had three major steelmaking companies. Wholly Government-owned Norsk Jernwerk used domestic ores at the Mo i Rana plant with a 600,000-ton-per-year capacity. Elkem-Spigerverket's Nydalen, Oslo, plant and Stavanger Stal's Jorpeland, Stavanger, plant had an aggregate capacity of about 400,000 tons.

About 9 companies produced ferroalloys at 15 locations. The largest among them was Elkem-Spigerverket A/S, with capacity at Svelgen, Kristiansand (south coast), Porksgrunn (south coast), and Salten (Bodö) totaling 332,000 tons per year. Others were Electric Products Co. Sauda (280,000 tons), and Tinfos Järnverk A/S at Notodden and Kvinesdal (270,000).

Magnesium.—Work continued on Norsk Hydro's 50,000-ton-per-year anhydrous magnesium chloride plant at Herøya, South Telemark Province, where production was scheduled to begin in 1977. The entire output of the plant is to be used for producing 15,000 tons per year of magnesium metal, with 40,000 tons of byproduct chlorine to be used at the company's Ranes petrochemical complex.

Norsk Hydro remained Norway's only magnesium producer at its 40,000-ton-per-year Porksgrunn plant at Herøya. In addition, the company produced 30,000 tons of magnesium oxide. Dolomite used as a raw material comes mostly from the north of Norway. Major producers were A/S Norvegian Talc from its Hammerfall mine near Bodö and Franzefoss Bruk, with a mine at Ballangen near Narvik.

Nickel, Cobalt, and Platinum-Group Metals.—The low operating rates of 1975 were maintained in 1976 at Falconbridge Nikkelverk's Kristiansand refinery, although export shipments were increased, partly from existing stocks. Falconbridge, a subsidiary of Falconbridge Nickel Co. Ltd. of Canada, remained Norway's only producer of nickel, cobalt, and platinum-group metals. Production was based mainly on nickel-copper matte imported from Canada, and smaller amounts of domestic sulfide concentrates produced as a byproduct of processing ilmenite ores at the Tellnes mine near Sokndal, south Norway.

Titanium.—Ilmenite production capability increased substantially due to new capacity commissioned in 1975 at the Sokndal mine of Titania, a subsidiary of NL Industries Inc. (United States) near Dalane, south Norway. Titania produced more than 99% of the country's ilmenite; the rest came from the Nesset mine of Rødsand Gruber A/S, on the Tingvollfjorden. Titania's Kristiansand titanium dioxide plant south of Oslo was expanded to 25,000 tons per year, leaving four-fifths of the domestically produced ilmenite ore for export.

NONMETALS

Cement.—Cement production and exports decreased slightly. A/S Norcem remained the country's only producer with plants at Brevik and Slemmestad in the south and Kjøpsvik in the north on the Finnish border.

Fertilizer Materials.—Increased inland consumption could not make up for decreased exports, and nitrogenous fertilizer production had to be further curtailed.

Norsk Hydro remained Norway's main producer of fertilizer materials. The company produced about 700 tons of ammonia per day, partly from electrolytic hydrogen at its Glomfjord plant near Mo.

Pyrite and Sulfur.—Production of pyrite concentrate decreased substantially, as traditional markets switched increasingly to less expensive native sulfur. A large share of domestic pyrite output was processed domestically for increased base-metal concentrate recovery. In 1976, 8 of the country's 12 base-metal sulfide mines produced some pyrites.

Other Nonmetallic Minerals.—Increasing amounts of nepheline syenite were produced by Elkem-Spigerverket A/S-Norsk Nefelin at an underground mine at Sternøy, Altafjord, in Finnmark. A/S Olivin produced about 170,000 tons of refractory sand and brick. KS Norddal Olivin A/S & Co.

produced about 90,000 tons of olivine. A/S Norwegian Talc had a 100,000-ton-per-year capacity at its Knarrevik mill near Bergen for finely ground dolomite, talc, and mica. The company produced dolomite at a rate of 400,000 tons per year at its Hammerfall mine near Bodö, about 15,000 tons of mica schist giving 3,000 to 5,000 tons of mica concentrate at Rendalsvik north of Mo, and up to 40,000 tons of talc at Altermark on the Ranafjord. KS Norfloat A/S & Co. produced flotation feldspar and quartz at Lillesand on the south coast. A/S Skaland Grafitverk produced a flotation graphite concentrate on Senja Island south of Tromsö. There were also several anorthosite quarries in the Egersund area in the south and many limestone quarries, mostly for cement, in various areas of the country, producing about 5 million tons per year of limestone.

MINERAL FUELS

Steadily growing North Sea oil and sizable hydroelectric power provided the bulk of Norway's energy supply in 1976. About three-quarters consisted of petroleum and petroleum products, one-fifth domestic hydroelectric power, the rest coal. The country was also increasingly a net oil exporter.

After a temporary decrease in 1974, energy consumption increased again in 1976 for the second consecutive year, exceeding previous highs. Norway's supply and apparent consumption of fuels and power in 1975 and 1976 are shown in table 5.

Coal and Coke.—In 1976, the Government-controlled Norske Spitzbergen Kulkompani A/S increased production at its Longyearbyen mine on Spitzbergen Island and continued to develop the Svea coalfield near Van Mijeffjorden. Coal was shipped mostly to the Mo i Rana steel plant and some ferroalloy plants. The U.S.S.R. continued to mine about 450,000 tons of coal per year at Barentsburg and Piramiden, both near Longyearbyen.

Hydroelectric Power.—Norway supplied all domestic electric power needs from hydroelectric stations. Construction continued on nine hydroelectric powerplants across the country, including the 1,200-megawatt Kvildal plant and the 640-megawatt Saurdal plant in the southwest.[6] Twenty-five more plants were in the planning stage. Production is to reach 86 million kilowatt-hours in 1980 and 102 million kilowatt-hours in 1985. In case of dry weather, 5 million kilowatt-hours are to be imported and an equal amount produced in thermal plants; nuclear plants are under consideration only for 1985.

Petroleum and Natural Gas.— *Production and Exploration.*—In 1976, development work continued at a moderate rate in the North Sea at the Ekofisk, Statfjord, and Frigg oilfields. Operators in the North Sea drilled 25 wildcat holes in 1976, and were expected to drill the same number of holes during 1977. In all these operations,

Source: Statistisk Månedshefte. Central Bureau of Statistics, Oslo, Norway, 1976, No. 12. Månedsstatistikk Over Utenriks-Handelen, Statistisk Sentralbura, Oslo, Norway, 1977.

the Norwegian Government exercised its control through Den Norske Stats Oljeslskap A.S. (Statoil), the State oil company, which is to have a controlling interest in all new North Sea blocs. Detailed seismic work was performed by Aratoil and other Norwegian companies in the offshore areas of More, Trondelag, Troms, and Finnmark. Sediments in these areas were said to be up to 4,000 meters thick, or 10 times thicker than oil-bearing sediments south of the 62d parallel.[7]

The Norwegian Government ordered offshore personnel to be housed on platforms separate from production platforms. This measure necessitated profound changes in future oilfield development plans, and has also caused a temporary standstill in Statfjord developments, where Mobil, an operator with 15% interest in the field (Statoil 44%), considered scrapping plans for the $1 billion Statfjord B production platform in favor of a series of smaller platforms, which would add $100 million to development costs.

At yearend, Norwegian oil reserves in the North Sea totaled 760 million tons and natural gas reserves, 650 billion cubic meters.[8]

Plans were made at the Statfjord oilfield to tow out the $270 million A platform in May 1977. Plans for the B platform were delayed. The oilfield in blocks 33/9 and 12 was to begin production in 1979 at a rate of 3 million tons per year. Original plans for Statfjord A, B, and C platforms called for a peak production of 45 million tons per year, with development costing $2.5 billion. Statoil was in charge of preparing a proposal for a 36-inch crude oil and a gas pipeline leading to the Norwegian mainland through the Norwegian trench, up to 300 meters deep.

The last Ekofisk platforms were installed in summer at the Edfisk, Albuskjell, and Edda Fields. Development drilling began at the Cod platform in December. Production from the block 2/4 area complex was at a rate of 18 million tons at yearend. The West Ekofisk and Cod Fields were to start production early in 1977, when natural gas liquids facilities were to be completed for separating the liquid from the gas for shipment of the liquid to England.

The Phillips Norway Group's 25-billion-cubic-meter-per-year, 440-kilometer-long pipeline from Ekofisk to Emden, West Germany, was ready for operation but lay idle because of the Danish Government's requirement that the line be buried 10 meters deep under the seabed.

Three platforms were installed during the summer months in the Frigg Field in block 24/11. Elf Norge A/S, the operator, planned to start production at a rate of 20 billion cubic meters per year. The gas was to be carried to St. Fergus in Scotland via twin 32-inch pipelines 350 kilometers long completed in 1975. There are to be eventually five platforms in the field.

The Amoco Norway Oil Co. and Noco-Norwegian Oil Consortium A/S & Co. group filed a development plan for its Hod-Valhall complex in block 2/8 near Ekofisk. A $550 million steel platform is to be installed for production in 1980.

Esso Exploration Norway Inc. was considering exploitation of its Odin gasfield and A/S Norske Shell was preparing plans for developing the Albuskjell Field in blocks 1/6 and 2/4.

In 1976, two major discoveries were Conoco Norway Inc., 960-ton-per-day oil strike in block 7/12 near Cod and Mobil Oil A/S Norge, 1,800-ton-per-day strike in block 33/9 near Statfjord. Both were Jurassic and both were through ¾-inch chokes.

The West German and Swedish Governments were actively seeking long-term agreements with the Norwegian Government for the purchase of its Government-owned oil and gas. Denmark has also expressed interest in Norwegian gas. Norway suggested that oil and gas found off north Norway might be produced and refined in a cooperative Nordic development effort; Finland, Iceland, and others expressed interest in the project.

Refining.—The country's main refineries included A/S Norske Esso's 5.5-million-ton Slagen and 0.2-million-ton Valloy refineries, Raffinor A/S & Co.'s 4-million-ton-per-year Mongstad refinery in Karmøy, and Norske Shell's 2.75-million-ton-per-year Sola, and 0.15-million-ton-per-year Valloy refineries. Statoil also had a 33% interest in the Bamble petrochemical project under construction, in which Norske Hydro had 51% and Saga Petroleum A/S Co. 16% interest.

The Mineral Industry of Pakistan

By David E. Morse [1]

Mineral development in Pakistan has lagged behind the rest of the economy because of low interest by private investors and insufficient Government funding for exploration. The index of mineral production has increased only slightly (10.3%) since fiscal 1969–70.[2] The Government has attempted to strengthen the mineral position of the country through several Government agencies. The Pakistan Mineral Development Corp. (PMDC) was responsible for the exploration and development of minerals. The Resource Development Corp. (RDC) was concerned exclusively with the development of the Saindak copper deposits. The Oil and Gas Development Corp. (OGDC) was responsible for the exploration and development of oil and gas resources in Pakistan. The Geologic Survey of Pakistan handled geological studies, mapping, and nonpetroleum exploration. The Board for Mineral Coordination was established to coordinate the activities of the provincial mineral development agencies: Baluchistan Development Authority, Punjab Mineral Development Corp., and Sarhad Development Board (of the North-West Frontier Province).

The Government has steadily increased allocations for mineral exploration in recent years, but the allocations have been restrained because of the country's economic difficulties and the swelling trade deficit. A Canadian-assisted aeromagnetic survey of 84,000 square kilometers in parts of Baluchistan was underway in 1976. Mineral exploration projects investigated copper mineralization in the Chāgai and Khuzdār Districts of Baluchistan, phosphate rock deposits in the Hazāra District and Khyber Agency of North-West Frontier Province, cement and ceramic raw materials in all provinces, and sulfide mineralization and pegmatites at Azād Kashmīr.

Pakistan's economy continued to grow at a modest rate, with the gross national product (GNP) increasing to $12,250 million [3] in fiscal 1975–76, about 5% above that of fiscal 1974–75. Industrial production for the same period grew at a rate of 1%. The public sector dominated the country's industries during the year. The climate for private investment was depressed, and private entrepreneurs were cautious because of past nationalizations. The Government continued to welcome foreign investors, particularly those who could provide advanced technology, capital input, and markets for export.

PRODUCTION

The mineral output of Pakistan exhibited many minor changes in 1976, but the overall results remained similar to those of 1974 and 1975. Production of natural gas from the Sui and Mari Fields increased slightly to meet domestic demand. Crude oil production increased 17% over that of 1975, but it was 14% below the 1974 output. Pakistan produced significant quantities of limestone and other stone, rock salt, coal, gypsum, various clay minerals, and sand and gravel. In addition, small amounts of a wide variety of minerals were produced: Barite, bauxite, chromite, and marble for export and mag-

nesite, ochers, soapstone, and sulfur for domestic consumption.

Processed mineral commodities were of significant importance to the country's economy. Production of cement, chemical fertilizers, and petroleum products reduced the need for expensive mineral imports. Pakistan planned to increase domestic production of all three products and to complete an integrated steelworks near Karāchi to further reduce imports of mineral commodities.

e Estimate. p Preliminary. r Revised.

TRADE

Pakistan's trade deficit continued to be substantial in 1975–76, increasing from about $330 million in fiscal 1973–74 to over $1.0 billion for the next two fiscal years. During fiscal 1975–76, exports increased almost 12%, but imports increased 10.7% over the same period. Pakistan has been able to finance a substantial portion of the deficit with foreign aid and remittances from Pakistani workers overseas.

Mineral trade constituted an important part of the trade deficit. Cement exports decreased from $29.6 million (revised) in fiscal 1974–75 to $7.82 million in fiscal 1975–76. Petroleum product and residual fuel oil exports were valued at $17.2 million, a slight increase over those of the previous fiscal year. Imports of crude oil and petroleum products increased from $337 million in fiscal 1974–75 to $377 million in fiscal 1975–76. Iron and steel and chemical fertilizers were the other major mineral imports. Pakistan planned to decrease the mineral trade deficit by increasing crude oil production, producing its own iron and steel, and expanding output of cement and chemical fertilizers.

The following tabulation lists the value of Pakistan's mineral imports, by major group:

Commodity or commodity group	Value of imports (millions)	
	1974–75	1975–76
Iron and steel, including ore and scrap	r $213.0	$171.6
Other metals, including ores and scrap	r 47.7	22.4
Fertilizer materials	r 104.0	11.8
Coal and coke	8.3	4.3
Crude and partly-refined petroleum	r 216.0	254.3
Petroleum refinery products	r 119.7	122.7
Other	r 18.4	11.6
Total	r 727.1	598.7

COMMODITY REVIEW

METALS

Bauxite.—A minor amount of bauxite was produced from small operations in the Salt Range of Punjab Province in 1976. Exploration by PMDC has proven 180 million tons of low-grade bauxite near Khushāb, Punjab, south of the Salt Range.

Chromite.—Production of chromite, the only metallic mineral that Pakistan produced for export, was about 10,136 tons in 1976. Production remained well below the average annual level of 25,000 tons during the 1960's owing to the high iron content of the ore, the generally low level of mechanization, and high transport costs. The bulk of the 1976 output came from the chromite deposits in the Muslimbagh area of Baluchistan. The Government planned to build a 15,000-ton-per-year ferrochrome plant near Muslimbagh with aid from West Germany.

Copper.—RDC completed evaluation of the Saindak copper deposit near the Pakistani-Iranian border in Chāgai District, Baluchistan. At a minimum grade of 0.3% copper, the northern, southern, and eastern ore bodies had proven reserves of 19 million, 54 million, and 264 million tons, respectively. The average grade was 0.5%, 0.5%, and 0.4%, respectively. In addition, the northern ore body contained 9 million tons averaging 0.51 gram of gold per ton and the southern ore body contained 54 million tons averaging 0.49 gram of gold per ton. The southern ore body also had 29 million tons of ore averaging 0.019% molybdenum, and the eastern ore body had 55 million tons of ore averaging 0.017% molybdenum. Seltrust Engineering Ltd. of the United Kingdom was appointed to complete a preinvestment feasibility study of the Saindak deposit by the end of 1977. One of the major obstacles to the development of this remote deposit was overcome when sufficient fresh water was found less than 80 kilometers from the area. Exploration drilling was conducted during 1976 on a copper prospect at Talarukh, Baluchistan, about 56 kilometers northeast of Saindak.

Iron and Steel.—The Government-owned Pakistan Steel Mill Corp. (PASMIC) continued erecting a 1.1-million-ton-per-year steelmill at Pipri, east of Karāchi, during 1976. Extensive technical and financial assistance for the project was provided by the U.S.S.R. The steelmill was to be in full operation by 1980 with initial production to commence in 1978. A new bulk cargo port was also being built at Qāsim to handle iron ore and coal imports for the steelmill. Domestic deposits were to supply the steelmill with limestone (400,000 tons per year), dolomite (270,000 tons per year), fire clay (44,000 tons per year), and fluorite (4,000 tons per year).

Pakistan has investigated domestic deposits containing over 400 million tons of iron ore, but the generally low iron content and limited accessibility of the deposits have deterred their development.

The remote Chitrāl deposits in western North-West Frontier Province, containing over 3 million tons of magnetite ore averaging over 50% iron, were to be studied in detail. A 100,000-ton iron and steel plant was to be built at Chilghaz in the Chāgai District of Baluchistan with aid from the People's Republic of China. The 2.4-million-ton, 43% to 53% iron ore deposit near Chilghaz was to be exploited to feed the new plant.

NONMETALS

Barite.—A 30,000-ton-per-year barite grinding plant came onstream in mid-1976 at Khuzdār in the mountainous region of east-central Baluchistan. The 1976 output of the plant came from the 1.2-million-ton Shekrān barite deposit. Barite production from the small-scale mines in North-West Frontier Province was about 4,000 tons during 1976. The bulk of barite produced was exported to the oil-producing countries of the Middle East.

Cement.—Output from Pakistan's nine cement plants decreased 4% during fiscal 1975–76. Cement exports during the same period fell drastically (73%). The Government had planned to increase the country's cement capacity by 3.5 million tons per year, but economic difficulties delayed the project.

Fertilizer Materials.—Phosphate rock deposits located in difficult mountainous terrain near Abbotābād in the Hazāra District of North-West Frontier Province were

under investigation during 1976. Reserves of about 4 million tons have been identified. Pakistan National Fertilizer Corp. planned to set up a phosphate fertilizer plant at Haripur to utilize these deposits. The plant was to produce urea, phosphoric acid, superphosphate, and diammonium phosphate.

Construction of the $100 million expansion to the Multān fertilizer plant was underway in 1976. The new unit, a joint venture of Pakistan and Abu Dhabi National Oil Company, was to be onstream in late 1977 and produce nitric acid, ammonium nitrate, and calcium nitrate. Domestic natural gas was to be used as feedstock for the plant.

A 1,000-ton-per-day ammonia, 1,750-ton-per-day urea plant was to be built with Saudi Arabia's assistance at Mīrpur Māthelo near Sukpur. The $200 million project was to begin operations in early 1977.

Salt.—Pakistan has large reserves of rock salt in the Salt Range of Punjab Province. Rock salt production has remained stable at about 400,000 tons for several years. PMDC planned to upgrade the Khewra, Worcha, and Kālābagh mines to increase annual production by about 250,000 tons. Solar-evaporated sea salt was produced by 20 small operations along the coast and output was estimated at 144,000 tons during 1976.

Stone.—*Limestone.*—Extensive deposits of limestone occur in all four provinces of Pakistan. Limestone was mined for use by the cement industry and as building and construction material. With the establishment of an integrated steel complex at Karāchi and the projected increase in cement output, limestone production was expected to increase from 3.1 million tons in 1976 to about 7 million tons per year in 1980.

MINERAL FUELS

Coal.—The coal deposits of Pakistan were low grade with generally poor coking properties. Total recoverable reserves were estimated at 400 million tons including 250 million tons in the Lakhra coalfields of Sind Province. Production of coal has remained fairly stable at 1.2 million to 1.5 million tons for nearly a decade. During 1976, coal output was estimated at 1.3 million tons, but as a large but unknown percentage of coal was used locally to fire brick kilns, an accurate figure was unattainable. The coal industry continued to have difficulties because the larger producers used old mining equipment, had very few trained personnel, and operated in rough terrain.

The Sharigh coalfields, near Quetta, Baluchistan, were the only fields that contained some coal of medium-coking quality. The Government planned to expand the existing mines and build a mechanical washing plant at Sharigh. The washed coal would augment the imported coking coal at the Karāchi steelmill.

The Government planned to develop coal mines in the Lakhra Field and use the output to power a 250-megawatt thermal power station to be built at Jām Shoro, Sind.

Natural Gas.—Natural gas was the only abundant mineral fuel in Pakistan in 1976. Output from the Sui and Mari gasfields was approximately 4.98 billion cubic meters, with the bulk of the production from the Sui Field. Gas reserves at the Sui and Mari Fields were estimated at 223 billion and 117 billion cubic meters, respectively, and in dormant gasfields and associated with petroleum, 65 billion cubic meters. Efforts continued to extend the service area of the country's natural gas companies to increase availability of natural gas to consumers in northern Pakistan.

During 1976, the Government and Esso Eastern Inc. signed an agreement in which the State acquired Esso's petroleum refining and retail interests. Esso agreed to invest the proceeds into developing the Mari gasfield. The increased output from Mari was to be used as feedstock for urea fertilizer plants.

Petroleum.—Domestic crude oil production from the Potwar Plateau fields increased from 300,000 tons in 1975 to 351,000 tons in 1976, but was well below the 400,000-ton output of 1974. Domestic production satisfied about 12% of domestic demand during the year. In December, the Prime Minister announced an important oil/gas discovery by OGDC at Dhodak, west of the Indus River in southern Punjab. It was the first liquid hydrocarbon discovery in Pakistan outside of the Potwar fields. Initial estimates of the find were placed at 200 million barrels of light oil and 4.5 trillion cubic feet of

sulfur-free natural gas. The payout zone was between 7,000 and 8,000 feet in the Cretaceous, and initial tests showed a potential flow of 2,000 barrels of crude per day and 19.5 million cubic feet of natural gas per day. Crude oil reserves in Pakistan had been estimated at 75 million barrels prior to the Dhodak discovery. Development of the field was to take 2 to 3 years, and, together with the planned development of older fields, Pakistan would produce 70,000 to 80,000 barrels of oil per day, sufficient to meet domestic demand.

On November 2, 1976, Ordinance No. XLIV of 1976 was published in an effort to stimulate oil exploration by foreign firms. The ordinance offered a new package of tax concessions to foreign oil companies. Exploration and drilling equipment imported by foreign petroleum companies prior to an oil discovery would not be subject to import or sales taxes. In addition, taxes imposed on foreign employees of the companies were to be significantly reduced.

The 12,500-barrel-per-day addition to the national refinery near Karāchi was nearing completion at yearend. New visbreaking and distillate hydro-desulfurization units were also being added with completion expected in 1977. The 40,000-barrel-per-day Pak-Arab refinery, a joint Pakistani-Abu Dhabi venture, was to be built at Multān in south-central Punjab. The refinery would be supplied with imported crude oil shipped by pipeline from Karāchi to the refinery site, a distance of about 750 kilometers. The Government also planned to supply the refinery with crude oil from the new Dhodak oilfield 160 kilometers from the Multān site.

The Mineral Industry of Peru

By Orlando Martino [1]

The reduced rate of economic growth experienced in 1975 continued into 1976. The real growth rate of the gross domestic product (GDP) was 3% for the year, compared with an average of almost 6% for 1972–74. There was a sharp increase in the rate of inflation to 45% in 1976 from 24% in 1975 and a 10.6% average annual increase for the decade ending in 1974.

Peru's mineral industry had a better than average performance in 1976, accounting for 7% of the estimated GDP of $13.7 billion [2] at current prices. The value of mineral exports increased 24% to $697 million and made up 51% of Peru's total export earnings. Peru's export-oriented mineral industry was again dominated by copper, zinc, silver, iron ore, and lead.

Two outstanding new developments in the minerals and mineral fuels area marked the year: Completion of the large-scale copper mining project at Cuajone and of the 853-kilometer trans-Andean crude oil pipeline. The former resulted in an 80% increase (156,000 tons per year) in Peru's copper capacity. The latter, designed to transport crude oil from jungle areas, offers the probability that Peru will become self-sufficient in crude oil in late 1978.

The mineral industry of Peru, excluding mineral fuels, is composed of the large-scale, medium-scale, and small-scale mining sectors. The large-scale group includes Empresa Minera del Perú (Minero Peru), involved in diversified mining outside central Peru; Empresa Minera del Centro del Perú (Centromin), involved in diversified mining in central Peru; Empresa Minera de Hierro del Perú (Hierro Peru), involved in mining of iron ore only; and Southern Peru Copper Corporation (SPCC). The four firms, three Government-owned and the last privately owned, accounted for 65% of Peru's mineral output (excluding mineral fuels).

At yearend, Minero Peru, created in 1970, was approaching completion of its first mining operation, the Cerro Verde copper complex, to produce 33,000 tons of fine copper per year. In November, it signed a contract with a Belgian firm for construction of the new zinc refinery at Cajamarquilla.

Centromin continued as Peru's second largest copper producer (after SPCC), deriving 22% of its total revenues from this commodity in cathode, blister, and wirebar forms. Copper was mined at Cobriza (the major producing mine), Yauricocha, Cerro de Pasco, Morococha, Casapalca, and San Cristóbal.

About 55% of the ore treated by Centromin came from mines not belonging to it. The major event of 1976 was the startup of the expanded copper refinery at La Oroya, which resulted in a 25% increase in Centromin's output of refined copper to 45,786 tons. In November 1976, Centromin entered into loan agreements with the World Bank and the Inter-American Development Bank for $73.4 million to finance expansion of the mine and concentrator at Cobriza from 2,000 tons to 10,000 tons per day and conversion of the mine-water treatment plant at Cerro de Pasco from scrap iron precipitation to a solvent extraction and electrowinning process.

The medium-scale mining sector was composed of 60 privately owned companies

---

[1] Physical scientist, International Data and Analysis.

[2] Where necessary, values have been converted from Peruvian soles (S/) to U.S. dollars at the annual average rate of S/55.8=US$1.00. At yearend, the rate was S/69.1=US$1.00.

primarily involved in the production of copper, lead, zinc, and silver ores. This sector employed about 26,000 workers and accounted for 30% of Peru's mineral output. The leading medium-scale producers of copper, lead, zinc, and silver were, respectively, Minas de Cobre de Chapi S.A., Cia. Minera Atacocha S.A., Cia. Minera San Ignacio de Morococha, S.A., and Cia. de Minas Buenaventura, S.A.

The small-scale mining sector comprised more than 1,000 privately owned small mines, although only 200 were officially registered. The majority of these operations were poorly mechanized and labor intensive. This sector accounted for only 5% of Peru's mineral output. The Small Private Enterprise Sector was recognized as a separate group by Decree Law 21435 of February 1976.

A large portion of the concentrates produced by the medium- and small-scale sectors were sold to Centromin for smelting and refining.

In 1976, the Banco Minero del Perú substantially increased its financial assistance to the medium and small miners by extending credits of $76.4 million. Under its metallurgical program, the Banco Minero planned to invest $450,000 in the construction and expansion of beneficiation plants in different parts of Peru to service small miners.

In the mineral fuels area, Government-owned Petróleos del Perú (Petroperu), Belco Petroleum Corp. del Perú, and Occidental Petroleum Corp. del Perú were the main crude oil producers.

During 1976, 77,000 were employed in mining and 12,000 in petroleum operations. Of the mining total, Centromin employed 15,900 and SPCC 5,500.

Government Policies and Programs.—At midyear, the Government initiated an austerity program to curb inflation and reduce the deficit in the balance of payments. The Peruvian sol was devaluated 45%, and a 15% tax was imposed on exports. The last sizable devaluation occurred in September 1967.

It was an active year for mining legislation. A number of laws and regulations were issued to financially assist the small-scale and medium-scale mining sectors through the Banco Minero. In addition, the Government released over 13.5 million hectares of mineral-rich areas previously reserved for the State in the Departments of Pasco, Junín, Ayacucho, Apurímac, and Cuzco for prospecting by private mine operators. Peru's mineral potential is largely undeveloped; only 1.6% of 86 million hectares with mining possibilities was in production at yearend.

Decree Law 21462 of April 1976 declared mining to be in a state of emergency and authorized mining companies to rescind labor contracts of workers engaged in illegal work stoppages. This action was reinforced in July when the Government declared a state of national emergency, making all strikes illegal.

PRODUCTION

Mineral production rebounded from the decline of 1975. The general increase was attributed primarily to the absence of labor strikes which had been declared illegal by the Government during the year. Mine output of copper increased 21%, rebounding from the depressed level of 1975, while output of refined copper increased 96%. Mine output of lead increased 4%, zinc 15%, and silver 5%. There was a sharp 38% decline in iron ore production as Hierro Peru sought to adjust its output to world market demand. Raw steel production declined 19%.

Centromin operated six mines and continued as a major producer of refined metals and subproducts at its complex metallurgical plant in La Oroya, west of Lima, as detailed in table 1.

Centromin also produced lead, zinc, and tungsten concentrates for export, which accounted for 21% of its sales revenues in 1976. The metallic content of tungsten concentrates declined 14% from 521 tons to 449 tons in 1976.

An annual record high of 201,514 tons was set by Centromin in the recovery of zinc, chiefly at its Cerro de Pasco mine. Centromin's major copper producer, Cobriza, increased its output 8.4%.

Crude oil production increased 6% in 1976. Production increases on the continen-

tal shelf and in the jungle areas more than compensated for the declining trend in the north-central area. Oil output from the jungle areas increased 43%. Production of natural gas from the coast decreased 6%, and production from the continental shelf increased 23%. Nationwide natural gas production remained about the same.

Data on total mineral production for 1974–76 are shown in table 2.

TRADE

The value of Peru's mineral exports increased 24% to $697 million from $560 million in 1975. Mineral exports represented 51% of total export earnings, compared with 45% in 1975. Preliminary export data for 1976 developed by the Peruvian Mining and Petroleum Society for the leading mineral commodities are shown in the following tabulation:

Commodity	Quantity	Value, f.o.b.		
		Million dollars	Percent of total	Percent increase over 1975
Copper ----------metric tons--	188,900	211.0	30	31
Iron ore ----------do----	3,250,000	66.1	10	27
Lead ----------do----	174,300	51.6	7	26
Silver ----------thousand troy ounces--	40,027	148.7	21	6
Zinc ----------metric tons--	442,100	164.9	24	11
Other ----------do----	NA	55.0	8	224
Total ----------	XX	697.3	100	24

NA Not available. XX Not applicable.

During a visit to Peru in November by the President of Brazil, an agreement was signed under which 35% of Brazilian imports of copper and zinc would come from Peru.

Although Peru exported a variety of minerals, exports of copper, iron ore, lead, silver, and zinc contributed 92% of total mineral export value. Marketing of the minerals overseas was centralized in the Government-owned company Minero Perú Comercial (Minpeco). To resume shipments of iron ore to Japan, Minpeco signed export contracts with Kobe Steel, Ltd., and Nippon Steel Corporation during 1976.

Exports of crude oil in 1976, mostly to Brazil and Argentina, increased 35% to 2.0 million barrels, while exports of petroleum products, mostly residual fuel oil, increased 99% to 1.4 million barrels. It was the second year of exports of crude petroleum from jungle oilfields; these exports increased 103% from 983,000 barrels in 1975 to 1,992,000 barrels in 1976. The major part of the exports went to Brazil by way of the Amazon River.

Imports of crude oil from Ecuador, Venezuela, and Colombia totaled 16.9 million barrels, a slight increase over those of 1975, while the cost of the oil imports increased 96%. Of the crude oil processed at Peru's refineries, 40% was imported. Peru spent $270 million to import crude oil and petroleum products in 1976. Less than 1% was imported from the United States.

COMMODITY REVIEW

METALS

Copper.—Production of copper increased significantly over the depressed level of 1975 owing primarily to the coming onstream of the new Cuajone project after nearly 10 years of effort and construction. The record high level, representing 3% of world production, ranked Peru 10th as a world producer. In value, copper exports represented 30% of Peru's total mineral exports.

SPCC was the main copper producer, operating the Toquepala and Cuajone open pit mines. At Toquepala, in production since 1960, mine output of copper increased 21% to 14.5 million tons, with an average ore grade of 1.05%. Initial mine production at Cuajone, located 16 kilometers from Toquepala, was 10.4 million tons, composed of sulfide ore grading 1.61% and oxide ores grading 0.98% to 3.98%. Full output from Cuajone of 156,000 tons of copper was expected in 1977. Estimated milling-grade ore reserves for Toquepala and Cuajone at yearend totaled 630 million tons of ore with an average grade of just under 1%.

Mine operations at Cuajone during 1976 involved a combination of pre-mine stripping, pit preparation for production of ore, and production mining. Copper ore began moving to the concentrator during the second quarter of the year. By yearend, capital expenditures for Cuajone amounted to $666 million, including land and net startup expenses. Total estimated project development costs increased to $675 million from the estimate of $355 million in mid-1969.

Minero Peru's only new mine development project, Cerro Verde, was in the final stage of construction at yearend, with 73% of construction work completed and $198 million invested. In stage I, Minero Peru planned to exploit 60 million tons of oxide

and mixed ores, of which 30 million tons was high-grade oxide ores. Initially, 33,000 tons of copper cathodes was to be produced. The feasibility study for stage II, involving the large adjacent sulfide deposit, was completed by Ralph M. Parsons Co. which indicated that an investment of $1.3 billion would be required to produce 165,000 tons of copper per year.

A commission composed of SPCC and Minero Peru was studying the possibilities of a joint venture through a special mining company to develop the Quellaveco deposit. Reserves at Quellaveco are estimated at 388 million tons of 0.85% copper. Since Quellaveco is equidistant from the Toquepala and Cuajone mines, its development could take advantage of existing infrastructure.

A feasibility study was completed on the Antamina copper deposit located north of Lima in the Province of Huari, Department of Ancash, at an altitude of 14,000 feet. This deposit will be developed by Antamina Special Mining Co., formed in January 1974 and owned 51% by Minero Peru and 49% by Geomin of Romania. The complex copper-zinc ore, estimated at 121 million tons, contains 1.56% copper, 1.27% zinc, 0.51 troy ounce of silver per ton, and 0.04% molybdenum. The $358 million project was designed to produce copper and zinc concentrates containing 75,000 tons and 59,280 tons per year, respectively, and 3,000 tons per year of molybdenum concentrate. Transportation will be by a 380-kilometer pipeline to the port of Huacho. Construction was estimated to require 5 years (1977–81).

In late 1976, SPCC completed expansion of its smelter at Ilo from 126,000 tons to 290,000 tons per year of blister copper, to provide capacity for treating the new Cuajone output. Initial output from Cuajone, in the form of fluxing ore, was received at the Ilo smelter in July 1976.

Minero Peru's Ilo refinery produced 94,000 tons of copper cathodes in 1976. Minero Peru decided to engage in a turnkey contract with Mitsui Mining & Smelting Co., Ltd., and Furukawa Mining Co., Ltd., to expand its Ilo refinery from 150,000 tons to 300,000 tons per year of copper. Financing entirely by Japan was arranged to cover the estimated cost of $84.5 million.

One of Centromin's priority projects was the rehabilitation and expansion of the copper smelter and refinery at the La Oroya complex, parts of which date from 1922. Capacity to produce refined copper was to be expanded from 58,000 tons to 80,000 tons per year at an estimated cost of $140 million. Financing was being sought in Canada and the United Kingdom.

Indium.—Indium was recovered by Centromin at the La Oroya metallurgical complex, primarily from lead and zinc concentrates. Centromin's output increased 106% over the depressed level of 1975 to almost 3,000 kilograms. Peru ranked fourth in world reserves of indium and accounted for 15% of U.S. imports.

Iron Ore.—Production of iron ore and concentrate by Hierro Peru declined sharply in 1976, owing mainly to marketing problems following nationalization of Marcona Mining Co.'s operation in 1975 and the continued worldwide recession affecting iron ore purchases. About 400,000 tons of the iron ore output was shipped to Peru's major steel plant at Chimbote. Exports of iron ore, Peru's fourth most valuable mineral export, were at the depressed levels of 1975, although earnings were 27% higher. In 1976, Hierro Peru shipped through Minpeco 3,250,000 tons of iron ore to world markets. It was reported that sales contracts were arranged in the nontraditional markets of Argentina, Romania, and Yugoslavia.

Since the Marcona nationalization, exports of Peruvian iron ore to Japan had been discontinued. In April, Minpeco signed a contract with Nippon Steel to supply pellets and pellet feed. In mid-1976, Minpeco signed a long-term contract with Kobe Steel for the export of pellet feed. Under the contract, Peru will export a total of 5.8 million tons during a period of 7 years and 3 months.

In response to market demand for a higher quality pellet having a lower sulfur content, Hierro Peru entered into a contract with Lurgi S.A. to study a new pelletization process. Plans were underway to expand the pellet plant from 4.0 million tons to 7.5 million tons, and relevant conversations were opened up with a Japanese consortium for financing.

In September, agreement was reached on compensation for the nationalization in July 1975 of Marcona's assets. The total compensation package equivalent to about $61

million included a cash payment, a freight contract, and a 4-year sales contract between Minpeco and Marcona whereby Marcona will purchase 3.7 million tons of pelletized iron ore for resale exclusively in the U.S. market.

Iron and Steel.—Production of raw steel declined again in 1976 by 19%. Empresa Siderúrgica del Perú (Siderperu) completed expansion of its steelworks at Chimbote from 425,000 tons to 700,000 tons of crude steel per year. A 100,000-ton-per-year tinplate line was installed at Chimbote by Mitsubishi Heavy Industries, Ltd. Siderperu was planning to increase annual steel capacity to 2.3 million tons by 1982 and 4 million tons by 1990 in order to meet national demands until the year 2000.

Lead.—Two new lead-zinc mines in the medium-scale mining sector were reported to have come onstream: El Farallon, located in the Province of Huarochiri, Department of Lima; and El Extrano, located in the Province of Yungay, Department of Ancash. Important lead producers in the medium-scale mining sector were Cia. Minera Atacocha S.A., Cie. des Mines de Huaron, Cia. Minera Milpo S.A., Cia. Minera Raura S.A., and Cia. Minera Santa Luisa S.A.

The contract signed by Centromin with Kaiser Engineers in November 1975 to provide engineering services for the new lead sinter plant at La Oroya did not become operative because of delays in arranging financing. Centromin was seeking financing for the lead sinter project estimated to cost $265.5 million.

Molybdenum.—SPCC was the major producer of molybdenum concentrate as a byproduct of its copper operations. In 1976, SPCC had a slight decrease in production of concentrate to 402 tons (metal content). Cia. Minera Turmalina and Cia. Minera San Diego were smaller producers of molybdenum concentrate. Peruvian reserves ranked fourth worldwide.

Rhenium.—Rhenium was recovered in West Germany and Sweden as a byproduct of the roasting of molybdenite concentrate imported from Peru. The 1976 output of rhenium attributed to Peru was estimated at 180 kilograms of metal. Worldwide, Peru ranked fifth in both production and re-

Silver.—Silver production increased significantly in line with increases in copper, serves of rhenium.

lead, and zinc output. Silver exports in 1976, valued at $149 million, continued to rank third after copper and zinc as Peru's most valuable mineral export. A medium-size mine, Puquio Cocha, ceased operations in 1976 because of depletion of reserves.

Uranium.—Peru's Nuclear Power Institute was studying plans for a trial plant to extract uranium from copper and lead ores from mines in the Andean Range. Depending on results, larger scale exploitation of uranium may be undertaken.

The Government and the International Atomic Energy Agency were planning a 5-year program to develop Peruvian uranium resources and establish nuclear power reactors.

Zinc.—In October, Centromin signed an agreement with Surveyer, Nenninger and Chenevert Inc. of Montreal to provide project management for the rehabilitation and expansion of the zinc circuit at La Oroya from 70,000 tons to 90,000 tons per year. In November, loan agreements wre signed with the Export Development Corporation and the Royal Bank of Canada for partial financing of the project estimated to cost $62.5 million. Construction of the civil works continued.

Following approval by the Government, Minero Peru signed a contract with Syndicat Belge d'Entreprises S.A. (SYBETRA) in November 1976 for construction of a $200 million zinc refinery at Cajamarquilla in Rimac Valley near Lima. The refinery will have an annual capacity of 200,000 tons of concentrates with an annual recovery of 101,500 tons of refined zinc, 176,000 tons of sulfuric acid, 335 tons of cadmium, and 16,630 tons of lead-silver residues. The refinery, scheduled for startup in 1980, was a high-priority project of Minero Peru. At yearend, all infrastructure works had been contracted and preliminary civil works initiated.

NONMETALS

Barite.—Peru continued as the leading producer of barite in Latin America and ranked seventh worldwide.

Fertilizer Materials.—The original plan for mining the Bayóvar phosphate deposit, located in northern Peru, was expanded by Minero Peru to include production of compound fertilizers. A total investment of $200

million was required to produce 150,000 tons of diammonium phosphate and 370,000 tons of triple superphosphate per year.

In December, Minero Peru signed an agreement with Spain's Instituto Nacional de Industria through its Empresa Nacional Adaro de Investigaciones Mineras S.A. (ENADINSA) to carry out and finance a feasibility study over a 10-month period. Upon completion of the study, ENADINSA plans to form a special mining company to exploit the phosphate desposit, totally with Spanish financing.

MINERAL FUELS

Peru's energy consumption and dependency situation are shown in tables 5 and 6.

Coal.—In April, Electricidad del Perú (Electroperu) and Minero Peru signed a contract with a joint venture of Kopex of Poland and Universal Engineering of Switzerland to carry out a technical-economic study, estimated to cost $1.8 million, of the Alto Chicama coal mine and energy complex. The Alto Chicama deposit lies 480 kilometers north of Lima and east of Trujillo.

The project in the first stage includes construction of a thermoelectric plant with a capacity of 200 megawatts and a mine complex to produce 2,000 tons of coal per day. In the second stage, capacity will be increased to 480 megawatts requiring 4,200 tons per day of coal output. The project is expected to be operational by 1982. The plant will supply energy for the proposed Michiquillay copper project and the proposed fertilizer-petrochemical complex at Bayóvar. Measured coal reserves at Alto Chicama were estimated at 50 million tons of anthracite. Inferred Alto Chicama reserves were 250 million tons.

Based on geologic studies and limited mining data, Peru's total coal reserves have been estimated at 1.06 billion tons, classified as follows: 830 million tons anthracite, 130 million tons bituminous, and 100 million tons lignite. Of this total, 130 million tons was considered to be of coke-making quality. Details on the coal areas studied are provided in table 7.

Table 5.—Peru: Primary energy consumption

(Thousand tons of standard coal equivalent [1])

Type of energy	1965		1970		1976		Annual average percentage increase

Petroleum.—Although production of crude oil increased 6% to 76,500 barrels per day, Peru continued to rely heavily on imports to meet domestic demand. Of the 41.5 million barrels of crude oil processed in 1976 in Peru's five refineries, 40% was imported—75% from Ecuador, 21% from Venezuela, and 4% from Colombia. Details on crude oil processed in 1976 are given in table 8.

The Government was forced to increase the price of petroleum products twice in 1976. Regular motor gasoline was increased in price first 53% and then 117% to about $0.90 per gallon. Domestic sales of petroleum products increased only 2% in 1976.

Crude oil production during 1976 came from the northwestern coast (43%), the continental shelf (42%), and jungle areas (15%). Production from the coastal area continued its downward trend, experiencing a further 7% decrease. Production from the continental shelf by Belco increased 12%. Petroperu and Occidental continued to be the only producers in the jungle areas from the Trompeteros and Shiviyacu oilfields, respectively, where crude oil production continued its upward trend during 1976, increasing 43% from 3.0 million barrels in 1975 to 4.3 million barrels in 1976. The major part of Occidental's production was shipped to Brazil.

Petroleum developments were marked by two major events: Completion of the 853-kilometer trans-Andean pipeline and reopening of offshore and jungle areas for new exploration and production contracts.

The trans-Andean pipeline from Jose de Saramuro in the Department of Loreto to Bayóvar on the coast was completed in December after 2 years of difficult and uninterrupted construction work. The pipeline was expected to initially transport 40,000 barrels per day by early 1977; by yearend, Peru was expected to decrease its imports of crude oil to 10,000 barrels per day. In September 1976, Petroperu signed a $108 million contract with a Mexican firm, Constructora Protexa S.A. de C.V., to construct the 250-kilometer spur pipeline from Occidental's oilfields to the trans-Andean pipeline. Completion of the spur was expected in April 1978.

Peru's crude oil production was expected to increase to 140,000 barrels per day in early 1978 and to 170,000 barrels per day in September 1978 when the entire pipeline complex would be in operation. Peru was then expected to achieve self-sufficiency and resume exports, which were discontinued in 1963.

The reopening of the offshore and jungle areas to operations contracts was announced in July 1976, but by yearend, the frame of reference governing the contracts had not been published; consequently, no new operating contracts were negotiated in 1976.

No major oil discoveries were made during 1976. Total proven reserves were estimated at 750 million barrels. By yearend, all areas devoted solely to exploration, with the exception of that assigned to Oceanic, had reverted to Petroperu. Occidental was the only foreign operator in the jungle areas. Petroperu continued exploration and production activities in the jungle areas.

Refinery capacity at the five refineries in Peru totaled 123,300 barrels per day in 1976. The La Pampilla refinery was undergoing expansion that would increase its capacity 65,000 barrels per day. When it is completed in mid-1977, Peru's refinery capacity will have increased to 188,300 barrels per day.

Table 8.—Peru: Crude oil processed in 1976

Refinery	Capacity (barrels per day)	Crude oil processed (thousand 42-gallon barrels)			
		Domestic	Imported	Total	Percent of total
Talara	75,000	23,004	2,560	25,564	61.6

Total	123,300	24,822	16,689	41,511	100.0

The Mineral Industry of the Philippines

By K. P. Wang [1]

The Philippine economy did not have a particularly good year in 1976, but it was better than in 1975. Real gross national product (GNP) growth was 6.3% in 1976, compared with 5.9% in 1975. The 1976 trade deficit was slightly over $1 billion[2] and the current account deficit was $565 million, nearly the same as that of the previous year. However, favorable capital flows reduced the overall deficit to $164 million, a marked improvement over the previous year's $520 million deficit. Inflation was held down to a modest rate of 6.2%.

At current prices, the Philippine GNP reached about $17.5 billion in 1976 compared with $15.7 billion (revised) in 1975. In terms of constant 1972 prices, the GNP attained respectively $9.75 billion and $9.42 billion, which equates to the 6.3% real growth. The sectors were led by construction which posted a 22% increase, much lower than the 1975 growth of 52% when office and hotel construction reached peak levels. Agriculture, fisheries, and forestry showed a 5.7% growth with high inputs from sugarcane, livestock, and forestry. Manufacturing expanded at 5.6%, with export processing and construction as important sources of stimulation. Mining managed a 2.4% boost in real growth with the modest recovery of copper prices.

A lower level of gross domestic capital formation in 1976 precluded a faster growth rate. Specifically, expenditures for private construction, which at 54% led all other GNP expenditure components in 1975, dipped to 20.3% in 1976. This slowdown was traceable to the completion during the year of several construction projects.

Mineral output value of the Philippines at about $620 million corresponded with 3.5% of the 1976 GNP. Value added for refined materials and metals has not been included, although this is relatively small for the Philippines. Minerals and metals are considerably more important in overall trade, constituting approximately one-fourth of overall exports in 1976. Moreover, 70% by value of all minerals produced were exported. In the case of imports, mineral fuels (mainly oil) alone represented one quarter of all imports in 1976, and base metals added another 6.7%. Purchases of fuels and metals have contributed heavily to the adverse balance-of-payments position of the Philippines.

The country has always been considered fairly rich in minerals, particularly copper. According to the Philippine Bureau of Mines, proven copper reserves in 1976 were sufficient for at least 50 years at present extraction rates, and estimated reserves were three times as much, or 2.9 billion tons of porphyry ore. Understandably, various producers have expansion programs underway and more will be done in this regard under high-price conditions. The gold potential was considered good also, but low gold prices were holding back expansion. Philippine chromite is world famous; however, production was down in 1976 because of sluggish demand by the world steel producers. Nickeliferous laterites may be abundant, but the infant

[1] Supervisory physical scientist, International Data and Analysis.

[2] Where necessary, values have been converted from Philippine pesos (P) to U.S. dollars at the rate of P7.44 = US$1.00 for 1976 and P7.25 = US$1.00 for 1975.

nickel smelting industry encountered more than the usual startup difficulties during the year. Mining of iron sands was expected to be not only resumed but also expanded. A new magnetite iron mine, located in Cagayan, Northern Luzon, was in the embryo stage of development. Extraction of mercury temporarily ceased, and manganese mining was resumed. In contrast, output of lead and zinc increased. The important cement industry continued to expand, and construction of the country's first perlite processing plant commenced.

The Atlas Consolidated Mining and Development Corp., the country's most famous mining company with principal operations on Cebu Island, grossed $157.7 million in 1976 and netted $25.4 million in profits. It produced 103,053 tons of mine copper, 73,258 troy ounces of gold, and 83,393 tons of pyrite in 1976, and reported reserves of 880 million tons of ore averaging 0.46% copper. Marcopper Mining Corp., with mines in Marinduque, grossed $50.8 million, netted $8.5 million in profits, and produced 47,534 tons of mine copper. Philex Mining Corp. produced only 30,641 tons of mine copper in 1976 along with 189,946 troy ounces of gold—the most in the Philippines. This explains why this Baguio-based firm grossed $60.1 million and realized a profit of $20 million during the year.

Lepanto Consolidated Mining Co. grossed $37.5 million in 1976 but showed only $1.8 million in profits from its Mankayon mine near Baguio which had shut down temporarily because traditional buyers could not handle its enargite ore. Lepanto had been a very important producer of high-gold-content copper ore. Benguet Consolidated Inc. suffered a small net loss in 1976 because of low gold prices. Its efforts to diversify still had not met with enough success to compensate for the gold dilemma. Marinduque Mining & Industrial Corp. had a $120.4 million gross but an $11.1 million deficit. Its copper mines, mainly Sipalay on the Negros which has reported ore reserves of 650 million tons analyzing 0.49% copper, made good profits in 1976, whereas its nickel operation in Surigao suffered losses and even forced Marinduque to obtain short-term loans. The previous account stresses the fact that the copper industry did all right whereas most other metal mining industries did not fare too well in 1976.

Under Martial Law, the Philippine mining industry attained considerable stability during the last few years. More controls were introduced but there was also more flexibility in the laws to help industries in trouble. For example, export duties for copper and gold were withdrawn. The depressed gold industry was able to obtain loans, although the hope was to obtain subsidies. Taxation was a percentage of gross rather than net profit. The new industry tax holiday was temporarily revoked. Savings in corporate tax was made possible through declaration of stock dividends. Percentage depletion was phased out, and cost depletion was introduced. The Government was considering reduction of allowable exploration and development costs. Various tax incentives under the Investment Incentive Act and Exports Incentives Act were created in an attempt to create a better mining investment climate. Foreign participation in joint ventures was encouraged, with equity share allowable still at no more than 40% and no less than 25%.

The Philippine Board of Investment made the announcement that mining accounted for one-third of the 806 million pesos ($108 million) worth of planned investment application made in the first half of 1976, almost equalling the total for 1975. The substantial increase was taken to reflect a better outlook for minerals and metals, with export prospects generally regarded as bright.

The country was made more attractive to foreign investors upon the promulgation of Presidential Decree 87 in 1976 which provided incentives in the form of exemptions from duties and taxes on machinery and equipment, repatriation of capital, and retention of remittances abroad of all foreign exchange earnings. As a further incentive, a plan was suggested to award exclusive geophysical contracts over onshore and deep offshore areas and to give the contractor first option as operator of resulting service contracts.

The Philippine electric power base did not show great change. Installed power capacity in 1976 was about 3.2 million kilowatts, which was two-thirds thermal (mainly diesel-fired) and one-third hydro, and two-thirds public and one-third indus-

trial. Overall electricity output increased possibly 1 billion kilowatt-hours, to 15 billion kilowatt-hours in 1976. Half of this was produced by Mesalco Co., and 20% by the National Power Corp. Scattered sources of geothermal power were investigated during 1976, and construction of a 3,000-kilowatt plant at Ormac, Leyte, was underway. In a further effort to diversify the energy base, the Government-owned National Power Corp. signed the country's first nuclear power contract on February 9, 1976, with Westinghouse Corp., for building a 620,000-kilowatt plant in Bataan by 1982. The plant will cost as much as $1.2 billion eventually but a source of uranium was still not obtained by early 1977.

PRODUCTION

Due to increases in base metal prices in 1976, the major metals led by copper, nickel, cobalt, lead, zinc, and metallurgical chrome registered significant gains, thereby reversing the sluggish trend in earlier years. Cement production continued to increase. Overall mineral production value increased from 3.9 billion pesos in 1975 to 4.6 billion pesos in 1976, compared with 4.5 billion pesos in 1974.[3]

The year 1976 saw the recovery of copper output, which has long since supplanted gold as the leading mineral product of the Philippines. Copper production value increased from 1.64 billion pesos in 1975 to 1.91 billion pesos in 1976. Gold output value declined 24% from 575 million pesos registered in 1975, owing to the price drop from about $160 per troy ounce to $125 per troy ounce in 1976 despite maintaining the same production level. Actually, cement has been the No. 2 mineral product of the Philippines during the last few years, and output value in 1976 was 1.04 billion pesos. In value, nickel spurted past gold registering 600 million pesos in 1976. The nickel industry still had startup difficulties and suffered severe financial losses, despite doubling the quantity of production. Refractory chromite was down 26% in tonnage but only 4% in value to 91 million pesos in 1976. Iron concentrate dropped from 91 million to 39 million pesos, but mine zinc increased from 32 million to 39 million pesos and metallurgical chromite increased from 21 million to 29 million pesos in 1976. Salt production was stable, at 68 million pesos for both 1975 and 1976.

On a world scale, the Philippines produced only five items of note. In 1976, chromite output was 5% of the world total, and the country has always been prominent in refractory chromite. The Philippines is a medium-size producer of copper, nickel, and gold, with 1976 output representing respectively 2.9%, 2.3%, and 1.3% of the world total. Cement was about 0.6% of world production. Generally the Philippines is well known for metals, particularly porphyry copper, gold, and nickeliferous laterites.

[3] The peso was valued at 13.4, 13.8, and 14.6 U.S. cents, respectively, in 1976, 1975, and 1974.

3 Includes unspecified earths.

TRADE

Total trade in 1976 was about $6.2 billion, compared with $5.8 billion in 1975. The trade deficit was cut down, although still large. Imports increased 5%, from $3.46 billion in 1975 to $3.63 billion in 1976, but exports increased 12% from $2.29 billion to $2.57 billion. The foremost import items were mineral fuels 24.5%, machinery other than electrical 17.2%, transport equipment 7.6%, base metals 6.7%, electrical machinery 5.2%, cereals 5.2%, and chemicals 3.9%. By value, Japan accounted for 27% of the Philippines' total imports, followed by the United States 22%, the Organization of Petroleum Exporting Countries (OPEC) 17%, and European Economic Community (EEC) countries 12%.

Philippine exports are tied to the economies of the industrialized nations. The world situation improved in 1976, but industrial demand became sluggish later in the year adversely affecting export prices for Philippine products.

Sugar was the leading export item in 1976, accounting for 16.6% of total exports. Next came coconut oil 11.5%, copper concentrates 10.3%, copra 5.8%, logs 5.3%, bananas 2.9%, lumber 2.6%, copra oil cake 2.1%, gold 1.9%, pineapples 1.8%, and plywood 1.7%. Principal export destinations were the United States 35.6%, Japan 24.2%, and EEC 18.8%. Mineral exports were valued at 3.24 billion pesos ($435 million), an increase of 14.4% (in pesos) over the 2.84 billion pesos ($392 million) in 1975. Copper exports registered 1.85 billion pesos ($249 million) in 1976, 85% of which went to Japan. Gold exports reached 381 million pesos ($51 million). Exports of refractory chromite were down considerably, to 66 million pesos ($8.9 million). However, exports of metallurgical chromite increased significantly to 86 million pesos ($11.6 million).

COMMODITY REVIEW

METALS

Aluminum.—To meet the increasing demand for aluminum, which had been primarily met by imports of several tens of thousand tons of the metal annually, Philippine planners have been looking into producing aluminum locally. One of the schemes suggested by an international consortium was to establish alumina facilities in Mindanao (and later aluminum reduction facilities), based upon bauxite imported from Weipa in Australia. This proposed project envisages very large tonnages for international markets, with a small spillover for Philippine consumption. Late in 1976, there were rumors that the venture might instead be sited in Australia. Earlier, Reynolds International Inc. was considering building a 100,000-ton reduction plant in Leyte, but this was also indefinite, since Reynolds subsequently relinquished 60% of its equity to the Government. Reynolds produces aluminum products in the Philippines. Comalco Ltd.'s $11 million cold-rolling mill at Cainta, Rizal, near Manila was on schedule, with startup planned for March 1978 for the production of about 6,000 tons of aluminum sheet and foil annually.

Chromite.—Eleven chromite producers (mostly on Luzon but some in Mindanao and elsewhere) were in operation during 1976, compared with only five in 1975. The Government had encouraged chromite mining in the form of tax incentives and other benefits. However, overall production was down from about 520,000 tons in 1975 to about 427,700 tons in 1976. Consolidated Mines Inc., by far the largest Philippine refractory chromite producer, shipped only 304,200 tons compared with 420,300 tons in 1975 and 484,600 tons in 1973. This was because Typhoon Didang caused serious damage to the mine at Coto, Zambales, and the road leading to the port as well. Total ore reserves at Coto were estimated at 6.3 million tons in 1976. It was too early to judge the potential performance of the new chromite producers like Velore Mining Corp., New Frontier Mines, Silveria Eleazar, and Misamis Exploration Corp., which together produced only about 17,000 tons in 1976. Output of Acoje Mining Co. Inc., with about 1.73 million tons of 22% metallurgical chromite reserves in Zambales, declined from 97,000 tons in 1975 to 84,800 tons in 1976. This was just about made up by the 13,700 tons produced by the newcomer, G. Lluch & Sons, Inc. Acoje Mining and G. Lluch were the only important Philippine metallurgical chromite producers during 1976. Nonchrome refractories were cutting into the market for Philippine refractory chrome and it has always been difficult to sell fines. On the other hand, demand for the country's metallurgical chrome should continue to be brisk.

Copper.—Copper, the major mineral product of the Philippines, recovered from the decline in prices that started in late 1974. The average copper price increased to 61 cents per pound in 1976, from 53 cents in 1975. Thus, despite an output increase of only 5.5%, total value increased 16.4%. The resumption of Lepanto Consolidated's operations during the latter part of 1976 plus the expansion effected by other mines further improved the copper picture. In fact, most of the 14 companies with 15 mines were in the process of expanding mine-plant capacity, with overall prospects of raising Philippine copper production about 20% by yearend 1977, to roughly 300,000 tons per year. The Philippine Bureau of Mines further projected in 1976 that the country's copper output might again double in a decade. According to data in late 1976, individual company expansion programs for production were as follows, in tons per day of ore:[4]

[4] Engineering and Mining Journal (New York). June 1977, pp. 233–234.

Company	Production		Completion date
	1976	Target	
Atlas Consolidated	65,000	100,000	Yearend 1977
Marcopper Mining	16,500	27,000	Yearend 1977
Philex Mining	21,000	28,000	Yearend 1978
Marinduque Mining (Sipalay)	14,000	18,000	Yearend 1977
Western Minolco Corp	15,000	30,000	Before 1980
Consolidated Mines	1,500	15,000	Yearend 1977
Baguio Gold Mining Co	3,500	8,000	Yearend 1977
Acoje Mining	500	1,000	Yearend 1977
CDCP Mining Corp	--	10,000	Yearend 1979
Sabena Mining Corp	--	10,000	1978 or 1979
Benguet Consolidated	--	12,000–27,000	1979 or 1980

Atlas Consolidated was again the largest Philippine copper producer, producing from two open pits (Frank and Biga) and one underground block-caving mine called Lutopan on Cebu Island. Atlas mined about 22 million tons of 0.51% copper ore during 1976, together with 70 million tons of waste. The new Carman pit and 32,000-ton-per-day flotation mill costing nearly $100 million were about 40% completed at yearend, and expected to come onstream in the fall of 1977. Marcopper Mining raised output at its Marinduque operations by one-third and strengthened its hold as the country's No. 2 copper producer by partially expanding its 16,500-ton-per-day mill about 50%. Marcopper beneficiated about 8.8 million tons of 0.59% copper ore during 1976, and successfully drilled through its "San Antonio" tailing pond to delineate additional reserves. Marinduque Mining produced just over 32,600 tons of mine copper (mainly from Sipalay in the Negros) in 1976, a slight decline from a year earlier. Marinduque plans eventually to triple Sipalay's mill capacity to 50,000 tons per day of ore. Philex Mining raised output of its Baguio block-caving properties only slightly. Its ore is only 0.4% copper but it is high in gold values. Production of mine copper in the Philippines, by individual producer, was as follows, in tons:

Company	1976
Acoje Mining	1,757
Apex Exploration & Mining Co., Inc	2
Atlas Consolidated	102,439
Baguio Gold Mining	4,380
Benguet Consolidated	1,521
Benguet Exploration Inc	45
Black Mountain Inc	3,379
Itogon-Suyoc Mines Inc	18
Lepanto Consolidated	4,197
Marcopper Mining	47,534
Marinduque Mining:	
Bagacay project	5,428
Sipalay project	27,216
Philex Mining	30,447
Western Minolco	8,949
Zambales Base Metals Inc	276
Other	558
Total	238,146

Philippine copper concentrates are all exported, predominantly to Japan. In 1975, 762,428 tons of copper concentrates were exported, including 648,060 tons to Japan, 43,180 tons to the United States, and 28,194 tons to the People's Republic of China. Atlas Consolidated's output went mainly to Mitsubishi Metal Corp. in Japan, Marcopper sold mainly to North America, Marinduque Mining shipped to Mitsui & Co., Ltd.'s smelters in Japan, Philex Mining exported to its Japanese affiliate Nippon Mining Co., Ltd., and Lepanto Consolidated traditionally sold its copper-gold concentrates to the Takoma smelter in Washington where the pollution problem has become an obstacle. Sale of copper concentrates to China is a recent development. The latest agreement with China calls for delivery of 40,000 to 60,000 tons of copper concentrates.

The country's first copper smelting project started to take shape in late 1976 under the Philippine Associated Smelting and Refining Corp. formed by the five leading companies and the Philippine Government. The 84,000-ton, $250 million Outokumpu Flash smelter and refining complex, to be built at Bantiqui Point, San Juan, Batangas, Luzon, was being engineered by Arthur G. McKee & Co. The target startup date for this smelter was late 1977. The Philippines had need for such a smelter in view of the growing market for copper. However, even with this project, most of the country's concentrate production would have to be exported.

Gold.—Production of gold held steady at just over 500,000 troy ounces per year. Benguet Consolidated, the foremost primary gold producer, put out only half the 1973 level. Depleting reserves and spiralling operating costs had taken its toll on Philippine gold producers. For 1976, average gold prices stood at about $125 per troy ounce, whereas unit production costs were $5 to $15 higher. Lepanto Consolidated was the second company primar-

ily responsible for the bad performance in 1976; its mine near Baguio was shut down most of the year, because foreign copper smelters shunned the use of Lepanto's high-gold-content enargite which releases arsenic in smelting. The byproduct gold producers (from copper) headed by Philex Mining, Atlas Consolidated, and Marcopper Mining, more than held their own. Philex Mining has been the country's leading gold producer for the last 2 years. Output records for the largest gold producers in the Philippines are as follows, in troy ounces:

Company	1975
Atlas Consolidated	79,700
Baguio Gold Mining	4,900
Benguet Consolidated	127,400
Benguet Exploration	13,300
Itogon-Suyoc Mines	28,600
Lepanto Consolidated	40,500
Marcopper Mining	31,800
Philex Mining	134,400
Western Minolco	19,400
Other	21,800
Total	501,800

To alleviate the serious financial difficulties of the gold industry, the Philippine Government extended a subsidy to primary gold producers through Presidential Decree 1070, in addition to loans. The amount of help was fixed at 70% of the difference between the cost of production per troy ounce (excluding depreciation, amortization, and headquarter overhead expenses) and the selling price. Following the improvement of gold prices near yearend, however, several primary gold producers partially liquidated their gold inventory and paid back the loans received under the Central Bank Gold Financing Assistance Plan.

By yearend 1976, the new gold refinery and mint of the Philippine Central Bank were nearly completed, with startup date scheduled for the second quarter of 1977. Capacity will be 600,000 troy ounces of gold and 450,000 troy ounces of silver per year.[5] The plant was to have provisions for future expansion to refine byproduct gold as soon as a copper smelter was built in the Philippines.

Iron Ore.—Philippine mining of iron ore, consisting totally of beach sand operations after the closure of Philippine Iron Mines Inc.'s facilities in 1974, came to a standstill in the second half of 1976. Filmag (Philippines) Inc. and Inco Mining Corp. were the last remaining operators working on titaniferous magnetite sands for sale to Japan. Philippine iron sand output for 1976 as a whole was not much more than 500,000 tons and only 42% of the tonnage in 1975. Apparently the closures were brought about as a result of alleged environmental damage to the beaches and dunes. In 1977, however, Filmag was permitted to resume its operations at Ilocos Sur. In late 1976, C. Itoh & Co. of Japan signed a $23 million contract with Apex Exploration & Mining Co. to import 2.25 million tons of iron sands over 8½ years starting in 1977, from the Gonzago mine on Luzon.

The country has also been producing annually about 100,000 tons of pyrite cinder. Most of the pyrite was produced by the copper companies, headed by Atlas Consolidated.

A 5-million-ton-per-year sinter plant of the Philippine Sinter Corp., a subsidiary of Kawasaki Steel Corp. of Japan, was scheduled to become operational by April 1977. This $230 million plant being built in Misamis Oriental, Mindanao, was scheduled to use iron ore imported from Brazil and Australia and local limestone (approximately 900,000 tons yearly).[6]

Iron and Steel.—A proposed direct reduction project for the Philippines was indefinitely shelved in mid-1976, because of high oil prices. Instead, a conventional integrated steel plant was decided upon, was scheduled for completion by 1981. The key is the blast furnace plant to supply pig iron for making 1.25 million tons per year of steel products initially. This would be located near the Kawasaki iron ore sintering plant in Northern Mindanao that in turn is 80 kilometers east of National Steel Corp.'s electric smelting and rolling plant at Iligan. Most of the raw materials for the proposed steel works will have to be imported.

The Philippines now consumes nearly 1.5 million tons of various steel products annually, which are mostly imported from Japan. Elizalde Steel Consolidated and National Steel are the main producers of

[5] World Mining (San Francisco). Catalog, Survey & Directory Number 1977. June 25, 1977, pp. 141–142.

[6] Mining Journal (London). Mining Annual Review 1977. June 1977, p. 426.

steel products. Elizalde took over National Steel's tin plant lines in 1976, and produces about 100,000 tons per year of tin plate from facilities concentrated at the Rizal works.

Nickel.—Production at the Surigao nickel refinery of Marinduque Mining was increased from 28% of designed capacity in 1975 to 45% in 1976 or about 15,000 tons of contained nickel. Two major shutdowns prevented the realization of 1976 production targets. The highest monthly output rate was attained in June 1976—62% of designed capacity. This Sherritt-Gordon process plant was still not able to totally solve its startup technical problems because of the high-moisture and low-grade nature of the ores. The mine on nearby Nonoc Island delivered 2.8 million wet tons (1.8 million dry) of ore to the refinery, analyzing 1.2% nickel, 0.12% cobalt, and 45% iron. A second project on Palawan by Atlas Consolidated, to use the Freeport ammonia-leach process, was postponed indefinitely. However, a third project under Rio Tuba Nickel Mining Corp. was preparing to ship sizable quantities of 2.4% nickel ore to Japanese firms from its operation on Palawan.

Other Metals.—Benguet Exploration Inc. produced all of the country's mine zinc from a mine in Baguio, with output in 1976 at 11,410 tons which was 9% higher than in 1975. In value this company produced as much in precious metals as it did in zinc. The Philippines also produced 4,580 tons of mine lead. Silver production declined another 6.6% in 1976. Derived as a byproduct of copper and gold, and of minor importance, the value of silver produced during the year was equivalent to only 3% that of copper and 6% that of gold. Philippine production of mercury ceased in 1976 and production of manganese ore was resumed.

NONMETALS

Cement.—The Philippine cement industry was close to 5 million tons per year in capacity and $120 million in annual gross sales. There were about 15 cement producers in 1976, headed by Island Cement Co., Northern Cement Co., Republic Cement Co., and Bacnotan Construction Industrial Corp. A massive road-building program has been underway and there has been much construction in metropolitan areas. Small quantities of cement have also found their way into the international markets.

Perlite.—Construction of a perlite plant in Legaspi City, Albany, northwestern Philippines, began during 1976.[7] Scheduled to start operations by mid-1977, this plant will be the first of its kind in the country. It is 60% Philippine and 40% U.S. owned, and managed by Grefco International. The most important use in the Philippines was filtering, but perlite is also consumed in sugar refining, food processing, nickel extraction, beer brewing, oil processing, lightweight aggregates, horticulture, and cryogenic insulation. Philippine perlite ore has already been exported in large volumes to Taiwan, Thailand, Singapore, and Australia.

Other Nonmetals.—Approximately 6.8 million tons of limestone was produced in 1976, predominantly for cement manufacture. The gypsum needed for making cement and plaster came from indigenous natural ores and more importantly, as a by-product of the phosphate fertilizer industry. The phosphate rock consumed in making chemical phosphates came entirely from the United States. Pyrite production (byproduct of copper mining) amounted to less than 200,000 tons in 1976. Annual clay output approached the 500,000-ton level. A 45,000-ton bentonite mine and drying plant, built as a joint venture of Lepanto Exploration (Asia) Inc. and Filmag (Philippines) Inc., was recently brought into production. Adequate lime was produced to meet demand. Yearly salt output has been in the 200,000-ton range in recent years, nearly adequate to meet demand.

MINERAL FUELS

Coal.—Philippine coal production and consumption remained at nominal levels. The long-range plan to develop a sizable steel industry had been based upon imports of good quality coal. Late in 1976, however, Philippine Government engineers confirmed the discovery of a workable "high-grade" coal deposit in the Naga-Uling region of Cebu, with initial recoverable reserves of 3.6 million tons.[8] Plans

[7] Asia Mining (Manila). March 1977, p. 19.
[8] World Coal (San Francisco). August 1977, p. 8.

have been made to start production by 1979.

Petroleum.—Exploration continued on a moderate scale during 1976. The Government requires the State-run Philippine National Oil Co. (PNOC) to be a partner in every search venture through converting all exploration concessions to Indonesian-style, production-sharing contracts. A presidential decree directed all operators (about 50 firms) to convert to contracts or lose exploration rights by August 26, 1976. In the event of commercial production and with oil companies taking all the risk, costs would be recovered from its first 40% of production. The remaining 60% was split 60–40 (later 65–35) in favor of PNOC. Much speculation has taken place in the stock market with no significant oil discoveries as yet. Offshore Palawan seems the most promising, especially in the light of a second discovery by Cities Service International Inc. in early 1977. Because of the fractured nature of Philippine geology, however, undue optimism did not appear warranted.

Meanwhile, all oil consumed by the Philippines continued to be imported. Crude oil imports have been close to 10 million tons annually, and refined petroleum imports over 500,000 tons. Three oil refineries [9] have a combined capacity of about 247,000 barrels per day or roughly 12.3 million tons per annum. The National Iranian Oil Co. was involved in the construction of a new 60,000-barrel-per-day refinery for the Philippines, location unknown. The country imported $943 million worth of oil in 1976, predominantly from the Middle East. Lately, however, important quantities were being purchased from China.

[9] Bataan Refining Corp.'s 108,000-barrel-per-day refinery at Limay, Caltex (Philippines) Inc.'s 71,000-barrel-per-day refinery at Batangas, and Shell Philippines Inc.'s 68,000-barrel-per-day refinery at Batangas.

The Mineral Industry of Poland

By Tatiana Karpinsky [1]

In 1976, Poland continued to hold 10th place in total world industrial output and fourth place (after the United States, the U.S.S.R., and the People's Republic of China) in the world production of bituminous coal. Poland had a significant share of world output of copper (3.6%), crude steel (2.3%), sulfuric acid (3.5%), and cement (2.7%). Capital investment in the economy in 1976 totaled 577 billion zlotys (Zl),[2] an increase of 19.2% over that of 1975.[3] The investment of industry totaled Zl278 billion, an increase of 16.2% over that of 1975.[4]

According to Polish sources, the national income of Poland in 1976 increased 7.5%, and industrial production increased about 10.7%.[5] The total value of gross industrial production in 1976 amounted to Zl2,096.8 billion.

Among branches of industry, the electrical and manufacturing industries were the most important. In 1976, they contributed 28.2% to Poland's total industrial output. The fuel industry contributed 12%, the metallurgical industry 11.5%, the chemical industry 9.9%, and the mineral industry 3.7%.[6]

Major projects put into operation in 1976 included the first stage of the Katowice foundry, the steel rolling mill at the Lenin foundry, two energy blocks at the Dolna Odra powerplant, and the addition of a second lane to the Warsaw-Katowice Highway. "The Chemical Factory Police II" project also started in 1976.

In 1976, employment in the mining industry accounted for 9.6% of the total national labor force. Of the 338,100 employees in the coal industry, a total of 220,600 were working in underground mines. Employment in steelmills accounted for 170,200 workers. There were 65 hard coal mines and 27 ironworks in operation in 1976.

Government Policies and Programs.—Poland's economy is centrally planned and controlled by the Government. The final targets for the 1977 annual plan were approved by the Seventh Congress of the Polish United Workers' Party and ratified by the Seym in December 1976. The plan places special emphasis on modernizing and expanding existing plant facilities, increasing labor productivity, improving the organization of production processes, and further increasing wages and real income.

The 1977 annual plan foresees an increase in national income of 5.7%. The plan calls for a 7.3% increase in gross industrial output with a 6% growth in the fuel industry, 5.7% in the metallurgical industry, 8.6% in the electrical equipment industry, 7.2% in the chemical industry, and 9.1% in the mineral industry.[7]

The planned increases in commodity production for 1977, in million tons unless otherwise specified, are as follows:

---

[1] Foreign mineral specialist, International Data and Analysis.

[2] Depending upon the purpose of the exchange, the value of the Polish zloty (Zl) may vary considerably. Where necessary, values have been converted from zlotys to U.S. dollars at the official exchange rates of Zl3.32 = US$1.00 (basic rate) and Zl19.92 = US$1.00 (special commercial rate).

[7] Manitor Polski (Polish Monitor). Dec. 27, 1976, pp. 445-453.

	Planned 1977 production	Percent increase over 1976
Copper	0.320	19.9
Iron and steel:		
Crude steel	18.2	16.7
Rolled products	12.2	6.1
Fertilizer materials:		
Nitrogen	1.7	13.3
Phosphorus	.9	--
Bituminous coal	186.0	3.7
Electrical energy billion kilowatt-hours	112.0	7.6
Natural gas billion cubic meters	7.6	13.4

In 1977, the U.S.S.R. will continue to supply primary commodities and materials of foremost importance to the Polish economy, including crude oil and petroleum products, natural gas, iron ore, potassium salts, and cement. Poland will supply the U.S.S.R. with coal, sulfur, chemical raw materials, and other materials.[8]

PRODUCTION

The 1976 plan for production of many mineral commodities was met, but output of chemical fertilizers, cement, building materials, and rolled steel products failed to meet the goals of the annual plan.[9]

Poland continued to develop its mining industry as part of the plan to expand its industrial base. The following production increases were reported for 1976 (in percent): Hard coal, 4.5; electric energy, 7.1; steel, 4.2; electrolytic copper, 8.6; and cement, 7.0.

The increase in production of bituminous coal in 1976 was 7.7 million tons, but brown coal production decreased 0.6 million tons in the same period.

The largest new investment project in the coal industry in 1976 was the development of the Lublin coal basin with the first output of coal planned for 1978. Development also began on the 40-million-ton-per-year-capacity surface mining operation in the Belchatow region. Modernization and development of mines in the Upper Silesia coal basin continued; the Swierklany mine with a capacity of 8,000 tons per day was underway. The first extraction of coal from this mine was expected in December 1979. Another mine was under development near Swierklany with a planned capacity of 12,000 tons per day. Coal output was increased not only by developing new mines and renovating existing ones, but also by improving labor organization.

In 1976, production of iron ore decreased 518,000 tons from that of 1975 and remained below the country's requirements. An additional 15.8 million tons was imported during the year. Crude steel production in 1976 reached 15.6 million tons, compared with 15.0 million tons in 1975.

In December 1976, the first stage of the Katowice steelworks was commissioned. After completion of the first stage in 1977, production is to increase to 4.5 million tons of crude steel per year. Poland's plan in the steel industry is to decrease use of the Martin process in steel production and increase use of the oxygen converter process. The usage of the oxygen converter process in production of steel increased from 12.8% in 1970 to 22.5% in 1975 and is planned to reach 45% in 1980.

In the nonferrous industry, Poland continued to develop its rich copper deposits in the Legnica Glogow region with loans from Western banks and to produce electrolytic copper and copper products instead of copper concentrates.[10] In 1976, production of electrolytic copper amounted to 270,100 tons, an increase of 21,500 tons over the 1975 level.[11] To develop the copper industry, Zl40 billion was invested during the past 15 years (until 1975). In the next 15 years, the sum required will reach Zl350 billion.[12]

In every branch of the nonferrous metallurgy industry, investments were in progress. In 1976, Poland produced 237,000 tons of zinc, 80,600 tons of lead, and 103,000 tons of aluminum.

Among nonmetallic minerals, sulfur production reached 4.89 million tons, 120,000 tons over that of 1975. About 60% of the

output came from the largest mine, Jeziorko, located in the Tarnobrzeg Basin. Total production of salt in 1976 amounted to 3.8 million tons, an increase of 6.9% over that of 1975. Mining of rock salt continued in the Klodawa and Inowroclaw regions and in the Carpathian foothills (Bochnia and Wieliczka).

Production of crude petroleum decreased from 553,000 tons in 1975 to 455,000 tons in 1976. About 15.1 million tons of crude oil was imported. Because supplies of Soviet oil were limited, Poland was also importing oil from the Middle East and northern Africa.

Output of gas was 6.7 billion cubic meters in 1976, an increase of 736 million cubic meters over that of 1975. In addition, 2.5 billion cubic meters was imported from the U.S.S.R.

Under the 1976–80 plan, both the quantity and the range of industrial output are to be expanded significantly. The plan foresees that in 1980 Poland will produce about 207 million tons of coal, 22.2 million tons of crude steel, 430,000 tons of copper, 150 million pieces of roller bearings, 135 billion kilowatt-hours of electric energy, and 26.6 million tons of cement.[13] Development of production of aluminum and other nonferrous metals is expected according to the plan.

[e] Estimate. [p] Preliminary. [r] Revised. NA Not available.

[1] In addition to the commodities listed, antimony, cobalt, germanium, gold, a variety of crude nonmetallic construction materials, and carbon black are also produced in Poland, but information is inadequate to make reliable estimates of output levels. Poland may also produce alumina in small quantities, but details on such an operation, if it exists, are not available.

[2] Includes content of multigradient fertilizers.

[3] Includes building gypsum as well as an estimate for gypsum used in production of cement.

[4] Total of listed commodities only; excludes products not reported individually in official sources, as well as refinery fuel and losses.

TRADE [14]

In 1976, Polish foreign trade turnover amounted to Zl82.7 billion, an increase of Zl6.9 billion or 9.1% over that of 1975. In 1976, total exports were valued at Zl36.6 billion, an increase of Zl2.4 billion or 7.0% over that of 1975, and the value of imports rose to Zl46.1 billion, an increase of Zl4.4 billion or 10.6% over the 1975 level. The trade balances indicated that the deficit increased 26.7% from Zl7.5 billion in 1975 to Zl9.5 billion in 1976. To redress this imbalance, the 1977 plan calls for a 13% increase in the value of exports with only a 2.7% increase in imports.[15]

In 1976, the trade balance of Poland with Council for Mutual Economic Assistance (CMEA) countries [16] showed a surplus of Zl0.2 billion, after a Zl1.2 billion surplus in 1975. The trade balance of Poland with developed market economy countries showed a deficit of Zl10.8 billion after a Zl9.8 billion deficit in 1975.

Poland's trade turnover with various country groups for 1976 is shown in the following tabulation:

Country group	Exports		Imports	
	Million zlotys	Percent	Million zlotys	Percent
CMEA and other [1] centrally planned economy countries	21,853	60	21,588	47
European Economic Community (EEC)[2]	6,724	18	12,250	27
European Free Trade Association (EFTA)[3]	2,511	7	5,225	11
Other developed countries	2,476	7	5,053	11
Developing countries	3,036	8	1,955	4
Total	36,600	100	46,071	100

[1] The People's Republic of China, Yugoslavia, Vietnam, and North Korea.
[2] Comprises the following countries: Belgium-Luxembourg, Denmark, France, West Germany, Ireland, Italy, the Netherlands, and the United Kingdom.
[3] Comprises the following countries: Austria, Iceland, Norway, Portugal, Sweden, and Switzerland.

In 1976, as in 1975, more than half of Poland's foreign trade was transacted with centrally planned economy countries of Eastern Europe. The largest turnover was achieved with the U.S.S.R. (30.3% of exports and 25.5% of imports), followed by East Germany (9.9% of exports and 7.6% of imports) and Czechoslovakia (7.8% of exports and 5.9% of imports).

Among the developed market economy countries, the largest turnover was achieved with West Germany (6.3% of exports and 8.7% of imports), followed by France (3.3% of exports and 5.8% of imports), the United States (2.6% of exports and 6.0% of imports), the United Kingdom (2.9% of exports and 4.8% of imports), and Austria (1.5% of exports and 4.2% of imports).

Among branches of the Polish industry, the most important in external trade was the electrical and manufacturing industry. In 1976, exports by the electrical and manufacturing industry contributed 44% of Poland's total exports; fuel and electric power, 18%; products of the metallurgical industry, 6%; chemical products, 2%; and products of other industries, about 30%.

The import value of manufacturing and electrical industries products accounted for 42%; products of metallurgy, 15%; chemical products, 11%; fuel and electric power, 10%; and products of other industries, about 22%.

The following were the most significant percentage increases in Poland's 1976 exports over those of 1975: 69% in petroleum products, 13% in sulfur, 8% in nitrogen fertilizers, 6% in copper, 6% in zinc and rolled zinc products, and 5% in rolled steel products. The following decreases in exports were noted: 10% in lignite and 1% in coke. The following were the most significant percentage increases in Poland's 1976 imports over those of 1975: 14% in rolled steel products, 13% in crude petroleum, 10% in pig iron, 3% in iron ore, 3% in petroleum products, and

[14] All data on 1975 Polish trade were taken from: Central Statistical Office of the Polish People's Republic. Maly Rocznik Statystyczny (Concise Statistical Yearbook), Warsaw. 1977, pp. 197–205.

2% in natural gas. The most significant decreases in imports were 9% in zinc concentrates, 2% in potash, 2% in phosphorites and apatites, and 1% in hard coal.

In January 1977, the plenary session of the Polish-Soviet Intergovernment Commission for Economic and Scientific-Technical Cooperation met in Warsaw to set foreign trade targets for the current 1976–80 5-year period. In this period, Polish-Soviet trade exchanges are to more than double (209%) the original target of the 1971–75 period.

The degree of Poland's dependence on Soviet raw materials is further underlined by the fact that the U.S.S.R. is scheduled to deliver, in the current 5-year period, 17,000 million cubic meters of natural gas, 35 million tons of iron ore, 100% of Poland's nickel consumption, and 80% of Poland's pig iron consumption. The Polish-Soviet Commission reviewed Poland's nuclear power plans as well as the U.S.S.R.'s supply of machinery and equipment for stage 2 of the Katowice steel complex. In exchange for the imports, Poland is to provide the U.S.S.R. with 47.5 million tons of hard coal, 3 million tons of coking coal, and 3.8 million tons of sulfur.[17]

COMMODITY REVIEW

METALS

Aluminum.—Production of aluminum totaled 103,000 tons in 1976, maintaining the same level as in 1975.

Poland imports all the alumina and bauxite required for the production of aluminum. In 1976, imports of alumina amounted to 281,000 tons, about 9,000 tons more than was imported in 1975. Imported alumina came from Yugoslavia and the United States. Bauxite was imported from Hungary and West Germany.

Production of alumina, using the Grzymek process, is expected to begin at Nowiny, near Kielce, in 1978 and reach a capacity of 100,000 tons by 1980. Primary reduction plants in the Skawina and Konin Basins are the principal aluminum production centers in Poland.

The Skawina aluminum plant, built 22 years ago with an annual capacity of 55,000 tons, is to be expanded. New potlines are to insure an 80,000-ton increase in aluminum production; half of the increase is to be accomplished during the 5-year period 1976–80 and the remainder after 1980.

Copper.—Production of copper ore totaled 19.7 million tons in 1976, an increase of 16% over that of 1975.

Five copper mines were in operation in Poland in 1976: Lublin, Polkowice, Konrad, Lena, and Rudna. Work was also started on another larger mine, the Sieroszewice, where productive capacity is estimated to be about 15 million tons of copper ore per year.

Construction and renovation of the concentrators at the three mines of the Glogow copper basin was in process. Plans were to complete those at the Lublin and Polkowice mines in June 1977 and at the Rudna mine in July 1977. The ore processing capacity of the concentrators is to increase by more than 6 million tons per year.[18]

Production of electrolytic copper was 270,100 tons in 1976, an 8.6% increase over that of 1975. It is expected that copper production will reach 320,000 tons in 1977 and about 425,000 tons by 1980.

In 1976, there were two main copper refining plants in operation: Legnica, with a capacity of 70,000 tons of electrolytic copper per year, and Glogow, with two lines of 80,000-ton-per-year capacity each. Glogow's new production unit with a capacity of 150,000 tons of copper per year

[18] Polish Foreign Trade, Warsaw. June 1976, pp. 17–23.

was reported to be under construction in 1976.[19] There is a plan to build a large foundry in Orsk on the Odra River.

In 1976, Poland exported 96,100 tons of copper, 5,800 tons more than in 1975. Exports of copper increased from 17,900 tons in 1970 to 96,100 tons in 1976. Of the CMEA countries, Czechoslovakia was the largest importer of copper from Poland in 1976. Exports of copper to Western Europe were approximately 60,000 tons in 1976, mainly to West Germany, the United Kingdom, France, and Belgium.

Under the agreement signed in December 1976 between Poland and West Germany, in exchange for a credit of 300 million Deutsche marks, Poland is to supply electrolytic copper and copper products amounting to 480,000 tons over a period of 12 years. Another agreement signed between West Germany and Poland provided for a $125 million credit over a period of 10 years to finance the development of Polish raw material resources in connection with copper mines.

Iron and Steel.—In 1976, Poland produced 674,000 tons of iron ore, a decrease of 518,000 tons or 43.5% from that of 1975.[20] The Polish steel industry is dependent upon imported iron ore. In 1976, total imports of iron ore amounted to 15.8 million tons, an increase of 407,000 tons or 2.6% over those of 1975. About 85% of this ore was imported from the U.S.S.R. and 15% from Sweden, Brazil, and East Germany.

Poland signed a contract with Sweden for the supply of 4.5 million tons of Swedish iron ore annually after 1980. Production of Poland's iron ore came mainly from the Swietokrzyskie Mountains, northeast of Krakow. Iron ore deposits in Poland are marginal, with an average metal content of approximately 30% to 35%. In 1976, production of pig iron reached 7.9 million tons, an increase of 4.1% over that of 1975. Imports of pig iron were about 2.0 million tons, an increase of 176,000 tons or 9.8% over the 1975 level.

In 1976, Poland produced 15.6 million tons of crude steel, accounting for 2.3% of world output. The 1976 production of crude steel was 4.2% above the 1975 level. In 1977, steel production in Poland is expected to reach 18.1 million tons and in 1980, about 22 million tons.

Output of rolled steel products reached 11.5 million tons in 1976, an increase of 3.8% over that of 1975. In addition, about 2 million tons of rolled products was imported, 243,000 tons more than was imported in 1975. Poland expects to produce 16.4 million tons of hot-rolled products in 1980.

The Lenin steelworks at Krakow, the largest in Poland, produced 55% of the entire pig iron output, 44.6% of the steel, 39.4% of the rolled products, 38.6% of the pipe, and 23% of the coke in 1976. Facilities at the steelworks included five blast furnaces, three oxygen converters, eight open hearth furnaces, and two tandem open hearth furnaces.[21]

A new steel rolling mill was put into operation at the Lenin plant in 1976. During the same year, the mill that was put into operation in 1975 with a projected capacity of 350,000 tons was producing thin sheet metal 0.4 to 2.2 millimeters thick. The second stage of the rolling mill was under construction and is to increase output of sheet metal more than 1 million tons per year by 1980.

At yearend 1976, the first installation for continuous steel casting was put into use at the Nawatko electric steel plant in Ostrowice. At the same time, the third 150-ton electric arc furnace was put into operation. After the project is completed, the plant is expected to produce 1.1 million tons of steel per year.[22]

In December 1976, the Katowice metallurgical plant at Losien produced its first steel. The agglomerating plant, blast and steel furnaces, and a rolling mill went into operation. Construction of a second blast furnace, a second sinter line, a third oxygen converter, and a large and a medium rolling mill for finished products are expected to be completed during 1977. The entire steelworks will then reach a capacity of 4.5 million tons of steel per year, to increase to 9 million tons after 1980.[23]

In 1976, the first blast furnace at the Katowice steelworks, with a projected capacity of 6,500 tons per day, produced 5,500 tons of pig iron per day. At the end of 1976, nearly 14,000 workers were em-

[19] Tribuna Ludu, Warsaw. Aug. 12, 1976.
[20] Work cited in footnote 11.
[21] Iron & Steel International. August 1976, p. 280.
[22] Polish Foreign Trade, Warsaw. April 1977, p. 12.
[23] Zolnierz Wolnosci (Soldier of Freedom), Warsaw. Nov. 25, 1975, p. 4.

ployed at the steelworks, including 1,100 engineers and 4,000 technicians.

Since Poland's iron and steel industry depends upon imported iron ore from the U.S.S.R., construction of a bridge is planned across the Bug River (at the border between Poland and the U.S.S.R.) for direct delivery of ore by railroad. It is expected to be completed by 1978. The new wide-gage rail line (Soviet type) is to be laid from the new bridge directly to the Katowice plant.

Lead and Zinc.—In 1976, output of zinc-lead ore amounted to 4,940,000 tons, an increase of 7.4% over that of 1975. The main production of zinc-lead ore was obtained from the Boleslaw, Olkusz, and Pomorzany mines (Boleslaw complex) and from the Orzel Bialy, Warynskiego, and Dobrowska mines (Orzel Bialy complex).

In the 2 years since the Pomorzany lead and zinc mine at Olkusz was put into operation, extraction of zinc ore has been brought to 100,000 tons per month. A rated capacity of over 2 million tons of ore per year is to be reached in 1978.

The Polish zinc industry imported 125,000 tons of zinc concentrate in 1976. Production of lead, primarily from domestic ore and scrap, is probably adequate for indigenous needs since Poland reports no imports of lead ore or concentrate.

In 1976, production of refined lead reached 80,600 tons, an increase of 5.8% over that of 1975. Production of zinc amounted to 237,000 tons, a 2.5% decrease from 1975 output. The target for 1980 calls for the production of 120,000 tons of lead and 260,000 tons of zinc. Exports of zinc metal and rolled products totaled 61,000 tons in 1976, about 30,000 tons less than was exported in 1975.

To increase production of lead and zinc, a new Imperial Smelting Furnace is planned to start operation in 1977 at the Huta Cynku Miosteczko Slaskie Works.

Prospecting on the periphery of the Upper Silesian coal basin, near old mines and on new sites, revealed rich new zinc and lead deposits in the region of Zawiercie and Tarnowskie Gory.

NONMETALS

Fertilizer Materials.—In terms of nutrient content, the Polish chemical industry produced 1.55 million tons of nitrogenous fertilizer and 0.93 million tons of phosphatic fertilizer in 1976, approximately the same level as in 1975. The goals for 1980 are to produce 2.2 million tons of nitrogenous fertilizer and 1.3 million tons of phosphatic fertilizer, and to use 250 kilograms of fertilizer per hectare of land in 1980.[24]

About 0.98 million tons of nitrogenous fertilizer was exported in 1976, an increase of 8.4% over that of 1975. The main importers were East Germany, India, Indonesia, and West Germany.

There is a shortage of phosphate ores and potash salts in Poland. In 1976, in terms of nutrient content, about 3.23 million tons of phosphorites and apatites was imported, a decrease of 2.4% from that of 1975. Potash salt imports totaled 2.86 million tons in 1976, compared with 2.93 million tons in 1975. In 1976, apatites, phosphorites, and potash fertilizers comprised approximately one-third of chemical industry imports.[25]

In 1976, the U.S.S.R. delivered about 2 million tons of potash fertilizer to Poland, with the remainder from East Germany. Apatites and phosphorites were imported mainly from the U.S.S.R. and Morocco.

Between July and December 1976, sales of fertilizer in the country dropped an average of 7%[26] and in some areas about 20% because nitrogenous fertilizer supplies decreased more than 40% at yearend. The shortage in fertilizer production was owing to a breakdown at the Wloclawek nitrogen works, one of the three main fertilizer plants. The other plants in Police and Pulawy, which depended on Wloclawek for their production of ammonia, also did not fulfill their targets.[27]

The Police I plant near Stettin, which began operation in July 1974, produced its millionth ton of complex fertilizer in 1976. To meet the domestic shortages of nitrogenous fertilizer, work began on the preparation of the site of the Police II fertilizer complex to be built with the help of the French firm, Creusot-Loire. Under the contract, Creusot-Loire is to supply equipment for two ammonia plants with an output of

750 tons per day each, one urea plant with a capacity of 1,200 tons per day, and a 2,600-ton-per-day complex fertilizer plant. Completion of the plants is scheduled for 1980.[28]

Sulfur.—In 1976, Poland produced 4.9 million tons of elemental sulfur, an increase of 120,000 tons or 2.5% over that of 1975.

Exports of sulfur increased from 3.1 million tons in 1975 to 3.5 million tons in 1976. The CMEA countries, together with Yugoslavia and the People's Republic of China, purchased over 50% of Poland's sulfur exports in 1976. The chief buyers among market economy countries were Norway, Austria, Italy, Finland, and the United Kingdom.

Poland has guaranteed to supply all of the sulfur required by the CMEA countries for the near future. Poland also exports sulfuric acid. Chemadex, a Krakow-based corporation, contracted for the delivery of three sulfuric acid units, worth 56 million rubles, to the U.S.S.R. in 1977–78 as part of a total of 15 sulfur units to be built in the U.S.S.R. by 1980.

In 1976, about 89% of the total output of sulfur was extracted by the Frasch process. This method was used in two mines, Jeziorko and Grzybow. Another method, open pit mining with flotation and refining, was used in the Machow mine.[29]

Sulfur deposits southwest of Staszow and south and east of Tarnobrzeg are the principal contributors to current production.[30] In 1976, new deposits of sulfur were reportedly found near Osiek and Baranow Sandomierska. The sulfur industry is under the supervision of the Mining Union for Chemical Raw Materials, located in Krakow.

MINERAL FUELS

Coal is Poland's most important energy source, providing 94% of the nation's energy supply. In 1976, Poland's total primary energy production amounted to 204 million tons standard coal equivalent (SCE), 8.5 million tons over that of 1975, comprised of coal (93.8%), natural gas (4.4%), and crude oil (0.3%), with peat, wood, and hydropower making up the balance.

Total consumption of primary energy in Poland increased from 179.2 million tons SCE in 1975 to 188.5 million tons SCE in 1976 and is expected to reach 212 million tons SCE in 1980.

In 1976, coal was supplying about 79% of the total energy consumed in Poland, compared with 12.5% for petroleum and 6.5% for natural gas. The share of crude oil and petroleum products in total consumption of primary energy increased from 4.3% in 1960 to 12.5% in 1976 and the share of gas increased from 1.1% in 1960 to 6.5% in 1976.

The total energy balance for 1975 and 1976 is shown in table 4.

e Estimate.
[1] 1 ton standard coal equivalent (SCE)=7,000,000 kilocalories. Conversion factors used are from the United Nations as follows: Hard coal, 1.0; brown coal, 0.3; coke, 0.9; crude oil, 1.47; petroleum products, 1.54; natural gas (per thousand cubic meters), 1.33; and hydroelectric power (per thousand kilowatt-hours), 0.125.

Source: Biuletyn Statystyczny (Statistical Bulletin), Warsaw. No. 2, 1977, pp. 16, 37–38.

The first nuclear powerplant in Poland is to be constructed around 1983 at the Zarnowieckie Lake in the Gdansk region with Soviet assistance. The U.S.S.R. will supply the reactor and fuel.

In 1976, electrical energy production (largely thermal) reached 104.1 billion kilowatt-hours, an increase of 7.1% over that of 1975. Installed capacity was 20,475 megawatts, an increase of 2% over that of 1975.[31] This production of electricity required 33.5 million tons of lignite and over 42 million tons of hard coal, or about 35% of Poland's annual production of coal.[32]

Coal.—In 1976, Poland produced a total of 179.3 million tons of hard coal, an increase of 7.7 million tons over that of 1975; about 15% of the bituminous coal produced represented coking coal.[33] Hard coal production is expected to reach 200 million to 210 million tons by 1980 and about 250 million tons by 1990.

Exports of bituminous coal increased from 38.5 million tons in 1975 to 39.9 million tons in 1976.[34] In 1976, the largest amount of coal was purchased by the U.S.S.R. (10 million tons), East Germany (4 million tons), and Czechoslovakia (2.3 million tons). Among market economy countries, France imported about 5 million tons; Finland, 3.3 million tons; and Italy, about 3 million tons. Japan has become an important importer of Polish coal with 820,000 tons in 1976. The United States imported 135,000 tons from Poland in 1976.

In 1976, brown coal production was 39.3 million tons, a decrease of 1.4% from that of 1975. Brown coal production is expected to reach 42 million tons in 1980 and 104 million tons in 1990.[35] Exports of brown coal amounted to 3.1 million tons in 1976. The main importers were Bulgaria, Yugoslavia, East Germany, and Romania.

Production of coke reached 18.8 million tons in 1976, of which 3.1 million tons was exported, mainly to the U.S.S.R. and East Germany. Among Western countries, the largest importers were Austria, West Germany, and Finland.

According to the Polish Central Geological Board's estimate, Poland's minable reserves in place of hard coal amounted to about 57,500 million tons on January 1, 1974,[36] of which 19,600 million tons was measured, indicated, and inferred, and 37,900 million tons was classified as undiscovered or speculative.

About 25% of the hard coal reserves represent coking coal. Of the 57,500 million tons of hard coal reserves, 55,400 million tons occurs in the Upper Silesian coal basin, about 500 million tons in the Lower Silesian coal basin, and about 1,600 million tons in the surveyed regions of the Lublin coal basin.

Poland's ultimate hard coal resources are estimated at about 70 billion tons. The surveying of these reserves is to be the object of intensive prospecting-surveying work carried out by the Geological Service of the Central Geological Board in the coming years.[37]

Brown coal reserves are estimated at 36 billion tons, of which about 15 billion tons is recognized as economically minable and 10 billion tons as probably minable.[38]

The calorific value of the Upper Silesian coals ranges from 4,800 to 7,800 kilocalories per kilogram.

The development of the coal mining industry in Poland continued in 1976. The Trzydziestoleca (30th Anniversary) mine, the latest of seven built in the Rybnik coalfield and commissioned a few years ago, increased its production to 4,000 tons of coal per day in 1976, with a projected capacity of 15,000 tons per day.

New shafts were sunk at the Jankowice mine to increase the production of coal by 1,400 tons per day. In addition, development was in progress at the Brzeszcze, Ziemovit, Andaluzja, and Halemba mines. In December 1976, the first seam of coal was reached in the newly developed Swierclany mine in the Rybnik Basin, where the first extraction level was to be at a depth of 580 meters and projected eventual depth, 835 meters. This mine, with a projected capacity of 12,000 tons per day, is expected to produce 8,000 tons of coal per day in 1979. The development of a new mine at Suszec started in 1976

[34] Page 205 of work cited in footnote 11.
[35] Polish Coal Review, Katowice. V. 14, No. 1–3/152–154, 1976, p. 5.
[36] Polish Coal Review, Katowice. V. 14, No. 1–3/149–151, 1975, pp. 4–5.
[37] Page 10 of work cited in footnote 36.
[38] Polish Coal Review, Katowice. V. 14, No. 1–3/152–154, 1976.

and production is scheduled to begin in 1982.

Work was progressing in the new Lublin coal basin; the first two shafts of a mine near Bogdanka reached a depth of over 500 meters and were sunk by a freezing method. These shafts are to be completed at yearend 1977 and the first million tons of coal is expected to be produced in 1980. With the completion of the first stage of the project, scheduled for 1990, its annual output is to be about 25 million tons.[39] Seven mines are to be developed in the Lublin Basin in the near future.

One of the largest brown coal mining projects during the current 5-year period is at Belchatow, where surface mining operations are to provide 40 million tons of brown coal per year. The Belchatow open pit is to become operational in 1980 and is to reach target output in 1985. In 1976, a rotary excavator 200 meters long, 75 meters wide, and 7,000 tons in weight was assembled at the Belchatow lignite strip mine. This excavator is to go into operation in July 1977. The Belchatow project includes two power stations, each with a generation capacity of 4,300 megawatts.

In 1976, an agreement was reached on the construction by Krupp Industries of a major coal gasification plant at Katowice, Upper Silesia. West German bank credits totaling 2,650 million Deutsche marks will be made available, to be eventually repaid by delivery of gas from the new plant.

Natural Gas.—Production of natural gas increased from 5,963 million cubic meters in 1975 to 6,699 million cubic meters in 1976. Some 87% of the total came from the Carpathian foothills. In addition, about 200 million cubic meters of gas was obtained by draining methane from hard coal mines in the Rybnik region. Imports of natural gas from the U.S.S.R. totaled 2.5 billion cubic meters in 1976.

The limited opportunities for obtaining natural gas from domestic sources makes it necessary for Poland to increase imports. By 1980, imports are to reach approximately 4 billion cubic meters and by 1990, 11 billion to 12 billion cubic meters.

In November 1976, the two sections of the Polish-Soviet gas pipeline were joined at Kermanovice, Przemysl Province. The pipeline begins at Komarno, crosses 80 kilometers of Soviet territory to the Polish border, and then runs toward Warsaw and Gdansk. In 1979, when the pipeline is linked to the European section of the Orenburg pipeline, it will supply 2.8 billion cubic meters of gas per year.

In May 1977, Polish workers are to complete two-thirds (380 kilometers) of the Polish section of the Orenburg pipeline. About 47.6% of Poland's proved gas reserves occur in Poland's lowlands and about 44.1% in the Carpathian foothills.[40]

Petroleum.—In 1976, the output of crude oil in Poland amounted to 455,000 tons, a decrease of 17.7% from that of 1975. It is unlikely that this output will substantially increase over the next few years.

About 15.1 million tons of crude oil was imported in 1976, an increase of 1.8 million tons over that of 1975. About 12 million tons was imported from the U.S.S.R. and about 3 million tons from the Arab countries, mainly Iraq. Poland is to receive 63 million tons of crude petroleum under the revised 1976–80 Soviet-Polish trade protocol, compared with 49 million tons in 1971–75. Most of the petroleum imported from the U.S.S.R. is delivered by way of the Friendship pipeline.

In 1976, the Plock refinery, together with several smaller plants, produced a total of 15.5 million tons of refined petroleum. The plans for the petrochemical industry call for the processing of about 20 million tons of crude petroleum by Polish refineries in 1980.

Imports of petroleum products in 1976 reached 3.2 million tons, an increase of 0.1 million tons over those of 1975. Exports of petroleum products in 1976 amounted to 2.7 million tons, compared with 1.6 million tons in 1975, going mostly to the Scandinavian countries.[41] Poland's foreign trade in petroleum products for selected years is shown, in thousand tons, in the following tabulation:

	1970	1975	1976
Exports	r 1,316	1,601	2.676
Imports	r 2,424	3,133	3,216

r Revised.

[39] Polish Foreign Trade, Warsaw. March 1976.

To increase processing of crude oil, construction of new facilities was accelerated at the Plock and Gdansk petrochemical complexes. In December 1976, the second cracking installation at the Plock petrochemical complex was put into operation. The installation was built with the help of U.S. and Japanese experts. It is planned to produce 750,000 tons of gasoline per year and several hundred thousand tons of intermediate products. In 1977, the Plock combine is to process 12.8 million tons of Soviet oil.

The Gdansk oil refinery was commmissioned in 1975, and in 1976 processed 1.4 million tons of crude oil. The propane and lubricating oil installations are to be put into operation in May 1977. The entire oil sections are to be completed by July 1977. In 1977, the refinery is expected to process 3 million tons of crude oil.

In 1976, construction of a refinery with a projected capacity of 3 million tons of crude oil per year was begun at the Blachownia petrochemical works in Kedzierzyn-Kozle, Opole Province. The cost of construction and equipment is estimated at Zl10 billion. The first stage of the refinery is to be completed in 1980.

Poland's recoverable reserves of crude petroleum are estimated at 6 million tons.[42] About 40% occur in Poland's lowlands, 40% in the Carpathian Mountains, and about 20% in the Carpathian foothills.[43] In 1976, intensified exploration resulted in the discovery of new crude oilfields, which did not, however, prove to be of major importance.

Plans for continued exploration for oil and gas include the drilling of 1.7 million meters of exploratory wells and 34,000 kilometers of seismic profiles during the period 1976–80. It is anticipated that 60% of the drilling will be in the Polish lowlands.[44]

The Mineral Industry of Portugal

By Roman V. Sondermayer [1]

During 1976, the principal mineral materials produced in Portugal were coal, tin, tungsten, pyrite, gold, copper, iron and steel, beryl, feldspar, uranium, and cement. Output was modest by world standards except for tungsten, which amounted to about 4% of the world total.

The gross national product (GNP) was $15 billion[2] in 1976, about the same in constant prices as in 1975 although inflation was at an annual rate of 30%. The mineral industry accounted for about 5% of the GNP and employed about 49,000 persons, or 3% of the total labor force.

Following 2 years of unsettled political conditions, the Government started planning during 1976 for development of Portugal's mineral resources. A general plan for exploration and an overall inventory of mineral resources resulted, but details about spending by commodities and organizations participating in the plan were not made public at yearend.

By Decree No. 350/76 of May 14, 1976, a new Ministry of Industry and Technology (Ministerio da Industria e Technologia) was established. The new department had, among others, a secretary for energy and mines (Secretario de Estado da Energia e Minas), in charge of mining, metallurgy, and energy of the country. Three directorates (Direcçàо Geral de Minas e Metalurgia, Direcçàо Geral dos Combustíveis, and Direcçàо Geral dos Servicos Electricos) and two institutes (Instituto Portuguès de Electricidade and Instituto de Geologia Minas et Metalurgia) were the major units of the Secretariat for Energy and Mines.

A 40-hour workweek was introduced in the mining industry, and wages and fringe benefits were improved for miners, but major weaknesses in the sector (high turnover, low pay, and low productivity) remained. An interministerial commission was charged with making an economic study of the present difficulties.

PRODUCTION

Most of the activities of the mining industry were modest by European standards. Table 1 shows production statistics for 1974, 1975, and 1976.

The mining industry's enterprises were owned by both private capital and the Government. The tabulation shows major companies and principal facilities in operation in 1976.

[3] Includes 14,000 tons for the Azores and 31,000 tons for Madiera Islands.

TRADE

Portugal remained a net importer of minerals; this deficit was caused mainly by the high cost of petroleum and petroleum refinery products.

Imports of minerals, valued at $0.9 billion, were 24% of the country's total imports during 1976. Exports of minerals, valued at $0.1 billion, were about 7.2% of total exports. The following tabulation shows a breakdown of Portugal's mineral foreign trade for 1975, in thousand dollars:

Commodity group	Imports	Exports
Crude nonmetals	32,548	14,532
Metal ores	14,872	15,804
Mineral fuels	588,479	39,572
Fertilizers	8,003	29,033
Cement, lime, etc	864	2,903
Ferrous metals	215,019	34,542
Nonferrous metals	64,914	3,512
Total	924,699	139,898

COMMODITY REVIEW

METALS

Iron and Steel.—The new national plan for steel called for tripling the present steel output of about 400,000 tons per year. A new steel plant was to be built by the French company, Sofresid, but there were no details on location and capacity; a 1.5-million-ton-per-year mine at Moncorvo (northern Portugal) was to supply iron ore. To assure faster development, the Moncorvo project will be transferred to a public company to implement the development. However, the problem of transportation of Moncorvo ore to the plant at Seixal or any other possible site remained unresolved, since the area where mining was planned is remote and lacks roads and railroads. It is expected that economic aid from the European countries and the United States will be needed for further development of the steel industry.

During 1976, two iron ore mines and two manganiferous iron ore mines (8.5% Mn) were in production. Siderurgia Nacional S.A.R.L., with a plant at Seixal, remained the major iron and steel producer in the country.

Pyrites.—Total utilization of pyrites with recovery of sulfur, copper, lead, and zinc, and production of iron pellets from cinder was the essence of the national plan for pyrites published during 1976 (Decreto No. 441/76 of June 4, 1976).

Pyrite reserves of Alentejo Province were estimated in the plan at 240 million tons of which 33 million tons were proven. Pyrite produced in this area has the following average content: Sulfur, 41% to 46%; copper, 0.8% to 1.6%; iron, 39%; lead, 0.9% to 1.2%; and zinc 2.2% to 3.4%. Two deposits, Aljustrel (80 kilometers east of Sines) and Lousal Caveira (about 36 kilometers north of Aljustrel), were in production; the Government of Portugal owned 90% of the operating company, Piritas Alentejanas.

During the 1970's production from both deposits was about 500,000 tons per year and employment was 1,300 persons. Aljustrel accounted for about two-thirds of the total output. Production was sold largely to two Portuguese companies, Companhia União Fabril (CUF) and Amoniaco Portugués, for production of sulfuric acid used in fabrication of fertilizers.

The cinder left after roasting was originally sold to Siderurgia Nacional, but the high lead content made it unusable and about 700,000 tons remained at yearend at

CUF's Barreiro facilities. To improve utilization of pyrite and use the large stocks of cinder, CUF was preparing to construct an installation for recovering nonferrous metals and producing iron pellets by the Japanese Kowa-Seiko method. A yearly output was planned as follows: Iron pellets, 342,000 tons (about 50% of consumption in the Siderurgia Nacional steel plant at Seixal); copper, 1,200 tons; lead, 2,100 tons; zinc, 4,200 tons; gold, 200 kilograms; and silver, 4,000 kilograms. In addition, a new 250,000-ton-per-year sulfuric acid plant was included in the project. Partial financing for a pelletizing plant has been assured through a $23 million loan from the European Investment Bank of the European Community.

To meet future increased demand for pyrite, the Government of Portugal examined possibilities for expanding the productive capacity of the Aljustrel mines. Plans for the expansion have not been completed, but the Government's Pyrite Commission foresees two phases of development. During the first phase (1978–81) the annual output of the Aljustrel mine should increase from 0.4 million tons to 1.4 million tons of pyrite at a cost of $140 million. Approximately $60 million will be for mining equipment. During the time of mine expansion, the Commission will determine the best metallurgical method for recovery of elements from the pyrite, and construction of the metallurgical plant should follow. Additional estimated costs for the metallurgical project were reported at $149 million. When the Aljustrel project is completed, mining and processing of pyrite should generate a total revenue of $203 million per year.

Tungsten.—Tungsten remained the most important mineral commodity produced in the country. To assure continuous production, additional prospecting for scheelite was conducted in the areas of Freixo de Espada a Cinta, Caminha, and Taronca. The Bureau de Recherche Geologique et Minière of France and Union Carbide Corp. were most active in tungsten exploration.

Other Metals.—A silicon metallurgy plant, owned by Milnorte S.A.R.L., was under construction near Regua. Production will be based on large reserves of quartz sand in the area. Completion date and capacity of the plant are not known.

During 1976, uranium resources were reexamined by the Portugueses Junta Nuclear. The Niza area and the red sands north of Coimbra were considered for production. However, no decision on the future of these resources was made public by yearend.

NONMETALS

Nonmetallic materials such as cement, ornamental stone, clays, gypsum, sand, gravel, feldspar, lime, lithium minerals, salt, and talc were produced in the country. Except for ornamental stone, which is exported, nonmetals are used domestically and their output was significant only to the domestic economy.

The possibility of starting production from the large sand deposits of Rio Major and the Setubal Peninsula was explored during the year.

Cement.—Five cement plants with 16 kilns and a total annual capacity of 3.5 million tons were operational during 1976. Two companies, Companhia Cimento Tejo S.A.R.L. and Companhia Geral de Cal e Cimento S.A.R.L., accounted for 50% of the country's cement output.

Stone.—About 300 stone-producing facilities were in production during 1976; employment averaged about 3,000 persons. A large variety of stone was produced; however, ornamental stone, marble, and granite remained the most important products, and significant quantities were exported to Italy for further processing. The area around Villa Vicosa-Borba-Estremos remained the major producer and accounted for about 70% of the total output.

MINERAL FUELS

Portugal's supply of fuels remained dependent on imports, mostly petroleum and petroleum refinery products. Some high-rank coal and coke were also imported. Coal, mostly anthracite, remained the principal source of energy produced in Portugal. Table 4 shows supply and apparent consumption of fuels and power in 1974 and 1975.

Coal.—Production of coal came from a mine located near Oporto. During 1976, production remained at the 1975 level, about 200,000 tons per year.

Natural Gas and Petroleum.—Portugal was completely dependent on imports of gas and oil to meet its requirements. To

Table 4.—Portugal: Supply and apparent consumption of fuels and power for 1974 and 1975 [1]

[3] Less than 0.1 million tons of SCE.

correct the situation, the Government took steps to stimulate interest in offshore exploration for oil and gas. A new Government organization was formed to oversee the exploration work and speed the Government's decisionmaking process.

Eight wells were drilled offshore Portugal during 1976; all were dry. Shell-Sacorex drilled three of these wells north of Lisbon with depths ranging from 2,300 meters to 2,600 meters; and Texaco also drilled three wells in the Cavala concession north of Oporto with depths between 1,200 meters and 1,700 meters. Two wells were drilled off the south coast, one by Challenger to a depth of 3,100 meters, and one by the Chevron-Geosul-Petrograbe consortium to 2,500 meters.

Construction continued on a new 6-million-ton-per-year refinery at Sines, 90 kilometers south of Lisbon, to replace the refinery at Lisbon. Total Portuguese refinery capacity will then be 15 million tons per year, far above domestic demand, and an export market for surplus petroleum products will have to be found. Two refineries with an annual capacity of about 9 million tons operated in Portugal and processed about 5 million tons of crude oil. Approximately 25% of the products were exported to various countries in Europe.

The Mineral Industry of Southern Rhodesia

By Janice L. W. Jolly [1]

Mineral production in Southern Rhodesia contributed about 12% to the nation's gross domestic product (GDP) estimated at $3,123 million [2] in 1976. Only the mineral and agricultural sectors showed real growth in output during the year. The overall real GDP declined 3.4% in 1976, compared with a 7.7% growth rate in 1975. The Southern Rhodesian Government continued to encourage both large and small mineral investors, in the belief that mining potential was best developed by private enterprise and that the profit motive provided the basic stimulus to economic activity. The Government provided prospecting grants, development grants, and loans to stimulate new projects; private prospectors were particularly encouraged.[3] A very active geological survey has been maintained which has mapped most of the country in detail and is expected to embark soon on a regional geophysical survey of the country, involving gravitational, magnetic, radiometric, and geochemical surveys. An Institute of Mining Research was also maintained by the Government.

There was a general decline in the volume of manufacturing production in both 1975 and 1976, with that of 1976 down 10%. Recession in the construction industry was a major factor in the slack capital goods demand. Increased limitations on foreign exchange, fuel rationing, and shortages of skilled manpower also had an effect.

Mozambique closed its border with Southern Rhodesia on March 8, 1976, confiscating many Southern Rhodesian railcars. The impact of this move was less than originally expected as exports were shifted to the South African rail system and ports. Southern Rhodesia was making greater use of the Beitbridge route, and only some 25% of its traffic was moving through the Botswana rail route after the closure. Southern Rhodesian traffic was competing with an estimated 30% of Zairian traffic also moving through Botswana. Additional transportation problems were caused when African Nationalist guerrillas blew up a railroad bridge in northwestern Southern Rhodesia in October 1976, plunging 11 cars loaded with Zairian copper into a river near the town of Matetsi.[4]

The third symposium on minerals was held at the University of Rhodesia in Salisbury in September 1976 and was attended by about 160 geologists, mainly from Southern Rhodesia and the Republic of South Africa, but also from Canada, West Germany, Australia, France, Botswana, and the Territory of South-West Africa. The first symposium in 1968 was on the Southern Rhodesian basement complex. The second one in 1971 was on granite.

PRODUCTION AND TRADE

Mineral production was valued at $368.8 million in 1976, compared with $271.7 million for 1975. Both the mineral unit value and volume indexes (1964=100) increased in 1976, 26% and 7%, respectively. In the past decade, the value of Southern Rhodesian mineral production has increased over 250%.[5]

Prior to the Unilateral Declaration of Independence (UDI) in 1965, foreign trade was mainly with the United Kingdom, Zambia, and southern African and European countries. Recent United Nations statistics indicated that some Southern Rhodesian exports continued after the UDI to several developed countries other than the Republic of South Africa, including Japan, West Germany, the Netherlands, Belgium, and Austria. Trade with central and southern African countries also continued to be important. Trade with the Republic of South Africa increased, and Southern Rhodesia's

[e] Estimate. [p] Preliminary. [r] Revised. NA Not available.

[1] In addition to the commodities listed, modest quantities of unlisted varieties of crude construction materials (including clays, stone, and sand and gravel) presumably were produced, but output is not reported quantitatively, and available information is inadequate to permit formulation of reliable estimates of output levels. Also, natural corundum, graphite, and mica have been produced in the past and output presumably has continued, but no basis for estimates of output levels is available. Through 1965, annual corundum output was at a level of several thousand tons, ranking Southern Rhodesia second only to the U.S.S.R. in world production.

[2] Data are for years ending Sept. 30 of that stated.

[3] Includes nickel content of nickel oxide and nickel fonte.

[4] Output of the Inyati mine only.

[5] Output of the Beardmore mine only.

[6] Data represent only an approximate order of magnitude.

[7] Data represent sales for years ending Aug. 31 of that stated.

changing relationship since the Mozambique border closure in March 1976 reinforced the importance of the Republic of South Africa as a trading partner. U.S. imports from Southern Rhodesia in 1975 were valued at about $60 million (up from $19.4 million in 1974) and comprised only nonfuel minerals. Ferroalloys were the principal U.S. imports, valued at $38.5 million. Other imports included nickel and its alloys ($9.1 million), crude asbestos ($2.3 million), and nonferrous metal ores and concentrates ($7.3 million). Complete data on Southern Rhodesian trade are not available.

COMMODITY REVIEW

METALS

Chromite.—One of the country's main chromite producers was Anglo American Corp. Rhodesia Ltd.'s Rhodesian Alloys Mining Division (RAMD), which operated the Vanad, Caesar, and Sutton mines. Since 1973, when Anglo American took over Rhodesian Vanadium Corp.'s mines, extensive developments and improvements have been made. It was estimated that some $2.9 million had been spent through March 1976.[6] A further sum of $1.8 million was earmarked for the year ending March 31, 1977. Most projects were concerned with underground development. Extensive overhaul work on the Vanad processing plant was also undertaken. Survey methods were reorganized, resulting in more detailed information for production planning. All RAMD mines also adopted the same basic mining methods, called resue stoping. A long-term mining technique, resue stoping involved nearly a year's work to develop each 800- by 304-meter section and is to result in a more efficient operation and increased productivity.

The Vanad mine was RAMD's top producer with seven underground sections. The incline shafts reached a depth of 350 meters as development continued. RAMD's concentrator and sorting plant were also situated at Vanad and handled fines (−2.54-centimeter) material from all three mines. Hard lumpy ore above this size with 47% Cr_2O_3 content constituted up to 13% of total ore and was delivered directly to the stockpile at the Sutton mine to be railed to Gwelo. At the Sutton mine, considerable expansion and development work has been carried out in the past 2 years, and production levels were approaching those at Vanad. The Sutton mine operated six underground sections. The Caesar mine was operating at a low production rate, but the mine had great potential. A reserve of 1.3 million tons of ore to a depth of 300 meters was established at the Caesar mine. Plans were for future output at Caesar to be greater than the combined output of the other two mines.

New furnaces for expanding charge chrome[7] production were to be installed at RAMD's ferrochrome plant in Gwelo. This was in an effort to switch RAMD's traditional production of high-carbon chrome, low-carbon chrome, and silicochrome to charge chrome as both low-carbon chrome markets and the tonnage outlets for chromite became more restricted. The plant included a 28-million-volt-ampere furnace for producing about 25,000 tons per year of high-carbon chrome, in addition to two 17-million-volt-ampere furnaces for producing 35,000 tons per year of silicochrome. Normally, the silicochrome was converted to 33,000 tons per year of low-carbon chrome in three furnaces totaling 22 million volt amperes. One or more of the older, smaller furnaces on low-carbon chrome was to be phased out as charge chrome production was introduced. Southern Rhodesia's other main ferroalloy producer, Union Carbide Rhomet, operated three furnaces totaling 45 million volt amperes with a capacity of about 100,000 tons per year of high-carbon and charge chrome.[8]

The United States imported an estimated 11% of total Southern Rhodesian chrome ore exports in 1976 and 21% of total ferrochrome exports. Estimated exports of chrome ore and ferrochrome to the United States as a percentage of total Southern Rhodesian exports of all commodities were

as follows: 1974—2%, 1975—8%, and 1976—4%.[9]

Copper.—The Minister of Mines announced that Southern Rhodesia had 1.2 million tons of copper reserves.[10] The low copper price was worrisome in 1976, but in general, the Southern Rhodesian copper industry still produced at a profit throughout much of the year.

The Messina (Transvaal) Development Co. Ltd. (M.T.D.) group of companies includes: M.T.D. (Mangula) Ltd., operating the Molly, Norah, and Silverside mines; Messina's own Beardmore mine (tungsten); Lomagundi Smelting & Mining (Pvt.) Ltd., operating the Alaska, Shackleton, Avondale, Angwa, Hans, and Gwai River mines; and Messina Rhodesia Investments Ltd. (Merits), operating several mines. M.T.D. (Mangula) enjoyed a successful year in 1976, declaring dividends totaling $8 million. The year's profits were boosted by sales of copper on which the production costs had been borne in previous years. To repeat this profit performance in 1977 would require higher copper prices.

M.T.D. (Mangula)'s performance was even more exceptional in view of an 8-week breakdown at the concentrator. One of two motors failed, resulting in a production loss of 96,000 tons of ore in May and June; the copper loss was 1,000 tons. The grade of ore taken from all three mines of M.T.D. (Mangula) was also slightly lower than anticipated, leading to a shortfall in production of some 1,200 tons of copper. Withdrawals from the concentrate stockpile at the Alaska smelter yielded production of over 950 tons of copper in excess of mine production, and this, combined with shortening of the pipeline, brought the sale tonnage to a satisfactory level.[11] The Silverside mine is expected to go out of production in 1977 as ore reserves were exhausted, but work was well advanced on doubling the concentrator capacity of the Norah mine to 42,000 tons per month and on boosting M.T.D. (Mangula)'s concentrator capacity 14%.[12]

Corsyn Consolidated Mines Ltd. speculated that unless there was a rise in the price of copper, the Inyati mine would have a short life. Losses were being incurred, and the mining position was subject to major policy changes which would include a further reduction in throughput. Other features apart from the low copper price were also significant. Payability was disappointing in some areas, and granite intrusives had affected ore reserves in the Era sections. Recovery of ore in areas affected by the pink granites was hazardous, expensive, and subject to dilution. The thickness (150 meters) of the flat-lying dolerite intrusive below the Era sections will have a severe effect on reserves in about a year. Shaft sinking through the dolerite made satisfactory progress, but an intersection with the gold reef was not expected until the end of the fiscal year when the grade and nature of the ore body would be known.

Gold.—The level of Southern Rhodesian primary gold output was estimated at 580,000 to 640,000 troy ounces per year from possibly 300 or more workings.[13] The four Coronation Syndicate Ltd. mines, Arcturus, Mashona Kop, Mazoe, and Muriel, produced 73,947 troy ounces in the year ending September 30, 1976. Blanket Mine (Pvt.), which was owned by Falconbridge Nickel Mines Ltd.'s subsidiary Ven- ounces of gold in 1976. There was also byproduct gold output from copper and nickel mining.

Southern Rhodesia's largest gold producer, Falcon Mines, produced 55,141 troy ounces of gold in fiscal year 1976, compared with 53,395 troy ounces in 1975. Working profit at the mine was $2.2 million in 1976, compared with $3.7 million in 1975. Falcon Mines operated five mining sections: Dalny, Arlandzer, Delcia and Beehive, Trukois, and Venice. During 1976, development footage was increased 30%; the average value and width of development were 11.4 grams of gold per ton and 160 centimeters. A major fault zone on the main Dalny ore body caused declining values. Ore reserves on September 30, 1976, were 1,081,000 tons averaging 12.5

[13] Mining Annual Review, 1977 (London). Rhodesia. P. 445.

grams per ton over a width of 176 centimeters. A gold price of $113 per troy ounce was used in reserve calculations. Plans for 1977 called for a milling rate of 20,000 tons per month and a recovery grade of 7.5 grams per ton.[14]

Anglo American's Champion mine at Odzi was closing because ore reserves were exhausted. The mine was rehabilitated in 1973 after having been closed since 1964. Between April 1973 and December 1976, the Champion mine produced 9,721 troy ounces of gold and 10,993 troy ounces of silver for a total value of over $1,360 million. Champion produced its last gold bar at the end of December 1976.

Grandeur Gold Mining Co. was placed in provisional liquidation after delayed startup. In August 1976, the shareholders were notified that the mine was short of funds. The 250 shareholders were to lose a combined $300,000. The sharp drop in gold prices and the shortage of capital and working funds were the main causes. The mine could break even at a recovery grade of 4.5 grams per ton with a gold price of $112 per troy ounce. However, the recovery grade when the mine was placed under provisional liquidation was about 3 grams per ton. One hundred and ten miners were to lose their jobs.[15]

The Nantwich gold mine near Que Que was being dewatered and was to be mined by a new company, Nantwich Gold Mining Co. (Pvt.) Ltd. The main shareholder was Bradco Nominees. The mine was being worked on a tribute agreement with the South African owner. The lease was extended for 3 years with option to buy. The company had an authorized capital of $250,000 and would start underground operations in a month or two. Initial output was expected to be about 300 tons of ore per month with a grade of about 12 grams per ton.

The value of gold and silver recovered from concentrates treated at the Que Que roasting plant in the year ending March 31, 1976, totaled $981,000. A total of 125 troy ounces of gold and 254 troy ounces of silver was recovered from the re-treatment plant during the year. The plant showed a deficit for the year of $1,700, compared with a profit of $258 in the previous year.

The Vubachikwe mine, operated by the Forbes and Thompson Group, milled 5,500 tons of medium- to low-grade gold ore monthly. Very lenticular in character, the gold reefs were widely spread along the strike length, resulting in a labor-intensive operation consisting of small mines within a mine. Additional reserves were developed that would augment the present production; sinking to the 25th level was in progress. The Freda gold mine, also owned by Forbes and Thompson, milled 6,000 tons of low-grade ore monthly from a large ore body. The 16th level came into production during the year. A program of reclamation in the upper levels of the mine was planned. The company had taken an exclusive prospecting permit in an area adjacent to the Freda claims, and geological work was well advanced. The Old Lone Hand mine was pegged some 3 years ago, and a plant to treat the dumps at 3,000 tons per month was operational. Forbes and Thompson acquired a controlling interest in the Moghul mine near West Nicholson in November 1975, and an extensive underground development program was implemented. The mining and milling equipment was upgraded in capacity. The Big Ben mine was made administrative center for the Group.

Iron and Steel.—Rhodesian Iron and Steel Co., Ltd. (RISCO) officially completed the second stage of development at the steelworks complex in Redcliff in December 1976. The increase in employment resulting from the development was nearly 22% for Europeans and just over 31% for Africans. The second stage made it possible to more than double the production of finished and semifinished steel. The rolling mills and related facilities were extended and modernized to cope with the greatly increased production. There were 19 major areas of development. Preliminary studies were made in 1972, and the first civil engineering work at the steelplant and ironplant started in March 1973. Construction of the second-stage development was completed with the expansion of the coke oven battery in February 1976. Some of the difficulties experienced during the second-stage program were financial arrangements, inadequate port facilities at Maputo necessitating construction of a $14 million steel wharf, closure of the Mozambique border, serious design faults in parts of the plant,

[14] World Mining. What's Going On In World Mining. V. 30, No. 9, February 1977, p. 79.
[15] Chamber of Mines Journal (Salisbury). Grandeur Gold Mine In Liquidation. January 1977, p. 30.

and the lack of opportunity to train operators overseas. The plant was supplied by the Buchwa mine, which was soon to be expanded.

TA Holdings Ltd. acquired the 49% interest held by foreign shareholders in Africa Strip Mining Co. (Pvt.) Ltd., operators of the major iron ore mine at Buchwa.[16] TA Holdings held 51% of the equity of the company before the transaction. During the next 12 months, it was expected that development work at Buchwa would be completed and full production levels reached. Difficulties in removing the ore were reportedly owing to the ore becoming harder as mining progressed, which meant additional expenditures for heavier equipment. Also, the mine is situated in one of the wettest parts of the country making working conditions difficult for part of the year. RISCO had to use a new source at South Hill to meet short-term needs until the Buchwa operation reached full production. Meanwhile, TA Holdings intended to proceed with development and bring the mine into full production as soon as possible.

Lead.—A new lead recovery plant was completed at Douglas Road, Workington, on December 6, 1976. The plant was used for the removal of lead dust from waste. The lead dust was recycled and made available as a raw material for secondary lead smelters to make antimonial unblended lead and soft lead for refining into pure lead.[17]

Nickel.—Ore milled at Johannesburg Consolidated Investment Co. Ltd.'s (JCI) Shangani mine was 418,000 tons for the year ending June 30, 1976. The ore-milling rate was raised above the design capacity of 75,000 tons per month in order to compensate for lower than expected nickel and copper recoveries. There were few mechanical problems during trial milling phases, and the initial metallurgical problems encountered were overcome with the concentration process working satisfactorily. Even so, nickel recovery was below target because of a high oxide-to-sulfide ratio in the ore. The nickel recovery was expected to improve as mining extended below the oxidized zone. In the open pit, 6.5 million tons of ore and overburden was mined, and underground mine planning was continuing. Prospecting was temporarily discontinued because of large reserves already indicated. A sharply undulating footwall contact, with a high nickel concentration in the first few meters above the contact, was indicated by drilling and pit exposures. The ore body inclined an average of 35° and ranged in width from a few meters at the extremities to about 80 meters at the center. The eastern ore body was open ended in depth with the possibility of finding additional reserves.

Rio Tinto (Rhodesia) Ltd. declared a net profit of $2.89 million for the 9 months ending September 30, 1976, down slightly from that of the comparable 1975 period.[18] Most of the profit came from the Empress mine. Rio Tinto's Perseverance mine made no contribution during the year, as operations were suspended during 1975 because of metallurgical problems. Research and experiments were being carried out to improve recovery techniques. Rio Tinto was to build a new cobalt plant to treat residues from the Empress mine, and a crushing and materials-handling plant was to be built at the smelter. There was also to be a new refinery residues processing unit before resmelting. The unit was expected to improve efficiency and overall recovery of metal. The cobalt plant production was to start by the end of 1977.

Rhodesian Nickel Corporation Ltd. (Rhonick), an Anglo American subsidiary, owned the entire share capital of Trojan Nickel Mine Ltd., Madziwa Mines Ltd., and Bindura Smelting and Refining Co. Ltd. Rhonick's assets totaled almost $77 million. Capital expenditures by Rhonick over the last 18 months totaled about $26 million. Rhonick also operated the new Epoch mine, which started production in January 1976 at a cost of $9.6 million. The new-technology high-energy flotation process gave a boost to nickel recovery at Epoch. Through energizing the pulpy milled ore in conditioners, agitation was stepped up to increase the temperature of the liquid, making it easier to separate the nickel.[19] Production was on target and exceeded the

[16] Chamber of Mines Journal (Salisbury). TA Holdings Buys Buchwa. January 1977, p. 30.
[17] Chamber of Mines Journal (Salisbury). Minister Sees New Lead Recovery Plan. January 1977, p. 28.
[18] Chamber of Mines Journal (Salisbury). Tinto Records Higher Profit. January 1977, p. 28.
[19] Chamber of Mines Journal (Salisbury). Epoch Right on Target. October 1976, p. 27.

rated milling capacity of 25,000 tons per month. By the end of May 1976, the mine had milled almost 90,000 tons. Underground development was going ahead on three levels, and the stoping methods used on the Copperbelt were being applied on other levels. The service shaft was being deepened to 315 meters and was expected to be completed by March 1977.

Epoch's concentrates, which contained about 15% nickel and 0.05% copper, were sent to Bindura for smelting and refining. Nearly $14 million was spent on the Bindura smelter to enable the complex to handle the influx of concentrates from Epoch and from JCI's new Shangani mine. A new electric smelting furnace was commissioned in November 1975, and a new converter was commissioned in February 1976. Capacity of the refinery was uprated in April 1976. The capacity was estimated to be about 15,500 tons of nickel per year. In 1973, the smelter was rated at 7,500 tons of nickel per year.

The Trojan mine was Rhonick's largest mine, where, despite technical problems at the mill, 848,000 tons of ore was milled with an average mill-head grade of 0.68% nickel. Improved metallurgical techniques made possible higher nickel production from the concentrates. The mining layout and configuration were changed and improved over the past 2 years. At Madziwa, 483,000 tons of ore was milled in 1976, more than in 1975. Both ore grade and metallurgical recoveries showed an improvement, resulting in a 23% increase in the production of nickel in concentrates. The subvertical hoist chamber and shaft at Madziwa were almost complete, and an extensive short-range diamond-drilling program was started to evaluate and delineate the ore.

Ore reserves of Southern Rhodesian nickel mines are shown in table 2. This table does not include figures for nickel contained in the Great Dyke igneous complex, where sulfide horizons grading 0.25% nickel were estimated to contain 3.5 million tons of recoverable nickel, and where oxides grading 1.0% nickel suitable for direct smelting could yield another 1.4 million tons of nickel.[20] In addition, there were other less well-known prospects of the same type (nickel-copper sulfides in serpentinitic rocks). Probably the most advanced was the Hunters Road nickel prospect of Union Corporation Ltd. (Unicorp). Geological work, geochemical sampling, pitting, trenching, and diamond drilling have been done in detail at Hunters Road. A prospect shaft and development work were to be completed soon.

Tin.—The Kamativi tin mine celebrated its 25th anniversary in mid-1976 with the prospect of better times owing to improved metal prices. Kamativi was called locally the "miracle mine" because of its low-grade ore and financial success. About 100 tons of rock must be mined to produce 25 kilograms of tin.

Tungsten.—The distribution of tungsten ores in Southern Rhodesia is very wide, and scheelite is associated with gold in many areas, notably in the Bulawayo and Filabusi Districts and at Gwanda. At Essexvale, wolframite and scheelite were mined from veins in granite, associated with galena, chalcopyrite, and fluorite. At the mine at Tshantanda near Wankie, wolframite occurs with chalcopyrite in pegmatites; a similar mixture occurs at the Tung mine (some 8 kilometers northeast of

[20] Chamber of Mines Journal (Salisbury). American Editor Writes of Rhodesia's Remarkable Success. January 1977, pp. 26–27.

Table 2.—Southern Rhodesia: Ore reserves at nickel mines

Mine	Operator	Quantity (million metric tons)	Percent nickel	Date of estimate
Madziwa	Rhonick (Anglo American)	12	0.75	1975

Tshantanda Siding). Tungsten concentrates were generally produced with a tungstic oxide (WO_3) content varying between 60% and 75%, upon which basis they were sold.

NONMETALS

Asbestos.—Southern Rhodesia remained the world's fifth largest asbestos producer, producing chrysotile, although official statistics have been unavailable since the UDI. Rhodesian & General Asbestos Corp. (Pvt.) Ltd. (RGA) operated the Shabanie, Gaths, Temeraire, and King mines in the Shabani and Mashaba Districts of Southern Rhodesia. RGA also owned asbestos-cement plants in Salisbury and Bulawayo. Pangani Asbestos Mine (Pvt.) Ltd. controlled the Bos Pangani, Rex, and Vanguard mines in the Bulawayo-Shabani area. The Kudu Mines (Pvt.) Ltd. asbestos mine near Essexvale was increasing its milling rate. A new asbestos ore body containing what was described as thick "packs" of exceptional quantity was discovered near Gwanda in shaft-sinking operations on a new section of the operating mine. Intersections of the ore, which was over 60 meters wide at the widest point, were made on three levels. The new ore body gave the mine an additional 6 years of life at the milling rate of 120,000 tons per month.[21]

Magnesite.—The Pande magnesite mine, located near Beitbridge, was being investigated along with similar nearby deposits. Mined by Vereeniging Refractories Ltd. of the Anglo American group, the Pande mine was considered to have a limited life. Modifications to the Pande operation to rework the waste dumps supplemented the rapidly diminishing reserves in the quarries. The group's underground magnesite mine at Gatooma had been unable to achieve its target in 1976 because of a shortage of rail trucks. Vereeniging's turnover last year was almost unchanged at $77.8 million, but profits dropped by about $960,000. Vereeniging was a major producer of refractory brick and roof tiles.

Pyrite.—Anglo American owned the Iron Duke mine near Mazoe. Started as a gold mine in 1914, the Iron Duke operations uncovered pyrite below the gold-bearing quartz 6 years later. The mine was the only pyrite producer in the country. This mineral was essential to sulfuric acid production consumed in the manufacture of fertilizer and in smelting operations. Anglo American geologists carried out an examination of the mine area and found a new ore body close to the mine with reserves estimated at 500,000 tons. This find increased pyrite reserves by over 1 million tons, prolonging the life of the mine.[22]

MINERAL FUELS

Coal.—Southern Rhodesia's only coal producer and one of the country's oldest mines, the Wankie coal operation, has been in production for 53 years. Anglo American acquired the operation as a highly developed coal producer in 1953, and productivity soared following an extensive program of mechanization after the takeover. Between 1971 and March 1976, the company spent about $38 million on replacements and major capital projects to modernize the operation.[23] These projects included the introduction of a new coke plant in 1971, new coal preparation and byproduct plants in 1972, and extensions to the coking coal plant and addition of the No. 4 colliery and a new slurry beneficiation plant in 1973. In 1974, extensive improvements were made to the coal preparation facilities and to the No. 4 colliery. By 1975, construction of special coal-loading facilities enabled the introduction of 36-truck liner trains to carry coke to the steel industry. A new drying and preheating plant was added for the cokeworks, along with other improvements to the crushing plant, beneficiation plant, and overland conveyor system.

At the beginning of 1976, an intensive 4-month campaign to increase coking coal throughput was started at Wankie. This resulted in a capacity improvement of 100% (from 70,000 tons to 140,000 tons per month). Wankie was operating two underground mines (Nos. 3 and 4) and three open cast areas (Nos. 1, 2, and 4). A fourth open cast operation (No. 3) was discontinued when the stripping ratio became excessive. The most economical open cast operation was No. 4, which had a low stripping ratio but a limited life, estimated to last until 1979. Production from the

[21] Mining Journal (London). Exploration. V. 290, No. 7432, Jan. 28, 1977, p. 66.
[22] Mining in Rhodesia 1976 (Salisbury). Iron Duke. 1976, p. 31.
[23] Mining in Rhodesia 1976 (Salisbury). Anglo Employs 13,000 Rhodesians. 1976, p. 29.

No. 4 pit was 312,224 tons in 1975. A total of 1,317,839 tons was produced in 1975 from the two underground mines. Underground mine No. 3 was the largest, with 823,492 tons produced. Total estimated coal production was 2.9 million tons.

A decline in the price of coal was to follow the signing of a new coal pact in early September 1976, allowing Wankie Colliery Co. sufficient profit to retain funds for capital expenditure. The agreement was for a 10-year period and dated back to September 1, 1975. The old agreement was based on a fixed profit margin for each ton of coal sold. This was changed to a return of capital employed of 12.5% after 1977. For the 1967–77 period, the pretax profit entitlement on Southern Rhodesian sales was to be increased to 10% of the capital employed. The return can be increased to a maximum of 15% to take some account of the tax payable. After 1977, the company would be able to take a maximum profit export sales of 5% of the capital employed.[24]

Total extractable Southern Rhodesian coal reserves were estimated at 744 million tons with 59% of the extractable material suitable for coking and about 220 million tons with higher ash content. In addition, there was a possible reserve of some 5 billion tons of coal and large reserves of carbonaceous shale with up to 60% ash. The coal could be utilized for steam raising and the carbonaceous shale for extraction of oil. Wankie coalfields had estimated reserves of 900 million tons, of which 300 million tons was extractable.[25]

Seven new coalfields were under investigation. Rio Tinto was reported to be investigating the Sengwa coalfield in the lowveld. Goldfields Ltd. was doing a feasibility study on the Bubi coalfield, located near Beitbridge, which was estimated to contain 15 million tons of high-grade coking coal.

The Mineral Industry of Romania

By Nikita Wells [1]

Romania's mineral resources have an important influence on the country's economy but are of little significance by world standards. Romania is primarily a producer of bituminous coal, lignite, crude oil, petroleum products, natural gas, crude steel, aluminum, cement, nitrogenous fertilizers, and salt. Domestic production supplies about one-half of the country's copper and about one-fifth of the iron ore requirements. The U.S.S.R. provides approximately one-half of Romania's coke and coking coal requirements, as well as 44% of the imported iron ore. Romania's crude oil production has leveled off, and in 1976, more than one-third of its crude oil requirements were imported from the Middle East, while Romania exported about an equal amount in petroleum products. Romania remains the only Council for Mutual Economic Assistance (CMEA) [2] country that does not import crude oil from the U.S.S.R.

During the current 5-year plan period (1976–80), Romania plans to open two new surface mines to produce low-grade copper ore and is to invest in some copper refineries and aluminum smelters. Aluminum and aluminum alloy production in 1980 is to increase 23% over that of 1976. In the iron and steel industry, crude steel production in 1980 is to be up 65% over that of 1976. This is to be achieved mainly by the expansion of the Galati iron and steel works and the operation of the new steel complex being erected at Călărasi on the Danube River.

In the nonmetals sector, Romania is to expand its cement production about 55% over that of 1976 by 1980. Most of the increase will result from the opening of the new cement plant at Taşca.

During the current plan period, Romania also expects to increase its crude oil and natural gas reserves by extensive deep drilling and offshore prospecting in the Black Sea. Romania's first offshore drilling rig was commissioned in 1976, and a second rig was in the planning stage.

Romania's total industrial production value in 1976 reached 661 billion lei,[3] an increase of 11.5% over that of 1975 and 1.3% over the planned figure. Ferrous metallurgy demonstrated a 7.6% increase, nonferrous metallurgy 11.6%, fuels 7.3%, and machine building and metal processing 12.2%.[4] Mineral production made up an estimated 7% of total industrial production.

In 1976, the national income reached 400 billion lei, a 10.5% increase over that of 1975. The development of the Romanian economy in 1976 was supported by investments totaling 149 billion lei (8.2% higher than in 1975). In 1976, labor productivity in industry increased 8.8% over that of 1975.[5]

Romania's total industrial labor force in 1976 was reported at 2.8 million persons. Of this number, 100,270 persons were employed in the fuel and power industry, 76,350 in the nonferrous metal industry, 812,490 in the engineering and metalworking industry, and 167,450 in the chemical industry.

PRODUCTION

In 1976, Romania continued to expand its iron and steel industry, showing a 12.4% increase in crude steel production and a 12.3% increase in pig iron production. Production of iron ore, however, decreased 7.5%. In the nonferrous metals sector, copper production increased 9.5% and that of aluminum metal increased 1.5%. In the nonmetals industry, cement production increased 8.9%, lime 8.4%, salt 9.8%, and nitrogenous fertilizer 3.0%.

The Romanian fuel sector in 1976 showed an 8.5% increase in natural gas production. Crude oil production increased less that 1% owing to the limit imposed by the Government to conserve depleting oil reserves. Total washed coal production in 1976 showed a decrease of 4.6% from that of 1975, owing mainly to the extensive program of overburden stripping carried out during 1976 to allow for the planned expansion of lignite mining in the current 5-year plan.

Production statistics for many mineral commodities are not reported by Romania, and therefore much of the data presented in table 1 are estimated.

Table 1.—Romania: Production of mineral commodities

(Metric tons unless otherwise specified)

Commodity [1]	1974	1975	1976 [p]
METALS			
Aluminum:			
Bauxite, gross weight [e]	700,000	800,000	800,000
Alumina, gross weight [e]	374,000	400,000	400,000
Ingot (including alloys)	187,000	204,000	207,000
Bismuth, mine output, metal content [e]	80	80	80
Cadmium, smelter [e]	90	88	100

[e] Estimate. [p] Preliminary. [r] Revised. NA Not available.
[1] In addition to the commodities listed, antimony, asbestos, gypsum, mica, and natural gas liquids, as well as a variety of crude construction materials, are produced, but output is not reported and available general information is inadequate to make reliable estimates of output levels.
[2] Romanian sources do not indicate whether or not refinery fuels are reported as a part of the listed product yields. Moreover, additional minor products may be produced but are not listed in official sources.

TRADE

Romania's foreign trade in 1976 registered a 14.5% increase over that of 1975. Exports were valued at 30.5 billion lei and imports at 30.3 billion lei.

In 1976, Romania imported 2.6 million tons of bituminous coal, 2.8 million tons of coke, 8.5 million tons of crude oil, 11.7 million tons of iron ore, 685,000 tons of apatite concentrate, and 109,500 tons of potassic fertilizer.

The only significant mineral exports in 1976 were 7.8 million tons of petroleum

products, 967,000 tons of rolled steel products, 77,600 tons of nonferrous metals, mostly aluminum, 1.93 million tons of nitrogenous fertilizers, and 2.7 million tons of cement.

In 1976, Romania's trade with CMEA countries was valued at 23,801 million lei, representing 39.1% of total trade. Romanian foreign trade by major commodity group for 1975 and 1976 was as follows:

	Value (million lei)		Percent of total	
	1975	1976	1975	1976
Exports:				
Metals, nonmetals, fuels	5,912	7,343	22.3	24.1
Building materials	772	921	2.9	3.0
Chemicals, fertilizers, rubber	2,857	2,526	10.8	8.3
Imports:				
Metals, nonmetals, fuels	10,153	12,409	38.2	41.0
Building materials	296	346	1.1	1.1
Chemicals, fertilizers, rubber	1,721	2,067	6.5	6.8

Source: Anuarul Statistic al Repblicii Socialiste România 1977 (Annual Statistics of the Socialist Republic of Romania 1977), Bucharest. 1977, pp. 430–431.

Romania's principal trading partners in 1975 and 1976 were as follows:

	Value (million lei)		Percent of total	
	1975	1976	1975	1976
U.S.S.R	9,858	10,864	18.6	17.9
Germany, West	5,039	4,644	9.5	7.6
Germany, East	2,909	4,254	5.5	7.0
Poland	2,073	2,731	3.9	4.5
Czechoslovakia	2,447	2,685	4.6	4.4
Iran	1,702	2,434	3.2	4.0
United States	1,174	2,320	2.2	3.8
People's Republic of China	2,164	2,240	4.1	3.7

Source: Anuarul Statistic al Repblicii Socialiste România 1977 (Annual Statistics of the Socialist Republic of Romania 1977), Bucharest. 1977, pp. 422–429.

The "most favored nation" status for trade agreements granted to Romania by the United States in 1975 was extended to 1976, thus continuing the favorable conditions for trade between the two countries. In 1976, trade with the United States soared to 2.3 billion lei, an increase of 98% over that of 1975, making the United States Romania's seventh largest trading partner.

Mineral trade statistics are presented in tables 2 and 3.

Table 3.—Romania: Imports of selected mineral commodities—Continued

(Metric tons unless otherwise specified)

Commodity	1974 [1]	1975 [2]	Principal sources, 1975
NONMETALS—Continued			
Cement, hydraulic	NA	126	All from France.
Chalk	700	1,528	France 968; United Kingdom 560.
Clays and clay products:			
Crude	15,501	31,586	Greece 11,665; Czechoslovakia 11,000; United Kingdom 6,541.
Products:			
Refractory	70,350	[4] 66,251	U.S.S.R. 23,282; Yugoslavia 20,533; Italy 7,457.
Nonrefractory	77	40	All from Italy.
Cryolite	1,011	NA	
Diamond:			
Gem, not set or strung value, thousands	NA	$1,459	All from United Kingdom.
Industrial do	$1,501	$2,534	Belgium-Luxembourg $2,462.
Diatomite and other infusorial earth	585	1,091	All from Iceland.
Feldspar and fluorspar	3,820	2,130	All from Italy.
Fertilizer materials:			
Crude, phosphatic: Apatite concentrate, gross weight	r 1,347,137	[3] 1,309,644	U.S.S.R. 559,681; United States 130,596.
Manufactured:			
Phosphatic	3,618	7,303	All from Israel.
Potassic, K_2O equivalent	64,700	[3] 91,900	East Germany 50,900; most of remainder from U.S.S.R.
Graphite	146	117	All from West Germany.
Magnesite:			
Crude	NA	2,994	Yugoslavia 1,995; Spain 999.
Products	40,430	45,439	Czechoslovakia 42,000; Hungary 3,339.
Mica, worked	38	16	France 12.
Pigments, mineral, iron oxides	924	428	West Germany 273; Hungary 155.
Pyrites, unroasted	21,000	123,320	All from Yugoslavia.
Stone, sand and gravel	266	1,880	Austria 1,551; Yugoslavia 291.
Sulfur:			
Elemental, including colloidal	64,972	115,954	Poland 114,000; West Germany 1,418; Yugoslavia 360.
Sulfuric acid	142,149	86,290	West Germany 35,755; United Kingdom 16,871; Poland 10,353.
Talc	380	205	All from Italy.
Other, crude	1,944	1,623	Netherlands 1,196; United Kingdom 427.
MINERAL FUELS AND RELATED MATERIALS			
Carbon black	521	2,187	West Germany 1,366; Italy 565.
Coal thousand tons	1,616	[3] 2,420	Czechoslovakia 804; U.S.S.R. 625; Poland 606.
Coke do	2,300	[3] 2,537	U.S.S.R. 999; Czechoslovakia 483; Italy 271.
Hydrogen, helium, rare gases	172	248	All from West Germany.
Petroleum:			
Crude thousand 42-gallon barrels	34,489	[3] 37,893	NA.
Refinery products:			
Distillate fuel oil do	52	1	All from Italy.
Lubricants do	14	[4] 12	Netherlands 6; Belgium-Luxembourg 2; West Germany 2.
Other do	166	144	West Germany 126.
Total do	232	157	
Mineral tar and other coal-, petroleum-, or gas-derived crude chemicals	21,410	13,172	Mainly from U.S.S.R.

COMMODITY REVIEW

METALS

Aluminum.—Expansion of facilities continued at Romania's single aluminum plant, located at Slatina. In 1976, aluminum and aluminum alloy production was 207,000 tons; it is to reach 255,000 tons by 1980 according to the 5-year plan. In 1976, Romania exported 84,700 tons of aluminum metal and semimanufactures to Western Europe and Japan.

Total bauxite production in 1976 was an estimated 800,000 tons and is to increase to 1.5 million tons by 1980. Romania's bauxite is surface mined from an ore body near Dobreşti, in the general area of Oradea. Since indigenous production is insufficient to meet domestic demand, Romania imports additional bauxite from Yugoslavia and Greece.

Romania's two alumina plants, one located at Tulcea in the Danube Delta and the other near the Oradea bauxite mines, each have a capacity of 250,000 tons per year. Romania imports approximately 100,000 tons of alumina per year from Greece, Italy, and Hungary.

Copper.—In 1976, Romania's copper production amounted to 40,500 tons, an increase of 9.5% over that of 1975. Romania's annual imports amount to approximately 30,000 tons of copper metal including alloys, about one-third of which comes from the U.S.S.R.

Romania is planning to develop two surface mines in the Moldova Nouă and Roşia Poieni areas with a combined annual capacity of 20 million tons of low-grade copper ore (less than 0.3% copper metal content). When in full operation, these mines are to increase Romania's copper ore output 50%.[6]

Iron and Steel.—Romanian crude steel production in 1976 reached 10.7 million tons, an increase of 12.4% over that of 1975. Pig iron production was 7.4 million tons, a 12.3% increase over that of 1975. Steel semimanufactures output totaled 9.4 million tons in 1976. Iron ore production, however, decreased to 2.8 million tons from 3.1 million tons in 1975.

In 1976, Romania imported a total of 11.7 million tons of iron ore, of which 5.1 million tons came from the U.S.S.R. Pig iron imports for the same year were 560,600 tons; rolled steel products, 1.9 million tons; steel pipe, 101,000 tons; and ferroalloys, 223,300 tons. Exports of rolled steel products in 1976 amounted to 967,000 tons and steel pipe, 377,000 tons.

Romania's iron and steel industry is undertaking a major expansion and modernization program. By 1980, Romania is to produce 17 million to 18 million tons of crude steel per year and by 1990, 25 million to 27 million tons per year. These goals are to be achieved mainly by the expansion of the Galaţi integrated iron and steel works, whose 1976 annual capacity of approximately 6 million tons is to be increased to 10 million tons by 1980, and by the operation of the new steel complex being built at Călărasi on the Danube.

The Utas steelworks at Tîrgovişte was being developed as Romania's most important alloy plant. Contracts for equipment and technology have been signed with Soviet, West German, and Japanese firms. In 1976, a contract was signed between Romania's trade enterprise Metorom and West Germany's Vacmetal GmbH for the design, construction, and startup of a 110-ton vacuum degasing unit.

In the next 13 years, Romania's foundry industry is to undergo thorough expansion and modernization. The annual planned growth rate is about 14% through 1990. In 1975, Romania's total foundry production amounted to 1.4 million tons, consisting of 282,000 tons of drawn steel, 1.0 million tons of cast iron, and 65,000 tons of nonferrous castings. By 1980, total foundry output is to reach 2.3 million tons and by 1990, 4.4 million tons. In 1976, Romania operated 257 foundries, of which less than 10% have an annual capacity in excess of 20,000 tons and nearly 50% have an annual capacity below 2,000 tons. By 1980, Romania is to build 60 additional foundries, of which 27 are to have an annual capacity greater than 10,000 tons.

In 1976, Romanian Metallurgical Facilities Import-Export Corp. signed a contract with a Japanese firm, Hitachi Kinzoku, for production technology to be used in a high-grade special steel bar plant that is to be part of an integrated steel plant being built by the Romanian Government. The plant, which is to have an annual capacity of

[6] Scînteia (Bucharest). Jan. 8, 1977.

10,000 tons of cold-finished steel bars, will cost about 10 billion yen and is to start operating in spring of 1978.[7]

Lead and Zinc.—In 1976, Romania's lead and zinc production reached 42,465 tons and 53,373 tons, respectively. Lead and zinc in Romania are associated with copper in complex sulfide ores and come mainly from the Baia-Mare mining complex, Bălan, and other smaller mines. The Copsa Mică smelting plant reduces most of the sintered concentrates and has an estimated annual capacity of 35,000 tons of lead and 60,000 tons of zinc.

Titanium and Zirconium.—Romania was planning to start developing the Black Sea coastal alluvial sand deposits, which contain titanium and zirconium, in 1977.

NONMETALS

Cement.—Total cement production in 1976 was 12.5 million tons, an 8.9% increase over that of 1975. By 1980, Romania is planning to reach an annual production of 19 million to 20 million tons. In 1976, Romania exported a total of 2.7 million tons, compared with 2.8 million tons exported in 1975.

During 1976, construction continued on Romania's largest and most technologically advanced cement plant, which is to produce high-quality cement employing the dry method. Construction on the plant, located in Taşca in Neamţ County, began in 1975. The first production line is to go into operation in 1977; the second line is to be commissioned by the end of 1978.

Fertilizer Materials.—In 1976, Romania continued to encourage the growth of its fertilizer industry and produced a total of 1.87 million tons of mineral fertilizers, of which 1.3 million tons was nitrogenous and 493,000 tons was phosphatic. Romania has no potassic or phosphatic raw materials and therefore relies exclusively on imports of these commodities. In 1976, Romania imported a total of 2.0 million tons of phosphate rock and apatite concentrates, of which 693,000 tons came from Morocco and 560,000 tons came from the U.S.S.R. Imports of potassic fertilizers totaled 109,500 tons.

Romania's exports of nitrogenous fertilizers have shown a dramatic increase in the past few years. In 1976, exports totaled 1.93 million tons, an increase of 36.5% over those of 1975. The bulk of these exports go to West Germany and France.

Romania has been constructing four identical compound fertilizer plants, each with an annual capacity of 891,000 tons. These plants are located at Tîrgu Mures, Craiova, Turnu Măgurele, and Arad. The plant at Tîrgu Mureş went into operation in October 1975 and that at Craiova in March 1976; the Turnu Măgurele plant is to be completed in March 1977; and the plant at Arad is to be commissioned by the end of 1977.[8] Each of the plants incorporates production lines that manufacture nitrogen-phosphorus-potassium fertilizer in the ratio of 2:1:1 and nitrogen-phosphorus fertilizer in the ratio of 2:1.[9]

The basic design for the Tîrgu Mureş plant was provided by Davy Powergas Ltd., based on the Norsk Hydro A/S process. The remaining three plants were built according to the Powergas design by Iprochim (the Romanian State engineering enterprise).

During 1976, work proceeded on the new nitrogen and compound fertilizer plant located at Bacău. The new complex is scheduled to be completed in 1978 and will include a 891,000-ton-per-year complex fertilizer plant, a 420,000-ton-per-year urea plant, a 300,000-ton-per-year ammonia plant, and a 480,000-ton-per-year nitric acid plant.

Lime.—Production of lime in 1976 reached 3.3 million tons, an increase of 8.4% over that of 1975. Production of lime is to double at the Bicaz binders and asbestos cement combine because a new kiln started operating there in late 1975.

Salt.—Romania has a large and well established salt mining industry, with total salt production of 4.2 million tons in 1976, 9.8% over that of 1975. Since 1970, Romania has been exporting over 600,000 tons of salt per year (with the exception of 1974, when exports dropped to 164,834 tons). In 1976, total exports reached 667,500 tons.

Romania's total salt reserves are estimated to exceed 20 billion tons and consist almost entirely of rock salt found mainly in salt domes. The salt is of good quality with a 98% to 99% NaCl content. About 48%

[8] Phosphorus and Potassium (London). No. 88, March-April 1977.
[9] Nitrogen (London). No. 102, July-August 1976, pp. 13–14.

of this salt is mined underground, using room-and-pillar methods, and 52% of the output is obtained from wells as brine.

Sulfur.—Romania is planning to mine its sulfur reserves, estimated to be among the largest in Europe, in the Calimiani Mountains of Transylvania. By 1980, 80% of the country's domestic consumption is to be supplied by the planned development. In 1975, Romania imported 114,000 tons of sulfur from Poland. Romania's sulfuric acid production in 1976 was 1.56 million tons, an increase of 7.4% over that of 1975.

MINERAL FUELS

In 1976, total primary energy consumption in Romania reached an estimated 89.9 million tons standard coal equivalent (SCE), an increase of 7.9% over that of 1975. Natural gas provided 54% of the total, oil 25%, coal 20%, and hydroelectrical power 1%. Production of primary energy derived from fossil fuels and hydroelectrical generation increased from 81.1 million tons SCE in 1975 to 84.6 million tons SCE in 1976.

Romania encouraged the use of coal, especially lignite, for the generation of electrical power to save hydrocarbons for the petrochemical industry. Total marketable coal production, which increased from 20.5 million tons in 1970 to 25.8 million tons in 1976, is to reach 56 million tons by 1980 and about 75 million tons by 1990. Production of lignite is to increase from 18.2 million tons in 1976 to 47 million tons in 1980 and 62 million tons in 1990.

During the current 5-year plan period, Romania expects to increase crude oil and natural gas reserves by extending deep drilling and oil recovery and prospecting on the Black Sea continental shelf. Approximately 2 million tons of oil reserves is expected to result from these activities, increasing annual crude oil production from 14.7 million tons in 1976 to 15.5 million tons in 1980. The first offshore drilling rig was put into operation during 1976, and a second rig is in the planning stage.

In 1976, Romania produced a total of 58.3 billion kilowatt-hours of electrical energy, an increase of 8.6% over that of 1975. Of this production, 8.1 billion kilowatt-hours (14%) was produced by hydroelectric powerplants and the rest by conventional thermal powerplants. During the 1976–80 period, Romania plans to install 7,200 megawatts of electrical power capacity, of which 59.2% is to be generated by coal-fired thermoelectric plants, 13.0% by oil-fired thermoelectric plants, 24.4% by hydroelectric plants, and 3.4% by thermoelectric plants using other fuels.[10]

The first nuclear powerplant is still in the planning stage and is to go into operation around 1985 with a 440-megawatt capacity.

Table 4.—Romania: Total primary energy balances, 1975 and 1976 [1]

(Million tons of standard coal equivalent [2])

Year	Total primary energy	Coal (lignite, anthracite, bituminous) and coke	Crude oil and petroleum products	Natural and associated gas	Hydroelectrical power
1975:					
Production	81.1	14.3	21.4	44.3	1.1
Imports	12.0	4.1	7.5	--	.4
Exports	9.8	--	9.1	.3	.4
Apparent consumption	83.3	18.4	19.8	44.0	1.1
1976:					
Production	84.6	13.7	21.6	48.3	1.0
Imports	17.4	4.5	12.5	--	.4
Exports	12.1	--	11.5	.3	.3
Apparent consumption	89.9	18.2	22.6	48.0	1.1

[1] Production and trade data were taken from the Statistical Yearbook of the Socialist Republic of Romania (Bucharest), 1977.

[2] 1 ton standard coal equivalent (SCE)=7,000,000 kilocalories. Conversion factors used are as follows: Hard coal, 1.0; lignite and brown coal, 0.33; crude oil, 1.47; natural gas, 1.33 (per thousand cubic meters); and hydroelectrical power, 0.125 (per thousand kilowatt-hours); factors were derived from: United Nations. World Energy Supplies, Statistical Papers, ser. J, No. 18, New York, 1975.

Coal.—Romania's total run-of-mine coal production in 1976 was 28.1 million tons, a 4% decrease from that of 1975. Production of marketable coal was 25.8 million tons, of which 1.9 million tons was for coke and semicoke production and 18.2 million tons was lignite.

Romania's metallurgical coal and coke requirements are supplied equally by domestic resources and imports. In 1976, Romania imported a total of 2.6 million tons of bituminous coal and 2.8 million tons of coke.

In order to insure adequate supplies of crude oil and natural gas for petrochemical feedstocks, Romania is launching a drive to increase the production of indigenous lignite to be used for electrical power generation. Production of lignite is to increase from 18.2 million tons in 1976 to 62 million tons by 1990. Romania's lignite deposits are mostly located south of the Carpathian Mountains in the area of Tîrgu Jiu, with some smaller deposits near Braşov. These deposits are divided into seven basins, of which only the Rovinari, Motru, and Jilt Basins have deposits suitable for strip mining. Eleven surface mines were operating in these three basins in 1976.

The ash content of the lignite is between 34% and 40%, and the moisture content is 39% to 45%. The calorific value is 2,000 to 2,200 kilocalories per kilogram (3,600 to 4,000 Btu per pound), but the effective value is decreased to 1,600 to 1,850 kilocalories per kilogram (2,900 to 3,450 Btu per pound) by the inclusion of refuse associated with the mining.

Romania signed an agreement with a private U.S. mining company for the joint development of a coal mine now under construction in Buchanan County, Va. Under the agreement, Romania is to pay an initial advance of $53 million toward the construction of the mine. Romania is to buy 14 million tons of coal at cost and has the option to purchase an additional 13.3 million tons at prevailing market prices over the next 30 to 40 years. The U.S. firm is to supply Romania with up to 27.3 million tons of high-grade metallurgical coal valued at about $2 billion. Development of the mine is to be completed in 4 years, with the first coal delivery to Romania scheduled for 1980. The mine is expected to have a total output of between 40 million and 50 million tons.[11]

The first phase of the agreement between Romania and West Germany's Krupp Industrie- und Stahlbau was completed near yearend. The agreement called for the joint construction of 14 bucket excavators and corresponding stackers. The construction was to take place in three stages. The first stage comprised four excavators and three stackers; the second stage, to be completed in 1979, included five excavators and three stackers.[12]

The bucket-wheel excavators are 132 meters long and 35 meters high, have a wheel diameter of 11.5 meters, and have a capacity of 1,800 cubic meters per hour. The stackers are 150 meters long and 37 meters high and have a capacity of 6,500 cubic meters (10,400 tons) per hour of overburden removal.[13] The machines built in the first and second stages will be used in the Rovinari Basin.

Natural Gas.—Romania's gross production of natural gas in 1976 reached 36.1 billion cubic meters, an 8.5% increase over that of 1975. Nonassociated gas production made up 29.8 billion cubic meters of this. Gross production of natural gas, however, is expected to decline to 26.8 billion cubic meters by 1980.

Romania was self-sufficient in gas in 1976 and has substantial reserves (approximately 220 billion cubic meters) centered in the Transylvanian Basin around Tîrgu Mureş. Romania planned to import some gas from the U.S.S.R., however, to conserve indigenous reserves of natural gas for use as feedstock for the fertilizer industry.

Romania is participating with other CMEA countries in the construction of the Orenburg natural gas pipeline, which links the large condensate deposits of the Orenburg region with the western border of the U.S.S.R. at Uzhgorod. The pipeline, whose construction began in 1975, is 2,750 kilometers long and will allow the participating countries to receive up to 15.5 billion cubic meters of Soviet natural gas annually. Romania is responsible for financing equipment and materials from Western countries and for purchasing and constructing gas-

[11] Journal of Commerce (New York). June 14, 1977, p. 8.
Wall Street Journal (New York). May 31, 1977, p. 5.

[13] Braunkohle (Düsseldorf). V. 1–2, January-February 1977, p. 44.

drying and sulfur-removal installations within the Orenburg complex. Upon completion of the pipeline in late 1978, Romania is to receive 1.5 billion cubic meters of Soviet natural gas.[14]

A gas pipeline connecting the Romanian gasfields to eastern Hungary has been operating for almost 20 years, with an annual export of 200 million cubic meters of Romanian natural gas. Other pipelines from the U.S.S.R. cross sections of Romanian territory to deliver Soviet gas to Bulgaria and Hungary.

Nuclear Energy.—Romania's nuclear power program has been delayed, and the first nuclear powerplant is now scheduled to go into operation in 1981. Approximately 20% of Romania's electrical power is to be generated by nuclear powerplants by 1990, but this goal appears to be overly optimistic because of the reported delay in the nuclear power program.

Petroleum.—Romanian crude oil production leveled off at 14.7 million tons in 1976, an increase of less than 1% over that of 1975. Since 1972, the Romanian Government has limited crude oil production growth to 1% per year to slow the depletion of oil reserves. Imports of crude oil have more than doubled since 1973, reaching 8.5 million tons in 1976, an increase of 67% over those of 1975. Crude oil is imported from Saudi Arabia, Iran, Iraq, Libya, Algeria, Venezuela, and the People's Republic of China. Romania remains the only CMEA country that did not import crude oil from the U.S.S.R. in 1976.

Romania's oil-refining capacity was 24 million to 25 million tons per year. Eleven refineries operated at nearly full capacity, processing indigenous crude oil and large crude oil imports from the Middle East. Romania's current policy is to produce a large surplus of petroleum products for export to some 50 foreign countries. In 1976, total exports of petroleum products amounted to 7.8 million tons, an increase of 27% over those of 1975.

Romania's oil deposits are located in three regions, of which the oldest and most productive is the area around Ploieşti, Piteşti, Tîrgovişte, and Telejean in the Prahova Valley. The second most productive area is the Bacău region on the Moldavian slopes of the Carpathian Mountains. The third is located in West Carpathia, southeast of the Carpathian range. In 1974, Romania had about 7,000 oil wells and 250 drilling rigs in operation. Proved crude oil reserves were about 100 million tons in 1971.

Romania's first offshore drilling rig, *Gloria,* was put into operation in September 1976 some 130 kilometers off the coast near the port of Constanţa in the Black Sea. It was launched by the Galaţi shipyard in October 1975 and was towed down the Danube River to the Black Sea in May 1976. A special pier was built at Constanţa to serve as the base for Romania's offshore drilling.[15] Exploration performed by the rig revealed the presence of oil and confirmed that the large onshore fields around Ploieşti extend under the Black Sea. Romania is planning to build a second drilling rig to establish the size of the oilfields. Romania will also be involved in a joint effort with Bulgaria in exploratory drilling off Bulgaria's coast in the Black Sea.

Negotiations continued during 1976 between Romania and Kuwait on the joint $1 billion refinery and petrochemical complex to be constructed on the Black Sea between Navodari and Cape Midia, north of Constanţa. This large complex, which is one of Romania's major investments during the current 5-year plan, is to process 8 million tons of Kuwaiti crude oil per year and produce 17 petroleum products, with special emphasis on premium gasolines. The annual production of the refinery is to include 3 million tons of fuel oil, 1.7 million tons of premium-grade gasoline, 900,000 tons of diesel oil, 300,000 tons of jet fuel, 100,000 tons of butane, and 80,000 tons of propane.

A special port facility will be incorporated into the complex to handle the imported oil. The startup of the complex is to be between 1982 and 1984. Romania is to control 51% of the venture and Kuwait 49%.

Construction of the joint industrial complex in the towns of Giurgiu, Romania, and Ruse, Bulgaria, which are located on opposite banks of the Danube River, began in December 1976. The complex is to produce a large variety of complete installa-

Romanian Foreign Trade (Bucharest). No. 103, February 1977, p. 2.

tions and equipment (especially shallow- and medium-depth drilling equipment) for the petrochemical, mining, and metallurgical industries. By the end of the current 5-year plan, the complex is to function at full capacity and employ about 10,000 workers.[16]

[16] Scînteia (Bucharest). Dec. 11, 1976.

The Mineral Industry of Saudi Arabia

By Candice Stevens [1]

In 1976, the petroleum industry accounted for 95% of Government revenues, virtually all export earnings, and 75% of Saudi Arabia's gross domestic product (GDP), estimated at $49 billion.[2] In December 1976, Saudi Arabia introduced a two-tier pricing system to the Organization of Petroleum Exporting Countries (OPEC) when it raised its crude oil prices 5% while other OPEC members opted for a 10% increase.

Oil revenues were expected to finance the major part of Saudi Arabia's second 5-year development plan (1975–79), which scheduled expenditures of $142 billion. Two complete industrial cities, whose construction was to be carried out over the next 11 years, were to be based on hydrocarbon-processing industries using oil and natural gas. At Yanbu, located on the Red Sea coast north of Jidda, crude oil and natural gas liquids (NGL) were to be delivered by transpeninsular pipelines to new refining centers. Projects at Yanbu included a petrochemical complex, an NGL plant, and a major crude oil refinery and export terminal. The second industrial center was to be located at Jubail on the east coast, 80 kilometers north of Dhahran. Projects at Jubail included an iron and steel complex, an aluminum smelter, several petrochemical facilities, and an oil refinery. Saudi Arabia also embarked on an extensive gas-gathering project on the east coast to produce basic feedstocks and energy.

Several Government organizations were established to supervise the various development projects. The Royal Commission for Jubail and Yanbu was entrusted with coordinating plans and awarding contracts for the two industrial centers. The Saudi Arabian Basic Industries Corp. (SABIC) was established to hold and implement the Government share of industrial joint ventures. The responsibility for petroleum, gas, and mineral projects was transferred from the General Petroleum and Mineral Organization (Petromin) to the Ministry of Industry and Electricity. Petromin continued to be responsible for refining, marketing, distributing, and transporting petroleum internally and abroad.

PRODUCTION

In 1976, Saudi Arabia became the second largest oil producer in the world, following the U.S.S.R. The Arabian American Oil Co. (Aramco), which produced all Saudi oil except the output shared by Saudi Arabia and Kuwait in the partitioned Kuwait-Saudi Arabia Neutral Zone, became the first oil company to produce more than 3 billion barrels in 1 year. Aramco's production increased 23.5% from 6.8 million barrels per day in 1975 to over 8.4 million barrels per day in 1976. The 1976 output brought Aramco's cumulative production to more than 27.4 bil-

[1] Economist, International Data and Analysis.
[2] Where necessary, values have been converted from Saudi riyals (SRls) to U.S. dollars at the rate of SRls3.53=US$1.00.

lion barrels. In the partitioned Neutral Zone, the Arabian Oil Co., Ltd. (Japan) (AOC) produced 152,000 barrels per day and the Getty Oil Company (GOC) produced 82,000 barrels per day in 1976. Saudi Arabia's proven oil reserves were set at 110 billion barrels at yearend 1976.

Saudi Arabia produced approximately 500,000 barrels per day of refined petroleum products and 185,000 barrels per day of NGL in 1976. Cement production totaled 1.2 million tons. Other mineral products included steel and aluminum semimanufactures and small quantities of nonmetals. Saudi Arabia's mineral production in 1976 is given in table 1.

[1] Includes Saudi Arabia's one-half share of crude oil and natural gas production in the former Kuwait-Saudi Arabia Neutral Zone, and its share of refinery output by its concessionaires in that area.

[2] Data presented are for Hejra calendar years, which correspond closely to Gregorian calendar years.

TRADE

Aramco exported approximately 8 million barrels per day of crude oil in 1976. Many of Saudi Arabia's direct sales contracts with other countries expired at the end of 1975, and it was decided in 1976 to extend these contracts 3 more years with volumes and terms unchanged. Buyers were required to lift at least two grades of crude oil, with no more than 75% being Arabian Light crude oil. The United States was Saudi Arabia's largest overall supplier in 1976, accounting for 18% of total imports at a value of $1.6 billion.

Owing to severe congestion at the country's ports, Saudi Arabia initiated a crash construction program to expand handling capacity. Jidda and Dammam, which handled over 90% of total imports, were unable to cope with the upsurge in imports, which more than tripled in value since 1973. The capacity of both ports was to be increased by 1980, and three

additional ports were to be constructed. The consortium of Skanska Cementgjuteriet AB (Sweden), Grands Travaux de Marseille (France), and Archirodon Construction Co. (Greece) was to dredge the harbor at Jidda and add two new piers. The consortium of Interbeton BV (the Netherlands), Philipp Holzmann AG (West Germany) and Archirodon was to increase capacity at Dammam from 1.7 million tons to 7 million tons per year.

Sir William Halcrow and Partners (United Kingdom) was the consulting engineer, and a consortium of private Saudi firms and Archirodon was to undertake the construction of a deepwater port at the new industrial center of Yanbu. The Republic of Korean firm Hyundai International Inc. was contracted to construct facilities at Jubail including an open-sea tanker terminal for handling tankers of 500,000 deadweight tons. Santa Fe International Inc. (United States) was to design and construct a new port at Ras Misha'ab near the Kuwait border.

Aramco also planned an expansion of its terminal at Ju'aymah, which had a loading capacity of 3 million barrels per day. A liquefied petroleum gas (LPG) loading facility was to be constructed at Ju'aymah by National Supply Co. (UK) Ltd. (United Kingdom). Aramco operated two other terminals on the Persian Gulf: The Ras Tanura terminal, rated as the world's largest offshore facility with an export capacity of 8 million barrels per day, and a small deepwater terminal serving the Marjan and Zuluf oilfields.

Several tanker companies were formed in Saudi Arabia during the past few years to take advantage of the new law giving preferential right for transport of Saudi oil to Saudi companies. During 1976, the number of tankers registered in Saudi Arabia increased from 7 to 14, totaling 1.3 million deadweight tons. Companies included the Saudi Maritime Co. (SAMARCO), a joint venture of Mobil Oil Corp. and private Saudi interests; the Saudinaft Tanker Co., a joint venture that included Shell Oil Co.; and the Saudi Arabian Shipping Co., a joint venture that included Mitsui O.S.K. Lines Ltd. of Japan.

COMMODITY REVIEW

METALS

Saudi Arabia allocated $189 million of its expenditures under the current 5-year plan to exploration for nonpetroleum minerals. The Directorate General of Mineral Resources (DGMR) granted several large-scale mineral exploration concessions in 1976. The agreements included exclusive rights to obtain mining leases for a 30-year period, with the Government retaining the option of acquiring a 50% interest in any venture. The Saudi mining code also provided for an initial tax holiday of 5 years on any mine and guaranteed the repatriation of capital and profits.

The DGMR was to continue geological mapping of the country. The first stage of the survey focused on the search for base metals in older rocks of the Arabian Shield in the western part of Saudi Arabia. Further studies were to concentrate on younger rocks to the north and east of the Arabian Shield where copper, phosphate, and uranium were to be the main targets.

The Arabian Shield Development Co. continued its study of the Wadi Qatan

nickel deposit and the Al Masani zinc-copper deposit, both in Asir Province. Noranda Mines Ltd. (Canada) was granted a license for general exploration of the minerals of the Arabian Shield. Rio Tinto Finance & Exploration Ltd. (Riofinex), a subsidiary of Rio Tinto-Zinc Corp. Ltd., received a contract for geological work that would be complementary to existing surveys being carried out by the U.S. Geological Survey (USGS) and the Bureau de Recherches Géologiques et Minières (BRGM) (France).

The Saudi-Sudanese Commission for the Exploitation of Red Sea Resources, established in 1974, awarded exploration contracts in 1976 for copper, lead, zinc, and silver nodules in the Red Sea. The Arabian Geophysical & Surveying Co. (ARGAS) was to undertake a $5 million study of oceanographic and environmental conditions of the Red Sea. The BRGM was to act as consultant to the study, which was scheduled to begin in spring 1977. Preussag A.G. (West Germany) was to subsequently begin feasibility studies on mineral exploitation. The first phase of the survey was to last 2 years and cost $9 million.

Aluminum.—Saudi Arabia's 5-year plan called for the construction of a 200,000-ton-per-year aluminum smelter. Design work for the smelter, to be located at Jubail, was postponed in 1976 owing to delays encountered in the natural gas gathering and utilization project. A number of small plants, having a combined capacity of 37,000 tons per year, manufactured a variety of aluminum products from imported aluminum.

Copper.—BRGM geologists continued their feasibility investigation of reopening the ancient copper mines at Um al-Dammar, 165 kilometers southeast of Medina. This study was part of an overall survey of the copper resources of the Jabal Sayid area undertaken by the Société d'Études de Recherches et d'Explorations Minières (SEREM) and United States Steel Corporation in 1974. Previous drilling by the Government at Jabal Sayid, 320 kilometers northeast of Jidda, revealed reserves estimated at 8 million tons.

Gold.—Gold Fields Mahd Adh Dhahab Ltd. (GFMAD), a consolidated Gold Fields Group subsidiary, concluded an exploration agreement with Petromin in 1976. The company was to prospect for gold on a 1,600-square-kilometer tract around Mahd adh Dhahab, 300 kilometers northeast of Jidda. A 4-year geological, geochemical, and geophysical investigation of this district was completed in 1975 by the USGS. Ore bodies at Mahd adh Dhahab were mined from 1939 to 1954 by the Saudi Arabian Mining Syndicate, Ltd., yielding a total of 766,000 troy ounces of gold and more than 1 million troy ounces of silver. Previous surveys indicated that the mining district still contained workable deposits of gold, silver, and other metals.

Iron and Steel.—Three principal iron ore deposits have been identified in Saudi Arabia. Wadi Sawawin, 20 kilometers inland from the Gulf of 'Aqaba, is a hematite deposit estimated to contain 40% iron. The largest deposit, Wadi Fatimah, is located 40 kilometers south of Jidda; it was estimated to contain 50 million tons of hematite reserves averaging 45% iron. Reserves at Jebel Idsas, a magnetite deposit in central Saudi Arabia, were reported at 6 million tons containing 69% iron. In 1976, Saudi Arabia concluded a contract valued at $15 million with British Steel Corp. for the evaluation of the Wadi Sawawin deposits. The 4-year study was to involve 3,000 meters of core drilling in 20 holes during the initial phase of testing. Previous studies of Saudi Arabia's iron ore deposits indicated that their small size, low grade, and isolated location would restrict commercial exploitation.

In 1976, an agreement was signed with Korf Stahl AG (West Germany) for the establishment of a major steel complex at Jubail. This contract replaced previous plans for the erection of a steel pellet plant at Jubail using iron ore imported from Brazil. The new agreement provided for an 800,000-ton-per-year Midrex direct reduction steel mill costing $100 million to $300 million. SABIC was to hold a majority interest in the venture and to make remaining shares available to private Saudi investors.

The Jidda steel-rolling mill was to be expanded from 45,000 tons to 250,000 tons per year. SABIC signed a letter of intent in 1976 with Broken Hill Pty. Co. Ltd. (Australia) for the expansion project. The Jidda plant, opened in 1967, produced reinforcing wires and rods, plates, angles, and other simple steel products from imported billets.

Guest Keen & Nettlefolds Ltd. (United Kingdom) was to participate in the establishment of a factory to produce 20,000 tons per year of steel-reinforcement fabric. The $8.7 million venture was to be owned 40% by the firm and 60% by private Saudi interests. The plant, which is located at Dammam on the Persian Gulf, was scheduled to begin production in 1978.

NONMETALS

Barite.—A barite grinding plant to produce oil well drilling-mud additives was to be constructed at Dammam by Dresser Industries Inc. Barite deposits in Saudi Arabia were located at Rabigh, 120 kilometers north of Jidda, and near Sanam, southwest of Riyadh.

Cement.—In 1976, Saudi Arabia produced approximately 1.2 million tons of cement from three plants. Cement consumption was expected to increase to 9 million tons per year by 1980, and the Government planned an expansion of facilities in order to reduce dependence on imported cement.

The Saudi Cement Co. plant, located at Hofuf in Eastern Province, was to be expanded from a capacity of 400,000 tons to 1.3 million tons per year. The Yamama Saudi Cement Co. Ltd. plant, located at Riyadh, was also to be expanded from 400,000 tons to 1.3 million tons per year. Polysius AG (West Germany) was contracted for the expansion work at both facilities. The Arabian Cement Co., which operated a 700,000-ton-per-year plant at Jidda, was to build a 1-million-ton-per-year plant at Rabigh, 120 kilometers north of Jidda.

Four other cement plants were in various stages of planning in 1976. The Saudi-Bahraini Cement Co., owned 75% by the Saudi Cement Co. and 25% by the Bahraini Government, was to construct a 2-million-ton-per-year cement plant at Abqaiq in Eastern Province. Two Japanese firms, Ishikawajima-Harima Heavy Industries Co., Ltd. (IHI) and Nichimen Co., Ltd., were to complete the construction of the plant by 1980. The Saudi-Kuwaiti Cement Co., owned 55% by Saudi Arabia and 45% by Kuwait, was to undertake the construction of a 2-million-ton-per-year plant in the partitioned Neutral Zone. In addition, the Saudi Government contracted Klockner-Humboldt Deutz (West Germany) for the construction of a 730,000-ton-per-year plant at Quassim-Buredah in Central Province, and Cementa AB of Sweden for the construction of a 1-million-ton-per-year plant at Yanbu.

Fertilizer Materials.—The Saudi Government postponed indefinitely plans to increase the country's fertilizer production capacity. Although designed to produce 1,100 tons per day of urea from 600 tons of ammonia, the Saudi Arabian Fertilizer Co. (SAFCO) plant has not exceeded a production of 600 tons per day of urea. The SAFCO plant, located at Dammam, was owned 51% by SABIC and 49% by private Saudi investors.

Phosphate.—The Saudi Government concluded an agreement with the Swedish firm Gränges AB to study phosphate deposits at Thaniyat in the northwestern corner of the country. Saudi Arabia was estimated to have reserves of 150 million to 300 million tons of phosphate ore in the northwestern Jauf-Sakaka sedimentary basin. Gränges was to undertake a 2-year (1977–78) feasibility study at a cost of $3.4 million. In the case of exploitation, a joint mining company was to be formed by the Government and Gränges on a 50–50 basis. Tests previously conducted by Gränges on methods of concentrating the phosphate were to be continued in a pilot plant under construction.

Salt.—Salt was produced by solar evaporation or primitive means in several localities in Saudi Arabia. Plans to exploit two large rock salt deposits were not yet put into effect. The Jizan salt domes, 600 kilometers south of Jidda, were estimated to contain 33 million tons of 96% pure sodium chloride. Another deposit of equal or greater size was located south of Dhahran on the Persian Gulf.

Sulfur.—The Petromin Sulfuric Acid plant (PETROCID) was expanded to process about 20,000 tons per year of sulfur obtained from natural gas processed at the SAFCO plant. The sulfuric acid output of PETROCID, located at Dammam, was sold to local industries and desalination facilities.

MINERAL FUELS

Natural Gas.—Saudi Arabia's proven natural gas reserves were reported at 80 trillion cubic feet, consisting almost exclusively of associated gas. Two deposits of

nonassociated gas, one near Dhahran and the other in Rub' al Khali, produced small amounts of gas for domestic consumption. Aramco, which was the operator and a partial owner of Saudi Arabia's gas-gathering system, continued exploration for natural gas in Rub' al Khali.

In 1976, natural gas production was estimated at 4.5 billion cubic feet per day, 80% of which was flared. Of the remainder, approximately 600 million cubic feet per day was reinjected, used as fuel locally, or piped to fuel other industries. Facilities at Ras Tanura and Abqaiq separated about 300 million cubic feet per day into propane, butane, and natural gasoline for export. In 1976, NGL production increased 33% over that of 1975 to 185,000 barrels per day; all production was exported making Saudi Arabia the world's largest exporter of NGL.

Work continued on the Aramco project to double its NGL production capacity to 360,000 barrels per day. A $1 billion NGL recovery and treatment system was to come onstream at Berri in 1977. The commissioning of several new facilities increased NGL production capacity nearly 60% in 1976. Fluor Engineers and Constructors Inc. was contracted for the Berri plant, which was to supplement Aramco's NGL facilities at Abqaiq and Ras Tanura. Production was to eventually comprise 210,000 barrels per day of NGL for export and 380 million cubic feet per day of gas for fuel for the Jubail industrial complex.

Aramco was also contracted by the Saudi Government to plan, construct, and operate a major gas-gathering system alongside its own operations. The original scheme called for the construction of NGL-processing centers at Shedgum, Uthmaniyah, Safaniya, and Khurais. These plants were to produce a residual pipeline gas for fuel and NGL to be pumped to a fractionation plant at Ju'aymah. The project was to process 6 billion cubic feet per day of associated gas and produce 2.5 billion cubic feet per day of gas fuel, 960,000 barrels per day of NGL, 400 barrels per day of ethane (to be used as feedstock for petrochemical plants), and 6,000 tons per day of sulfur. However, owing to high costs, a poor market forecast, and ceilings on petroleum production, the project was subject to reappraisal in 1976. Originally estimated at $5 billion, cost projections for the gas gathering were reported to total $16 billion. The system was to be scaled down to an oil production rate of 10 million barrels per day from an original rate of 12 million barrels per day. The completion date was extended from 1979 to the mid-1980's. The Ju'aymah fractionation plant was to be the first operational unit; it was scheduled for completion in 1981 at an initial processing capacity of 300,000 barrels per day. Construction work also began in 1976 at the Shedgum and Uthmaniyah facilities. The principal contractors were Fluor Engineers and Constructors for project design and management, Bechtel International Ltd. for design of gas and NGL pipelines, the Ralph M. Parsons Co. Ltd. for design of utility plants and sulfur-recovery facilities, and Hudson Engineering Corp./J. Ray McDermott & Co., Inc., for the design of offshore pipelines and separation facilities. Fluor Engineers and Constructors also received letters of intent from Aramco for preliminary engineering work for an NGL plant and terminal at Yanbu on the west coast.

Petroleum.—*Production.*—In 1976, the Saudi Government and Aramco reached general accord on the principal issues of a 100% takeover of the company's assets in Saudi Arabia. Saudi Arabia had acquired 60% ownership of Aramco in 1974; the remaining 40% was owned by Exxon Corp., Mobil Oil Corp., Standard Oil Co. of California, and Texaco Inc.

According to the March 1976 agreement, Saudi Arabia was to pay compensation for Aramco's assets on the basis of their net book value. Aramco was to operate and market the bulk of production, with buying companies taking crude in the previous volumes and proportions. Petroleum exploration was to be conducted by the companies with their own risk capital, but bonuses, fees, and extra crude oil entitlements were to be received for successful results. Aramco was to receive a fee for its services in the form of discounts on each barrel of crude lifted. The Government was to set prices for crude, but those charged to the oil companies were not to be higher than those charged to third-party customers. Aramco was to retain a 50% interest in the Ras Tanura refinery, which processed nearly 70% of Saudi Arabia's crude oil production. The effective takeover date was January 1, 1976,

but details of the arrangement had not been worked out by yearend 1976.

The Saudi Government, which had previously imposed a production ceiling of 8.5 million barrels per day on Aramco, authorized a production increase to 10.5 million barrels per day in December 1976. The Aramco concession covered 222,000 square kilometers and comprised 37 major oilfields. Under a 3-year expansion program, production capacity was to be increased to more than 14 million barrels per day. In 1976, the Ghawar Field, rated as the world's largest oilfield with reserves of 68 billion barrels, produced 5,367,000 barrels per day. Construction began on a seawater treatment plant at Qurayyin as part of a project to inject 4.2 million barrels per day of water in Ghawar by mid-1978.

The Safaniya Field, rated as the world's largest offshore oilfield, was also undergoing capacity expansion. The Safaniya Field extended into the partitioned Neutral Zone, the Saudi portion of which contained reserves of 25 billion barrels. The most recent producing fields were the offshore Zuluf and Marjan Fields, which produced 200,000 barrels per day out of a combined capacity of 450,000 barrels per day. However, both fields were shut down in early 1976 owing to the production ceiling.

Aramco added 3.2 billion barrels to its proven reserves through the discovery of three new oilfields in 1976: The Hasbah Field, located 30 kilometers offshore south of the Marjan Field; the Sharar Field, located offshore 10 kilometers west of the Manifa Field; and the Suban Field, located onshore 100 kilometers southeast of the partitioned Neutral Zone. The Watban Field, located 20 kilometers west of Juraybat, was drilled in 1975 and determined commercial in 1976. Aramco drilled a total of 193 wells in its concession area during 1976. Petromin also conducted petroleum exploration in its concession area, which covered 110,000 square kilometers in Rub' al Khali and along the Red Sea coast.

Kuwait and Saudi Arabia shared the production of the partitioned Neutral Zone, where Saudi oil was produced by AOC and GOC. AOC planned to increase production of its offshore Khafji and Hout Fields to 385,000 barrels per day by 1978. The GOC concession covered all of the onshore partitioned Neutral Zone and 6 miles of the offshore territorial waters, and was operated in conjunction with American Independent Oil Co. (Aminoil). Total estimated reserves of the Wafra, South Umm Gudair, and South Fawaris Fields were 600 million barrels. In 1976, GOC was renegotiating its contract with Saudi Arabia which sought an increase in royalty and income tax rates.

Pipelines.—Aramco completed and put into service 222 kilometers of pipeline during 1976, 60% of which was for natural gas and NGL transmission. Contracts were granted for the construction of Saudi Arabia's longest crude oil pipeline, which was to transit the peninsula linking the eastern oilfields with Yanbu on the west coast. The 48-inch, 1,207-kilometer line was to carry 1.85 million barrels per day of oil from the Ghawar and Khurais Fields to the new Yanbu refinery and for export from Red Sea ports. The $1.6 billion pipeline was scheduled to be completed in 1981; further expansion was to increase capacity to 2.3 million barrels per day by 1985. Brown & Root Ltd. was awarded the design and engineering contracts for the line and Mobil Overseas Pipeline Co. was contracted for construction work. Contracts were not yet awarded for the NGL pipeline, which was to parallel the crude oil line and carry 250,000 barrels per day of NGL to the planned Yanbu petrochemical complex.

Ownership of the Trans-Arabian Pipe Line Company (TAPline) was to revert to the four participating oil companies—Exxon, Texaco, Standard Oil of California, and Mobil—upon completion of the takeover of Aramco. The 31-inch TAPline crossed Saudi Arabia (867 kilometers), Jordan (177 kilometers), Syria (127 kilometers), and Lebanon (42 kilometers) in carrying crude oil to the Mediterranean port of Sidon in Lebanon. Normal operations of TAPline were suspended in 1975 when it became more economical to ship oil by supertanker from the Persian Gulf. In 1976, TAPline carried limited amounts of crude oil to supply local needs in Jordan and Lebanon.

Refining.—Five refineries with a total capacity of approximately 600,000 barrels per day operated in Saudi Arabia in 1976, as follows:

Company	Location	Startup date	Capacity (barrels per day)
Aramco	Ras Tanura	1945	415,000
GOC	Mina Sa'ud	1958	100,000
AOC	Ras al-Khafji	1966	30,000
Petromin/Saudi Arabian Refinery Co. (SARCO)	Jidda	1968	40,000
Petromin	Riyadh	1975	15,000

Petromin planned to expand its two refineries and entered into joint ventures for the construction of new petroleum and lubricating oil facilities. The Jidda refinery, owned 75% by Petromin and 25% by SARCO, was to be expanded from 40,000 barrels to 210,000 barrels per day. The Riyadh refinery, which was supplied by a 170-kilometer pipeline from the Khurais Field, was to be expanded from 15,000 barrels to 100,000 barrels per day. The emphasis in both the Jidda and Riyadh projects was to be on maximizing the yield of light products. Construction contracts were concluded with the Japanese firms Chiyoda Chemical Engineering & Construction Co., Ltd., and Mitsubishi Corporation.

Two large export refineries were planned for the new industrial centers of Jubail and Yanbu. A 50–50 joint venture between Petromin and Shell was formed for the construction of a 250,000-barrel-per-day refinery at Jubail, to be completed in 1978. Petromin and Mobil entered into a 50–50 joint venture for the construction of a 250,000-barrel-per-day refinery at Yanbu, to be completed in 1984. Each refinery was to cost approximately $1 billion and was to be expanded to 500,000 barrels per day at a later date.

The Petromin Lubricating Oil Co. (Petrolube) was to be expanded from a 75,000-barrel-per-year to a 500,000-barrel-per-year blending capacity. Petrolube, which manufactured, blended, and stocked basic lubricating oils, was owned 61% by Petromin, 36% by Mobil, and 3% by the Saudi company Apsco. Petromin and Mobil began the construction of a second lubricating oil plant in Jidda, which was to produce 1 million barrels of lubricating oil base stocks per year. The $1 billion venture was owned 70% by Petromin and 30% by Mobil.

Petrochemicals.—Saudi Arabia allotted $18 billion of its 5-year plan expenditures to petrochemical development. Joint ventures were entered into for the construction of five petrochemical complexes, but none were to be operational before 1980. Combined output of the plants was to be more than 2 million tons per year of ethylene equivalent for export. In all the agreements, the foreign company was to undertake management of the plant and marketing of products. The Saudi Government and the foreign company were to provide equal shares of the equity, with the remaining financing to be obtained from commercial banks and the Saudi Public Investment Fund.

Four of the complexes were to be located in the Jubail industrial center. Exxon signed an interim agreement for a $720 million joint venture complex to produce 240,000 tons per year of ethylene and low-density polyethylene. Dow Chemical Co. was to undertake the construction of an $800 million plant to produce 250,000 tons per year of ethylene, low-density polyethylene, and glycol. Shell signed a $10 million contract for economic and engineering studies for a 500,000-ton-per-year plant to produce ethylene-based petrochemicals. In 1976, Mitsubishi requested a 3- to 5-year postponement on the construction of a 300,000-ton-per-year plant to produce ethylene, glycol, ethylene dichloride, and caustic soda. Mitsubishi signed the original contract for the $2 billion plant in 1970.

The fifth facility was to be located at Yanbu on the west coast. Mobil signed a $10 million contract for initial technical and economic studies for the petrochemical complex. The Yanbu facility was to process ethylene transported by pipeline from the east coast and produce 500,000 tons per year of polyethylene, glycol, and styrene.

Table 4.—Saudi Arabia: Selected oilfields, 1976

Company and oilfield	Discovery date	Average production (barrels per day)	Gravity (degrees API)	Sulfur content (percent)
Saudi Arabia:

The Mineral Industry of Sierra Leone

By Candice Stevens [1]

Decreased mineral production, particularly that of iron ore and diamond, contributed to the depressed level of economic activity in Sierra Leone in 1976. The increased cost of imports, stagnation in exports, and decline in capital inflows necessitated major revisions in the investment program of the 1974–79 development plan, including a 15% reduction in expenditures by all Government departments. In an additional effort to offset the Government budget deficit, a number of new tax measures were introduced, including an increase in company taxation to 55%, a consular fee of 1.5% on all imported goods, and a general increase in custom and excise duties. Also in 1976, the United States announced that it would resume bilateral aid to Sierra Leone, after a lapse of 8 years, to be channeled through the Agency for International Development (AID).

Plans were being finalized for the construction of a large hydroelectric plant on the Sewa River near Bumbuna. Expansion of the mining sector was to be assisted by improved infrastructure. A network of all-weather roads was recently completed, linking Freetown, the capital, with each of the provincial capitals and with the principal diamond area. There were plans to construct more than 800 kilometers of additional roads.

PRODUCTION AND TRADE

Production of Sierra Leone's major mineral commodities, diamond and bauxite, declined in 1976, as well as output of refined petroleum products. Production of iron ore, which previously accounted for 10% of export earnings, ceased in 1975 owing to the liquidation of Sierra Leone Development Co., Ltd. (DELCO). Mineral production figures are given in table 1.

Sierra Leone's balance-of-trade deficit increased from $44 million [2] in 1975 to $59 million in 1976. This was attributable to a decline in export value from $132 million in 1975 to $100 million in 1976. Efforts to reduce the import bill resulted in a decrease from $176 million in 1975 to $159 million in 1976, but this was not sufficient to offset the decline in exports.

Diamond production, which accounted for approximately 53% of total export value, was sold to the Central Selling Organization, Diamond Corporation of West Africa Ltd. (DICORWAF), and a small number of licensed buyers. All bauxite was exported unprocessed, principally to Switzerland, the Netherlands, and Canada. Approximately 350,000 barrels of petroleum products from the Freetown refinery (25% of production) was exported in 1976, primarily to Liberia. Sierra Leone imported about 1.6 million barrels of crude oil, 92% of which was from Nigeria. Overall, the United Kingdom remained Sierra Leone's principal trading partner, supplying more than 27% of total imports and receiving more than 55% of total exports.

---

[1] Economist, International Data and Analysis.

[2] Where necessary, values have been converted from Sierra Leonean leones (Le) to U.S. dollars at the rate of Le0.9=US$1.00.

During the year, Sierra Leone and Liberia signed an agreement to harmonize their customs duties and establish a common external tariff. These provisions, which were to become effective April 1, 1977, were established under the Mano River Union formed in 1973 to foster economic cooperation between the two countries. The Mano River Union was open to participation by other western African countries, particularly the remaining members of the Economic Community of West African States (ECOWAS).

Table 1.—Sierra Leone: Production of mineral commodities

Commodity [1]		1974	1975	1976 [p]
Aluminum, bauxite, gross weight	thousand metric tons	672	655	651
Diamond:				
Gem	thousand carats	670	[e] 560	433
Industrial	do	1,000	[e] 840	650
Total	do	1,670	[e] 1,400	1,083
Iron ore, gross weight	thousand metric tons	2,014	1,454	--
Petroleum refinery products:				
Gasoline	thousand 42-gallon barrels	369	797	231
Jet fuel	do	144	201	109
Kerosine	do	153	56	185
Distillate fuel oil	do	469	304	407
Residual fuel oil	do	536	--	423
Other	do	12	61	3
Refinery fuel and losses	do	68	--	29
Total	do	1,751	1,419	1,387

[e] Estimate. [p] Preliminary.
[1] In addition to the commodities listed, a variety of crude construction materials (clays, sand and gravel, and stone) is produced, but quantities are not reported and available general information is inadequate for the formulation of reliable estimates of output levels. Gold production may occur, but data are not available for estimating production. Sierra Leone annually refines 4,000 to 10,000 metric tons of salt from imported crude marine salt, but this is not included in the body of the table because it would represent double counting of material credited to the country where the salt was originally collected.

COMMODITY REVIEW

METALS

Bauxite.—Production of bauxite by Sierra Leone Ore and Metal Co. (SIEROMCO), a wholly owned subsidiary of Swiss Aluminium Ltd. (Alusuisse), decreased from 655,000 tons in 1975 to 651,000 tons in 1976. SIEROMCO has mined bauxite in the Mokanji Hills area near Moyamba in southwestern Sierra Leone since 1963. Reserves in this region were estimated at 70 million tons of ore containing 47% Al_2O_3 and 4.5% SiO_2. Alusuisse, in conjunction with the Norwegian firms Norsk Hydro A/S and A/S Ardal og Sunndal Verk, was planning a second bauxite operation at Port Loko. Reserves were estimated at 60 million tons containing 50% Al_2O_3. The proposed operation would employ up to 2,000 people and extract 1.5 million tons of bauxite annually. Construction of an alumina refinery at Port Loko was also under consideration.

In 1976, SIEROMCO and the Sierra Leonean Government concluded negotiations regarding ownership of the Mokanji mine, which have proceeded intermittently since 1972. SIEROMCO was to continue the operation without Government partnership until 1978 when mining leases will expire and are to be renegotiated, but its royalties and mining lease fees were doubled and company taxes were raised from 52% to 60%. SIEROMCO reportedly offered the Government a majority partnership in the larger bauxite venture proposed for Port Loko. The International Bauxite Association, of which Sierra Leone has been a member since its founding in 1974, met in Freetown in November 1976 to develop minimum pricing formulas for bauxite and alumina, but adjourned without a final consensus.

Iron.—No iron ore has been mined in Sierra Leone since the liquidation of DELCO's operations in October 1975. Es-

tablished in 1930, DELCO started mining the Marampa deposits in Port Loko District in 1933. Production increased from 24,000 tons in 1933 to 1.5 million tons in 1975, when Sierra Leone joined the Association of Iron Ore Exporting Countries. Reserves at the Marampa deposits were estimated at 67 million tons of 38% iron in 1974. Reserves at a second location, Tonkolili, about 80 kilometers northeast of Marampa, were estimated at 124 million tons of 55% to 56% iron. DELCO's major creditors included William Baird & Co. Ltd. (Scotland), Barclays Bank Limited (United Kingdom), three Japanese steel companies, and the Sierra Leonean Government. In 1976, the Government made an offer of $1 million for the major realizable assets of DELCO. Negotiations continued throughout the year with Bethlehem Steel Corp. (United States), which was considering reopening the Marampa mine and exploiting the Tonkolili deposits as a joint project with the Government.

Tin.—In 1976, the Government invited bids for prospecting and developing cassiterite deposits in Kongombadu, located 24 kilometers northeast of Yengema in Kono District; Mimini Hills, located 16 kilometers from Sefadu in Kono District; and Kalangba, located 24 kilometers from Makeni in Northern Province.

Titanium.—Sierra Rutile Ltd. (SRL), a joint venture of Bethlehem Steel (85%) and Nord Resources Corp. (15%), continued development of its rutile operation at Gbangbama in Moyamba District. Reserves were estimated at 187 million tons of black sands containing 3 million tons of rutile. In 1976, the design for extraction and processing facilities was completed, including a custom-designed bucket-ladder dredge. Primary concentration is to be through a gravity-separation system consisting of Reichert Cones and concentrating tables, and finishing is to be by electrostatic separation. Onsite construction is to begin in spring 1977, and production of 100,000 to 125,000 tons of rutile is scheduled for late 1978. SRL acquired the Gbangbama leases from Sherbro Minerals Ltd., which liquidated in 1971 after preliminary development of the project.

A joint subsidiary of the West German firms Bayer A.G. and Preussag Metal A.G. continued with exploration work, water supply investigations, and construction of a pilotplant in their rutile concession. Bayer-Preussag acquired a 5-year exclusive prospecting license on a 6,700-square-kilometer area of Southern Province in 1974. Reserves at deposits in Moyamba and Bonthe Districts were estimated at 11 million tons of 0.75% to 1.0% rutile.

NONMETALS

Cement.—Since the closing of Sierra Leone Cement Works Ltd. in 1970, all of Sierra Leone's cement needs have been imported, primarily from Egypt and Europe.

Clays.—In 1976, an agreement was signed with Hoeke Engineering of Belgium for the construction of a brick-manufacturing factory in Freetown. The $7 million plant is to open in 1977 and was expected to reduce Sierra Leone's dependence on imported cement. Locally produced materials, including clay, sand and gravel, and stone, were to be used in the production of 80,000 tons of brick per year. Discussions were in progress with the Republic of Korea for the construction of a ceramics factory in the same vicinity.

Diamond.—Diamond production continued a downward trend, declining from 1.4 million carats in 1975 to approximately 1.1 million carats in 1976. Diamond occurs in the lower basin of the Sewa River in southeastern Sierra Leone. The primary source of alluvial diamond is Cretaceous kimberlite dikes and small pipes presumed to have intruded in Precambrian granites. About 50% of production and approximately 41% of reserves were from deposits occurring in the channels of the principal rivers, the Sewa, Bafi, Male, and Moa.[3]

The major share of the diamond production was by National Diamond Mining Co. (DIMINCO), created in 1970 when the Government purchased 51% of Sierra Leone Selection Trust Ltd., a subsidiary of Consolidated African Selection Trust. DIMINCO's two concessions, one in the Yengema region of Kono District and one in the Tongo region, 50 kilometers south of Yengema, comprised 805 square kilometers. In 1976, DIMINCO announced major management changes as part of an

[3] Bardet, M. G. Géologie du Diamant. Deuxieme Partie: Gisements de Diamant d'Afrique (Geology of Diamond. Part Two: African Diamond Deposits). Bureau de Recherches Géologiques et Minières, Paris. 1974, pp. 176–188.

attempt to increase Sierra Leonean participation in the diamond-mining industry. For the first time, the positions of general manager, chief accountant, and senior geologist were to be held by Sierra Leoneans. In addition, contract mining privileges within the Kono concession were to be extended to certain sections of the Kono population. DIMINCO's operations involved the removal of a great deal of overburden to mine lower-grade deposits; in the face of diminishing reserves, DIMINCO undertook prospecting in new areas in the southern part of Sierra Leone. One-half of DIMINCO's production was sold to DICORWAF, a subsidiary of De Beers Consolidated Mines Ltd., while five licensed buying firms received fixed percentages of the remaining output.

The balance of the diamond production was controlled by the Alluvial Diamond Mining Scheme (ADS), established in 1956 to discourage illicit digging. Licenses were issued to Sierra Leoneans or firms with a Sierra Leonean majority for individual diamond digging in 23,000 square kilometers of designated area outside the DIMINCO concessions. The diggers, who for the most part continued to recover diamond by primitive hand-panning methods, were permitted to work in a maximum area of 4 acres for a period of about 6 months. In 1976, the number of mining licenses issued under the ADS declined owing to excessive rains during the year.

Diamond smuggling continued to present a problem to the Sierra Leonean Government, which announced a new campaign to curb illicit dealings. All licensed diggers were to submit accounts of their mining operations, and penalties for diamond smuggling were to be increased from a $200 fine or 6-month imprisonment to a $10,000 fine or 12-month imprisonment.

MINERAL FUELS

Petroleum.—Offshore exploration, which had previously yielded no commercial petroleum or natural gas deposits, was at a standstill in 1976 with the expiration of most prospecting licenses. Sierra Leone Petroleum Refining Co., whose refinery opened in Freetown in 1976, processed crude oil imported primarily from Nigeria. Although the refinery's reported annual capacity was about 3 million barrels, output was running at 1.4 million barrels per year. The refinery was jointly owned by the Sierra Leonean Government and five oil companies: British Petroleum Co. Ltd., Texaco Inc., Shell Oil Co., Mobil Oil Corp., and Azienda Generale Italiani Petroli S.p.A. (Agip). In 1976, a plant for production of bottled gas for home use came onstream. The gas was supplied by Sierra Leone Refining Co., and the bottling plant was jointly owned by Shell and Mobil.

The Mineral Industry of the Republic of South Africa

By Miller W. Ellis [1] and Charles W. Sweetwood [2]

The Republic of South Africa's mineral industry contributed greatly to the country's economy, and industries based on mineral products supported the country's position as the dominant commercial and economic nation of the African continent. Mineral products accounted for more than 16% of the gross domestic product (GDP) and more than one-half of export sales. Domestic sales of minerals increased slightly, but the value of imports (excluding petroleum) increased more than 20% as restrictions were lowered because of increased demand from domestic consumers.

The value of mineral production exceeded $5 billion for the third consecutive year, reaching a total of $5.4 billion [3] out of a GDP of $33.37 billion. The value of mineral production increased nearly 10% and the GDP increased 12% in terms of domestic currency. Both the Government and private industry continued with scheduled expansion programs, but no new major undertakings were announced. The Government-controlled South African Iron and Steel Industrial Corporation Ltd. (ISCOR) completed the railroad from Sishen in the northern part of Cape Province to its new port at Saldanha Bay from which iron ore was exported after September 23, 1976. South African Coal, Oil, and Gas Corp., Ltd. (SASOL) started work on its new Secunda colliery and oil-from-coal plant.

After taking over ISCOR's Grasvally Chrome Mine and Ferrometals Ltd.'s ferrochrome plant at Witbank in return for a 45% holding interest, the private-sector South African Manganese Amcor Ltd. (SAMANCOR) became the country's leading manganese and ferroalloy producer. Coal-loading equipment was installed at Richard's Bay, and ore-loading facilities were improved at Durban, East London, and Port Elizabeth. An offshore oil discovery was reported southeast of Cape Agulhas in December.

PRODUCTION

The Republic of South Africa remained the world's leading producer of chromite, gem diamond, gold, platinum, and vanadium and was one of the top three producers of antimony, asbestos, industrial diamond, manganese, uranium, and vermiculite. Important quantities of cement, coal, copper, fluorspar, iron, phosphate, salt, tin, and zinc were produced for export as well as for domestic industry. Details of mineral production are shown in table 1.

e Estimate. p Preliminary. r Revised.
[1] Data include osmiridium from gold ore estimated at 2,500 troy ounces each year.
[2] Includes asbestos reported in source as anthophyllite, Cape blue, and Transvaal blue.
[3] Local sales plus exports. Production not reported.

TRADE

South African minerals continued to be important to the world economy. The importance of the country's industrial and transport facilities to the mineral production of other countries in southern Africa became increasingly apparent in 1976 when rail and port facilities in Mozambique were undependable and those in Angola remained closed. While gold continued to be the Republic's major source of foreign exchange, the trade balance was adversely affected by oil imports.

e Estimate. r Revised.

[1] Because official South African trade statistics provide data only on the total value of exports of each commodity class (no data on quantity or destinations), this table has been compiled chiefly from information appearing in the quarterly publication "Minerals" issued by the Department of Mines of the Republic of South Africa. Figures obtained from supplemental sources and U.S. Bureau of Mines estimates are individually footnoted.

[2] World Bureau of Metal Statistics. World Metal Statistics. July 1978, 108 pp.

COMMODITY REVIEW

METALS

Aluminum.—The country's production of aluminum metal continued to come from the Alusaf (Pty.) Ltd. refinery at Richard's Bay. Imports of alumina from the Swiss Aluminium Ltd. (Alusuisse) operation at Gove, Australia, increased from nearly 135,000 tons in 1975 to about 160,000 tons in 1976 and should have allowed the Alusaf plant (20% owned by Alusuisse) to reach its projected annual capacity of 78,000 tons of metal. Ingot prices at Richard's Bay increased from $963 to $1,216 per ton during the year owing to increased power and other in-plant costs. More than one-half of Alusaf's production was sold to Hullets Aluminium Ltd. (Hulamin) for its 40,000-ton-per-year Maritzburg plant, where modifications to increase efficiency and quality control reportedly continued on schedule. Hulamin produced flat and coil sheet, extruded forms, and cable, as well as aluminum paste for the paint industry.

The Republic of South Africa imported about 11,350 tons of aluminum metal products in 1976, compared with some 15,600 tons in 1975. More than 40% of the 1976 imports came from the United States. Australia remained the chief source of imported bauxite. Modest quantities of calcined or activated bauxite and alumina were imported for the chemical, refractory, and abrasives industries.

Antimony.—Consolidated Murchison Ltd. (CML) continued as the Republic's sole producer of antimony ore and concentrate. Production of ore from CML's mines north and northwest of Phalaborwa increased from 637,500 tons in 1975 to 642,800 tons in 1976; the equivalent antimony content of the ore decreased from 2.89% to 2.32%. Concentrate (plus cobbed ore) production declined from 26,160 tons in 1975 to 18,341

tons in 1976. Byproduct gold production declined from 3,300 troy ounces in 1975 to 2,700 troy ounces in 1976. Approximately 3,800 tons of high-arsenic concentrate containing about 1,100 tons of antimony was not included as production but was added to a stockpile of similar material for future treatment. Concentrate exports averaged nearly 2,000 tons per month from January to June largely to deplete the 6,000-ton stockpile, but decreased to slightly more than 1,000 tons per month during the last half of the year. Domestic sales also diminished in the latter part of the year.

Most of CML's local sales of concentrate went to the Antimony Products (Pty.) Ltd. plant on CML property at Gravelotte, where the sulfides were converted to trioxides used in the manufacture of a fire-retardant. This plant was being expanded, and a small plant for the extraction of precious metals from the slag was planned. CML completed a pilot plant for the treatment of high-arsenic concentrate and other products accumulated over several years.

Chromite.—Production of chromite increased 16% to 2.4 million tons in 1976. Domestic sales increased 45% to 804,000 tons, and exports dropped 34% to less than 600,000 tons. Increased mining activity and expansion of the ferrochrome production facilities reflected the industry's reaction to world demand and the national policy of enhancing commodity value by expanding domestic production of ferrochrome for export. Chrome sand production increased about 30% to nearly 700,000 tons, but for this commodity the market trends were reversed. Domestic sales decreased 50% to less than 100,000 tons, and exports increased 74% to nearly 600,000 tons. Despite the enhanced value of chromite on the world market, the Republic's mining and export capacities were not fully utilized because of the breakdown of loading facilities at the Mozambique harbor of Maputo. Loading facilities at Durban were temporarily increased to handle 400,000 tons annually but were to be abandoned when rail and loading facilities at Richard's Bay were available. Meanwhile, the Republic was prepared to allocate up to 1 million tons of chromite annually for export from Maputo, provided capacity and prompt loading facilities were available.

Copper.—Production of copper ore increased marginally, but with improved ore grades the output of concentrate and metal was about 10% higher than in 1975. Domestic sales improved marginally, but exports increased more than 25% to 127,000 tons. All four of the major copper producers reported financially satisfactory operations, partly owing to the higher rand equivalent of the world price for copper following devaluation of the rand in September 1975. The Messina (Transvaal) Development Co. Ltd. operation recovered from its 1975 loss with decreased operating costs and by treating a lower tonnage of ore at a higher grade than in 1975. Ore production by Prieska Copper Mines (Pty.) Ltd. (PCM) was about 5% greater and ore grade was about 10% lower than in 1975. Improved concentrator operations resulted in approximately 5% less concentrate with 10% higher copper content. PCM's return to profitability was largely owing to increased sales of zinc and pyrite concentrate, as copper production remained unchanged at 25,000 tons. Some of PCM's concentrate was smelted on a toll basis by O'okiep Copper Co. Ltd. near Springbok, 500 kilometers west of Prieska. O'okiep's production of ore, concentrate, and blister copper decreased slightly in 1976, but greater amounts of concentrates were bought or smelted on a toll basis, and output of blister copper increased from 38,843 tons in 1975 to 41,526 tons in 1976.

Expansion of the refinery at Palabora Mining Co. Ltd.'s open pit operation in the northeastern Transvaal was completed by yearend. Nearly 80 million tons of material, including almost 20 million tons of ore with an average copper content of 0.55%, was excavated during 1976. Nearly 260,000 tons of concentrate containing almost 95,000 tons of copper was produced, and the smelter output of nearly 105,000 tons of anode copper included 12,500 tons derived from concentrates purchased or treated on a toll basis. Refinery output increased from 70,600 tons in 1975 to more than 80,000 tons in 1976, including more than 8,000 tons treated on a toll basis. Palabora's byproducts include vermiculite, magnetite, zirconium-hafnium, and precious metals.

The following tabulation shows quantity, grade, and copper content of ores milled and quantity and grade of ore reserves de-

clared by the four major copper producers in 1976. Quantity and copper content are in metric tons, and grade is in percent copper.

Company	Ore milled			Ore reserves	
	Quantity	Grade	Metal content	Quantity	Grade
Messina	783,000	1.24	9,709	4,303,000	1.37
O'okiep	2,383,700	1.35	32,180	27,245,000	1.67
Prieska	2,620,000	1.12	29,344	48,000,000	1.74
Palabora	19,627,200	.55	107,950	300,000,000	.60
Total	25,413,900	.71	179,183	379,548,000	.83

Copper is an important constituent of South African platinum ores and, except for a small amount sent to Norway for extraction, is recovered as electrolytic cathode copper at domestic refineries. Output of copper by Rustenburg Platinum Mines Ltd. exceeded production by Messina during 1976.

The Phosphate Development Corp. Ltd. (FOSKOR) operation near the Palabora mine recovered 16,800 tons of copper sulfide concentrate containing about 35% or nearly 5,900 tons of copper. Smelting and refining was done at the Palabora plant, and the copper metal was sold by Rio Tinto Management Services, Palabora's marketing agency, on behalf of a FOSKOR subsidiary.

Exploration and feasibility studies of several cupriferous sulfide deposits in the northwestern part of Cape Province continued throughout 1976.

Gold.—Gold production dropped slightly from 22,937,850 troy ounces to 22,936,018 troy ounces in 1976. Declining world prices caused deactivation of some of the lower grade marginal mines, but many higher grade large producers continued to flourish. The average price realized by the South African gold industry declined from $148.45 per troy ounce in 1975 to $119.34 per troy ounce in 1976.[4]

Gold mines in the Witwatersrand region near Johannesburg produced nearly 701,300 kilograms (22.5 million troy ounces); the Barberton mines to the northeast accounted for 1,200 kilograms (38,600 troy ounces); and about 10,900 kilograms (351,000 troy ounces) came from small mines or was recovered as a byproduct of base metal ores. Production for 1975 and 1976 and proven reserves of various companies are shown in table 5.

Most South African mines produced their own bullion containing approximately 88% gold, 10% silver, and 2% base metals in bars weighing 25 to 27 kilograms (55 to 60 pounds). Rand Refinery Ltd. at Germiston assayed and purchased the bars on behalf of the South African Government's Reserve Bank, and payment was made to the mines within 5 days. The Refinery, with an annual capacity of 1,000 tons of gold and 100 tons of silver, produced 996-fine gold for coinage, 999-fine gold for industry and the arts, and electrolytically refined silver and platinum-group metals.

International Gold Corporation Ltd. (Intergold) arranged for gold sales to manufacturers, wholesalers, and retailers of gold products throughout the world. Sales of 1-troy-ounce Krugerrand coins dropped from about 4.7 million in 1975 to slightly more than 3.0 million in 1976, but sales of 2-rand coins increased from 108,000 to 172,000, mostly to distributors in West Germany and Switzerland, at a substantially higher premium than was realized on the Krugerrand.

Development work on the twin shafts at the Deelkraal mine near Carltonville, west of Johannesburg, progressed to nearly 1,000 meters each (3,200 and 3,250 feet). Ore reserves were estimated at 45 million tons at an average grade of 0.334 troy ounce per ton. At Anglo-American Corp. of South Africa Ltd.'s nearby Elandsrand property, shafts were at 1,300 and 800 meters (4,300 and 2,600 feet), and ore reserves were claimed to be 60 million tons at 0.379 troy ounce per ton. Surface installations were reportedly on schedule, and production was planned for 1981 at an estimated capital cost of more than $100 million for each mine. Anglo-American's plant for re-treatment of slimes from seven mines in Orange Free State was scheduled for startup in 1977, and a similar plant for 16 Transvaal mines was to commence operations in 1978. Annual output was expected to be some

[1] Fully developed and blocked-out ore only; calculated at gold prices between $125 and $130 per troy ounce and at current operating costs. Additional indicated and inferred (possible) reserves are not included.

200,000 troy ounces of gold, 180 tons of U_3O_8, substantial amounts of pyrite for sulfuric acid, and some copper.

The concentration of many of the world's deepest mines in a relatively small area near Johannesburg has resulted in the development, testing, and installation of improved techniques in mining, ventilation, temperature control, automation, and remote control of mine and plant operations, and monitoring of rock stress for improved mine safety. The South African Government's Department of Mines collaborated closely with the Chamber of Mines, the individual operators, and international equipment manufacturers in ongoing studies to improve efficiency and safety of mining operations.

Iron and Steel.—ISCOR, the Government-owned industrial giant, was the country's leading producer of iron ore and accounted for about 78% of the pig iron output and 72% of the rolled and drawn steel products output. The recently emerged SAMANCOR, partly owned but not controlled by the Government, was the leading producer of ferroalloys, accounting for about 32% of the country's total output during the year.

Iron Ore.—Production of hematite ore, particularly in the Sishen area, increased 30% from 9.4 million tons in 1975 to 12.2

million tons in 1976. Sishen ore continued to be stockpiled near the mine railhead until May 1976, when the Sishen-Saldanha Bay rail link was completed. Later, the ore was shipped to the 2.4-million-ton stockpile facility at the Saldanha Bay loading area. On September 23, loading of the 120,000-ton Norwegian ore carrier *Fernsea* started, and the ship commenced its maiden voyage on the following day. Outloading from Saldanha Bay during the remainder of the year was largely responsible for the increase in hematite exports from 2.5 million tons with a value of $26 million in 1975 to about 6.2 million tons worth approximately $60 million in 1976. The entire Sishen-Saldanha Bay operation was handled by ISCOR, and at yearend the value of hematite exports moving through the new port was estimated at about $10.2 million per month. Production, domestic sales, and exports increased during 1976 for both hematite and magnetite ores.

Production of liquid and pig iron increased 12% from 5.2 million tons to 5.8 million tons during 1976, and except for iron castings, increases were recorded in production of all other iron and steel products including ferroalloys. Exports of rolled and drawn steel products increased from 130,000 tons to more than 300,000 tons, while imports in this category declined from 740,000 tons to barely more than 300,000 tons because of expanded capacity of domestic plants. Reported production of ferroalloys is shown in the following tabulation, in tons:

	1975	1976
Ferrochrome	216,830	238,470
Ferromanganese	425,890	469,010
Ferrosilicon	104,580	115,220
Ferrovanadium	300	300
Total	747,600	823,000

Manganese.—Despite a decline of about 5% in total output, the Republic of South Africa remained the world's second largest producer of manganese ore (after the U.S.S.R.), and the largest exporter among market economy countries. Most of the output came from the Postmasburg and Sishen areas in the northern part of Cape Province where transport facilities were improved by the completion of the railroad to the newly commissioned ore port at Saldanha Bay. Proved ore reserves in this area were reported at 2.37 billion tons, and resources were estimated at 10 times this figure. SAMANCOR accounted for about 65% of the country's manganese ore output from its Hotazel, Mamatwan, and Lohatla open pits and the Wessels underground mine. A new inclined shaft to double the 250,000-ton-per-year capacity at Wessels was scheduled for completion in 1977. SAMANCOR's ores for export were shipped 800 kilometers by rail to Port Elizabeth during 1976. The second largest producer, Associated Manganese Mines of South Africa Ltd., started expansion of open pit operations near Kuruman in northern Cape Province and planned expanding the Feralloy Ltd. plant operated by a sister company in the Transvaal.

Exports and domestic sales of manganese ores increased marginally in volume, but their value increased more than 25% in terms of domestic currency.

Nickel.—Electrolytically refined nickel was a byproduct of South African platinum mines. The 1976 mine output of 22,371 tons of metal content was the highest yet recorded, although it was only about 8% more than the 1975 production. About 85% of the nickel production was exported, and the stainless steel industry was the largest domestic consumer.

Platinum-Group Metals.—The Republic of South Africa accounted for 45% of the world's production of platinum-group metals in 1976 and ranked first in the production of platinum. Most of the 2.7 million troy ounces of platinum-group metals was extracted from 14.2 million tons of ore handled by four mining companies operating on the Merensky Reef. This represented an increase of about 4% over the 1975 output of 2.6 million troy ounces from 13.4 million tons of ore. Platinoids from the Merensky Reef had a platinum-palladium ratio of about 2.3:1, compared with byproducts of Canadian copper-nickel ores with about equal parts of platinum and palladium and Soviet platinoids that reportedly include more than twice as much palladium as platinum.

Approximately 6,000 troy ounces of byproduct platinoids from the Witwatersrand gold mines consisted largely of iridium and osmium, the heaviest and hardest of the platinum-group metals. Tankhouse residues from the Palabora copper refinery con-

tained nearly 3,000 troy ounces of the platinum-group elements.

Tin.—Output of cassiterite concentrate was virtually unchanged for 1976, but the metal content improved, averaging 49.5% tin compared with 46.8% in 1975. Tin metal production continued to decline from 780 tons in 1975 to 683 tons in 1976. Gold Fields of South Africa Ltd. was the parent company of Union Tin Mines Ltd., whose operations were being phased out because of declining grade, and of Rooiberg Minerals Development Co. Ltd., which experienced metallurgical problems but continued underground development. Zaaiplaats Tin Mining Co. Ltd. continued both mining and custom-smelting operations.

Uranium.—Production of uranium peaked at 5,847 tons of U_3O_8 in 1959 and again at 3,800 tons in 1971. A subsequent downward trend to 2,934 tons in 1975 was reversed in 1976 when 3,254 tons of U_3O_8 was produced, 3,111 tons of this by Witwatersrand gold mines. Output from the Palabora copper operation increased from 125 tons to 143 tons during 1976. Anglo-American on August 3, 1976, officially opened its plant to recover uranium, pyrites (for an associated sulfuric acid plant), and gold by re-treating tailings from seven mines in Orange Free State. Three supplementary flotation plants were to be added to the complex in 1977, and a similar plant to treat old tailings at abandoned mines in the Transvaal was scheduled to start operations in 1978. Installation or reactivation of uranium recovery equipment at other gold mines was also contemplated if world demand and prices warrant.

Except for Palabora, all South African uranium producers sold through the Nuclear Fuels Corporation (NUFCOR), which reportedly renegotiated higher contract prices for its products with the United Kingdom, West Germany, and Japan during 1976. It was estimated that about 2,600 tons of U_3O_8 valued at about $70 million was exported in 1976, a notable increase over the 2,348 tons valued at some $58 million estimated for 1975. NUFCOR also supplied raw material to the Government-owned Uranium Enrichment Corporation's (UCOR) pilot plant, which increased the percentage of U_{235} from its natural level of 0.7% to the 3.5% needed as fuel in nuclear powerplants. UCOR announced that the pilot plant was successful and that construction of a full-scale plant with a capacity of 5,000 tons of product per year was planned. The cost of such enrichment at full-scale operation was expected to be about 25% lower than the 1980 projected price for enrichment elsewhere. Exploration activity in the Karroo Basin of Cape Province was reportedly accelerated during 1976 by several firms. The opening of a uranium mine in this area by 1985 was predicted.

Vanadium.—Nearly one-half of the vanadium from market economy countries was produced in the Republic of South Africa from titaniferous magnetite deposits in the prolific Bushveld Igneous Complex of the northern Transvaal. Highveld Steel and Vanadium Corp. Ltd. and Ucar Minerals Corp. operated open pit mines, and Transvaal Alloys (Pty.) Ltd. used stockpiled ore to produce vanadium pentoxide (V_2O_5). Highveld produced V_2O_5, two grades of ferrovanadium, and slag containing 25% V_2O_5. Ucar's products included V_2O_5, metavanadate (V_2O_3), and Carvan (vanadium carbide). The total V_2O_5 equivalent of these products was reported at 17,600 tons in 1976, a drop of 7% from the 19,000 tons reported for 1975.

Zinc and Lead.—PCM, a subsidiary of Anglo-Transvaal Consolidated Investment Co. Ltd., accounted for the country's zinc output in 1976. The mine and concentrator in east-central Cape Province handled more than 2.2 million tons of ore with an average grade of 3.55% zinc (plus 1.12% copper) and produced nearly 150,000 tons of zinc sulfide concentrate with 52.4% zinc, an increase of 17.5% over the 1975 output of about 128,000 tons with 51.9% zinc. Because of the relatively stable price of zinc and the depressed copper price, PCM's zinc output accounted for the company's profitability in 1976. PCM also produced more than 90,000 tons of copper sulfide and nearly 1,800 tons of lead concentrate and increased its production of pyrite (for sulfuric acid) from 75,000 tons in 1975 to nearly 160,000 tons in 1976. Part of PCM's concentrate was sold to Gold Fields' subsidiary, Zinc Corporation of South Africa Ltd. (ZINCOR), and most of the remaining 86,000 tons of concentrate was exported to West Germany. ZINCOR's output of 66,200 tons of electrolytically refined zinc was derived in part from concentrate imported from Canada.

Exploration of several large lead-zinc-copper deposits in the northwestern part of Cape Province continued throughout the year. Feasibility studies of one deposit near Aggeneys indicated a 38-million-ton ore body with 6.35% lead, 2.85% zinc, 0.45% copper, and 2.6 troy ounces of silver per ton. Development as an underground mine appeared to involve considerably lower capital cost than starting as an open pit operation.

NONMETALS

Asbestos.—Increases were recorded in output, domestic sales, and exports of chrysotile and Cape blue crocidolite asbestos during 1976, and overall production rose from nearly 355,000 tons in 1975 to about 370,000 tons in 1976. Domestic sales were reportedly about 10% of production, but exports were estimated at 690,000 tons. Neither stockpiling nor the import volume, reported at 30,000 tons, accounted for the discrepancy between output and export volume.

Cement and Limestone.—The construction industry reflected the cautious reaction of other major industries in curtailing unnecessary expansion during the period following local currency devaluation. The output and domestic sales of limestone, burnt lime, and cement remained virtually unchanged. Of the 17 million tons of limestone produced, nearly 14 million tons was reported as sold locally. The cement industry consumed nearly 10 million tons of limestone (and nearly 400,000 tons of shale), about 1.5 million tons was calcined into lime, 1.7 million tons went to the metallurgical industries, and 1.4 million tons went to agriculture. Imports and exports of limestone and lime were insignificant, but about 300,000 tons of cement was exported.

Diamond.—Output of diamond at 7.0 million carats was 4% lower than the nearly 7.3 million carats reported in 1975. Sales decreased from more than 8 million carats to 7.6 million carats, but the value increased from $238 million to more than $247 million. Worldwide demand for small gem stones strengthened, and De Beers' Central Selling Organization increased prices 3% in January and 5.75% in September. Worldwide sales of gem diamond through the Central Selling Organization amounted to $1,524 million (R1,325 million), an increase of 46% over those of 1975 in terms of U.S. dollars and 70% in terms of rands.

DeBeers Consolidated Mines Ltd.'s Finsch mine in eastern Cape Province was the largest producer with 2.20 million carats, down from the 2.29 million carats produced in 1975. Output from the Premier mine in the Transvaal decreased from 2.04 million carats to 1.83 million carats.

Table 6 shows the marketed output of diamond and the U.S. dollar equivalent of average prices realized from various South African sources.

Fertilizer Materials.—*Phosphate.*—Production of crude phosphate ore set a record high of nearly 12.4 million tons, a 6.3% increase over the previous high of 11.6 million tons reported for 1975. Domestic sales of crude ore and concentrate increased to 109,000 tons and 1.6 million tons, respectively, and exports declined from 13,230 tons to 11,120 tons of contained P_2O_5. FOSKOR was the country's largest producer from its open pit mine in the apatite-rich "ring" surrounding Palabora's carbonatite

Table 6.—Republic of South Africa: Marketed diamond output, by province

Province	1975		1976	
	Output (carats)	Price per carat	Output (carats)	Price per carat
Mine diamond:				
Transvaal	2,413,380	$9.78	2,083,709	$11.55
Cape Province	3,771,586	22.61	3,642,727	22.95
Orange Free State	470,087	38.28	408.942	52.84
Total	6,655,053	19.06	6,135,378	21.07
Alluvial diamond:				
Transvaal	12,590	98.08	10,784	104.16
Cape Province	1,344,897	81.73	1,404,959	83.22
Orange Free State	91	93.46	61	207.38
Total	1,357,578	81.88	1,415,804	83,38
Grand total	8,012,631	29.71	7,551,182	32.75

deposit. Approximately 40% of FOSKOR's mill feed was tailings pumped directly from the Palabora concentrator. FOSKOR's ore also contains copper, iron, and zirconium minerals marketed by a subsidiary company. FOSKOR was the largest phosphate producer with nearly 1.4 million tons of P_2O_5 in concentrate, followed by SAMANCOR with 230,000 tons and Gold Fields' Glenover operation with nearly 109,000 tons. Transport and railcar shortages restricted both domestic sales and exports.

Fluorspar.—The Republic's potential as a major supplier of fluorspar was demonstrated by an overall increase of about 44% in output from nearly 203,000 tons in 1975 to almost 291,000 tons in 1976. Domestic sales of metallurgical grades increased from nearly 15,000 tons to more than 25,000 tons, and exports of all grades increased from about 126,500 tons to 229,000 tons. The newly completed operation at Marico in the Transvaal had a steadily increasing output during the year and, with a capacity of 120,000 tons of acid-grade and 50,000 tons of metallurgical-grade fluorspar per year, was expected to boost the country's exports to the 300,000-ton mark in 1977–78.

MINERAL FUELS

Coal.—Most of the country's electrical energy was derived from thermal powerplants that consumed nearly 60% of the output of its extensive coal deposits. About 13% of the coal output was of sufficient quality for the production of coke, chiefly for metallurgical industries. During 1976, an effort was made to import high-quality coking coal and export larger quantities of steam coal; in April, a coal export facility was commissioned at Richard's Bay. Total output of coal increased 11% to 77.1 million tons; increases were recorded in all categories, as shown in table 7.

Bituminous and subbituminous coal accounted for 97% of the total value of domestic sales but only 71% of the total value of exports of all types of coal; the remaining 26% of exports consisted of more than 1.5 million tons of Natal anthracite. Of the domestically consumed coal, 41.2 million tons or 58% was burned to produce electricity; 9.2 million tons or 13% was used to produce 4.7 million tons of coke; 12% went to local industries; 5% was for household consumption; 3% went to produce coal gas; 2% (nearly 1.5 million tons) each went to other gas producers, the oil-from-coal project, consumption at coal mines, and for transport; and 1% was consumed at other mines.

SASOL announced that a new company, Sasol (Transvaal) Ltd., would own and operate the Secunda oil-from-coal works under SASOL's management, and the mine at Secunda, near Trichardt, will remain a SASOL activity. Plant site preparation began in July 1976, a railroad line was under construction, and mechanical construction was scheduled to start by mid-1977.

Petroleum.—Imports of crude oil for South African refineries decreased from 122.5 million barrels (U.S. 42-gallon barrels) in 1975 to 116 million barrels in 1976. The SASOL oil-from-coal conversion plant produced 4,375,000 barrels of synthetic crude petroleum.

On December 17, 1976, the Department of Mines announced that significant amounts of oil had been discovered in an offshore well in the Agulhas Bank area, 61 kilometers south of Stilbaai between Cape Agulhas and Mossel Bay. The oil reportedly occurred in a massive, tightly cemented sandstone bed with a 55% maximum satu-

ration level and low porosity and permeability that could preclude economic recovery. Limited quantities of natural gas were also reported. The well was the second in a series of holes scheduled for a 2-year period at a cost of $60 million, provided by the Government-owned Southern Oil Exploration Corp. Pty. Ltd. (SOEKOR). Drilling was done by a Sedco K floating unit operated by Southeastern Drilling Company (SEDCO) of Dallas, Tex., under contract to SOEKOR.

The Mineral Industry of the Territory of South-West Africa

By Candice Stevens [1]

The mineral industry of the Territory of South-West Africa contributed approximately 44% to the 1976 gross domestic product (GDP) estimated at $650 million.[2] The major minerals produced were diamond ($170 million), copper ($60 million), lead ($20 million), and other base metals ($36 million). Two firms, Consolidated Diamond Mines of South-West Africa Ltd. (CDM) and Tsumeb Corporation Ltd., accounted for nearly 90% of the value of mineral output. It was predicted that Rössing Uranium Ltd.'s uranium mine, scheduled to begin full production in 1978, would bring a return exceeding that of the diamond industry and increase the contribution of the mineral sector to 65% of the GDP.

In general, mining activity in 1976 was at low levels because of both falling metal prices and political uncertainties. Tsumeb closed two mines during the year resulting in a 30% decrease in the value of metal sales by the company. The startup of full production at both the Rössing uranium mine and Otjihase Mining Co. (Pty.) Ltd.'s copper mine was deferred owing to technical difficulties. Although new prospects were indicated in uranium and diamond, exploration for other minerals showed an overall decline. In the petroleum sector, exploration ceased both on- and offshore as additional companies relinquished their concession areas.

Negotiations continued throughout 1976 at the Turnhalle Conference regarding the structure of an interim government to be established prior to the Territory's independence, targeted for December 31, 1978. Among the questions to be decided were future policy concerning the Territory's commercial and economic resources and the status of Walvis Bay, the only deepwater port in the Territory. Legislation was introduced in 1976 to transfer the administration of Walvis Bay back to the Republic of South Africa, which had held ownership rights to the port since 1884.

The Republic of South Africa made a large investment in the Ruacana Falls hydroelectric scheme, a prospective source of power for the Territory's mineral industry. The $280 million project, involving the construction of a series of dams, hydroelectric plants, irrigation facilities, and canals along the Cunene River on the Angolan border, was the result of an agreement signed in 1969 between the Republic of South Africa and Portugal. Two major segments of the project, the Gove regulating dam and the Calueque pumping station, were completed in 1976. Three of the four generating sets at the Ruacana power station were scheduled to be commissioned in mid-1978. However, all construction ceased in September 1976 owing to a political dispute between Angolan and South African authorities.

---

[1] Economist, International Data and Analysis.
[2] Where necessary, values have been converted from South African rand (R) to U.S. dollars at the rate of R1 = US$1.15. The rate in 1975 was R1 = US$1.3663.

PRODUCTION AND TRADE

The South-West Africa Administration, Republic of South Africa, continued its policy of not disclosing mineral production statistics for the Territory. Most of the statistical data on production of mineral commodities listed in table 1 were derived from the annual reports of the companies operating in the Territory, primarily Tsumeb, CDM, and the South-West Africa Co., Ltd. (SWACO). Although the Territory traditionally produces a variety of other minerals, particularly nonmetals, output data are not available and these commodities are not listed in table 1.

Production of most minerals declined in 1976. Copper production at the major mines of Tsumeb, Oamites, and Otjihase was at low levels. The output of Tsumeb's other products—arsenic, cadmium, and silver—also decreased. Similarly, tungsten and lead-zinc production and diamond recovery decreased slightly.

The Territory's foreign trade in mineral commodities was included in the trade statistics of the Republic of South Africa and was not differentiated. It was estimated that minerals accounted for approximately 60% of the value of total exports of the Territory in 1976. Diamond, which was marketed by De Beers Consolidated Mines Ltd., constituted about 66% of total mineral exports. All metals produced by Tsumeb, which contributed about 20% of mineral exports, were transported on a 640-kilometer company-owned railroad to Tsumeb's loading facilities at Walvis Bay. Copper and lead were exported as blister copper and refined lead; zinc was shipped as concentrate for refining elsewhere. Tsumeb also imported lead concentrate from the United States for refining and reexport.

[e] Estimate. [p] Preliminary. [r] Revised. NA Not available.

[1] In addition to the commodities listed, the Territory of South-West Africa, prior to 1967, produced bismuth concentrate, cesium ore, columbite-tantalite concentrates, gold, manganese ore, molybdenum concentrate, graphite, lime, mica, precious stones, kyanite, sillimanite, and a variety of crude construction materials (clays, stone, sand and gravel). No official statistics have been published since yearend 1966, and available information is inadequate to ascertain whether production has continued or not, and if so, at what levels.

[2] Data are compiled from operating company reports as follows: Tsumeb Corp. Ltd. (arsenic, mine and refined cadmium, mine and blister copper, mine and refined lead, mine and smelter silver, mine zinc, and pyrite concentrate); South-West Africa Co. Ltd. (SWACO) (mine lead, mine tin, mine tungsten, mine vanadium, and mine zinc); South African Iron and Steel Industrial Corporation Ltd. (ISCOR) for Imcor Zinc (Pty.) Ltd.'s Rosh Pinah mine (mine lead and mine zinc), and for ISCOR's own Uis mine (mine tin); General Mining & Finance Corp. Ltd. (Republic of South Africa) for Klein Aub Koper Maatskappy Ltd.'s mine near Rehoboth (mine copper and mine silver); and Falconbridge Nickel Mines Ltd. (Canada) for Oamites Mining Co. (Pty.) Ltd.'s Oamites mine (mine copper). Data from Tsumeb and Falconbridge are for calendar years; data from other companies are for fiscal years ending June 30 of the year stated.

[3] White arsenic equivalent of all arsenic products reported as being produced.

[4] Figures comprise reported production of Tsumeb and Oamites plus an estimate for Klein Aub for 1974, 1975, and 1976, and an estimate for the Republic of South Africa's Johannesburg Consolidated Investment Co. Ltd. (JCI) (Otjihase copper mine) for 1975 and 1976.

[5] Figures comprise reported production of Tsumeb for 1974 and 1975, plus estimates for Oamites and Klein Aub.

[6] Figures comprise reported production of ISCOR for Imcor's Rosh Pinah mine plus estimates for Tsumeb (based on ore milled) as well as for SWACO for 1976.

[7] Total figures reported by De Beers Consolidated Mines Ltd. in company annual reports for calendar years; detail on gem and industrial diamonds are estimates, assuming output to be 95% gem quality.

[8] Output has not been officially reported since 1966, but presumably has continued since a number of countries record imports from "South Africa", which in total quantity considerably exceed reported output of the Republic of South Africa proper, and presumably include shipments from the Territory. Quantities given represent imports of the United States and the European Communities reported as originating in the Republic of South Africa, but the reader is cautioned that a portion of the material may have been mined in Southern Rhodesia.

COMMODITY REVIEW

METALS

Tsumeb continued in 1976 as the Territory's largest producer of nonferrous metals, principally copper, lead, zinc, silver, cadmium, and arsenic. The closure of two mines during the year caused total metal sales to decrease from $75 million in 1975 to $52 million in 1976. However, Tsumeb lowered its net loss in 1976 to approximately $2 million from the $3 million deficit in 1975. Newmont Mining Corporation (United States) was the manager and a principal shareholder (29.6%) of Tsumeb, whose other owners included AMAX Inc. (29.6%), Selection Trust Ltd. of the United Kingdom (14.2%), O'okiep Copper Co. Ltd. of the Republic of South Africa (9.5%), Union Corporation Ltd. of the Republic of South Africa (9.4%), and SWACO (2.4%).

Tsumeb has traditionally accounted for about 80% of the nonferrous metal production in the Territory through its mine at Tsumeb (located 400 kilometers north of Windhoek), the nearby Kombat and Asis mines, and the Matchless mine (located 42 kilometers south of Windhoek). In 1976, the Tsumeb mine, the largest of the ore bodies, milled 443,000 tons of ore grading 4.25% copper, 9.04% lead, and 2.39% zinc. The Matchless mine milled 102,000 tons of ore grading 2.40% copper. In March 1976, the Kombat and Asis Ost mines suspended operations because of low metal prices and the need to shift to the development of a new ore body at Asis West. Prior to the suspension, the two mines milled 60,000 tons of ore grading 1.49% copper and 1.92% lead. Both the Kombat mine and the Asis Ost mine, a joint venture of Tsumeb (75%) and SWACO (25%), were scheduled to resume operations in 1978.

Development drilling continued during 1976 at the Asis West mine, located immediately west of the Kombat mining district. The main mine shaft at Kombat was deepened and the lower levels extended in order to gain access to the Asis West reserves. Estimates of reserves at the new mine increased the tonnage to 1.4 million tons grading 7.78% copper and 4.33% lead. Production at Asis West, under the joint ownership of Tsumeb (85%) and SWACO (15%), was scheduled to begin in late 1978.

Smelter production at Tsumeb in 1976 was 21,900 tons of copper, including 7,500 tons of custom-smelted metal, and 39,600 tons of lead, including 5,100 tons of custom-smelted metal. Both copper and lead output decreased from the 1975 levels of 36,410 tons and 44,272 tons, respectively. During 1976, a total of 2,000 tons of zinc metal contained in concentrates was exported from Walvis Bay for overseas smelting and refining. Tsumeb and O'okiep continued to cooperate on the currently suspended joint venture, Cape Copper Refinery, aimed at refining the copper output of the smaller producers in the Territory and the Republic of South Africa.

Copper.—The other major copper producer in addition to Tsumeb was Oamites Mining Co. (Pty.) Ltd., a joint venture of Falconbridge Nickel Mines Ltd. (Canada) (74.9%) and International Development Corp. (IDC) of the Republic of South Africa (25.1%). The Oamites mine, located 55 kilometers south of Windhoek, milled over 600,000 tons of ore in 1976 compared with 568,000 tons in 1975. However, recoverable copper output decreased from 6,852 tons in 1975 to 6,384 tons in 1976 because of the lower grade of ore. Mine development during the year involved completion of underground ore transportation facilities and a crushing station, plant improvements, and the addition of new employee accommodations. Reserves at yearend 1976 were estimated at 4.05 million tons grading 1.21% copper and 0.54 troy ounce of silver per ton. Production statistics for the Oamites mine for 1975 and 1976 follow:

	1975	1976
Ore milled ----metric tons--	568,000	601,000
Mill-head grade -percent Cu--	1.13	1.14
Mill recovery -----percent--	93.40	92.99
Concentrates produced dry tons--	19,000	20,000
Recoverable copper metric tons--	6,852	6,384

Production at the mine owned by Klein Aub Koper Maatskappy Ltd., a subsidiary of General Mining & Finance Corp. Ltd.

(Republic of South Africa), remained at the 1975 level of approximately 9,000 tons of concentrates. Total ore reserves were reported at 8 million tons of copper-silver ore grading 2.5% copper. The company planned to expand production at the mine and possibly exploit additional deposits at Okasewa.

The Otjihase copper mine, which came onstream in October 1975, suffered financial losses in 1976 as a result of a combination of production problems and low metal prices. In addition, a new smelter that was opened at Tsumeb in 1976 to handle Otjihase concentrates incurred serious technical problems. As a result of the difficulties encountered underground, the tonnage milled did not attain the target rate of 100,000 tons per month. In 1976, approximately 430,000 tons of ore was milled and 30,000 tons of 22% copper concentrates was produced. In addition to copper, important quantities of precious metals were recovered at the refining stage, and approximately 35,000 tons of pyrite concentrates was sold on a contractual basis to Rössing. The Otjihase mine, situated 27 kilometers northeast of Windhoek, was brought into production at a cost of $48 million. The major shareholder was Johannesburg Consolidated Investment Co., Ltd. (JCI) (52.5%). The remaining shares were held by Minerts Development (Pty.) Ltd., owned equally by Fedmar Ltd. (Republic of South Africa) and Continental Ore Corp. (United States).

Navarro Exploration Co., a wholly-owned subsidiary of Zapata Heron, Inc. (United States), continued to operate its small copper mine and mill at Onganja, located near Okahandja north of Windhoek. Milling capacity at Onganja, opened in 1973, was estimated at 200 tons per day. Reserves were estimated at 320,000 tons with an average grade of 2.7% copper.

Lead, Zinc, Vanadium.—The major producer of lead, zinc, and vanadium was the Berg Aukas mine, operated by SWACO. Milling capacity was 125,000 tons per year, leading to an average production of 40,000 tons of concentrates. Output was composed of lead vanadates, zinc sulfide, lead sulfide, and zinc silicates. The company continued development activity, including shaft deepening and dewatering operations, in 1976.

The other major lead-zinc producer in the Territory was the Rosh Pinah mine, operated by Imcor Zinc (Pty.) Ltd., a subsidiary of the South African Iron and Steel Industrial Corporation Ltd. (ISCOR). In 1976, zinc concentrate production decreased from 27,100 tons in 1975 to 25,030 tons with a zinc metal content of 50.6%. The total output of zinc concentrates was processed at Zinc Corp. of South Africa Ltd.'s (ZINCOR) electrolytic refinery near Springs, Republic of South Africa. Lead concentrate production, which was marketed in the Territory, increased from 5,288 tons in 1975 to 7,023 tons in 1976. Reserves at the original underground mine at Rosh Pinah, located in the Namib Desert about 27 kilometers north of the Orange River, were completely exhausted during 1976, and operations were switched to the new open pit mine without any loss in production.

Tin and Tungsten.—The Territory's major tin producer was the Uis tin mine, operated by Industrial Minerals Corp. (Pty.) Ltd., a wholly-owned subsidiary of ISCOR. Its production decreased slightly from 1,177 tons of tin concentrate (with a tin metal content of 64.6%) in 1975 to 1,262 tons of tin concentrate (with a tin metal content of 63.4%) in 1976. Output from the Uis mine, located northeast of Swakopmund near Brandberg, was shipped to ISCOR's smelting plant at Vanderbijlpark Steel Works in the Republic of South Africa.

SWACO continued trial operations at its Brandberg West tin-tungsten mine in 1976. Operations were suspended in 1973, but overburden stripping and plant rehabilitation were resumed a few years later. Reserves were estimated at 6.6 million tons grading 0.24% combined tin and tungsten.

Tungsten was the main product at the Krantzberg tungsten mine, owned by Nord Resources Corp. (United States) (40%) and Ebco Mining Co. (60%), a subsidiary of Bethlehem Steel Corp. (United States). Nord served as operator and marketed all output of the Nordex Joint Venture Ltd. Although the price of tungsten increased significantly during 1976, equipment breakdowns and a reduction in ore grade resulted in net losses for the year. Krantzberg's production capacity of concentrate was rated at 7,500 tons per year, but the plant was reported as operating at half

of capacity for most of the year. Substantial mill modifications and repairs were made in the latter part of 1976, and mining commenced in the new "C" ore zone. An improvement in operating results in 1977 was expected at the Krantzberg mine, situated northwest of Windhoek near Omaruru.

Uranium.—The large uranium mine operated by Rössing came onstream in mid-1976 with annual production totaling 850 tons of U_3O_8. Rössing originally planned to achieve full capacity of 5,000 tons of U_3O_8 per year by the first half of 1977. However, because of technical problems in the treatment plant, full design output will not be achieved until mid-1978, a delay of 18 months. Rössing encountered another problem in November 1976 when it was hit by a brief strike by approximately 500 of its 1,500-employee work force. Production at the plant was maintained by utilizing stockpiled ore.

The large, low-grade (0.04%) uranium ore body, situated 70 kilometers northeast of Swakopmund, has been under development since 1966. The latest estimate of reserves was 150,000 tons of uranium oxide. Scheduled to become one of the largest uranium mines in the world when full production is reached, the Rössing mine's initial cost was estimated at $210 million. The initial mining rate of ore and waste from the open pit was 60,000 tons per day, scheduled to increase to 120,000 tons per day by 1980. An underground mining section was also under development and was scheduled to be in operation in the second half of 1977.

The largest shareholder in the Rössing venture was Rio Tinto-Zinc Corporation Ltd. of the United Kingdom (42.5%). Also holding interest in the mine were IDC, General Mining, and Total Compagnie Minière et Nucleaire (France). The delays in production necessitated a renegotiation of Rössing's uranium supply contracts. Shipments to the United Kingdom Atomic Energy Commission, which contracted to receive 7,500 tons of uranium oxide between 1977 and 1982, were deferred. Although individual buyers were not divulged under the South African Atomic Energy Acts, the balance of production was to be marketed in Western Europe and Japan.

Several other companies were active in the search for uranium in the areas north and east of Swakopmund. General Mining reported the discovery of uranium in two extensive layers of calcrete at Langer Heinrich mountain near Tinkes, east of Swakopmund. A feasibility study completed in 1976 indicated that a profitable mining venture could be undertaken; marketing and financing investigations were in progress.

Anglo-American Corp. of South Africa Ltd. planned to put increased emphasis on its uranium exploration activities in the Territory. Investigations were being conducted in the Karoo region in conjunction with Empresa Nacional del Uranio S.A. (ENUSA), a Spanish nuclear fuel company. Exploration was also underway in the Swakopmund and Lüderitz areas in conjunction with Minatome S.A. (Japan), Union Corporation, and Société Nationale des Pétroles d'Aquitaine (France).

Gold Fields of South Africa Ltd. was conducting studies of a large deposit discovered at Trekkopje, adjacent to the Rössing property. Other companies involved in uranium prospecting in the Territory included JCI and Falconbridge.

NONMETALS

Diamond.—The largest contributor to the nation's mineral industry was CDM, a company noted for its production of virtually all gem stones. The 1976 output of CDM, a wholly-owned subsidiary of De Beers Consolidated Mines Ltd., represented 16% of De Beers' total production. The tonnage treated at Oranjemund increased from 12.25 million tons in 1975 to 12.88 million tons in 1976, but the grade decreased from 0.1427 carat to 0.1315 carat per ton. Final diamond recovery decreased from 1.75 million carats in 1975 to 1.69 million carats in 1976. Although total carats recovered showed a decrease, the average stone size increased from 0.73 carat in 1975 to 0.95 carat in 1976.

CDM has surface-mined marine terraces since 1920 in its 8,000-square-kilometer tract that stretches along the coast from the Orange River to Lüderitz. In the 1970's, CDM launched commercial mining in the foreshore area after construction of a seawall allowed mining to be extended to a distance of 190 meters to the seaward

side of the high water mark. The installation of a bucket wheel excavator increased overburden removal capacity to 1,000 cubic meters per hour. Overburden stripping increased from 42 million tons in 1975 to nearly 50 million tons in 1976. Further refinements in the dewatering system and stability improvements to the seawall were to allow operations to progress 200 meters seaward of the high water mark in the Western Block, a 9-mile strip just north of the mouth of the Orange River.

CDM's No. 2 conglomerate plant, commissioned in early 1975, was reportedly operating at full capacity during 1976. The No. 3 plant was commissioned toward yearend 1976 and was building up to the full production rate of 360,000 tons per month. Site leveling for the installation of an Electricity Supply Commission (ESCOM) power system for the mine began in May 1976; the project was scheduled for completion in May 1978.

CDM accelerated its pace of reconnaissance prospecting but initial results were not encouraging. At Arrisdrif, on the north bank of the Orange River, samples from nine pits sunk to bedrock were tested, but only one pit showed diamonds of commercial interest. Seismic equipment was employed in locating possible diamond traps on the foreshore, and sampling of extensive marine gravel deposits in the sea continued. In 1977, CDM planned to emphasize diamond sampling in the Western Block.

A second private firm, Kwazulu Mining Co., reported a diamond discovery in its 8,000-square-kilometer prospecting area east of CDM's Diamond Area No. 1. Fifty diamond pipes were located in the Huns Berge area, southwest of Keetmanshoop. Technical and feasibility studies were in progress at yearend.

MINERAL FUELS

Petroleum.—Southern Oil Exploration Corp. (South-West Africa) (Pty.) Ltd. (SWAKOR), the State agency responsible for granting oil exploration concessions, reported that petroleum prospecting was limited in 1976. SWAKOR is a subsidiary of Southern Oil Exploration Corp. (Pty.) Ltd. (SOEKOR), the South African organization entrusted with coordinating oil exploration in both the Republic and the Territory. The majority of foreign companies engaged in prospecting in the Territory relinquished their concessions during the period 1974–76. Among these were Getty Oil Co., Continental Oil Co., Phillips Petroleum Co., Chevron Oil Co., Texaco Inc., and Aquitaine (South-West Africa) Ltd. In addition, the assets of B. J. H. duPreez, who held four offshore concessions totaling 50,000 square kilometers, were taken over by Standard Bank of Southern Africa Ltd. during 1976.

Canada Southern Petroleum Ltd., as operator for a group that included Damson Oil Co., Aminex Ltd., and Asmera Ltd., all of Canada, and Aracca Petroleum Co. of the United States, continued seismic surveys in its 13,000-square-kilometer tract near the mouth of the Orange River. Another Canadian firm, Etosha Petroleum Co. (Pty.) Ltd., a subsidiary of Brilund Mines Ltd., held rights to a 300,000-square-kilometer onshore tract. No discoveries were reported during 1976.

The Mineral Industry of Spain

By Roman V. Sondermayer [1]

In 1976, Spain was an important producer of mercury, pyrite, fluorspar, strontium, gypsum, magnesite, lead, potash, feldspar, zinc, and petroleum refinery products. Production of other minerals and fuels was of only domestic significance.

The country's output of nonferrous ores, iron ores, and fuels did not meet local demand, and imports were essential for continued industrial activity. The mineral industry accounted for about 10% of the gross national product (GNP) or $10 billion[2] at current prices. However, the share of the extractive sector of the mineral industry was less than 1% of the GNP. The general economic situation was characterized by unemployment averaging 345,000 persons during the year, by an increase in the cost of living of 19.1%, and by a significant trade deficit of $7.3 billion. The mineral industry employed 212,000 persons. Labor unions were in a transitional stage from being government controlled to being similar to unions in other nontotalitarian countries in Europe. The Ministry of Industry implemented the minerals laws, regulated the private sector, and managed most Government-owned companies of the mineral industry through Instituto National de Industria (INI).

The Mining Development Law and the National Fuels Plan were approved by the Government during 1976. The Mining Development Law is expected to constitute the basis for future development of the mining sector. It contained several innovations. The most important were compulsory preparation of a 2-year national plan for the supply of minerals, a decision to set up a geological and mining data bank, regulation of activities abroad, financing of mining, and revision of the tax system for the mineral industry.

There were a number of significant developments during 1976. Construction continued on a 175,000-ton-per year aluminum plant and on an 800,000-ton-per-year alumina plant near San Ciprián (Province of Lugo), development continued at the Aznalcollar (Seville) mining complex, discovery of a new iron ore deposit near Granada was announced, development continued on lead and zinc deposits near Rubiales, and construction was completed on a 50,000-ton-per-year lead smelter. At the Almáden mercury mine, two new levels were prepared for production, and a new haulageway was excavated. Construction was underway on the site of an installation for total utilization of pyrites near Huelva, and a new plant for production of superfine and micronized red oxides was under construction near Malaga. Development of two lignite mines continued in the Province of La Coruña, and the first crude oil was discovered offshore Asturia in northern Spain.

PRODUCTION

Spain continued to develop new domestic mineral resources, and renovation of installations and introduction of modern equipment throughout the industry continued. The aim was to increase production of ores and concentrates and consequently cut imports of raw materials needed for the growing mineral processing and refining

[1] Physical scientist, International Data and Analysis.

[2] Where necessary, values have been converted from Spanish peseta (Ptas) to U.S. dollars at the rate of Ptas70=US$1.00.

industry. Mine operations were characterized by low levels of mechanization and fragmented operations, resulting mostly from difficult geological and mining conditions. However, many metallurgical and petroleum processing plants were of modern design. As table 1 shows, trends in output were mixed. In spite of recession, outputs of some commodities during 1976 were higher than during 1975. The following tabulation shows major producers of minerals in Spain and their share in the country's total production:

Commodity	Major companies, principal facilities, and ownership	Percent of domestic output
Aluminum	ENDASA S.A.—plants at Áviles, Valladolid, Government 54%	61
Bituminous coal	Hunosa S.A.—mines at Caudal, Aller, and Nalón, Government 100%	54
Cement	Cía. General de Asfaltos y Portland Asland S.A.—7 plants	18
Copper ore	Rio Tinto Patinò S.A.—mines at Rio Tinto, Union Explosivos Rio Tinto (UERT)	90
Copper, refined	Rio Tinto Patinò S.A.—smelter and refinery at Huelva, UERT	60
Ferroalloys	Soc. Española de Carburos Metalicos S.A.—plants at Cee and Berga	50
Do	Hidro Nitro Española S.A.—plant at Monzón	30
Do	Ferroaleaciones Españolas S.A.—plant at Medina del Campo, Cargill Inc., United States	10
Iron ore	Cía. Andalusa de Minas S.A.—mine at Marquesado, Mokta 62%	34
Lead ore	Sociedad Minera y Metallurgica de Peñarroya de España S.A.—mines at Mantas de los Azules, Union, Peñarroya, France 98%	30
Lead, smelter	Sociedad Minera y Metallurgica de Peñarroya de España S.A.—smelter at Santa Lucía, Peñarroya, France 98%	70
Mercury	Ministry of Finance—mine and smelter at Almáden, Government 100%	100
Petroleum, refined	Empresa Nacional del Petróleo S.A.—refineries at Valle de Escombreras and Puertollano, Government 72%	42
Do	Cía. Esp. de Petróleos S.A.—refineries at St. Cruz de Tenerife, Algeciras, Banco Central	24
Potash	Potasas de Navara S.A.—mines near Pamplona, Government 100%	42
Do	Minas de Potasas de Suria S.A.—mines at Suria, Solvay, Belgium	18
Do	Unión Explosivos Rio Tinto S.A.—mines at Balsareny/Sallent and Cardona	21
Pyrite	Tharsis Sulfur and Copper Co.—mines at Tharsis and La Zarza, 51% Spanish private capital	46
Steel	Empresa Nacional Siderurgica S.A.—works at Áviles, Felguera, Gijón-Moreda, Gijón-Verina, Government 88%	46
Do	Altos Hornos de Vizcaya S.A.—works at Baracaldo-Sestao, U.S. Steel, about 20%	32
Zinc ore	Real Cía. Asturiana de Minas S.A.—mines at Reocín and Rubiales	50
Zinc, smelter	Real Cía. Asturiana de Minas S.A.—electrolytic zinc plant at San Juan de Nueva	85

e Estimate. p Preliminary. r Revised. NA Not available.
1 Revised to none.
2 Thousand metric tons.
3 Data presented include recorded production of salable acid grade fluorspar from both fluorspar mines and lead–zinc–fluorspar mines, plus some salable acid grade fluorspar obtained by beneficiating a portion of total reported salable metallurgical grade output.
4 Includes sand obtained from the washing of kaolin: 1974—250,246 cubic meters; 1975—578,635 tons.

TRADE

During 1976, the latest year for which complete data were available, Spain's balance of foreign trade was negative. Imports of ores, concentrates, and fuels, especially crude oil, contributed largely to the deficit. African and Middle Eastern countries were the largest suppliers of minerals. Value of mineral imports was reported at $6.0 billion, or 37% of total imports. Fuels, mostly crude oil, accounted for $4.1 billion, or 25% of total imports. Mineral exports, consisting mostly of various forms of metals and petroleum refinery products, totaled $1.1 billion, or 15% of total exports. European countries were the principal purchasers of Spanish mineral industries' products. Tables 2 and 3 show Spanish foreign trade in minerals.

Commodity	1974	1975	Principal destinations, 1975
METALS			
Aluminum:			
Oxide and hydroxide	60	59	United Kingdom 24; Portugal 14; Turkey 10; Bolivia 10.
Metal including alloys:			
Scrap	264	273	West Germany 158; Canada 54; Italy 40.
Unwrought	2,485	2,389	Portugal 1,538; Canada 722.
Semimanufactures	10,049	6,547	United States 1,346; Cuba 801.
Antimony metal including alloys, all forms	231	139	France 44; Netherlands 40; United States 35; Republic of South Africa 15.
Arsenic:			
Trioxide, pentoxide, acids	(1)	2	All to Argentina.
Metal including alloys, all forms	(1)	NA	
Beryllium metal including alloys, all forms kilograms	NA	NA	
Bismuth metal including alloys, all forms do	22	NA	
Cadmium metal including alloys, all forms	40	176	United States 93; Netherlands 50.
Chromium:			
Oxide and hydroxide	33	18	Colombia 7; Greece 5; Venezuela 3.
Metal including alloys, all forms	10	NA	
Copper:			
Ore and concentrate	3,909	3	All to United Kingdom.
Matte	1,275	NA	
Copper sulfate	(1)	2	All to Venezuela.
Metal including alloys:			
Scrap	176	141	NA.
Unwrought	7,163	17,230	France 11,124; United Kingdom 2,012; Netherlands 1,825.
Semimanufactures	5,881	8,207	Algeria 5,146; Israel 645.
Gold metal, worked and partly worked troy ounces	NA	NA	
Iron and steel:			
Ore and concentrate, except roasted pyrite thousand tons	2,962	1,960	West Germany 918; Netherlands 333; France 304.
Roasted pyrite do	516	531	Mainly to West Germany.
Metal:			
Scrap	2,333	1,529	Netherlands 906; France 240.
Sponge iron, powder, shot	5,857	6,162	France 1,862; Italy 1,782; Finland 770; West Germany 769.
Ferroalloys:			
Ferromanganese	35,943	17,215	West Germany 4,377; Sweden 3,931; France 3,414; Romania 2,502.
Other	r 47,229	25,432	West Germany 8,235; Romania 4,455; United Kingdom 4,152.
Steel, primary forms	66,258	15,603	United States 11,124; France 2,025.
Semimanufactures:			
Bars, rods, angles, shapes, sections	391,908	1,109,000	Iran 279,406; West Germany 132,215; Morocco 95,260; Turkey 86,764.
Universals, plates, sheets	100,490	279,237	United Kingdom 43,004; West Germany 40,344; Italy 27,398.
Hoop and strip	5,868	6,803	France 2,567; People's Republic of China 2,421.
Rails and accessories	164	14,624	Egypt 13,969; Poland 619.
Wire	7,140	7,642	Algeria 2,051; Portugal 1,318; Morocco 1,042.
Tubes, pipes, fittings	87,190	128,381	France 25,398; United States 15,880; West Germany 14,214.
Castings and forgings, rough	6,964	14,624	West Germany 2,929; Belgium-Luxembourg 1,692; Canada 1,637; Poland 1,459.
Lead:			
Oxides	8	1	All to Andorra.
Metal including alloys:			
Scrap	NA	NA	
Unwrought	342	1,564	Netherlands 1,001; United States 256.
Semimanufactures	274	74	Saudi Arabia 38; Nigeria 12.

COMMODITY REVIEW

METALS

A variety of metals was produced in Spain during 1976. The following tabulation shows the commodities, with the approximate number of mines for each:

Commodity	Number of mines
Copper	6
Iron ore	33
Iron-pyrites-copper	11
Lead	23
Lead-zinc	22
Lead-zinc-pyrites	4
Lead-zinc-fluorspar	8
Gold-silver	1
Pyrite-copper	--
Pyrite	10

Production of metals was adversely affected by increased costs for power, labor, and transportation. Value of metal mining accounted for about 23% of the total value of mining output in Spain.

Aluminum.—Construction continued on the alumina and aluminum complex of Aluminio Español S.A. (formerly Aluminio de Villagarcía S.A.) at San Ciprián (Province of Lugo). Annual production of the complex will be 800,000 tons of alumina and 175,000 tons of aluminum. The facilities will be built so that capacity can be doubled for alumina and increased to 270,000 tons for aluminum. Empresa Nacional del Aluminio (ENDASA) (controlled by INI) owned 55%; Aluminio de Galicia S.A. (ALUGASA), 20%; and others, 25% of the total capital of Aluminio Español. The plants will have a total payroll of 2,000. The San Ciprián facility is part of a large expansion program to increase aluminum-producing capacity in Spain from 216,000 tons in 1975 to 411,000 tons per year by 1980.

During 1976, four primary smelters were in operation. The aluminum industry suffered from the stagnation of the economy. The Government-owned company, ENDASA, was the major producer of aluminum and operated the country's largest smelter, a 110,000-ton-per-year plant near Aviles.

With its modest production of bauxite, Spain remained dependent on imports to meet the requirements of domestic refiners.

Copper.—Development of the Aznalcollar (Sevilla) mining complex operated by Andaluza de Piritas S.A. (APIRSA) continued. In addition to the mine, the complex includes a beneficiation plant, a water supply system, and auxiliary facilities. Yearly planned targets for the opencast operation were set at 2 million tons of pyrites and 1.5 million tons of copper pyroclast with an overburden-to-ore ratio of 3.2 to 1. The yield should be about 51,000 tons of copper concentrate, 42,000 tons of lead concentrate, and 98,000 tons of zinc concentrate. Proven reserves amounted to 78.5 million tons; approximately 44.5 million tons were complex sulfide ores (average metal content: 0.58% copper, 1.78% lead, 3.33% zinc, and 67 grams per ton of silver), and 34 million tons were cupriferous pyrite ores (average metal content: 0.58% copper, 0.40% lead, and 10 grams per ton of silver). The beneficiation plant will include crushing and milling facilities, differential flotation systems for sulfides, and dewatering installations. The complex is scheduled to start production in 1978.

During 1976, 29 mines produced copper, but Spain remained dependent on imports of concentrates and matte to meet demand. Six mines produced copper as main products, 10 pyrite mines produced copper as a byproduct, and 13 mines produced copper as a byproduct of iron output. Most of the copper mines were located in the Province of Huelva. There were four copper smelters and six copper refineries in operation during 1976. The largest smelter and refinery were located in the Province of Huelva and were operated by Rio Tinto Patino S.A.

Iron Ore.—Exploration continued on the iron ore deposit found during 1975 in the Marquesdado zone of the Province of Granada near the Alquife mines. Reports indicated reserves of about 30 million tons of high-grade ore. An annual production of 1 million tons was planned for the new mine. In addition, expansion of capacities was underway at the Andaluza de Minas (Province of Granada), Mineral del Andevalo (Provinces of Huelva and Badajoz), Agraminas (near Bilbao), and Sierra Minera mines (Provinces of Teruel and Guadalajara).

At Andaluza de Minas, output was planned to reach 4 million tons in 1980, about 1.3 million tons more than in 1975. Reserves were reported at 80 million tons

of hematite with an iron content of 47%. The mine was an open pit with 8-meter benches. Loading was with a 4.3-cubic-meter shovel, and transportation was in 32-ton dumpers. The mineral was crushed and upgraded to 56% iron by dense media. To facilitate shipments, a sea-loading facility capable of taking 80,000-ton ships and having a loading capacity of 2,500 tons per hour was under construction at Almeria. Investments for mine and port will total 2,000 million pesetas ($9 million).

At Minera del Andevalo, current production of 1.7 million tons should increase to 2.7 million tons by 1979. Mining was opencast with 12-meter benches. Loading was with 4- and 8-cubic-meter shovels, and ore and overburden were moved in 35- and 50-ton dumpers. After crushing, ore is magnetically concentrated to a product containing 60% iron. Investments will total 1,500 million pesetas ($22 million).

At Agrominas, present output of 8 million tons was planned to rise to 26 million tons of ore in 1979. Reserves were 81 million tons of 35% iron (mostly oxide and carbonate). The area was mined both underground (Bodovale) and opencast (Gallarta). At Bodovale, the mining method was room (25 meters) and pillar (20 meters). Loading and transportation were with 7-cubic-meter scooptrams. At Gallarta benches were 10 meters high. Loading was with 8-cubic-meter shovels, and transportation was with 75-ton dumpers.

At Sierra Minera, output of 1.8 million tons should reach 3.5 million tons by 1980. Reserves were of limonite (45% iron and 1.2% manganese). Mining was opencast with 10-meter benches. There was little use of explosives. Loading was with 5-cubic-meter shovels, and transportation was in 30- and 50-ton dumpers. From the drying plant, 2.5 million tons of fines were separated for sintering, and 1 million tons of ultrafines, which were mixed with imported high-grade ore, were converted into 2 million tons of 60% to 64% iron pellets. Investments were planned at 4,900 million pesetas ($72 million).

Iron and Steel.—During 1976, Empresa Nacional Siderúrgica S.A. (ENSIDESA) remained the principal steel producer in the country. With plants located at Áviles, La Felguera, Gijón-Moreda, and Gijón-Verina, this firm accounted for approximately 43% of the country's pig iron production and about 46% of steel output.

There were no installations for direct reduction of iron ore in operation during 1976, but two plants were planned. One installation, with two modules using natural gas as reductant, will be located in northern Spain near the port of Bilbao. Capacity will be 1 to 1.2 million tons per year. The other facility, with one module using manufactured gas as reductant, will be located in the Bay of Algeciras in southern Spain. Annual capacity will be 0.5 million tons. Both projects are planned to start operation at the end of 1980.

Lead and Zinc.—In 1976 development of the lead and zinc deposit near Rubiales in the province of Lugo, expansion of San Juan de Nieva zinc smelter, and completion of a new lead smelter at Linares continued. At Rubiales, the underground mine was scheduled for production in 1977. Annual output of approximately 115,000 tons of zinc concentrates and 15,000 tons of lead concentrates was planned. When in operation, mining will be by cut and fill in stopes 3.5 meters high and 250 meters long. Hydraulic filling, suspended timbering, and use of self-propelled jumbos and 5-ton shovels for loading were planned. Transportation will be by scooptrams and 10-ton trucks, and hoisting will be by means of skips driven by a 1,600-kilowatt Ward-Leonard unit. A 12% incline ramp will enable all the heavy materials to be lowered.

A differential flotation plant will have parallel circuits with 10 cells, four of which will be roughers. Proven reserves were reported at 7.5 million tons with an average zinc content of 9.9% and 3% lead. The development was financed by Cominco (45%), Union Corporation of South Africa (27%), and Asturiana de Zinc and Banco Urquijo (25%). In addition, lead and zinc concentrates will be produced at the new mining operation, Aznalcollar, Seville, described in the copper section of this chapter. Expansion continued on the zinc smelter at San Juan de Nieva, owned by Peñarroya. When completed in 1977, smelter capacity will have been increased from 130,000 tons to 205,000 tons of zinc per year.

A 50,000-ton-per-year lead smelter was completed near Linares in mid-1976, replacing an obsolete plant. By yearend, lead output totaled 21,000 tons. Five companies were participating in the venture (Peñar-

roya, El Adaro, Los Guindos, La Cruz, and CARM).

During 1976, there were 23 lead mines, 22 lead and zinc mines, 4 zinc-lead-pyrite mines, and 7 zinc-fluorspar mines operating in Spain. Approximately 50% of the zinc produced in Spain was mined in the north near Santander, and about 30% was mined in the district of Cartagena in southern Spain. Two zinc smelters and four lead smelters were operating at yearend 1976. Peñarroya was the largest producer of lead and operated the largest lead smelter in the country, located near Santa Lucía, Cartagena. Asturiana de Zinc S.A. was the major zinc producer and operated the largest Spanish zinc plant, the San Juan de Nieva. At yearend, installed capacity in Spain for production of zinc was 110,000 tons per year, and there was 106,000 tons of lead production capacity. Spain was dependent on imports of lead and zinc raw materials to supplement domestic supply. However, this position should improve after all lead-zinc mines become operational.

Mercury.—With the Almáden mercury mine and smelter, Spain remained the largest mercury producer in the world during 1976. Major activities were in developing a new transportation system for ore and materials and preparing two levels (about 12 years of production at present rates) for production. During 1976, ore was brought to the surface through a shaft far from the smelter. A new main haulageway was excavated at the 570-meter level, and a shaft near the smelter will be used for hoisting ore. Production was cut because of low demand, but stocks of mercury increased. However, development of new levels for production continued, financed by the Government, which owned Almáden.

In addition, exploration was underway on a mercury deposit situated approximately 15 kilometers southeast of Almáden. Two new mercury-bearing veins were discovered; preliminary tests indicated that both extended under a river and a road, but opencast mining was considered. The new ore was suitable for smelting in the available smelter. However, a final decision to start a new mine was not arrived at during the year.

At the smelter, which operated far below its capacity of about 70,000 flasks per year, corrosion of condensers remained a major problem. At Almáden, two methods were adopted to combat corrosion. One was to replace cast iron condensers, which have a 1-year life, with condensers made of corrosion-resistant steel, which last 5 years. The other was to replace the condensers with a new unit developed in Almáden. Testing of the new installation, which required large quantities of water, was hampered by extreme drought in the area of Almáden during 1976.

Pyrites.—Production of pyrite was from mines operated by Union Explosivos Rio Tinto and Compania de Azufre y Cobre de Tharis.

Construction of a plant for recovering base metals and pelletizing iron cinders from pyrite for use in the steel industry was underway. When construction of the plant is completed in 1979 or 1980, the Aprovechamiento Integral de Piritas S.A. will process about 1 million tons of pyrite and recover 0.9 million tons of 63% iron pellets, 10,000 tons of copper concentrate, 8,000 tons of 65% lead concentrate, 32,000 tons of 66% zinc concentrate, and lesser quantities of cadmium, silver, and gold.

Exploration activity continued at Sotiel in the Province of Huelva. The decision as to how the orebody would be mined had not been reached, but the management was trying to determine the viability of opencast production from a deposit located far from existing railroads, where the overburden to ore ratio was 10:1 and where the method of benefication was not established. The opencast project called for an annual output of 2 million tons. Reserves, confirmed by drilling, were reported at 42 million tons. In addition to sulfur and iron, average metal content of Sotiel ore was 0.8% copper, 3.1% zinc, and 0.4% lead. A flotation pilot plant was completed at yearend. Contractor and designer for the plant was Metallgesellschaft A.G. of West Germany.

Other Metals.—No major events were reported in production of tin (18 mines), tungsten (5 mines), tin-tungsten (4 mines), antimony (2 mines), and gold and silver (1 mine) during 1976. Output of these mines was of only domestic significance.

NONMETALS

Spain produced a large variety of nonmetals. Their importance was mostly limited to the domestic economy, but potash, ocher, natural sodium sulfate and

celestite were significant by European standards.

Barite.—About 26 barite producers operated mines and plants in Spain during 1976. The principal zone of production was the Espiel area of Cordoba. The major producer in the Espiel area was Minas de Baritina S.A., a subsidiary of Kali-Chemie A.G. of West Germany, which operated a 50,000-ton-per-year barite plant producing high-quality oil-well-drilling grades.

Celestite.—Spain remained one of the few world sources of the strontium mineral celestite. Together with the United Kingdom, Spain provided the only commercial output in Europe. The output came from an operation situated at Montevive, Granada.

Cement.—Spain was among the world's principal exporters of cement during 1976. Production capacity of the Spanish cement industry was 34 million tons at yearend. The following companies were among the largest producers during 1976: Cía. General de Asfaltos y Portland Asland S.A., Barcelona (4.2 million tons of kiln capacity, seven plants); Portland Vardirrivas S.A., Madrid (2 million tons, two plants); Cementos Uniland S.A., Barcelona (1.9 million tons, two plants); and Compania Valenciana de Cementos Portland S.A. (1.9 million tons, three plants).

Mineral Pigments. — *Ocher.* — During 1976, a new 12,000-ton-per-year plant for production of superfine and micronized grades of red oxide was under construction in Malaga. The investor was Oxidos Rojos de Malaga S.A., a subsidiary of Golden Valley Colours Ltd. of the United Kingdom.

In Spain, seven mines produced ocher. Most of the mines were situated in the Provinces of Jaen and Granada. The crude ore was processed in Malaga by Oxidos Rojos de Malaga S.A. and in Almeira by Oxidos del Sur S.A.

In addition, Spain produced red, yellow, and black oxides in the Saragoza area. Most of the production of oxides was exported.

Potash.—Four potash mines were in production during 1976. Three were located in the Province of Barcelona, but one mine in Navarra accounted for about 34% of the output. At Minas de Potasa de Suria, work continued to increase annual output by 50,000 of K_2O and reach production of 200,000 tons per year in 1980. The program included development of a new mine in the Suria area.

Potasas de Navara started development of new zones within the potash deposit near Pamplona. To be able to handle additional ore, capacity for carnallite beneficiation in the area will be increased to 150,000 tons of K_2O by 1978–79.

Salt.—Rock salt, salt from brine, and marine salt were sources of supply in Spain during 1976. Domestic output was adequate to meet demand. Some exports were made, mostly marine salt from a new, large operation (annual capacity 500,000 to 1 million tons), situated at Torrevieja (Alicante) and owned by Union Salinera de España S.A.

The largest rock salt producer remained Solvay Cie. S.A. (part of Belgian Solvay Group, with the Polanco mine near Santander), with an annual capacity over 1 million tons. Potasas de Navarra produced salt as a byproduct of potash mining in Navarra. Another rock salt producer was Industrial Salinera Aragonesa.

Brine salt was produced at 59 operations. However, three producers, located in Alicante, accounted for 27% of total brine salt output.

Sodium Sulfate.—Although thenardite and glauberite occurred at a number of locations, only two mines were in operation in Spain: El Castilar thenardite mine at Villarubia de Santiago in Toledo Province, operated by Union Salinera de España S.A.; and the glauberite mine at Cerezo del Rio Tiron in the Province of Burgos, operated by Criaderos Minerales y Derivados S.A.

Other Nonmetals.—Recent trends in output of other nonmetallics are shown in table 1. For selected commodities the approximate number of producing facilities are listed in the following tabulation:

Commodity	Number of facilities	Provinces with largest output and number of facilities
Andalusite	8	Coruña (7), Pontevedra (1)
Bentonite	26	Almeria (21), Madrid (3), Toledo (2)
Kaolin	125	Valencia (33), Teruel (25)
Feldspar	14	Lugo (3), Madrid (2)
Fluorspar	20	Oviedo (10)
Magnesite	3	Madrid (1), Lugo (1), Navarra (1)
Quartz	20	Coruña (4), Guadalajara (3), Vizcaya (3)
Sand and gravel	536	Barcelona (76), Madrid (35), Burgos (38), Oviedo (29), Baleares (22)
Gypsum	343	Barcelona (19), Murcia (19), Zaragoza (23), Alicante (18)

MINERAL FUELS

Petroleum, mostly imported, remained the principal source of energy in Spain. During 1976, about 83% of Spain's apparent fuels consumption was met through imports. Crude oil and petroleum refinery products accounted for about 94% of fuels imports. Coal was the principal fuel produced in the country and provided 13% of apparent fuel consumption. However, additional imports of high-rank coals were necessary to meet demand. Table 4 shows supply and apparent consumption of fuels and power for 1975 and 1976 in million tons of standard coal equivalent (SCE).

Approximately 60,000 persons were employed in the fuel industry of Spain.

Coal.—Activities in the coal industry included expansion and renovation of coal mines, stimulated by the tax relief and credit policies of the Government. During 1976, a number of firms within the coal mining sector entered into Concerted Action Agreements with the Spanish Government for the purpose of increasing coal production. These agreements call for an output of 33.7 million tons of coal by 1980.

Development of the Meirama and Puentes de Garcia Rodriguez lignite deposits, both in the Province of La Coruña, were among the major projects related to Concerted Action Agreements. The Meirama deposit, with 70 million tons of proven reserves of lignite (calorific value 2,000 kilocalories per

Table 4.—Spain: Supply and apparent consumption of fuels and power in 1975 and 1976

(Million tons of standard coal equivalent [1])

	Total energy	Coal and coke	Petroleum and refinery products	Natural gas	Fuelwood	Hydroelectric power and nuclear power
1975:						
Production	19.9	12.7	2.6	(2)	(2)	4.6
Imports	66.8	4.3	62.5	(2)	(2)	(2)
Exports	4.0	(2)	4.0	(2)	(2)	(2)
Apparent consumption	82.7	17.0	61.1	(2)	(2)	4.6
1976:

Imports	77.8	4.8	73.0	(2)	(2)	(2)
Exports	4.5	.1	4.4	(2)	(2)	(2)
Apparent consumption	93.5	17.1	72.1	(2)	(2)	4.3

[1] 1 ton standard coal equivalent (SCE) = 7,000,000 kilocalories.
[2] Less than 0.01 million tons of standard coal equivalent.

kilogram), was planned for an opencast mine. The mining will be in two phases. During the first phase, benches will be 10 meters high, and 1,320-cubic-meter-per-hour shovels will be used. During the second phase, benches will be 30 meters high, and 6-cubic-meter draglines will be used. When in operation, mine output should reach 24 million tons per year.

A 122-million-ton-per-year opencast lignite mine was under development at Puentes de Garcia Rodriguez. Reserves were reported at 350 million tons of lignite (1,800 kilocalories per kilogram). The mine will have benches 35 meters high and will use 1,400- and 1,800-cubic-meter bucket wheels.

During 1976, Spain produced anthracite (69 mines), bituminous coal (39 mines), and lignite (34 mines). The Provinces of Oviedo and Leon were the largest producers of anthracite and bituminous coal. Most of the lignite was produced in the Provinces of Tereul, Barcelona, and Coruna. Imports of coal, mostly coking coals, were an important part of the supply.

At yearend 1976, a formed-coke plant went onstream near the port of Musel, north Spain. Annual processing capacity was 7.6 million tons of coal, and there was 800,000 tons of storage space. The total investment exceeded $36.8 million.

Petroleum and Natural Gas.—During 1976, domestic output of crude oil and natural gas was modest, and Spain remained almost totally dependent on imported crude oil and natural gas. Exploration, both offshore and onshore, continued in an effort to lessen this dependence.

Onshore exploration, including field geology and seismic, was conducted in the Provinces of Logrono, Gerona, and Galicia and near Barcelona. Most of the onshore wells were dry. Onshore production declined, leaving offshore areas as the most promising regions for future oil and gas production.

Exploration, both seismic and drilling, was concentrated in the Mediterranean and in the Bay of Biscay off the northern coast of Spain. Results of exploration were mixed. The drilling in the Gulf of Cadiz and off Andalusia was negative, the importance of the Mediterranean between Barcelona and Valencia was confirmed, and a discovery was made in the waters of Asturia in northern Spain.

The most significant event of the year was the confirmation of Chevron's discovery of oil in the Casablanca Field, situated west of the Amposta Field. Based on a flow test of 9,500 barrels per day, reserves were reestimated at 225 million barrels. Reserves of that magnitude make the Casablanca discovery the most important one in the northern Mediterranean. In addition, Shell's Castellon B–5 well produced 7,100 barrels per day during one test. This well confirmed results of drilling with well Castellon B–2 and establishment of a modest oilfield, Tarraco. Shell announced discovery of oil in Mare Cantabrico, offshore Asturias. Tests showed an output of 7,000 barrels of crude oil per day, but further drilling is needed for evaluation of the discovery.

A large new oil port was under construction near Bilbao; partial operation had started during 1975. The new port will have facilities for berthing ships of up to 500,000 deadweight tons. Completion of construction was expected during 1977.

Two new oilfields, one near Burgos and one near Tarragona (total yearly output, about 2 million tons), and 10 refineries (installed capacity, 59.6 million tons) were in operation in Spain during 1976; the refineries operated at 70% of installed capacity. The following tabulation shows operational petroleum refineries in Spain:

Company	Location	Annual capacity (million tons)
Empresa Nacional del Petróleo, S.A. (ENPETROL)	Escombreras	10
Do	Puertollano	6
Do	Tarragona	7
Compania Iberica Refinadora de Petróleos, S.A. (PETROLIBER)	La Coruña	5
Compania Española de Petróleos, S.A. (CEPSA)	Santa Cruz de Tenerife	8
Do	Algeciras	6.5
Petróleos del Mediterraneo, S.A. (PETROMED)	Castellon de la Plana	4
Union Explosivos Rio Tinto, S.A. (ERT)	Huelva	4
Refineria de Petróleos del Norte, S.A. (PETRONOR)	Somorrostro	8
Asfaltos Españoles S.A. (ASESA)	Tarragona	1.1
Total		59.6

Retail prices for petroleum refinery products during 1975 and 1976 are shown below in cents per gallon (except for bunker "C" fuel oil, which is given in cents per 42-gallon barrels):[3]

	July 1976	July 1975
Motor gasoline:		
Regular	121	113.6
Premium	150	129.8
Household kerosine	69	64.9
Motor lubricating oil	472	454.1
Distillate fuel oil	40	34.5
Bunker "C" fuel oil	1,143.6	1,108.6

The modest domestic output of natural gas was far below the country's demand. Imports of liquefied natural gas were supplied largely by SONATRACH of Algeria. Construction was underway during the year to expand the Barcelona regasification plant to 240 million cubic feet per day.

The preliminary study for building a gas pipeline between Algeria and Spain was completed in 1976. Sociedad de Estudios del Gasoducto Mediterraneo Occidental, formed in 1972 by SONATRACH of Algeria (50%), Gas de France (25%), and ENAGAS (25%), coordinated and financed the study.

Uranium.—Spain became a regular producer of uranium concentrate, (yellow cake U_3O_8) during 1976. After a trial production, which started in May 1975, a 112-ton-per-year U_3O_8 concentrator, situated in Ciudad Rodrigo, was fully operational in 1976. Uranium mines in the area supplied ore to the plant. The installation was operated by Empresa Nacional del Uranio S.A. (ENUSA), a company owned 60% by the Government of Spain through INI and the rest by seven Spanish utility companies. Development of another uranium deposit continued in Ciudad Rodrigo, and expansion of the existing concentrator was underway. The objective was to create a uranium mining and beneficiation complex with a capacity of 600 tons of U_3O_8 by 1979. Construction of nuclear power plants continued in Spain. Three nuclear powerplants (1,120 megawatts electrical), were in operation and five (6,555 megawatts electrical) were under construction.

The Mineral Industry of Sweden

By Joseph B. Huvos [1]

In 1976, the mineral industry of Sweden remained small but technologically advanced. Sweden was one of the world's largest iron ore producers and exporters and there was a significant production of nonferrous metals and hydroelectric power. Fossil fuels and many important industrial minerals were imported. The most important mineral products of the country and approximate percentages of world totals were as follows: White arsenic, 20%; selenium, 4%; iron ore, 3%; lead (mine), 2%; lead (smelter), 1%; zinc (mine), 2%; pyrite, 2%; feldspar, 2%; copper (mine), 0.6%; copper (refined), 0.7%; and tungsten, 0.5%.

In 1976, Sweden's gross national product (GNP) was about $74 billion.[2 3] Mining and quarrying including stone and clays contributed approximately 2%; iron and steel and metals, about 2%; and the chemical industry, 3%. The national labor force was about 4.1 million.

The recovery of the economy was delayed by slower than expected economic recovery abroad; the Government attempted to dampen the growth of consumer demand by higher taxes and maintained a full employment policy.

Indices of mineral industry production in 1975–76 are shown in the following tabulation:

Industry sector	1968=100	
	1975	1976
Iron ore mining	117	111
Nonmetallic mineral products	95	89
Base metal industries	121	117
Mining, quarrying, manufacturing	130	129

There were many significant developments in Sweden's mineral industry in 1976. The Government made studies for reorganizing the country's steel industry. The "Steelwork 80" project was shelved. Boliden AB reorganized its corporate structure; the company's Stekkenjåkk mine was commissioned; Société des Mines et Fonderies de Zinc de la Vieille Montagne S.A. completed the expansion of its Åmmeberg mine; and construction at Luossavaara-Kiirunavaara AB's (LKAB) maritime iron ore loading facilities continued. Finally, Boliden closed two mines and Surhammars Bruks AB closed three mines.

PRODUCTION

In 1976, production of many mineral industry products continued to decrease because of a slow recovery in export markets. Production of mineral commodities is shown in table 1. The following tabulation shows major producers of commodities:

Commodity	Major companies, principal facilities, and ownership	Percent of domestic output
Aluminum	Gränges Aluminium AB, smelter at Sundsvall, Gränges AB 79%, Alcan Aluminum Ltd. 21%	100
Cement	Cementa AB, plants at Slite, Limhamn, Skövde, Hällekis, Stora Vika, and Degerhamn, Industri AB Euroc 95%; LKAB 5%	100
Copper	Boliden AB, mine at Aitik, smelter at Rönnskär, Royale Asturienne des Mines, Belgium	85
Do	Stora Kopparbergs Bergslags AB (SKB), mine at Falun	15
Ferroalloys	Airco Alloys AB, plant at Vargon, AB Airco Inc., United States	50
Do	AB Ferrolegeringar, plant at Trollhättan, Metallurg Inc., United States	30
Iron ore	LKAB, mines at Kiirunavaara, Tuolluvaara, Leveäniemi, and Nukutusvaara, Government	83
Do	Gränges AB, mines at Grängesberg and Stråssa, Vestra Ormbergs Grufve AB	5
Do	SKB, mines at Dännemora, Rikberg, Håksberg, Blötberg, and Vintjärn	5
Iron and steel	SKB, plant at Domnarvet	40
Do	Gränges Stål AB, plant at Oxelösund, Vestra Ormbergs Grufve AB	33
Do	Norbottens Järnverk A/S (NJA), plant at Luleå, Government	27
Lead and zinc	Boliden AB, mine at Laisvall, lead smelter at Rönnskär	70
Do	Vieille-Montagne, mine at Åmmeberg, Vieille Montagne, Belgium	30
Petroleum products	Skandinavska Raffinaderi AB (Scanraff), refinery at Lysekil, Government, Texaco Oil AB	40
Do	BP Raffinaderi AB, refinery at Göteborg, BP	27
Do	Koppartrans Olje AB, refinery at Göteborg, Svenska Shell	24
Pyrite	Boliden AB, mines at Falun, Långsele, Kristineberg, Rävliden, and Rutjebäcken	90
Tungsten	LKAB, mine at Yxsjöberg	100

[e] Estimate. [p] Preliminary. [r] Revised. NA Not available.

[1] In addition to the commodities listed, cobalt, nickel (as nickel sulfate) and metallic titanium are also produced but output is not reported and available information is inadequate to make reliable estimates of output levels.

[2] Production of sponge iron is as follows in thousand tons: 1974—197; 1975—175; 1976—187.

[3] Represents material for sale, not produced.

[4] Includes strontium minerals, unspecified minerals, and fragments of ceramic materials.

TRADE

Export market conditions caused Sweden's trade deficit to almost double in 1976. Otherwise there was no major change in the country's mineral trade pattern. Sweden continued to trade with about 170 countries, although the bulk of the trade was with the other Scandinavian countries and West Europe. The main mineral commodities exported in 1976 included iron and steel, iron ore, and nonferrous metals.

Trade statistics for mineral commodities in 1974 and 1975 are shown in tables 2 and 3.

Metal including alloys:			
Scrap	353	932	France 584; West Germany 148; Belgium-Luxembourg 136.
Unwrought	20,632	22,202	United Kingdom 6,235; West Germany 5,368; Finland 4,316; France 2,667.
Semimanufactures	53,015	46,308	Norway 10,081; Denmark 5,968; United States 5,772; Algeria 5,000.
Iron and steel:			
Ore and concentrate, except roasted pyrite thousand tons--	33,105	23,081	West Germany 5,463; Belgium-Luxembourg 4,988; Netherlands 3,980; United Kingdom 2,742.
Roasted pyrite ---------do----	418	430	United Kingdom 307; West Germany 82.
Metal:			
Scrap ---------do----	11	11	West Germany 7; Belgium-Luxembourg 2; Denmark 2.
Pig iron [2] ---------do----	313	283	Italy 98; United States 55; Finland 38.
Ferroalloys ---------do----	85	67	United Kingdom 23; West Germany 17; United States 7.
Steel, primary forms ---------do----	189	120	West Germany 68; Denmark 22; Finland 12.
Semimanufactures:			
Bars, rods, angles, shapes, sections ---------do----	591	457	United Kingdom 80; Denmark 51; Finland 45.
Universals, plates, sheets --do----	792	737	West Germany 141; Denmark 133; Norway 84.
Hoop and strip ---------do----	92	69	Finland 8; Denmark 7.
Rails and accessories -----do----	26	25	East Germany 12; Norway 9; West Germany 3.
Wire ---------do----	82	58	United States 9; West Germany 7.
Tubes, pipes, fittings -----do----	242	200	West Germany 22.
Castings and forgings, rough do----	3	3	Denmark 1; Finland 1; Norway 1.
Lead:			
Ore and concentrate	46,690	49,520	West Germany 33,924; Belgium-Luxembourg 10,672.
Oxides	577	293	NA.
Metal including alloys, all forms	29,396	28,188	West Germany 12,005; Italy 6,495; Finland 3,511; Denmark 3,398.
Magnesium metal including alloys:			
Scrap	214	299	United States 114; West Germany 86; Netherlands 33.
Unwrought and semimanufactures	15	NA	
Mercury ---------76-pound flasks--	203	145	Denmark 58; Finland 29; West Germany 29.
Molybdenum ore and concentrate	416	884	Belgium-Luxembourg 507; United Kingdom 256.
Nickel:			
Metal including alloys:			
Scrap	622	714	West Germany 313; United Kingdom 108.
Unwrought	2,507	2,902	Netherlands 2,430; United States 385.
Semimanufactures	2,287	2,100	Brazil 393; Romania 284.

See footnotes at end of table.

Table 2.—Sweden: Exports of mineral commodities—Continued

(Metric tons unless otherwise specified)

Commodity	1974	1975	Principal destinations, 1975
METALS—Continued			
Platinum-group metals and silver:			
Waste and sweepings, value, thousands	$8,980	$8,435	West Germany $3,695; United Kingdom $2,596; Norway $1,364.
Metal including alloys, unworked or partly worked:			
Platinum group, do.	$1,064	$642	Finland $468; Denmark $83.
Silver, thousand troy ounces	4,501	8,198	Norway 64; Denmark 32; West Germany 32; Mexico 32.
Silicon, elemental	14,655	9,587	East Germany 2,200; West Germany 1,872; United Kingdom 1,338; U.S.S.R. 1,008; Czechoslovakia 958.
Tin metal including alloys:			
Scrap	14	14	Norway 13.
Unwrought and semimanufactures	90	83	Netherlands 56; Finland 22.
Titanium:			
Ore and concentrate	72	NA	
Oxides	242	76	Norway 37; Finland 31.
Tungsten:			
Ore and concentrate	33	NA	
Metal	99	101	West Germany 65; Poland 10.
Zinc:			
Ore and concentrate	231,066	210,112	West Germany 79,675; Belgium-Luxembourg 48,117; Norway 45,785.
Oxide and peroxide	477	520	Norway 198; United Kingdom 171; Turkey 70.
Metal including alloys:			
Powder	84	75	Denmark 32; Norway 21; Netherlands 12; Greece 8.
Scrap	1,103	511	United Kingdom 106; West Germany 82; Norway 73; Belgium-Luxembourg 67; Italy 63.
Unwrought and semimanufactures	2,044	582	Norway 273; United Kingdom 81.
Zirconium ore and concentrate	62	14	All to Norway.
Other:			
Ash and residues containing nonferrous metals	32,526	33,663	Norway 28,239.
Oxides, hydroxides, peroxides of metals, n.e.s	59	14	West Germany 5; Netherlands 5; Brazil 3.
Base metals including alloys, all forms	913	1,296	West Germany 368; Netherlands 259; United Kingdom 241.
Unspecified	7	5	Denmark 2; Finland 1; West Germany 1.
NONMETALS			
Abrasives, natural, n.e.s.:			
Pumice, emery, natural corundum, etc value, thousands	$6	$8	Finland $3.
Dust and powder of precious and semi-precious stones, do.	$4	$30	U.S.S.R. $24; Netherlands $3.
Grinding and polishing wheels and stones	2,558	2,413	West Germany 427; Finland 364; Denmark 288.
Asbestos	60	173	Norway 140; Finland 17.
Borates, crude	122	NA	
Cement, hydraulic	473,405	337,282	NA.
Chalk	9,383	7,446	Denmark 3,024; Norway 2,058; Finland 830.
Clays and clay products (including all refractory brick):			
Crude clays	1,201	966	Denmark 326; Norway 307.
Products:			
Refractory (including nonclay bricks)	37,789	29,466	Norway 8,584; Finland 6,280; Denmark 5,486.
Nonrefractory	40,913	26,916	Norway 10,253; Denmark 4,552; Finland 2,825; Belgium-Luxembourg 2,722.
Diamond:			
Gem, not set or strung, value, thousands	$3,923	$648	Finland $120; Netherlands $103; Belgium-Luxembourg $100; Denmark $96; Norway $88.
Industrial, do.	$93	$117	Netherlands $35; United Kingdom $29.

See footnotes at end of table.

Table 2.—Sweden: Exports of mineral commodities—Continued

(Metric tons unless otherwise specified)

Commodity	1974	1975	Principal destinations, 1975
NONMETALS—Continued			
Diatomite and other infusorial earth	216	124	Norway 70; Finland 33.
Feldspar, fluorspar, etc	39,412	32,157	United Kingdom 14,619; East Germany 8,679.
Fertilizer materials:			
Crude phosphatic	22,200	23,617	Norway 23,615.
Manufactured:			
Nitrogenous	88,521	56,220	East Germany 4,862; Finland 3,785; Ireland 3,389.
Phosphatic	173,041	59,287	Norway 4,953.
Potassic	—	1,803	All to Belgium-Luxembourg.
Other including mixed	19,598	7,358	Norway 6,322.
Graphite, natural	246	73	All to West Germany.
Gypsum and plasters	1,224	138	NA.
Lime	2,236	584	Norway 538.
Magnesite	1,060	84	Denmark 25; Norway 23; United States 16.
Mica including splittings and waste	5	13	United Kingdom 10.
Pigments, mineral:			
Crude	20	9	All to Sri Lanka.
Iron oxide	101	76	Finland 29; Norway 24; Belgium-Luxembourg 10.
Salt and brine	730	261	Norway 206.
Stone, sand and gravel:			
Dimension stone:			
Crude or partly worked:			
Granite, gneiss, sandstone, etc	325,581	74,517	West Germany 21,737; Italy 13,927; Japan 13,827; Denmark 9,760.
Marble and other calcareous	2,670	2,324	Denmark 1,813; Netherlands 293.
Slate	10,570	11,614	Norway 6,076; Belgium-Luxembourg 3,730.
Worked	15,273	15,066	Denmark 11,788.
Dolomite, chiefly refractory grade	4,628	3,424	Norway 1,921; Finland 749; Denmark 712.
Gravel and crushed stone—thousand tons	1,382	1,551	West Germany 791; Denmark 528; Poland 139; Norway 65.
Limestone	858,204	738,944	Finland 372,916; West Germany 243,187; Denmark 121,095.
Quartz and quartzite	124,847	91,928	Norway 50,868; West Germany 18,699.
Sand, excluding metal bearing	62,894	87,799	Norway 51,445; Poland 20,506; Denmark 11,070.
Sulfur:			
Sulfuric acid	73,075	69,730	Canada 61,252.
Sulfur dioxide	9,952	11,360	Norway 10,540.
Talc, steatite, soapstone, pyrophyllite	3,590	4,110	United Kingdom 2,896; Netherlands 524.
Other nonmetals, n.e.s.:			
Crude	19,603	9,870	Denmark 4,992; Norway 4,023.
Slag, dross and similar waste, not metal bearing	150,815	122,927	East Germany 45,939; Norway 26,712; United Kingdom 23,994; Finland 16,436.
Oxides and hydroxides of magnesium, strontium, barium	65	53	Denmark 19; Ireland 13; Brazil 7.
MINERAL FUELS AND RELATED MATERIALS			
Asphalt, natural	36	20	Denmark 10.
Carbon black	6,069	6,822	Finland 2,864; Norway 2,811; Denmark 756.
Coal and coke including briquets	83,056	51,354	West Germany 24,005; Finland 15,204; Denmark 8,676.
Hydrogen, nitrogen, rare gases	3,151	2,848	Denmark 2,480.
Peat including briquets and litter	18,349	18,250	Denmark 9,662; Norway 6,195.
Petroleum refinery products:			
Gasoline —thousand 42-gallon barrels	708	1,413	Denmark 587; Norway 456.
Jet fuel —do	226	249	United Kingdom 194; Denmark 40.
Kerosine —do	72	98	Norway 89.
Distillate fuel oil —do	1,747	3,466	Denmark 2,269; Norway 967.
Residual fuel oil —do	2,506	5,403	Denmark 3,916; Norway 1,052.
Lubricants —do	552	452	Norway 138; Finland 86; Denmark 84; United Kingdom 72.

See footnotes at end of table.

Table 2.—Sweden: Exports of mineral commodities—Continued

(Metric tons unless otherwise specified)

Commodity	1974	1975	Principal destinations, 1975
MINERAL FUELS AND RELATED MATERIALS —Continued			
Petroleum refinery products—Continued			
Other:			
Liquefied petroleum gas thousand 42-gallon barrels	249	153	Norway 82; Denmark 56.
Unspecified ---do---	3,500	398	Denmark 169; Norway 123; Finland 58.
Total ---do---	9,560	11,632	
Mineral tar and other coal-, petroleum-, or gas-derived crude chemicals	9,069	18,019	United Kingdom 6,345; Netherlands 5,691; Belgium-Luxembourg 5,176.

NA Not available.
[1] Less than ½ unit.
[2] Includes shot, grit, spiegeleisen, etc. of iron and steel.

Table 3.—Sweden: Imports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1974	1975	Principal sources, 1975
METALS			
Aluminum:			
Bauxite and concentrate	97,121	68,042	Greece 39,406; Australia 12,857; Guyana 10,872.
Alumina	188,165	220,221	Jamaica 123,237; West Germany 47,191; Surinam 43,894.
Metal including alloys:			
Scrap	1,947	1,140	Romania 479; Norway 208.
Unwrought	54,360	43,772	Norway 19,983; Ghana 8,471; United Kingdom 5,030.
Semimanufactures	50,071	48,546	Norway 9,871; West Germany 7,433; Austria 6,610.
Chromium:			
Chromite	270,287	395,735	U.S.S.R. 180,574; Turkey 83,354; Finland 58,991.
Oxide and hydroxide	2,594	2,250	West Germany 1,144; U.S.S.R. 580.
Cobalt oxide and hydroxide	5	3	Belgium-Luxembourg 2; United Kingdom 1.
Copper:			
Ore and concentrate	40,360	56,387	Norway 31,155; Ireland 13,984; Canada 8,955.
Matte	3,118	6,685	France 6,666.
Metal including alloys:			
Scrap	5,036	8,485	United States 2,568; France 2,325; Finland 1,823.
Unwrought	70,399	75,003	Chile 19,217; Belgium-Luxembourg 16,221; Zambia 13,057. Canada 9,269.
Semimanufactures	27,182	28,461	United Kingdom 8,888; West Germany 5,363; Finland 3,719.
Iron and steel:			
Ore and concentrate, except roasted pyrite	82,000	319,000	Liberia 280,000; Brazil 38,000.
Metal:			
Scrap	368,234	338,144	United States 99,628; U.S.S.R. 95,996; Denmark 53,357.
Pig iron, including cast iron	216,013	223,820	East Germany 74,766; Finland 66,600; West Germany 25,742.
Ferroalloys	214,596	185,590	Norway 75,739.
Steel, primary forms	141,030	216,602	Finland 158,566; West Germany 41,625.
Semimanufactures:			
Bars, rods, angles, shapes, sections	576,079	783,618	West Germany 152,119; Belgium-Luxembourg 123,453.
Universals, plates, sheets	1,098,594	1,039,392	West Germany 185,714; Belgium-Luxembourg 166,769; Japan 160,545; Italy 133,728.
Hoop and strip	129,059	102,585	West Germany 29,843; Poland 18,592; Belgium-Luxembourg 13,155.

See footnote at end of table.

COMMODITY REVIEW

METALS

Aluminum.—In 1976, the upturn in the market enabled Gränges Aluminium AB, a subsidiary of Gränges AB, and Sweden's only producer of primary aluminum, to increase metal production to 98% of its capacity. The company's 85,000-ton-per-year reduction plant was located at Sundsvall on the Baltic about 300 kilometers north of Stockholm. The company's Avesta secondary smelter, 100 kilometers northwest of Stockholm, remelted 13,000 tons of scrap in 1976, which was near its capacity.[4]

Copper, Lead, and Zinc.—In 1976, Boliden AB started regular operations at the Stekenjåkk copper-zinc mine located near the Norwegian border in Västerbotten County. The mine, leased from the Government and developed since 1973 by Boliden, was provided in 1976 with a 400,000-ton-per-year flotation plant. Adak, another mining concession, leased by Boliden from the Government and located north of Malå in Norbotten County, began to be phased out according to plans, with the closing of the Brännmyra mine. Because of the lagging economy, exploration at Boliden's mines fell slightly behind in replacing depleted reserves.[5]

SKB almost completed the rebuilding and modernization of the concentration plant at its Falun mine in Kopparberg County northwest of Stockholm. At the Falun cop-

[4] Gränges AB. Annual Report 1976, p. 6.
[5] Boliden AB. Annual Report 1976, p. 12.

per works a dust precipitator at the sinter plant and a sulfuric acid plant for smelter gases were completed.[6] AB Statsgruvor continued a large-scale drilling program at the Yxsjöberg mines, located in Örebro County west of Fagersta, and the Stollberg mines, located south of Borlänge in Kopparberg County.

In 1976, Boliden continued to account for most of the copper and lead produced in Sweden and operated the country's only large nonferrous smelter at Rönnskär near Skellefteå on the Gulf of Bothnia. At yearend, Boliden reorganized its structure. Boliden became an operating holding company controlling five Swedish subsidiaries including Boliden Metall AB and Boliden Kemi AB, which were formerly divisions of Boliden. Foreign subsidiaries of Boliden AB such as Norzinc AS, Preussag-Boliden-Blei GmbH (50% owned), and others were not affected.

Sweden's nonferrous sulfide ore mines are shown in the following tabulation:

Company and county	Name of mine	Approximate ore output (thousand tons per year)	Type of ore
Boliden AB:			
Norbotten	Aitik	8,600	Copper.
	Laisvall	1,300	Lead and zinc.
Västerbotten	Långsele	380	Zinc, copper, pyrite.
	Stekenjåkk	370	Copper and zinc.
	Udden	320	Zinc, copper, lead, pyrite.
Kopparberg	Vassbo	310	Lead.
Västerbotten	Kristineberg	270	Copper, zinc, pyrite.
	Näsliden	250	Copper and zinc.
	Rävlidmyr	220	Zinc, copper, lead, pyrite.
Kopparberg	Garpenberg-Odal	200	Zinc, lead, copper.
	Garpenberg-Norra	200	Copper, zinc, lead.
Västerbotten	Adak	190	Copper.
	Renström	160	Copper, zinc, lead.
	Långdals	110	Zinc, copper, lead.
	Rudtjebäck	110	Do.
Kopparberg	Säxberg	90	Do.
Västerbotten	Rävliden	70	Do.
Kopparberg	Gräns	60	Zinc, lead, copper.
Örebro	Ljusnarsberg	20	Copper, zinc, lead.
Västerbotten	Kimheden	1	Copper and pyrite.
Stora Kopparbergs Bergslags AB: Kopparberg	Falun	320	Zinc, copper, lead, pyrite.
Vieille Montagne: Örebro	Ämmeberg	360	Zinc and lead.
AB Statsgruvor:			
Örebro	Yxsjöberg	170	Vanadium and copper.
Kopparberg	Stollberg	180	Zinc, lead, iron.
Total		14,261	

In 1976, Vieille Montagne expanded from 300,000 tons to 600,000 tons of lead-zinc ore per year its Ämmeberg area lead-zinc mines in the Tylo Forest, at the northern tip of Lake Vättern. This made Vieille Montagne, the country's only foreign-owned mining operation, Sweden's largest zinc producer. The expansion included a new haulage shaft, ore mill, and flotation plant and permitted the closing of older facilities. Vieille Montagne, which produced about 30% of Sweden's zinc ore, exported its production to Belgium for processing at the company's smelter.

Iron Ore.—In 1976, iron ore production ran at about 80% of capacity, and deliveries reached 70%. Stockpiles at mines and docks increased to almost a 5-month mine output.

Production cutbacks enabled companies to redeploy more personnel into exploratory and preparatory operations. At LKAB's Kiirunavaara mine in Swedish Lappland, mining operations were terminated at the 420-meter level, leaving the 540-meter level as the main producer. Development continued at 775 meters and exploration at 960 meters. Modernization of the beneficiation plant continued.

At LKAB's Tuolluvaara mine near Kiirunavaara, mining was concentrated mostly on old low phosphorus iron ores. At the mine's Tuollajärvi deposit, development work was halted as ores discovered were mostly of the high phosphorus type. At the company's Leveäniemi mine near Swappavaara, about 25 kilometers southeast of Kiirunavaara, a fourth beneficiation

[6] LKAB. Annual Report 1976, p. 3.

plant was completed and plans were made to expand pelletizing capacity to 3 million tons per year. At Malmberget, development work was well advanced for the new 815-meter haulage level. At the ore loading facilities at Luleå on the Gulf of Bothnia, work continued to expand loading capacity to 10 million tons per year, and at Narvik (Norway), Kiruna's outlet on the Atlantic, construction of a new wharf and storage yard were nearing completion.

In central Sweden, operations were terminated at Surhammars Bruks AB's Eskilback, Mimer, and Kallmorberg mining areas, all in the community of Norberg near Avesta.

Ownership, name, location, and approximate output of ore and concentrates of Swedish iron ore mines in 1975 are shown in the following tabulation:

Company and mine	Location	Quantity (million tons)

Iron and Steel.—In 1976, production of crude steel decreased for the second consecutive year, because of the failure of the international steel market to recover. Inventories reached almost one-third of 1976 production at some mills. The difficulties of Sweden's steel industry have been growing since 1974. There was a wide-based concensus that a large-scale restructuring was essential to restore its competi-

tive position. Two official studies were made for such a reconstruction.

In the first study the specialty steel industry was analyzed. The industry's eight companies, operating 24 steelworks and employing about 36,000 workers, were covered. The proposal recommended merging of the three leading manufacturers, Gränges, Fagersta, and Avesta. It recommended a 10% cut in personnel during the next 3 years, and the merger and shutdown of unprofitable mills. The Government's participation as a partner in the steel industry was also considered.

The second study covered the commercial steel industry, composed of 10 companies operating 11 plants and employing about 18,765 people in 1976. The study recommended the closing of SKB's Domnarvet ore smelting plant and the three smaller open-hearth plants of Boxholm, NJA and Oxelösund. The plan recommended consolidating all ore smelting at NJA and Oxelösund. The plan reccommended also a reduction of the work force to 15,000.

The three largest steel producers, the only ones with ore smelting capability, accounted for 81% of the country's steel capacity. The remaining 19% capacity was divided among seven companies with only scrap smelting capability.

In 1976, because of lower steel demand, "Steelworks 80," the large Government steel project planned at Luleå on the Gulf of Bothnia, was shelved indefinitely. The plant was to have originally a 4-million-ton-per-year steel capacity, reduced later to 2.6 million tons before being shelved.

Tungsten.—Production of scheelite increased in 1976. Selective flotation tests conducted for separating scheelite from copper were encouraging. The process is intended to replace the wet-mechanical concentration process used at present at LKAB's Yxsjöberg mine located near Grängesberg.

Uranium.—LKAB continued experimentally mining a deposit of 6 million tons of Billingen alum shale at Ranstad near Skövde. In a new decision, the uranium processing experiment has been reoriented toward the recovery of all shale components including uranium, alumina, alloying metals, fossil fuels, and fertilizers. A 10-year development plan was to result in mining 1 million tons of shale per year.

NONMETALS

Cement and Limestone.—In 1976, Sweden's cement consumption declined to 7.7 million tons, and exports declined to 100,000 tons. Cementa AB, owned 95% by Industri AB Euroc and 5% by LKAB, remained the country's sole cement producer since 1973. The company controlled seven cement and four limestone plants. Adjustment to the shrinking market continued during the year. Production was reduced at the Limhamn plant in Malmö, and employment decreased by 120. The Köping plant, near Arboga, and the Stora Vika plant, near Nynashamn, were converted to coal, with the rest of the plants to follow. A decision was made to expand the Slite plant on Gotland Island with a 1.5-million-ton dry process unit by 1979. By 1980, only four plants are to handle the present output, all using the dry process.

Fertilizer Materials.—Sweden continued to import all raw materials for producing manufactured fertilizers except nitrogenous fertilizers, about half of which is produced domestically.

Svenska Salpeterverken AB operated the 54,000-ton-per-year Kvantorp and the 49,000-ton-per-year Köping ammonia plants. Uddeholms AB and Elektrokemiska AB each operated one 3,000-ton-per-year plant, located at Skoghall and Bottun.

In 1976, Sweden's agricultural sector used limestone equivalent to 650,000 tons of CaO.

Other Nonmetals.—In 1976, Sweden's sole feldspar producer, the LKAB-owned AB Forshammars Bergwerk, almost doubled sales from its Forshammar feldspar mine, located east of Kopparberg. The company purchased the Swedish Silica Works, enabling it to build up a market for silica products. Sales of quartzite from Forshammar and Ånimskog mines south of Mellerud also nearly doubled.

Sweden's only olivine producer, the Höganäs AB-owned Handöls Taljstens AB, operated its olivine mine at Handöl on the Norwegian border facing Trondheim, producing 10,000 to 20,000 tons of olivine per year for Höganäs' refractories.

Production of fluorspar concentrate continued without change at AB Stätsgruvor's Stollberg mine in Örebro County.

MINERAL FUELS

In 1976, Sweden supplied one-fifth of her energy needs domestically from hydroelectric power and fuelwood. The rest was imported petroleum, coal, and some enriched uranium fuel.

The Board of Energy Research prepared a study on Sweden's energy supply through the year 2000. In particular, the study should make it possible to decide the appropriate rate of development for nuclear power, hydroelectric power, and imports of fossil fuels including natural gas. Nuclear and hydroelectric power remain at present controversial subjects.

Supply and apparent consumption of fuels and power in 1975–76 are shown in table 4.

Table 4.—Sweden: Supply and apparent consumption of fuels and power for 1975 and 1976

(Million tons of standard coal equivalent [1])

	Total energy	Coal and coke	Petroleum and refinery products	Black liquor, fuelwood, and waste	Hydroelectric power [2]	Nuclear power [3]
1975:						
Production [4]	12.4	0.1	--	5.2	7.1	--
Imports	51.9	2.7	47.0	--	.8	1.4
Exports	5.4	(5)	4.7	--	.7	--
Apparent consumption	58.9	2.8	42.3	5.2	7.2	1.4
1976 p:						
Production [4]	12.1	.1	--	5.3	6.7	--
Imports	57.1	3.1	51.4	--	.8	1.8
Exports	4.7	--	4.1	--	.6	--
Apparent consumption	64.5	3.2	47.3	5.3	6.9	1.8

p Preliminary.
[1] 1 ton standard coal equivalent (SCE) = 7,000,000 kilocalories.
[2] Includes foreign trade of all electric power.
[3] Thermal burnoff of imported uranium fuel.
[4] Includes only primary energy.
[5] Insignificant.

Coal, Coke, and Peat.—In 1976, Höganäs AB continued to produce marginal quantities of coal near Skäne near Lake Vänern. Sweden continued to import its coal and coke requirements; however, about one-third of coke used was domestically produced. There was a modest production of peat at several locations throughout the country.

Hydroelectric Power.—In 1976, further expansion of the country's hydroelectric power was delayed. Originally the Swedish Parliament's 2-year-old energy program was to provide an additional 5 million megawatt-hours of electricity per year by 1985. Sweden's present hydroelectric installations comprise a capacity of about 12,900 megawatts.

Nuclear Power.—In 1976, nuclear power remained a controversial subject in Sweden, and there was uncertainty about the rate of future development. During 1976, there were five nuclear powerplants in operation, totaling 3,180 megawatts; one plant was to be commissioned in 1977 (the second 580-megawatt unit at Barsebäck near Malmö), and four other plants were under construction.

Petroleum.—In 1976, marginal production from small discoveries continued in the Gotland Island area. Drilling was suspended for lack of funds and further plans were under discussion.

The country's refining capacity (throughput) remained unchanged with about 20.7 million tons at six locations as shown in the following tabulation:

Company	Principal facilities and ownership	Approximate throughput (million tons per year)
Skandinavska Raffinaderi AB (Scanraff)	Lysekill (Government, Texaco Oil AB)	8.3
BP Raffinaderi AB	Göteborg (BP)	5.5
Koppartrans Olje AB	Göteborg (Shell)	5.0
AB Nynas Petroleum	Nynashamn (Rederi AB Nordstjernan)	1.4
Do	Göteborg	.3
Do	Malmö	.2

The Mineral Industry of Switzerland

By Roman V. Sondermayer [1]

In 1976, landlocked Switzerland was a producer of nonmetals, a processor of imported raw materials, and an exporter of finished products. Aluminum, steel, petroleum products, salt, and construction materials were the commodities produced. Significance of the minerals industry remained local; it contributed about 2% to the gross national product (GNP) and employed 1.4% of the total labor force. The inflation rate was about 3%. No major events related to the mineral industry were reported during 1976.

PRODUCTION

Downward trends in production continued. The mineral industry was privately owned with modern and efficient facilities. The following tabulation shows principal companies in operation in Switzerland during 1976:

[1] Physical scientist, International Data and Analysis.

Commodity	Major companies, principal facilities, and ownership	Percent of domestic output
Aluminum	Schweizerische Aluminium AG, plants at Steg and Chippis	80
Cement	Cement Werk Wuerenlingen, plant at Siggenthal	36
Petroleum refined	Raffinerie du Sud-Ouest S.A., owned by BP Benzin, Ente Nazionale Idrocarburi (ENI), Esso Standard (Switzerland), refinery at Collombey	40
Do	Raffinerie de Cressier S.A., owned by Shell Oil Petroleum N.V. and Gulf Oil, Great Britain, Ltd., refinery at Cressier	40
Do	Raffinerie Rheintal S.A., owned by ENI, refinery at Sennwald	20
Steel, crude	Von Roll Ltd., plant at Gerlafingen	50

[e] Estimate. [p] Preliminary. [r] Revised.
[1] In addition to the commodities listed, a variety of crude construction materials (common clay, sand, gravel, and stone) are undoubtedly produced, but output is unreported and available general information is inadequate to make reliable estimates of output levels.

TRADE

The mineral trade of Switzerland was not a complete reflection of activities in the mineral industry of the country. Many strictly commercial transactions in mineral commodities were recorded as imports and exports. The value of mineral imports was $2.5 billion or 19% of total imports in 1975, the latest year for which complete data were available. Fuels accounted for 54% of mineral imports. Value of mineral exports was $0.5 billion, or 4% of total exports. Tables 2 and 3 show details of Swiss foreign trade in minerals and related commodities.

Universals, plates, sheets	5,438	9,322	France 2,584; West Germany 2,442; Austria 2,430.
Hoop and strip	10,459	12,029	Austria 7,080; West Germany 3,946.
Rails and accessories	3,406	2,069	Greece 546; France 354; Colombia 291.
Wire	3,435	3,104	Austria 556; West Germany 525.
Tubes, pipes, fittings	83,285	90,053	West Germany 16,779; Austria 12,777; Netherlands 8,288.
Castings and forgings, rough	946	624	West Germany 354; Austria 65; Denmark 65.
Ingots and semimanufactures, alloy steel and high carbon	14,251	18,330	Italy 8,446; France 4,244.
Lead:			
Ore and concentrate ——kilograms—	—	25	NA.
Oxides	70	71	Austria 68.
Metal including alloys:			
Scrap	9,105	5,485	Austria 2,063; Italy 1,717.
Unwrought	1,391	1,768	Italy 1,374; France 228.
Semimanufactures	56	58	Belgium-Luxembourg 30; France 10.
Magnesium metal including alloys, all forms	259	367	West Germany 145; United Kingdom 73.
Manganese oxides	11	41	United Kingdom 18; Sweden 17.
Mercury ——76-pound flasks—	141	97	Netherlands 25; France 20; Bulgaria 17.
Molybdenum metal including alloys, all forms	1	4	United Kingdom 3.
Nickel:			
Matte, speiss, similar materials	225	129	West Germany 120.
Metal including alloys:			
Scrap	843	334	West Germany 260; Italy 65.
Unwrought and semimanufactures	r 1,170	1,634	Poland 371; West Germany 227; France 175.
Platinum-group metals and silver including alloys:			
Platinum-group —thousand troy ounces—	393	428	Japan 91; Netherlands 70; France 49.
Silver ——do—	r 37,863	26,763	Italy 11,198; Austria 7,054.

See footnotes at end of table.

Table 2.—Switzerland: Exports of mineral commodities—Continued

(Metric tons unless otherwise specified)

Commodity	1974	1975	Principal destinations, 1975
METALS—Continued			
Tin:			
Oxides ----------kilograms--	18	793	West Germany 738.
Metal including alloys:			
Scrap ----------	55	70	France 36; West Germany 34.
Unwrought ----------	123	52	France 40; Austria 8.
Semimanufactures ----------	r 41	39	West Germany 10; Sweden 9; Iran 8.
Titanium oxides ----------	373	114	Austria 76; West Germany 19; France 12.
Tungsten metal including alloys, all forms ---	97	19	West Germany 14.
Uranium and thorium oxides including rare-earth oxides ----------kilograms--	1,307	2,155	West Germany 569.
Zinc:			
Oxide ----------	4	12	Austria 10.
Metal including alloys:			
Scrap ----------	1,251	945	Italy 479; France 318; West Germany 99.
Blue powder ----------	217	28	Austria 20; France 7.
Unwrought ----------	587	641	Netherlands 549; West Germany 58.
Semimanufactures ----------	r 116	9	West Germany 4.
Other:			
Ore and concentrate, n.e.s ----------	193	73	Bangladesh 30; France 16; West Germany 14.
Ash and residue containing nonferrous metals ----------	24,795	22,116	West Germany 10,826; Italy 7,348.
Waste and sweepings of precious metals -	229	120	France 44; West Germany 42; Italy 22.
Oxides, hydroxides, peroxides of metals, n.e.s ----------	361	241	United Kingdom 114; Italy 69; France 26.
Metals including alloys, all forms:			
Metalloids ----------	r 11,274	7,155	West Germany 3,779.
Alkali, alkaline earth, rare-earth metals ----------kilograms--	1,609	1,074	West Germany 91; Belgium-Luxembourg 81.
Pyrophoric alloys ----------do----	2,565	865	France 734.
Base metals including alloys, all forms, n.e.s ----------	132	81	West Germany 28; Austria 11; United Kingdom 9.
NONMETALS			
Abrasives, natural, n.e.s.:			
Pumice, emery, natural corundum, etc ---	16	7	West Germany 2; Italy 2.
Dust and powder of precious and semiprecious stones --------kilograms--	3,272	1,111	Italy 301; France 205; West Germany 174.
Grinding and polishing wheels and stones	970	892	West Germany 180; United Kingdom 163.
Asbestos ----------	136	82	France 60.
Barite and witherite ----------	(1)	4	All to West Germany.
Boron materials:			
Crude natural borates ----------	7	1	NA.
Oxide and acid ----------	26	58	West Germany 50.
Cement ----------	r 30,987	28,666	West Germany 21,837; Austria 4,141.
Chalk ----------	141	125	France 68; West Germany 18.
Clays and clay products (including all refractory brick):			
Crude clays, n.e.s ----------	12,239	11,123	West Germany 10,506.
Products:			
Refractory (including nonclay bricks)	r 1,139	1,458	Tunisia 506; West Germany 168.
Nonrefractory ----------	r 44,537	48,172	West Germany 18,067; France 13,911; Austria 11,259.
Cryolite and chiolite ----------	24	2	NA.
Diamond:			
Gem, not set or strung -value, thousands--	$66,371	$101,589	Israel $34,911; France $16,615; Belgium-Luxembourg $13,326.
Industrial ----------do----	$2,128	$2,006	West Germany $992; Hungary $264.
Diatomite and other infusorial earth --------	13	12	Yugoslavia 10.
Feldspar and fluorspar ----------	288	380	West Germany 227; Peru 80; Sweden 45.
Fertilizer materials:			
Crude, phosphatic ----------	2	1	NA.

See footnotes at end of table.

Table 2.—Switzerland: Exports of mineral commodities—Continued

(Metric tons unless otherwise specified)

Commodity	1974	1975	Principal destinations, 1975
NONMETALS—Continued			
Fertilizer materials—Continued			
Manufactured:			
Nitrogenous	936	424	Belgium-Luxembourg 41; Italy 40.
Phosphatic	1	34	Italy 16.
Potassic	17	1	NA.
Other including mixed	1,847	1,695	Sweden 490; West Germany 369; France 261.
Ammonia	r 80	75	Austria 63.
Graphite, natural	14	11	Iran 5; West Germany 1.
Gypsum and plasters	r 5,674	3,190	Austria 2,976.
Lime	5,210	4,185	West Germany 3,114; France 1,070.
Magnesite	r 60	33	Iran 13; France 3.
Mica:			
Crude including splittings and waste	87	44	West Germany 13; Belgium-Luxembourg 5.
Worked including agglomerated splittings	443	467	Sweden 88; United Kingdom 66; Hungary 44.
Pigments, mineral:			
Natural, crude	58	66	Peru 36; Iran 23.
Iron oxides, processed	108	35	Austria 11; United Kingdom 5; Yugoslavia 4.
Precious and semiprecious stones, except diamond:			
Natural ---value, thousands--	$85,085	$107,594	France $33,913; West Germany $16,091; United Kingdom $14,314.
Manufactured ---thousand carats--	r 236,760	233,205	U.S.S.R. 75,115; West Germany 65,760.
Pyrite (gross weight) ---kilograms--	--	48	NA.
Salt and brine	r 2,250	711	France 682.
Sodium and potassium compounds, n.e.s	r 51,025	29,063	Austria 11,229; France 8,165; West Germany 6,924.
Stone, sand and gravel:			
Dimension stone:			
Crude and partly worked	r 37,819	34,762	West Germany 25,692; Italy 4,822.
Worked	11,877	9,976	West Germany 8,692.
Dolomite, chiefly refractory grade	27	35	Austria 32.
Gravel and crushed rock	51,031	19,350	West Germany 9,665; France 7,729.
Limestone (except dimension)	4	1	All to West Germany.
Quartz and quartzite	39,876	27,982	Italy 23,836; West Germany 2,807.
Sand, excluding metal bearing	13,858	10,818	France 4,361; West Germany 3,178; Italy 1,742.
Sulfur:			
Elemental:			
Other than colloidal	159	5	NA.
Colloidal	7	22	NA.
Sulfur dioxide	220	1,130	West Germany 809; Austria 320.
Sulfuric acid	33,114	16,756	West Germany 5,900; Yugoslavia 5,289; East Germany 4,789.
Talc, steatite, soapstone, pyrophyllite	r 1,056	151	Italy 85; Austria 27.
Other nonmetals, n.e.s.:			
Crude:			
Meerschaum, amber, jet --kilograms--	--	225	NA.
Other	3,490	1,336	West Germany 763; Italy 205; France 155.
Slag, dross and similar waste, not metal bearing:			
From iron and steel manufacture	4,906	5,569	West Germany 4,560; France 642.
Slag and ash, n.e.s	238	119	Italy 118.
Oxides and hydroxides of magnesium, strontium, barium	22	18	Italy 4; West Germany 4; Spain 2.
Bromine, iodine, fluorine	56	43	Ireland 40.
Building materials of asphalt, asbestos, and fiber cement, and unfired nonmetals, n.e.s	r 2,457	2,853	West Germany 1,045; Austria 719; France 440.

See footnotes at end of table.

Table 2.—Switzerland: Exports of mineral commodities—Continued

(Metric tons unless otherwise specified)

Commodity	1974	1975	Principal destinations, 1975
MINERAL FUELS AND RELATED MATERIALS			
Asphalt and bitumen, natural	10	12	France 11.
Carbon black and gas carbon:			
Carbon black	59	16	U.S.S.R. 5; West Germany 4; France 3.
Gas carbon	r 1	--	
Coal, all grades, including briquets	33,693	11,652	West Germany 10,395.
Coke and semicoke	47,266	13,349	West Germany 7,221; France 4,314; Belgium-Luxembourg 1,553.
Gas, hydrocarbon, manufactured	97	87	Mainly to France.
Hydrogen, helium, rare gases	63	25	Austria 12; Egypt 8.
Peat including peat briquets and litter	1,115	1,472	France 740; Austria 725.
Petroleum refinery products:			
Gasoline (including natural) thousand 42-gallon barrels	5	497	Mainly to Austria.
Distillate fuel oil ---do---	r 101	32	Austria 18; Italy 3; Yugoslavia 3.
Residual fuel oil ---do---	r 1,113	341	Austria 337.
Lubricants ---do---	r 1	1	Mainly to Poland and Austria.
Other:			
Liquefied petroleum gas ---do---	164	314	Italy 229; Austria 43; West Germany 37.
Petroleum coke ---do---	5	(1)	Mainly to West Germany.
Bitumen and other residues, and bituminous mixtures, n.e.s ---do---	8	4	Austria 1; Kuwait 1.
Unspecified ---do---	2	2	Austria 1.
Total ---do---	r 1,399	1,191	
Mineral tar and other coal-, petroleum-, or gas-derived crude chemicals	r 5,971	467	West Germany 291.

r Revised. NA Not available.
1 Less than ½ unit.

Table 3.—Switzerland: Imports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1974	1975	Principal sources, 1975
METALS			
Aluminum:			
Bauxite and concentrate	15,990	20,230	France 17,168; Italy 2,737.
Oxide and hydroxide	198,438	158,074	Guinea 75,842; Australia 75,386.
Metal including alloys:			
Unwrought	41,600	16,100	Norway 5,785; Iceland 2,431; Poland 2,135.
Semimanufactures	25,285	16,435	West Germany 5,362; Austria 3,120; Norway 1,641.
Antimony metal including alloys, all forms	62	122	People's Republic of China 106; Belgium-Luxembourg 15.
Arsenic trioxide, pentoxide, acids	58	43	France 42.
Beryllium metal including alloys, all forms kilograms	725	788	United States 514.
Chromium:			
Chromite	5,002	4,232	South Africa Customs Union 1 3,554.
Oxide and hydroxide	586	443	West Germany 288; Italy 76.
Cobalt oxide and hydroxide	15	4	Belgium-Luxembourg 3.
Columbium and tantalum metal including alloys, all forms, tantalum	4	1	Mainly from United States.
Copper:			
Ore and concentrate	37	19	Mainly from Australia.
Matte	31,176	33,890	Belgium-Luxembourg 7,624; West Germany 7,212; Canada 3,679.
Copper sulfate	722	547	U.S.S.R. 325; France 124.
Metal including alloys:			
Scrap	r 1,985	4,170	United States 2,443; West Germany 800.
Unwrought	r 1,437	1,239	West Germany 794; United Kingdom 216.
Semimanufactures	r 57,100	45,651	United Kingdom 21,223; West Germany 11,241.

See footnotes at end of table.

Table 3.—Switzerland: Imports of mineral commodities—Continued

(Metric tons unless otherwise specified)

Commodity	1974	1975	Principal sources, 1975
METALS—Continued			
Gold metal, unworked or partly worked thousand troy ounces	140	121	West Germany 52; United Kingdom 31; France 14.
Iron and steel:			
Ore and concentrate including roasted pyrite	39,489	44,640	Mauritania 35,980; Italy 6,452.
Metal:			
Scrap	110,355	96,803	West Germany 79,605; Netherlands 9,402.
Pig iron and similar materials	80,739	60,944	West Germany 37,549; France 8,084.
Ferroalloys	r 27,484	11,641	Norway 2,980; West Germany 1,930; France 1,768.
Steel, primary forms	r 150,592	95,683	France 31,379; West Germany 23,705; Belgium-Luxembourg 19,164.
Semimanufactures:			
Bars, rods, angles, shapes, sections	r 486,304	291,258	West Germany 97,449; France 63,700; Belgium-Luxembourg 60,715.
Universals, plates, sheets	r 617,115	358,430	West Germany 119,187; France 83,127; Belgium-Luxembourg 37,889.
Hoop and strip	r 182,147	104,456	Belgium-Luxembourg 29,699; West Germany 29,269; Austria 17,233.
Rails and accessories	55,726	53,968	Austria 34,210; West Germany 10,939.
Wire	r 28,479	15,645	Austria 6,630; West Germany 5,207; Belgium-Luxembourg 1,748.
Tubes, pipes, fittings	170,282	75,878	West Germany 33,428; France 12,516; Italy 9,981.
Castings and forgings, rough	3,117	2,364	West Germany 705; Belgium-Luxembourg 650; France 405.
Ingots and semimanufactures, alloy steel and high carbon	165,626	116,277	West Germany 43,824; France 17,435; Italy 17,230.
Lead:			
Ore and concentrate	4	7	Mainly from Morocco.
Oxides	r 162	66	West Germany 21; Mexico 15; United Kingdom 12.
Metal including alloys:			
Scrap	46	62	France 34; West Germany 27.
Unwrought	22,378	14,355	United Kingdom 4,643; Canada 3,753; West Germany 2,114.
Semimanufactures	r 1,551	1,243	West Germany 1,158.
Magnesium metal including alloys, all forms	r 1,809	1,286	Norway 944.
Manganese oxides	730	472	Belgium-Luxembourg 151; West Germany 136; Japan 131.
Mercury 76-pound flasks	590	735	West Germany 296; U.S.S.R. 174; People's Republic of China 109.
Molybdenum metal including alloys, all forms	r 18	31	West Germany 19; Austria 6.
Nickel:			
Matte, speiss, similar materials	1,336	1,739	Norway 405; Canada 266; U.S.S.R. 245.
Metal including alloys:			
Scrap	56	160	West Germany 86; Austria 38; Sweden 25.
Unwrought and semimanufactures	r 2,251	1,836	West Germany 622; United Kingdom 587; United States 392.
Platinum-group metals and silver including alloys:			
Platinum group thousand troy ounces	r 651	538	West Germany 208; United States 79; United Kingdom 78.
Silver do	r 16,825	41,422	United Kingdom 10,689; United Arab Emirates 7,166; United States 4,779.
Tantalum metal including alloys, all forms	4	1	Mainly from United States.
Tin:			
Ore and concentrate kilograms	6	--	
Oxides	38	8	United Kingdom 6; West Germany 1.

COMMODITY REVIEW

METALS

Aluminum.—The Swiss aluminum industry started to recover from a recession during the second half of 1976, although the total output of the three aluminum plants was slightly lower than in 1975. Most of the domestic aluminum was consumed in the country. Apparent consumption in thousand tons follows:

Year	Quantity
1970	90.7
1974	105.0
1975	r 84
1976	e 96.5

e Estimate. r Revised.

Two Swiss Aluminium Ltd. (Alusuisse) plants (one in Chippis, Valais, and the other in Steg, Valais) and one owned by Usine d'Aluminium in Martigny operated during 1976. Switzerland was not a producer of bauxite and alumina, but imported alumina from Surinam, Guinea, and Australia.

Other Metals.—Four steel plants, located at Bodio (Monteforno Acciaerie e Laminatori S.A.), Lucerne (AG der von Moosschen Eisenwerke), Gerlafingen (Von Roll Ltd.), and Wöhlen (Ferrowöhlen AG) (aggregate capacity 700,000 tons), produced about 547,000 tons of steel, or about 22% of domestic demand. A large number of steel traders distributed domestic and imported steel to consumers. Some steel traders had elaborate facilities for decoiling, slitting, and other methods for preparing steel to the customer's desired specification.

Two ferrosilicon plants, situated in Bodio, were in operation during 1976. Monteforno Acciaerie e Laminatori operated an 8,000-ton-per-year plant, and Gothardwerke für Electrochemische Industrie operated an 800-ton-per-year plant. Data on output of ferrosilicon in the country were not published.

NONMETALS

Switzerland produced cement, lime, sand, gravel, gypsum, and salt; output was of domestic significance only.

Fifteen cement plants, with 6 million tons per year of installed capacity, operated at 62% of capacity during 1976. In addition, four clinker-grinding plants were in operation. The largest producer of cement was Cement Werk Wuerenlingen with a plant at Siggenthal.

Production and consumption of other construction materials reflected the general status of the Swiss economy and followed the general trend of cement.

MINERAL FUELS

Except for some hydropower (about 3% of total demand) and noncommercial fuels, Switzerland depended on imports to meet its demand for fuels. The apparent consumption of fuels and power for 1974 and 1975 is shown in table 4. Petroleum, all imported, remained the principal fuel and accounted for about 77% of the country's fuel consumption. Three petroleum refineries, with an annual capacity of 6.8 million tons, were in operation during 1976 and operated at 60% of rated capacity. The petroleum refinery at Collombey, operated by Raffinerie du Sud-Ouest S.A., and the refinery at Cressier, operated by Raffinerie de Cressier S.A., accounted for about 80% of petroleum refinery output.

There was a modest exploration effort for gas and petroleum in Switzerland during 1976, but no drilling activity was reported. Geophysical work was in the general areas of Zurich and Lucerne. Most of the exploration was related to the Molasse Formation of Miocene age. Domestic capital with some participation of large oil companies financed exploration.

Three nuclear powerplants were in operation (1,000 megawatts electric), two were under construction (1,862 megawatts electric), and two were on order (2,065 megawatts electric).

Table 4.—Switzerland: Supply and apparent consumption of fuels and power for 1974 and 1975

(Million tons of standard coal equivalent [1])

	Total energy	Coal and coke	Petroleum and refinery products	Natural gas	Fuelwood	Hydroelectric power	Nuclear power

The Mineral Industry of Taiwan

By E. Chin [1]

Taiwan's gross national product (GNP) for 1976 was estimated at $17.1 billion [2] at current prices and at $9.9 billion at 1971 prices, compared with $14.7 billion and $8.9 billion, respectively, for 1975. In absolute values, the growth in GNP for 1976 was 6.1%, compared with 5.5% in 1975 and 2.7% in 1974. The higher costs for fuels and other raw materials caused a slowdown in the economy during 1973–74. However, during 1975 and 1976, the real growth in Taiwan's GNP was approaching the average annual growth rate of 7.3% recorded during the 1953–76 period. The growth in the nation's economy was led by the manufacturing sector, which was up 18%; followed by utilities, 16.5%; and mining, 15.7%. The construction and transportation-communication sectors grew 10.2%, with services following at about 7%. Growth in the agricultural sector was 5.3% owing to favorable weather conditions that resulted in a rice harvest of 2.7 million tons. The monthly average in industrial production was up 23.7% over the 1975 average, compared with 5.8% in the prior year.

Because of the general sluggishness in the worldwide economy, competition in the foreign market was severe, frequently resulting in price reductions to maintain business volume for the country's export-oriented industries. On the other hand, the higher cost of imports during the year was a significant factor in pushing up domestic price levels. The overall increase in prices during 1976 was 4.5% at the wholesale level and 3.1% at the consumer level. Despite the competitiveness in both domestic and foreign markets, there was only moderate inflation in 1976. Wages increased about 15% during the year. The index of average industrial wages (1973=100) in 1976 was 186.2, compared with 158.7 in 1975 and 134.2 in 1974. However, the inflationary effect of higher wages was partially offset by a corresponding increase in labor productivity. The index of average labor productivity (1973=100) increased 15.9% to 140.8 in 1976.

At the end of 1976, Taiwan had about 375,000 factories and businesses, of which more than 56,000 were engaged in manufacturing. Electronic plants numbered around 720, employing about 135,000 people. The largest industry was textiles, which relied on imported cotton, principally from the United States. However, Taiwan's growing petrochemical industry was producing more feed materials for synthetic fibers and plastics.

After a 2-year decline, foreign investment in Taiwan took an upturn in 1976 and approved investments increased 19.71% from $118.2 million to $141.5 million. The upswing was due mainly to increased investments by European and Japanese concerns. U.S. investments were down from $41.2 million in 1975 to $21.8 million in 1976.

The value of Taiwan's processing activities of imported minerals and metals overshadowed the value of indigenous extraction. In 1976, the mineral-processing sector outweighed the domestic mining sector 18 to 1 in output value compared with a 16-to-1 ratio in 1975. The total industrial input into the GNP in 1976 was $5.2 billion and by sector was constituted as follows, in million dollars: Manufacturing,

---

[1] Physical scientist, International Data and Analysis.

[2] Where necessary, values have been converted from New Taiwan dollars (NT$) to U.S. dollars at the rate of NT$38=US$1.00.

3,848; construction, 759; utilities, 344; and mining, 297.[3]

A breakdown by value of output for certain mineral-related sectors, in million dollars, follows:

Industrial sector	1975	1976
Mining:		
Crude oil and natural gas	99	116
Coal	102	115
Metals	25	27
Evaporated salt	4	7
Miscellaneous nonmetals	25	32
Manufacturing:		
Chemical products	2,076	2,563
Oil and coal products	1,016	1,462
Basic metals	479	614
Nonmetallic mineral products	422	535
Metal products	137	175
Total	4,385	5,646

Coal, natural gas, and limestone (including marble), ranked by value, remained the three leading mineral products mined in Taiwan. However, output of these minerals was not significant in terms of the world market. Other economically important minerals included copper, dolomite, gold, salt, sulfur, and talc. The reserves of the principal minerals in Taiwan were estimated at yearend 1976 as follows, in million tons: Asbestos, 0.75; copper ore, 14.8; dolomite, 119.8; gold ore, 6.9; limestone, 455,000; marble, 299,777; pyrite, 1.8; sulfur, 2.4; and talc, 2.4. Reserves of mineral fuels were coal, 215 million tons; petroleum, 2.5 million kiloliters; and natural gas, 28.8 billion cubic meters.[4]

Taiwan's new 6-year economic development plan (1976–81) got underway in 1976. The objectives of the plan were to improve the nation's economic structure, promote modernization, expedite development of resources, and strengthen the country's ability to adapt to change. The goals established for growth in the economy included increasing the GNP 7.5% annually to $22.3 billion in 1981, increasing the real national income from $11.3 billion in 1976 to $17.6 billion in 1981, and increasing the per capita income from $700 to $1,400 in 1981. The input of the agricultural sector to the GNP would decline from 14% to 10.5%, while that of industry would increase from 43.7% to 47.5%. Electric power capacity would increase from 5.3 million kilowatts to 9.6 million kilowatts during the 6-year plan. The total volume of trade was targeted to increase nearly threefold. Farm employment was to drop while employment in industry and services was slated to increase. Generally, the living standard would be raised 23.3% in terms of per capita income.

In the 1970's, the Government initiated a program to be completed by the end of the decade to bring Taiwan into the ranks of developed countries. This plan, called the Ten Major Construction Projects, was estimated to cost about $7.0 billion, adjustable upward owing to inflation. By yearend 1976, Taiwan Shipbuilding Corp. had essentially finished the construction of its shipyard at Kaohsiung that would have an annual vessel construction capacity of 1.5 million tons of total displacement. Construction of the first stage of Taiwan's integrated steel mill was about 50% complete at the end of 1976. When the facility is completed in 1979, annual production capacity will be 1.5 million tons of steel ingot. Projects involving the petrochemical industry included expanding the production of basic petrochemical raw materials and the production of intermediate and consumer products. Expansion of capacity to produce basic materials was essentially completed by yearend; that for xylene production, about 40% complete; for acrylonitrile, 45%; and for caprolactum, 90%. Construction of generator No. 1 of Taiwan's first nuclear powerplant was about 85% complete at the end of 1976. Generation from this 636,000-kilowatt unit was expected in early 1978. Construction of a second unit with identical capacity was about 55% complete. During the year, construction of a second nuclear plant with two 985,000-kilowatt units was initiated on the coast of northern Taiwan. A third plant with two units of 950,000 kilowatts each was also proposed as part of this nuclear energy project.

The remaining six projects were concerned with transport. Estimated construction status of these follows: Taichung harbor, 85% complete; Suao port, 35% complete; westcoast mainline railroad electrification, 50% complete; extension of the westcoast mainline railroad from Suao to Hualien, 25% complete; the north-south freeway linking Keelung and Kaohsiung,

[3] Industry of Free China. No. 1, July 1977, pp. 44–45.

[4] Mining Research and Service Organization (Taipei). Mineral Resources Development in Taiwan, China. July 1977, p. 1.

65% complete; and Taoyüan International Airport, 40% complete.

During 1976, Taiwan's total supply of energy was estimated at 23.0 million kiloliters, expressed in oil equivalent. Production from domestic fuels accounted for about 24% of the total and by sector was as follows: Coal, 42%; natural gas, 33%; hydroelectric power, 21%; and crude oil, 4%. Imports provided 76% of the country's energy supply and were distributed as follows: Crude oil, 83%; petroleum products, 16%; and coal, 1%.

Taiwan's industries consumed 18.4 billion kilowatt-hours of electricity in 1976. Estimated breakdown of consumption in the mineral-related industries was as follows, in million kilowatt-hours: Iron and steel, 1,726; cement, 1,127; metal products, 523; chemical fertilizers, 472; aluminum, 334; mining and quarrying, 364; basic industrial chemicals, 1,236; and other chemical products, 2,519.

In July 1977, two typhoons struck Taiwan, causing widespread damage. The power supply to many industries was cut off completely and then subsequently restricted for a month. Because of the damage, the Government initiated measures aimed at stimulating the economy and also began to reevaluate the targets for industrial production as set forth for the second year of the current 6-year plan.

PRODUCTION

By value, coal was the most important mineral commodity mined in Taiwan. Output of bituminous coal in 1976 increased 3% to 3.2 million tons valued at $115 million. Crude petroleum production was only 247,232 kiloliters, a 15% increase over that of 1974. The principal significance of indigenous oil was as a very small supplement to imported crude oil in the production of refinery products. Production of natural gas increased 17% to 1.8 billion cubic meters. While output was of little consequence by world standards, natural gas production was important to the domestic economy.

The value of Taiwan's principal mine products in 1976 follows, in million dollars: Copper ore, 22.4; limestone, 18.0; marble, 12.0; salt, 6.8; and gold and silver, 4.4. The value of mine output of asbestos, dolomite, gypsum, pyrite, sulfur, and talc collectively totaled $2.0 million.

Production of pig iron and crude steel ingot in 1976 increased 57% and 15%, respectively. Overall output in iron and steel products showed an increase owing to the demand in both domestic consumption and export shipments. Output of iron and steel semimanufacturers in 1976 follows, in metric tons (1975 production is in parentheses): Rods and bars, 931,273 (665,141); sections, 377,863 (291,277); tubes and pipes, 140,282 (108,265); ball, 2,387 (1,474); cable, 11,915 (8,758); and cast iron pipe, 59,908 (31,543).

Production of primary aluminum metal dropped 9% to 25,512 tons. The aluminum industry continued to be plagued by higher production costs primarily because of electrical energy consumed. Mine copper output was nearly 2,500 tons and smelter production was about 12,000 tons in 1976. Limestone production, principally for cement manufacture, totaled 9.6 million tons, up slightly over that of 1975. Cement production, however, increased 29% to 8.7 million tons in 1976. The production levels for compound fertilizer, urea, and ammonium sulfate were up over the 1975 output.

[4] Excludes sulfur produced by oil refineries.

[5] Largely processed into natural gas liquids.

TRADE

Taiwan's two-way trade in 1976 totaled $15.7 billion, up 40% from that of 1975. Exports increased from $5.3 billion in 1975 to $8.1 billion in 1976. Similarly, imports increased from $5.9 billion to $7.6 billion. The largest import categories during 1976 were machinery, appliances, and electrical equipment, $1.7 billion; mineral products and liquid fuels, $1.4 billion; food products, $817 million; chemicals, $739 million; and base metals, semimanufactures, and articles, $717 million. By value, shipments from Japan accounted for 30% of Taiwan's total imports, followed by the United States, 28%; Kuwait, 7%; West Germany, 6%; Saudi Arabia, 4%; and Indonesia, 3%. The remaining 22% was contributed by many countries.

Textiles and articles of apparel constituted 36% of total exports, or $2.9 billion, followed by machinery, appliances, and electrical equipment, $1.5 billion; foodstuffs, $997 million; and wood products and articles, $464 million. Principal export destinations were the United States, $1.8 billion; Japan, $691 million; Hong Kong, $361 million; and West Germany, $315 million.

By cargo value, shipments to and from Taiwan's largest port at Keelung amounted to $7.5 billion in 1976. The two-way ocean shipping at Kaohsiung port totaled $6.8 billion, while that at Taipei harbor was $1.3 billion.

In 1976, the value of mineral and metal products imported represented 28% of all imports, compared with 7% for this category in total exports, reflecting Taiwan's reliance on imported raw materials and semimanufactures. Table 2 shows the principal mineral categories traded during the last 3 years, and table 3 indicates the tonnage and value of major mineral products imported in 1976.

Table 2.—Taiwan: Value of principal mineral exports and imports
(Million New Taiwan dollars)

Commodity	1974	1975	1976
EXPORTS			
Iron and steel products	4,241	4,045	4,226
Nonferrous metals	895	604	847
Cement products	462	277	463
Refined oil products	1,015	2,063	4,906
IMPORTS			
Iron and steel products	23,981	15,008	16,980
Scrap iron	3,830	2,020	1,115
Iron ore	130	101	130
Nonferrous metals	5,584	4,447	7,085
Bauxite	108	106	126
Copper ore, concentrate, matte	230	103	119
Asbestos	158	189	352
Chemical fertilizers	1,470	1,764	904
Phosphate rock	556	601	512
Sulfur	411	328	188
Crude oil	27,257	23,732	40,025
Refined petroleum	5,080	5,849	7,802

Table 3.—Taiwan: Selected mineral and metal imports, 1976

Commodity	Quantity (metric tons)	Value (thousand New Taiwan dollars)	Principal sources (metric tons)
Metal ores:			
Bauxite and alumina	166,029	$126,146	Malaysia 151,593; Indonesia 10,000; India 4,036.
Chromite	4,579	12,395	Philippines 2,700; India 1,378.
Copper ore, concentrate, matte	8,025	119,059	Chile 5,170; Philippines 2,854.
Iron ore	151,156	129,582	India 101,977; Australia 42,735; Malaysia 6,444.
Manganese ore	41,310	84,643	Malaysia 18,580; Thailand 8,001; India 6,440; Brazil 4,485; Australia 3,321.
Metals:			
Aluminum, unwrought	36,358	1,218,877	United States 12,164; Bahrain 5,987; Japan 5,298; Ghana 3,889; Australia 3,574.
Copper, unwrought	23,736	1,267,906	Japan 9,640; Chile 6,797; Zambia 5,395; Canada 1,050.
Iron and steel:			
Steel products (excluding pig iron and ferroalloys)	NA	16,980,089	Mainly from Japan.
Ferroalloys	6,088	162,565	Republic of South Africa 4,904; Japan 1,050.
Pig iron	68,556	302,396	Japan 47,433; India 21,023.
Iron and steel scrap	297,090	1,115,261	United States 213,864; Hong Kong 56,438; Australia 18,756.
Lead, unwrought	6,341	112,081	Australia 4,711; Japan 1,051.
Platinum, unwrought	2	405,085	Mainly from Japan.
Nickel, unwrought	968	170,972	Canada 640; Japan 259; Australia 29.
Tin, unwrought	814	227,786	Malaysia 704; Indonesia 63; Japan 21.
Zinc, unwrought	26,068	773,261	Australia 15,447; Japan 7,612; Canada 2,653.
Nonmetals:			
Abrasives	2,463	35,669	Japan 1,840; United States 572.
Asbestos	19,157	352,047	Republic of South Africa 12,796; Canada 3,212; Japan 1,736.
Bentonite	3,903	19,862	United States 2,420; Japan 1,462.
Fire clay	933	13,195	Japan 668; Hong Kong 99; West Germany 94.
Graphite	5,451	105,794	Republic of Korea 4,060; Japan 1,229.
Gypsum	250,197	141,098	Japan 158,826; Republic of Korea 64,903; Mexico 22,596.
Kaolin	28,119	76,100	Republic of Korea 13,688; United States 8,876; Hong Kong 2,670.
Phosphate rock	227,578	512,172	Jordan 131,270; United States 35,612; Israel 22,166.
Salt	1,220,374	293,236	Australia 1,152,445; Austria 67,929.
Steatite	1,868	11,224	Republic of Korea 1,425; Japan 239; United States 154.
Sulfur	89,122	187,779	Canada 63,906; Japan 25,198.
Fuels and fertilizers:			
Coal	200,863	343,768	Australia 99,343; Republic of South Africa 55,508; India 36,275.
Coke	23,953	59,227	All from Japan.
Chemical fertilizers	327,026	905,494	Canada 155,425; Japan 97,194; United States 44,587.
Crude oil	12,392,047	40,024,630	Kuwait 6,695,578; Saudi Arabia 4,660,432.
Refined petroleum	2,889,681	7,802,054	Kuwait 1,664,860.

NA Not available.

Table 4.—Taiwan: Exports and reexports of mineral commodities [1]

(Metric tons unless otherwise specified)

Commodity	1974	1975	Principal destinations, 1975
METALS			
Aluminum:			
Oxide and hydroxide	[2] 626	975	Republic of Korea 550; Indonesia 232; Singapore 140.
Metal including alloys, all forms	7,445	5,174	Hong Kong 1,803; Indonesia 822; Japan 581.
Beryllium metal, waste, scrap	--	353	All to Japan.
Copper:			
Ore and concentrate	708	792	Do.
Copper sulfate	10	60	Indonesia 30; Philippines 10; Malaysia 9.
Metal including alloys:			
Scrap	712	400	Mainly to Japan.
Unwrought	1,424	1,673	Japan 1,647.
Semimanufactures	4,540	4,702	Japan 1,979; Hong Kong 1,325; Singapore 534.
Iron and steel metal:			
Scrap	43,072	32,348	Japan 21,974.
Pig iron, ferroalloys, similar materials	21,639	53,883	United States 22,079; Japan 12,949.
Steel, primary forms	[r] 5,068	5,658	Thailand 2,130; Japan 1,800; Indonesia 1,251.
Semimanufactures:			
Wire rod and other bars and rods	23,185	106,074	Saudi Arabia 45,365; Indonesia 31,318.
Angles, shapes, sections	7,301	21,883	Indonesia 8,530; United States 3,043.
Universals, plates, sheets	22,077	23,676	Japan 9,286; Oman 3,439; Saudi Arabia 2,739.
Hoop and strip	6,963	13,419	Indonesia 8,002; Saudi Arabia 2,915.
Rails and accessories	115	255	Thailand 210.
Wire	4,973	8,863	United States 2,528; Saudi Arabia 1,613.
Tubes, pipes, fittings	126,378	64,312	United States 16,474; Saudi Arabia 14,973.
Castings and forgings, rough	5,041	5,316	United States 3,213; Japan 891.
Lead metal including alloys, all forms	344	932	Japan 478; Hong Kong 186.
Magnesium metal including alloys, all forms	544	247	United States 176; Japan 70.
Manganese oxides	5	1	All to Brunei.
Mercury ---76-pound flasks	--	17	All to Thailand.
Nickel:			
Matte, speiss, similar materials	35	61	Japan 42; United States 19.
Metal including alloys:			
Scrap	195	202	All to Japan.
Unwrought and semimanufactures	69	56	Mainly to Japan.
Platinum-group metals and silver:			
Waste and sweepings:			
Silver ---troy ounces	193	2,347	All to Hong Kong.
Other ---do	233,768	579	All to United Kingdom.
Metals including alloys:			
Platinum group ---do	707	3,247	Japan 3,215.
Silver ---do	707	155,545	Hong Kong 148,922.
Tin metal including alloys, all forms	34	60	Singapore 23; Hong Kong 31.
Titanium oxides	--	820	Mainly to United States.
Tungsten (wolfram) metal including alloys, all forms	2	5	West Germany 4.
Zinc:			
Oxide and peroxide	465	847	Japan 590; Philippines 148.
Metal including alloys, all forms	149	43	Malaysia 14; Indonesia 10; Philippines 10.
Other:			
Ash and residue containing nonferrous metals	29	61	All to Japan.
Oxides, hydroxides, peroxides of metals, n.e.s	57	10	Mainly to Indonesia.
Metals including alloys, all forms:			
Metalloids, silicon	--	184	Japan 100; Thailand 50; United States 20.
Alkali, alkaline earth, rare-earth metals	--	1	All to Philippines.
Pyrophoric alloys	[3]	15	All to West Germany.
Base metals including alloys, all forms, n.e.s	16	10	Mainly to Japan and Hong Kong.

See footnotes at end of table.

Table 4.—Taiwan: Exports and reexports of mineral commodities [1]—Continued

(Metric tons unless otherwise specified)

Commodity	1974	1975	Principal destinations, 1975
NONMETALS			
Abrasives, n.e.s.:			
Natural:			
Pumice, emery, natural corundum, etc	32	9	Japan 6.
Dust and powder of precious and semiprecious stones—kilograms	514	--	
Grinding and polishing wheels and stones	855	778	Thailand 148; Philippines 146; Japan 139.
Manufactured: Artificial corundum	18	--	
Asbestos	--	8	All to Indonesia.
Barite and witherite	--	3	Mainly to Mozambique and Saudi Arabia.
Boric oxide and acid, borates, perborates	r 340	37	West Germany 35.
Cement—thousand tons	346	243	Saudi Arabia 150; Singapore 54.
Clays and clay products (including all refractory brick):			
Crude clays, n.e.s.:			
Bentonite	130	960	All to Hong Kong.
Fire clay	30	3	Philippines 2; Thailand 1.
Kaolin	66	--	
Other	1,455	74	Hong Kong 41; Philippines 20; Thailand 9.
Products:			
Refractory (including nonclay bricks)	r 10,217	6,477	Indonesia 3,186; Malaysia 1,601.
Nonrefractory	12,157	11,447	Japan 3,376; Hong Kong 2,797; United States 1,001.
Diamond:			
Gem:			
Not set or strung—thousand carats	r 5,685	--	
Manufactured—do	145	30	Japan 15; United States 10; France 5.
Industrial:			
Unworked—do	45	--	
Manufactured—do	5	--	
Diatomite and other infusorial earth	2	31	Mainly to Indonesia.
Feldspar and fluorspar	231	130	Indonesia 80; Malaysia 50.
Fertilizer materials:			
Manufactured:			
Nitrogenous	r 3,500	1	All to Hong Kong.
Potassic	--	2	All to Vietnam.
Other, including mixed	4,599	16	Hong Kong 8; South Vietnam 8.
Ammonia	206	85	Malaysia 59; Vietnam 26.
Graphite, natural	44	314	Japan 270; Hong Kong 44.
Gypsum and plasters	150	210	Indonesia 164; Philippines 25; Singapore 20.
Lime	1,566	4,893	Hong Kong 4,783.
Magnesite—kilograms	41	--	
Mica, all forms	7	(3)	All to United States.
Pigments, mineral: Iron oxides, processed	20	48	Saudi Arabia 33; Philippines 10.
Precious and semiprecious stones, except diamond:			
Natural—kilograms	r 5,182	12,252	United States 8,359; Hong Kong 1,414.
Manufactured—do	r 1,275	10,731	United States 5,051; West Germany 2,279.
Salt and brine	400	6,600	Hong Kong 6,350.
Sodium and potassium compounds, n.e.s	14,286	14,694	Indonesia 7,804; Hong Kong 2,393.
Stone, sand and gravel:			
Dimension stone:			
Crude and partly worked	17,812	5,477	Japan 5,115.
Worked	r 37,751	12,104	Japan 11,049.
Dolomite, chiefly refractory grade	2,602	1,175	Indonesia 500; Philippines 460; Malaysia 200.
Gravel and crushed rock, n.e.s	124,100	53,052	Japan 42,727; Ryukyu Islands 10,000.
Limestone (except dimension)	364	1,201	Mainly to Hong Kong.
Quartz and quartzite	r 35	1	All to Japan.
Sand, excluding metal bearing	213	31,129	Japan 20,928; Ryukyu Islands 10,000.
Sulfur:			
Elemental:			
Other than colloidal	20,426	1,188	Indonesia 953; Philippines 165.
Colloidal	142	91	Indonesia 35; Hong Kong 31; Philippines 25.
Sulfuric acid and oleum	r 31,533	2,278	Hong Kong 1,749.

See footnotes at end of table.

Table 4.—Taiwan: Exports and reexports of mineral commodities [1]—Continued

(Metric tons unless otherwise specified)

Commodity	1974	1975	Principal destinations, 1975
NONMETALS—Continued			
Talc, steatite, soapstone, pyrophyllite	538	457	Indonesia 285; Thailand 154.
Other nonmetals, n.e.s.:			
Crude:			
Meerschaum, amber, jet	(3)	10	All to Singapore.
Other	283	139	Japan 70; Hong Kong 28; Malaysia 25.
Slag, dross, similar waste, not metal bearing: Slag and ash, n.e.s	3,481	2,616	Singapore 2,405.
Oxides and hydroxides of magnesium, strontium, barium	37	6	Singapore 5; Philippines 1.
Building materials of asphalt, asbestos, and fiber cement, and unfired nonmetals, n.e.s	r 1,168	1,742	Hong Kong 1,197; Philippines 289.
MINERAL FUELS AND RELATED MATERIALS			
Carbon black and gas carbon:			
Carbon black	292	134	Thailand 104; Singapore 20.
Gas carbon	2	6	All to Hong Kong.
Coal	--	1	All to Australia.
Coke and semicoke	3,147	11,310	Thailand 5,710; Indonesia 2,735; Malaysia 1,150.
Rare gases, argon ----kilograms	--	2,216	Singapore 2,060.
Petroleum refinery products:			
Gasoline ----thousand 42-gallon barrels	233	--	
Kerosine, jet fuel, white spirit----do----	61	--	
Distillate fuel oil ----do----	519	3,435	Japan 369.
Lubricants ----do----	139	194	Republic of Korea 159.
Other:			
Nonlubricating oils, n.e.s ----do----	(3)	2	Mainly to Hong Kong and Malaysia.
Pitch and pitch coke ----do----	12	307	Indonesia 301.
Total ----do----	r 964	3,938	
Mineral tar and other coal-, petroleum-, or gas-derived crude chemicals	126,679	40,311	Japan 38,812.

r Revised.

[1] Compiled from official Taiwan trade returns, Monthly Statistics of Trade, Republic of China, May 1975, v. 1 and May 1976, v. I.

[2] Excludes artificial corundum. See nonmetals, abrasives.

[3] Less than ½ unit.

Table 5.—Taiwan: Imports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1974	1975
METALS		
Aluminum:		
Bauxite and concentrate ---thousand tons--	106	114
Oxide and hydroxide	25,691	6,250
Metal including alloys:		
Scrap	8,148	5,886
Unwrought	18,338	11,573
Semimanufactures	r 5,008	2,033
Arsenic:		
Natural sulfides	16	1
Trioxide, pentoxide, acids	313	93
Beryllium metal including alloys, all forms ---kilograms--	--	34
Chromium:		
Chromite	21,173	3,467
Oxide and hydroxide	911	836
Cobalt oxide and hydroxide	18	10
Columbium and tantalum, tantalum metal including alloys, all forms ---kilograms--	6	12
Copper:		
Ore and concentrate	12,743	10,000
Matte	18	10
Copper sulfate	122	76
Metal including alloys:		
Scrap	2,324	5,662
Unwrought	22,569	19,544
Semimanufactures	9,216	9,547
Germanium metal including alloys, all forms ---kilograms--	100	2
Gold metal, unworked or partly worked ---thousand troy ounces--	r 309	80
Iron and steel:		
Ore and concentrate	143,862	143,342
Roasted pyrite	5,000	17,590
Metal:		
Scrap	785,874	407,913
Pig iron, ferroalloys, similar materials	r 58,451	8,410
Steel, primary forms	r 70,543	16,501
Semimanufactures:		
Bars, rods, angles, shapes, sections	278,840	180,035
Universals, plates, sheets ---thousand tons--	1,155	633
Hoop and strip	17,784	11,164
Rails and accessories	14,481	1,688
Wire	17,591	9,465
Tubes, pipes, fittings	65,153	58,930
Castings and forgings, rough	1,001	645
Lead:		
Oxides	r 1,123	610
Metal including alloys:		
Scrap	3,350	4,474
Unwrought	4,384	5,171
Semimanufactures	420	23
Magnesium metal including alloys, all forms	757	70
Manganese:		
Ore and concentrate	28,885	79,371
Oxides	2,875	1,543
Metal	67	16
Mercury ---76-pound flasks--	r 406,262	3,573
Molybdenum metal including alloys, all forms	217	7
Nickel metal including alloys, all forms	r 1,731	339
Platinum-group metals and silver:		
Ore and concentrate ---thousand troy ounces--	--	32
Metals including alloys:		
Platinum group ---do---	r 39	176
Silver ---do---	r 2,109	654
Selenium, elemental ---kilograms--	432	1,390
Silicon metal	477	172
Tin:		
Ore and concentrate	1	70
Oxides ---kilograms--	1	1
Metal including alloys, all forms	1,221	1,191
Titanium oxides	7,469	6,300
Tungsten metal including alloys, all forms	7	8
Uranium and thorium:		
Ore and concentrate	31	--
Oxides	17	(1)
Zinc:		
Oxide and peroxide	436	340
Metal including alloys:		
Scrap	1,446	1,425
Blue powder	93	65
Unwrought	22,277	12,307
Semimanufactures	1,088	507

See footnotes at end of table.

COMMODITY REVIEW

METALS

Aluminum.—Taiwan Aluminum Corp. (Talco) was the country's sole producer of primary aluminum metal. Talco was 100% Government owned and was integrated from alumina production through the metal-semifabricating stage. In September 1976, Talco completed the expansion of its alumina-aluminum facilities at Kaohsiung whereby annual primary metal production capacity was increased from 38,000 tons to 70,000 tons and alumina capacity from 76,000 tons to 150,000 tons. New rolling capacity was also added in this expansion program.

In 1976, Talco produced about 47,700 tons of alumina and 25,512 tons of primary metal ingot (down 2,599 tons from that of 1975). Manufacture of aluminum sheet was 18,617 tons; foil, 2,119 tons; and miscellaneous aluminum products, 32,322 tons. Talco produced the bulk of the sheet and foil, while China Wire & Cable Co. and Walsin Lihwa Electric Wire & Cable Corp. accounted for the bulk of the output of extrusions, castings, and semimanufactures. In 1976, the aluminum industry consumed 333.5 million kilowatt-hours of electricity.

During the year, 161,593 tons of bauxite was imported, of which 94% was from Malaysia and the remainder was from Indonesia. In addition, 4,436 tons of alumina was imported from Guyana, India, and Japan.

In July 1977, typhoon Thelma hit southern Taiwan; Kaohsiung, one of Taiwan's major seaports and its second largest city, sustained the most serious damage of the storm area. Of Kaohsiung's major industrial plants, Talco sustained the most damage. The company estimated that the cost of the damage to the facility could reach as high as $25 million.

Copper.—Output of mine copper was about 2,500 tons in 1976, all from Chinkuashih in northern Taiwan. Enargite was the chief copper mineral in the Chinkuashih auriferous copper deposit, and the grade of the ore was 0.5% to 0.8% copper. Taiwan Metal Mining Corp. (TMMC), a Government-owned company, controlled most of the copper industry in Taiwan. TMMC operated the mine at Chinkuashih and the 10,000-ton-per-year copper smelter near the mine site. In 1976, 8,025 tons of copper concentrate was imported from Chile and the Philippines for smelting. An additional 5,388 tons of copper waste and scrap was imported for refining, and domestic scrap was used also. Total production of copper metal in 1976 was 11,660 tons, compared with 8,539 tons in 1975. TMMC was considering the feasibility of establishing a 50,000-ton-per-year refinery at Taichung, equipped with a 150,000-ton sulfuric acid plant to treat foreign copper ore.

Copper requirements in Taiwan had been increasing about 20% annually since 1974. In 1976, Taiwan imported 23,736 tons of refined copper and about 10,000 tons of copper products. The country's rolling and fabricating facilities were mainly in private hands, and an important manufacture was cable and wire which was a significant export item.

Iron and Steel.—Taiwan's small magnetite placer operations were located along the northern coast between Tanshui and Wanli. Limonite workings in Tayukeng were shut down several years ago. In 1976, Taiwan imported 151,143 tons of iron ore and concentrate (primarily from India and Australia), 29,479 tons of roasted iron pyrite (mainly from the Philippines), and 35,426 tons of slag, dross, scalings, and waste.

Although Taiwan had produced from 100,000 to 150,000 tons of pig iron annually in recent years, output of steel products had been closer to 1.5 million tons. Iron ore consumption was relatively small, and domestic and imported industrial scrap and ship scrap were the principal iron raw materials. Taiwan's ship-scrapping industry was large by world standards. All types of old ships were brought in for scrapping after special materials (engines, instruments, and equipment) were first salvaged. In 1976, 1.8 million tons of ships and other vessels was imported from 25 countries for scrapping. In addition, imports of iron and steel waste and scrap metal totaled 297,090 tons, mostly from the United States.

China Steel Corporation continued construction of its integrated steelworks at Kaohsiung. The steel mill was about 60%

finished at yearend 1976, and construction was expected to be completed by late 1977. Capacity will be about 1.5 million tons of steel per year when production begins in 1978, and a planned expansion program should double capacity by 1982. The ultimate capacity is 6 million tons per year, although no date had been set to attain that output level. Initial facilities included coke and sintering plants, blast furnace and basic oxygen steel production facilities, continuous casters for billet and slab production, plate and rod and bar mills, and installations for processing, warehousing, and shipping. The requirements for iron ore and coking coal will be provided through imports.

There were about 160 small steel mills operating in 1976, producing steel products. The two largest companies were Taiwan Iron Manufacturing Corp. and Tang Eng Iron Works. The principal steel products produced in 1976 follow, in tons: Rods and bars, 931,273; structural sections, 377,863; and tubes and pipes, 140,282. Estimated electric power consumption by the iron and steel industry was 1.7 billion kilowatt-hours in 1976.

Other Metals.—Gold was produced from vein deposits at the Chinkuashih mine. No placer gold deposit was presently being worked in Taiwan. In 1976, Taiwan produced about 27,000 troy ounces of gold, a 22% increase over the 1975 output. Silver production in 1976 was about 100,000 troy ounces.

Taiwan did not produce any primary zinc, lead, tin, or nickel, but consumed sizable tonnages of these metals. In 1976, 26,068 tons of unwrought zinc, valued at $20.3 million, was imported, principally from Australia and Japan. In addition, 2,156 tons of zinc scrap was imported, mainly from the United States. Imports of unwrought lead totaled 6,341 tons, valued at $2.9 million, of which Australia supplied 74%; scrap lead imports amounted to 7,575 tons, valued at $1.8 million, of which 60% was from the United States. Imports of unwrought tin totaled 814 tons, valued at $6.0 million, most of which was from Malaysia. Imports of unwrought nickel were 968 tons, valued at $4.5 million, and were principally from Canada, Japan, and Australia, in that order.

NONMETALS [5]

Cement.—Cement production totaled 8.7 million tons, 1.9 million tons more than in 1975. Exports of cement increased sharply, reaching 543,251 tons in 1976. The principal export destinations were Hong Kong, Singapore, and Saudi Arabia. Domestic demand for cement continued to increase owing to consumption resulting from the construction in connection with Taiwan's Ten Major Construction Projects.

There were 14 operating cement plants in Taiwan—6 in the south, 6 in the north, and 2 in the east. Most of the cement plants had their own limestone quarries, and only a few small plants purchased limestone raw materials from quarries operated by others. Taiwan Cement Corp. (TCC) was the largest producer on the island with four plants—one each at Kaohsiung, Chutung, Suao, and Hualien—and a combined annual capacity of 3.8 million tons. Asia Cement Corp., with a 2.5-million-ton plant at Tahu near Hsinchu, ranked next to TCC. The remaining cement capacity, 4.7 million tons, was distributed among nine plants of eight companies.

Fertilizer Materials.—In 1976, Taiwan produced 569,598 tons of ammonium sulfate, 388,831 tons of anhydrous ammonium, 263,292 tons of compound fertilizers, 195,460 tons of calcium superphosphate, 191,475 tons of urea, and 11,114 tons of nitrochalk. Taiwan has no potash resources and only small apatite resources. During 1976, Taiwan imported 170,133 tons of potassium chloride, mainly from Canada. Imports of phosphate fertilizers were 25,264 tons, all from the United States. The remainder of fertilizer imports totaled 131,629 tons, consisting almost wholly of ammonium sulfate, and was from Japan, Australia, the United States, and others, in that order.

Gypsum.—Taiwan's production of gypsum was nominal, and the cement industry was by far the largest consumer. The bulk of the gypsum supply came from imports, which totaled 250,197 tons in 1976, principally from Japan, the Republic of Korea, and Mexico, in that order.

Salt.—All of the salt was produced by the Taiwan Salt Works, a Government monopoly. The salt fields are distributed

[5] Pages 28–34 of work cited in footnote 4.

along the southwestern coast, and crude salt was produced by solar evaporation. In 1976, salt production totaled about 497,000 tons, nearly twice the 1975 level. In 1976, imports of salt were 1.2 million tons, predominantly from Australia. One of the largest consumers of salt in 1976 was the soda-chlorine industry, which produced 91,922 tons of caustic soda (79,891 tons in 1975), 247,870 tons of liquid soda (190,892 tons in 1975), 74,358 tons of soda ash (67,274 tons in 1975), and 27,129 tons of liquid chlorine (23,633 tons in 1975).

Stone.— *Dolomite.*—Dolomite deposits are extensive and widespread, particularly in rugged and little-explored eastern Taiwan where reserves may be 120 million tons averaging 18% to 20% magnesia. Alluvial dolomite mining by hand-sorting took place in streambeds south of Hualien where flooding replenishes the supply. The most important dolomite quarries were situated along the Tachoshuichi stream north of Hualien, with lesser quarries operating near Hoping, Hojen, and Chungte. Taiwan's most promising dolomite deposit at Chingchangshan was being actively explored and developed for China Steel's integrated steelworks at Kaohsiung. Total production of dolomite in 1976 was 172,421 tons, compared with 135,952 tons in 1975. Most of the dolomite was used by the ironworks, glass manufacturers, and chemical plants.

Limestone.—Commercial limestone deposits occur in many parts of Taiwan, and large quarries were being worked, particularly in the southwest and the east. Limestone reserves had been estimated at more than 450 billion tons. Production in 1976 totaled 9.61 million tons compared with 9.48 tons in 1975. The cement industry was the largest consumer of limestone. Moreover, cement consumption was rising sharply owing to the many construction programs on the island. Considerable quantities of limestone were also used for sugar refining. Burned or calcined limestone went into lime manufacture, and high-purity raw limestone was the chief raw material for making raw carbide cyanamide fertilizer.

Marble.—The crystalline limestone in the metamorphic terrain of eastern Taiwan is classified as commercial marble. The calcareous rock is capable of being polished and is suitable for use as a decorative building stone. The marble occurrence has four color variations: White, light gray, dark gray, and light green. Mottled color patterns and shades of mixed colors also occur. Stone works and marble mills were recently installed to manufacture ornamental marble products for domestic and foreign markets. The production of marble (crystalline limestone) in 1976 totaled 3.27 million tons, compared with 1.36 million tons in 1975. Most of the demand was by the cement and fertilizer industries. The percentage of the total output of marble used as a building stone was quite small but was increasing. The output of decorative marble in 1976 was 1.2 million tons, compared with 0.5 million tons in 1975 and 0.3 million tons in 1974.

Other Nonmetals.—Sulfur production was mainly from the Kaohsiung refinery of the Chinese Petroleum Corp. (CPC). Sulfur recovery in 1976 was 5,770 tons. Pyrite production was dependent on the scale of copper mining output. Each ton of copper ore mined yielded about 176 pounds of pyrite, which could be further processed into a pyrite concentrate containing 40% sulfur. The copper operation at Chinkuashih was the leading producer of pyrite; small amounts were recovered at Chingfeng. Output of pyrite concentrate in 1976 was 9,386 tons, down 4,789 tons from the 1975 production. The bulk of the domestic demand of sulfur was supplied by imports. In 1976, 89,122 tons of sulfur was shipped to Taiwan, almost wholly from Canada and Japan.

Serpentine of commercial quality is found in the localities of Yüli and Juisui. The rock occurs in the colors of dark green, light green, and yellowish green, and with mottled color patterns. Seven operating mines, all hand-sorting fluviatile boulders along the streambeds in eastern Taiwan, produced 15,639 tons of serpentine in 1976, compared with 22,453 tons in 1975.

Asbestos and talc appear in schistose rocks in eastern Taiwan. Asbestos mining was only marginal at present. In 1976, 853 tons of asbestos was produced, down 884 tons from the 1975 output.

Talc production increased from 12,050 tons in 1975 to 15,481 tons in 1976. Most of the production was actually sericite

schist, which was used as a substitute for talc in the manufacture of insecticide. Small amounts of feldspar, which is used largely by the ceramic industry, were produced near Tungao. Mica, which is associated with the feldspar, occurs in the same pegmatite veins. In 1976, mica production totaled 448 tons, compared with 292 tons in 1975.

Glass sand deposits of commercial value are located in the white sandstone beds of coal-bearing formations at Hsinchuhsien and Miaolihsien in northwestern Taiwan. The white sandstone was crushed and ground, then washed to remove clay, rock fragments, and other impurities. The resultant pulverized sand was used directly by Taiwan's growing glass industry with only small amounts of glass sands being shipped for export. Production of glass sands in 1976 was estimated at 290,000 tons, 50,000 tons over that in 1975.

Clays, which are used in the manufacture of brick and tile, occur commonly and are widespread throughout Taiwan. They were extracted from the areas where kilns were situated. Ceramic and fire clays were produced mainly in Peitore in northern Taiwan. The clay quality is generally inferior, and high-grade clay had to be imported to blend with local clays to manufacture high-quality porcelain, pottery, and whiteware. Production of clay used in cement totaled 1.8 million tons in 1976.

MINERAL FUELS

Coal.—Coal, the most important mineral commodity mined in Taiwan, occurs mainly in northern Taiwan. The coalfields are geologically complicated, having abundant faults and folds. In some areas, the coal has been pulverized, and the hanging wall and the foot wall are weak. The beds are usually thin and steeply inclined and vary greatly in thickness. Two slopes were generally driven down along the coalbed to be mined, one serving as the intake airway and the other as the return. The common practice was to use the advancing shortwall technique combined with the room-and-pillar system.

Coal was mostly dug with hand or pneumatic coal pick. Hand-push baskets, chain conveyors, steel troughs, and chutes were used for face transportation. Hand-push mine cars and rope haulage were generally used for level transportation. There was no blasting except for rock excavation. Timber and steel supports were used at faces and on the levels.

The complexities of mining this type of coalbed formation eliminated the possibility of mechanizing the industry to any great extent. Local coal mining relied heavily on manual labor and the productivity per man-month was low, averaging 8.89 tons in 1976. During the year, 3.2 million tons of coal was mined, valued at $115 million, or 39% of the output value of Taiwan's total mining industry.

Domestic coal served as the chief fuel in powerplants, railroads, sugar mills, cement factories, ceramic kilns, and papermills. Smaller amounts of coal were used in fertilizer plants, aluminum plants, and textile mills, and in alcohol manufacture. Low-grade coking coal was converted to a semicoke for household use. Since 1965, there had been no exports of coal. In 1976, 200,863 tons of steam coal was imported, primarily from Australia, the Republic of South Africa, and India, in that order.

About 20% of the coal produced in Taiwan was classified as coking coal. Pioneer Chemical Corporation and Hsin-Chu Chemical Corporation operated the only byproduct coke plants in Taiwan; both also produced coal gas for municipal use. Both companies had exported part of their output since 1966 and in 1976 shipped 9,095 tons to Indonesia, Malaysia, Singapore, and four other Asian countries. Total production of coking coal in 1976 was 228,000 tons. The principal domestic coal-using industries were iron and steel works, carbide manufacturers, and the plastics industry. Imports of coking coal during the year totaled 23,953 tons (all from Japan), valued at $1.6 million. The domestic market for coking coal was limited. However, when China Steel's integrated iron and steel plant at Kaohsiung comes on-stream, Taiwan will need to import large tonnages of coking coal on a continuing basis.

Natural Gas.—Output of natural gas in 1976 totaled 1.8 billion cubic meters. Production was largely from the 20 producing wells in the Chinshui gasfield and from the 29 producing wells in the Tiehchenshan Field. A small amount of gas was produced at the Chutouchi Field. Field exploration

and test drilling in Taiwan indicated that the Pashatan and Yunghoshan Fields in north-central Taiwan were potential producers of commercial gas and condensate oil. Additionally, test drilling in the Paoshan Field indicated natural gas reserves in the northern part of the western basin of Taiwan. Plans were made for further exploration of the southern part of the same basin. Taiwan's reserve of natural gas was estimated at 28.8 billion cubic meters.

Petroleum.—Production of oil in 1976 was 247,232 kiloliters (about 210,000 metric tons), a 15% increase over crude production in 1975. Domestic production equaled less than 2% of crude oil imports in 1976. During the year, Taiwan imported 12.4 million tons of crude oil of which 6.7 million tons was from Kuwait, 4.7 million tons from Saudi Arabia, and the remainder from Brunei, Indonesia, Iran, and Singapore. Imports of crude oil in 1976 were valued at $1.1 billion, and refined oil imports at $205.3 million.

CPC, a Government-owned enterprise, was the sole oil company in Taiwan. CPC's refinery at Kaohsiung had a capacity of 334,500 barrels per day (multiply by 50 to convert to metric tons per year). The corporation was responsible for all phases of the petroleum industry in Taiwan from exploration, production, and refining to marketing. CPC was the sole operator for onshore oil exploration and development. However, CPC had entered into a joint-venture agreement with foreign companies on the continental shelf. During 1976, six companies held joint-venture agreements covering 98,480 square kilometers offshore: Continental Oil Co.-Amoco International, Ocean Exploration, Clinton International Ltd., Texfel Pacific Corp., Superior Oil Co., and Comoro Petroleum.

The single successful offshore hole to date was the F–1 gas-condensate discovery made by Continental Oil Co. with Amoco International, about 60 miles southwest of Taiwan in 400 feet of water. The strike indicated a well capability of 25 million cubic feet per day of gas and 250 barrels per day of condensate. The second successful strike was the CDA–1 well of CPC about 16 kilometers off the coast of Lukang in central Taiwan. The well tested undisclosed amounts of oil from a depth of about 3,600 meters from a sandstone formation. Taiwan's domestic crude oil reserves were estimated at only 24 million barrels (roughly 3.3 million tons), plus 15,000 million barrels of condensate reserves.

The Mineral Industry of Tanzania

By David E. Morse [1]

During 1976, mineral production in Tanzania was small by world standards. Diamond was the leading mineral export, followed by salt and gem stones. In general, production of minerals declined during 1976 partly as a result of the country's economic difficulties. Tanzania's foreign exchange shortage caused reduced imports of crude oil and spare parts that resulted in a fall in mineral output. No changes were made in the Government's 1974 foreign exchange control program that had suspended repatriation of all foreign business capital, earnings, and fees.

The Tanzania-Zambia Railway (TAZARA) was officially opened in July 1976, although the line had been completed in mid-1975 and some traffic had used the new rail link in late 1975. The volume of materials on the line grew steadily during 1976 and caused considerable congestion at the port of Dar es Salaam in the middle of the year, but by yearend, most of the congestion had been relieved. The line generated significant revenues during the year because a large share of the import-export traffic generated in landlocked Zambia made use of the rail link. The new railroad was expected to stimulate mineral development in southwestern Tanzania where deposits of coal, iron ore, gold, and mica have been studied.

During 1976, mineral exploration activity in Tanzania was conducted by the Geology and Mines Division of the Ministry of Water Development, Energy and Minerals, the State Mining Corp., foreign governments, the United Nations, and private industry. Teams from the People's Republic of China continued investigations of iron ore and coal deposits near the TAZARA route to determine the feasibility of establishing an iron and steel industry in Mbeya District. Studies sponsored by a consortium of Japanese companies and the Government of Tanzania were conducted to establish a soda ash industry based on the Lake Natron alkali deposits. Heavy beach sands deposits near Dar es Salaam were studied and pilot plant operations were conducted under a joint Tanzania-Romania agreement. The United Nations Development Program supported geologic surveys in the northwest, continued systematic geochemical and geophysical exploration of ultrabasic intrusive bodies with lateritic nickel potential, and began a detailed surface investigation of a large ultrabasic body in Kabanga. Systematic geologic mapping on a scale of 1:125,000 was continued by the staff of the Geology and Mines Division. Exploration for oil continued offshore without positive results; the natural gas deposit discovered in 1974 on Songo Songo Island was further evaluated during 1976.

[1] Physical scientist, International Data and Analysis.

PRODUCTION

Diamond retained its position as the most important mineral produced in Tanzania and accounted for more than 85% of the value of all minerals produced during 1976. Compared with 1975 production, diamond output dropped 2% and caused a decline in the value of all mineral production. Output of cement, precious and semiprecious stones, and salt also declined during the year.

TRADE

Exports of diamond in 1976 were valued at about $19.1 million, a 1% increase compared with those of 1975. Exports of solar evaporated salt almost doubled in value to nearly $900,000, and the export value of semiprecious and precious stones increased from about $337,000 in 1975 to nearly $500,000 in 1976. Exports of petroleum products and residual oil from the refinery at Dar es Salaam were valued at $21 million.

Imports of mineral commodities and crude oil were restrained during 1976 owing to Tanzania's foreign exchange difficulties. The import value of fuels dropped 23%, that of ferrous metals declined 16%,

and that of fertilizers fell 43%. Imports of cement increased 40% and the import value of nonferrous metals increased about 27%.

COMMODITY REVIEW

METALS

Gold.—Production of alluvial gold decreased to 10.5 troy ounces because of low rainfall. Prospecting for gold was continued by the State Mining Corp. and the United Nations. The major area under investigation was between Nzega and Kahama on the plateau south of Lake Victoria. Alluvial deposits along the Sira River near Chunya were to be exploited with assistance from the Soviet Union.

Iron Ore.—The Government planned to develop the Chunya iron ore deposits in southwest Tanzania. Teams from China continued a program of study and evaluation on the deposits during 1976. The cost of iron and steel imports during the year was about $33 million, and in an effort to reduce the trade deficit, the Government planned an iron and steel industry based on Chunya iron ore and coal from the Songwe-Kiwera coalfields.

Tin.—The most important metallic export from Tanzania in 1976 was 22 tons of tin concentrate, a 1-ton increase compared with that of 1975. Tin concentrate output for both 1975 and 1976 was low compared with the previous year owing to the lack of rainwater used in tin washing.

Titanium.—Beach Sands Mining Co., Ltd., a joint venture of the Tanzanian and Romanian Governments, operated a pilot plant to process beach sands containing ilmenite and rutile at Siversands near Dar es Salaam. The feasability of mining heavy beach sands at Mtwara and on Pemba Island was under study during 1976.

NONMETALS

Cement.—Production from Tanzania's only cement plant at Wazo Hill near Dar es Salaam continued to decline. Output from the 340,000-ton-per-year plant was 241,000 tons in 1976, a decrease of 10% compared with that of 1975 and 19% below the 1974 level. To meet Tanzania's cement demand, imports increased 40% compared with those of 1975. The Government projected that yearly cement consumption in Tanzania would be 800,000 to 900,000 tons in the early 1980's. To meet the increased demand, the Government began expansion of the Wazo Hill plant to 600,000 tons per year, and was to build a 500,000-ton-per-year cement plant at Tanga on the north coast and a 250,000-ton-per-year plant near Mbeya in the southwest near the Zambian border.

Diamond.—Diamond production decreased 2% in quantity and 15% in value during 1976. The Mwadui mine and adjoining New Alamasi mine in northern Tanzania accounted for all of the 1976 diamond output, with the Mwadui responsible for the bulk of production. The lower diamond output was expected, as evidenced by the mining plan at Mwadui, which called for treating lower grade ores to prolong the life of the mine.

The State Mining Corp. completed a program of trenching and pitting for diamondiferous kimberlites in northern Tanzania but did not report any new deposits.

Gem Stones.—Tanzania's small-scale mines produced a variety of gem-quality minerals including beryl, emerald, garnet, rhodolite, zoisite (tanzanite), and quartz (amethyst). Production of gem stones remained depressed during 1976 owing to marketing difficulties experienced by Tanzania Gemstones Industries, Ltd., the country's only dealer in precious and semiprecious stones. Most of the gem stone production was from mines near Merelaui and Longido in the north between Mt. Kilimanjaro and Lake Natron.

Salt.—Exports of salt from the Uvinza saltworks of Nyanza Salt Mines, Ltd., located east of Kigoma, increased to 9,100 tons in 1976 and in value to $890,000, a 44% increase in value compared with 1975. Salt was produced by solar evaporation of brines from wells and natural springs, and was the second most important Tanzanian mineral export after diamond. The coastal saltworks near Mtwara and Lindi in the extreme south and near Tanga in the north produced salt for domestic consumption. The Lindi saltworks was to be expanded 69 acres at a cost of about $130,000.

Soda Ash.—A team from the Japan International Cooperation Agency conducted a feasibility study on the proposed soda ash project at Lake Natron in northern Tanzania on the Kenya border. The rift valley alkaline shallow lake deposit was estimated to contain over 100 million tons of soda ash. A joint venture of five Japanese companies and the Tanzanian Government planned to construct a 30,000-ton-per-year refining plant on the lake and transport facilities to either the port of Mombassa in Kenya or Tanga in Tanzania. The bulk of the output was to be exported to Japan.[2]

MINERAL FUELS

Coal.—The State Mining Corp., with the assistance of teams from China, continued to investigate the coalfields at Songwe-Kiwera in southwestern Tanzania, near the Malawi border. Prime interest in the coal was its suitability for use in the production of iron and steel.

Petroleum.—Exploration for petroleum continued in Tanzanian waters and on Songo Songo Island, but no important discoveries were made during 1976. The Oil and Natural Gas Commission (ONGC) of India abandoned a wildcat on Songo Songo after a gas blowout at 3,200 feet. ONGC planned to spud a second well on the island in late 1976 or early 1977. Azienda

[2] Japan Chemical Week. Japan-Tanzania Soda Ash Venture to be Studied Again. V. 17, No. 824, Feb. 12, 1976, p. 5.

Generale Italiani Petroli S.p.A. (AGIP) continued exploration activities offshore, and Oceanic Exploration Co. began preliminary seismic surveys in its deepwater concession area off the north coast of Tanzania.

Tanzania imported about 7 million barrels of crude oil to meet most of its 1976 energy demands. The cost of crude petroleum, about $82 million in 1976, continued to strain Tanzania's foreign exchange reserves. The gas deposits on Songo Songo Island and domestic coal resources were studied for possible development to reduce the country's imports of mineral fuels.

The petroleum refinery at Dar es Salaam had an input of about 7.0 million barrels during 1976, an increase of nearly 31% compared with that of 1975.

The Mineral Industry of Thailand

By Gordon L. Kinney [1]

Despite a politically turbulent year, which saw a major cabinet reshuffle, an election campaign marred by considerable violence, a change of prime ministers, and finally the military overthrow of the elected Government, the Thai economy as a whole showed good improvement and largely paralleled the general recovery of the world economy. The year showed very graphically that the economy, which is strongly based on agricultural exports, was almost entirely independent of the nation's politics, which are controlled mainly by the population of Bangkok.

Industrial activity was on the upswing, and the mining industry ended the year showing a significant comeback after a poor showing in 1975 and early 1976. The gross domestic product (GDP) increased 6%, which was about the planned target. Manufacturing, trade, services, transportation, and construction all turned in higher growth rates than in 1975, but growth in agriculture slowed a little from the excellent 1975 crop year. The consumer price index increased by about 4.2%, down from the 5.4% recorded in 1975 and much less than the 24%+ of 1974. The manufacturing sector grew 7.5% during 1976. Agricultural processing plants stepped up activity, processing the large output of the 1975–76 crop year. Overall, the manufacturing sector increased from 17.6% of GDP in 1975 to 18.3% in 1976. The gross national product (GNP) at current prices was estimated at $16.2 billion,[2] up 11% over that of 1975. The GNP at constant 1962 prices was estimated at $8.7 billion, up nearly 6%. Balance of payments showed a nominal $4 million deficit, compared with a $143 million deficit in 1975.

Mineral output declined slightly in 1974 and substantially in 1975. Counter to the general economic upturn in 1976, the nontin-mining sector continued to falter well into the year, mainly because investors and company officials were hesitant about implementing plans owing to political uncertainties. Policy decisions, particularly relating to mining development issues, either went against proposed new projects or were left unsettled during Prime Minister Seni's 5 months in office.

The failure of the Seni Government to effectively guide the country's affairs led to a decision by the Armed Forces to overrule the constitution and dismiss the parliament. Thanin Kraivichien was appointed the new Prime Minister in October. The new Government dealt firmly with labor unrest, banning all strikes and lockouts. After the military takeover, a policy of improving the climate for business and investment was announced, and a new Investment Act was passed to help attract foreign capital.

By yearend 1976 the Thailand Exploration and Mining Co., Ltd. (TEMCO) offshore-tin-mining problem was nearing a solution. The Government approved a management contract with Billiton Thailand Ltd., TEMCO's successor, to work the former TEMCO concessions off Phuket. Negotiations between the new Government and Thai Zinc Ltd. (TZL) for rights to construct a large zinc refinery and to mine a high-grade zinc deposit had progressed satisfactorily and were in the final stages at yearend. Negotiations over the natural gas pipeline project were carried on throughout the year. After the change of Government in

[1] Physical scientist, International Data and Analysis.

[2] Where necessary, values have been converted from Thai baht (B) to U.S. dollars at the rate of B20.30 = US$1.00.

October, an agreement between the Ministry of Industry and the Union Oil Company of Thailand was reached on all points except for the gas pricing structure.[3]

Mining in Thailand is based mainly on the tin dredges and many kinds of small-scale, labor-intensive operations. Over 700 mines reportedly were in production at yearend. These provided full-time employment for about 53,000 persons in 39 of Thailand's 71 provinces. Thailand produced 29 kinds of minerals in 1976, headed prominently by tin but also including by-product minerals like tantalite, ilmenite, monazite, and xenotime.

[3] U.S. Embassy, Bangkok, Thailand. Industrial Outlook Report: Minerals. State Department Airgram A-40, Feb. 11, 1977, pp. 1-13.

PRODUCTION

Production of Thailand's three most valuable minerals went up substantially. In 1976, tin production was valued at $151 million, tungsten at $30 million, and antimony at $13 million. Quantitywise, mine output of tin, tungsten, and antimony all increased more than 15%. Fluorite and barite, the fourth- and fifth-ranking minerals, both suffered from lack of demand, with output dropping more than 25% in both cases. Overall mineral production value increased 28%, from $168 million in 1975 to $215 million in 1976, just short of the 1974 record year of $231 million. Prospects for tin look favorable for 1977, owing to the fact that the country's biggest dredge did not contribute to production in 1976. The dredge had been kept in operating condition throughout the year and should be ready to resume operations soon after a new tin contract is signed between the Government and Billiton. Thailand smelts its own tin, and output increased by more than 22% in 1976.

TRADE

Thai exports increased about 33% in 1976, and imports went up over 7%. The higher export earnings reflected larger sales volumes in most cases since prices for many of Thailand's exports were down from the 1975 levels. Tin and rubber were the major exports to show significant price increases. Thailand was second to the

United States in world export of rice in 1976. More rice was sold in the first 9 months of 1976 than in all of 1975. Other agricultural products also did well. Comparing the first 4 months of 1976 with the corresponding period in 1975, sugar exports were up over 80% in value, rubber 77%, and tapioca over 50%. The trade deficit narrowed significantly in 1976. Exports totaled approximately $3.0 billion and imports, $3.6 billion. The roughly $600 million balance of trade deficit was much lower than the $1 billion deficit in 1975. However, the improvement was not entirely favorable since it also reflected a lower demand for capital equipment needed to create new productive capacity.

Thai mining activity is heavily export oriented. Mineral products earned about 10% of the total export income; tin was the most important contributor by far. Eleven other kinds of minerals and metals were exported during the year; namely, antimony, barite, feldspar, fluorspar, gypsum, kaolin, lead, manganese, tantalite, tungsten, and xenotime.

Mineral export earnings totaled approximately $213 million, a 40% increase over the earnings for 1975. The 1976 figure topped by 3% the previous record set in 1974. The value of four of the first five ranking minerals exported registered increases, with only barite showing a nominal decrease because of a lower demand for heavy drilling mud in oil exploration within Southeast Asia.

Exports of tin metal from the Thaisarco tin smelter totaled 19,616 tons in 1976, a 13% increase over the 1975 exports. The United States was the largest purchaser of Thai tin in 1976 with 7,665 tons, followed by Japan with 6,151 tons and the Netherlands with 5,700 tons. Total tin exports were valued at about $144 million, compared with $112 million in 1975. In 1976, tin represented about two-thirds of the total value of mineral exports, and 5% of all exports.

Thailand imported about 7,800,000 kiloliters of crude petroleum in 1976 (a 1-million-kiloliter increase over the 1975 output). Petroleum products imports amounted to 2,300,000 kiloliters in 1976. The import bill for crude oil was $697 million, and that for refined products was $200 million. Petroleum supplied over 80% of the country's energy requirements. Imported crude oil continued to be refined at the 65,000-barrel-per-day Thai Oil Refinery Co., the 65,000-barrel-per-day Summit Industrial Corp. refinery, and the 35,000-barrel-per-day Esso Petroleum Co. Ltd. refinery, all near Bangkok.

COMMODITY REVIEW

METALS

Antimony.—A new mine was commissioned in 1976 at Phahad in Phrae Province, the country's first modern mechanized underground antimony operation. Phluang Thong Thai Co., an affiliate of the Hochschild Group, is the owner. Annual output was planned at 1,000 tons of mine antimony.[4]

The Hibino Metal Industrial Corp. Ltd., of Japan reported it would begin operating a new property near Chiang Mai. Planned production would be 100 tons per month of 60% concentrate. Technical problems at Hibino's present 150-ton-per-month Banpin workings (also near Chiang Mai) were making mining at this location increasingly difficult.

Production of antimony, Thailand's third most important mineral, increased 17% to 8,637 tons of 60% concentrate. About 480 tons of refined metal were also produced. Exports for 1976 were reported at 5,861 tons of concentrate worth $4.6 million, most of which went to Western Europe. Two hundred fifty-three tons of refined metal was also exported.

Iron and Steel.—Iron ore production remained at very low levels. The iron ore was consumed locally by two small blast furnaces. Production of steel from imported scrap dropped 32% to 370,000 tons.

A 150,000-ton-per-year sponge iron plant using lignite as the reductant was being planned for Thailand. The project was reportedly being promoted by the G. S. Steel Co., with the New Zealand Steel Ltd. scheduled to provide technical know-how. In light of the availability of iron ore reserves within Thailand, an early start on construction of the proposed plant appears unlikely.

The Ministry of Industry was planning to explore for additional iron ore in 11 provinces in the central and eastern parts of the country. The latest estimate on Thailand's iron ore reserves is only 40 million tons.

Manganese.—One of the bright spots in the mining sector was manganese. Total mine output value came to $2.2 million for some 50,000 tons of product, or roughly

[4] Mining Journal (London). Mining Annual Review 1977. June 1977, p. 411.

twice the 1975 figures. Most of Thailand's manganese ore has been exported. Japan and Taiwan were the main customers in 1976, using Thai manganese in iron and steel smelting and in the making of dry cell batteries. During 1976, trial shipments also went to the United Kingdom, West Germany, the Netherlands, and Sweden. Domestic consumption was 4,000 to 5,000 tons of battery-grade ore, by several dry cell companies.

There were 9 to 11 operating mines in 1976, employing altogether 500 to 600 workers. The Sahachart Mining Co. owns Thailand's largest manganese mine and mill, located at Mae Tang in Chiang Mai Province. During the year, the mill was expanded from 200 to 1,000 tons of ore per day.

Tantalum-Columbium.—Six tons of tantalite and seven tons of tantalum-columbium concentrate were reportedly produced in 1976. This does not, however, include the rather considerable tonnage of tantalum–columbium–rich tin slag produced by the Thaisarco tin smelter in Phuket. Exports of the slag were known to have been made during the year, mainly to the United States, but no values or tonnages were reported. The Ta_2O_5 content of the Thaisarco slags that were exported was about 12%, and the Cb_2O_5 content was about 10%. This slag is one of the major sources of tantalum-columbium in the world, with a real value running into several million dollars annually.

Tin.—Tin again was the dominant factor in the mineral economy of Thailand in 1976. Output of tin concentrates increased sharply to nearly 28,000 tons, and output of smelter tin increased to 20,390 tons. Thailand ranked fourth among market economy countries as a producer of tin. The bulk of the production came from gravel-pump operations and lowland dredging of placer deposits. About 15% came from small lode and open pit mines in the mountainous areas, and more than 25% came from offshore marine dredging operations. The bucket line dredges *Aokam No. 2* and *Aokam No. 3* and the *Sea Dredge* operated only during favorable parts of the year. The Aokam Tin Bhd., Tongkah Harbour Tin Dredging Bhd., and Southern Kinta Consolidated Ltd. dredges encountered labor troubles in January which were not settled until April. Lease renewals were not agreed on between Southern Kinta and the Government, and this prevented the company from operating its dredge the remainder of 1976. The big *TEMCO II* suction dredge was not operated during the year.

As a result of cancellation of TEMCO's offshore mining leases in 1975, Billiton bought out all of TEMCO's holdings and equipment and began negotiations with the Government's newly formed Offshore Mining Organization (OMO). OMO wanted to lease the valuable offshore mining rights near Phuket on the west coast to Billiton on a contractual basis. Negotiations remained stalled through most of the year, but, after the change in Government in October 1976, the new administration made a more concerted effort to reach a mutually agreeable settlement.

In December, OMO and Billiton were nearing a settlement and OMO had agreed to a sliding-scale revenue-sharing arrangement. Billiton had no claim to OMO's concession areas, but remuneration from working them would be derived from the revenue of the mined tin. Details of the agreement were reported as follows: 68.75% of the profit of the first 1,300 tons of tin goes to Billiton, and the remaining 31.25% goes to OMO; the split is 60–40 for the next 200 tons, and for the following 200 tons, it is 50–50; for any production over 1,700 tons per year, the split is 60–40 in favor of OMO.[5] The new Thai Cabinet had approved the conditions on December 8 and were awaiting Billiton's signature at yearend. The period of the agreement was to be for 5 years with option of renewal for 2 years longer. The settlement was viewed as a direct encouragement to foreign investment and will probably be used as a model for other mineral contract negotiations.

After the TEMCO operation ceased in 1975, a fleet of small illegal tin-mining boats operated in the area east of Phuket. These ranged from small boats with individual divers using primitive air hoses and wicker baskets, to converted fishing boats using diesel-powered suction hoses. The boats had onboard sluices which gave a product averaging 30% tin. During the year, as many as 5,000 boats operated in the shallower waters. More than 38,000

[5] The Wall Street Journal. V. 188, No. 114, Dec. 10, 1976, p. 10.

persons were then employed in the dredging and beneficiation of the ore, both onshore and offshore. The boats were winning a great deal of high-grade ore, and most of this was smuggled out of the country without the Government receiving any revenue. To get the problem under control, the Government finally allowed the Phang Nga Province administration to license and legalize these boats to use a small area of the former TEMCO leases. The boats were restricted to 20 meters in length, a maximum of 150 horsepower, and suction hose no more than 10 centimeters in diameter. All of the concentrates must be sold to the Government, and boat owners were to pay a royalty of 80 bahts per picul (about 3 cents per pound).[6]

The importance of these small suction boat operations can be seen from the fact that over 6,000 tons of tin concentrate was reportedly produced during 1976, or nearly 23% of the national total.[7]

Cooperation between Thai and Malaysian authorities during 1976 and the above-mentioned licensing of the small mining boats have significantly reduced the incidence of tin smuggling from western Thailand's waters. Thus, the recorded increase in Thailand's 1976 tin production was actually due more to the reduction in smuggling and the first-time reporting of the suction boat operations than to any really significant increase in actual tin production.

It was reported late in the year that Charter Consolidated Ltd., a British mining company, in partnership with Bethlehem Steel Corp. and Aluminum Co. of America, was interested in offshore dredging activities in Thailand. Charter prospected in about 20 meters of water 1 to 2 kilometers off Phuket Island and confirmed a large volume of ore judged marginal at 1976 prices. Charter has reportedly spent $8 million on the surveying and on the design of a new dredge that can be used 10 months of the year instead of the more standard 6-month period. The project may run into difficulty on environmental grounds because a crucial part of the ore reserves are in Patong Bay off Phuket Island. Patong is a prime tourist resort, and land developers plan a considerable expansion in the area.

Sierra Mining Co. was considering setting up a new tin-dredging operation on the Tha Khwai River in Nakhon Si Thammarat Province in southern Thailand. Sierra owns an old dredge that could be brought from northern California.

World tin prices showed a considerable improvement after a poor year in 1975. Average monthly prices, which dropped in all but 2 months in 1975, climbed steadily through all but 2 months of 1976. The average Metals Week composite price in the United States during 1976 was $3.80, and at yearend the price was $4.40 per pound.

The Thaisarco plant at Phuket is Thailand's only modern tin smelter. It continued to smelt virtually all of the country's tin.

Tungsten.—Production of tungsten concentrate, Thailand's second most valuable mineral, increased from 3,441 tons in 1975 to 3,976 tons in 1976, reversing the downward trend of the last few years. Value of the concentrate produced was nearly $30 million. While production increased 16% the value of the concentrate increased nearly 38% because of increased world prices. Thailand's tungsten production ranked third in the world among market economy nations. Exports of tungsten were in the form of scheelite and wolframite concentrate. In 1976, 624 tons of scheelite was shipped for $4.4 million, and 3,300 tons of wolframite was exported for $20.7 million.

The Sichon tin–tungsten lode-mining project of Faber Merlin began trial operation of its mill on February 15, 1976. Full operation was scheduled for September, at 3,000 tons of ore per month. Yield was expected to be 500 piculs of tin (30 tons) and 60 piculs of tungsten (4 tons) per month.

At yearend 1976, 16 wolframite and scheelite lode mines were in operation, together with 175 tin–tungsten placers. About 40% of Thailand's tungsten is produced in conjunction with tin. The Khao Soon mines in Nakhon Si Thammarat Province accounted for nearly half of the total tungsten output. Illegal mining and smuggling by thousands of freelance miners in Khao Soon had made for a politically unstable environment during the last few years, adversely affecting production. In June 1976, however, the Government sent

[6] World Mining. V. 30, No. 4, April 1977, pp. 43–45.

[7] Pages 409–413 of work cited in footnote 4.

a large security force into the area to restore and maintain order, and this no doubt was instrumental in increasing production.

Zinc.—All mining and shipment of zinc ores stopped during 1976 pending the outcome of protracted negotiations between TZL and the Thai Government. TZL planned to construct a 60,000-ton-per-year electrolytic zinc refinery at the provincial capital of Tak, about 370 kilometers north-northwest of Bangkok. The refinery would process the rich zinc silicate ores of Mae Sot, 70 kilometers west of Tak. Ore reserves are relatively small (4 million tons), but the grade averages 25% zinc. TZL, a subsidiary of New Jersey Zinc Co., was reportedly nearing a final agreement with the new Thai Government at yearend. Most major bargaining points had been agreed to by both parties, and only the profit-sharing arrangements were left to be worked out. Thai officials want assurances that the best interests of the country are met in the exploitation of Thailand's nonrenewable natural resources. While being cautious with the financial aspects of the contract, the Government was nevertheless eager to complete the arrangements. It was hoped that the project would show other potential foreign investors that the new Government was actively trying to fundamentally improve the private investment climate in Thailand.

It was reported that Hwashin Industrial Corporation of the Republic of Korea had obtained the primary contract for the construction of the $40 million refinery. The total project was to cost about $95 million and would represent the largest foreign investment in Thailand.

Other Metals.—The Thai board of investment reportedly approved the Bangkok-based Euro-Thai Co.'s planned 900-ton-per-year copper and 670-ton-per-year tin mine at Tambol Tham Thalu, in the Amphoe Bannang Sata area of Yala Province.[8]

Canadian-Siam Resources Co. began mill testing of ore at its Lusah lead-zinc-silver-tin mine.

NONMETALS

Barite.—Production of barite, the fifth most important Thai mineral in value, dropped more than 40%, to about 150,000 tons, valued at over $4 million. The decline was attributed not to a lack of ore or to mining problems, but to a reduction in foreign demand due to a severe cutback of petroleum exploration drilling in Southeast Asia. The international oil industry is the main consumer of heavy barite drilling mud.

In June 1976, a new 50,000-ton-per-year barite milling plant was opened in Tha Sala, Nakhon Si Thammarat Province, by the Thailand Barite Co., an affiliate of Dresser Industries. Output of the plant, however, was at a minimum level pending an increase in demand for drilling mud.

Endeavour Oil N.L. explored a barite find at its Thung Wa property. Diamond drilling indicated additional possible reserves, and further exploration work was planned for the site.

Cement.—The cement industry had a good year in 1976, reflecting expanded activity in Government and private housing construction and in the construction of new commercial buildings. Domestic consumption was up 24% for the year, compared with the 6% increase recorded in 1975. Another factor that stimulated production was the price increases sanctioned by the Government in March and July. These increases allowed an equitable profit margin for the privately owned cement operators, who had reportedly been operating at a loss in the face of rising production costs.

Total production capacity increased to 5.1 million tons with the completion of the Kaeng Koi plant in Saraburi Province in late 1975. The production for 1976 of nearly 4.5 million tons was an increase of 12.8% over 1975.[9] Thai cement producers anticipated that domestic demand will increase about 11% per year over the next 5 years.

Cement exports totaled 604,000 tons in 1976, a decline of 17% from that of 1975. However, to encourage exports, the Government removed its export license requirements in November, thereby permitting long-term contracts to be entered with foreign buyers. Increased competition from Japan, Republic of Korea and Taiwan had cut into Thailand's export sales.

---

[8] Tin International (London). V. 49, No. 11, November 1976, p. 396.

[9] U.S. Embassy, Bangkok, Thailand. Cement Production and Sales in 1976. State Department Airgram A-46, Feb. 18, 1977, 3 pp.

Fluorspar.—Output of fluorspar, declining since 1973, dropped sharply again in 1976. Production of metallurgical-grade ore was down 27% to 128,000 tons worth $5.7 million, and low-grade ore production 35% to 72,000 tons worth $1.6 million. Export tonnages fared better, with over 200,000 tons of metallurgical-grade fluorspar valued at $8.4 million and over 90,000 tons of acid-grade fluorspar valued at $5.3 million shipped in 1976. Unfavorable world prices and demand forced many fluorspar mines to cease operations. By December 1976 only 38 mines were at work compared with 66 during some months of 1974. Thailand was and still is one of the world's major producers of fluorspar, although output tonnage and value have been cut more than half compared with peak levels in the past.

Gypsum.—Gypsum production rose a modest 5% for the year, but exports continued to decline. In 1976, exports were only 62,000 tons, a decrease of 33% from the 1975 level. Malaysia, Taiwan, and Indonesia have been the major recipients. Increased activity in the construction industry accounted for improved domestic consumption, which increased 23% to 164,000 tons in 1976. The value of production for gypsum was $3.4 million, which ranked it sixth in minerals produced in Thailand.

Silica Sand.—The Thai Glass Industries Ltd. in Bangkok completed a $6.7 million expansion program in October. Construction of a 160-ton-per-day glass production furnace, the largest in Southeast Asia, was the major expense. Technical experts from Australian Consolidated Industries Ltd. utilized latest technology in the design and construction of the plant. Designed capacity is 350 tons per day of blown and pressed glass containers, for consumption within Thailand. Silica sand production dropped 30% in 1976 but should pick up in 1977 with the startup of the new furnace line.

Other Nonmetals.—The Department of Mineral Resources continued its evaluation of the Cretaceous evaporite deposits of northeastern Thailand. Large reserves of rock salt, gypsum, and potash (carnallite, $KMgCl_3 \cdot 6H_2O$; and sylvite, KCl) have been known for some time. It was announced that the Asian Development Bank would finance a detailed feasibility study of the deposits. The main project presently envisioned is a 360,000-ton-per-year soda ash plant based on the very pure rock salt reserves. A rock salt mine with a 1.6-million-ton-per-year capacity would support the plant. The $160 million project would be a cooperative venture of the Association of Southeast Asian Nations. Soda ash (Na_2CO_3) is a basic industrial chemical used in glass manufacturing, ceramics, soap and detergents, pulp and paper, textiles, and metal and petroleum refining.

MINERAL FUELS

Coal.—*Lignite.*—Despite the highly publicized natural gas discoveries, lignite remained the only significant fuel produced in Thailand during 1976. Production increased 47% to a record 680,000 tons. The two most important mines were at Krabi in the south and Mae Moh in the north. The Department of Mineral Resources was evaluating other lignite occurrences throughout the country.

The main consumer of lignite is the Electricity Generating Authority of Thailand, which operates lignite-fired powerplants near the two mines and at Bangkok. Growing amounts of lignite also are being used as fuel in industrial applications. The lignite consumed in Thailand represented 2.3% of the total energy used in 1976.

Petroleum and Natural Gas.—Continued exploration in the Gulf of Thailand confirmed considerable reserves of natural gas and condensate but only small showings of oil. In June 1976 the Union Oil Co. of Thailand consortium made the first strike in exploration Block 10 in 73 meters of water. The well was reported testing at 538,000 cubic meters per day (19 million cubic feet) and 700 barrels per day of condensate. It was the 32d exploration hole drilled in the Gulf and the 9th to show encouraging amounts of natural gas, gas condensate, or in two cases a small amount of light crude oil.

In October another strike was reported in Block 15 by the Texas/Tenneco group. The well produced gas and condensate from 12 zones at a depth of 2,400 meters. Some zones showed considerable carbon dioxide content, but further test results were not available.

The Thai Government awarded supplemental petroleum concessions to British

Petroleum Company Ltd., and Tenneco Thailand Inc., and four new participants.[10] The new companies were Texas Pacific Thailand Inc., Canadian Superior Oil Company Limited, and Highland Thailand Ltd. The concessions were in parts of Blocks 1 through 4 and 14 through 17 in the Gulf of Thailand.

Drilling off the west coast of Thailand continued during the year, and Esso Exploration Inc.'s *Discoverer 534* completed its fifth hole. Each of the last four holes set world records for commercial exploration in deep water. The last hole was drilled in 1,055 meters of water. *Discoverer 534*, one of the largest and most sophisticated drilling ships afloat, uses an anchored mooring system attached to a stationary mooring collar under the center of the ship. The entire ship rotates freely around the collar and maintains proper heading in rough weather by computer-controlled dynamic positioning.

Unfortunately, no commercial quantities of oil or gas were reported in the 11 wells drilled by Esso and Union in their respective W–9 and W–8 concession blocks. At yearend, Esso was still evaluating the results of its drilling program. Any discovery made in these deepwater blocks would have to be very large in order to justify the cost of developing an oilfield in water over a kilometer deep.

Planning continued for the exploitation of the natural gas deposits in the Gulf of Thailand. Continued exploration drilling during the year indicated more reserves than originally believed. Blocks 10, 12, 13, and 15 were now reported to contain an aggregate total of 110 billion cubic meters of recoverable reserves.[11]

Negotiations between the Government and Union Oil Co. were conducted again in 1976, but no contract had been agreed to at yearend. The key points of contention were the pricing structure that would be allowed by the Department of Mineral Resources and the ultimate natural gas pipeline ownership. To break the deadlock, the Government hired a British firm to advise them in determining an equitable price and a French firm to determine the best size and route for the pipeline to Bangkok.

The Government originally wanted Union to take full responsibility for the pipeline construction. However, it was pointed out that the financing of the project would be easier and at lower interest rates if the Government owned the pipeline. Also, if owned by the Government, the procurement of the overland section of right-of-way would be easier, and the line could be used as a common carrier to transport gas from each of the private company's fields. The Government finally agreed to be owner and operator of the line. Pricing of the gas had not been settled at yearend, and negotiations could continue into mid-1977 before an accord is reached. The Government felt the delivered price of gas at Bangkok should be substantially below that of an equivalent amount of imported oil. Union wanted a wellhead price of around $1.60 per thousand cubic feet in order to justify the huge cost of developing the offshore gas and to provide a fair return on its investment. At yearend estimated cost for the project was reported to have risen to $250 million for laying the pipeline and to an equal amount for developing the gasfields.

The Defense Energy Department reportedly was to launch a survey for additional onshore oil production from Fang District in Chiang Mai Province. A Romanian oil company may assist in the work. Romania was already helping the Thai oil industry with a training program for Defense Energy Department officials in Romania. The very small Fang oilfield is currently the only active oil producer in the country; its total reserves are less than 1 million barrels.

A proposal for the construction of a lubricating oil plant was made by the Royal Dutch/Shell Group of Companies. Prospects for the plant being approved were considered better since the October change in Government. Shell and the previous administration were deadlocked on the financial arrangements and the ownership details. The plant would be built at the Thai oil refinery in Sriracha, about 120 kilometers from Bangkok. Because of the sophisticated equipment and technology needed for this modern plant, it would cost about $114 million, about $15 million more than the original 65,000-barrel-per-day refinery. Capacity of the lubricating oil plant, which would operate as part of

[10] Petroleum Times (London). V. 80, No. 2033, August 6, 1976, p. 4.
[11] Business Review. The Gas in the Gulf. V. 5, No. 2, March 1977, pp. 78–83.

the flowsheet of the refinery, was planned at 180,000 tons per year.

Consumption of refined products in 1976 was down about 5%; the biggest declines were in gasoline and diesel oil. Fuel oil, kerosine, liquefied petroleum gas and jet fuel showed small increases. Fuel oil consumption was held down by the nearly 50% increase in domestic lignite production, much of which was used to replace fuel oil in boiler furnace uses.

The Mineral Industry of Tunisia

By E. Shekarchi [1]

The Tunisian economy continued to display strength and versatility in 1976. Its excellent performance during the fourth development plan (1973–76) was attributed in part to a revival of private investment activity throughout the economy. The economic policy of the Government encouraged the private sector to take an active role in development. The Government, meanwhile, retained the prerogative to guide and direct the path of development, to invest actively in crucial economic sectors that required large capital outlays, and to finance infrastructure. In addition, Tunisian legislation granted tax and other advantages to domestic and foreign investors in labor-intensive projects.

Viewing the economy on a sectoral basis, the industrial sector, which overall advanced about 4%, was heavily influenced by a weak mining and energy sector. Although phosphate shipments recovered in 1976, prices were down, from $56 per ton in 1974 to $32 [2] per ton in 1976, and production was cut back to reduce excess stocks accumulated in 1975. Petroleum output was down as onshore production at the El Borma Field continued to fall and the results of new exploration were not yet realized. Resolution of a border dispute with Libya over a highly promising offshore operation was still pending.

The preliminary gross domestic product (GDP) for 1976, based on current prices, was estimated at $4.41 billion, a 1.6% increase over the 1975 GDP, also calculated using 1976 prices. The contribution of the mineral industry, including both minerals energy, was 15% in 1976.

Details of the fifth development plan (1977–80) were released in the latter part of 1976. Investment for the fifth plan was targeted at $9.6 billion. Economic planners projected a job for each new entrant to the labor force by 1981, or a total of 233,000 new nonfarm jobs over the 5-year period. Projects and plans that were to affect the mineral industry follow:

A major offshore natural gasfield, Miskar, discovery of which was announced in early 1975, was to be developed by the Tunisian Government as major shareholder and the French company Elf-Aquitaine as a partner. Also, to reduce Tunisian imports of refined petroleum products, the Government plan called for immediate major expansion of the Bizerte refinery. Extensive expansion programs in phosphate mining, road construction, land reclamation, dam construction, and construction of a nitrogenous-phosphatic fertilizer plant were foreseen in the fifth plan.

In the field of construction and engineering services for cement and electrical power, the new plan proposed two additional cement plants by yearend 1980; Tunisia imported more than half of its cement needs in 1976.

The fifth plan included proposals for railway modernization including new track, rolling stock, signal systems, a new terminal for Tunis, and linkup with the Trans-Maghreb railroads.

The agreement concluded between Tunisia and the European Economic Community (EEC) in 1969 was broadened further in 1976. Under the new provisions, member States of the EEC and Tunisia granted to workers active in each other's territories, the same rights as those enjoyed by their own citizens as far as working conditions, wages, and social security were concerned.

[1] Supervisory physical scientist, International Data and Analysis.

[2] Where necessary, values have been converted from Tunisian dinars (TD) to U.S. dollars at the rate of TD1 = US$2.32.

Also, by the terms of the new agreement, the EEC proposed to invest in the promotion of Tunisian production and infrastructure in the areas of industry, agriculture, trade, technology, science, and environmental protection. The EEC agreed to make available to Tunisia a fund totaling $100 million, of which about $18 million was a gift and the remainder a loan. This cooperation was aimed primarily at intensifying trade between the partners and at providing Tunisian products with easier access to the Common Market.

PRODUCTION AND TRADE

Available data on mineral production are given in table 1. Data on exports and imports are given in tables 2 and 3, respectively.

COMMODITY REVIEW

METALS

Iron and Steel.—For the second consecutive year iron ore production decreased, declining 20% in 1976 from the 1975 output. With depletion of Tunisian hematite-type iron ore deposits, reserves of iron carbonate had to be utilized, which required more expensive underground mining. Tunisian exploitable iron carbonate reserves were estimated at about 14 million tons; however, only one-third of this reserve was located above the water table, and the remainder had to be mined at higher costs.

Under the fifth plan, the iron and steel industry was allocated $6 million for iron ore mine development, a sintering plant, and replacement of old equipment. The El Fouladh steel mill, constructed in 1966, with an annual capacity of 60,000 tons of finished products, had increased its capacity by 1976 to 140,000 tons. Under the fifth plan it was anticipated that plant capacity would reach 180,000 tons by 1980. An electric arc furnace of 30,000-ton capacity was to be in operation by mid-1977. All iron ore requirements for El Fouladh were mined domestically, while all the needed coking coal was imported.

Lead.—Lead ore production (43% to 55% Pb) decreased 5% in 1976, from 17,825 tons to 17,000 tons. Refined lead metal production increased 0.3% from 23,396 tons in 1975 to 23,476 tons in 1976. The slight increase in lead metal production was due to imports of lead ore from neighboring countries. Lead ore imports in 1976 were 5,000 tons from Belgium and 3,000 tons from West Germany. Refined lead metal was exported to the following countries: Italy, 8,000 tons; Greece, 7,000 tons; Algeria, 3,000 tons; and smaller amounts to five European countries. All the lead ore was produced by the Government-owned mining company Société Tunisienne d'Expansion Minière (SOTEMI).

Zinc.—The Fradj Hassan mine started limited production of zinc ore during the year. Total Tunisian zinc ore production (45% to 55% Zn) increased 3.7% from the 1975 output of 12,917 tons to 13,400 tons in 1976. Production of refined zinc metal was reportedly 618 tons for the year, well below the capacity of the plant which was undergoing repair. Most of the zinc metal production was used locally, whereas zinc concentrates were exported primarily to France.

Other Metals.—As a byproduct of lead-zinc smelting, some silver recovery was reported by SOTEMI.

NONMETALS

Cement.—Production of cement decreased 22.4% in 1976, owing to technical difficulties in the plants and to losses attributed to old equipment generally. New cement production capacity was given priority status in the fifth plan, including expansion of the Bizerte and Djebel Djelloud plants. Two new plants, one at Gabes with 700,000 tons annual capacity, which was well underway in 1976, and the other at Thala near Algerian border, with 1 million tons capacity, were to be producing cement by 1980. Demands of the construction industry were so intense that the Tunisian Government was obliged to import more than 500,000 tons of cement during 1976.

A decision was made in the latter part of the year to install a new plant at Bizerte for manufacturing asbestos cement products, primarily pipe. The plant, which was to produce 21,000 meters of pipe for irrigation and sanitation purposes by 1979, would cost $10 million, and was to be financed by a group of private investors, Ciment-Amiante-Tunisia.

Fertilizer Materials.—Production of phosphate rock, primarily consisting of the higher 65% to 68% BPL grade (bone, phosphate, lime), by Cié. des Phosphates de Gafsa (CPG), decreased 5.7% in 1976 from the 1975 output. The decrease was largely due to lower prices of phosphate rock and generally unfavorable world economic conditions. Production of hyperphosphate in 1976 reached about 90,000 tons from 9,000 tons in 1975, apparently owing to the repair of the plant in 1975. Output of simple superphosphate decreased about 4% while production of triple superphosphate increased 90% in 1976. Tunisia's early diversification into intermediate and finished fertilizer products for export gave rise to a larger domestic phosphate rock

demand. During 1976, the domestic phosphate industry consumed 1.2 million tons of raw material. The growing preference among fertilizer producers for imported intermediate products led to a massive growth in phosphoric acid trade in 1976 which allowed Industries Chimique Maghrebines (ICM) to increase exports of acid by 130%. ICM's second phosphoric acid plant at Gabes, which came on stream in late 1974 but was not effectively utilized in 1975, worked at nearly full capacity throughout 1976. The Société d'Engrais Phosphates et Azotes (SEPA) project, which was to incorporate the construction of additional phosphoric acid facilities at Gabes, would further augment domestic phosphate rock requirements beginning in 1979.

During the next 5 years, CPG was to implement plans to double the level of production achieved in 1976, with a target of about 7 million tons of phosphate rock per year by 1981. The bulk of this increase was to be contributed by two mines—Kef es Schfair and Sehib, the former an open-cast mine, and the latter an underground operation. The mining operation at Kef es Schfair, which was carried out by a contractor and produced 536,000 tons in 1976, was to be taken over gradually by CPG engineers, who expected to produce 2.2 million tons per year by 1981. Also by 1981, the Sehib mine was expected to yield 2 million tons. The remaining expected increase of phosphate rock production was to come from the Mdilla and M'rata mines, both located in the Gafsa Basin. Concurrently with these expansions of phosphate rock production, four new washing plants, which were in different stages of construction, were to come into operation. Those at Sehib, Mdilla, and Maulares were slated to start operation in 1979, while the plant at Matlaoui, which would be the fourth at this location, was to be operational in mid-1980.

Outside the Gafsa Basin, CPG's Kalaa Djerda mine was to be expanded to produce 240,000 tons of phosphate rock per year from 1978 onwards. Construction of a washing plant at the Kalaa mine was under consideration during 1975, but no firm decision was made.

Fluorspar.—Fluorspar output rose again in 1976, reaching 34,800 tons, a 3% increase from the 1975 level. Most of the fluorspar was earmarked for export. However, starting in the latter part of 1976, Tunisia began processing the raw material domestically. Industries Chimiques du Fluor's (ICF) aluminum fluoride plant at Gabes, constructed by Heurtey Industris at a cost of about $14 million, started initial tryouts in 1976. ICF signed a contract with SOTEMI for the supply of 31,000 tons of granular fluorspar per year.

SOTEMI's mine is 45 kilometers south of Tunis near the city of Zriba. Fluorspar mineralization occurs along the bedding planes of dense, gray limestone and is associated with a high percentage of barite. The barite is accumulated with other waste material in ponds. The processing plant consists of grinding, screening, and 12 flotation cells and produces granular fluorspar mainly for European markets.

Other Nonmetals.—Barite production as a byproduct of fluorspar mining increased 57% in 1976 over the 1975 output. Most of the barite accumulated in waste ponds at fluorite mine sites. SOTEMI had not been able to find a market for this byproduct. Lime production increased 12%, reflecting a substantial amount of construction activity, while marine salt production decreased 31% during 1976.

MINERAL FUELS

Natural Gas.—Production of natural gas decreased about 50% to 450 million cubic meters in 1976. Of this amount, about 214 million cubic meters was consumed by domestic industries for power generation and industrial processes, while 166 million cubic meters was flared. Almost all the production was from El Borma Field, and the contribution of the Cap Bon gasfield was small. The newly discovered oilfields and gasfields in the Gulf of Gabes (1975) remained untouched in 1976, owing to the objection from neighboring Libya, which also claimed ownership. By yearend, the border dispute over the oilfields and gasfields in the Gulf of Gabes was submitted to the International Court of Justice at The Hague. With further drilling, the reserves of natural gas were increased from 50 billion cubic meters to 150 billion cubic meters during the year. The Government of Tunisia intended, as part of its fifth plan, to use this energy source in the petrochemical industry, cement plants, steel facilities, and power-generating stations. Engineering

studies for most of these projects were finalized in 1976, and the Government intended to open bids for them in 1977. Initial production in 1981 is expected at the level of 2 billion cubic meters, rising to 5 billion cubic meters by 1990.

The construction of a natural gas pipeline from Algerian gasfields to a port on Sicily, through Tunisia, remained in the discussion stage. Apparently, the level of transportation fees which Algeria would pay to the Tunisian Government was the stumbling block, and no agreements were reached by yearend.

Petroleum.—Crude petroleum production decreased 19.5% in 1976 from the 1975 output. Ashtart and El Borma were the leading producing fields; contributions from Douleb and Sidi El Itayem were similar to those of 1975. Exploration and drilling activities onshore and offshore in 1976 were the same as in 1975. In the offshore Isis oilfields, where a promising showing was found in 1974, work came to a standstill owing to the dispute over ownership between Libya and Tunisia. The dispute was finally submitted to the International Court of Justice at The Hague, and both countries agreed to adhere to the Court's decision.

The output of the country's only refinery at Bizerte in 1976 was used domestically and was supplemented by a total of about 520,000 tons of imported product. The imported products included 218,000 tons of kerosine and 190,000 tons of distillate fuel oil. The export of petroleum products was minimal.

The Mineral Industry of Turkey

By E. Shekarchi [1]

Based on calculations made by Maden Tetkik ve Arama Enstitüsü (MTA) (Mineral Research and Exploration Institute), Turkey's gross national product (GNP) for 1976 was estimated at $40.1 billion [2]; the share of the mining industry was put at $445 million. Thus, as in 1975, the mining industry's direct contribution to the GNP was only 1.1%. However, MTA pointed out that this figure was restricted to mining and that the contributions of smelting and refining to produce products such as aluminum, blister copper, ferrochromium, and mercury were not taken into consideration. Applying the multiplier effect of the mining industry's contribution of fostering secondary industries such as manufacturing, the share was calculated at about $6 billion or roughly 14.5% of the total. MTA expected a significant increase in both direct and indirect contributions as soon as desired levels of production of iron ore and phosphate rock were achieved, indigenous and external demand for industrial raw materials increased, and lignite production met total demand of thermoelectric plants.

Although continuing to struggle with high inflation, rising unemployment, and growing external deficits, the Turkish economy nevertheless showed real dynamism in 1976. Figures released by the State Institute of Statistics indicated a real annual growth rate of 7.2% for the year. The 1976 figure, although below the 5-year plan projections, indicated that since 1971, in spite of internal problems, the international recession, and high energy costs, Turkish economic growth in real terms averaged an increase of over 7% per year.

Faced with the need to insure continuity in its planned economic development (which would call for a 6.8% annual increase in energy consumption) at the lowest possible price, Turkey initiated attempts to develop to the maximum its most promising alternative indigenous resources of energy in 1976. The plan included acceleration of exploration of lignite fields and research on various projects for better consumption of lignite; development of two nuclear power stations (600 and 900 megawatts); exploration for more uranium reserves; research in the field of geothermal energy, including a 0.5-megawatt pilot turbine already in service; and setting up a solar energy coordination board.

Over the past 30 years, Turkey expanded its road network to more than 37,000 miles; however, only about 2,000 miles were built to modern two-lane geometric standards. Turkey planned to participate in a $14 billion project for construction of a trans-European highway, extending through 10 countries from Gdánsk, Poland, to Karāchi, Pakistan, passing through Iran and Turkey. Negotiations for financing this project through the World Bank continued during 1976.

The State-owned MTA remained the main research and development organization on mining, exploration, geology, and metallurgy during the year. The budget of MTA for 1976 was about $87 million, of which $16 million was spent for exploration of metallic ores and $13 million for materials related to energy. MTA's exploration program for 1976, deviating from the previous practice of working on a wide range of minerals, gave priority to

[1] Supervisory physical scientist, International Data and Analysis.

[2] The Turkish lira (LT) was devaluated in October 1976 from LT16=US$1.00 to LT16.5=US$1.00.

those most critical to Turkish industry—coal, iron, copper, and phosphates. Minerals such as molybdenum and tungsten, actively pursued in the 1975 program, were deleted from the 1976 program.

Turkey placed great emphasis on the urgent necessity of achieving industrial maturity prior to obtaining full membership in the European Communities (EC) in 1995. High priority was placed in the country's development plans on the processing of ores by the national industry before export. Efforts toward this goal were being made by several major State and private organizations: Etibank, Türkiye Komuleri Işletmesi Kurumu (TKI) (Turkish coal works), Black Sea Copper Co., Cinkur Kursun Metal Sanayii A.S. (CINKUR), Metas Mining Ltd., Türkiye Demir ve Çelik Işletmaleri (Turkish iron and steel works), the Turkish cement industry, and Ereğli Demir ve Çelik Fabrikalari T.A.S. (ERDEMIR) (Ereğli iron and steel works).

PRODUCTION

Mining activities in Turkey stagnated during 1976, although earnings from mineral production were higher. Production of some of the foreign exchange earners for the country, such as boron, chromite, lead, and mercury, was down, whereas production of antimony, barite, clays, copper, sulfur, and zinc was higher compared with 1975 figures.

[3] Does not include limestone used in the manufacture of cement.

TRADE

The value of mineral exports increased 11% to approximately $130 million. The proportionate value of minerals in Turkey's overall export trade fell from 8.3% to 6.5% in 1976.

An export boom in early 1976 was artificially stimulated by Turkey's sale of accumulated stocks of raw materials, and was accompanied by a rise in imports of only 5%. This resulted in a 13% reduction in the trade deficit for the first 9 months of 1976, and a total deficit for the entire year somewhat lower than in 1975. Workers' remittances from abroad fell to about $1.2 billion, some $150 million below the planned level. Consequently, major borrowing was still required to balance the year's deficit, and the country's debt commitments continued to rise.

COMMODITY REVIEW

METALS

Aluminum.—According to MTA calculations, Turkey possessed 4% of the world's known bauxite reserves, yet in 1976 it accounted for less than 1% of world production. Production of bauxite was 17.4% below the 1975 level.

The Seydisehir Integrated Aluminum (SIA) plant, financed by the U.S.S.R. and operated by Etibank since 1973, was expected to produce 200,000 tons of alumina, 60,000 tons of aluminum, and 34,000 tons of semifinished products annually when in full operation. However, construction difficulties and sharply increased prices for caustic soda and petroleum coke hampered the effort to achieve full production. The SIA plant primarily processed the boehmite and gibbsite types of bauxite found near the city of Seydisehir. There were reportedly substantial additional resources at Milas in Muğla Province in the form of diasporite as well as large reserves in the central Taurus region. Etibank, a major shareholder in SIA, made plans to double its production to 120,000 tons of aluminum ingot. The plant expansion was to cost an estimated $200 million.

Antimony.—Antimony mineralization is generally associated with mercury in Turkey. Total reserves of antimony from four different mines were given at approximately 1 million tons, of which about one-fourth was located in the Tokat area. In 1976, the main production came from the Turhal mine near Tokat, central Anatolia.

Tokat ore averaged about 14% antimony, whereas that at the other mines ranged from 5% to 6% antimony. Antimony production increased 21% in 1976. The mine setup and the presence of considerable reserves suggested that, if demand were higher, the Turhal mine production could be doubled.

Chromite.—Ultrabasic rocks with which chrome ore is associated occur in about 4% of the area of Turkey. Over 2,000 occurrences of alpine-type chromite mineralization in the form of pods and lenses were known in 1976. Two chrome ore-bearing belts were recognized: The northern belt extended from Bursa through Eskişehir and Sivas to Erzincan, while the southern belt extended from Muğla through Denizli, Burdur, and Adana to Elâziğ.

Total chromite ore production from both State and private concerns reached 839,000 tons, a decrease of 11.3% from the 1975 production level. Construction of Etibank's ferrochrome plant at Elâziğ continued during the year and partial production was expected to start in mid-1977. When in full operation, the plant would produce about 50,000 tons of high-carbon ferrochrome per year. The cost of the ferrochrome plant was estimated at $20 million in 1968, but the estimate was revised upward in 1976 to $30 million. In addition to the Elâziğ plant, Etibank operated the Antalya ferrochrome plant during the year and produced about 8,000 tons of ferrochrome, some of which was exported.

Copper.—The year 1976 was a poor one for the copper mining industry in Turkey. Production of copper ore (average grade 1.6% copper) decreased to 1.9 million tons in 1976 from about 2.3 million tons in 1975. Although blister copper production increased 4% in 1976, Turkish copper smelting capacity remained low and the byproduct sulfuric acid from copper smelting was not fully and efficiently consumed by fertilizer plants during 1976. New concentrators or expansion of existing ones were planned for Kure, Cayeli, Siirt, and Murgul to increase the output of concentrate and meet the export demand set by the State Planning Organization.

Gold.—MTA reported gold occurrences at Arpadag near Izmir, at Manisa near Aydin, at Madendag and Kurtaldge near Canakkale, and in Bilecik and Kars Provinces. One of the most intensive exploration programs undertaken in 1975–76 was at Manisa, where gold placer deposits occurred in thick Neogene conglomerates and very interesting values were found. A detailed exploration by MTA was also carried out near Aydin, where the gold occurred in association with arsenopyrite mineralization in mica schists.

No gold production was reported by yearend, and Turkey depended on overseas sources for most of the gold used in its industrial operations.

Iron Ore.—Production of iron ore in 1976 was 3.4 million tons, an increase of 47% over that of the previous year. The 1976 demand for iron ore by Turkey's steel industry was on the order of 7 million tons. It was estimated that demand could increase to 20 million tons per year within the next 10 years. There are three major areas of important iron ore occurrences in Turkey. In Sivas and Malatya Provinces, two substantial occurrences are found, the Divrigi and Hassan Celebi deposits. The Divrigi deposit supplied directly chargeable 57% iron lump ore for the steel industry. Capacity of the mine was to be doubled to 5.2 million tons per year by 1979. The Hassan Celebi deposit, a low-grade ample-tonnage occurrence, was on MTA's development program in 1976. This ore consisted of a low-grade magnetite in nine massive occurrences and occasionally in disseminated form. A feasibility test showed that coarse concentrates could be obtained from the massive bodies that were suitable for sinter feed, while fine concentrates could be obtained from the disseminated ores that were suitable for pelletization. Farther west, a second iron belt of sedimentary origin and with ample supply occurs in Kayseri and Adana Provinces. Although a large tonnage was present in the area, much of it was of low grade, and required some beneficiation before use. The third belt covers an extensive area in the Bitlis Massif in southeastern Turkey. This deposit is associated with metamorphic rocks and generally occurs as magnetite and apatite. Thus, this area was found important not only for iron ore which needed beneficiation, but also for the presence of phosphate in apatite for the fertilizer industry. Obviously, opportunity existed to increase Turkish iron ore

production, and emphasis on production expansion to meet expected demand by 1980 could eventually reduce imports considerably. Turkish imports of iron ore were 234,000 tons in 1975 and about 400,000 tons in 1976; they are expected to increase in the near future.

Iron and Steel.—The performance of the third integrated steelmill at Iskenderun in the first year of operation was commendable. The details of a new agreement between the Turkish Government and Soviet authorities to increase the production capacity of the Iskenderun steel plant 50% were not available by yearend. The installed annual capacity of the plant in 1976 was given at 2 million tons of steel. Production from the Ereğli integrated steel plant, the Karabük steel plant, and the Iskenderun steelworks was a record high 1.9 million tons, of which 474,000 tons was pig iron, 1.5 million tons steel ingot, and about 17,000 tons steel castings. No figures were available on rolled steel by yearend.

Lead-Zinc.—MTA identified three belts of base metal mineralization that not only constitute the most important mining regions of Turkey for copper, lead, and zinc, but exhibit substantial indications of yet unrealized potential. The first of these belts extends along the northern section of the country from the eastern Black Sea region to the tip of western Turkey where it splits into two, one arm extending through northern Thrace into Bulgaria and the other arm passing to the south of the Sea of Marmara through Balikesir. The second belt was identified as being associated with the basic volcanic units of the ophiolite rocks that occur in the southeast of Turkey. In this belt, the most significant of the occurrences are the lead-zinc deposits at Madenkoy in Siirt Province. Extensive exploration activities by MTA in this area were planned for the future. The third belt extends through the central Taurus region of southeastern Turkey. Mineralization here was found to be of the stratabound type and contained lead and barite. To the east of this belt, at Bolkardag and particularly at Zamanti, extensive reserves of zinc carbonate were found and actively exploited during the year. MTA reported reserves of about 1.3 million tons of lead metal content and 3.6 million tons of zinc metal content for all three belts.

Production by the new CINKUR lead-zinc plant at Kayseri in central Anatolia officially started in the latter part of 1976. The plant was to process concentrates from the Zamanti mines to recover 31,000 tons of zinc ingot, 5,000 tons of lead, and about 119,000 troy ounces of silver.

Production of argentiferous lead ore processed by domestic mills in 1976 was about 2,600 tons, a 20% decrease from that of 1975. No figures were available on the production of primary and secondary refined lead. Production of zinc-lead ore, which was sorted by hand in 1976, decreased 5%; production of zinc concentrate declined 16% during the year. It was expected that the full effect of the CINKUR operation on lead-zinc metal production would be apparent in 1977. High tariffs were imposed on zinc imports for 1977 to protect the new industry.

Manganese. — Manganese production from both the private and public sector decreased 41% in 1976. Most of the decrease was of low-grade ore (below 35% manganese), from deposits operated by small private mining companies. There was no ferromanganese production in Turkey during 1976, and almost 5,000 tons of ferromanganese for steel production was imported from Japan, West Germany, and the United States. Generally, manganese deposits in Turkey occur as small lenses, veins, and pods, with only a limited amount of battery-grade ore reported in a few locations. The other occurrences were metallurgical-grade ore with a high percentage of deleterious elements such as phosphorus and zinc.

Mercury.—Mercury production decreased for the second consecutive year; 1976 production of 76,000 tons of mercury ore was 18% lower than that of 1975. The important producers of mercury were the Halikoy and Turkonu mines near Aydin, the Karaburun mine near Izmir, and the Sizma and Sarayonu mines near Konya. Mercury mineralization occurred in western and central Anatolia and it was reported that there were many undeveloped occurrences with considerable reserves. The MTA report maintained that there was no doubt that mercury production could be greatly expanded if world demand were to improve. However, world

demand remained in a decline, owing to the health hazards attributed to mercury.

Tungsten.— The Ulu Dağ tungsten mine and concentrator, a joint venture of Salzgitter A.G. of West Germany and Etibank, the Turkish State-owned mining enterprise, came into production for the first time in 1976. The mine, located at a 2,200-meter elevation in the Ulu Dağ Mountains near the city of Bursa, provided employment for about 1,500 people. Owing to unpredictable road conditions as a result of snow and storms, provisions have been made to sustain operation without outside help for 15 days. The mine produced close to 2,000 tons of scheelite concentrate, which was sent primarily to West Germany for further processing.

A typical chemical analysis of Ulu Dağ scheelite concentrate is as follows: WO_3 65%, copper 0.004%, calcium 10.8%, SiO_2 1.56%, and traces of phosphorus, zinc, arsenic, and bismuth. The concentrator was designed to treat scheelite, the typical ore of the Ulu Dağ mine, at a rate of 560,000 tons annually. Etibank expected the mine and concentrator to be in full operation by 1977. Reportedly, the cost of the project, estimated at $26 million in 1974, was to be increased considerably because of worldwide inflation and a fire at the mine that delayed operation and damaged equipment.

Etibank planned to double the production of the Ulu Dağ mine by 1981, at an estimated cost of $15 million.

Uranium.—Extensive ground and airborne surveys were carried out in the Manisa-Afyon area on the Neogene sediments during 1976. These surveys were a continuation of a previous survey by MTA that had located uranium deposits and had outlined a more detailed exploration target. In 1976, the Government successfully completed the construction of a pilot-plant at Koprubas which produced some yellowcake. Surveys were also being made on the Neogene basins around Thrace and Beypazari near Ankara, where, according to MTA reports, the possibility of finding new uranium resources was excellent.

NONMETALS

Asbestos.—Construction of an asbestos processing plant with a 10,000-ton-per-year capacity by Amyant Sanayii A.S. at Mihaliceik, east of Eşkisehir, continued in 1976. The company expected to go into production by mid-1977. Production of asbestos decreased 6,000 tons in 1976, or 41%. Turkey was obliged to import about 12,000 tons of asbestos, mostly in fiber form, in 1976. No export was reported in 1976.

Barite.—Barit Maden Turk A.S. (BMT) was the only producer of barite in the country during 1976. The new ruling by the Government that after 1976 all barite exports should be in a packaged ground form had a dampening effect on the steady growth of the industry. Owing to shortages of foreign exchange in Turkey in 1976, the company, although willing to follow the Government ruling, was not certain that a grinding mill could be imported, installed, and operational by the end of 1976, so it remained to be seen what effect this situation would have on the export of barite.

Production of run-of-mine barite reached a new high of 20,000 tons in 1976. According to MTA's report, known barite reserves were estimated at 33 million tons of ore at yearend 1977.

Boron.—According to a report by MTA, measured reserves of Turkish boron ore constituted over 80% of the known world reserves in 1976. Most of the boron deposits occur in Neogene lacustrine sediment associated with old volcanic activity. The main boron occurrences are in the region of Kütahya-Eskişehir-Balikesir in western Turkey, where the active mines of Kirka, Emet, and Bigadic are located. Production decreased 5.3% from a 960,000-ton level in 1975 to 910,000 tons in 1976. Turkey challenged the United States as the world's largest producer in 1976, and the two countries competed for the world market, especially in Europe where Turkey benefited from advantages in transportation costs. Diversification of the boron industry continued and Etibank announced plans to construct a 100,000-ton-per-year boric acid plant at Bandirma, near the Sea of Marmara, with a completion date in 1979. It was also planned that the sodium borate treatment plant at Kirka was to eventually include refining facilities to produce 163,000 tons of crude pentahydrate borax, 60,000 tons of crude and refined anhydrous borax, and 15,000 tons of refined decahydrate borax per year. The completion date for these facilities was

scheduled for the end of 1977 or the beginning of 1978.

Cement.—By yearend 1976, Turkey had 34 cement plants with a total capacity of 14.5 million tons. However, cement production by both the private and public sectors amounted to only 12.3 million tons. The regional location of plants, their capacity, and production in 1976 were as follows, in thousand tons:

Region	Number of plants	Annual capacity	Production
Marmara	8	3.8	3.1
Ic Anadolu	8	2.7	1.9
Karadeniz	6	2.3	1.7
Ege	4	1.1	1.1
Akdeniz	3	2.6	1.7
Dogu Anadolu	3	1.0	.7
Guneydogu Anadolu	2	1.2	1.1
Total[1]	34	14.5	12.3

[1] Data may not add to totals shown because of independent rounding.

Although Turkey exported almost 1 million tons of cement to the neighboring countries of Iraq, Iran, and Syria, Turkey itself experienced a shortage of cement during the peak construction season, owing to an inadequate transportation system. Turkey's largest cement plant at Adana was undergoing expansion in 1976, from 900,000 tons to 1.5 million tons per year, slated for completion by yearend 1977. Other major expansions of existing cement plants were underway in 1976, and Turkey expected to have a cement production capacity of 19.2 million tons by 1980.

Fertilizer Materials.—Production of phosphatic fertilizer was reportedly about 597,000 tons in 1976, an increase of almost 200%, while production of nitrogenous fertilizer increased almost twofold over 1975 production. The increases were attributed to the plant expansion of Azot Sanayii T.A.S., which came onstream in 1976, and to the new facilities of Gubre Fabrikalari T.A.S., which became partially operational during the year. Azot Sanayii was in the process of planning a fourth fertilizer complex in Cukrova-Mersin to be operational by 1979. The company expected to annually produce 630,000 tons of sulfuric acid, 215,000 tons of phosphoric acid, 544,000 tons of ammonia, 330,000 tons of urea, and 420,000 tons of ammonium phosphate. Commissioning of the Gubre Fabrikalari fertilizer complex at Iskenderun was successfully completed in 1976. The complex, with an annual capacity of 230,000 tons of sulfuric acid and 75,000 tons of phosphoric acid, was expected to meet the country's acid requirements for the downstream triple superphosphate complex and to eliminate the need for further imports of these acids. A feasibility study on the construction of a fertilizer plant at Rize in northeastern Turkey neared completion in 1976. A company consisting of the Turkish Industrial Development Bank and Rize local administrative and agricultural cooperatives was to be established to operate the plant, but no further details were available by yearend.

Phosphates.—The Mazidag phosphate deposits, located in southeastern Turkey, remained under exploration. Etibank, the owner of the major findings in the Mazidag area, announced in 1976 that a beneficiation plant to upgrade phosphate in the area was under consideration. Etibank predicted that about 250,000 tons of phosphate rock would be required at the plant by 1978, but no details regarding the plant capacity or state of purchase were given. During 1976, all of the phosphate requirements for the Turkish fertilizer industry were met by imports from Morocco, Tunisia, Jordan, and Israel, causing a major drain on foreign exchange.

Magnesite.—Magnesite, which has become an important foreign exchange earner for Turkey, remained at the same export level as in 1975. Production of magnesite, most of which is slated for export, decreased 15% in 1976 reflecting a decline primarily in the production of chemical-grade magnesite rather than of deadburned magnesite. During 1976, a new plant owned by Kütahya Manyezit Işletmeleri A.S. (KUMAS), located at Kütahya in west-central Turkey, started production of deadburned magnesite.

The Government-owned refractory magnesite brick plant at Konya was expanded and produced close to 50,000 tons of brick per year, most of which was consumed domestically in the steel and ferroalloy industries. It was projected that Turkey's consumption of refractory brick by 1985 would triple that of 1976.

Perlite.—Perlite was becoming an export commodity of some significance for Turkey as more uses were found in the building industry as a sound and heat in-

sulator and in the agricultural field as a soil conditioner. Turkey produced about 23,000 tons of perlite in 1976, which was almost double the output of 1975. The principal deposit of perlite was in a belt running through the center of Turkey from west to east; resources appeared to be almost limitless. The most important producing regions were Van, Erzurum, and Nevşehir Provinces, all in the southwest of the country. The deposits were ideally located near excellent transportation routes, should the demand for Turkish perlite in the overseas market increase.

Pyrite.—Demand for Turkish cupreous pyrite increased during the year, and production emerged from the slump of 1975 to reach a new high of about 85,000 tons in 1976. Most of the cupreous pyrite production was exported to West Germany for processing under a barter agreement.

Stone.—*Marble.*—Turkey has long been known as a producer of high-quality marble. The value of marble produced for export has ranged from $4.4 million to $6 million per year. The known primary reserves are located in Denizli, Izmir, Kirşehir, Sivas, and Erzurum Provinces and on Marmara Island. The prized variety produced in Sivas and Erzurum known locally as onyx marble was exported both as unfinished blocks and as finished ornamental products in 1976.

MINERAL FUELS

The Ministry of Energy and Industry put into motion a long term energy program. Coal production, particularly lignite, was to increase about threefold. By 1987, production of hydroelectricity, which in 1976 furnished only 8% of the nation's power, was to be increased 43%. By 1985, one nuclear power station of 600 megawatts-electric was to be in operation, and by 1980, a 15-megawatt-electric geothermal power station was to be operational, provided that exploration obstacles were removed. In the area of research, the Government intended to provide funds and personnel for a bituminous shale extraction project and promote solar energy production on a national basis.

Turkey imported 300 million kilowatt-hours of electrical energy from neighboring Bulgaria and expected to import 500 million kilowatt-hours in 1977 at even higher prices. The electrical power produced in Turkey in 1976 was 16.5 billion kilowatt-hours, whereas consumption reached 16.8 billion kilowatt-hours during the year.

Coal.—The Afsin Elbistan lignite project moved toward reality in 1976. The cost, estimated at $150 million for the entire project including an open cast mine and a thermoelectric powerplant, was financed by the World Bank and a Japanese consortium comprising Nippon Conveyor Co., Ishikawajima-Harima Heavy Industries Co., Ltd., and Mitsubishi Corporation. The Elbistan deposit was estimated to contain about 3 billion tons of lignite. TKI, the Turkish coal works, planned to mine 20 million tons of lignite per year, of which 17.5 million tons was to be used in the thermal plant and 2.5 million tons for other domestic fuel requirements. TKI slated initial production of lignite for late 1978.

In September 1976, at the first National Coal Congress (NCC), it was noted that in the past 16 years, a total of 72 million tons of salable bituminous coal was produced at the Zonguldak coalfields in Turkey. It was also reported that 3.2 million tons of bituminous coal produced in 1975 was used by industry, approximately 1.1 million tons by thermoelectric powerplants, and about 242,000 tons for heating. NCC reported that lignite reserves, which are found in Thrace and almost everywhere in Anatolia, totaled 5 billion tons. TKI owned 4 billion tons of this reserve and the remainder was distributed among several private producers. Production in the past 16 years was 87.3 million tons, of which TKI produced 68%; the remainder was by the private sector.

In 1976, the future bituminous coal and lignite requirements of Turkey by various sectors of industry were anticipated to be as follows, in thousand tons:

Year	Heating	Electricity	Industry	Communication	Total
Bituminous:					
1976	495	1,034	5,845	650	8,024
1977	495	714	4,707	650	6,566
1978	495	535	4,978	650	6,658
1979	495	535	6,378	650	8,058
1980	495	535	6,978	650	8,658
1992	495	535	6,978	650	8,658
Lignite:					
1976	10,295.0	3,518	3,229.0	--	17,042.0
1977	10,945.0	5,270	3,249.1	--	19,464.1
1978	11,536.0	5,490	3,561.0	--	20,587.0
1979	12,159.0	10,935	3,902.8	--	26,996.8
1980	12,816.5	21,665	4,277.4	--	38,758.9
1992	22,050.4	31,098	12,181.3	--	65,329.7

Petroleum.— Türkiye Petrolleri Anonim Ortakligi (TPAO), a State-owned Turkish petroleum company, prepared for an extensive exploration activity program in 1976. In addition, to meet growing oil product requirements completely from domestic refineries and considering demand forecasts for the coming years, a refinery construction program was prepared. In accordance with this program, Turkey would be able to meet all of its requirements by 1981.

By yearend 1976, TPAO had 6,251 employees. The number of licenses and leases for petroleum and natural gas exploration increased in 1976. The following tabulation shows the number of licenses, by district, as of yearend 1976 compared with that as of yearend 1975:

District	Yearend 1975	Yearend 1976
I:		
Onshore	15	16
Offshore	21	21
II:		
Onshore	13	16
Offshore	8	4
III:		
Onshore	16	16
Offshore	18	18
IV:		
Onshore	15	15
Offshore	31	31
V	14	14
VI	13	14
VII:		
Onshore	8	11
Offshore	4	4
VIII	16	16
IX	24	24
X:		
Onshore	7	7
Offshore	11	11
XI	7	8
Total	241	246

A total of 14.4 million barrels of crude oil, produced by TPAO and other companies, was transported by Turkish pipelines. An additional 227,000 barrels of oil produced at the Thrace fields in northwestern Turkey was transported to Zeytinburnu by tanktruck and from there to TPAO's refinery by tanker.

In 1976, the TPAO refinery at Batman processed 1.0 million tons of crude oil and the one at Izmir processed 3.1 million tons, as follows, in thousand tons:

Product	Batman refinery	Izmir refinery
Liquefied petroleum gas	11	62
Naphtha	35	93
Gasoline	99	389
Solvent	7	--
Kerosine	29	112
Diesel oil	182	887
Fuel oil	464	1,290
Asphalt	201	13
Jet fuel	--	32
Lubricating oils	--	129
Unfinished products, slop	--	69
Total[1]	1,029	3,074

[1] Data may not add to totals shown because of independent rounding.

One of the peculiar characteristics of TPAO was its statutory objective of promotion and implementation of ventures in the national interest. TPAO, as the result of intensive vertical integration, was a shareholder in seven different firms related to refinery, pipeline, or petrochemical ventures. Istanbul Petroleum Refining Company (IPRAS) was established in 1960 with capital of $10 million contributed by TPAO and the Caltex group. Later, TPAO became the sole owner and raised the capital to $15 million. During 1976, IPRAS processed 5.4 million tons of crude oil in its facilities.

Petkim Petrokimya A.S. was established with capital of $25 million in 1965. By vertical integration and new financial arrangements, TPAO held 33% of the shares, and the total capital of Petkim was evaluated at $250 million.

Ipragaz A.S., established in 1966 to deal with distribution of liquefied petroleum gas (LPG), was jointly owned by TPAO (49%) and Eureka Metals Corp. with capital of $1 million. Ipragaz distributed about 159,000 tons of LPG in 1976.

Istanbul Ammonia-Urea Manufacturing Co. was under control of TPAO which owned 60% of the shares. The ammonia-urea plant under construction was expected to produce 1,000 tons per day of ammonia and 1,550 tons per day of urea by mid-1978. Total capital in this company was estimated at $80 million.

Table 5.—Turkey: TPAO drilling activities, 1966–76

Year	Exploration		Confirmation		Development		Injection		Total	
	Number of wells drilled	Depth (meters)	Number of wells drilled	Depth (meters)	Number of wells drilled	Depth (meters)	Number of wells drilled	Depth (meters)	Number of wells drilled	Depth (meters)
1966	15	30.051	7	13.527	30	43.418	--	--	52	86.996
1967	11	18.938	1	3.527	50	69.581	1	1.495	63	93.541

1969	9	32.836	--	--	25	36.179	--	--	34	69.015
1970	24	40.156	5	7.932	14	26.188	--	--	43	74.276
1971	11	29.384	7	13.404	10	15.525	4	5.362	32	63.675
1972	19	36.113	7	12.917	10	15.894	--	--	36	64.924
1973	25	47.748	24	42.870	1	--	--	--	50	90.618
1974	26	52.941	18	26.605	16	24.392	--	--	60	103.938
1975	42	72.059	5	7.538	19	32.693	--	--	66	112.290
1976	41	70.607	13	22.793	30	42.885	4	5.670	88	141.955

Marine Operations and Transportation Co. was established in 1974 with capital of $5 million to transport petroleum and petroleum products. TPAO held 45% interest in this company in 1976.

Fuel Distribution Co. was established in 1974 with capital of $10 million to market and distribute petroleum products in domestic and foreign markets during 1976. TPAO's share in the firm was reported at 45%.

Petroleum Pipeline Corp., with capital of $50 million and completely owned by TPAO, started functioning in 1974. One of the major undertakings of this company was the construction and supervision of the Iraq-Turkey pipeline in 1976.

Construction of the 1,000-kilometer Iraq-Turkey crude oil pipeline was completed in 1976. It linked the northern oilfields of Iraq near Kirkuk to the Turkish port of Dörtyol on the Mediterranean coast and was to be commissioned early in 1977. The pipeline construction was contracted to Mannesman-Export of West Germany with a subcontract on the Iraqi portion to Banister-Price at a total cost of approximately $450 million. The line had three major river crossings, one of the Khabur River and two of the Tigris River. The pipeline, with an initial capacity of 500,000 barrels per day, provided Iraq with an additional outlet to the Mediterranean. The peak capacity is expected to be up to 700,000 barrels per day. Turkey was to buy 200,000 barrels per day of petroleum in 1977–79, with an option to expand that to 280,000 barrels per day when the pipeline capacity was expanded. Iraq National Oil Company agreed to pay Turkey a transit fee of 35¢ per barrel for a 20-year period, starting with the transmission of crude oil.

Feasibility studies on a 2-billion-cubic-foot-per-day natural gas pipeline to transport Iraqi natural gas to Istanbul were carried on by TPAO planners during the year. No decision or financial details were available by yearend.

A technical and commercial protocol between the Governments of Turkey and Romania pertaining to the implementation of a refinery with a 5- or 10-million-ton-per-year capacity was signed in Ankara in 1976. Construction work started during the latter part of the year at Hacilar village near Kirikkale, central Anatolia. Details on financing of the project, as well as the completion date of construction or the start of production, were not available by yearend.

Exploratory work in the Aegean Sea continued during the year and TPAO planned to drill three wildcat test wells. The dispute between Turkey and Greece over the offshore rights of both countries remained unresolved in 1976, although discussions on the subject continued. Shell Company of Turkey remained the largest foreign operator in Turkey, producing about one-half of the country's total oil output from 66 wells in 14 fields. In 1976, the company drilled five successful oil development wells and four wildcat wells, three of which were dry and one suspended.

Petroleum production averaged 51,000 barrels per day from 385 producing wells in 1976, down a substantial 17% from that of the year before. There were three producing natural gas wells.

The Mineral Industry of the U.S.S.R.[1]

By V. V. Strishkov [2]

The U.S.S.R. maintained its position in 1976 as the world's second largest producer of industrial products. Production schedules are coordinated and production targets predetermined, in principle, by the national plan for economic development. In the U.S.S.R., 1976 marked the first year of the tenth 5-year plan, 1976–80. The following production increases over 1975 figures were reported (in million tons): Raw coal, 10.2; crude oil (including gas condensate), 28.7; iron ore, 6.3; pig iron, 2.5; crude steel, 3.5; finished ferrous rolled metals, 2.7; steel pipe, 0.8; mineral fertilizers (Soviet standard), 2.3; and cement, 1.9. Electrical power output increased 73 billion kilowatt-hours. Output of many nonferrous metals, rare and precious metals, petroleum refinery products, and nonmetallic minerals was also higher than in 1975.

The U.S.S.R. in 1976 was the world's leading producer of iron and manganese ores, platinum-group metals, petroleum, crude steel, potash salts, asbestos, and cement. It occupied second place, following the United States, in world output of aluminum, lead, natural gas, coal, and phosphate rock; it ranked second to Canada in the production of nickel; and it followed the Republic of South Africa in gold and chromium ore production.

Although the U.S.S.R. led in the production of several mineral commodities, how much the country can produce was secondary to the question of how it used what it produced and how effective it was at technological innovation. The structure of the Soviet economic system discourages innovation, which leads to a lack of incentive and a lack of growth.

The growth rate of the Soviet economy during 1976 failed to meet substantially reduced goals in a number of key areas, and gains in industrial output were the lowest since World War II. Reportedly, industrial output increased 4.7% (4.3% planned), and reported national income rose 5.0% (5.4% planned) to 380 billion rubles.[3] Heavy industry output rose 5.5% (4.9% planned), and consumer goods production rose 3.0% (2.7% planned). Capital investment rose to 117 billion rubles at the planned rate of 4%.

Reportedly, the 1976 plan in industrial output was overfulfilled, and its value increased from 509 billion rubles in 1975 to 533 billion rubles in 1976. The level of Soviet industrial production as planned and reported in 1976 is given in the following tabulation, in million tons unless otherwise specified. The Soviet mineral industry is expected to grow over the next decade but at a reduced rate.

Commodity	Production	
	Planned	Reported
Raw steel	147	145
Finished ferrous rolled metals	103	101
Steel pipe	17.0	16.8
Mineral fertilizers (Soviet standard)	94.5	92.3
Raw coal (bituminous, anthracite, lignite)	715	712
Natural gas billion cubic meters	313	321
Crude oil (including gas condensate)	520	519.7
Electrical power billion kilowatt-hours	1,095	1,111

[1] This chapter is based on a review of the sources published by the U.S.S.R.

[2] Physical scientist, International Data and Analysis.

[3] The official exchange rate in December 1976 was 1 ruble=US$1.34. The approximate buying power of 1 ruble in the United States for hard goods and food ranges from about $0.20 to $0.50.

Production of electrical power and natural gas exceeded plan targets; crude oil production, including gas condensate, closely approached the target; and raw coal output fell short of the plan. Production of chemicals and petrochemicals rose 8% over that of 1975 (7% planned), and output in machine-building and metalworking rose 10% (8.6% planned). Slight shortfalls were reported in output of many key industrial products: Raw steel, finished ferrous rolled metals, mineral fertilizers, and steel pipe.

Despite reports of difficulties in crude oil production, the country reached its goal of 519.7 million tons. Virtually the entire increase of 28.7 million tons came from western Siberia, which accounted for about 35% of total Soviet crude oil output in 1976.

Expansion in the mineral industry continued to be achieved mainly through increased use of labor and capital rather than advancing technology. Because of shortages of mineral commodities, efforts directed chiefly toward fulfilling quantitative goals detracted from necessary attention to quality considerations. A considerable part of the industrial output did not meet Soviet standards of quality. Labor turnover remained a serious problem at many mines and plants, particularly in the north and northeast. This was attributed mainly to delays in housing construction schedules, inadequate medical and other public services, low material incentives, and the heavy manual work involved.

A special decree emphasized the importance of eliminating cheating in reported statistics by managers. For example, a construction directorate reported that it had completed a nonexistent road. In another case, a plant that had fulfilled its plan by 69% was able to show by means of "additions" that it had fulfilled the plan 100%.[4]

The Ministry of Ferrous Metallurgy was unable to meet the 1976 plan for production of many types of products. As a result, consumers of these products in construction, transportation, industry, and agriculture did not receive enough of the products required. Insufficient production of high-quality steel of special strength required for items such as aircraft, nuclear reactors, and pipe, and the shortage of many shapes of ferrous rolled products compelled the machine-building industry to use substitute products. This was reflected in the quality of machines and led to excessive use of metal, a significant part of which was wasted as shavings.[5] The U.S.S.R. reported imports of ordinary steel sections, steel pipe, and special steel from Japan and Western countries.

Practically all sectors of the mineral industry maintained a greater number of production personnel than called for by plan targets. According to Soviet trade journals, the ferrous and nonferrous metals industries employed over 3 million workers; the ferrous metals industry alone accounted for about 1.4 million "production" (a Soviet term used in its statistics) workers, 75,000 university graduate engineers, and 125,000 graduate technicians. Soviet newspapers reported that the coal industry employed 2,152,700 men and women, including 1.2 million production workers, some 700,000 nonproduction workers, 215,000 graduate engineers and technicians, and 27,800 managers and general managers. The coal industry employed 770,000 women, including 109,000 at underground mines. There were 638,000 workers in the Donets coal basin alone in 1975.

The oil, gas, and petrochemical industries employed 2.6 million people including over 250,000 in the development of oilfields and gasfields. According to press reports, the crude oil extraction industry employed about 740,000 persons. The standard workweek in the U.S.S.R. is 41 hours.

Expenditures by Soviet scientific and research establishments amounted to 4.8% of the national income and 20% of the annual capital investment. During 1965–73, the expenditure on science and research in the U.S.S.R. increased 80%; in 1970–73 it increased 16.8%, amounting to 7,502 million rubles in 1973.[6] There are 250 scientific and research organizations alone in the Academy of Sciences, employing 160,000 persons in 1975.[7]

There were 132,000 graduate mining engineers in the Soviet economy in 1974. Of these, 34.4% were employed by the coal industry, 10.6% by the ferrous metals industry, 10.4% by the nonferrous metals

industry, 4.3% by heavy machine construction, 4.3% by the Ministry of Higher Education and the Academy of Sciences, and 36% by other branches of the national economy.[8]

The productivity of labor and equipment continued to be below planned levels. Press reports and trade journals indicate that more than one-half of the machinery employed in the mining industry was idle, owing largely to the quality of machines and the unsatisfactory supply of spare parts at mines and plants. Much of the equipment used in the Soviet mineral industry is standardized and of a type made earlier in Western Europe and the United States. Production of mining and metallurgical equipment has grown substantially, but the technical standards and quality of equipment are poor. Many plants preferred to manufacture outdated equipment rather than undertake new technology.

At many mines and plants, up to one-half of the production workers were employed in manual labor, including the surface loading and unloading of supplies and equipment. At polymetallic mines in Kazakhstan, the degree of mechanization in mining did not exceed 34%, and most of the auxiliary operations were manual. In underground coal mining, over 50% of the workers were employed in nonmechanized tasks. In 1975, official reports stated that 50% to 65% of the workers were engaged in auxiliary jobs in all branches of the Soviet mineral industry.

Consumption of materials exceeded established norms at many enterprises and construction projects, particularly those for metals, fuels, electrical power, and cement. Stocks of materials and equipment were 50% to 80% higher than necessary. Because of improper storage, equipment, metal, and other mineral products deteriorated and frequently were not suitable for use.[9]

Losses of metals, fuels, and other materials continued to be excessive. According to Soviet sources, the U.S.S.R. used between 25% and 100% more ferrous metals per unit of industrial output than did the United States. For example, oxygen converters with a capacity of 100 tons manufactured by the Zhdanov heavy machine-building plant are 200 tons heavier than similar converters produced by Western firms.[10] Yearly losses of coal in rail transportation were reported at 20 million tons, and additional expenditures for cleaning up coal spills from the railroads, 50 million rubles.

The available losses of mineral commodities are not known completely, nor have they been adequately quantified, but estimates have been reported widely in the Soviet press. A careful study of Soviet publications shows, for example, that only about 45% of the total raw steel production is efficiently used in the Soviet economy; 55% is remelted or lost as a result of low technology.

Although the U.S.S.R. does not publish statistical data on injuries in the mineral industry, available Soviet information and Western mining engineering experience indicate that fatality rates are significant. Official reports state that in the first half of 1976, fatal injuries occurred at 35% of the Soviet coal mines and open pits and 1% of the metallic and nonmetallic mines and open pits. The largest number of accidents have for many years occurred at production and developmental faces as a result of roof collapse. The second largest number of accidents occur during underground haulage, followed by accidents with machines and electrical current accidents. Blasting and handling of explosives accounted for the next largest group of accidents. Accidents caused by roof falls are the result of inadequate support, mainly owing to the shortage of props. Accidents at beneficiation and metallurgical plants have been caused mainly by operating wornout machinery, the low level of equipment repair, and violations of technological processes.[11]

The accumulation of dust at work sites in underground mines and metallurgical plants of the U.S.S.R. is high and often exceeds the industrial health standard. Some mineral industry enterprises are not being adequately equipped with dust and gas treatment facilities, according to published reports. Sanitary facilities, as well as

Sotsialisticheskaya industriya (Socialist Industry), Moscow. July 21, 1976, p. 2.

protective outer garments, are few and considerably below the official Soviet standard. There were especially unsatisfactory conditions at the Kuznetsk metallurgical complex, the Chelyabinsk and western Siberian metallurgical plants, the Zhdanov coke plant, the Belov zinc plant, and the enterprises of the Severovostokzoloto (Northeastern Gold) Association and the nonmetallic industry.

Soviet statistical agencies do not publish data on the actual earnings of mineral industry workers, with the exception of highly paid production workers. The average official monthly earnings of Soviet workers and employees in 1976 was 151 rubles, compared with 146 rubles in 1975, an increase of 3.4%. In 1976, the raising of the monthly minimum wage from 60 rubles to 70 rubles continued in the north and the Soviet Far East and in some European regions of the U.S.S.R. The reported average monthly earnings, including all types of bonuses, of selected highly paid production workers are shown in the following tabulation, in rubles:

Sector	1974	1975
Extractive	209.5	219.0
Of which, mining	229.3	239.9
Manufacturing	149.4	155.9
Power engineering	160.2	167.3
Coal	262.0	274.9
Ferrous metallurgy	177.9	188.0
Chemical and petrochemical	159.1	165.2
Machine-building and metalworking	157.5	164.1
Construction materials	159.7	165.4
Glass	148.1	154.1
China	138.4	142.8
Consumer goods	119.1	124.6
Food	140.3	145.9
Average (all industry)	155.5	162.2

Source: Vestnik statistiki (Herald of Statistics), Moscow. No. 8, August 1975, pp. 87–92.

According to Soviet calculations, a minimum family income amounts to between 100 and 150 rubles per person per month,[12] but a Soviet study of wages earned by workers in large cities has shown that the average family income is 50 rubles or less per person. Forty percent of workers' families had a monthly income of 51 to 71 rubles per person, and only about 25% of such families had a monthly income of more than 75 rubles per person. The Soviet study also showed that in smaller towns, the family income per person was even lower than these averages.[13]

The corollary is that most blue-collar workers (and an even larger percentage of white-collar workers, whose average earnings are lower) have a family income that is less than half what is officially regarded as adequate.

The piece-rate principle, previously condemned, has become an important feature of industry. Soviet labor legislation requires that workers achieve a minimum output within a given period. This minimum is the work norm and is established for virtually every phase of employment. In connection with a significant increase in output quotas established during the last 2 years, there was a substantial increase in the proportion of workers who did not meet the increased quotas. For some mineral industry enterprises it amounted to 15% or more in 1975.[14]

Whereas trade unions in Western countries are principally wage-negotiating organizations, their Soviet counterparts function largely as an avenue for increasing labor productivity and fulfillment of planned quotas. The unions operate the insurance systems and also work with management on safety. Practically every worker, including the entire management team, belongs to the union.

About two-thirds of the total tonnage of mineral industry products transported in the U.S.S.R. in 1976 was shipped by rail.[15] The average distance of rail deliveries of ores increased from 689 kilometers in 1970 to 754 kilometers in 1975, and that of ferrous metals increased from 1,360 kilometers to 1,413 kilometers during the same period.

Government Policies and Programs.—Soviet mineral policy continues to be based on the principle of maximum self-sufficiency at all costs. Actual or estimated costs of production are not a prime factor in the selling price of a commodity on the domestic or international market. The Soviet system permits the establishment of selling prices at any level believed desirable to meet political or economic requirements. Therefore, many mineral ventures in the U.S.S.R. would be uneconomic by Western standards.

One of the most striking contrasts be-

[12] Gordon, T. A., and E. V. Klopov. Chelovek posle raboty (Man After Work), Nauka-Press, Moscow. 1972, p. 36.

[13] Page 7 of work cited in footnote 12.

[15] Zheleznodorozhnyy transport (Railroad Transportation), Moscow. No. 3, March 1976, p. 35.

tween Soviet and Western mineral economies is the clear direction given to the development of Soviet mineral policy. In most market-oriented economies, national mineral policy is largely an accommodation of often divergent and conflicting sectors of the economy. In contrast, the U.S.S.R.'s 5-year plans and year-to-year plans set a definite policy in unmistakable terms for all mineral commodities. In addition to setting national priorities within which each industry must operate and individual industry goals, the plan is also law and carries mandatory obligations. Mineral development, as the basis for industrial growth, holds a key place in Soviet economic policy. Substantial funds distributed over a dozen specialized ministries are spent on mineral exploration and development.

The State plan for 1977 was ratified by the Supreme Soviet on October 29, 1976. The original target for 1977, which was part of the 1976–80 plan, was reduced, and heavy industry production is to be stressed for the year. Industrial growth is to be 5.6%, compared with the average annual rate of 6.5% projected in the 5-year plan. Heavy industry is to grow 5.9% and consumer goods industries 4.9%. National income is to increase 4.1%, and capital investment is to total 121,500 million rubles, a 3.8% rise over that of 1976. Major investment areas in 1977 will continue to be the fuel energy sector and the ferrous, nonferrous, chemical, and machine construction industries.

Special attention in the 1977 plan (as in the 1976 plan) is to be focused on the fuel and power sector. Generation of electrical power is to be increased; because of the continuing fuel crisis and to improve the fuel energy balance in the European part of the U.S.S.R., impetus will be given in 1977 to the rapid expansion of nuclear powerplants. The planned increase in crude oil extraction (including gas condensate) is to come from western Siberia. The increase in natural gas output is to come from western Siberia, Soviet Central Asia, and Orenburg Oblast. The main increase in raw coal (bituminous, anthracite, and lignite) output is to be from open pit lignite operations in Siberia and Kazakhstan. Increased hard coal production will be from the Donets and Kuznetsk Basins.

Raw steel and pig iron output is to be increased, as is that of finished ferrous rolled metals. It is planned to produce 243.3 million tons of usable (477.5 million tons of crude) iron ore (including 166.6 million tons of concentrate), 158 million tons of sinter agglomerate, 36.4 million tons of pellets, and 10.3 million tons of usable (20.3 million tons of crude) manganese ore in 1977.

Soviet industrial production, in million tons unless otherwise specified, is summarized in the following tabulation:

Commodity	1976		1977
	Planned	Reported	planned
Iron ore	NA	239	243.3
Pig iron	NA	104	110.2
Raw steel	147	145	151.1
Finished ferrous rolled metals	103	101	105.4
Steel pipe	17	16.8	17.6
Raw coal (bituminous, anthracite, lignite)	715	712	733
Crude oil (including gas condensate)	520	519.7	550
Natural gas—billion cubic meters	313	321	342
Mineral fertilizers (Soviet standard)	94.5	92.3	98.5
Cement	NA	124	NA
Electrical power—billion kilowatt-hours	1,095	1,111	1,160

NA Not available.

Relations with CMEA Countries.—Much attention is now being devoted to economic integration and industrial cooperation among the Council for Mutual Economic Assistance (CMEA) [16] countries, and this tends to make Eastern Europe, Mongolia, and Cuba more dependent upon the Soviet mineral industry. The 29th session of the CMEA held in Budapest in June 1975 concentrated primarily on closer integration of economic plans for the 1976–80 period and the specialization of industrial production. The Plan for Multilateral Integration Measures for the CMEA incorporates, among other Soviet projects, joint construction

[16] The CMEA (or Comecon) was founded in January 1949. The founding members were Bulgaria, Czechoslovakia, Hungary, Poland, Romania, and the U.S.S.R. Albania joined in February 1949 but ceased to take part in meetings in 1961. East Germany was admitted in 1950, Mongolia in 1962, and Cuba in 1972. Yugoslavia obtained permanent observer status in 1965.

and financing of the Kiyembay asbestos complex, development of the Orenburg gasfield and the gas pipeline from Orenburg to the western Soviet border, the 750-kilovolt transmission line from Vinnitsa to the Hungarian border, and new facilities for iron ore mining and petroleum refining elsewhere in the U.S.S.R. Reportedly, the total investment in joint projects involves about 9 billion transferable rubles by participating CMEA countries, with provisions for repayment to be made in raw materials produced (asbestos, iron ore, natural gas, petroleum, and electrical power).

In July 1976, the CMEA member countries announced their plan for economic development throughout the next 15 years. The U.S.S.R. is to be Eastern Europe's supplier of mineral raw materials. A Soviet-led CMEA planning committee was to submit a draft report at the 1977 annual meeting.

The following are the principal goals for economic integration over the next 15 years:

The nine CMEA nations regard the coordination of their 5-year plans as a basic element of planned cooperative development and as a principal approach to the main aims of forming a stable economic reciprocity. The countries aim to streamline cooperation in mutual trade, including questions of price formation, and to develop trade with centrally planned economy nations not within the CMEA group. Long-term commercial agreements are to continue, based on the results achieved in the coordination of national economic plans.

The program also calls for joint planning of branches of industry and specialization by each country so as to divide labor more rationally, for cooperation in prospecting, for joint economic forecasting, and for standardization of machine systems, equipment, and instruments.

In the iron and steel industry, special attention is to be devoted to increasing the beneficiation and agglomeration capacity in the U.S.S.R. to insure long-range supplies. The requirements of CMEA members for metallurgical coke are to be met mainly by deliveries from Poland, the U.S.S.R., and Czechoslovakia.

Plans also call for increased production of copper and zinc in the U.S.S.R. These metals will be made available to CMEA members in proportion to their capital investments in the new projects in the U.S.S.R. and Poland. Additional capacities for production and transportation of crude oil and natural gas are to be created in the U.S.S.R. and for coal in Poland, Czechoslovakia, and the U.S.S.R. These countries are indicated as the principal producers and exporters of coal and coke to other members; the U.S.S.R. is the chief supplier of crude oil and natural gas.

The CMEA nations also agreed to integrate their efforts in geological prospecting, construction of mineral projects, joint development of mineral resources, and scientific and technological research.

CMEA member countries are placing great importance on their international banks—the International Investment Bank and the Bank of Economic Cooperation. The former will promote the development of medium- and long-term credit systems for joint enterprises connected with the expansion of economic cooperation among member countries. The activity of the latter, concerned with short-term credits, will be directly involved in insuring the transferability of the collective currency. The introduction of free convertibility of member nation currencies, based on a transferable ruble, has already been implemented.

In certain circumstances, the U.S.S.R. extends credit for the construction of industrial projects under "aid" for the industrialization of CMEA nations, where rich resources of ores and fuels exist. However, the production goes to the U.S.S.R. to offset credits and interest and to pay for services, fuels, and metals that are imported from the U.S.S.R. In this way, the uranium resources of Czechoslovakia and Hungary, the bauxite of Hungary, the nickel of Cuba, the polymetallic ores and concentrates of Bulgaria, the fluorspar, gold, and coppermolybdenum ores of Mongolia, and the coal and zinc of Poland go directly to the U.S.S.R.

In June 1976, for example, Bulgaria signed an agreement with the U.S.S.R. for joint development of the Bulgarian nonferrous metals industry in 1976–80 and beyond. The U.S.S.R. is to aid Bulgaria in the construction and renovation of 14 projects. In September 1976, a new protocol on increasing the activities of Mongolian-Soviet Nonferrous Metals (Mongolsovtsvetmet), a joint economic trust created in 1973, was

signed in Moscow. The protocol calls for the mining of a new fluorspar deposit in Mongolia. Mongolsovtsvetmet is engaged in the mining and processing of various nonferrous metals in different regions of the country, including the Erdenet copper-molybdenum complex.

In 1976, the U.S.S.R. concluded agreements with Poland and Hungary for joint construction of a new broad-gage railroad to link the Soviet frontier with the steel complex under construction at Katowice, Poland, and a petroleum product pipeline to Hungary. Soviet experts are taking part in construction and renovation of some 50 projects in Yugoslavia.

Relations with Developed Countries.—In its economic relations with developed market economy countries, the U.S.S.R. strives for all-around economic cooperation. Long-term agreements on developing economic, scientific, technical, and industrial cooperation were signed in 1974–76 with the United States, West Germany, France, Italy, the United Kingdom, Denmark, Austria, the Netherlands, and Portugal, and with many individual companies in the West. These provide for cooperation in construction of industrial complexes, expansion and modernization of existing industrial enterprises, and research planning.

Soviet law does not permit private ownership of the "means of production." Foreign investors, however, are invited to develop deposits and construct plants in the U.S.S.R., with repayment to be made in some cases in future deliveries of the product of these operations. In other cases, exchanges of other goods or cash payment is arranged. Thus the U.S.S.R. is able to bring much needed investment and technology from Western countries by using "joint" or "compensation" venture arrangements. They provide joint operations in such fields as computer technology and instrument building and in the chemical, ferrous and nonferrous metals, oil, coal, and mineral fertilizer industries. The U.S.S.R.'s announced policy is to expand scientific and technological cooperation with the United States, as Western technology is needed to solve many of the problems in the mineral industry.

Relations with Developing Countries.—The U.S.S.R. encourages State-managed mineral resource development in the developing countries. The U.S.S.R. sends technicians and makes loans to countries willing to promote State development and distribution of fuels and minerals. Soviet technical assistance and economic aid programs include 426 industrial projects in about 70 countries at a cost of some 5 billion rubles. Soviet specialists provide technical assistance for geological research, prospecting, and exploration in 30 developing countries.

In many instances, developing countries repay the U.S.S.R. with mineral commodities. The U.S.S.R. is thus able to secure a significant flow of mineral imports at low cost from friendly developing countries. Indications are that this policy, which results in exclusive access to the resources in question for the U.S.S.R. and other CMEA countries, is to be continued and expanded.

The number of projects built or being built in the developing countries with Soviet assistance (as of January 1, 1976) was as follows, for selected sectors:

Sector	Total under agreement	Already commissioned
Industry:		
Power engineering	74	33
Ferrous and nonferrous metallurgy	38	15
Coal, gas, and oil extraction	37	18
Chemicals, oil refining, petrochemicals	26	13
Mechanical engineering and metalworking	53	40
Construction materials	35	10
Consumer goods and food	149	67
All industry	426	208
Agriculture	138	66
Transportation and communications	88	58
Prospecting for minerals	63	28
Education, culture, health	215	129
Total projects	954	507

Source: Vneshnyaya torgovlya S.S.S.R. (Foreign Trade of the U.S.S.R.), Moscow. No. 6, June 1976, pp. 10–11.

A geographical distribution of the industrial projects follows:

Country	Total under agreement	Already commissioned
Asia:		
Afghanistan	38	17
India	46	28
Iraq	51	15
Pakistan	5	1
Sri Lanka	5	4
Syria	12	6
Turkey	10	6
Yemen, People's Democratic Republic of	5	3
Total Asia	278	129
Africa:		
Algeria	31	22
Congo	4	1
Egypt	45	30
Guinea	9	5
Mali	1	1
Somalia	12	5
Sudan	6	6
Total Africa	137	78
Total industrial projects	426	208

Source: Vneshnyaya torgovlya S.S.S.R. (Foreign Trade of the U.S.S.R.), Moscow. No. 6, June 1976, pp. 10–11.

The following annual productive capacities, in million tons unless otherwise specified, had been constructed in developing countries with Soviet assistance as of January 1, 1976:[17]

Iron ore	6.70
Pig iron	6.18
Crude steel	4.86
Rolled steel products	2.73
Cement	.10
Raw coal	3.27
Crude oil	40.10
Powerplants ——million kilowatts	4.71

A new management system for the nonferrous metals industry was approved in 1976. The number of independent industrial enterprises decreased from 360 in 1969 to 274 in 1976; the number of small enterprises with up to 600 production workers was reduced by one-third. As a result, enterprises with over 1,200 production workers have over 95% of the total. All-union industrial associations for aluminum, polymetallic ores, copper, nickel, rare metals, gold, secondary nonferrous metals, and others were established.

Although during the past 6 years some progress has been made in reorganizing the management structure of the Soviet economy, the visible results of this effort are so far minimal with regard to output and efficiency.

Transfer of Technology.—Scientific and technical cooperation with developed market economy countries involves the transfer of knowledge and experience in the field of economics and natural sciences and the application of technology and experience to the U.S.S.R. The expansion of scientific and technical cooperation with the Western countries has resulted in the practical application of Western know-how in the U.S.S.R.

Cooperation with regard to the transfer of Western technology is aimed at: (1) Establishing a close link between science and the application of scientific knowledge to production; (2) transfer of Western experience and knowledge through the exchange of specialists in the fields of planning, management, and organization over the entire national economy; (3) transfer of technology, licenses, design and planning materials, standards, instructions, and other documentation; (4) transfer of the acquisition, processing, and use of scientific, technical, and economic data; (5) assistance in the creation and expansion of scientific and technical (research, design, and advisory) centers and in the normal activities of such organizations; (6) training and improvement of the qualifications of specialists in educational institutions, universities, and enterprises; (7) transfer of scientific and technical know-how in the construction, expansion, and commissioning of production enterprises, facilities, and machinery; and (8) promoting the creation and expansion of the scientific and technical potential of the U.S.S.R.

Soviet imports of Western plants and technology related to mineral industry projects fall into the following six major categories:

(1) Extraction, transportation, loading, and refining of crude oil, and construction of petrochemical complexes. Armco Steel Corp. announced that it will provide the U.S.S.R. with offshore oil and gas production technology. In addition, the $30 million agreement involves technology and equipment from Rucker Co. of Oakland, Calif., and Steward & Stevenson Oil Tools Inc. of Houston, Tex. France's Cie. Maritime d'Expertises (COMEX) won a $6 million contract for underwater hardware for offshore oil extraction in the Caspian Sea. West Germany's Blohm & Voss AG received a second 100-million-Deutsche-mark (DM)

[17] Ekonomicheskaya gazeta (Economic Gazette), Moscow. No. 25, June 1976, p. 21.

order for structural-steelmaking equipment, which is to be delivered in 1977–78 to Astrakhan. The equipment will be installed in a plant to be built by the Soviets to produce offshore oil extraction equipment. Brown & Root (U.K.) Ltd., George Wimpey & Co. Ltd., and British Petroleum Co. Ltd. (BP) sold technology for the design and construction of offshore platforms to be used in the Caspian Sea.

Cooper Industries, Inc., of which Cooper Energy Services Co. of the United States is a subsidiary, announced that its British joint venture associate, Coberrow Ltd., has been awarded a $165 million contract for the pump-drive system of a Siberian pipeline similar to the 800-mile Alaskan oil pipeline. Japan's Niigata Engineering Co., Ltd., signed a contract worth 1,900 million yen (Y) for an automated oil-loading installation at the Black Sea port of Novorossisk. Inquiries that could lead to sales of about $1 billion were being made of U.S., Western European, and Japanese manufacturers concerning oil-extracting equipment for the large Samotlor and Fëdorov oilfields.

Reportedly, a French-Soviet agreement worth $1 billion calls for Cie. Française d'Études et de Construction Technip (TECHNIP) to supervise the construction of two identical petrochemical plants at Omsk and Ufa, and to take products of equal value in exchange. Engelhard Industries (France) was presently supplying the U.S.S.R. with catalyst technology for petroleum refining. Soviet engineers were studying the operation of the Montedison S.p.A. petrochemical plant in Italy and were being trained for work at a similar plant now under construction in the U.S.S.R. Soviet plans include the construction of eight major refineries and four auxiliary units in the U.S.S.R., with the assistance of Western firms.

(2) Extraction, transportation, and processing of natural gas. A 100-million-pound (£) contract for gas turbine compressor stations for the 600-mile Siberia-Chelyabinsk gas pipeline was awarded to Cooper Energy Services. The British firm Brown Engineering Co., Inc., and West Germany's AEG-Kanis Turbinefabrik are to deliver compressor station equipment for the Orenburg-West gas pipeline. Other equipment for this gasline was being supplied by West Germany's Gebrueder Windhorst (DM8 million) and Honeywell Austria GmbH ($3.2 million). Fluor Engineering and Construction Inc. will provide design and engineering services to the Japanese steelworks for the supply of equipment for three gas-processing plants for the U.S.S.R.

(3) Coal-mining, heavy earthmoving, and other equipment. The first 10 (of a total of 20) Marion Power Shovel Co. "Super Front" shovels, each with a 26-cubic-yard bucket, have been shipped from Japan, where they were manufactured. The shovels will be used at the Neryungra coalfield in the southern region of Yakutia. The U.S.S.R. also ordered 30 trucks (costing $40 million) from the Canadian subsidiary of Unit Rig & Equipment Co. for southern Yakutia's coalfield. In the future, the U.S.S.R. will need 100 trucks for coal production.

Under an agreement signed in April 1974, Japan is to provide the U.S.S.R. with $450 million worth of coal-mining and railroad equipment for the Neryungra coalfield between 1975 and 1981.

(4) Equipment for the steel industry, including pellet plants, rolling mills, pipemaking equipment, forging complexes, electric furnaces, coating plants, equipment for production of special steels, computer-controlled testing machines, and complete steel plants. Reportedly, Austria's State steel enterprise Vöest-Alpine was negotiating a contract for the construction of a pellet plant in the U.S.S.R. worth over 1 billion schillings (S) ($56 million). Japan's Tanabe Kakoki Co. and Mitsui & Co., Ltd., will supply the U.S.S.R. with six large electric furnaces to be used to smelt ferromanganese. Schloemann Siemag AG, of Düsseldorf and Hilchenbach, West Germany, in consortium with Siemens AG, of Erlangen, West Germany, will deliver the DM257-million cold-rolling mill to the Novo-Lipetsk plant. The plant, with a capacity of 2.5 million tons of strip steel per year for the production of sheet, is scheduled to go into operation in 1979.

A complete plant for the production of powder-based special steel is being supplied by Sweden's Allmänna Svenska Elektriska AB (ASEA) /Stora Kopparbergs Bergslags AB. The £3.4-million plant is scheduled for delivery in 1977.

The French firm Creusot-Loire was negotiating a contract with the U.S.S.R. for a

steel pipe plant worth $300 million. Japan's C. Itoh & Co., Ltd., and Yamamoto Suiatsu Kogyosho Co. signed a Y1,300-million contract with the U.S.S.R. for the supply of 27 hydraulic pipe-bending machines. The U.S.S.R. informally indicated to Japan's companies that it is very much interested in purchasing a plate mill and pipe-making equipment.

Four British companies supplied the Chelyabinsk metallurgical plant with a steel strip-coating plant. A continuous-annealing plant, with an annual capacity of 500,000 tons of coils, is to be supplied to the U.S.S.R. by a Japanese firm. It will form part of the current 5-year plan expansion of the Novo-Lipetsk plant. Schloemann Siemag will supply two complete pickling lines, worth over DM200 million, for the Novo-Lipetsk steelplant.

The British firm Davy-Loewy Ltd. will supply the U.S.S.R. with two forging complexes worth £13.6 million. The United Kingdom's Instron Ltd. signed a contract worth £800,000 to supply computer-controlled material-testing machines and systems to the Leningrad Izhorski plant.

(5) Equipment for the nonferrous metals industry, including heavy earthmoving equipment, beneficiation of polymetallic ores, nickel and copper smelters, titanium dioxide plants, aluminum and alumina plants, and ship-offloading facilities. Equipment valued at over $6 million was being delivered by Suomen Puhallintehdas Ltd. of Finland to the Norilsk copper and nickel plants. Péchiney Ugine Kuhlmann (PUK) is to construct a 1-million-ton-per-year alumina plant at Nikolayev on the Black Sea and a 500,000-ton-per-year aluminum smelter at Sayanogorsk in Siberia. The cost of the alumina plant is over 1 billion francs (F), and that of the aluminum smelter and the associated aluminum fabrication plants is F5 billion. The French company will buy 50,000 tons per year of Soviet aluminum for a 10-year period to pay for the projects. Montedison was negotiating for the supply of a titanium dioxide plant, which will be constructed at Shevchenko in Kazakhstan; Montedison supplied a 20,000-ton-per-year plant at Sumi in the Ukraine in the 1960's.

Poclain S.A. of France signed a contract for F22.7 million for heavy earthmoving equipment for the Siberian nonferrous metals industry. This contract followed Poclain's sale of 15 large cranes to the U.S.S.R. in 1975. Bartles Ltd. is to send 17 Bartles-Mozley wet-gravity separators; this will be the third Soviet order for these concentrators. Ingersoll-Rand Co. of the United States signed a $14 million contract for delivery of 10 large vertical reciprocating pumps; the pumps will be used to transport abrasive polymetallic concentrates through pipelines (presumably at Norilsk). A DM-38-million contract was awarded to Krupp Kranbau of West Germany for the construction of three ship-offloading facilities in 1978. These are to be built at Nikolayev on the Black Sea to offload bauxite for the new alumina plant now under construction by PUK.

A second contract could go to the United Kingdom's Rio Tinto-Zinc Corp. Ltd. for construction of the Udokan copper pilot plant in eastern Siberia. The U.S.S.R. once again proposed to Western firms to consider the establishment of "joint" compensation agreements for development of the Udokan copper deposit.

(6) Ammonia, urea, potash-processing, phosphoric acid, and superphosphate plants and communications systems for ammonia pipelines. The Soviet chemical industry is receiving priority treatment under the 1976–80 plan, with a growth rate of 11%. This growth can only be achieved through major applications of advanced Western technology. The French firms PEC Engineering and Azote et Produits Chimiques are to supply seven identical plants, each producing 1,200 tons per day of P_2O_5 and valued at $72 million. Four of these plants will be constructed in the Ukraine by 1977, two in the European part of the Russian Soviet Federated Socialist Republic (R.S.F.S.R.) by 1979, and one in the Baltic States region. The Norwegian firm Norsk Hydro A/S, with Toyo Engineering Corp. of Japan, is to build five 675,000-ton-per-year fertilizer plants over a 4-year period. The Belgian Coppee-Rust S.A. group received a $135 million order to install four phosphoric acid plants, with a capacity of 1,100 tons per day each. Montedison is to supply equipment for two 450,000-ton-per-year urea plants in 1977 and 1978. A £100,000 contract was given to Doulton Industries U.K. for filtration equipment for fertilizer plants being built at Gorlovka and Odessa in the Ukraine. The Toyo Engineering-Mitsui Group is to supply a $100 million

fertilizer complex, consisting of both ammonia and urea plants, with capacities of 1,300 tons and 1,500 tons per day, respectively. Technimont will supply two 1,500-ton-per-day urea plants, together valued at more than $100 million. The plants are to be built at Kemerovo in Siberia and Berezniki in the Urals.

The U.S.S.R. was negotiating with Japan's Toyo Engineering-Mitsui Group for the purchase of two more ammonia plants, each with a capacity of 1,360 tons per day, at a cost of about $203 million. The U.S.S.R. was also negotiating with Imperial Chemical Industries Ltd. (ICI) of the United Kingdom for the purchase of technology to build an ammonia plant. The U.S.S.R. was planning to build two 100-ton-per-hour potash-processing plants in the Urals with the assistance of Western companies, using Western equipment.

Three French firms will provide a communications system to be installed along the 1,500-mile ammonia pipeline between Togliatti and Odessa. The cost of the system is F50 million.

Western industrial equipment sales to the U.S.S.R. fill gaps the Soviet economic system has not been able to accommodate. Imports of Western technology and highly technical machines and plants assist the U.S.S.R. and its allies in accelerating industrial development.

Exploration.—Over 5,000 deposits of various minerals were being exploited in 1976. Extensive prospecting and exploration for practically all commodities was carried out on a large scale. There were over 500,000 employees in the geological and prospecting organizations of the U.S.S.R. in 1976, including 65,000 graduate specialists with university educations and about 55,000 graduate technicians. A total of about 4 billion rubles was allocated for geological exploration in 1976. About 2 billion rubles was for oil and gas exploration,[18] and some 200 million rubles was for coal exploration. Over 2,500 geological and geophysical teams were permanently employed in prospecting and exploration for oilfields and gasfields, and about 2,200 exploratory wells are completed each year, using some 2,500 drilling rigs.

Construction.—The U.S.S.R. continued to experience difficulty in completing mineral industry projects on schedule owing to deficiencies in planning, inadequate coordination, and equipment and materials shortages. The construction of new projects remained slow and expensive, and material and manpower resources were frequently dispersed over a large number of projects, so that leadtimes were two to three times as long as specified by the U.S.S.R. State Construction Committee. The 10- to 15-year period required to develop a mine with a capacity of 1 million to 2 million tons per year contributed to disparities between capacities of mines, concentration mills, and metallurgical plants in the iron and steel industry, the nonferrous metals industry of Kazakhstan, and many other projects. The practice of resorting to expedients resulted in great inefficiencies and prolonged delays in reaching design capacity. For example, published reports stated that on January 1, 1975, planned capacity goals had not been reached at 12 lead-zinc, 4 copper, 7 aluminum, and 6 nonferrous rolled metals enterprises. At the Achinsk alumina plant, only 53.6% of design capacity was achieved.

Other public statements citing specific shortcomings were numerous. The Rovny nitrogen and Uvarovo chemical plants utilized only 40% to 60% of their capacities. As of January 1, 1976, of fifty 185-meter rotary kilns in operation in the cement industry, thirty-seven did not achieve their design capacity. The planned capacity goals were not achieved at several enterprises of the mineral fertilizers industry. Construction plans of many projects were met according to ruble expenditures, but facilities were not put into operation.

In 1976, the capital construction emphasis was on expansion and renovation of existing enterprises, rather than on new construction. The proliferation of the Zhlobin method (self-accounting construction brigades taking on building contracts of their own free will) was mentioned in all documents pertaining to the 1976–80 plan as a principal means of curing the continuing defects in construction work. However, the number of Zhlobin brigades was growing very slowly, and the shortage of construction materials and equipment continued to affect all but a few brigades. As a result, the average shaft-sinkisg speed of rather small shafts (averaging 5 meters in diameter and

[18] Ekonomika neftyanoy promyshlennosti (Economics of the Petroleum Industry), Moscow. No. 7, July 1976, p. 15.

500 meters deep), for example, was only 15 to 20 meters per month.[19]

Capital investment in the Soviet economy amounted to 117 billion rubles in 1976, 4% over that of 1975, compared with a 9% growth in 1975. The growth rate of commissioning of new capacity fell to 2%.

New enterprises that became operational in the iron and steel industry included a rolling mill at the Kuznetsk steel complex, the pipe-rolling mill at the Severskiy plant, a coke-oven battery at the Avdeyevka works, and new facilities at the Ermakovsk ferroalloy plant, the Karaganda sintering shop, and the Sokolovsk-Sarbaysk iron-mining and processing complex. It was planned to increase capital investment in the iron and steel industry 10.5% over that of 1975.

New capacities for the production of nonferrous metals included the Novo-Berëzovskiy mine at the Irtysh polymetallic complex, the second stage of mine No. 65 at the Dzhezkazgan copper complex, the Koksu mine at the Tekeli lead and zinc complex, and the first stage of the Zhayremsk lead and zinc mine. Additional facilities were installed at the Achisay and Leninogorsk polymetallic complexes, the Ust-Kamenogorsk titanium and magnesium complex, and the Turgay bauxite mine. In 1976, over 2 billion rubles was invested in the development of the nonferrous metals industry, including some 90 million rubles in the development of the secondary nonferrous metals industry. In the mineral fertilizers industry, new capacities included facilities at the Kingisepp phosphorite complex. The first stages of the Armenia nuclear powerplant, with a capacity of 405 megawatts, and the Kursk nuclear plant, with a capacity of 1,000 megawatts, were put into operation in 1976, as was the fourth stage of the Bilibino plant, with a capacity of 12 megawatts.

New production capacity, including new or expanded plants and renovation of existing facilities, was reported for the past several years as follows, in million tons per year unless otherwise specified:

Commodity	1973	1974	1975	1976
Iron ore, crude	39.0	24.4	27.3	45.0
Pig iron	3.7	4.0	1.8	2.25
Raw steel	--	3.0	4.0	1.2
Finished ferrous rolled metals	3.5	1.6	3.3	4.0
Cement	3.7	5.6	4.4	1.85
Mineral fertilizers (Soviet standard)	8.9	7.0	11.7	7.3
Raw coal	34.0	19.4	24.7	12.6
Electrical power million kilowatts	11.0	10.0	13.0	11.9

Total capital investment in the U.S.S.R. for the 1976–80 period was set at 621,400 million rubles, 26% over that of the 1971–75 period, and is to amount each year to the following percentages of the 1975 level: 1975—100%, 1976—105.1%, 1977—108.9%, 1978—112.1%, 1979—114.3%, and 1980—114.6%. According to the 1977 State plan, 121,500 million rubles is to be invested in the Soviet economy in 1977.

Construction of the 3,200-kilometer Baykal Amur Railway (BAM) continued in 1976. There were 58,000 people working on the Railway, including some military workers. The completion date is currently set for 1982. So far, 600 kilometers has been completed.

PRODUCTION

A Soviet decree of April 1956 classifies all data on production capacity and production plans of nonferrous, precious, and rare metals and some nonmetallic enterprises as State secrets. Although the U.S.S.R. does not publish official statistics on many mineral commodities, information is available on most minerals. Published information on industrial development, however, provides some basis for estimating output of many other commodities. The increase in Soviet mineral production in 1976 was largely owing to additional capacity and labor rather than to productivity gains. The U.S.S.R. devotes one-fourth of its gross national product (GNP) to investment, compared with one-sixth in the United States. Total Soviet industrial production remains about one-half that of the United States.

During 1971–75, reported production of nonferrous metals in the U.S.S.R. increased 34.7%; aluminum, nickel, titanium, and hard alloys 50%; copper 30%; rare metals 190%; and semiconductor metals 270%. Output of sulfuric acid at nonferrous operations reached almost 5 million tons, or 25% of the total national production. The

[19] Shakhtnoye stroitel'stvo (Mine Development), Moscow. No. 8, August 1976, pp. 15–16.

working capital at the enterprises of the nonferrous metals industry amounted to 5 billion rubles in 1976.

The Asian part of the U.S.S.R. (east of the Ural Mountains) provided about 45% of total Soviet coal and lignite output, more than 35% of the natural gas, over 33% of the crude oil, and over 30% of the electrical power. The R.S.F.S.R. continued to rank first among the 15 Soviet republics in mineral production. It produced over 80% of the gold and silver, practically all of the platinum-group metals, more than 80% of the petroleum, about two-thirds of the phosphate ores and the electrical power, over half of the pig iron, steel, and ferrous rolled products, and roughly half of the coal and natural gas. The Ukraine continued to rank first in output of coking coal, manganese ore, and iron ore, and second in natural gas.

The Asian Republic of Kazakhstan, one of the most important base-metal-producing areas in the U.S.S.R., occupied third place in Soviet mineral production and was the nation's leading producer of chromite, copper, lead, zinc, and rare metals. During 1971–75, Kazakhstan's production of copper ore increased 21.5%, lead-zinc ore 14.2%, refined copper 40.6%, refined lead 14%, titanium 41%, alumina 23.7%, and sulfuric acid 52.4%. The Urals produced over 30% of the Soviet pig iron in 1976, about 40% of the steel and steel pipe, and about 50% of the potassium fertilizers. The Ural-Volga region produced nearly one-half of the nation's crude oil. Most of the U.S.S.R.'s increased petroleum production was, however, derived from the western Siberian fields.

Production facilities at the Balkhash and Dzhezkazgan copper complexes continued to experience ore shortages and losses owing to unsatisfactory ore reserve estimates at the Kounrad, Sayak, and Dzhezkazgan mines, according to published reports. The slow development of new mines resulted from disparities between mine, mill, and metallurgical plant capacities, particularly in Kazakhstan. The losses of ore at the Kazakhstan nonferrous mines were high. At the underground mines of the Dzhezkazgan mining and metallurgical copper complex, the losses of ore increased from 20.6% in 1970 to 27.5% in 1975. The same is true for the Achisay and Tekeli polymetallic complexes, the Zolotushinsk polymetallic mine, and the Turgay bauxite open pits. The engineering plans at the mines were frequently not followed, and selective mining of rich sections was practiced, according to press reports.

The U.S.S.R. has been increasing production of metals and fuels from year to year, but the economy has been experiencing chronic shortages of coal and ferrous and nonferrous rolled metals. Although many minerals are mined and processed in the U.S.S.R., insufficient attention is being paid to the comprehensive use of mineral resources. During the last 5-year plan, there was a slight increase in extraction from ores into concentrate, but publications maintain that planned extraction targets for many nonferrous metals were not achieved and continued to be much below the Western level. At some beneficiation plants, recovery of gold, silver, and copper from ores in concentrates has even decreased. At the Dzhezkazgan complex, only 48% of the total value of metals was recovered from the ore in concentrate in 1976. It was reported that because of a shortage of reagents, 80% to 90% of rare metals was lost in the tailings at the beneficiation plants at Dzhezkazgan. For example, recovery of rhenium at this complex amounted to only 10% to 12%. Academic mining institutions report that the low recovery of metals by copper-producing plants in the Urals resulted in losses of thousands of tons of copper, zinc, and other nonferrous metals and of large quantities of gold and silver.

Many enterprises, such as the Balkhash and Dzhezkazgan copper mining and metallurgical complexes, the Irtysh polymetallic complex, and the Tekeli lead and zinc complex in Kazakhstan, regularly do not fulfill the plan for labor productivity. Although the mechanization of production has increased, labor productivity at 14 of the 30 underground mines in Kazakhstan decreased during the past 3 years.

At the open pits of the Kadzharan and Agarak copper-molybdenum complex and the Madneuli copper complex, the utilization of drilling rigs did not exceed 20% to 30%. The utilization of excavators at the same open pits in the nonferrous metals industry was only 36% to 40%. It was reported that the utilization of dump trucks was low at the Kadzharan, Tyrny-Auz, and Madneuli nonferrous complexes. The Adrosmansk, Koytash, Chorukh-Dayronsk, and

Akchatausk nonferrous concentration plants operated with large interruptions, and their equipment utilization did not exceed 80%. At the iron ore mines of the Krivoy Rog Basin, published reports show the utilization of machinery in 1976 as follows: Underground mines—electric locomotives 30% to 60%, loading machines 27% to 35%, and drilling rigs 40% to 50%; and open pits—excavators 35% to 55%, rotary excavators 25% to 65%, drilling rigs 37% to 45%, and locomotives 55% to 65%.

The 1976 planned production goals were not met by many mineral industry enterprises. Poor performance was reported, for example, at the Kazzoloto (Kazakhstan Gold) Association, the Balkhash, Leninogorsk, Akchatausk, and Irtysh polymetallic complexes, and other enterprises of Kazakhstan.

Many projects have operated over a long period with lower capacities than originally planned. Only 75% of new projects achieve rated capacity. For example, on January 1, 1975, planned capacity goals had not been reached at 12 lead-zinc, 4 copper, 7 aluminum, and 6 nonferrous rolled metals enterprises. Only 53.6% of design capacity was achieved at the Achinsk alumina plant; 67% of design capacity of the oxygen converter at the Karaganda metallurgical complex was achieved.

The Soviets are increasingly conscious of the age and obsolescence of their mining and metallurgical equipment. Industries continue to produce obsolete models; because of the emphasis on production, no time can be taken for retooling. There is resistance to the use of new and untried equipment with its inherent risk of failure, and the inclination is to use the old but safe and familiar equipment.

Soviet reports also have documented obsolete equipment in 30 cement plants, 43 blast furnaces, 80 open-hearth furnaces, 97 rolling mills, about one-half of the power units, and a large percentage of the metal products plants. Of the 200 coking batteries in the U.S.S.R., more than one-half have been operating for more than 20 years, some of them for 40 years, according to official publications. Many became obsolete or were worn out long ago.

Because of a shortage of some needed equipment, there was a rapid increase in stocks at many establishments. At the beginning of 1976, above-plan uninstalled equipment constituted 36% of equipment as a whole. Much the same applies to equipment bought abroad. During the past 5 years, the value of uninstalled imported equipment increased to 2,100 million rubles. At the same time, many other projects could not be completed because of shortages of equipment.

In many sectors of the Soviet economy, more electrical power, fuels, and metals are consumed per unit of product than required with modern technology. For example, in 1975, this overconsumption of materials was valued at 5.3 million rubles at enterprises in the copper industry, 4 million rubles in the aluminum industry, and 1.5 million rubles each in the lead-zinc and nickel-cobalt industries. In many Soviet industrial enterprises, enormous quantities of secondary power, fuels, and metals are insufficiently utilized.

TRADE

Foreign trade is within the State monopoly and is administered by the Foreign Trade Ministry, operating through more than 60 foreign trade organizations. Political objectives exert a strong, and often determining, influence on foreign trade. The U.S.S.R. trades with 115 countries, and in 91 cases the trade is based on inter-State agreements. Trade continues to be oriented toward imports of large quantities of Western industrial machinery and technology (including complete industrial plants) and substantial grain purchases. The Soviets rely heavily on both foreign-government-backed and commercial credits to finance the increasing foreign currency deficit. Exports of minerals help pay for these imports.

In the Soviet mineral economy, international trade is given high priority. Since the value and volume of trade are both outlined in the national plans, foreign trade reflects national goals and priorities. There is, therefore, an implied commitment to export to achieve a desired trade balance. The high priority placed upon achieving the goals can result in sales below world commodity prices. Domestic consumer demand is a less important motivation than fulfilling export quotas. Almost all Soviet exports could easily be consumed domestically.

In the overall economy, foreign trade is relatively less important to the U.S.S.R. than to many other industrialized nations. However, definite political and economic objectives are sought through trade, and the U.S.S.R. intends to expand the volume of trade. In terms of foreign policy, the dependence of some countries upon Soviet trade gives the U.S.S.R. varying degrees of economic influence. Sales and purchases in appropriate places enable the U.S.S.R. to exert political pressure. Because the U.S.S.R. has a dominant position in the CMEA, the total volume of trade it influences is significantly greater than the trade volume of the U.S.S.R. alone.

The U.S.S.R.'s exports of fuels, metals, and energy permit a controlling influence over the economies of its CMEA satellites. In Eastern Europe, this control rests largely on the fuels and energy trade. Romania is the only country producing moderate quantities of oil; all others are heavily dependent upon liquid fuel imports. The U.S.S.R. has a controlling influence over the metallurgical industries of the CMEA nations through exports of coke and ferrous and nonferrous metals.

Official Soviet foreign trade turnover (exports plus imports) in 1976 reached 56,784 million rubles, an increase for the year of 6,080 million rubles or 12%. The increase mainly reflected higher prices. Official exports increased by 3,989 million rubles to 28,022 million rubles. Official imports increased by 2,092 million rubles to 28,762 million rubles. Soviet trade turnover with centrally planned economy countries amounted to 31,557 million rubles (about 56% of total trade), of which 28,825 million rubles (about 51% of total trade) was with CMEA nations; trade with developed Western countries amounted to 18,661 million rubles (33%); and trade with developing countries amounted to 6,567 million rubles (over 11%).

The value of official trade with leading developed market economy countries, in million rubles, follows:

Country	1972	1973	1974	1975	1976
Germany, West	827	1,210	2,209	r 2,777	3,013
United States	538	1,161	742	r 1,599	2,202
Finland	602	777	1,540	r 1,755	1,979
Italy	468	614	1,137	r 1,427	1,773
France	544	722	941	r 1,296	1,697
United Kingdom	558	715	890	r 959	1,232
Japan	816	994	1,683	r 1,922	1,131
Netherlands	222	356	571	451	540

r Revised.

Soviet figures for foreign trade in 1976 highlight the declining importance of centrally planned economy countries in the U.S.S.R.'s external trade. Whereas trade with centrally planned economy countries in 1971 represented 65.4% of the total, it was only 58.5% in 1973 and about 56% in 1976. Trade with CMEA countries declined from 59.6% of the total in 1972 to about 51% in 1976.

Official Soviet trade turnover with CMEA countries, in million rubles, was distributed as follows:

Country	1972	1973	1974	1975	1976
Germany, East	3,705	3,965	4,315	5,623	5,997
Poland	2,803	3,000	3,584	4,853	5,235
Czechoslovakia	2,626	2,760	3,029	3,911	4,545
Bulgaria	2,345	2,555	2,904	3,991	4,465
Hungary	1,882	2,064	2,282	3,274	3,492
Cuba	822	1,110	1,642	2,589	2,875
Romania	1,053	1,130	1,191	1,526	1,600
Mongolia	287	338	404	480	614

Official trade with Yugoslavia increased from 569 million rubles in 1972 to 1,821 million rubles in 1976. Trade with Vietnam was 296 million rubles (up from 180 million rubles in 1973); with North Korea, 300 million rubles (down from 357 million rubles in 1973); and with the People's Republic of China, 314 million rubles (up from 201 million rubles in 1973).

The U.S.S.R. has trade agreements with more than 70 developing countries. The official trade turnover with leading nations, in million rubles, follows:

Country	1973	1974	1975	1976
Iraq	332	453	r 600	715
India	589	615	r 686	647
Egypt	541	728	710	531
Brazil	126	202	396	446
Iran	275	496	510	445
Syria	119	172	168	235

r Revised.

Most of the U.S.S.R.'s 1976 export trade in minerals was with Europe (particularly West Germany) and Japan. Quantitatively, there was no significant change in the patterns of Soviet mineral trade in 1976 from those of 1975. Fuels, metals, and mineral raw materials continued to play the major part in exports, representing about 40% of the official total during 1976. Along with gold, platinum-group metals, chrome ore, manganese ore, aluminum, zinc, lead, asbestos, apatite concentrates, potassium, cement, pig iron, ferroalloys, steel, coal, petroleum, and coke, the country now exports diamond, titanium, nickel, copper, rare metals, and natural gas.

The U.S.S.R. provides nearly 100% of the CMEA countries' imports of crude oil, natural gas, pig iron, and electrical power, two-thirds of their petroleum products, ferrous rolled metals, and phosphorous fertilizers, 60% of their coal and manganese ore, and up to 90% of their iron ore. Exports of Soviet petroleum to CMEA members rose from 138 million tons during the 1966–70 period to some 243 million tons in 1971–75. In 1976–80, the U.S.S.R. is to increase fuel supplies to CMEA countries 43% over the amount supplied during the previous 5-year plan. However, a significant portion of this fuel is required by the CMEA countries to meet their commitments for Soviet industrial orders. The economies of the CMEA countries have been largely reoriented in the direction of the U.S.S.R. Relations among CMEA countries entered a new phase in 1975 when the U.S.S.R. raised oil prices on exports to Eastern Europe an average 130%.

Hitherto, most of the Soviet mineral trade has been with centrally planned economy countries, but the U.S.S.R. is now aiming increased exports to Western countries and especially to the United States. Deliveries of natural gas and petroleum to Western countries are to be increased in the future and are to become an important factor in Soviet exports to Western Europe, largely under 20-year trade agreements. In return, the U.S.S.R. is to receive equipment, pipe, and materials for the development of gasfields and the construction of gas pipelines. The U.S.S.R. provides natural gas to Austria, Italy, Finland, and West Germany, and in January 1976, exports of natural gas to France began.

Mineral commodity imports in 1976 included ferrous semimanufactures, nonferrous ores, concentrates, and semimanufactures, steel pipe, bauxite and alumina, tin, tungsten concentrates, talc, and mica. Soviet petroleum imports come mainly from the Middle East and northern Africa. Natural gas is imported from Iran and Afghanistan.

Table 2.—U.S.S.R.: Exports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1974	1975	Principal destinations, 1975
METALS			
Aluminum metal:			
Unwrought	528,713	502,365	East Germany 114,454; Hungary 101,482; Czechoslovakia 90,316; Japan 42,948.
Semimanufactures, rolled only	r 116,318	101,510	Poland 23,587; Bulgaria 9,931; Cuba 7,719; Czechoslovakia 7,373.
Cadmium, unwrought	925	635	Netherlands 210; East Germany 208.
Chromium, chromite ore and concentrate thousand tons	1,139	1,171	United States 270; West Germany 156; Sweden 140; Czechoslovakia 131; Poland 109.
Copper:			
Copper sulfate	20,776	20,361	Bulgaria 7,881; Hungary 4,520.
Metal:			
Unwrought:			
Unalloyed	247,978	205,618	Czechoslovakia 38,746; Netherlands 35,224; Hungary 33,121; West Germany 12,481.
Alloyed	3,747	4,241	West Germany 2,787; Netherlands 786.
Semimanufactures, rolled only:

r Revised. NA Not available.

[1] Data possibly incomplete; total not officially reported. Totals given here represent sum of quantities reported officially for all countries listed individually in source.

[2] Detail on principal destinations include shipments of vanadium slag and manganese metal, if any, to the listed countries, but total shipments of these commodities are reported separately under vanadium and manganese in this table.

[3] Detail on destinations of crude oil and refinery products are not officially reported separately. Total exports of crude oil and refinery products are reported by destination as a single total on a gravimetric basis, but this cannot be converted to a volumetric basis owing to the varying specific gravities of the different products that constitute the country total. Percentage figures provided here represent each country's share of total crude oil and refinery products exports on a gravimetric basis.

Percentage figures provided here represent each country's share of total refinery products imports on a gravimetric basis.

COMMODITY REVIEW

METALS

Development of the ferrous and nonferrous metals industries lagged behind goals established for the 1976–80 5-year plan; however, production of metals and alloys continued to grow. Many products of the industry were not up to quality and variety requirements. Metallurgical plants frequently reported shortages in raw materials because of the postponement of scheduled leadtimes of new facilities for mining and processing.

Nonferrous ore beneficiation facilities continued to experience poor recovery of metal, particularly from oxide and mixed ores. Lead concentrates produced from mixed ores at the Zyryanovsk and Leninogorsk complexes in Kazakhstan contained about 60% of the lead contained in the ore, and zinc concentrates carried only 30% to 50% of the zinc contained in these ores. Some 80% to 90% of rare and dispersed elements was discarded in tailings at the beneficiation plants at Dzhezkazgan in 1976, according to official reports. As a result, the millions of tons of metallurgical slag at nonferrous metal plants of Kazakhstan contains more rare metals than does rich ore mined for production of these metals. At the Kadzharan copper and molybdenum mining and concentration complex in Armenia, some 16 million tons of tailings contain more copper and molybdenum than the ore mined in other places. Because of poor technology to utilize reverberatory gases and dust, large quantities of nonferrous metals were lost in 1976.

Serious shortcomings exist in the disproportion of officially explored and actual reserves of ores at many enterprises. For example, the copper complexes of Kazakhstan were hampered by the inability of the copper mines at Kounrad, Dzhezkazgan, and Sayak to reach design production as a result of overestimation of the quality and quantity of reserves, owing to poor geological study of the deposits.

Utilization of machinery and equipment continued to be considerably below the planned levels, and modernization and replacement of obsolete equipment was slow. As a result, productivity, even at advanced enterprises in Kazakhstan's nonferrous metals industry, was lower than at comparable enterprises in the West.

Soviet reports show that mining and metallurgical equipment is utilized at an average rate of 40% to 45% of designed working time. Downtime owing to breakdowns was common, according to reports.

Aluminum.—The U.S.S.R. is the world's second largest producer of aluminum; probable annual production capacity in January 1977 was 1.95 million tons. Estimated production in 1976 was about 1.75 million tons (including 150,000 tons of secondary), a 4% increase over 1975 output. Production fell short of the 6% planned increase because planned capacity goals had not been reached at seven aluminum plants, according to published Soviet reports, and output did not start at the new potline at the Krasnoyarsk plant in Siberia.

The increase in production of aluminum and alumina during the ninth 5-year plan (1971–75) was the highest in the industry's history. Under the new 5-year plan, output in 1980 is scheduled to be 30% above the 1975 level. To achieve these goals, it is planned to complete construction of the Bratsk and Krasnoyarsk plants, commission the first half of the Regar plant in Tadzhikistan, and complete construction of the first potline at the Sayanogorsk plant in Siberia. It is also planned to accelerate construction of additional alumina production facilities at the Bogoslovsk and Uralsk aluminum plants in the Urals. The Nikolayev alumina plant, with an annual capacity of 1 million tons, is to be completed by 1980. In the current 5-year plan, the regions east of the Urals are to account for the entire increase in the U.S.S.R.'s aluminum production. Soviet output of primary and secondary aluminum may reach 2.2 million tons by 1980.

In the 1976–80 period, an increase in output of crystalline silicon is to be accomplished by commissioning a silicon plant at the Irkutsk aluminum plant and expanding production of silicon at the Dneprovskiy aluminum plant. Increased fluoride salt production is to be provided through additional facilities built at existing plants and expansion of regenerated cryolite output. Considerable capital investment is being

directed to development of the aluminum industry in the 1976–80 period.

Aluminum is produced more for export than for domestic consumption, and the U.S.S.R. has exported over 500,000 tons in each of the past 4 years. Soviet exports are expected to increase to about 700,000 tons in 1980. The U.S.S.R. exports primary and secondary aluminum to Western European countries and Japan and plans to export large quantities to the United States in the future.

Construction continued at the Bratsk, Krasnoyarsk, and Regar primary aluminum plants. At Bratsk, the largest aluminum plant in the country, one potline was completed in 1976. The new potline at Krasnoyarsk, which was to come onstream in 1976, was not completed. The rated annual aluminum capacity of new Soviet potlines (korpus) is 30,000 tons.

PUK concluded an agreement for construction of a 1-million-ton-per-year alumina plant at Nikolayev on the Black Sea and a 500,000-ton-per-year primary reduction plant at Sayanogorsk, Krasnoyarsk Kray, in Siberia. Part of the cost (estimated at $2,600 million) will be repaid by product shipments to France. Construction of these plants, with the assistance of French experts, began in 1975. The alumina plant and the first potline of the refinery are to be completed during the 1976–80 period. Power is to be supplied by the Sayano-Shushensk hydroelectric plant, which is under construction.

Because of the delayed completion of scheduled construction of alumina and cryolite plants, there was a disparity between aluminum capacity and raw material supply. At many aluminum plants, more electrical power and materials are consumed per unit of production than is required with modern technology. In 1975, overexpenditures amounted to 4 million rubles. The Krasnoyarsk, Dneprovskiy, and Novokuznetsk aluminum plants used 500 to 1,000 kilowatt-hours more electrical power per ton of aluminum than the Soviet average. Mechanization of labor-intensive manual work in the Soviet aluminum industry is also making slow progress. For example, the degree of mechanization of work performed manually without machines in transportation and warehouse operations was 42.6%.

During the 1971–75 period, output of aluminum doubled at Bratsk. The first potline at the Regar plant, commissioned in 1975, attained design capacity in 1976. Three potlines at Regar were planned for completion by 1975, but only one had been constructed and put into operation as of September 1976. PUK assisted in constructing the plant and supplied some of the equipment. The second potline was under construction in 1976, and full operation was rescheduled for the 1980's. It is planned to make Regar the third largest producer after Bratsk and Krasnoyarsk. Regar operates on imported alumina.

Although the U.S.S.R. is a large producer of low-grade bauxite, supplies are insufficient and the country is developing alumina production from nepheline and alunite. Alumina is produced from nepheline at the Volkhov alumina-aluminum plant and the Pikalëvo complex in Leningrad Oblast using nepheline concentrate from the Apatit complex on Kola Peninsula, and at the Achinsk alumina plant in Siberia.

The nepheline-based alumina capacity in Leningrad Oblast is limited to processing only 1.5 million tons of nepheline concentrate. Because the quality of the nepheline concentrate decreased from 29% alumina in 1970 to about 28% in 1975, according to documentation, consumption of nepheline concentrate per ton of alumina must be at least 4.5 tons. Therefore, the Pikalëvo complex and the Volkhov plant could not have produced more than 335,000 tons of alumina from nepheline in 1975. The Achinsk alumina-from-nepheline plant, based on the Kiya-Shaltyrsk deposit, was reported to have achieved only 53.6% of its design capacity (800,000 tons per year) in 1975. A second nepheline mill, with an annual capacity of 2 million tons of concentrates, was reported under construction at the Apatit complex and is scheduled for completion in 1980.

Soviet output of primary aluminum in 1975 and 1976, by source of raw material, is indicated in the following tabulation:

Raw material	1975		1976	
	Thousand metric tons	Percent of output	Thousand metric tons	Percent of output
Bauxite	1,101	72.1	1,173	73.3
Nepheline:				
Kola Peninsula	169	10.9	167	10.4
Achinsk	215	14.1	215	13.5
Total	382	25.0	382	23.9
Alunite	45	2.9	45	2.8
Grand total	1,530	100.0	1,600	100.0

The principal reserves of bauxite are situated on the eastern slopes of the Urals, in the Turgay area of Kazakhstan, and in the Tikhvin region of Leningrad Oblast. The Northern Urals continued to be the main bauxite- and alumina-producing region. Four underground mines in this region were being expanded, but the opening of two new underground operations progressed slowly, and production was rescheduled for 1980.

Plans are to increase production of alumina at the Bogoslovsk aluminum plant in the Urals 52.5% in 1980 over 1975 output, using reserves of the Krasnaya Shapochka deposit. The plant consists of three sections; the first is to be commissioned in 1978, while the others are to be completed in 1979–80.

The second largest bauxite- and alumina-producing region is Kazakhstan, where the Pavlodar No. 1 alumina plant is among the nation's largest. The No. 2 alumina plant is under construction. During 1971–75, production of alumina at Pavlodar increased 23.7%. It is planned to increase alumina production in Kazakhstan 10% in 1980 over that of 1975. Completion of development of the Krasnooktyabr'sk and Belinsk open pits in northern Kazakhstan was rescheduled for 1980.

The Kirovabad alumina-from-alunite plant in Azerbaydzhan performed poorly in 1976. Massive capital investment was allocated to this plant for 1976–80. New facilities for alumina production were to be commissioned in 1976, but the goals were not met. The construction was undermanned by 50 to 70 persons, and available labor was not being fully utilized in 1976. Idle time was enormous. There were shortages of construction materials. The design for renovation was based on equipment which had not been produced by industry, according to official publications.

In 1976, important attention was being paid to improving the raw materials base and creating alumina facilities to overcome the gap between alumina and aluminum production capacity. A serious deficit in alumina production seems probable in the future. The U.S.S.R. is also seeking to meet the deficit by integrating the industries of Eastern Europe and by assisting with projects in Greece, Guinea, and India. Meanwhile, the U.S.S.R. continues to import substantial quantities of high-grade bauxite and alumina from Hungary, Yugoslavia, Greece, and Guinea.

Reportedly, the U.S.S.R. will build a 500,000-ton-per-year alumina plant in India. The $400 million project is to be financed by a loan from the U.S.S.R. and is to be repaid in alumina. The U.S.S.R. will help Indonesia build a 600,000-ton-per-year alumina plant on Bintan Island. The $360 million plant is expected to be completed by the early 1980's. The U.S.S.R. also agreed to construct an alumina-from-alunite plant in Iran. The U.S.S.R. and Algeria signed an agreement for construction of a $75 million, 140,000-ton-per-year aluminum plant at M'sila. The U.S.S.R. will finance the entire loan for the project, and repayment is to be in aluminum.

The U.S.S.R. operated 14 secondary aluminum units with a total estimated annual capacity of 185,000 tons in 1976. Production has been estimated at 150,000 tons of aluminum and aluminum alloys. The average selling price of secondary aluminum in the U.S.S.R. was about 490 rubles per ton in 1976.

A shop for production of secondary aluminum was put into operation at the Sumgait primary aluminum plant in Azerbaydzhan in November. New aluminum scrap is supplied to this shop by the Volgograd and Sumgait primary aluminum plants. The second stage of the Rustavi sec-

ondary nonferrous metals plant in Georgia was commissioned for the smelting of secondary aluminum in October 1976.

Antimony.—The Kadamdzhay complex in Kirgiz S.S.R. is the principal antimony center, where integrated facilities produce most of the country's refined products. Development continued on a new underground level at the mine, and ore extraction is to be doubled in the future. The recovery of antimony in concentrate at this complex increased from 89.5% in 1971 to 91.5% in 1976, and the metal content of the concentrates increased from 29% to 35%.

Construction of the new Aznob mine and mill unit (Dzhidzhikrutskiy complex) in Tadzhikistan continued slowly in 1976. Completion of the first stage was scheduled for 1975 but has been rescheduled for 1980. About 40 million rubles has already been invested on construction of the first and second stages, but the management of the project reported no set completion date. An antimony ore deposit associated with gold was under development at Sarylakh in Yakutia near the Arctic Circle.

Beryllium.—The U.S.S.R. continued to be the world's largest producer and one of the largest consumers of beryl, beryllium alloys, and metal in 1976. There are numerous deposits, mainly in Kazakhstan, Kola Peninsula, Transbaykal, the Urals, the Soviet Far East, and Western Ukrainia. Production is being expanded, and the probable level was 1,650 tons of beryl (10% to 12% BeO) in 1976. It is planned to recover beryllium from the ore of the Dzhidinsk tungsten and molybdenum complex in Buryat A.S.S.R.

Cadmium.—Cadmium is recovered at various Soviet lead and zinc smelters. Kazakhstan has recently become an important producer of cadmium. The Leninogorsk polymetallic complex in Kazakhstan, which increased cadmium production 25% during 1971–75, continues to be one of the largest producers. Production of cadmium was also increased at the Almalyk zinc plant in Uzbekistan and at the Balkhash polymetallic complex in Kazakhstan. Construction of facilities for cadmium recovery at the Dzhezkazgan complex in Kazakhstan continued in 1976. The U.S.S.R. has been the principal European cadmium supplier for many years, but in 1976 it made substantial purchases from Japan and Canada.

Chromium.—With an estimated output of 2.12 million tons, the U.S.S.R. was the world's second largest chrome ore producer and exporter in 1976. Almost 50% of production was exported, and 75% of this was destined to Western countries. Less than one-half was consumed in the U.S.S.R., as follows: Metal production 45%, refractories 32%, and chemical and other industries 23%. The price of Soviet metallurgical chromite ore was about $150 per ton f.o.b. Black Sea ports for 48% Cr_2O_3 ore with a 4:1 chromite to iron ratio. Ores with 54% to 55% Cr_2O_3 and a chromite to iron ratio of 4:1 represent the bulk of Soviet exports. The price of Soviet chrome ore sold abroad may be increased, depending on the embargo on Southern Rhodesian chrome ore.

According to a trade agreement, the Philippines will export chromite ores to the U.S.S.R. as payment for Soviet imports of platinum, palladium, and mining equipment.

Estimated data on production, exports, and consumption of chromite (Cr_2O_3) in selected years are as follows, in thousand tons:

	1970	1976	1980
Production (30% to 56%)	1,750	2,120	2,300
Exports (48% to 56%)	[1] 1,200	[1] 975	1,250
Consumption and stocks (30% to 56%)	550	1,145	1,050

[1] Reported in Soviet sources.

About 94% of total Soviet chromite reserves are situated in Kazakhstan, with the balance in the Ural Mountains. There are over 20 deposits in Aktyubinsk Oblast in western Kazakhstan; Molodëzhnoye, Millionnyy, and Almaz-Zhemchuzhina are the largest, with total gross reserves of some 60 million tons. Chromite ores in this region vary considerably with respect to composition; Cr_2O_3 content ranges from 5% to 63%. The Donskoy mining and concentration complex at Khromtau in Aktyubinsk Oblast of Kazakhstan, which produces over 90% of the Soviet output, is the only supplier of high-quality ore. Kazakhstan's chromite ore production is expanding each year.

There are many deposits of chromite ores in the Urals (Saranovskoye, Verblyuzhinskoye, Alapayevskoye, Monetnaya, Dacha, Khalilovskoye, etc.), the most important of which is the Saranovskoye deposit in Perm

Oblast. Deposits of chromium ores in the Urals, which have a low Cr_2O_3 content (20% to 40%) as well as a low chromite to iron ratio, are mostly used in the chemical and refractory industries.

The Donskoy deposits are presently mined selectively at five small open pits. The grade of most ores is adequate for direct shipping after hand picking. In 1976, 100-ton Unit Rig trucks and large Caterpillar bulldozers were used for the first time. There were two mills in operation at Khromtau in 1976, with a design capacity of 1.5 million tons per year of marketable ore (2.5 million tons of crude ore). The first Soviet chromite concentrator at Khromtau, with a capacity of 688,000 tons per year of marketable ore (950,000 tons of crude ore), has been under construction since 1965. The first section of this mill, with a capacity of 300,000 tons per year, was commissioned in 1974, and the second stage, which is under construction, is scheduled for operation in 1980.

The Cr_2O_3 content of the ores of the Donskoy complex was 45% for crude (to crushing mills) and 53.9% in marketable form. It is planned to increase production of marketable ore 10% in 1980 over that of 1975.[20]

Output of marketable chromite from the Saranovskoye underground operation is estimated at about 10% of total Soviet production, or about 200,000 tons. There was one crushing and grinding mill in operation at Saranovskoye in 1976, which classified ore into two sizes. After hand picking, the 10- to 100-millimeter-size ore was shipped to consumers. The recovery of ore in concentrate was about 70%, 16% was 0- to 10-millimeter-size and was dumped, and 14% was barren rock.

Cobalt.—Gross cobalt reserves are estimated at about 100,000 tons of contained metal, chiefly in nickel-cobalt ores and in cobalt ores of the Khovu-Aksy deposit in Tuva A.S.S.R. Production continued to be concentrated at Norilsk in western Siberia; at Monchegorsk and Pechenga on Kola Peninsula; in the Urals at the Yuzhuralnikel, Ufaley, and Rezhsk plants; and at some copper plants. Recovery of cobalt remained low, especially from the copper pyrite ore of Bashkiria. Only some 25% of the cobalt in slag was recovered. Average recovery was about 55%. The planned production cost of cobalt in concentrate at the Pechenganikel complex was 6,780 rubles per ton in 1975. It was reported that slow development and assay of ores at the Tuvacobalt complex resulted in low recovery in the beneficiation and metallurgical processes. Although cobalt production rose 16% between 1970 and 1975, it will probably remain constant during the 1976–80 period.

Copper.—Production of blister copper in 1976 was estimated at 965,000 tons, including 165,000 tons of secondary copper. The estimated 4% increase in output arose from new facilities commissioned in 1975. About 10% of primary copper output was recovered as a byproduct. Under the 1976–80 plan, output in 1980 is scheduled to be 20% to 30% over 1975 levels. The plan provides for 80% of the copper production to come from the Asian part of the U.S.S.R. and 20% from the European part by 1980. Output of blister copper may reach 1 million tons by 1977, rising to 1.15 million tons by 1980. Exports increased from 123,100 tons in 1970 to 205,600 tons in 1975. Estimated exports in 1976 were 250,000 tons, to rise to about 350,000 tons in 1980.

Reverberatory smelting continued to be the basic process for smelting of blister copper. According to Soviet sources, the changeover of most reverberatory furnaces to natural gas fueling has improved conditions for workers and made it possible to improve copper extraction; at the Almalyk complex in Uzbekistan and the Sredneural'sk plant in the Urals, the use of oxygen in the reverberatory furnaces made it possible to improve the melting of the charge 20% to 25%. In 1975, the Soviet copper industry used more materials and energy at a cost of 5.3 million rubles than was planned. Plans are to replace reverberatory smelting of blister with the oxygen-flash smelting process at the Krasnouralsk plant in the Urals.

Kazakhstan maintained its position as the main production center of the U.S.S.R., and the Balkhash complex was the largest copper producer in 1976. The 1976–80 plan calls for a 25% increase in refined copper production in Kazakhstan. Published plans called for an increase of 6% in 1976 over that of 1975. Open pit methods, which accounted for about 60% of total output in

[20] Izvestiya vysshikh uchebnykh zavedeniy, Seriya gornyy zhurnal (University Herald, Seria Mining Journal), Sverdlovsk. No. 2, February 1976, p. 21.

1976, employ both rail transportation and 40-ton off-highway trucks. The second stage of the No. 65 underground mine at Dzhezkazgan was put into operation in July 1976. Development of the third and final stage of this mine was not completed in 1976 and was rescheduled for 1977. Only 48% of the total value of metals in Dzhezkazgan ores was recovered in 1976, according to trade journal reports.

Expansion of the Kounrad open pit at the Balkhash complex continued in 1976 and was scheduled for completion in 1979. News accounts reported that a shortage of spare parts idled the shovels at this pit for a substantial time in 1976. Development of the Sayak open pit at Balkhash was completed in 1976. Recovery of copper in concentrate at the Balkhash beneficiation mill decreased from 89.44% to 85.92%, and the copper content of the concentrate decreased 1%, according to Soviet trade journals.

Development of the first stage of the Novoberëzovka underground mine at the Irtysh polymetallic complex in Kazakhstan was completed in April 1976. At the pilot plant of this complex, a Kivtset process (electrosmelting with oxygen blasting) for treating copper-zinc sulfide concentrates was tested. It is planned to complete the first stage of the Karaygalinsk, Orlovsk, and Nikolayevsk mills by 1980 and to construct an additional smelting unit at the Irtysh complex in Kazakhstan. Development of the 50-let Oktyabrya mine in Aktyubinsk Oblast, western Kazakhstan, continued in 1976. Exploration for new copper deposits in Kazakhstan continued, but news accounts reported that the shortage of drilling rigs and trucks limited operations.

The Urals is the second largest copper-producing region. Copper ore is surface-mined at Uchalinskiy, Mezhozerskiy, Sibayskiy, and Gayskiy, and deep-mined at Degtyarsk, Karabash, Gayskiy, Imeni III International, and Levikhinskiy. The share of surface mining increased from 39.3% in 1958 to over 70% in 1976. This was attributed to the development of the Gayskiy, Uchalinskiy, and Ob'edinennyy open pits of the Uchalinskiy complex and the decline of the Degtyarsk, Krasnouralsk, and Karabash underground mines. This trend is expected to continue, although the Krasnouralsk, Kirovograd, and Karabash copper smelters in the Northern Urals were experiencing a major shortage of concentrates. One-third of the total smelter consumption was transported from Soviet Central Asia, the Altay region, the Caucasus, and other regions.

The detailed exploration of the Kal'makyr deposit at the Almalyk complex in Uzbekistan which started in 1951 was completed in 1976. Ore reserves increased 50%. The Sarycheku copper deposit has also been delineated, and the development of an underground mine is to start there in 1977. It is planned to complete exploration of the Dal'neye and Balykty copper deposits in Uzbekistan by 1980.

The Kafan and Agarak copper-molybdenum complexes and the Alaverdy metallurgical plant showed poor performance in 1976. The planned production goals were not met. The recovery of copper in concentrate and in blister was far below design expectations. Much copper and molybdenum is lost during the concentration and metallurgical processes, according to local press accounts. During 1967–74, labor productivity at the open pit of the Kafan complex decreased 16.7%.

The percentage recovery of copper in concentrate at the principal Soviet copper ore-dressing plants in 1976 was as follows:

Plant	Copper content of ore		Copper content of concentrate		Recovery of copper in concentrate	
	Design	Actual	Design	Actual	Design	Actual
Kazakhstan:						
Balkhash	1.35	0.6	20.0	18.87	90.0	85.92
Dzhezkazgan No. 1	2.0	1.81	20.0	37.8	93.0	93.37
Dzhezkazgan No. 2	1.76	1.62	25.0	35.89	94.0	93.53
Uzbekistan: Almalyk	.80	.732	18.0	17.1	83.0	73.82
Armenia:						
Agarak	.64	.659	21.0	18.68	82.83	75.02
Kadzharan	.60	.342	22.0	12.21	78.0	70.88

The bulk of Soviet secondary copper is produced at the Kirovograd copper complex in the Urals. Productivity of blast furnaces at this plant is 80 to 85 tons. Only 16% of copper scrap is used for production of special alloys, 50% is used for production of

bronze and brass, and some 34% is remelted at blast furnaces and converters for blister. Trade journals report that the quality of copper scrap is declining each year.

According to Soviet sources, gross reserves of the Udokan deposit in eastern Siberia amount to about 1,200 million tons of ore with an average copper content of 1.5% (20% oxides, 80% sulfides). Plans are to develop this deposit in 1981–90 and to produce 35 million tons per year of ore yielding a refined copper output of 400,000 tons per year. The U.S.S.R. has been negotiating with British, French, and Japanese companies to develop the Udokan deposit "jointly." At the same time, the U.S.S.R. was assisting Mongolia in construction of the Erdenet copper-molybdenum complex and has offered assistance to India to consider the feasibility of establishing a copper operation there.

Gold.—In 1976, the U.S.S.R. produced an estimated 7.7 million troy ounces of gold and was the world's second largest producer. Over two-thirds came from the Soviet Far East and eastern Siberia (mainly from placers at Kolyma, Aldan, Dzhugdzhur, Indigirka, Yana, and Chukotka); most of the balance came from gold and polymetallic ores in the Urals, Kazakhstan, Armenia, Uzbekistan, and western Siberia. Substantial quantities are produced as byproduct at the nonferrous metals operations.

Soviet gold production has maintained a steady annual growth rate of 3% to 4% over the years. Prompted by higher international prices, the U.S.S.R. plans to increase production and has been importing large-scale equipment from Western Europe, the United States, the Republic of South Africa, and Japan. Based on ore reserves, geological and mining conditions in the country's largest gold-producing regions, and fragmentary, indirect reporting, production is estimated to be 248 tons in 1977 and 270 tons in 1980.

Because data on gold sales are classified as State secrets, there are no accurate figures, but according to some estimates, the U.S.S.R. sold more than 200 tons of gold in 1976, compared with some 140 tons in 1975. Reportedly, the Soviet Bank for Foreign Trade concluded an agreement with Continental Gold Corp. for direct sales to the United States.

Magadan Oblast is the main gold-producing center with 32 placer mines, 23 dredges, over 500 sandwashing rigs, and about 1,500 bulldozers. The Severovostokzoloto Association of Magadan Oblast fulfilled its 1976 gold production quota by November 5. Despite a considerable deterioration of geological and mining conditions in working placer deposits, the use of new foreign equipment made it possible to handle a considerably greater volume of stripping in 1976 than in 1975. The Polyarny, Bilibino, and Tenkin complexes fulfilled their annual gold extraction quotas by September, owing largely to dredges especially at the Frunze placer mine.

The Northeastern Territorial Geological Organization of Magadan Oblast did not fulfill the 5-year planned quota for discovery and exploration of additional placer gold reserves. There were shortcomings in the preparation of gold mining enterprises of the Severovostokzoloto Association for the 1977 season. Trade journals reported that a shortage of electrical power was causing difficulties in the operation of many enterprises in 1976. During 1965 to 1975, return on capital decreased 37.1%.

At Magadan placers, the thickness of overburden, which was up to 5 meters in the 1971–75 period, is expected to increase to 15 meters by 1980. The use of bulldozers for overburden removal will decrease from 86% in 1975 to 24% in 1980, when excavators and trucks will be employed. Mining journals report that during 1977–80, because of the deterioration of geological and mining conditions, the mining of placers by underground methods will become complex. Recently delivered foreign heavy bulldozers were assigned to the preparation of new mining sections. Construction of the Kramken mining and concentration complex in Khasinskiy Rayon and the Dukat ore mine in Magadan Oblast, both of which are classified as "most important enterprises," was behind schedule.

In Yakutia, the second largest gold-producing region, the mines of the Indigirzoloto and other complexes were supplied with new imported bulldozers, trucks, and large scrapers. Four enterprises of the Kazzoloto Association did not meet the annual planned quotas, according to news accounts, and the recovery of gold at some enterprises decreased 3% to 3.5% in 1976.

The first stage of the Zodskiy mining and concentration complex in Armenia, which

has been under construction since 1970, was put into operation in April 1976. The Zodskiy open pit, which is located in the mountains more than 2,000 meters above sea level, ships ore to the gold recovery plant in the Ararat Valley by the Sevan-Shora-Zod railroad. The Zodskiy ore is complex and difficult to concentrate. About 33% of design capacity at the Zodskiy open pit was attained in 1975 and about 50% in 1976; design capacity is expected to be reached by 1980. Plans are to put the second stage of the Zodskiy complex into operation and to develop the Shaumyan deposit by 1980. The Ararat gold-recovery plant is to process ores from the Zodskiy, Shaumyan, Megradzorsk, Lirkvazsk, and other deposits in Transcaucasia and the North Caucasus. Detailed exploration of the Shaumyan deposit continued in 1976.

Published accounts report dissatisfaction with the byproduct recovery of gold at all copper-molybdenum enterprises of Armenia.

Iron Ore.—The iron and steel industry of the U.S.S.R. operated 71 underground mines and 63 open pits with a total capacity at the beginning of 1977 of 274 million tons of usable ore (532 million tons of crude ore). Over 82% of ore production was from open pits; seven major pits, each producing over 10 million tons per year, contributed almost one-half of the total.

Reported production of usable ore was 238.4 million tons (455 million tons of crude ore), an increase of 6.45 million tons over that of 1975. Production of usable ore is scheduled to reach 243.3 million tons (477.5 million tons of crude ore) in 1977, and 277.6 million tons (560 million tons of crude ore) in 1980. The 1977 production plan set goals of 166.6 million tons of concentrate, 158 million tons of sinter agglomerate, and 36.4 million tons of pellets. Exports of iron ore increased from 38.4 million tons in 1972 to 43.1 million tons in 1976. The principal increase was in exports to CMEA countries, which account for 90% of total exports. In 1976, 45 million tons of new annual production capacity was added, compared with 27.3 million tons of new capacity in 1975.

There were 92 iron ore concentrators, of which 29 had sintering and 6 had pelletizing facilities in operation in 1976. Iron ore production in the U.S.S.R. is shown in the following tabulation:

	1975	1976
Output of usable ore million metric tons	r 231.95	238.40
Iron content of usable ore percent	59.30	59.32
Iron content of crude ore, concentrated do	32.60	32.59
Output of iron ore concentrate million metric tons	150.97	159.15
Iron content of concentrate percent	62.50	62.44
Share of concentrated ore do	82.10	82.50

r Revised.

Source: Gornyy zhurnal (Mining Journal), Moscow. No. 1, Jan. 1, 1977, p. 6.

The iron content of ores from open pits was 34% in 1975 (34.6% in 1971); that of ores from underground mines was 46.4% (47.3% in 1971). Soviet iron ore operations are not able to meet the demands of industry in all regions. The local raw material base for steel plants in the Southern Urals continued to be under stress. Many years of prospecting there have not led to the discovery of large iron ore deposits.

The new 5-year plan calls for the output of 122 million tons of pig iron and 154 million tons of crude steel in 1980. To meet this plan, it will be necessary to produce 277.6 million tons of usable ore (560 million tons of crude ore), including 203 million tons of concentrates (a 35.2% increase over that of 1975) and 60 million tons of pellets (a 91.1% increase). The increase is to come mainly from the opening of new open pits and the expansion of existing complexes: Lebedin, Mikhaylov, Kachkanar, Olenogorsk, Kovdar, Severnyy, Dneprovsk, and others. The share of open pit ore production is to increase from 82% in 1975 to 83% in 1980. The volume of underground ore production is to be increased 20% by 1980, and the average annual production capacity of the mining administrative unit should increase from 2 million tons of crude ore in 1975 to 2.9 million tons in 1980.

Soviet iron ore mining is generally less efficient than equivalent operations in the West, owing to a technical lag stemming from poor dissemination of technical knowledge and technically inferior equipment. Despite considerable mechanization, productivity of Soviet miners has been much below that of miners in the West. Ore beneficiation in the Soviet iron ore industry is less sophisticated. Agglomeration techniques are copies of old-fashioned

Western sintering; modern pelletization has been introduced with the assistance of Western firms but still has a very limited application.

The Ukraine accounted for over 52% of total Soviet iron ore output, and the Krivoy Rog Basin produced about 89% of the Ukraine's total in 1976. The Urals was the second largest producer, followed by Kazakhstan, Kursk Oblast, Siberia, and Kola Peninsula. There were 23 underground mines and 9 large and several small open pits in operation in Krivoy Rog in 1976. Lack of mechanization in the auxiliary operations of underground mining in this basin resulted in low labor productivity. Support of workings, installation of mining equipment, all forms of transportation and delivery of materials, and many other operations in most cases were not fully mechanized. Soviet documentation shows, for example, that more than 2,300 workers were engaged daily just in support of workings in Krivoy Rog in 1976.

Construction of the first stage of an iron ore pelletizing plant at the Dneprovsk complex in the Ukraine, with assistance and equipment supplied by Allis-Chalmers Corp., was completed in December. A West German group, Lurgi Chemie und Huettentechnik GmbH, will supply equipment for a pelletizing plant in Krivoy Rog. The design capacity of the plant will be 9 million tons per year of pellets.

Construction of the Lebedin iron ore mining and concentration complex in the Kursk Magnetic Anomaly (KMA) area (Belgorod and Kursk Oblasts), with an annual capacity of 13 million tons of concentrates (39 million tons of crude ore), was completed in November. The pellet plant at Lebedin achieved its design capacity of 4.3 million tons per year of pellets in July. This is to be supplied to the Oskol electrometallurgical complex (which is under construction) for production of steel by direct reduction. The first stage of the pellet plant at the Mikhaylov complex in the KMA area, with an annual capacity of 3.1 million tons of pellets, was commissioned in December. According to the tenth 5-year plan, production of crude iron ore in the KMA area is to reach 88 million tons per year by 1980.

The Urals metallurgical plants, which treat some 53 million tons per year of usable ore, are supplied by the Urals (some 26 million tons), Kazakhstan (some 18 million tons), and the KMA area and Kola Peninsula. Transportation of Kursk and Kola Peninsula ores raises the cost of metal substantially, according to documentation.

The iron ore for the Kuznetsk complex in Siberia is shipped from six mines. The first stage of the seventh mine, the Krasnokamenskaya mine, with an annual capacity of 1 million tons of concentrates (1.8 million tons of crude ore), was completed in April. Construction of the Kachar mining and concentration complex in Kustanay Oblast, Kazakhstan, started in June. There were 800 workers in the development of an open pit at this complex in 1976.

Iron and Steel.—The Soviet iron and steel industry leads the world in total quantity of iron ore mined and in production of coke, refractories, crude steel, and steel pipe. Each year, the plan for rolled steel output is overfulfilled, while at the same time there is a shortfall in deliveries of millions of tons of rolled products. A great proportion of the supply of rolled products and distribution of the output by specific products does not match the products in demand. In spite of large imports of rolled products, shortages of many steel products in the U.S.S.R. raise problems in the Soviet economy.

According to the chief specialist of the U.S.S.R. Planning Committee, "The U.S.S.R. expends 1.5 times more ferrous metals per unit of output than the United States. This is explained by the inadequate level of their quality, the narrower assortment, the insufficiently progressive production structure and the backwardness of the technology for processing metals.

"... There are 2 to 3 times more steel and iron chips formed in the U.S.S.R. than would be necessary with modern technology. This resulted in loss of 3 to 4 million tons of metal worth about 2,000 million rubles a year, not counting the 5,000 million rubles worth of capital investments in plants where the metal is processed. For excess chips it is necessary to increase production of approximately 20 million tons of metallurgical raw materials (ore, coke, refractory and other materials) annually and to create capacity for production of raw materials. . ." [21]

[21] Ekonomika i organizatsiya promyshlennogo proizvodstva (Economics and Organization of Industrial Production), Novosibirsk. No. 3, May-June 1976, pp. 29-40.

In 1976, 36 enterprises, operating 137 blast furnaces, produced 104.4 million tons of pig iron, a 2% increase over the 1975 output. Estimated figures for 1977 and 1980 are 110.2 million tons and 120 million tons, respectively. The average blast furnace capacity increased from 1,135 cubic meters in 1971 to 1,258 cubic meters in 1976. About one-half of all blast furnaces use oxygen for enrichment; over 83% of the pig iron was being produced by the use of natural gas injection and 75% by use of oxygen enrichment. More than 184 million tons of iron ore, 20.5 million tons of flux, 61.2 million tons of coke, 8,200 million cubic meters of natural gas, and 10,200 million kilowatt-hours of electricity were used in the production of pig iron in 1976.

The capacity (useful volume) of the 137 Soviet blast furnaces in 1976 averaged 1,258 cubic meters and was distributed as follows:

Capacity (cubic meters)	Number of furnaces
123 to 600	42
600 to 725	10
930 to 1,060	23
1,140 to 1,242	10
1,300 to 1,410	24
1,500 to 5,000	28

Production of the different types of pig iron in 1976, in percent, was as follows:

Steelmaking	91.0
Foundry	8.0
Ferromanganese	.9
Other	.1

Construction of the No. 6 blast furnace (3,200 cubic meters; 2.9 million tons per year of pig iron) began at the Novo-Lipetsk plant in 1976. Completion was scheduled for 1978. The blast furnace that was being built at the Kommunarsk works in the Donets Basin was to be put into operation by 1977. Reportedly, a blast furnace with a capacity of 5,500 cubic meters was being designed in Leningrad. The new furnace is to be built at the Cherepovets plant. It is to be 110 meters high and 15.1 meters in diameter and is to produce 4.5 million tons per year of pig iron.

Crude steel production from 76 metallurgical works increased 2% to reach 145 million tons in 1976 (planned goal, 147 million tons). It is planned to produce 151.1 million tons of crude steel in 1977 and 168.5 million tons in 1980.

Distribution of steel production by process was as follows, in percent:

Process	1960	1970	1976
Open hearth	84.4	72.6	64.0
Oxygen converter	3.8	15.3	28.0
Electric furnace	8.9	10.7	7.4
Bessemer	2.9	1.4	.6

There were 41 continuous-casting machines, with a total annual capacity of 10 million tons, in operation in 1976. At year-end 1975, there were 37 operating oxygen converters, of which 30 had capacities of 100 tons or more. Renovation of the No. 1 converter shop at the western Siberian plant began in 1976. The average annual capacity of newly constructed oxygen converters increased from 855,000 tons in 1960–70 to 1.72 million tons in 1971–75. The Soviets have been proceeding slowly in the installation of Linz-Donawitz oxygen converters, although several 300-ton units are in operation.

Electric steel production was characterized by lower capacity furnaces and power transformers. The largest size of electric furnace was 100 tons and of transformer, 25,000 kilovolt-amperes. At the Azovstal' plant in Zhdanov and the Lenin works in Bekabad, Georgia, electric furnace shops (one at each location) were under construction in 1976.

Soviet ferrous rolled metals output in 1976 totaled 118 million tons (of which 101 million tons was finished products), a 2.3% increase over that of 1975. Despite increases in total output, production of many structural shapes remained inadequate. Output of rolled products is measured in tons, and since quotas, premiums, and incentives emphasize quantity, metallurgical plants tend to favor heavy products at the expense of thin sheet and light sections. It was planned to produce 105.4 million tons of finished ferrous rolled metals in 1977 and 117.5 million tons in 1980.

In terms of tonnage, the U.S.S.R. was the largest world producer of steel pipe, with a total of 16.8 million tons in 1976, a 5% increase over the 1975 production. The quality of the pipe produced in the U.S.S.R. does not always correspond even to the prescribed State standards. Fabrication was, however, inadequate for internal demand, and some 25% of requirements had to be imported from Western Europe and Japan.

About 60% of total Czechoslovak pipe production goes to the U.S.S.R. It was estimated that production of steel pipe may reach 17.6 million tons in 1977 and 20 million tons in 1980. Renovating existing pipe plants, eliminating obsolete equipment, and improving the quality of pipe are to continue during 1977–80. One of the main tasks facing Soviet pipe production is to increase the quantity and quality of pipe for the petroleum and natural gas industries.

New, expanded, or renovated production facilities commissioned during the year follow, in million tons: Pig iron, 2.25; crude steel, 1.2; and finished ferrous rolled metals, 4.0. The following main facilities were put into operation: The renovated blast furnace No. 1 at the western Siberian plant, new facilities of the No. 2 oxygen converter plant at the Il'ich plant in Zhdanov, a 70-ton electric furnace at the Novo-Lipetsk plant, a new medium-size section mill with an annual capacity of 1.5 million tons at the western Siberian works, and a light section mill at the Nizhneserginskiy plant. The first stage of the pipe-rolling mill, with an annual capacity of 320,000 tons of casings for the petroleum and gas industries, was put into operation at the Severskiy pipe plant in 1976, as were a new section (with a capacity of 15,700 tons per year) at the Azerbaydzhan pipe plant and a renovated pipe-rolling mill at the Pervouralsk pipe plant in Sverdlovsk Oblast.

Reportedly, the steel strip-coating plant supplied by four British companies was put into operation at the Chelyabinsk plant in September. The plant has an annual capacity to coat 90,000 tons of steel strip and to roll 100,000 tons of galvanized strip up to 1,500 millimeters wide.

Expansion and renovation of the western Siberian works and the Rustavi plant in Georgia were underway in 1976. Technical plans for renovation of the first stage of the Magnitogorsk complex were approved in December. During 1977–80, it is planned to expand the first stages of the Magnitogorsk, Novo-Lipetsk, and Karaganda complexes, the Serp i Molot plant in Moscow, the Krasnyy Oktyabr plant in Volgograd, and the Il'ich plant in Zhdanov. The plan for renovation of ferrous metallurgical plants includes 3 blast furnaces, 6 steel-smelting units, 26 rolling units, and 23 pipe mills. During the 1976–80 period, it is planned to invest 20,900 million rubles in the ferrous metals industry and to construct new production facilities, including blast furnaces at the Cherepovets and Novo-Lipetsk plants with capacities (useful volumes) of 5,000 to 5,500 cubic meters and 3,200 cubic meters, respectively.

A preliminary technical plan for the first stage of the Oskol electrometallurgical complex was submitted by West German experts to the U.S.S.R. Ministry of Foreign Trade in July 1976. More than 3,000 West Germans are expected to be working on the project in the Saryy Oskol-Kursk region. More than 6,400 Soviet workers were employed on the construction of this complex in 1976. The Oskol complex will be the first direct-reduction steel plant in the Soviet ferrous metals industry.

According to the West German project, iron ore concentrate containing more than 70% iron will come to the Oskol works from the Lebedin mining and concentration complex. The concentrate is to be reduced by natural gas to make 90% to 92% iron content sponge iron, which will be charged continuously into electric steel-smelting furnaces. The project provides for an ore-pelletizing plant with an annual capacity of 7.3 million tons, a direct-reduction plant with an annual capacity of 5 million tons of sponge iron, an electric steelworks and continuous-casting plant with an annual capacity of 3.75 million tons, a profile steel-rolling mill with an annual capacity of 1.5 million tons, a sheet mill with an annual capacity of 1.2 million tons, and ancillary facilities. The total land dimensions of the complex are to be 3.7 kilometers by 2.1 kilometers, and the population of the new town to be established is expected to be more than 300,000 in the early 1980's.

The first stage of the Oskol electrometallurgical complex, with an annual capacity of 4 million tons of iron pellets (two lines), 2.5 million tons of sponge iron, 1.8 million tons of crude steel (four electric furnaces with a capacity of 200 tons each), and 1.5 million tons of rolled products, is to be completed by 1980. More than 1,500 million rubles is to be invested in the project during the 1976–80 period.

The U.S.S.R. was signing contracts for new Western technology and machinery to increase its steel output and upgrade steel products, especially tinplate, steel sheet, and electric steel. About one-half of these pur-

chases involved rolling mills. In addition to imports from Hungary, East Germany, Poland, and Czechoslovakia, rolling equipment was imported from the United Kingdom, West Germany, and France. At the same time, the U.S.S.R. was assisting in the renovation of the Isfahan steelworks in Iran. The design institute in Leningrad has begun preparing technical plans for an iron and steel plant in Yugoslavia, with an annual capacity of 1.5 million tons of crude steel. The U.S.S.R. will also be one of the suppliers of equipment for the project. The U.S.S.R. was also involved in construction of a 1.1-million-ton crude steel plant in Karachi, Pakistan.

Lead and Zinc.—The Soviet lead and zinc industry was probably the second largest in the world. Estimated output of primary metal in 1976 was 500,000 tons of lead and 720,000 tons of zinc. Production in 1980 is estimated to be 530,000 tons of lead and 760,000 tons of zinc. Lead exports increased from 92,400 tons in 1970 to 98,900 tons in 1975, and zinc exports rose from 95,100 tons to 100,600 tons in the same period. In 1976, the U.S.S.R. imported a substantial quantity of zinc from Japan. According to Soviet documentation, many of the Soviet lead and zinc production complexes did not attain their production capacities and recovery of metals. Nor were output quotas achieved in 1976 owing to ore shortages, slow construction of new facilities, and low metal recoveries. About 10% of total lead and zinc production was recovered as byproduct in 1976.

Kazakhstan continued to be the leading lead and zinc producer, followed by the Urals, Siberia, Uzbekistan, the North Caucasus, and the Ukraine. Production of lead-zinc ores in Kazakhstan increased 13.6% and that of lead metal rose 14% during the 1971–75 period.

New lead and zinc production facilities commissioned in 1976 include the Achisay, Zhayremsk, and Leninogorsk complexes in Kazakhstan, the second stage of the Sadovyy mine, and the first stage of a new mine of the Dalpolimetal (Far East Polymetallic) Association. This Association was established on the basis of the Dal'nevostochnyy Lenin mining and metallurgical complex (at Tetyukhe) and the Dal'nevostochnyy mining and concentration complex in September 1976. A new smelting furnace at the Chimkent lead plant in Kazakhstan was put into operation in November.

Reportedly, the first automatic control system in the U.S.S.R. was installed at the concentrator of the Zyryanovsk lead complex in Kazakhstan in November. At the concentrator of the Leninogorsk complex, a new dense-media beneficiation section was commissioned in 1976. This is the fourth heavy-media section to be installed in the Soviet nonferrous metals industry. According to news accounts, the Leninogorsk mining and metallurgical complex in Kazakhstan did not use 3.8 million rubles of funded programmed capital investments in 1976.

The 1976–80 plan calls for an increase in lead and zinc ores and concentrates production by completion of the Zhayremsk and Karayglinskiy complexes in Kazakhstan, increasing capacities at the Achisay and Ust-Kamenogorsk metallurgical complexes in Kazakhstan, and renovation of the Belovskiy (Siberia) and Elektrotsink (Ukraine) zinc plants and the Dalpolimetal Association's lead plant in Maritime Territory.

Priority is to be given to discovery and exploration of new and existing lead and zinc ore deposits.

Magnesium.—Five magnesium plants with an estimated combined annual capacity of 70,000 tons produced about 63,000 tons in 1976, 5% more than in 1975. Exports of metal decreased from 27,900 tons in 1974 to 11,400 tons in 1975. The U.S.S.R. is still one of the largest producers and exporters of magnesium. A renovation program employing a new electrolysis system has been partially completed, yielding an increase in capacity of about 20%.

Reportedly, during the ninth 5-year plan, output of magnesium and its alloys increased 20.2%. In 1976, magnesium produced by the Berezniki titanium and magnesium complex was the cheapest in the country. According to the 1976–80 plan, output of magnesium and its alloys is to increase 23.3% to 74,000 tons by 1980 from an estimated 60,000 tons in 1975.

Manganese.—The Soviet manganese industry remains the largest in the world, with an output of 8.2 million tons of marketable ores. Gross output in 1976 was about 20 million tons, of which over 70% came from the Nikopol basin in the Ukraine; the second largest producing area was the Chiatura basin in Georgia. Small

amounts of manganese were produced at the Dzhezdinsk and Atasuysk mines in Kazakhstan. Exports of manganese ore increased from 1.2 million tons in 1970 to 1.34 million tons in 1976. Estimated production of marketable ore in 1977 and 1980 is placed at 8.3 million tons and 10 million tons, respectively.

Two concerns, Ordzhonikidze and Marganets, operate in the Nikopol manganese basin. There were 18 underground mines, 10 open pits, and 8 concentrators in operation in 1976. More than 75% of the ore mined in the Nikopol basin came from open pit operations. Nikopol basin ore averages 26.4% manganese. Of the concentrated ore, 45% to 48% had a manganese content of over 45%; the balance contained 34%. The second stage of one of the concentrators at the Marganets complex (with a capacity of 1 million tons per year of crude ore) was under development.

The Chiatura basin in Georgia produced about 2.5 million tons of concentrates from 23 underground mines and open pits and 8 concentrators in 1976. Of the total beneficiated ore, two-thirds contained 48.7% manganese and the balance contained 25.6% manganese. Development of four small mines began in 1975. They are to be commissioned during 1977–80.

Mercury.—Output of mercury was estimated at 56,000 76-pound flasks, an amount sufficient to meet national requirements in 1976. The Khadarkan complex in southern Kirgiz S.S.R., the largest Soviet mercury operation, had four mines and a recovery plant in operation. At this complex, mercury is mined by both underground and open pit methods. Sinking of the Ulug-Too shaft at the complex began in 1976. It is to be 850 meters deep, the deepest shaft in Soviet Central Asia. After full capacity is attained at the Ulug-Too mine by 1980, output of mercury will be increased 10%. Renovation of metallurgical facilities at the Khadarkan complex began in 1976 and is scheduled for completion in 1980.

The Nikitovskiy complex in the Ukraine, where 80% of ore is mined by underground and 20% by open pit methods, is the second major producer of mercury. Two underground mines (2-bis Novaya and Novo-Zavodskaya) and the Polukupol Novyy open pit were in operation at this complex in 1976.

Mercury output in Magadan Oblast was higher in 1976 than in 1975. Construction of the new Dzidzikrutskiy (Aznob) mercury-antimony complex in Takzhikistan continued during the year. Completion of the first stage of this complex has been rescheduled from 1976 to 1980. Development of small deposits is planned in the North Caucasus, at Chukotka in Magadan Oblast, and in other regions of the U.S.S.R.

Molybdenum.—Output of molybdenum concentrates was estimated at 9,350 tons of contained metal, 3% above that of 1975. About 50% came from copper-molybdenum ores in Armenia, Kazakhstan, Sorskoye, and other areas in Siberia; over 30% came from molybdenite ores in Uzbekistan and Siberia; and the remainder came from tungsten-molybdenum ores of Tyrny-Auz (Kabardia in the North Caucasus) and Dzhida (Buryat A.S.S.R.). Production of molybdenum in the U.S.S.R. has quadrupled during the last 20 years and is expected to reach 10,700 tons by 1980. Soviet reserves of molybdenum in ore may approach 200,000 tons.

Armenia was the largest producer of molybdenum concentrates from copper-molybdenum ores, but the concentrate was shipped out of the Republic for further treatment. The Kadzharan copper-molybdenum complex in this Republic supplied over 20% of Soviet molybdenum in 1976. Output of molybdenum concentrates at this complex is to be increased by 1980.

Construction of the Zhireken molybdenum complex in Chita Oblast, completion of which was originally planned for 1975, lagged behind schedule in 1976. The Eastern Kounrad No. 6 underground mine for producing molybdenum, tungsten, and bismuth was completed at the Balkhash complex in Kazakhstan. The Kounrad open pit at this complex was being enlarged, and small open pits were being developed at the Sayak copper deposit. Development of the Mikulanskiy open pit at the Tyrny-Auz tungsten and molybdenum complex continued in 1976. Plans have been prepared for renovation of the Tyrny-Auz concentrator. When the open pit and new concentrator are commissioned, the complex will be able to increase production 70%.

Preliminary exploration of a small molybdenum deposit at Upchul'skoy in Krasnoyarsk Kray was completed in 1976. It is planned to complete detailed exploration

of the Dal'neye copper-molybdenum deposit at the Almalyk complex in Uzbekistan by 1980. It is also planned to increase the processing of tungsten-molybdenum ores at the Akzhalsk concentrator of the Akchatausk complex in Kazakhstan 80% during 1977–80.

Nickel.—The U.S.S.R. retained its position as the world's second largest producer of nickel, with an estimated 160,000 tons of smelter products, 5.3% more than in 1975. It is planned to increase metal production 20% to 30% in 1980 over the 1975 output. Production is estimated at a probable 168,000 tons in 1977 and 190,000 tons in 1980. Sulfide ores are mined at Norilsk in western Siberia and in the Pechenga-Monchegorsk area of Kola Peninsula. Oxide ores are produced in Aktyubinsk Oblast in the Southern Urals, the Ufaley area of the Middle Urals, and the Ukraine. The centers of production, in order of importance, continued to be Norilsk, the Urals, and Kola Peninsula. Of the seven smelters in operation, Norilsk is the most important; the Ufaley, Rezh, and Khalilovo smelters in the Urals are close seconds. The Monchegorsk and Pechenga smelters are third, and the Pobuzhsk ferronickel plant in the Ukraine is fourth. In the future, the U.S.S.R. will be an important nickel exporter, based on both Soviet and Cuban concentrates.

The Norilsk complex in western Siberia produces copper, nickel, cobalt, platinum-group metals, selenium, and other rare metals, and recent expansion there has been rapid. In 1980, production of nickel at Norilsk is to be increased almost 80% over that of 1975; a substantial part of the increase is to come from the Nadezhda complex, which is under construction. About 50% of the ore production will come from the Oktyabr'skiy mine. Prospecting is being carried out north of Norilsk. With a total population of 210,000 in the city in January 1977, the Norilsk complex employed about 100,000.

One open pit (Medvezhiy Ruchey) and one underground mine (Zapolyarnyy) operate at the Norilsk sulfide deposit, where the ore averages 0.5% nickel, 0.75% copper, and up to 0.35 troy ounce per ton platinum-group metals (mainly palladium and platinum). Two underground mines (Mayak and Komsomol'skiy) operate at the Talnakh deposit, where ores average about 1.5% nickel, 3% copper, and up to 0.35 troy ounce per ton platinum-group metals. Three stages of the Oktyabr'skiy underground mine were in operation at the Oktyabr'sk deposit, where ores average 3.65% nickel, 4.7% copper, and 0.13% cobalt and are associated with platinum-group metals. The fourth stage of this mine is under development. Full planned capacity is to be reached in four stages by 1980. The Oktyabr'skiy mine is the largest underground mine in the Soviet nonferrous metals industry and is to produce 50% of the total ores at Norilsk in 1980. The Kola Peninsula copper and nickel enterprises are supplied partially with ore from Norilsk. In the future, these deliveries are to be increased.

There was one concentrator in operation at the Norilsk complex, and a second was under construction in 1976. Sinking of the 1,500-meter-deep Taymyr shaft started in April, and construction of the third Messoyakha-Norilsk gas pipeline began in November 1976.

Construction of the 1-billion-ruble Nadezhda metallurgical complex at Norilsk, a major project of the tenth 5-year plan, continued with the technical assistance of Finnish companies. Over 5,000 workers were employed in construction of this project in May, and the number was to be doubled by yearend. The complex is to consist of 15 plants and is to produce copper, nickel, cobalt, and platinum-group and rare metals; the first stage, originally scheduled for completion in 1974, has been rescheduled for 1977. The autoclaves to be used here are the first in Soviet nonferrous metallurgy.

Because of the complex ores and the need for time to develop improved concentration technology, the first stage of the Nadezhda complex is expected to operate at less than desired productivity. Consumption of reagents is expected to be high, nickel in concentrates is expected to be low (10% to 12%), and large losses of cobalt (up to 40%) and platinum-group metals are expected.

Construction of the Norilsk-Nadezhda railroad complex (around 30 kilometers) was completed in November. Laying of the 35-kilometer pipeline for concentrate shipment from the mill to this complex began in 1976 and is scheduled for completion in 1980.

Monchegorsk ore averages about 0.7% nickel and 0.4% copper and contains some cobalt and precious metals. At the Lovnozersk deposit, ore values average 0.9% nickel, 6.5% copper, and 0.04% cobalt, in association with some precious metals. The ores at the Severonikel complex at Monchegorsk are mined by both open pit and underground methods. The Zhdanov complex is the largest operation in this area. Four small underground mines (Kaula, Kotselvaara, Kammikivi, and Northern) and two small open pits (Kaula and Kammikivi) were in operation at the Pechenganikel complex. Three mills of the second stage of the No. 1 ore-dressing plant at the Pechenganikel complex were put into operation at the end of 1976. Enlargement and renovation of concentrators and smelters continued. A No. 2 smelter with the same capacity as the existing unit is planned.

The port of Murmansk continued to carry Norilsk ore for the Severonikel complex in 1976. During the 7 to 8 months of the navigation season, some 200,000 tons of ore was shipped. In the future, shipments are to be increased. The metal content of the Norilsk ore shipped to the Kola Peninsula enterprises was 3.1% to 3.5% nickel, 2.8% to 3.2% copper, 0.11% to 0.14% cobalt, and some precious metals.

During 1971–76, the Yuzhuralnikel complex was renovated and its output was increased about 16%. A total of over 112 million rubles was invested. The 20-ton converters (2.3 meters in diameter and 5.54 meters long) were replaced by 30-ton units (2.8 meters in diameter and 6.1 meters long). Development of the first stage of the Shcherbakovskiy open pit, the largest in the Kimpersay nickel ore administration of the Yuzhuralnikel complex, was completed in December. In 1977, this stage is to produce 0.5 million tons of ore, and the pit, which will supply the Yuzhuralnikel plant, is to be fully operational by the end of 1980. A small open pit was put into production at the Buruktal nickel deposit in May. The ore, with an average of 0.88% nickel and 0.08% cobalt, is smelted in an electric furnace.

The U.S.S.R. was financing a $600 million expansion of Cuban nickel production, with output of 90,000 tons per year scheduled for 1985. Two existing plants (Nikaro and Moa) are to be renovated, and a new plant (Punta Gorda), with an annual capacity of 30,000 tons of nickel plus cobalt, was under construction in 1976.

It was reported that the U.S.S.R. will import nickel from the Philippines in repayment for Philippine purchases of Soviet goods.

Platinum-Group Metals.—The U.S.S.R. remains the world's largest producer and exporter of platinum-group metals, supplying 20% to 25% of international exports of platinum and more than 50% of world consumption of palladium and rhodium. The U.S.S.R. is steadily expanding its output of platinum-group metals; the estimated output was 2.8 million troy ounces in 1976, about 6% over that of 1975. Reserves are adequate to maintain production and increased exports for many years. In 1975, it was planned to increase production of platinum-group metals at Norilsk 60% over 1970 levels. The 1976–80 plan calls for platinum-group metals output at Norilsk to rise about 80% over that of 1975. Soviet primary production is forecast to increase at an annual rate of 4% to 5%. Production of platinum-group metals may reach 2.95 million troy ounces in 1977.

Production of platinum-group metals comes principally from the Norilsk copper and nickel complex in western Siberia, the Severonikel and Pechenganikel complexes on Kola Peninsula, and several small placer deposits in the Urals. Virtually all platinum-group metals were produced as byproducts, with about 75% coming from Norilsk. The high priority given to the Norilsk development suggests that the Soviets are determined to proceed with increased production of platinum-group metals despite high costs imposed by the harsh northern climate. Expansion is expected to accelerate in a few years, with the completion of the Oktyabr'skiy underground mine and No. 2 concentrator. The mine has been under development since 1969 and is scheduled for completion in four stages by 1980.

Silver.—Output of silver was estimated at 44 million troy ounces, 2.3% above that of 1975. Almost all silver is produced as a byproduct of nonferrous metals operations, with production centered mainly in the Soviet Far East, eastern Siberia, the Urals, Kazakhstan, and Armenia. During the year, 14 gold treatment plants also extracted silver. The Norilsk complex in western Siberia and some of the Kola Peninsula copper-nickel

enterprises also produced silver. In 1976, production of silver increased at the Gaysk complex in the Urals.

Recovery of silver at beneficiation plants in the Urals ranged from 15% to 20% from complex ores containing 0.2 to 0.5 troy ounce per ton silver. It is planned to organize production of silver in Armenia, using the Zod, Gey-Lirkvaz, Megradzor, and Shaumyan deposits. All nonferrous metals enterprises in Armenia recover very small amounts of silver from copper-molybdenum ores.

Tin.—Although Soviet policy has emphasized self-sufficiency, tin output continued to be inadequate, and about one-fourth of requirements had to be imported in 1976. Primary tin production in 1976 was estimated at 31,000 tons, 3.3% over that of 1975. The Soviet Far East, Yakutia, and Transbaykal were the main tin producing areas. In 1976, over 25% of total output was from placers, and the Soviet northeast placers accounted for 75% of this. Maritime Territory is the largest producer, and the Khrustal'nyy complex, which operates both lode and placer deposits, is the largest enterprise there.

The Khrustal'nyy complex operated the Khrustal'nyy, Ege-Khaya, Imeni Lazo, Kholodnyy, and Alyaskitovyy mines in 1976. The Ternistyy and Arsen'evskaya mines of this complex, which were scheduled for completion in 1975, were under development in 1976 and were rescheduled for completion by 1980. A major overhaul of the concentrator at the Iul'tin complex in Magadan Oblast was not completed on time, causing tin production at this complex to fall short of goals in 1976. Construction of small tin and copper smelters at Solnechnyy in this region began in 1976, with completion scheduled for 1980. When the smelters go into service, tin and copper concentrates will no longer be shipped for further treatment.

The first Soviet unit to extract tin from cassiterite ore tailings was put into operation at the Khinganolovo (Khingan tin) complex at Birobidzhan (Jewish Autonomous Oblast), Khabarovsk Kray, in June 1976. Mining of a small tin deposit at this complex began in April.

Three known tin refineries were operating in the U.S.S.R. in 1976: Novosibirsk, Ryazan, and Podolsk (near Moscow). At the Novosibirsk plant, which is the largest in the U.S.S.R., the No. 3 furnace was put into operation in May. The Ryazan refinery began treating all types of concentrates and secondary sources of tin in 1976. Output of secondary tin in 1976 was estimated at 11,000 tons, 10% above that of 1975. Construction of a tin-processing unit began at the Rustavi secondary nonferrous metals plant in Georgia in 1976.

Reportedly, the U.S.S.R. is to provide technical plans for the second low-grade tin volatilization plant to be built in the area of Machaçamarca, Bolivia.

Titanium.—Titanium production in 1976 was estimated at 32,000 tons, 6.7% over that of 1975. Development of the titanium industry continues to be based mainly on Ukrainian and Siberian ilmenite and rutile. Reports indicated that a titaniferous slag containing 83% titanium dioxide was being produced at the Zaporozhye plant in the Ukraine. During the 1971–75 period, a 40% planned expansion was almost met. The tenth 5-year plan for development of the titanium-magnesium industry will be devoted to renovation of equipment at the existing plants. Production of titanium is programmed to be raised 40% in the 1976–80 period. Estimated output for 1977 and 1980 is 35,000 tons and 42,000 tons, respectively.

During the ninth 5-year plan, output of titanium sponge at the Berezniki complex increased 43.5%; the planned increase for 1976–80 is 34.4%. It is planned to increase production of titanium at the Ust-Kamenogorsk complex in Kazakhstan 8.6% in 1977 over the 1976 output.

With the forthcoming expansion of Soviet titanium production, exports of titanium sponge are to be increased significantly. Reportedly, West Germany's Fried. Krupp GmbH will import Soviet titanium. The price of Soviet titanium sponge for the first half of 1976 was around $2.45 per pound, approximately 11% below the price charged for deliveries in the second half of 1975.

Tungsten.—The estimated production of 8,000 tons of tungsten in concentrate was insufficient for growing domestic needs, and about one-third of requirements had to be imported. The industry continued to be centered mainly in the North Caucasus, Transbaykal, the Soviet Far East, Soviet Central Asia, and Kazakhstan. Production is estimated at 8,200 tons in 1977 and 8,700 tons in 1980. Consumption of tungsten by

the Soviet steel industry is much higher than that by the ceramic hard alloys industry. The 1976–80 5-year plan calls for special attention to be given to exploration for tungsten deposits.

The main producer of tungsten concentrates is the Tyrny-Auz tungsten and molybdenum complex in the North Caucasus, where both underground and surface methods are used.

The capacity of the Ingichinsk tungsten concentrator in Uzbekistan, which was put into operation in 1973, is some 25% greater than the capacity of mines supplying the plant. As a result, the concentrator reportedly was idle for considerable periods, and the recovery of tungsten in concentrate was much below the planned level of 87.5%. At the Vostok-2 tungsten mine in Maritime Territory, a concentration mill was under construction in 1976. Exploration of the Lermontovskoye deposit in this region continued in 1976.

Vanadium.—The U.S.S.R., with large vanadium resources, is becoming an important producer and exporter. The principal sources of vanadium continued to be slag from smelting titaniferous magnetite from Kachkanar open pits in the Urals and iron ore from Lisakovsk (0.06% vanadium) in Kazakhstan. The Nizhniy Tagil metallurgical complex and the Chusovskoy metallurgical plant in the Urals are the enterprises in the U.S.S.R. that produce raw material for the production of vanadium and its alloys. Nizhniy Tagil, where the vanadium slag is produced from 130-ton oxygen converters, is the only modern enterprise. The vanadium content of the pig iron at the Chusovskoy plant is 0.54%, and that at the Nizhniy Tagil complex is 0.44%. After devanadization of the pig iron, the average V_2O_5 content of the slag at the Chusovskoy plant is 17.2% and that at the Nizhniy Tagil complex is 21.2%.

The growth of vanadium output depends on developing the titanomagnetites, located chiefly in the Urals. The feasibility of processing these ores is determined by the integrated utilization of iron and vanadium. The construction of the Kachkanar iron ore mining and concentration complex and the processing of vanadium at the Nizhniy Tagil metallurgical complex has made it possible to increase output of vanadium products considerably.

It is planned to develop the Kachkanar No. 2 unit and to increase production of vanadium in the future. It is also planned to construct special units at some alumina plants to recover V_2O_5 as a byproduct of bauxite and other raw materials.

Minor Metals.—The U.S.S.R. possesses commercial deposits of all the rare metals that have assumed importance in modern rocketry, aircraft, and nuclear energy. The main deposits are in Kazakhstan, Kola Peninsula, Uzbekistan, Armenia, the Urals, the Ukraine, Norilsk, Transbaykal, and the Soviet Far East.

Byproduct rhenium is recovered at the Balkhash and Dzhezkazgan complexes in Kazakhstan, the Kadzharan copper-molybdenum complex in Armenia, the hard-alloy plant in Uzbekistan, and some other plants.

Selenium and tellurium are extracted at electrolytic copper plants at the Balkhash complex in Kazakhstan, the Norilsk complex in eastern Siberia, and some other plants. In 1976, the Novosibirsk tin refinery started to recover indium from tin concentrates, and the Almalyk complex in Uzbekistan is recovering indium from zinc wastes. It is planned to begin recovery of gallium from bauxite and nepheline used to produce alumina by 1980.

NONMETALS

The U.S.S.R. produces a wide variety of nonmetallic minerals. However, the resource position varies from adequacy of many nonmetals to apparent shortages of others, such as barite, fluorspar, mica, and talc.

Asbestos.—The Soviet asbestos industry remains the largest in the world, with an estimated output of the seven grades at 2.29 million tons in 1976 (390,000 tons over that of 1975). Over 67% of total production came from the Uralasbest complex, about 28% from Dzhetygara in Kazakhstan, and 4% from the Tuvaasbest complex in Tuva A.S.S.R. Exports rose from 385,300 tons in 1970 to 613,300 tons in 1975, with about 60% going to Western markets. Despite the asbestos export expansion in recent years, the reported domestic deficit was expected to be 100,000 tons in 1976. Estimated output for 1977 and 1980 is 2.37 million tons and 2.52 million tons, respectively.

Development in the asbestos industry has been concentrated in the Urals, Kazakhstan, and Tuva A.S.S.R. Total output of the

seven grades of asbestos at the Uralasbest complex was estimated at 1.54 million tons. Three open pits at this complex produced 35 million tons of crude ore and moved and dumped over 91 million tons of overburden in 1976. It is estimated that mining of crude ore and overburden will be increased from 126 million tons in 1976 to about 150 million tons in 1980, but production of marketable asbestos is expected to remain unchanged at about 1.54 million tons because of the decreasing asbestos content of the ore. The old No. 3 concentrator, with an annual capacity of 120,000 tons of marketable ore, is now obsolete and is to be replaced by a new No. 7 plant.

In Kazakhstan, a large complex has been organized for developing the Dzhetygara deposit in Kustanay Oblast, which is the second largest installation in the U.S.S.R. The first mill at this complex, with an annual capacity of 200,000 tons, was commissioned in 1965. During 1971–75, this mill was renovated, and production increased from 259,000 tons in 1970 to an estimated 360,000 tons in 1976. The Dzhetygara No. 2 mill, with an annual capacity of 400,000 tons, was completed in 1975 and produced an estimated 290,000 tons in 1976. Total output at the Dzhetygara complex will be increased from 650,000 tons in 1976 to an estimated 760,000 tons in 1980. The first mill of the Tuvaasbest complex, with an annual design capacity of 25,000 tons, was put into operation in 1966. This mill produced an estimated 30,000 tons in 1976. The second mill at this complex, with a capacity of 195,000 tons per year, was commissioned in April 1976; estimated production from this mill was only 70,000 tons in 1976. Total output at Tuvaasbest will be increased from an estimated 100,000 tons in 1976 to 225,000 tons in 1980.

The Kiyembay asbestos deposit in Orenburg Oblast (Southern Urals) is to be the second of 10 joint investment projects (with a total value of 9 billion transferable rubles) approved under the CMEA's comprehensive program. It calls for a total contribution of 100 million transferable rubles from the six Eastern European member countries. In exchange, the U.S.S.R. will supply an equivalent value of asbestos over a 12-year period at CMEA "world prices." In terms of volume, this represents about one-half the planned production capacity for each of the 12 years of the agreement, which can be extended an additional 10 years beyond 1991.

Development of the Kiyembay deposit started in 1968 and continued in 1976. The design capacity is 500,000 tons per year of grades III to VI from 24 million tons of ore with an average grade of 4.4%. The complex is to be completed in two equal stages. The first is to be completed in 1979, and its output will be shared among the CMEA members according to the share contributed to the construction.

A breakdown of investment contributions and the annual tonnage of asbestos receivable when full production is reached in 1982 follows:

Country	Investment (million rubles)	Tonnage receivable (thousand metric tons)
Bulgaria	24.0	40
Czechoslovakia	8.4	14
Germany, East	24.0	40
Hungary	1.8	3
Poland	30.0	50
Romania	18.0	30
Total	106.2	177

In 1976, 14 prospecting teams were conducting a detailed study of a 20,000-square-kilometer area in Tuva A.S.S.R., mainly to search for resources of asbestos and cobalt. Examination of the Sayan asbestos deposit in this region was completed in 1976. Asbestos reserves estimated at 6 million tons are situated near the Usinskiy highway on the Krasnoyarsk Kray border, where an asbestos complex is to be built.

Barite.—Barite is mined by both open pit and underground methods, and at many operations crude output is concentrated by flotation. Estimated domestic production in 1976 totaled 400,000 tons, a 14% increase over that of 1975. About 60% of the country's barite consumption in 1976 was produced domestically; the balance was supplied by imports of high-grade barite mainly from North Korea, Yugoslavia, and Bulgaria. The main centers of production continued to be Georgia, western Siberia, and Kazakhstan. Construction of a 45,000-ton-per-year complex at Khaishi in Svanetia, Georgia, and development of the underground mine at the Zhayremsk polymetallic complex in Kazakhstan continued in 1976.

Diamond.—The U.S.S.R. continued to make rapid progress in expanding its dia-

mond industry, which is centered in Yakutia where about 20 deposits have been discovered. Production in this region started with one small plant in 1957. In January 1977, the industry consisted of the large Mirnyy open pit with five concentrators, the Udachnaya placer mine and concentrator (near the Arctic Circle), and the Irelyakh placer mine with two dredges. Small quantities of gem and industrial stones were produced from the Vishera River region placers in Perm Oblast, where four dredges and two separation plants were operated at two placers in 1976. In 1976, output was estimated at 7.9 million carats of industrial quality and some 2 million carats of gem quality. Production of diamond is estimated at a probable 10.1 million carats in 1977 and 10.7 million carats in 1980. Next to fossil fuels and precious metals exports, diamond accounts for the largest share of the U.S.S.R.'s overall foreign currency balance.

Gem stones are cut at Leningrad, Sverdlovsk, and Smolensk, where Belgian specialists have been employed. Sales of cut stones are rising steadily, and substantial increases are expected in 1977–80. The U.S.S.R. has arranged to market part of its diamond output in Antwerp through a newly formed Soviet-Belgian company in which the Soviet export organization Almazyuvelirexport has a controlling interest. The U.S.S.R. State Committee for Science and Technology signed an agreement with a Belgian company on scientific and technical cooperation in the production and use of diamond tools.

The first stage of the No. 12 concentrator at the Udachnaya diamond deposit in Yakutia has been approved for operation, and construction on the second stage began in 1976. The Yakutalmaz (Yakutia diamond) complex, the Aykhalalmaz (Aykhal diamond) enterprise, and the Yakutniiproalmaz research and design institute were reorganized into the Yakutalmaz Association in 1976. A substantial but unknown quantity of synthetic diamond was also produced in 1976 by plants in Moscow, Kiev, Yerevan, Tashkent, and Poltava.

Fertilizer Materials.—Production totaled about 22 million tons in nutrient content, or 92.3 million tons in gross weight,[22] an increase of 3% over that of 1975. This increase was obtained mainly through the commissioning of new capacities. In 1976, plant capacities were expanded by 7.3 million tons per year of fertilizers (Soviet standard), although the planned quota for construction of new facilities was not met. The average nutrient content increased from 29% in 1970 to 37% in 1976. It is estimated that nitrogen fertilizers constitute around 38%, potassium fertilizers 37%, phosphate fertilizers 21%, and phosphorite fines 4%.

The Soviet mineral fertilizer industry did not meet its production goals of 94.5 million tons for 1976. Eleven of the twenty-three plants operated by the Ministry of Chemical Industry failed to meet 1976 production quotas. Most plants also failed to attain design capacity in 1976. A published Soviet review of basic reasons for the prolonged leadtimes for new plants to attain planned capacity listed the following: Inadequacy in planning, turning over facilities for operation while substantial construction and installation work remains incomplete, equipment defects, inadequacies in raw materials and supply, and failure to secure qualified personnel. Because of the unsatisfactory conditions of the equipment at the Uvarovo double-superphosphate ammonium phosphate plants, the degree of capacity utilization was only 34.1% in 1974 and 42% in 1976.

Over 97% of the fertilizers were shipped by railroad, mostly in bulk, causing large losses, moisture penetration, and difficulties in loading and unloading. Deliveries were made to some 7,000 railroad stations where bulk unloading was done with manual labor. As a result, about 15% of the total fertilizers shipped are lost each year according to Soviet industry estimates. Because of the enormous losses of mineral fertilizers, the Communist party Central Committee and the U.S.S.R. Council of Ministers adopted a resolution on June 20, 1976, entitled "On Measures to Further Increase the Effectiveness of Mineral Fertilizers; to Reduce Their Loss During Transport, Storage and Application; and to Perfect the Agrochemical Services of Kolkhozes and Sovkhozes." The resolution primarily reflected a concern with shortcomings in the handling and use of fertilizers.

[22] The average content (nitrogen, phosphorus, and potash) is expressed in Soviet standard units. Nitrogen is expressed as ammonia sulfate at 20.5% nitrogen, phosphorus is expressed at 18.7% P_2O_5, potash is expressed at 41.6% K_2O, and ground phosphate rock (phosphorite fines) is expressed at 19% P_2O_5.

Growth of the Soviet mineral fertilizer industry has high priority with Soviet planners. The State plan envisages output (Soviet standard) of 98.5 million tons in 1977 and 143 million tons in bulk (32 million tons of nutrients) in 1980 (plus some 5 million tons to be used as chemical additives to fodder). Actual production for 1977 and 1980, however, is estimated at 97 million tons and 130 million tons, respectively. During the 1976–80 period, 55.4 million tons per year of new fertilizer capacity is to be commissioned. Ammonia capacity is to be increased by 13.4 million tons per year and sulfuric acid capacity by 10 million tons per year. In 1980, phosphorous fertilizers are to amount to 33.1% of the total output of mineral fertilizers, compared with 24.1% in 1970. Complex fertilizer production is to account for 88.3% of total output in 1980, compared with 77.8% in 1975, and average nutrient content is to reach 40%.

Five large ammonia plants (each with a 450,000-ton-per-year capacity) together have a capacity equal to about 17% of the national Soviet capacity in 1975. All of these plants (two at Novomoskovsk and the others at Novgorod, Nevinnomyssk, and Severodonetsk) were constructed by Toyo Engineering. According to the new 5-year plan, by 1980, over one-half of the total ammonia is to be produced by plants with a capacity of 400,000 to 450,000 tons per year. During the 1976–80 period, equipment for 23 new ammonia plants, each with a capacity of 450,000 tons, is to be supplied by Western companies. These plants will be constructed in the U.S.S.R. with the assistance of Toyo Engineering (15 plants), Chemico Engineering Co., Ltd. (4 plants), and Creusot-Loire (4 plants).

The following seven ammonia plants were under construction and scheduled for completion in 1976: Berezniki, Chernorech'ye, Ionava, Kuybyshev, Nevinnomyssk, Novokemerovo, and Severodonetsk. The other 16 ammonia plants, which are to be put into operation in 1978–79, are as follows: Cherepovets, Cherkassy, Dneprodzerzhinsk, Dorogobuzh, Gorlovka (2 plants), Grodno, Novgorod, Novomoskovsk, Odessa (2 plants), Rossosh', and Togliatti (4 plants).

An agreement between the U.S.S.R. and four CMEA nations was signed for the construction of the Kingisepp mineral fertilizer plant in Leningrad Oblast. Bulgaria, Czechoslovakia, Hungary, and East Germany have supplied the equipment and materials for this plant in exchange for Soviet deliveries of ammonium phosphate over 10 years, beginning in 1976. The ore contains only 6% to 7% P_2O_5 but is easily beneficiated. The first stage for the production of mono-ammonium phosphate at this plant was commissioned in 1974, and the second stage was under construction in 1976 and was rescheduled for completion in 1977.

Phosphate.—Estimated output of phosphate rock totaled 71 million tons in 1976, including 37 million tons of apatite ore (17.7% P_2O_5) and 34 million tons of sedimentary rock (13% P_2O_5). The main centers continued to be the Apatit Association on Kola Peninsula and the phosphorite deposits at Karatau in Kazakhstan. Deposits of phosphorites also occur in Upper Kama in the Urals, Egorevsk and Lopatino in Moscow Oblast, Kingisepp in Leningrad Oblast, and some other regions, but the P_2O_5 content is rather low. Generally, they produce phosphorite fines with about 19% P_2O_5.

The Khibiny apatite nepheline deposits are the largest single phosphate source. Mined ore averaging 16% to 21% is upgraded to 39.4% P_2O_5 with 92% recovery. The Apatit complex produced an estimated 15.9 million tons of concentrate (37 million tons of ore) in 1976 from three underground mines and one open pit, and it provided about 70% of all raw materials for the production of phosphatic fertilizers. New facilities with an annual capacity of 0.9 million tons of apatite ore were commissioned at the first stage of the Yukspor mine in 1976. During the year, the 27th section of the dressing plant with an annual capacity of 230,000 tons of concentrate was put into operation.

A new apatite deposit at Mount Koashva was assigned to the Apatit Association in 1973. The Koashva mine, with an annual capacity of 7 million tons of ore, was under development in 1976. The first stage of this mine is scheduled for completion in 1978 and will be linked to Kirovsk by rail. Construction of the experimental mill at the Zabaykal'sk complex in Buryat A.S.S.R. continued in 1976. Between 1977 and 1980 this mill is to begin experimental production of an apatite concentrate from the Oshurkovo deposit, where reserves are large but contain only 4% P_2O_5. In the future, the

Zabaykal'sk apatite complex, with an annual capacity of 1.3 million to 1.5 million tons of concentrate, is to be built. At the Kovdor iron ore complex on Kola Peninsula, an apatite concentrate plant, with a first-stage capacity of 880,000 tons, was commissioned in 1975; the second stage was under construction in 1976. It processes tailings from the iron ore concentration complex.

It is planned to produce 220 million tons of ore and 80 million tons of concentrate at the Apatit Association during the 1976–80 period. By 1980, annual production of apatite concentrate is to be raised to 18.2 million tons at the Apatit Association, plus 1.38 million tons at the Kovdor mining and concentration complex, which forms a part of the Apatit Association. During the 1976–80 period, new capacities for production of 15.4 million tons of apatite ore and 3 million tons of apatite concentrate are to be put into operation.

The 45 commercial deposits in the Karatau area of Kazakhstan contain 1,500 million tons of minable phosphorite. The five largest deposits, Dzhantas, Aksay, Chulaktau, Koksu, and Kokdzhone, contain more than one-half of the total reserves. Seven open pits at the Aksay and Dzhantas deposits and the Molodëzhnyy underground mine at the Chulak-tau deposit produced an estimated total of 9.6 million tons in 1976. About 6.7 million tons came from the Dzhantas deposit. The ore content ranges from 21% to 25% and was upgraded to 28.5% P_2O_5, but recovery was low. New facilities for the mining of 1.7 million tons of ore and 0.65 million tons of marketable products were put into operation at the Tsentral'nyy mine at yearend. It is planned to produce about 20 million tons of phosphorite in the Karatau area in 1980. During 1977–80, the following mines are to be commissioned: Kokdzhone (annual capacity of 4.75 million tons of ore), T'esay (annual capacity of 2 million tons), Koksu, Ur-Bas, Geres, Kis-Tas, and other small mines, with a total capacity of 20 million tons of ore and 13 million tons of marketable products.

The Voskresensk complex in Moscow Oblast produced over 2 million tons of phosphorite fines in 1976. Production of ground phosphate rock in the Verkhnekamsk phosphorite area reached about 500,000 tons in 1976 and is to increase 50% during 1976–80.

Potassium.—The U.S.S.R. is one of the world's leading countries in potassium ore reserves, potassic fertilizer output, and exports of potash salts. Estimated output (41.6% K_2O) was 20.5 million tons in 1976 or 8.5 million tons in nutrient content; this was about 7.3% higher than the 19.1 million tons (7.9 million tons in nutrient content) of 1975 and about 109% higher than the 9.8 million tons (4.1 million tons in nutrient content) of 1970. Under the 1976–80 plan, output of potash is to increase 35% over the 1975 level to 26 million tons (10.8 million tons in nutrient content). Estimated actual levels of potash output for 1977 and 1980, however, are 21.7 million tons and 25 million tons, respectively. The total output of the potassium mines in the U.S.S.R. exceeded 60 million tons of ore in 1976 and is to be increased to 85 million to 90 million tons by 1980.

Gross potash reserves are reported at 22,900 million tons of 16% to 40% nutrient content (3,800 million tons of K_2O). About two-third of the reserves are located in the Upper Kama Basin in the Northern Urals. The four major producing areas are Solikamsk and Berezniki (49.6% of the total) on the western side of the Urals, Soligorsk in Belorussia (43.6%), and Stebnikov (2.9%) and Kalush (2.7%) in Western Ukrainia. Some 1.2% of the total was produced by enterprises of the nonferrous metals industry. The following 10 complexes were in operation in 1976: Berezniki Nos. 1, 2, and 3; Solikamsk Nos. 1 and 2; Soligorsk Nos. 1, 2, and 3; and the first stages of the Novostebnikov and Kalush complexes.

In 1976, three complexes were under construction: The first stage of Soligorsk No. 4 in Belorussia, Berezniki No. 4, and Novosolikamsk in the Urals. By the end of the new 5-year plan, construction of Soligorsk No. 4, Berezniki No. 4, and Novosolikamsk are to be completed. It is also planned to enlarge Solikamsk No. 1 and Soligorsk No. 3 by 200,000 tons per year each and Berezniki No. 3 by 140,000 tons per year during 1977–80. The nutrient content of the concentrates is to be increased from 53% K_2O in 1975 to 58.1% K_2O in 1980.

Fluorspar.—Fluorspar output remained below domestic requirements despite efforts to achieve self-sufficiency. Imports of fluorspar from Mongolia, the People's Republic of China, Japan, and Thailand increased

from 144,700 tons in 1970 to 493,900 tons in 1975. Estimated levels of fluorspar output for 1976 and 1980 were 490,000 tons and 540,000 tons, respectively.

Maritime Territory (the Yaroslavsk deposit), Transbaykal (the Kalanguysk, Abagatuysk, and Usuglinsk deposits), Uzbekistan, and Kazakhstan were the main producing areas in 1976. The mined ore contained 20% to 45% CaF_2. Hand picking, classification, heavy media, and flotation methods are used for concentration. During the 1971–75 period, despite a deterioration in the CaF_2 content of the ore, extraction of CaF_2 at the Yaroslavsk concentrator increased 1.8%; that at Kalanguysk rose 5.1%, and that at Usuglinsk rose 4.4%. The Central concentrator in Uzbekistan, which treats ores containing 24.3% to 26.5% CaF_2, produced a 95% CaF_2 concentrate with about 85% recovery. The dressing mill in Maritime Territory treats ores containing an average of 40.5% CaF_2 with about 76% recovery in a 92% CaF_2 concentrate. Exploration of the Suppatash, Kengutan, and Shabres deposits continued in 1976.

Mica.—The domestic supply of mica was augmented by large imports, despite the increasing use of substitutes. Strategic-grade mica continued to be imported from India to meet special industrial demands. Imports of mica increased from 160 tons in 1968 to 498 tons in 1975. Estimated output of mica is 43,000 tons in 1976 and 47,000 tons in 1980.

Irkutsk Oblast continued to be the main supplier of muscovite mica; 75% of all muscovite deposits in the country are in Mamsko-Chuyskiy Rayon of Irkutsk Oblast. Over 1,500 veins have been discovered in this area, and 9 small underground mines were in operation in 1976.

The Irkutsk and Petrozavodsk mica factories are the largest in the U.S.S.R. Mica is also mined in Murmansk Oblast on Kola Peninsula, Karelia, and Yakutia. The Kovdor deposit of vermiculite in Murmansk Oblast is mined by both surface and underground methods. The average 38.2% vermiculite content of the ore is upgraded to 88% with recovery of about 64%. The capacity of the Kovdor concentrator is 56,000 tons per year of concentrate. It is planned to develop the Slyudyanoy Bor deposit in Karelia in the future.

Salt.—The U.S.S.R. is one of the world's leading countries in salt reserves, production, and exports. Production in 1976 was estimated at 14 million tons. It was originally planned to increase salt production from 12.4 million tons in 1970 to 14 million tons in 1975 and to 20 million tons in 1980. However, production reached only 13.7 million tons in 1975 and the revised production level for 1980 is 18 million tons. Exports increased from 293,600 tons in 1970 to 320,700 tons in 1975. Salt development is concentrated in the Donets Basin, the Urals, eastern Siberia, Armenia, and Western Ukrainia. The increase in production came mainly from the Iletsk mine in Orenburg Oblast and the Avansk mine in Armenia. The Donets Basin continued to account for over 40% of total output in 1976. Development of a new mine with an annual capacity of 2 million tons at Artemovsk in this region continued in 1976. The Nizhniy Baskunchak salt complex, with a capacity of 700,000 to 900,000 tons per year, was also under construction. Construction of the Verkhnekamsk salt complex in Perm Oblast and renovation of the Iletsk mine continued in 1976. Construction of the Mozyr salt complex in Belorussia, which began in 1974 based on rock salt deposits that lie at a depth of up to 700 meters, continued in 1976. The planned capacity of the complex is 360,000 tons per year. The survey of a rock salt deposit near Gusev in Kaliningrad Oblast was completed in 1976. The U.S.S.R. awarded a contract to Technimont for the engineering of the 270,000-ton-per-year Sterlitamak salt plant in Bashkiria. The plant will be based on Montedison technology and is due to start up in 1977.

Sulfur.—The U.S.S.R. has large reserves of relatively low-grade, high-cost sulfur. Estimated production of contained sulfur totaled 8.3 million tons in 1976, of which 3.8 million tons was recovered from pyrite, 2.5 million tons from native sulfur, and 2.0 million tons from other sulfur sources. Estimated total sulfur output for 1977 and 1980 is 9.5 million tons and 11 million tons, respectively. Elemental sulfur exports, mainly to CMEA countries, decreased from 464,000 tons in 1970 to 441,000 tons in 1975. Imports of sulfur increased from 216,700 tons in 1970 to 690,000 tons in 1975. The principal producers of native sulfur continued to be Rozdol (Western Ukrainia), Gaurdak (Turkmenistan), and the Volga group of the Kuybyshev sulfur complex,

which together produced the bulk of the country's requirements.

The dressing mills of all three complexes treat ore with a sulfur content of 8% to 40% and produce a flotation concentrate with a 70% to 85% sulfur content. Sulfur production by the Frasch process at the Gaurdak complex has increased rapidly since the No. 2 installation (100,000 tons per year) went into service in 1975. The No. 3 100,000-ton-per-year installation using the Frasch process at this complex was under construction in 1976. The Rozdol complex produced concentrates containing 72% to 75% sulfur from ore containing 22% to 23% sulfur. It is planned to recover 895,000 tons of sulfur from Orenburg sour gas in 1977. Agreements have been signed for the supply by Poland of three sulfuric acid production units to the U.S.S.R. with a capacity of 1,515 tons per day each. The U.S.S.R. has already purchased 25 sulfuric acid plants from Poland.

Talc.—The U.S.S.R. produced an estimated 440,000 tons of talc in 1976, 4.8% more than in 1975. In 1976, only the Onot mine in Irkutsk Oblast, with an annual capacity of 45,000 tons of talc, produced high-grade material. Despite large reserves and the development of new mines and beneficiation facilities, imports of talc from North Korea and Bulgaria increased from 44,900 tons in 1973 to 90,950 tons in 1975. Estimated levels of talc output for 1977 and 1980 are 460,000 tons and 520,000 tons, respectively.

The Miass and Shabrovsk deposits in the Urals and the Kirgiteysk deposit in Krasnoyarsk Kray were the major Soviet producers of low-quality talc in 1976. Some talc is mined from the Tetri-Mindorskoye and Kvashevskoye deposits in South Ossetia, Georgia. The raw material at the Onot deposit is shipped for processing to the Miass talc mill in the Urals. The Medvedevskoye talc deposit in Chelyabinsk Oblast was under development in 1976.

MINERAL FUELS

Estimated production of primary energy derived from fossil fuels, fuelwood, and hydroelectric and nuclear generation increased from 1,610 million tons standard coal equivalent (SCE) in 1975 to 1,670 million tons SCE in 1976. Output of primary energy from all sources in 1980 is to rise to over 2 billion tons SCE. The 1980 production of crude oil is to rise 27% over that of 1975, natural gas 51%, coal 11%, hydroelectrical power 48%, and nuclear power 233%. The share of petroleum and natural gas in total Soviet primary energy production increased from 65% in 1975 to 67.3% in 1976, while that of coal (anthracite, bituminous, and lignite) declined from 30.6% in 1975 to 28.7% in 1976. In 1980, the share of petroleum and natural gas in total energy production is to be about 69% and coal will supply about 27%, with 4% to be provided by other sources.

Estimated consumption of all types of primary energy in the U.S.S.R. increased from 1,405 million tons SCE in 1975 to 1,429 million tons SCE in 1976. The share of petroleum and natural gas in total Soviet primary energy consumption increased from 61.4% in 1975 to 63.3% in 1976, while that of coal declined from 33.6% to 32.1%. Total consumption of all types of primary energy in the U.S.S.R. is expected to be about 1,743 million tons SCE in 1980. Clearly there will be a trend toward greater use of oil in the future. However, it is expected that the U.S.S.R. will make great efforts to substitute coal and natural gas for petroleum in order to make the latter available for export.

Among the Soviet resources of other fuels and energy in 1976 were hydroelectrical power, nuclear energy, peat, oil shale, and fuelwood. Peat (fuel), oil shale, and fuelwood together accounted for 7.7% of total Soviet primary energy production in 1960, but by 1976 their aggregate share had fallen to an estimated 2.8%. There was, however, an absolute increase in the production of these commodities, a trend which is expected to continue into the future.

According to published long-term agreements between the U.S.S.R. and other nations and the trade objectives announced in the various CMEA countries' 1976–80 5-year plans, it has been estimated that fuel exports from the U.S.S.R. to market economy countries will be increased from 94 million tons SCE in 1975 to 125 million tons SCE in 1980. Some 75 million tons of crude oil and petroleum products, 12 million tons of coal and coke, and about 22.9 billion cubic meters of natural gas is to be exported to market economy countries in 1980.

In 1976, the U.S.S.R. produced 519.7 mil-

lion tons of crude oil including gas condensate, 712 million tons of run-of-mine coal and lignite, and 321 billion cubic meters of natural gas. Soviet long-range forecasts place the demand for raw coal and lignite at over 800 million tons in 1980 and 1 billion tons by the year 2000.

The estimated total primary energy balance of the U.S.S.R. for 1976 and 1980 is shown in table 4.

Table 4.—U.S.S.R.: Total primary energy balance, 1976 and 1980
(Million tons of standard coal equivalent [1])

	Total primary energy	Coal (bituminous, anthracite, lignite) and coke	Crude oil and petroleum products	Natural and associated gas	Peat (including agricultural)	Oil shale	Hydropower	Nuclear power	Fuelwood
1976: [2]

[3] Forecast.

Coal.—In 1976, the U.S.S.R. produced 711.5 million tons of run-of-mine bituminous coal, anthracite, lignite, and brown coal, the equivalent of an estimated 408 million tons of clean coal according to Western practice, placing it second among world coal producers. This was over 10 million tons (or 1.5%) more than was produced in 1975. In the U.S.S.R., coal output is recorded on a ton-for-ton basis of unbeneficiated coal.

New facilities with an annual capacity of 12.6 million tons of run-of-mine coal and lignite were commissioned during the year. Construction of new projects continued to be slow, expensive, and frequently below established Western professional standards. At many mines, construction schedules were twice as long as plan specifications. Many new coal mines did not reach their planned capacity in 1976. Some of them have been lagging behind their annual targets for many years. Of 50 new and renovated mines in the Donets coal basin in the past 10 years, 38 had not attained their capacities, according to industry reports.

Gross production of the U.S.S.R.'s 10 major and numerous minor coalfields amounted to an estimated 470 million tons of bituminous coal, 78 million tons of anthracite, and 163.5 million tons of brown coal and lignite. About 32.6% of the total output was surface-mined.

Production in 1976 of raw coal and lignite in the major areas was as follows, in million tons: Donets Basin, 223.7; Kuznetsk, 138.9; Karaganda, 47.4; Moscow, 30.9; Kansk-Achinsk, 29.1; Pechora, 25.8; and other areas, 215.7.

The following coal-producing associations reported enterprises not fulfilling targets: Intaugol', Pervomayskugol', Prokopyevskugol', Kuzbassugol', and Sverdlovskantratsit. No rise in the average productivity of labor was attained for enterprises in the Ukraine. In such associations at Makeyevugol' and Dobropol'ugol', there was even a decline in labor productivity from that of 1975.

Production of raw coal and lignite is planned to rise to 733 million tons in 1977 and 750 million tons in 1980. In the 1976–80 period, 17 coal beneficiation plants with a total annual capacity of 57 million tons of raw coal are to be constructed or renovated. Development of the Ekibastuz,

Kansk-Achinsk, and southern Yakutia coal basins will be accelerated. It is planned to increase production of coal and lignite in this period by 28.2 million tons at Ekibastuz, 24.8 million tons at Kuznetsk, 14.4 million tons at Kansk-Achinsk, 11.8 million tons at Donetsk, and 7.5 million tons at Pechora. The share of surface coal mining is to be about 35% by 1980.

Soviet coal and coke statistics are presented in table 5.

Table 5.—U.S.S.R.: Salient coal and coke statistics [1]

(Million metric tons)

[1] Production data are from: National Economy of the U.S.S.R., Moscow. 1960, 1965, 1970, and 1975; and Ugol' (Coal), Moscow. No. 4, 1977, p. 67. Trade data are from: Vneshnyaya torgovlya S.S.S.R. (Foreign Trade of the U.S.S.R.), Moscow. 1960, 1965, 1970, 1975, and 1976.

[2] As reported in Soviet sources.

[3] Estimated in accordance with Western practice and experience.

[4] All from centrally planned economy countries.

Electrical Power.—Total electrical power generation in 1976 amounted to 1,111 billion kilowatt-hours, a 7% increase over that of 1975. Electrical power generation is planned to rise to 1,160 billion kilowatt-hours in 1977 and 1,207 billion kilowatt-hours in 1978.

At yearend, the total installed capacity of Soviet electric powerplants reached 228 million kilowatts, of which 43 million kilowatts (18.9%) represented hydroelectric capacity and about 6.5 million kilowatts (2.9%) was nuclear capacity. Most of the future development of electrical power capacity will be centered on new thermal powerplants, most of which will be fueled by lignite. There were plans to commission 12.19 million kilowatts of new electrical power generating facilities in 1976, comprising 8.48 million kilowatts thermal, 1.01 million kilowatts nuclear, and 2.7 million kilowatts hydroelectric capacity. Only 11.9 million kilowatts, however, was actually commissioned during the year. Under the 1976–80 plan, 71 million kilowatts of new electrical power generating facilities are to be commissioned and are scheduled to produce 1,380 billion kilowatt-hours of electrical power annually by 1980. The output of hydroelectrical power may reach 212 billion kilowatt-hours by 1980. In 1980, the capacity of hydroelectric powerplants may reach approximately 56 million kilowatts. Capital investment in construction of new powerplants for the next 5 years has been set at a level of 26 billion rubles, compared with 22 billion rubles under the 1971–75 plan.

Exports of electrical power rose from 11.3 billion kilowatt-hours in 1975 to 11.6 bil-

lion kilowatt-hours in 1976 and included over 10 billion kilowatt-hours to centrally planned economy countries and over 1.5 billion kilowatt-hours to Finland and Norway. Hungary remained the principal importer of Soviet electrical power, followed by Bulgaria, Czechoslovakia, and Poland. Under long-term contracts, the U.S.S.R. will export some 15 billion kilowatt-hours of electrical power annually by 1980, including some 2 billion kilowatt-hours to Finland and Norway. Hungary is expected to remain the principal importer of Soviet electrical power until 1980. After 1980, the U.S.S.R. will deliver some 4 billion kilowatt-hours to Finland annually.

About 85% of all Soviet electrical energy is generated at thermal power stations, fueled mainly by lignite, as indicated, in percent, in the following tabulation:

Source of fuel	1965	1970	1975	1980 [e]
Coal and lignite	60.0	48.6	43.0	45.0
Mazout	11.5	23.0	29.5	28.0
Natural gas	22.1	23.1	22.1	22.0
Peat, oil shale, other	6.4	5.3	5.4	5.0

[e] Estimate.

Source: Elektricheskiye stantsii (Electric Powerplants), Moscow. No. 1, January 1975, p. 3; and No. 6, June 1976, p. 5.

Coal and lignite will continue to play a leading role in electrical power generation in the foreseeable future, and the share of coal- and lignite-fueled electrical power generation is to increase. Up to 75% of the solid fuels burned at the U.S.S.R.'s thermoelectric powerplants has a calorific value of 1,500 to 5,500 kilocalories per kilogram (2,650 to 9,850 Btu per pound).

About one-half of the total capacity of hydroelectric power stations of the U.S.S.R. is concentrated at plants with a capacity of over 1 million kilowatts. The largest operating station is the Krasnoyarsk Kray hydroelectric powerplant with a capacity of 6 million kilowatts.

Consumption of power by major branches of the Soviet economy in 1975 is shown in the following tabulation:

Consumer	Billion kilowatt-hours	Percent of total
Industry	582.0	56.2
Powerplants and losses	151.6	14.7
Domestic (urban)	123.5	11.9
Transportation	74.4	7.2
Agriculture and rural population	72.5	7.0
Construction	20.0	1.9
Exports	11.0	1.1
Total	1,035.0	100.0

Source: Elektricheskiye stantsii (Electric Powerplants), Moscow. No. 1, January 1976, p. 2.

Hydroelectrical Power.—The economic-technical potential of hydroelectrical power in the U.S.S.R. was placed at 1,095 billion kilowatt-hours per year. In the overall energy economy of the U.S.S.R., however, water power is of relatively small significance. Hydroelectrical power supplied 135 billion kilowatt-hours, or 12.2% of all electrical power generated in 1976.

Nuclear Energy.—At the beginning of 1976, the U.S.S.R. was operating eight atomic powerplants with a total capacity of 5,076 megawatts, or about 2.3% of the total capacity of all electric powerplants, as follows: Leningrad (two reactors, total capacity of 2,000 megawatts), Novo-Voronezh (four reactors, 1,455 megawatts), Kola Peninsula (two reactors, 880 megawatts), Shevchenko (one reactor, 350 megawatts), Beloyarsk (two reactors, 300 megawatts), Melekess (one reactor, 50 megawatts), Bilibino (three reactors, 36 megawatts), and Obninsk (one reactor, 5 megawatts). In December 1976, the following nuclear powerplants were put into operation: The fourth stage (one reactor) at Bilibino with a capacity of 12 megawatts, the first stage (one reactor) at Armenia with a capacity of 405 megawatts, and the first stage (one reactor) at Kursk with a capacity of 1,000 megawatts. Thus, the total installed capacity of the 10 Soviet nuclear powerplants at yearend was 6,493 megawatts, or 2.8% of the total capacity of all electric powerplants in the U.S.S.R.

In 1976, Soviet nuclear powerplants generated over 25 billion kilowatt-hours (25% more than in 1975), or 2.2% of all power supplied in 1976. Several nuclear powerplants were under construction in 1976, some of which were scheduled for completion by 1980. Plans are to install 13,750 megawatts of new nuclear capacity by 1980, although actual new capacity is estimated at only 10,920 megawatts, bringing the 1980 total to an estimated 15,000 to 17,400 megawatts. Although plans are to generate 80 billion kilowatt-hours of nuclear energy in 1980, the U.S.S.R. will probably increase its production to only 50 billion kilowatt-hours. Nuclear energy output is to represent about 3.6% of national electrical power production and 0.4% of total Soviet primary energy output by 1980.

According to Soviet sources, construction and initial fueling of nuclear power stations is more expensive than that of conventional thermal powerplants of similar capacity. However, operating costs at nuclear power stations are being constantly reduced, particularly at the large-capacity stations. The generation cost of 1 kilowatt-hour at the Novo-Voronezh nuclear powerplant was reduced from 0.95 ruble in 1971 to 0.65 ruble in 1975.

Soviet nuclear energy capacity is presented in the following tabulation:

Nuclear plant and unit	Startup date	Yearend capacity (megawatts)	
		Actual 1976	Estimated 1980

[1] The first dual-purpose nuclear powerplant using a sodium-cooled fast reactor with a design capacity of 150 megawatts and desalination capacity of 120,000 cubic meters per day of fresh water.
[2] Figure differs from that given on table 6 owing to a difference in source.

A major 5-year nuclear power expansion program is placing greater emphasis on nuclear energy in the Soviet energy balance. The reactors are to be installed in 10 new 1,000-megawatt-capacity nuclear powerplants to be built under the 1976–80 plan. The standard nuclear reactor now being produced at the Izhorsk plant in Leningrad is a 440-magewatt pressurized-water reactor. Using this model, the U.S.S.R. can turn to the West for the supply of equipment, technology, and know-how for its nuclear industry. The Soviets are interested in key components and equipment to be manufactured in Western Europe, Japan, and the United States.

The U.S.S.R. has meanwhile embarked on a program to develop its own reactor-

equipment-building facilities. The key to this program is the establishment of a very large reactor production plant near Volgodonsk on the River Don. The new complex, to be known as Atommash ("atomic machines"), will specialize in assembly line production of 1,000-megawatt reactors and other equipment for nuclear powerplants. The first stage of the plant is to be on-stream by November 7, 1977, and completion is scheduled for 1980. However, according to Soviet sources, problems have been encountered in construction of the Atommash plant,[23] including housing of the more than 16,000 construction workers on the project in 1976.

The U.S.S.R. provides technical assistance in the construction of nuclear powerplants in CMEA countries. In December 1972, the first Czechoslovak nuclear powerplant, with a capacity of 140 megawatts, was put into operation at Jaslovske Bohunice in West Slovak Region, with the aid of Soviet engineers. The second stage of this plant was under construction in 1976. The first stage (440 megawatts) of the Kozloduy nuclear powerplant in Bulgaria was completed in 1975, and the second stage, with the same capacity, is to be put into operation in 1977. Construction of similar nuclear powerplants, with a capacity of 440 megawatts each, began in Hungary (Paks) and Romania in 1974, scheduled for completion by 1985. The aggregate capacity of nuclear powerplants operating in CMEA countries was about 7,500 megawatts in 1976.

The first nuclear powerplant in Poland, with a capacity of 440 megawatts, is to be built on Lake Zarnowieckie, Gdánsk Province, during the 1990's. Cuba's first atomic power station is to built in Las Villas Province with Soviet assistance. The U.S.S.R. is to supply equipment for the plant, and the generating capacity of its first stage is to be 440 megawatts.

The first stage of the Loviisa nuclear powerplant in Finland, with a capacity of 440 megawatts, was under construction with Soviet assistance in 1976. Under a Finnish-Soviet agreement, the main machinery, reactor units, and turbines, as well as the nuclear fuel, will be delivered by the Soviet foreign trade organization Atomenergoexport. The Finns are responsible for the actual construction work as well as for the delivery of various components and electrical equipment. Reportedly, 750 Soviet engineers, technicians, and mechanics working on the nuclear powerplant have been living at the construction site. An agreement has been signed by the U.S.S.R. and Finland concerning the enrichment of uranium for the Olkiluoto nuclear powerplant.

According to a long-term agreement, Spain will import an estimated $400 million worth of Soviet uranium concentrate to fuel its nuclear powerplants. Reportedly, Rheinisch-Westfälisches Elektrizitätswerk AG (RWE) of West Germany has a contract with the U.S.S.R. worth DM1 billion and valid until 1990 that will insure a sufficient supply of uranium for the country's nuclear powerplants. A contract for the enrichment of uranium for Austria's second nuclear power project for a 12-year period was signed by the U.S.S.R. on May 23. This nuclear powerplant is scheduled for operation in 1980 or 1981. Reportedly, uranium will be enriched for Spanish nuclear powerplants by the Soviet firm Tekhsnabeksport between 1978 and 2000.

Electrical power generation and the year-end capacity of Soviet powerplants, by type, are shown in table 6.

[23] Sotsialisticheskaya industriya (Socialist Industry), Moscow. Sept. 2, 1977.

Table 6.—U.S.S.R.: Salient electrical power statistics

Type of powerplant	1970				1976				Forecast 1980			
	Yearend capacity		Production		Yearend capacity		Production		Yearend capacity		Production

National Economy of the U.S.S.R., Moscow. 1975, p. 215.

Natural Gas.—The U.S.S.R. is among the world's largest producers and consumers of natural gas and is a net exporter of this commodity. In 1976, the U.S.S.R. produced 321 billion cubic meters of usable gas, 11% more than in 1975, exceeding the planned target of 313 billion cubic meters. Of this quantity, over 99% consisted of natural and oil-associated gas, and less than 1% was gas from gasification of coal and oil shale. In 1976, natural gas accounted for 22.8% of Soviet primary energy production and 25.5% of primary energy consumption. Of 5,000 wells in more than 650 gas, gas condensate, and gas-oil fields in 1976, 15% to 20% were idle. For the first time since 1956, the gas industry was able to meet its original annual production goal.

The 1976 extraction of gas in the main regions, in billion cubic meters, was as follows:

Region	Quantity	Percent change from 1975
Ukraine	68.7	--
Turkmenistan	62.6	+21
Western Siberia	47.8	+34
Uzbekistan	36.0	−3
Orenburg Oblast	31.8	+59
Komi A.S.S.R	19.6	+6

Source: Ekonomicheskaya gazeta (Economic Gazette), Moscow. No. 6, February 1977, p. 2.

The recovery of associated gas rose from 22.9 billion cubic meters in 1970 to 28.6 billion cubic meters in 1975. Significant losses of associated gas were encountered in many oil-producing regions. It was planned to carry out a number of important measures for increasing the effectiveness of utilization of associated gas, which rose from 61.6% in 1970 to 85% in 1975. The extraction target for 1975 had been set at 41.5 billion cubic meters in 1970; actual production, however, reached only 28.6 billion cubic meters. In 1976, the utilization of associated gas was only 64.9%, according to trade journal reports.

Production of natural and oil-associated gas, in billion cubic meters, was as follows:

	1970	1971	1972	1973	1974	1975
Natural gas	175.0	187.4	195.7	209.8	232.9	260.7
Oil-associated gas	22.9	25.0	25.7	26.5	27.7	28.6
Total	197.9	212.4	221.4	236.3	260.6	r 289.3

r Revised.

Source: Ekonomika neftyanoy promyshlennosti (Economics of the Petroleum Industry), Moscow. No. 7, July 1976, p. 47.

It was planned to extract 342 billion cubic meters of natural gas in 1977, an increase of 21 billion cubic meters over 1976 output. Most of the increase is expected to come from fields in western Siberia.

Extraction of natural gas in 1980 is planned at 435 billion cubic meters, about 146 billion cubic meters over that of 1975. Most of the increase is to come from the following gasfields: Urengoy, Medvezh'ye, Vyngapurovsk, Komsomol'sk (western Siberia), and Orenburg.

The Ministry of Construction of the Enterprises of the Oil and Gas Industry did not fulfill plans for the development of oil and gas fields and construction of gas pipelines, compressor stations, and underground gas storage, according to official reports.

During the 1971–75 period, capital investment in the Soviet gas industry totaled 10,180.2 million rubles, distributed as follows, in million rubles: 1971—1,383.1; 1972—1,674.7; 1973—2,036.1; 1974—2,501.0; and 1975—2,585.3.[24]

Gasfields.—The Ukraine maintained first place in the production of gas in 1976, accounting for 21.4% of the national output. Thirty-four gasfields were in operation in 1976, including Shebelinka and Efremovka.

Production of gas in the Bukhara-Khivinskiy region (eastern Turkmenistan and western Uzbekistan) reached 98.6 billion cubic meters in 1976, an increase of 11% over that of 1975. In 1976, 21 gasfields were in operation (including 6 in eastern Turkmenistan), and 15 gasfields were under development. The gasfield at Gazli, the largest in Uzbekistan, produced over three-fourths of the Republic's total gas output from 351 developmental wells.

Western Siberian gas production increased from 9 billion cubic meters in 1970 to nearly 36 billion cubic meters in 1975 and 47.8 billion cubic meters in 1976. The region is to produce 115 billion to 145 billion cubic meters in 1980, 26% to 33% of

[24] Ekonomika gazovoy promyshlennosti (Economics of the Gas Industry), Moscow. No. 4, April 1977, pp. 3–13.

the Soviet total. Almost two-thirds of total Soviet natural gas reserves are located in western Siberia. Four fields were in operation in this region—Punga, Igrim, Pakhomovsk, and Medvezh'ye. The latter is the largest of the four. Development of the Urengoy gasfield in this region, the U.S.S.R.'s largest gasfield, began in 1975. It is expected that gas production here will begin in 1978.

As most of the older producing regions are past their peak, current development is shifting attention to gasfields in western Siberia. About 85% of the planned increase in production during the 1976–80 period is expected to come from this region.

The Orenburg gas condensate field was one of the largest projects of the ninth 5-year plan. Two stages of the Orenburg complex, with a combined annual capacity of 30 billion cubic meters of natural gas, 800,000 tons of sulfur, and 2.4 million tons of gas condensate, were put into operation in 1974 and 1975. The third and last stage, also with a capacity of 15 billion cubic meters of gas, is scheduled for completion in 1978. This stage will consist of 100 operational wells and processing plants. Under a contract signed in September 1975, the French firm Creusot-Loire is to supply the U.S.S.R. with extraction and field processing equipment for the third stage. Reportedly, the French firm TECHNIP and the Soviet firm Tekhmashimport have signed an Fl-billion contract for a natural gas desulfurizing plant for the third stage. The plant is to have a processing capacity of 15 billion cubic meters of gas per year, the same as that of the first two, which were also constructed by TECHNIP.

Production of gas at the Vuktyl gas condensate field in Komi A.S.S.R. increased from 18.5 billion cubic meters in 1975 to 19.6 billion cubic meters in 1976.

Transportation.—The great distance between the principal consuming centers and the gasfields requires large pipelines for the bulk of natural gas. About 95% of the 1976 natural gas production was carried by trunk pipelines, and only 5% was consumed at or near the place of production. The total length of gas trunk pipelines increased from 99,200 kilometers in 1975 to 104,700 kilometers in 1976. Completion of an additional 6,500 kilometers of gas trunk pipelines, and 42 compressor stations is planned for 1977.

The total length of major gaslines and branches at yearend, in thousand kilometers, was reported or expected to be as follows: 1970—67.5; 1975—101.2; 1977—114.0; and 1980—137.0.[25]

Capital investment in gas transportation accounts for more than 60% of total investment in the gas industry. During the 1971–75 period, it totaled 6,260.5 million rubles, as follows, in million rubles: 1971—769.4; 1972—1,088.7; 1973—1,276.4; 1974—1,540.0; and 1975—1,586.0.[26]

Transportation costs of gas, in rubles per ten thousand cubic meters, were as follows: 1971—12.11; 1972—12.24; 1973—11.90; 1974—12.21; and 1975—13.44.[27]

A Government decree published in December 1976 provided for the construction in 1976–80 of a new facility at the Vyksun plant in the Urals to produce welded multilayered pipe with a diameter of 1,220 to 1,420 millimeters. The annual capacity of the new plant is to be 1 million tons per year.

The 1977 plan calls for construction of about 2,000 kilometers of gas pipelines and 20 compressor stations in the Tyumen Oblast-Ukhta-Western Border system in the northern regions. Among the gas pipeline construction projects to be in progress in 1977 were Nadym-Punga (fourth stage), Punga-Vuktyl-Ukhta (first stage), Ukhta-Torzhok (third stage), Torzhok-Minsk-Ivatsevichi (second stage), and Ivatsevichi-Dolina-Uzhgorod-Western Border (first stage). More than 1,000 kilometers of gas pipeline is to be laid in the Nizhnevartovsk-Kuybyshev system. Sections of considerable length are to be constructed on the Nizhnyaya-Tura-Perm (third stage) and Perm-Kazan-Gor'kiy (second stage) routes.

In 1976–80, 36,500 kilometers of underground gaslines is to be built. Almost 30% of this consists of 1,420-millimeter-diameter pipe. Compressor stations are to be outfitted with gas-pumping aggregates with a capacity of up to 25,000 kilowatts.

Exports.—Although the U.S.S.R. became a net exporter of natural gas only in 1974, the role of Soviet gas in the international market has grown in recent years. Exports of natural gas from the Ukraine totaled

[25] Ekonomicheskaya gazeta (Economic Gazette), Moscow. No. 6, February 1977, p. 2.
[26] Ekonomika gazovoy promyshlennosti (Economics of the Gas Industry), Moscow. No. 5, May 1977, pp. 3–10.
[27] Work cited in footnote 26.

25.8 billion cubic meters in 1976, a 6.5-billion-cubic-meter increase over those of 1975. The share of Soviet gas production exported reached 8%, compared with the previous year's 6.7%. Prices for exported gas rose along with volume and earnings as foreign natural gas sales increased from 451.3 million rubles in 1975 to 733.4 million rubles in 1976. Gas should soon rank next to oil as an important Soviet hard-currency export commodity.

Soviet exports of natural gas in 1973–76 are given, in billion cubic meters, in the following tabulation:

Destination	1973	1974	1975	1976
Czechoslovakia	2.4	3.2	3.7	4.3
Germany, West	.4	2.1	3.1	4.0
Italy	--	.8	2.3	3.7
Germany, East	.7	2.9	3.3	3.4
Austria	1.6	2.1	1.9	2.8
Poland	1.7	2.1	2.5	2.5
Bulgaria	--	.3	1.2	2.2
Hungary	--	--	.6	1.0
France	--	--	--	1.0
Finland	--	.5	.7	.9
Total [1]	6.8	14.0	19.0	25.8

[1] Data may not add to totals shown because of independent rounding.

Czechoslovakia remained the biggest buyer of Soviet natural gas in 1976, while East Germany, the second largest importer in 1975, fell to fourth place behind West Germany and Italy. France bought Soviet pipeline natural gas for the first time in 1976.

Austria was the first Western European country to import Soviet natural gas under a 23-year agreement signed in 1968 and a letter agreement signed in 1974. The U.S.S.R. has three agreements (1970, 1972, and 1974) with West Germany's Ruhrgas AG for delivery of gas over 20 years in exchange for large-diameter steel pipe and pipeline construction equipment. West Germany began to receive Soviet gas in 1973.

In 1974, Italy joined the group of Western European importers of Soviet natural gas. Beginning in 1977, 6 billion cubic meters of Soviet gas will be sent annually to Italy under a 20-year agreement. Deliveries of Soviet gas to Finland under a 20-year agreement started in 1974 and will be raised to 1.4 billion cubic meters per year. Also starting in 1977, 2.5 billion cubic meters of Soviet gas will be sent annually to France under a 20-year agreement.

The U.S.S.R. intends to further increase deliveries of natural gas to Western European countries by means of a second international pipeline of 28-billion-cubic-meter annual capacity, to be constructed by 1978. This will also increase deliveries of gas to Czechoslovakia and begin supply of gas to Yugoslavia.

The total length of both stages of the international gasline, including branches, is to be 10,000 kilometers. The main distribution center is Czechoslovakia, whence gas flows through several branch lines to East Germany, West Germany, Austria, and Italy. An additional branch line to France is planned. It is expected that annual Soviet exports of natural gas to Italy, in exchange for additional equipment and plants, will rise from the anticipated 7 billion cubic meters to 10 billion cubic meters.

The North Star Siberian gas project for the extraction, liquefaction, and export of natural gas to the United States and Western Europe from the Urengoy gasfield was abandoned in 1974, following unfavorable reception of the plan in the U.S. Congress.

Under a new proposal, British, French, and West German banks and financial institutions are to make loans to the U.S.S.R. to buy a French liquefied natural gas plant, West German pipe, and British auxiliary equipment for the project. The U.S.S.R. was studying this proposal in 1976.

Soviet deliveries to CMEA countries in 1976 increased about 19% over those of 1975 and are to be doubled by 1980. The U.S.S.R. plans to substitute natural gas for oil wherever possible in exports to Eastern Europe.

Under the Soviet-Hungarian agreement of 1971, delivery of natural gas through the first stage of the Soviet-Hungarian Brotherhood Gas Pipeline began on May 1, 1975, and through the second stage in February 1976. Hungary received 0.6 billion cubic meters of Soviet gas in 1975 and 1 billion cubic meters in 1976; deliveries are to be increased substantially by 1980 to provide gas for both Hungary and Yugoslavia. The annual capacity of the pipeline was 2 billion cubic meters in 1976 and is to be 2.6 billion cubic meters in 1979.

Deliveries of Soviet natural gas through the joint CMEA pipeline from the Orenburg field have been planned for the early 1980's at 15.5 billion cubic meters annually, with 2.8 billion cubic meters each to Czech-

oslovakia, Poland, East Germany, Hungary, and Bulgaria and 1.5 billion cubic meters to Romania. The 1,420-millimeter-diameter pipeline will be 2,677 kilometers long. The capacity of this line is to be 28 billion cubic meters per year. Over 13,000 Eastern European workers were working in the U.S.S.R. in 1976 on construction of this line, which is to be completed in spring of 1979.

According to a Soviet-Bulgarian agreement, the U.S.S.R. is to supply Bulgaria with 3 billion cubic meters of natural gas annually by 1980. Bulgaria is also to receive 2.8 billion cubic meters per year from the Orenburg pipeline. A contract for the supply of 4.5 billion cubic meters of natural gas to Czechoslovakia in 1977 was signed in Prague on December 9, 1976.

Soviet gas reserves are about 25 trillion cubic meters, but the development of all these reserves would be extremely difficult and costly. One problem of development at the western Siberian gasfields is that it takes about 1.5 years to get a piece of heavy equipment in place. Despite the enormous gas reserves, the U.S.S.R. is not likely to become a major world gas exporter. Siberian gas will, however, become a major factor in the domestic energy balance.

Soviet exports will be offset to some extent by imports of gas from Iran and Afghanistan, which decreased from 12.5 billion cubic meters in 1975 to 11.8 billion cubic meters in 1976.

The route of the pipeline from the Soviet-Iranian frontier, which will pump Iranian gas to West Germany through the U.S.S.R.'s gas transport system, was designed in 1976. The transcontinental pipeline, some 4,000 kilometers long, will carry over 12 billion cubic meters per year. On the basis of long-term loans, West German firms supply the U.S.S.R. with pipe and equipment to speed up development of gasfields. Repayment is to be made in future deliveries of gas to West Germany.

Soviet natural gas statistics are presented in table 7.

Table 7.—U.S.S.R.: Salient natural gas statistics [1]

(Billion cubic meters)

	Actual				Forecast

r Revised.

[1] Production data are from: National Economy of the U.S.S.R., Moscow. 1970, 1974, and 1975; and Pravda, Moscow. Jan. 23, 1977. Trade data are from: Vneshnyaya torgovlya S.S.S.R. (Foreign Trade of the U.S.S.R.), Moscow. 1970, 1974–76.

Oil Shale.—Soviet minable oil shale reserves in place in the measured, indicated, and inferred categories are 6.4 billion tons, and in the potential category 6 billion tons. About 75% of the reserves are concentrated in the Baltic Basin (the Estonian and Leningrad Oblast deposits), with some in the Volga region (the Kashpari desposit). The largest oil shale reserves are in Estonia. Production of oil shale increased from 32.5 million tons in 1975 to 33.0 million tons in 1976; it may reach 36 million tons in 1977 and 38 million tons in 1980. Over two-thirds of the extracted shale in the U.S.S.R. is burned at the Pribaltiyskaya and Estonskaya thermoelectric powerplants. The remainder is processed into furnace oil, gasoline, fuel gas, phenols, and aromatic hydrocarbons. Oil shale is also used in everyday commercial needs. The world's largest powerplant fueled by oil shale in Tallinn has reached a capacity of 1.6 million kilowatts.

There were 13 underground mines with a total capacity of 22.3 million tons and 4 open pits with a capacity of 12.1 million tons in operation in 1976. The main center of production, as in prior years, was Estonia, where output totaled about 29 million tons in 1976 and is expected to exceed 30 million tons in 1980. In 1976, there were eight underground mines and four open pits in operation in Estonia. Production of oil shale in this Republic has increased more than 50% over that of 1970. The first and largest walking excavator in the country, with a bucket of 35 cubic meters, was put into operation at the Oktyabr' open pit in Estonia in April.

Most of Estonia's oil shale occurs in thin seams at depths of 20 to 30 meters. An increasing proportion is obtained from open pits. The future development of the Republic's oil shale industry is impeded by limited reserves of untapped shale deposits, shortage of manpower, limited capacity of existing petrochemical enterprises, and environmental protection. According to Soviet sources, dust and pollution of air, rivers, and ground water exceed permissible standards at many places in the Estonian oil shale basin. It has been decided to begin development of the middle-Dnepr oil shale deposit, which has been estimated to contain over 3 billion tons of oil shale.

In 1976, three underground oil shale mines in Leningrad Oblast produced some 5 million tons; over 1 million tons came from two underground mines in the Volga region.

Reportedly, Thailand has accepted an offer from the U.S.S.R. of technical assistance for oil shale development.

Peat.—The U.S.S.R. produced an estimated 191.6 million tons of peat in 1976. Of this quantity, 60 million tons consists of fuel peat and 131.6 million tons is agricultural peat. Production of 99 million tons of agricultural and 40 million tons of fuel peat came from collective farms. The R.S.F.S.R. occupied first place in peat production in the U.S.S.R. in 1976 and produced some 120 million tons, including an estimated 40 million tons of fuel peat. Belorussia, with an estimated output of 44 million tons, was the second largest peat-producing region.

Soviet gross reserves of peat increased between 1955 and 1975 from about 20 billion tons to 39 billion tons SCE. However, about 11% of the current minable reserves are located in the central European part of the U.S.S.R.—Belorussia, the Baltic States, and the Ukraine region—which produced over 80% of the national output in 1976. Analysis of past trends and Soviet potential facilities indicate that extraction of peat may reach 220 million tons (including 80 million tons of fuel peat) in 1980.

There were 79 electric powerplants fueled by peat in operation in the U.S.S.R. in 1976, with a total capacity of about 4,000 megawatts. A number of new powerplants with a capacity of 600 megawatts each were being constructed in different regions of the U.S.S.R. in 1976. Fuel peat is also used in domestic heating.

Petroleum.—In 1976, the U.S.S.R. produced 519.7 million tons of crude oil and gas condensate, a 5.8% increase over 1975 output. For the third year, the U.S.S.R. remained the world's largest oil producer. The country continued to expand exports of crude oil and petroleum products even though supplies available for internal consumption were tight. Nearly 29% of the total (148.5 million tons) was exported either as crude oil (110.8 million tons) or as refinery products (37.7 million tons). Exports of crude oil and products in terms of value accounted for as much as 27.4%

of total official Soviet exports in 1976. Soviet imports of crude oil and petroleum products increased from 4.6 million tons in 1970 to 14.7 million tons in 1973 and dropped thereafter to 5.4 million tons in 1974, 7.6 million tons in 1975, and 7.2 million tons in 1976. The share of petroleum in the U.S.S.R.'s total primary energy production reached an estimated 44.5% in 1976, and its share of consumption was 37.8%.

In 1976, over 500 (including 36 large) oil and gas condensate fields were in operation, with a total of over 67,000 wells. Increased production came from 9 of the 26 producing regions, mainly western Siberia, Udmurt A.S.S.R., Komi A.S.S.R., Perm Oblast, and Georgia. In western Siberia, which has over 140 oilfields, 21 fields were producing in 1976, the largest of which was Samotlor.

The 1976 oil production quota was filled by putting 4,798 (instead of the 4,453 planned) new wells into operation, putting in new pumping equipment at 874 wells, switching 3,215 wells to mechanized methods of operation, and putting 1,184 inactive wells into production. To maintain the formation pressure, 1,100 million cubic meters of water was pumped into producing levels, 115 million cubic meters more than in 1975. In 1976, the U.S.S.R. drilled about 12.1 million meters of developmental and exploratory wells, 0.4 million meters more than in 1975.

The U.S.S.R. plans to increase oil recovery from oilfields under current exploitation. To the Soviets, it is more rational to increase secondary and tertiary recovery of petroleum than to develop new oilfields. The use of chemical agents and the injection of warm water and steam have been tested successfully and are being introduced.

The U.S.S.R. invests considerable sums of money and material resources in oil industry development. The fixed capital invested in the industry was more than 20 billion rubles by January 1, 1976. In 1976 alone, 4.4 billion rubles was invested in the oil industry.

Underground mining of oil sands has been practiced in Komi A.S.S.R. (the Yarege mine) since 1972. Operations there consisted of shaft sinking, drifting, drilling of production boreholes, and injection of steam, followed by underground separation of crude oil and waste and pumping recovered oil to the surface.

Development of an underground oil-producing mine in Azerbaydzhan began in 1976, with completion scheduled for 1980. The mine is to be developed by two vertical shafts to a depth of 400 meters.

Reportedly, the U.S.S.R. and Algeria have agreed to expand cooperation in the oil and gas industries. Some 15 Soviet drilling rigs have been sent to Algeria, and representatives of the two countries have studied the possibility of Soviet participation in construction of a number of oil refineries in Algeria.

Exploration and Reserves.—The U.S.S.R. is rich in oil. However, despite new discoveries, the rate of incremental growth in oil reserves is lagging behind the growth rate of crude oil extraction.

Crude oil reserves (indicated plus inferred) in place increased by about 400 million tons in 1975. As of January 1, 1976, the gross reserves of crude oil in place in the U.S.S.R. may total 23 billion tons, including 1.5 billion tons measured (Soviet category A), 3.3 billion tons indicated (category B), 5.2 billion tons inferred (category C_1), and 13 billion tons potential (category C_2). The ratio of A plus B reserves in place to production was 10:1 in 1975. A 30% to 40% recovery of crude oil in place was claimed in 1975. The reserve-to-production ratio for the country as a whole has declined 45% from that of 1955 and 20% from that of 1970.

Future Soviet plans covering the development of the oil industry's prospecting and drilling operations were based on a reserves-in-place-to-production ratio. This ratio, which governed exploration activities, included reserve categories A, B, and C_1 and was set at 20:1 to 25:1 for planning purposes. In actual fact, however, the ratio was 20:1 during 1975.

Planning has departed from earlier practices to assume greater risk in petroleum development decisionmaking. The reserves to be developed in category C_1 have been extended to include 80% to 85%, while those in category B have been reduced by a factor of 2.0 to 2.5. The share of reserves in the lowest category classed among commercial reserves, C_1, increased from 32.6% in January 1959 to 52.1% in January 1974.

During 1959–72, more detailed exploration confirmed only 61.5% of the reserves of category C_1, shifting them to categories A and B. The degree of confirmation of

reserves of category C_2 over most of the country is too low to meet standards of prospective planning and development. Only 40% of the crude oil reserves classified as category C_2, the lowest category, were transferred to category C_1 during 1959–72.

In support of the planned increase in crude oil output, more than 12 million meters of exploratory and developmental wells was drilled in 1976, an increase of 3.5% over that of 1975. The plan for drilling of developmental wells was overfulfilled 2.7%, but fell 5.8% short for exploratory drilling. Some 4,946 developmental wells and more than 900 exploratory wells were drilled in 1976. Despite these figures, 30% of the drilling enterprises did not meet planned targets in drilling. Especially poor performance was shown by units operating near the Caspian Sea and in Azerbaydzhan, Turkmenistan, Orenburg, Saratov, Belorussia, western Siberia, Mangyshlak Peninsula, and other associations. In 1976, geologists in Tyumen Oblast (western Siberia) failed to fulfill the plan for increasing proved reserves of oil. Transportation remained a basic problem, and there was a shortage of many kinds of equipment and materials.

The average depth of wells increased from 1,665 meters in 1970 to over 1,850 meters in 1976, and the drilling cost per well increased from 123,000 rubles to about 170,000 rubles for the same period.

The Soviet-Japanese agreement for joint exploration of offshore oilfields adjacent to Sakhalin Island added to exploration work and is to aid the U.S.S.R. in putting a significant exploration effort into offshore areas in the northern Barents and Kara Seas and the Sea of Okhotsk in the Soviet Far East.

Production.—In 1976, oil was produced in 26 regions, the most significant of which are located in the Volga-Urals area. Western Siberia was next, followed by the regions in the North Caucasus and Kazakhstan. Most of the U.S.S.R.'s increased production was, however, derived from the western Siberian fields, where about 182 million tons was produced in 1976. The Volga-Urals area is to maintain its leading position until the developing oilfields of western Siberia, Mangyshlak Peninsula, and Turkmenistan come onstream. Nineteen of the country's twenty-six oil-producing regions fulfilled the 1976 production goal. The Mangyshlak Peninsula, Turkmenistan, Ukraine, Caspian Sea, Belorussia, Lower Volga, and Azerbaydzhan oil-producing associations did not meet the 1976 production targets.

Among the oil-producing regions, western Siberia held the leading place, followed by Tatarstan, Bashkiria, Kuybyshev Oblast, Perm Oblast, and Mangyshlak Peninsula in Kazakhstan. In 1976, the increase in oil extraction amounted to 28.7 million tons. Oil extraction in western Siberia increased by 33.9 million tons and in Komi A.S.S.R. by 1.6 million tons.

There were over 140 oilfields in western Siberia on January 1, 1977, but only 21 fields were in operation in 1976. These included the Severo-Vareganskoye Lokosovskoye, Severo-Pokurskoye, Yuzhno-Surgatskoye, Yuzhno-Balykskoye, and Vakhskoye fields which were put into operation in 1976. Some 1,286 developmental wells were completed in western Siberia in 1976; this was 26.6% more than in 1975. Some 319.2 million cubic meters of water was injected in 1976, 60.8 million cubic meters more than in 1975. Especially intensive development took place at the Samotlor field, where 546, or 42.5%, of the total new western Siberian developmental wells were put into production. Oil extraction in western Siberia increased from 148 million tons in 1975 to about 182 million tons in 1976, an increase of 23%. The Samotlor oilfield in Tyumen Oblast, the largest oilfield in the U.S.S.R., accounted for 55% of the oil extracted in western Siberia. About 2,000 wells were producing at this field in 1976. The Fëdorov field was the second largest in western Siberia in 1976.

In the Volga-Urals area, the so-called Second Baku, output was concentrated in Tatarstan, Bashkiria, and Kuybyshev Oblast. For 7 years, Tatarstan, where the basic oilfields have entered the late stage of their development, has maintained an annual extraction level of 100 million tons. In 1976, 1,075 developmental wells were put into operation. The Romashkino oilfield is the largest in this Republic. Exploitation of the Kalauzhskoye oilfield began in May. Bashkiria produced about 40 million tons of crude oil in 1976.

Komi A.S.S.R.'s crude output increased from 7.1 million tons in 1975 to 8.7 million tons in 1976, an increase of 23%. Some 70

developmental wells were drilled in this Republic in 1976. In Azerbaydzhan, extraction of crude oil has been declining at onshore and offshore fields for the past several years.

Offshore oil extraction began in 1949 in the area of Neftyanyye Kamni (Oil Stones) in Azerbaydzhan. The fields are 20 to 25 kilometers from the coast and accounted for about two-thirds of the total output of Azerbaydzhan in 1976. Although the cost of developing offshore fields was considerably higher than that for onshore fields, the production cost was 30% to 35% below that of onshore fields because of the greater average yield. About 2,000 developmental wells have been drilled from steel trestles, which extend more than 200 kilometers from shore. Until 1976, drilling platforms were installed at a water depth of 10 to 30 meters, but construction of platforms at greater depths has since been undertaken.

Oil was also produced from several offshore wells in Turkmenistan, where several oilfields have been found. Development of the Zhdanov and Lam fields in Turkmenistan continued in 1976. It is expected that the offshore oilfields of Azerbaydzhan and Turkmenistan will merge in the Caspian Sea in the future.

During 1971–76, about 900,000 meters was drilled offshore Azerbaydzhan. The average depth of wells was steadily increasing, and by the end of 1976, it was to exceed 5,000 meters. According to Soviet calculations, 60% to 65% of the predicted reserves of oil and gas in Azerbaydzhan are to be found offshore. To make full use of these reserves, however, the U.S.S.R. would have to use new techniques and practices.

A floating drilling rig, the *Kaspiy,* designed in Baku and built at the Krasnye Barrikady shipyard in Astrakhan, became operational in the Caspian Sea in October 1974. It is capable of drilling a 6,000-meter well in water depths up to 60 meters. The *Kaspiy* is the first of 10 such rigs to be constructed during 1970–80. The second rig of this series, the *Baku,* with similar capabilities, was activated in summer of 1975. The third rig, the *60 Years of October,* was under construction in 1976 and was scheduled for completion in 1977. According to Soviet sources, this rig, being built in Astrakhan, will drill wells up to 6,000 meters deep in water up to 75 meters deep.

The Ministry of the Oil Industry set up a new organization, the Administration for Exploratory Drilling from Floating Rigs, which has special responsibilities for operating the floating rigs. This administration will manage the *60 Years of October* and future floating rigs as they are completed.

Soviet offshore oil production has thus far been concentrated in the shallow waters of the Caspian Sea. Deep offshore drilling was limited by the available equipment. The U.S.S.R.'s lack of floating rigs caused the Soviets to accelerate fabrication of fixed platforms in water 15 to 20 meters deep. The largest platform was designed for use in 80 meters of water.

Reportedly, Armco Steel Corp. of the United States and Rauma-Repola Oy of Finland have signed an agreement to build a $40 million semisubmersible oil-drilling vessel for the U.S.S.R. The ship will be used for offshore oil drilling in the Caspian Sea. The U.S.S.R. is shopping in the West for several plants to manufacture fixed platforms for offshore oil production, movable drilling rigs, and subsea production equipment.

Refining.—Direct information pertinent to refining and utilization of petroleum products is classified as a State secret and is not available. Indirect information indicates, however, that for many years, Soviet practices in dewatering, desalting, and crude stabilization have lagged behind the technical level of other countries.

The Soviet oil supply chain follows the oilfield-pipeline-refinery pattern. Water and other impurities in the crude, amounting to several million tons, cause difficulties and affect the performance of refineries. Water content in the crude received by Soviet refineries reached 1% to 2%, with 300 to 3,600 milligrams of chloride salts per liter, compared with a norm of 0.2% water and 40 milligrams of salt per liter.

As a result of inadequate pretreatment of crude in the oilfields, according to Soviet sources, refinery consumption and losses amount to 13.4%. The total losses incurred by refining insufficiently desalinated crude oil have been reported at more than 200 million rubles per year. Losses in storage and transportation to refineries of crude oil are estimated at 1.6%. Because of the high water and salt content, corro-

sion and wear of refinery equipment is greater.

Assuming a yield of 85% of the reported crude petroleum input because of the documented losses and quality factors mentioned, Soviet output of refined products in 1976 has been estimated at 352 million tons, 8 million tons over that of 1975. Available production and trade data indicate Soviet consumption of refined products in 1976 to be an estimated 315 million tons. Production of lower quality petroleum products, including low-octane gasoline and high-sulfur diesel fuel, continued in 1976.

The 1976–80 5-year plan envisaged a petroleum product output increase of 25% to 30% over that of 1975. In 1976, however, the planned goal was not achieved. Estimated refinery capacity at yearend totaled 395 million tons per year, an increase of 15 million tons over the 1975 level. Over 80 refineries were in operation in 1976.

With the participation of Western firms, the first stage of the Lisichansk oil refinery in the Donets Basin and new facilities at the Kremenchug (Ukraine) and Novo-Baku (Azerbaydzhan) refineries were put into operation in 1976. The following new oil refineries were under construction: Achinsk, Chardzhou, Chimkent, Lisichansk, Mažeikiai, Mozyr, Pavlodar, Tobolsk, Tomsk, Vinnitsa, and Zaporozhye. Modernization of the Novobaku Vladimir Il'ich oil refinery continued in 1976.

Transportation.—Some 85% of the total tonnage of crude oil and refinery products transported in the U.S.S.R. in 1976 was moved by pipeline. The remainder was delivered by rail. Because of incomplete construction of pipelines, about 15 million tons of crude was carried by rail routes paralleling pipelines. Product transportation by pipeline continued to be small. Crude oil and products represented about 15% of Soviet railroad freight traffic in 1976. The average distance of railroad deliveries in 1976 was 1,242 kilometers.

The total length of crude oil and petroleum product trunk pipelines in 1976 was 58,500 kilometers. Only about 70% of total pipeline capacity was utilized. The network of crude oil and petroleum product lines increased by an estimated 1,600 kilometers in 1976 and included the second stage of the Okha-Komsomol'sk pipeline, the Bulla-Baku underwater pipeline, and other crude oil pipelines. Construction began on two 1,200-millimeter-diameter pipelines in 1976: Surgut-Perm-Gor'kiy-Polotsk (3,900 kilometers long) and Omsk-Pavlodar-Chimkent (1,620 kilometers long). The Polotsk-Birzhai-Mazheykyay pipeline (442 kilometers long) was being constructed by Polish workers.

The Friendship pipeline, with a total length of 4,648 kilometers, crosses five countries. Through this pipeline the U.S.S.R. supplies crude oil to refineries at Plock in Poland and Schwedt in East Germany in the north and Százhalombatta in Hungary and Bratislava-Trnava in Czechoslovakia in the south. The Friendship pipeline branch to Klaipėda in Lithuania supplies oil for export to the Scandinavian countries. The Friendship No. 2 crude pipeline was under construction, scheduled for completion in 1977.

The growth of the estimated total length of crude oil and petroleum product trunk pipelines is shown, in thousand kilometers, in the following tabulation:

Year	Crude oil pipelines	Product pipelines	Total
1940	4.0	0.1	4.1
1945	4.0	.4	4.4
1950	4.5	.9	5.4
1955	8.4	2.0	10.4
1960	14.3	3.0	17.3
1965	23.2	5.0	28.2
1970	31.6	5.8	37.4
1975	48.6	8.3	56.9
1976	50.0	8.5	58.5

Pipeline construction in the U.S.S.R. lagged behind schedule, mainly because of a shortage of pipe. Thus far, only 75% of Soviet pipe requirements came from indigenous suppliers; during 1971–75, about one-half of the requirements for large-diameter pipe came from West Germany, Austria, Italy, Sweden, and Japan. Soviet steel pipe imports, mostly large-diameter sizes used for oil and gas lines, reached about 3 million tons in 1976, compared with 2.7 million tons in 1975. The largest foreign suppliers of pipe in 1976 were West Germany, Italy, Japan, Romania, and France. Much of the pipe imported from Western European countries will be paid for by long-term deliveries of Soviet natural gas.

A Soviet-Nigerian contract provides for the construction of two pipelines in Nigeria. The value of the contract is estimated at

$137.5 million. Delivery of the equipment is to be completed in the first half of 1977.

The supply of tankers is a key factor in the export of Soviet oil from Baltic and Black Sea ports to Western Europe. The U.S.S.R. attaches great importance to having its own tanker fleet. As of June 30, 1970, the tanker fleet (vessels in the 6,000-deadweight-ton and over class) consisted of 187 vessels totaling 4.3 million deadweight tons. In 1970, some 74 million tons of oil was carried by tankers, including 42 million tons in non-Soviet shipping. The 1971–75 plan called for increases of 50% in tanker tonnage and 65% in the tanker fleet cargo turnover. By 1980, Soviet tanker fleet tonnage may reach 9 million tons. These published data confirm Soviet intentions to increase oil exports to Western Europe in 1980 over those of 1975. The first large Soviet-built tankers, the 182,000-ton *Krym* and *Kuban,* successfully completed trial runs in the Black Sea in 1974–76. These tankers are 2.5 times larger than the *Sofiya*-type Soviet tankers. Two large tankers, *Kavkaz* and *Kuzbass,* were under construction in 1976.

Exports.—The U.S.S.R. became a net exporter of crude oil in 1951 and of petroleum products in 1954, and has gradually strengthened its position since that time. Crude oil exports increased from 0.9 million tons in 1951 to 93.1 million tons in 1975, and exports of petroleum products rose from 4.4 million tons in 1954 to 37.3 million tons in 1975. In 1976, exports of crude oil and petroleum products totaled 148.5 million tons (13.9% over those of 1975) and consisted of 110.8 million tons of crude oil (75%) and 37.7 million tons of petroleum products (25%). The U.S.S.R. exported more than 17% of its production in 1976.

Because of inadequate Soviet refining facilities, overall exports of crude oil are known to have risen far more rapidly than overall exports of products.

Crude oil and petroleum product exports from the U.S.S.R. to market economy countries rose from 52.6 million tons in 1975 to 64.5 million tons in 1976, an increase of about 23%. As usual, most of these exports were absorbed by Western European markets in 1976, where they serve to pay for imports of industrial goods. Italy imported 12 million tons of crude oil and petroleum products, emerging as the largest purchaser of Soviet oil in the West, followed by Finland and West Germany. Soviet oil exports to the United States and the United Kingdom more than doubled in 1976, but there was an actual decline in sales to the Netherlands and Sweden.

Crude oil and petroleum product exports to centrally planned economy countries increased 8% from 77.8 million tons in 1975 to 84 million tons in 1976 (including 77.6 million tons to CMEA nations). Czechoslovakia remained the largest importer of Soviet oil, followed by East Germany, Poland, Bulgaria, Cuba, Hungary, and Yugoslavia.

Exports of crude oil and petroleum products from the U.S.S.R. in 1973–76 are shown in table 8. The weighted average value of Soviet exports of crude oil and petroleum products for the period 1973–76 is given in table 9.

Imports.—Imports of crude oil (all from market economy countries in Africa and the Middle East) and petroleum products (mainly from Western Europe) increased from 4.6 million tons in 1970 to 14.7 million tons in 1973 and then decreased to 7.6 million tons in 1975 and 7.2 million tons in 1976.

Iraq and the U.S.S.R. have contracted for the delivery to the U.S.S.R. of crude oil produced at the first national oilfield in Iraq at northern Rumaila. This oilfield was equipped with the financial and technical assistance of the U.S.S.R. In accordance with the contract, Iraq was to deliver 1 million tons of crude oil in 1972 and 2 million tons per year in the subsequent 3 years. In 1976, delivery of crude oil from Iraq amounted to 5.8 million tons.

Soviet imports of petroleum are presented in table 10.

State Plans.—Crude oil extraction (including gas condensate) is slated to rise to 550 million tons in 1977, an increase of 30.3 million tons or 5.8% over that of 1976. Expansion of output will depend largely on development of the Samotlor and other oilfields in western Siberia. Output of crude in this region is to rise by 32.5 million tons to 214.5 million tons in 1977.

It is planned to drill 12 million meters of wells, put 4,700 new developmental oil wells into operation, and lay 4,000 kilometers of oil pipelines. About 2,000 kilometers is to be laid on the Kuybyshev-Lisichansk, Lisichansk-Kremenchug, and Snegirëvka-Odessa crude oil pipelines. Capital investment is to rise 2.3% over that of 1976, reaching 4.5 billion rubles. Facilities with the following capacities are among those to be commissioned during 1977, according to trade journals: Crude oil collection, 100 million tons and crude oil preparation, about 70 million tons; 37 pumping stations are to be commissioned. To maintain the formation pressure, water injection is to rise 9% over that of 1976, reaching 1,190 million to 1,200 million cubic meters.

The 1977 plan calls for a 4.5% increase in primary refining of crude. Because of insufficient capacities for secondary refining of petroleum, problems arose with respect to the production of certain types of light petroleum products.

Planned Soviet production of crude oil in 1977, by region, is as follows, in million tons: [29]

[28] Average prices given are f.o.b. foreign port or frontier.

The tenth 5-year plan envisages production of 620 million to 640 million tons of crude oil and gas condensate in 1980. The plan calls for the development of about 500 million tons of new capacity during the 1976–80 period; over two-thirds of this is to offset the decline in crude oil production at old fields, and about one-third (151 million tons) is to be available for a net growth in production. The average annual growth in crude oil extraction is to be increased to 30 million tons during the tenth 5-year plan.

A rapid increase in exploration and development of new oilfields and expedient application of the latest equipment and technology are the basic elements in the Soviet oil industry policy during the tenth 5-year plan. The central task of the oil-extracting industry during 1976–80 is to maintain the same level of output of crude oil in the Volga-Urals area and to bring about a great increase in oil extraction in western Siberia, Kazakhstan, Komi A.S.S.R., and Turkmenistan. The older and established petroleum regions of Azerbaydzhan, the North Caucasus, and Soviet Central Asia could not produce more petroleum than they produced in 1975.

The entire growth in oil production during the 1976–80 period is to be accounted for by the eastern regions of the country, particularly the fields in western Siberia and on Mangyshlak Peninsula, which are to provide about three-fourths of the 1976–80 production. Production of petroleum in western Siberia is slated to increase from 148 million tons in 1975 to 300 million to 310 million tons in 1980. In 1976–80, about 30 new oilfields are to be put into operation, and new capacities for collecting and preparing crude oil are to be built.

Development of large oil-producing regions calls for the construction of crude oil trunk pipelines. Completion of about 15,000 kilometers of crude oil and 3,500 kilometers of product pipelines is required for the 1976–80 period. This represents 33% of the total pipeline length built in all the years before 1976.

Refining of crude oil is to increase 25% to 30% in 1980 over that of 1975. One of the basic measures of the 1976–80 plan is construction and completion of combined enlarged units with an average primary distillation capacity of 6 million tons per year instead of 2 million to 3 million tons per year as earlier planned; an average catalytic reforming capacity of 0.6 million to 1 million tons, instead of 0.3 million tons; an average dewatering capacity of up to 2.6 million tons instead of 1.2 million tons; and an average coking capacity of 1.5 million tons instead of 0.6 million tons. It is planned to complete and enlarge the following refineries: Achinsk, Tobolsk, Tomsk, Lisichansk, Pavlodar, Mažeikiai, and Chardzhou. It is also planned to build the new large Nakhodka refinery during 1976–80.

The actual and planned growth in Soviet production of crude oil is shown in table 11.

Based on signed trade agreements and the latest Soviet forecasts, crude oil and petroleum product exports from the U.S.S.R. are expected to increase from 130.4 million tons in 1975 to 175 million tons in 1980. Exports to market economy countries will probably grow from 52.6 million tons in 1975 to 75 million tons in 1980.

Exports from the U.S.S.R. to other centrally planned economy countries will continue to grow, perhaps attaining 100 million tons per year by 1980. Deliveries of crude oil to CMEA countries increased from 138 million tons in 1966–70 to 228 million tons in 1971–75, about 94% of the planned goal of 243 million tons. The U.S.S.R. is to supply 364 million tons of crude oil to other CMEA countries during the 1976–80 period, 60% more than in the past 5 years. In light of Soviet moves to step up oil sales in the West to offset the cost of Western technology imports, it is possible that the U.S.S.R. will not deliver in 1976–80 all of the amounts of crude oil for which CMEA countries contracted. The Soviets are also facing a situation of tighter domestic petroleum supplies.

The 1975 price for Soviet crude oil deliveries to CMEA countries was set at a level about 130% above that charged during 1971–74. The price may rise by one-third in 1977, compared with the planned increase of 8% in 1976.

Exports of crude oil and petroleum products to European CMEA countries are shown in table 12.

The average growth of crude oil extraction in the western Siberian oilfields since exploitation began in 1969 was 23 million tons per year. In 1976, the Samotlor field accounted for 55% of the total annual production and the Fëdorov field accounted for 26%. Every year, more than 1,000 wells with an average depth of 2 to 2.5 kilometers are drilled in western Siberia. By 1980, there are to be about 40 developed oilfields in operation. In 1976, western Siberia produced 182 million tons. The planned target for 1977 is 214.5 million tons, which has good prospects for achievement. By 1980, this region is to produce 308 million tons of petroleum.

Soviet crude oil and petroleum products statistics are presented in table 13.

The Mineral Industry of the United Arab Emirates

By Candice Stevens [1]

On December 2, 1971, the United Arab Emirates officially became a sovereign Federal State comprising seven former Trucial Coast sheikdoms coexisting under a provisional constitution for an initial period of 5 years. On December 2, 1976, the seven emirates—Abu Dhabi, Ajman, Dubai, Fujairah, Ras al-Khaimah, Sharjah, and Umm al-Qaiwain—opted to extend the life of the provisional constitution for an additional 5 years. The drafting of a permanent constitution was thwarted by disagreement regarding the degree of central government authority over the individual emirates and the appropriate contribution of each emirate to the federal budget. Under the provisional charter, the emirates continued to maintain strict independence in oil policy and exercised individual control over internal budgets.

In 1976, the economy of the United Arab Emirates remained almost entirely dependent on the petroleum industry which contributed more than 95% of total Government revenue. Petroleum income of the three oil-producing emirates—Abu Dhabi, Dubai, and Sharjah—amounted to $5.6 billion,[2] a 17% increase over 1975 earnings. The development program for 1976 prepared by the United Arab Emirates Ministry of Trade and Economy calculated overall expenditures in the emirates at $5.68 billion. The largest allocation of $1.7 billion was for various development projects, followed by $1.5 billion in general expenditures. Foreign aid comprised $1.2 billion of the United Arab Emirates expenditure. This was channelled primarily through the Abu Dhabi Fund for Arab Economic Development (AFAED), established in July 1971 to aid other Arab countries through loans, grants, or direct participation in projects. The 1976 federal budget of the United Arab Emirates was $1.2 billion of which approximately 95% was contributed by Abu Dhabi.

Both Abu Dhabi and Dubai, the largest oil producers and the wealthiest of the emirates, were to use their petrodollars in the construction of complete industrial cities. In 1976, Dubai awarded various design and construction contracts for the free zone city of Jebel Ali, situated about 17 kilometers from the city of Dubai. Among the projects envisaged for the area were an aluminum smelter, a natural gas liquefaction facility, a steel plant, a fertilizer plant, a petroleum refinery, and a deepwater port. In Abu Dhabi, the Arthur D. Little Co. (United States) completed a feasibility study for the industrialization of Ruweis, situated 160 kilometers to the west of the city of Abu Dhabi near the crude loading facility at Jebel Dhanna. The essential elements in this scheme, apart from a new port and airport, would be a natural gas liquefaction facility, a petroleum refinery, an ammonia/urea plant, an iron and steel pelletization plant, and a petrochemical complex.

A geological survey completed in 1976 for the Ministry of Petroleum and Natural Resources by Hunting Geology and Geophysics Ltd. (United Kingdom) [3] in-

[1] Economist, International Data and Analysis.
[2] Where necessary, values have been converted from United Arab Emirates dirhams (UAED) to U.S. dollars at the rate of UAED3.94 = US$1.00.
[3] Hunting Geology and Geophysics, Ltd. Geological Survey of the United Arab Emirates Northern Emirates. London, 1976, 88 pages.

dicated important zones of copper and chromite mineralization. The survey, which covered 11,500 square kilometers of the northern emirates, also identified potential commercial deposits of industrial minerals, including gypsum, talc, dolomite, and salt. Priority areas scheduled for further investigation were two copper occurrences, one south of Wadi Ham and the other on Fujairah's east coast, and the chromite deposits at Manama, Shawkah, and Siji.

PRODUCTION

Petroleum production increased approximately 16% from 1,663,800 barrels per day in 1975 to 1,936,400 barrels per day in 1976. Abu Dhabi remained the largest producer with output increasing 14% to nearly 1.6 million barrels per day. The other two producing emirates were Dubai (313,400 barrels per day) and Sharjah (37,000 barrels per day). Reserves in the three emirates were estimated at 31.2 billion barrels. Exploration continued both onshore and offshore and showed considerable promise in the producing emirates as well as Fujairah and Ras al-Khaimah.

At the December 1976 meeting of the Organization of Petroleum Exporting Countries (OPEC), Abu Dhabi followed Saudi Arabia in adopting the minority 5% increase in the price of oil exported. Dubai and Sharjah, although not members of OPEC, similarly increased their crude prices by 5%. No decision was reached concerning the price of exports from the El Bunduq Field, which was shared equally by Abu Dhabi and Qatar. Abu Dhabi ordered no major increase in oil output other than a previously planned alteration in the production ceiling for its offshore fields to meet natural gas requirements.

Marketed gas production in 1976 was approximately 1.2 billion cubic meters in Abu Dhabi and 0.8 billion cubic meters in Dubai. Gas reserves in Abu Dhabi, Dubai, and Sharjah were estimated at 637 billion cubic meters. The only other mineral commodity produced in quantity in 1976 was cement for use by local construction industries.

Table 1.—United Arab Emirates: [1] Production of mineral commodities [2]

Emirate, commodity and unit of measure	1974	1975	1976 [p]

[e] Estimate. [p] Preliminary. [r] Revised. NA Not available.

[1] In addition to the emirates listed, there are three others: Fujairah, Ras al-Khaimah, and Umm al-Qaiwain; these record no mineral production but presumably produce small quantities of crude construction materials.

[2] In addition to the commodities listed, crude construction materials such as common clays, stone, sand, and gravel presumably are produced, but output is not recorded quantitatively and general information is inadequate for formulation of reliable estimates of output levels.

[3] Includes gas reinjected to reservoirs, if any.

[4] No marked production reported; there probably is some small field use.

TRADE

Mineral trade consisted primarily of crude oil exports and imports of refined petroleum products and construction materials. The primary recipients of the United Arab Emirates' oil exports continued to be Japan, France, the United Kingdom, the United States, and the Federal Republic of Germany. Although the United Arab Emirates imported goods from 85 or more countries in 1976, the vast bulk of imports emanated from Western Europe, Japan, and the United States. During 1976, the United Arab Emirates imported approximately 9 million barrels of processed petroleum products from Iran, Kuwait, and other Persian Gulf countries. The imported products consisted of fuel oil (5,545,000 barrels), motor gasoline (1,900,000 barrels), jet fuel (1,455,000 barrels), and kerosine (135,000 barrels).

Increased congestion at the United Arab Emirates' terminals was to be relieved by the expansion of existing facilities and the construction of six new ports. In Abu Dhabi, tenders were issued for the extension of port facilities at Mina Zayed by the addition of five deepwater berths. A construction contract was also awarded to the South Korean Dong Ah Construction Ind. Co., Ltd., for the construction of a complete new port alongside Mina Zayed. The project, estimated to cost $609 million, was to consist of 34 general cargo berths with container facilities. Another deepwater port comprised of 12 general cargo berths was planned for the industrial city of Ruweis.

In Dubai, a $210 million contract was awarded to Costain-Taylor Woodrow (United Kingdom) for the extension of Port Rashid, Dubai's artificial deepwater harbor completed in 1972. The agreement provided for over 5 kilometers of breakwaters, 22 new cargo berths, transit sheds, and other port facilities. The construction of the Dubai drydock complex, also by Costain-Taylor Woodrow under the direction of Sir William Halcrow and Partners, continued on schedule. The largest dock of 525 meters was to accommodate tankers of 1 million deadweight tons, while three smaller docks would have 500,000- or 350,000-deadweight-ton capacities. A deepwater port planned for Jebel Ali, the new free zone industrial area, was expected to be one of the largest in the gulf at its completion in 1980. The port design provided for 74 berths, accommodating ships up to 90,000 deadweight tons laden and 150,000 deadweight tons unladen. Dredging of the ports was to be carried out by Gulf Cobla, a joint venture of Costain-Blankevoort International Dredging and Dubai Transport; the construction of breakwaters and other civil engineering work was to be handled by Balfour Beatty Construction and Al Futtaim-Wimpey.

In Sharjah, an intermodal transportation system, "Sharjahport," was to comprise specialized container terminals at two ports linked to a fully containerized airport handling facility. The first two container berths in the gulf were completed at Port Khalid in August 1976. The contractors—Archirodon S.A. (Greece), Hochtief AG (West Germany), and Six Construct (Belgium)—were to provide five additional general cargo berths. A second deepwater port was under construction at Khor Fakkan on the east coast to provide transoceanic container ships an alternative to passing through the congested Straits of Hormuz. Both ports were to be managed by Seatrain Gulf S.A., a subsidiary of the U.S. container and shipping company, Seatrain Lines Inc.

Umm al-Qaiwain also contracted for port expansion in 1976. The construction of a 300-meter-long pier and a deepening of the main port to 7.5 meters was to be completed in May 1977. In Ras al-Khaimah, construction began on the Khor Kuwait deepwater port by Contracting and Trading Co. (CAT) of Lebanon and Archirodon S.A.

COMMODITY REVIEW

METALS

Aluminum.—Plans were finalized for the construction of the aluminum smelter in Jebel Ali by the Dubai Aluminium Co. (DUBAL), owned 80% by the Dubai Government, 7.5% by Southwire Aluminum Co. (United States), 7.5% by Nissho-Iwai Co., Ltd. (Japan), and 5% by various local interests. Financing for the

$500 million smelter was to be managed in large part by Morgan Grenfall & Co. and Lloyds Bank International, both of the United Kingdom. The smelter was to commence production in 1979 with an initial output of 20,000 tons per year rising to 135,000 tons per year by 1981. British Smelter Construction Ltd. (BSCL) was contracted for construction work and John Brown Engineering Gas Turbines Ltd. (United Kingdom) was to supply gas turbine generators and associated equipment. Power requirements were estimated at 60 million cubic feet per day of natural gas from Dubai's offshore Fateh Field. Southwire and Nissho-Iwai signed 12-year contracts to purchase 80% of the smelter's output with the balance to go to local industries including a 3,000-ton-per-year extrusion plant also to be constructed by BSCL.

Iron and Steel.—A direct reduction steel mill was planned for the new industrial city at Ruweis in Abu Dhabi. The plant, which was scheduled for completion in 1980, would have an initial capacity of 400,000 tons per year; design plans also provided for the construction of a second unit of the same capacity to be completed in an additional 4 years. The Abu Dhabi Government and Kobe Steel, Ltd. (Japan), concluded an investment sharing agreement, which provided for Abu Dhabi to cover 70% of the $200 million construction cost and Kobe Steel to provide the balance of the financing. However, this agreement was negated at yearend 1976, and the project was opened to bids from other potential foreign partners.

NONMETALS

Cement.—To meet heavy demands from the United Arab Emirates construction industries, expansion programs were planned at existing cement plants and four new facilities were in various stages of development. In Abu Dhabi, the Al Ain cement plant, which went onstream in May 1976 with a 600-ton-per-day capacity, was scheduled for an increase in output. The plant was constructed by Ishikawajima-Harima Heavy Industries Co., Ltd. (IHI), at a total cost of $30.4 million. The Ittihad Cement Co., operators of the Al Ain facility, contracted for a second cement plant by IHI. The $68.3 million plant, due for completion in 1979, was to produce 1,500 tons of cement per day.

The construction of the Dubai national cement plant by Costain Civil Engineering (United Kingdom) continued on schedule with startup planned for mid-1978. During the year, Dubai awarded Costain an additional $12 million contract for the installation of various types of equipment to be designed and supplied by F.L. Smidth (United Kingdom).

In Ras al-Khaimah, construction was in progress for doubling the capacity of the Union Cement Co. plant by the addition of a duplicate kiln. The plant, which was under the management of Norcem Co. of Norway, was to produce 1,400 tons of portland cement per day by yearend 1977. The construction of a second cement plant with a 700-ton-per-day capacity was to begin in January 1977. The plant was to be built by Mothercat Ltd. (United Kingdom and Lebanon) at a cost of $20 million and to be completed in 1978.

In Sharjah, a 700-ton-per-day cement plant was due to come onstream in 1977. Construction of the $25 million plant was by Six Construct of Belgium, with management to be provided by Associated Portland Cement.

Fertilizer Materials.—The Abu Dhabi National Oil Co. (ADNOC) commissioned Snam Progetti, a subsidiary of Ente Nazionale Idrocarburi (ENI), to undertake a feasibility study of a fertilizer complex for the Ruweis industrial area. The plant, which would use natural gas from Abu Dhabi's onshore fields as feedstock, was to produce 2,000 tons of ammonia and 1,500 tons of urea daily. The feasibility study was to include an analysis of the world fertilizer market and an appraisal of necessary infrastructure. Abu Dhabi also entered into negotiations with the Indian Government concerning a joint venture for the construction of a second fertilizer plant to supply Indian markets.

MINERAL FUELS

Energy.—Of the 1976 federal budget, $83 million was applied to the execution of electric power projects undertaken by the Ministry of Electricity and Water. A number of mobile diesel generators and 33 other electric power units, representing an overall power potential of 45.3 megawatts,

were to be imported, assembled, and distributed throughout the emirates. In addition, Abu Dhabi planned the installation of four generating facilities at Umm al Nar with a total capacity of 240 megawatts, a large electric generating plant at Port Zayed with an output of 1,400 megawatts, and three electric generators at Al Ain raising the capacity of that power station to 120 megawatts. Other electric power projects scheduled for 1977 were the construction of three thermal power units of 60 megawatts capacity at Jebel Ali, Dubai, by Mitsubishi Heavy Industries, Ltd. (Japan); a 50-megawatt power station in Ras al-Khaimah by Kier International (United Kingdom); and an electric powerplant in Umm al-Qaiwain with a total capacity of 15 megawatts. These projects would make a combined addition of 2,030 megawatts to the installed generating capacity of the United Arab Emirates.

Natural Gas.—In March 1976, Abu Dhabi formally nationalized its natural gas reserves. From that date, all gas reserves discovered in Abu Dhabi, both associated and nonassociated with oil, together with all gas produced from oil and gas wells, were to be the exclusive property of the State. The decree also provided for ADNOC to have all rights to gas exploitation, either alone or in joint ventures where ADNOC retained a minimum 51% shareholding.

Startup of the Das Island natural gas facility under construction by the Abu Dhabi Gas Liquefaction Co. Ltd. (ADGLIC) was delayed until mid-year 1977. Designed to utilize 550 million cubic feet per day of associated gas from the offshore Umm Shaif, Zakum, and El Bunduq Fields, the plant was to produce 15 million barrels of liquefied natural gas (LNG), 5.6 million barrels of liquefied petroleum gas (LPG), 1.5 million barrels of light distillate, and 1.6 million barrels of pelletized sulfur per year. The entire production of LNG and LPG was earmarked for the Tokyo Electric Power Inc. which concluded a new agreement with Abu Dhabi during the year. The two parties agreed to relate the price of LNG to the landed price of crude oil imported into Japan with full equivalence achieved in stages over the course of 3 years. Under the original supply contract signed in 1972, the price for delivery of LNG was set at $1 per million Btu; the new formula provided for an initial price of $2 per million Btu. The new arrangements were expected to increase revenues from deliveries to Tokyo Electric Power from $2 to $6 billion over the 20-year contract period.

Negotiations continued between ADNOC and the foreign partners in the Abu Dhabi Petroleum Co. (ADPC) regarding the scheme to process associated gas from Abu Dhabi's onshore fields. It was estimated that up to 185,000 barrels per day of natural gas liquids could be extracted from associated gas from the Bab, Bu Hasa, and Asab oilfields. In April 1976, ADPC signed an agreement with the Government to form a company on a 60/40 basis with ADNOC having the same 60% shareholding as in ADPC. With borrowed funds accounting for 75% of the capital for the project, the foreign companies would be obligated to contribute 10% of the equity. However, at yearend, the Abu Dhabi Government and the companies concerned, which included British Petroleum Co., Ltd. (BP), Compagnie Française des Pétroles (CFP), Shell International Petroleum Co., Ltd., Exxon Corp., and Mobil Oil Corp., had not completed the details of the financing arrangement.

In Dubai, plans were being concluded for the construction of a $120 million gas processing plant at Jebel Ali. Sunningdale Oils Ltd. of Canada was to construct the plant and market all output, expected to total 4 million barrels per year of natural gas liquids.

Table 2.—Oilfields of the United Arab Emirates in 1976

Location	Oilfield and discovery date	Company	Date of first production	Rate of production (average barrels per day)	Gravity (°API)	Sulfur content (percent)

Petroleum.— *Abu Dhabi.*—In 1976, the Government-owned ADNOC maintained its 60% participation in major oil operation and announced it would assume full responsibility for developing new offshore oilfields. ADNOC scheduled a change in offshore production ceilings which were first imposed in 1974 for conservation purposes. Allowable output for the offshore fields operated by Abu Dhabi Marine Areas, Ltd. (ADMA) was to rise progressively quarter by quarter through 1977 to reach 580,000 barrels per day in the last quarter as compared with 450,000 barrels per day in 1976. The additional output was intended to provide sufficient associated gas to feed the gas liquefaction plant under construction on Das Island. Allowable output for the onshore fields operated by the ADPC was to remain at the 1976 level of 1,035,000 barrels per day.

ADNOC once again concluded new marketing arrangements with its operating oil companies for the coming year. In 1976, the production split was 40% equity, 30% buyback, and 30% State crude oil; in 1977, equity was to remain at 40%, but buyback was to be cut to 20%, with ADNOC increasing its offtake to 40% of crude oil production. In addition, buyback arrangements were to be converted to regular commercial deals with each equity holding company under those contractual terms applicable to other direct sale customers. ADNOC's emphasis in crude oil sales was on long-term contracts of 4 to 5 years duration and on the sale of oil on a delivered basis in an attempt to secure employment for its two tankers, the *al-Dhafra* and the *al-Dalma*. One agreement was concluded with Japan's Idemitsu Petrochemical Company Limited for the purchase of 20,000 barrels of crude oil per day in early 1977 increasing to 60,000 barrels per day by the end of the 5-year contract period, with provisions for cooperation in the tanker business. Overall, ADNOC's sale of crude oil to Japanese refiners was expected to double in 1977 to 160,000 barrels per day, as negotiations continued with other Japanese buyers, including Japan Line Ltd., Mitsubishi Oil Co., Ltd., Showa Oil Co., Ltd., and C. Itoh & Co., Ltd.

Onshore, ADPC continued development drilling and water injection programs designed to raise production capacity in its four fields to 1.4 million barrels per day by yearend 1978. Production from the Bab, Bu Hasa, and Asab Fields was supplemented by a 10,000-barrel-per-day flow from the new Sahil Field to raise total output to 1,020,000 barrels per day in 1976. The fields were spread over a wide area approximately 200 kilometers from the city of Abu Dhabi and were linked by pipeline to the loading facilities at Jebel Dhanna.

Offshore, a total of 11 rigs were engaged in the ADMA concession, drilling new injection and production wells, maintaining existing wells, and continuing delineation and exploration. In 1976, the Umm Shaif and Zakum Fields averaged 450,000 barrels per day, a 6% increase over the 1975 level. Additional production in 1977 was to come entirely from the Umm Shaif Field, the site of an extensive water injection scheme intended to raise output from 200,000 to 330,000 barrels per day. The new supercomplex, which comprised an oil and gas production plant in addition to water injection facilities, was built under the supervision of BP at a cost of $110 million. A similar water injection scheme was planned for the neighboring Zakum Field and was expected to come into operation within 2 years.

Abu Dhabi's four other offshore oilfields were in various stages of development in 1976. The Abu Al Bu Koosh Field, operated by a consortium including Sunningdale Oils Ltd., and Amerada Hess Corp., evidenced a 17.5% increase in output from 66,000 barrels per day in 1975 to nearly 80,000 barrels per day in 1976. Production at the smaller Mubarraz Field, operated by the Japanese consortium Abu Dhabi Oil Co., Ltd. (ADOC), remained at the 1975 level of 20,000 barrels per day. The El Bunduq Field, owned jointly by BP, CFP, and United Petroleum Development of Japan, was inaugurated in February 1976 at an initial rate of 20,000 barrels per day due to rise to 30,000 barrels per day in early 1977. Four wells were completed in the Amerada Hess group's Arzanah Field with commercial production to begin in mid-1977. The group first tested the 1973 discovery at a rate of 4,000 barrels per day of 45°API gravity, 1.0% sulfur crude oil.

In 1976, ADNOC entered into a 50/50 joint venture with CFP to develop two offshore oilfields originally discovered by ADMA. The Saath al-Razboot Field, situated about 130 kilometers off Abu

Dhabi, was to begin production in 1979 at a rate of 100,000 barrels per day expected to decline after a few years to 80,000 barrels per day. The Upper Zakum Field, which was to remain under ADMA operation until 1978, was to reach a production level of 500,000 barrels per day within 6 to 8 years. A new terminal to be built 61 kilometers east of Zakum Field on Zirka Island would handle crude from the two fields.

ADNOC's 15,000-barrel-per-day refinery at Umm al-Nar Island came onstream in May 1976. Constructed by Kellogg Company (United States) at a cost of $35 million, the refinery processed crude pumped through a 120-kilometer pipeline from Abu Dhabi's onshore fields. Plans were being considered for the expansion of capacity to 50,000 barrels per day.

Bids were invited for the construction of a second refinery in the Ruweis industrial zone. The preliminary feasibility study and market survey for the refinery was completed during the year by the French group BEICIP. Production of the refinery, which was to rise from an initial 120,000 to 240,000 barrels per day, was to include fuels, oil, asphalt, and other products to meet the United Arab Emirates domestic demand. It was estimated that the refinery would require 3½ years for completion at a cost of $500 million.

Ajman.—No exploration activity was reported in 1976 by Occidental Petroleum Corp., the only concession holder in Ajman's offshore.

Dubai.—Development drilling continued throughout 1976 in the offshore Fateh and Southwest Fateh Fields owned by the Dubai Petroleum Co. (DPC). At the beginning of the year, the Fateh Field Mishrif water injection plant was brought up to design output and was injecting approximately 250,000 barrels of water per day. A water injection scheme in the Southwest Fateh Field was in partial operation in late 1976 and was scheduled for completion in 1977. The two fields, linked by a 16-kilometer pipeline, averaged 315,000 barrels of crude per day in 1976, a 20% increase over the 1975 level. Delineation drilling was planned for the Rashid discovery area, about 24 kilometers south of Fateh, which previously tested oil and gas in significant quantities.

The 1 Falah well, situated 24 kilometers west of the Fateh Field, was drilled by DPC at yearend 1976. The dual zone discovery was completed at 9,630 feet and yielded a 2,500-barrel-per-day combined flow. The upper zone at 8,000 feet tested 25.4° API gravity oil and the lower zone at 8,760 feet yielded 47.1° API gravity oil. The well was drilled by a Rowan International rig which was to drill another prospect in DPC's 3,360-square-kilometer concession area in 1977.

Fujairah.—Reserve Oil and Gas Co. (United States), which held a 1,500-square-kilometer concession in the Gulf of Oman, was to resume exploratory drilling after a hiatus of many years. The NBR–1 was to be drilled in 300 feet of water approximately 18 kilometers off Fujairah's east coast.

Ras al-Khaimah.—Deutsche Schactbau und Tiefbohrgesellschaft (Federal Republic of Germany) replaced Vitol Exploration B.V. (Netherlands) as the operator for a multinational exploration group in a 2,330-square-kilometer offshore concession area. In 1976, the 1 R.A.K. wildcat drilled 37 kilometers offshore, tested 4,000 barrels per day from two zones. The Government agreed to take a 50% working interest in a venture to exploit the discovery, which lies between Sharjah's Mubarek Field and the Henjan discovery in Iranian waters. The group planned to spud a second wildcat 24 kilometers to the northeast at yearend.

Onshore, Norsk Hydro A/S relinquished its 1,700-square-kilometer concession after a 3-month seismic program proved unsuccessful.

Sharjah.—The rewards from Sharjah's oil operation have been small compared with Abu Dhabi and Dubai owing to the need for revenue sharing and difficult working conditions that caused a decline in production in 1976. An agreed formula provided for oil revenue from the offshore Mubarek Field to be divided among Iran, Umm al-Qaiwain, and Sharjah (which received 35%). The field, which came into production in July 1974, was scheduled to attain an output of 60,000 barrels per day. However, technical difficulties caused by the depth of the reservoir and other geological features have kept production at a maximum of 38,860 barrels per day (1975), which declined to 37,500 barrels per day

in 1976. Output was sold directly to the shareholders in the Crescent Petroleum Co., with the major part of production marketed in the United States and Japan.

During 1976, Crescent Petroleum relinquished a quarter of its 2,000-square-kilometer concession area around Abu Musa Island to Houston Oil and Minerals (United States), which completed seismic studies and was expected to commence drilling in 1977. The only other concession offshore was held by Reserve Oil and Gas Co., who was also planning to start exploratory drilling in 1977.

Onshore, Crystal Oil Co. relinquished its 1,400-square-kilometer concession area in western Sharjah owing to high drilling costs. Exploration rights in this area were acquired by Pinnacle Gas and Oil/Nicklos Drilling (United States). The agreement provided for the first well to be drilled within 10 months with the two companies investing $12 million in the first 3 years of prospecting and drilling to depths of not less than 16,000 feet. In the event of a commercial discovery, Sharjah was to receive 55% of oil revenues and 16.65% of duties on oil and gas, with the right to 60% partnership in the company within 3 months of the discovery.

Umm al-Qaiwain.—Exploration continued in 1976 offshore by both the Umm al-Qaiwain Oil Group, with Zapata Exploration Co. (United States) as operator, and United Refining Co. Occidental Petroleum retained its claim to its offshore concession area but no activity was reported. Onshore, Houston Oil and Minerals was awarded the entire land concession area during the year.

The Mineral Industry of the United Kingdom

By William F. Keyes [1]

Although 1976 saw a recovery from the previous year's recession, the British economy remained sluggish. Gross national product, which was about $196 billion,[2] increased only 1.2% in real terms; however, there was another large deficit in the current account and a substantial depreciation in the pound sterling. Late in 1976, the Chancellor of the Exchequer announced a series of fiscal policies, monetary targets, and measures dealing with employment and investment (including a 1-billion-pound cut in public spending), increases in excise taxes, and limits on credit expansion. This was the second round of such measures in the same year.

Although there was an increase of 10% in steel production, the industry was still working below capacity. A new tin mine started operating in Cornwall, and interest in several tungsten prospects was intense. The potash mine continued to strive to meet production goals, and chances of a second potash mine opening were improved by a change of ownership of a leading prospect.

The extractive industries in the United Kingdom consisted largely of fuel producers in 1976. Natural gas from the North Sea supplied all the country's needs, and petroleum production, also from the North Sea, was increasing rapidly; these North Sea sources should make the United Kingdom self-sufficient in energy in the 1980's. Coal was the only solid mineral mined in large tonnages in 1976, although moderate amounts of other metalliferous and nonmetallic ores were also produced, as were sufficient amounts of the ubiquitous construction materials.

As of March 1976, aid amounting to 1.46 million pounds had been granted by the Department of Industry under the Mineral Exploration and Investment Grants Act for 1972; however, the amount actually disbursed by 1977 was only about 740,000 pounds. Thirty-two companies with 126 projects had been granted assistance; 12 of these grants were made in the fiscal year ending March 31, 1976, including 5 for fluorspar, 1 for barite, and 6 for nonferrous metals.

The Government did not take action in 1976 to implement the Stevens Report, which had been completed the previous year (see 1975 Minerals Yearbook), and which recommended improvements in Government control of mining operations.

PRODUCTION

Coal production declined, but overall hydrocarbon production continued upward; consequently, from 1975 to 1976, the index of mining and quarrying production increased about 4%, from 86.0 to 89.2 (1970=100). The index of metal production increased over 8%, from 78.6 to 85.3; the increase stemmed mainly from a 10% increase in steel production.

[1] Supervisory physical scientist, International Data and Analysis.

[2] The average exchange rate in 1976 of the United Kingdom pound (UK£) in relation to the U.S. dollar was UK£1.00=US$1.80.

Coal production should increase as the effects of an ongoing modernization plan become visible. The start of the approaching great buildup in North Sea oil production was clearly seen, as output soared to almost 10 times that of 1975. Natural gas production increased 9%.

The major mineral and metal producers in the United Kingdom in 1976 are listed in the following tabulation:

Commodity	Major companies, principal facilities, and ownership	Percent of domestic output
Aluminum	British Aluminium Co. Ltd., smelters at Invergordon, Fort William, and Kinlochleven	39
Do	Alcan (U.K.) Ltd., smelter at Lynemouth, Alcan (Canada)	33
Do	Anglesey Aluminium Ltd., smelter at Holyhead, Kaiser Aluminum & Chemical Corp. and Rio Tinto-Zinc Corp. Ltd. (RTZ)	28
Cement	Associated Portland Cement Co. Manufacturers Ltd., plants at Northfleet, Hope and Dunbar	70
Do	Rugby Portland Cement Co. Ltd., plants at Rugby, Barrington, and Southampton	12
Do	Tunnel Holdings Ltd., plants at West Thurrock, Pitstone, and Padeswood	11
Coal	National Coal Board (NCB), mines in south Scotland, Durham, Midlands, and south Wales, Government	100
Copper	British Copper Refiners Ltd., refinery at Liverpool	50
Do	IMI Refiners Ltd., refinery at Birmingham	20
Ferroalloys	British Steel Corporation (BSC), plant at Workington, Cumberland, Government	80
Fluorspar	Laporte Industries Ltd., mines near Eyam, Derbyshire	60
Iron ore	BSC, mines in Lincolnshire and Northamptonshire, Government	100
Lead	Britannia Lead Co. Ltd., refinery at Gravesend, Mt. Isa, Australia	70
Natural gas	British Petroleum Ltd. (BP), Shell U.K. Ltd., Esso U.K. Ltd., Amoco (UK) Ltd., Phillips Petroleum U.K. Ltd., and Gulf Oil (Great Britain) Ltd., in North Sea fields	100
Nickel	Inco Europe Ltd., plant at Clydach, Wales, Inco Ltd. (Canada)	100
Petroleum, crude	BP, Forties Field, North Sea	60
Do	Hamilton Brothers Oil and Gas Ltd., RTZ, and Texaco Ltd., Argyll Field, North Sea	40
Petroleum, refined	BP, Isle of Grain, Grangemouth, Llandarey, and Belfast	21
Do	Esso Petroleum Co. Ltd., Fawley, Milford Haven	22
Do	Shell, Stanlow, Shellhaven, and Teesport	24
Potash	Cleveland Potash Ltd., mine at Boulby, ICI Ltd., Charter Consolidated (North Sea Explorations) Ltd	100
Steel	BSC, mills at south Wales, Scunthorpe, south Teesside, and Motherwell, Government	90
Tin ore	Geevor Tin Mines Ltd., mine at Geevor	25
Do	St. Piran Ltd., mine at South Crofty	35
Do	Wheal Jane Ltd., mine at Truro, Consolidated Gold Fields Limited	38
Do	Cornwall Tin and Mining Ltd., Mt. Wellington mine at Truro, Excomm (United States), start 1976	--
Zinc	Commonwealth Smelting Ltd., smelter at Avonmouth, RTZ	100

e Estimate. p Preliminary. r Revised. NA Not available.

[1] Includes antimony content of antimonial lead and antimony compounds.

[2] Less than ½ unit.

[3] Includes wheels, centers, tires, and axles, and semimanufactures for sale.

[4] Lead refined from imported bullion.

[5] Lead refined from scrap materials and domestic ores.

[6] Year ending May 31 of that stated.

[7] Excludes plaster.

[8] Consists of bricks, retorts, molds, and other refractory products made from clays, silica, siliceous material, magnesite, alumina, and chrome materials.

[9] Gas made at gasworks plus purchased coke-oven refinery gas.

TRADE

The value of United Kingdom trade increased 29% in 1976, to total values of 31.1 billion pounds for imports and 25 billion pounds for exports. Crude minerals and ores represented 878 million pounds (2.8%) of the imports and 260 million pounds (1.0%) of the exports; crude and refined petroleum represented another 5.5 billion pounds (18%) of the imports and 1.2 billion pounds (5%) of exports. The role of the United Kingdom as a minerals processor and consumer was underlined by imports of metals and metal manufactures valued at 3.8 billion pounds (12%) and exports valued at 2.3 billion pounds (9%).

U.S. exports to the United Kingdom were mainly in the form of metal scrap for smelting and refining, coal and coke, and iron and steel products; total U.S. exports of minerals and metals to the United Kingdom were valued at $460 million in 1976. U.S. imports from the United Kingdom included crude and refined petroleum, radioactive elements, diamonds, and metal manufactures, for a total value of $760 million in 1976.

Table 2.—United Kingdom: Exports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1974	1975	Principal destinations, 1975
METALS			
Aluminum:			
Bauxite and concentrate	248	396	NA.
Oxide and hydroxide	110,572	24,669	Spain 3,405; Ireland 2,769; Portugal 2,058.
Metal including alloys:			
Scrap	13,033	16,720	West Germany 8,811; Netherlands 2,922.
Unwrought	86,901	87,695	People's Republic of China 23,163; Netherlands 16,904; West Germany 8,950.
Semimanufactures	86,270	54,313	Nigeria 4,939; Ireland 4,167; France 3,661.
Antimony metal	r1 1,100	NA	
Arsenic trioxide, pentoxide, acid	2,471	2,608	New Zealand 1,593.
Beryllium metal including alloys, all forms	1	6	NA.
Bismuth metal including alloys	r1 466	NA	
Cadmium metal including alloys	r 193	NA	
Chromium:			
Chromite	4,450	2,851	NA.
Oxide and hydroxide value, thousands	r $1,251	$2,029	NA.
Metal including alloys, all forms	r1 4,406	NA	
Cobalt:			
Oxide and hydroxide	158	149	Spain 16.
Metal including matte, speiss, etc	r1 300	NA	
Columbium and tantalum metal including alloys, all forms, tantalum	33	63	United States 27.
Copper:			
Ore and concentrate	r 677	161	West Germany 131.
Metal including alloys:			
Scrap	29,954	35,323	West Germany 15,312.
Unwrought	72,081	43,754	West Germany 11,235; Italy 8,282.
Semimanufactures	115,835	122,578	Switzerland 20,939; Ireland 8,393.
Gold, unworked or partly worked:			
Bullion, refined thousand troy ounces	r1 21,808	NA	
Other do	r 1,154	NA	
Iron and steel:			
Ore and concentrate, except roasted pyrite	375	249	NA.
Metal:			
Scrap thousand tons	312	916	NA.
Pig iron, ferroalloys, similar materials do	325	61	West Germany 9; Sweden 6; Netherlands 4.
Steel, primary forms do	224	256	United States 77; Italy 36; West Germany 30; Spain 27.

See footnotes at end of table.

Table 3.—United Kingdom: Imports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1974	1975	Principal sources, 1975
METALS			
Aluminum:			
Bauxite and concentrate thousand tons	324	296	Ghana 224; Greece 40.
Oxide and hydroxide do	603	558	Jamaica 449; Guyana 69.
Metal including alloys:			
Scrap do	22	14	NA.
Unwrought do	281	160	Norway 81; Iceland 17.
Semimanufactures do	132	79	NA.
Arsenic trioxide, pentoxide, acids	5,934	5,120	NA.
Beryllium metal including alloys, all forms	(1)	8	NA.
Bismuth metal including alloys, all forms	r 2 501	NA	
Cadmium metal including alloys, all forms	r 2 1,336	NA	
Chromium:			
Chromite thousand tons	151	144	Republic of South Africa 81; Philippines 53.
Oxide and hydroxide value, thousands	$508	$191	NA.
Cobalt:			
Oxide and hydroxide	1,065	884	Canada 790.
Metal including alloys, all forms	r 2 2,807	NA	
Columbium and tantalum, tantalum metal including alloys, all forms	53	27	United States 20; Belgium-Luxembourg 3.
Copper:			
Ore and concentrate	46	301	NA.
Matte	1,570	--	NA.
Metal including alloys:			
Scrap	26,132	10,237	United States 2,030; Ireland 1,567; West Germany 1,317.
Unwrought	458,658	451,858	Zambia 136,166; Chile 101,480; Canada 87,773.
Semimanufactures	44,120	23,895	West Germany 5,843; Finland 3,612.
Gold, worked or partly worked: Bullion:			
Refined thousand troy ounces	17,289	15,407	NA.
Unrefined do	311	311	NA.
Other do	2	1	NA.
Iron and steel:			
Ore and concentrate, except roasted pyrite thousand tons	19,675	15,783	Canada 3,061; Sweden 2,242; Venezuela 1,803.
Roasted pyrite do	617	304	Sweden 283.
Metal:			
Scrap do	140	88	United States 64; Netherlands 13.
Pig iron including cast iron, sponge, powder, and shot do	143	87	Canada 28; Norway 28.
Ferroalloys:			
Ferromanganese do	124	96	Norway 54; Republic of South Africa 32.
Other do	198	230	NA.
Steel, primary forms do	447	622	West Germany 130; Netherlands 114; Belgium-Luxembourg 99.
Semimanufactures:			
Bars, rods, angles, shapes, sections:			
Wire rods do	114	141	Italy 15; Netherlands 15.
Other bars and rods do	450	277	Sweden 64; West Germany 47; Spain 45.
Angles, shapes, sections do	364	99	Belgium-Luxembourg 19; Sweden 16; Ireland 14.
Universals, plates, sheets:			
Heavy and medium plates and sheets, uncoated do	r 1,534	689	West Germany 208; Belgium-Luxembourg 142; Japan 90.
Light plates and sheets, uncoated do	r 975	853	Netherlands 277; West Germany 182; Belgium-Luxembourg 176.

COMMODITY REVIEW

METALS

Aluminum.—Production increased in 1976, in spite of a loss of about 8,000 tons caused late in the year by a fire at the Invergordon plant of British Aluminium Co. Ltd. The Lynemouth smelter of Alcan (U.K.) Ltd. operated near full capacity during the year, and Invergordon did as well until the fire; even the troubled Anglesey smelter, now owned by Kaiser Aluminum & Chemical Corp. and Rio Tinto-Zinc Corp. Ltd. (RTZ), was operating near capacity.

Two additional small plants, at Kinlochleven and Fort William, Scotland, were operated by British Aluminium. Total industry capacity was about 360,000 tons of aluminum ingot per year.

Copper.—Planning permission was granted to Messina (Transvaal) Development Co. Ltd. of the Republic of South Africa to drill 15 exploratory boreholes in the Shetland Islands. Opencast mining was carried out on the islands until 200 years ago, and preliminary boreholes by the Department of Industry indicated mineralization to a depth of 100 meters along a strike length of 500 meters.

A contract was awarded by BICC Metals Ltd., operators of the refinery at Prescot, for expansion of anode-casting facilities and construction of a new tankhouse, increasing total capacity to 55,000 tons of electrolytic copper per year. Remaining domestic copper-refining capacity was at Widnes, operated by the same company, and at the plant of IMI Refiners Ltd. at Birmingham.

The only copper mined in the United Kingdom was a minor amount recovered as a byproduct of tin mining in Cornwall.

Iron and Steel.—A record loss of 255 million pounds (about $450 million) was registered by the nationalized British Steel Corp. (BSC) in the 1975–76 financial year, and this was followed by a further loss of 95 million pounds ($165 million) in 1976–77. By yearend 1976, the British industry had followed the world industry into a severe recession. BSC, producer of about 90% of the national total, needed to operate at or near full capacity (about 25 million tons per year) to make a profit; but, although production increased about 10% over that of 1975, market conditions made that impossible. The losses also reflected falling export prices owing to the depressed value of the pound sterling and severe import competition. Basic to the entire problem was BSC's lack of competitiveness owing to overstaffing and an aging plant.

A reorganization of BSC along regional lines took effect in 1976, replacing the former product division organization, which had endured since 1970. All six new divisions (Scottish, Scunthorpe, Sheffield, Teesside, Welsh, and Tubes) except Sheffield shared in the losses.

In April, the European Economic Community approved a 150-million-pound ($260 million) loan to BSC; this was the largest loan yet made under the European Coal and Steel Community (ECSC) treaty. It was to finance BSC's investment program at the Redcar and South Teesside works and it brought the total amount loaned to BSC by the ECSC to 390 million pounds ($680 million).

An iron ore reduction plant using North Sea gas was to be built by BSC at Jarrow, east of Newcastle, at a cost of 90 million pounds; production by 1979 would be at the rate of 800,000 tons annually. At Hunterston, Scotland, the ore terminal and reduction plant on the coast near Glasgow were to come into operation by late 1978; the terminal would have a capacity of 4 million tons per year, and the first of two Midrex modules would produce 400,000 tons of reduced iron per year starting in 1978.

Lead and Zinc.—An underground exploration program was planned at the Force Crag mine near Keswick, in the Lake District of Cumbria, which had operated for these metals until early in this century. Reserves at the property, controlled by New Force Crag Mines Ltd. of Toronto, were currently about 16,000 tons with 1.75% lead, 8.6% zinc, and 6.7% barite.

The United Kingdom's lead-zinc production continued to originate as a byproduct of fluorspar mining by Laporte Industries Ltd. in the Peak District of Derbyshire, and as a byproduct of tin mining at the Wheal Jane mine in Cornwall.

Nickel.—A fluidized-bed roaster was to be added to the Clydach, Wales, nickel refinery at a cost of 8 million pounds. The refinery, owned by Inco Europe Ltd., has treated sulfide matte from Canada for 75 years. Upon completion, the roaster also will treat matte from Inco's new laterite mines in Guatemala and Indonesia. Class I and Class II nickel products will be produced. A 90-ton-per-day sulfuric acid plant will take most of the sulfur dioxide byproduct.

Tin.—Relief for the hard-pressed Cornish tin mining industry came during the year in the form of higher prices, which increased to 5,000 pounds per ton by yearend compared with about 3,000 pounds per ton early in the year.

A fourth major producer started production in Cornwall in March 1976, when Cornwall Tin and Mining Ltd. brought Mount Wellington onstream. The mine, located at Baldhu near Truro, was designed to handle 220,000 tons of ore per year and produce about 1,600 tons of tin in concentrate, which would make it the largest tin mine in the United Kingdom. Proven reserves were put at 1 million tons; additional possible ore was approximately 3 million to 4 million tons. Cornwall Tin and Mining was a subsidiary of Prado Exploration Ltd. of Toronto and Excomm of Bermuda.

Marine Mining (Cornwall) Ltd., a subsidiary of a U.S. firm of similar name, received permission to operate two walking platform dredges in St. Ives Bay (and later off Cligga Head and St. Agnes Head) on the north coast of Cornwall. The material would be conveyed 6 kilometers up the Red River to Roscroggan for treatment.

The other three major tin producers in Cornwall were Geevor Tin Mines Ltd., at Pendeen on the north coast, which used a 300,000-pound grant from the Department of Industry to continue developing its sublevel incline to connect beneath the sea with the inactive Levant mine; St. Piran Ltd. with two mines, South Crofty and Pendarves, near Camborne, which was proceeding with a 500,000-pound investment program; and the Wheal Jane mine of Consolidated Gold Fields Ltd. (CGF), which was carrying out a 4-million-pound ($7 million) development plan in the mine and mill. All three were producing approximately 1,000 tons per year of tin.

Tungsten.—A 1-year option to reopen the Carrock Fell tungsten mine, 12 miles west of Penrith, Cumbria, in the Lake District, was granted by the owner, Weco Development Corp. of the United States, to Amalgamated Industrials (AI) in September. Ore reserves at the mine, as determined by the United Kingdom Ministry of Supply in World War II, were inferred to be around 50,000 tons averaging 1% WO_3 in scheelite and wolframite. A mill built on the property by Weco in 1972 was to be reactivated. AI was to obtain 50% of the new venture and Weco, 31.5%.

A tungsten-tin prospect at Hemerdon, east of Plymouth in Devon, was examined by Hemerdon Mining and Smelting Ltd., a Bermuda-based company, through a small-scale core-drilling program. Results were sufficiently encouraging for the company to request permission for a phase 2 drilling program and a pilot concentrating plant. The ore is a kaolinized granite, and production of byproduct kaolin would be significant.

Production of tungsten in ore in the United Kingdom is not officially reported, but it has been only a few tons annually in recent years. Tungsten occurs associated with tin in Cornwall and in the granites of the Lake District of Cumbria.

NONMETALS

Fluorspar.—Oversupply led to only small growth in fluorspar output, but companies in both producing areas, Derbyshire and Durham County, continued to plan for increases when the market improved.

Five applications for assistance in fluorspar exploration were made to the Department of Industry between April 1975 and March 1976, under the Mineral Exploration and Investment Grants Act of 1972.

Laporte Industries Ltd., the largest producer, received permission from the Secretary of State, after a refusal by the local planning authority, for construction of a tailings pond at its Cavendish mill near Blakedon, Derbyshire, which treats ore from all of its mines. Output from the Ladywash and Sallet Hole mines near Eyam, Derbyshire, also was to be expanded.

The concentrating plant at Hopton, Derbyshire, operated by C. E. Giulini (Derbyshire) Ltd., which treated ore from several local mines, was shut down during the year.

The Weardale Lead Co., a subsidiary of ICI Ltd., blocked out about 800,000 tons of ore in the Greenclough Vein in the Rookhope Valley, Durham County, and received permission to plan for a new mine there.

Swiss Aluminium Mining (UK) Ltd. (SAMUK) reactivated a project for a 160,000-ton-per-year processing plant at Frosterley, Durham County; this plant is to produce 70,000 tons per year of acid-grade fluorspar. The plant will treat ore from the nearby SAMUK mines under development, including the Cornish Hush, Stanhopeburn, and Cambokeels properties. SAMUK also was negotiating to acquire Weardale from ICI.

BSC received permission during 1976 to erect a fluorspar-concentrating plant at West Blackdene to serve four mines it holds in the Northern Pennine area of Durham County: The Beaumont, Blanchland and Groverake mines near Allenheads, and the Blackdene mine near Stanhope.

Fertilizer Materials.—*Nitrogen.*—The Scanitro project, planned to produce about 350,000 tons of ammonia per year at Peterhead, Scotland, was delayed during the entire year by failure to receive planning permission from the local authorities, the Banff and Buchan District Council; permission had already been obtained from the Scottish Secretary of State. It was reported that the local council delay was caused by a request to Scanitro for financial support for infrastructure projects. Scanitro, controlled by Norsk Hydro and Supra, two Scandinavian fertilizer producers, was to use natural gas piped from the United Kingdom-Norwegian Frigg Field in the North Sea.

Shellstar Ltd., a subsidiary of Unie Van Kunstmestfabriken (UKF), controlled by DSM of the Netherlands, still planned to erect a second ammonia plant on its site at Ince in Cheshire, near Liverpool, but was awaiting planning permission from the Secretary of State for the Environment.

The nine ammonia plants in the United Kingdom had a total capacity in 1976 of about 1.65 million tons per year.

Potash.—About 3 years after the originally scheduled startup date, production continued to be delayed at the Boulby mine of Cleveland Potash Co. in the North Yorkshire Moors National Park; the problem was mainly the erratic nature of the potash seam. The potash bed is extremely variable in thickness and undulating, and has a weak roof. Less than 50,000 tons of K_2O was produced in 1976, compared with a scheduled capacity of 1 million tons per year. Additional funds were allocated by the parent companies, Charter Consolidated and ICI, for mine operation and improvements.

Early in 1977, CGF reached agreement with Shell International Petroleum Co., Ltd., for the purchase of Shell's Whitby Potash Ltd. subsidiary, which holds exploration rights and mineral options over approximately 12,000 acres near Whitby. The potash deposit, which lies at 4,000 to 5,000 feet, would be mined by solution, and the resultant brine would be treated at a plant to be built on the outskirts of Whitby. The projected rate of 450,000 tons annually of K_2O took into account (1) the growth of the United Kingdom market, presently about 750,000 tons per year, (2) the fact that Cleveland Potash would wish to export part of its production to fulfill requirements of its parent companies, and (3) the production difficulties Cleveland Potash was experiencing.

Salt.—BP Chemicals International Ltd. announced that it would close down its natural brine mine at Sandbach, Cheshire, because of subsidence problems. British Salt would in the future supply natural brine to BP from a new brinefield at Warmingham.

Salt production was concentrated in Cheshire, south of Manchester, where Triassic beds yield rock salt, natural brine, and brine from solution mining; an undisclosed amount of rock salt was produced in Northern Ireland. The following tabulation lists the producers in Cheshire during 1976:

Ownership	Mine location	Product	Capacity (million metric tons per year)
ICI Ltd. (Mond. Div., Salt Group).	Winsford	Rock salt	2.5
	Northwich (solution mining).	Vacuum salt	1.2
		Salt in brine	5.5
British Salt Ltd. (Staveley Industries, 75%; Ranks, Hovis, McDougall, 25%).	Middlewich (solution mining).	Vacuum salt	.8
Ingram and Thompson and Sons, Ltd.	Marston	Natural brine	Small [1]
New Cheshire Salt Ltd	Wincham	----do	Small [1]
Total			[1] 10.5–11.0

[1] Estimates are included in total.

Actual production of salt was only about 75% of capacity during the year, mainly because mild weather reduced demand for rock salt for road de-icing to only about one-quarter of capacity.

Strontium.—Production of celestite (strontium sulfate) in 1976 more than doubled that of 1975, and a further increase was expected. Output was mainly exported to other European countries.

The United Kingdom is one of the world's leading producers of celestite. The only mine is operated by the British Mineral Co. Ltd. near Yate, northeast of Bristol. The mineral occurs in the Keuper Marl, of Triassic age, and is mined in shallow surface pits, followed by hand sorting, crushing, and washing.

MINERAL FUELS

Almost two-thirds of the British consumption of energy was supplied in 1976 by domestic production, compared with less than 60% in 1975. Although the bulk (58%) of domestic energy production was coal, the contribution of North Sea oil increased from 1% in 1975 to 10% in 1976.

Table 4 presents the balances of fuel and power production in the United Kingdom in 1975 and 1976.

Coal.—Closely following development of the Selby coalfield was the announcement of unexpectedly large reserves found in the Vale of Belvoir, southeast of Nottingham, a rural area of scenic beauty. National Coal Board (NCB) officials, in esti-

Table 4.—United Kingdom: Supply and apparent consumption of fuels and power for 1975 and 1976

(Million tons of standard coal equivalent [1])

	Total energy	Coal and coke	Petroleum and refinery products	Natural gas	Hydroelectric and nuclear power
1975:					
Production	194.7	129.5	2.3	52.1	10.8
Imports	156.7	5.0	150.4	1.3	[2]
Exports	22.2	[3] 2.1	[3] 20.1	--	[2]
Apparent consumption	329.2	132.4	132.6	53.4	10.8
1976:					
Production	209.5	121.8	20.3	54.7	12.7
Imports	146.3	2.8	142.0	1.5	[2]

Source: Adapted from Department of Energy, "Energy Trends," London, August 1977, 8 pp.

mating the reserves as at least 450 million tons of recoverable coal, declared it to be the largest such discovery in Western Europe in modern times. Reserves in the Selby area, announced in 1975, totaled about 400 million tons of recoverable coal. Six seams were delineated in the Vale using about 80 boreholes and 250 miles of seismic survey. Seam depths ranged from 1,300 to 2,790 feet, over an area of 90 square miles. Two seams lie beneath the Vale: The Deep Main, which averages 8.5 feet thick, and the Parkgate, 9 feet thick. Together, these seams account for 220 million tons of coal. In late 1976, it was announced that the two Vale seams hold additional reserves amounting to 90 million tons in the southwest, west of Melton Mobray. East of the Vale, toward Grantham, the two seams are not in evidence; however, two others are workable, the Top Bright (5 to 17 feet thick) and the Dunsil-Waterloo (5 to 7 feet thick), which together hold about 140 million tons. Total recoverable reserves in the Vale were expected to ultimately exceed these figures considerably.

In June, a consultant's report recommended the establishment of a colliery to produce 3 million tons of coal per year at Hose, in the Vale. The subsequent discovery of the magnitude of the reserves around Melton Mobray and Grantham led to the possibility of establishing mines at Ashfordby and Saltby as well. Opposition on environmental grounds was expected to be strong.

The NCB's intense exploration program produced other concrete results: About 50 million tons of coal was discovered under the Firth of Forth off Musselburg, Scotland, leading to an expectation of eventual production of 500,000 tons of coal per year from seven seams ranging from 1 to 3 meters thick; a 2.4-meter seam was located in an area between Bantry and Blyth, Nottinghamshire; and new reserves were located northwest of Coventry in Warwickshire.

The United Kingdom's first new coal mine in 12 years, Kellingley colliery at Royston, northern Yorkshire, was officially opened in September; it will produce 400,000 tons per year for more than 30 years. Mining will be done using a highly mechanized retreat method on three relatively thin (26 to 47 inches) seams: Sharlston Top, Sharlston Low, and Sharlston Yard, ranging from 200 to 450 feet below the surface. Production efficiency was expected to be more than twice the industry average, and estimated cost of production was less than 7 pounds per ton, compared with over 16 pounds for the industry at large.

In December, the chairman of the NCB reviewed the progress to date on the NCB's Plan for Coal and stressed the significance of the opening of the Royston mine as the forerunner of many larger projects. About 47 million tons of new capacity (including 22 million tons at existing mines) would be commissioned through 1985, thus maintaining the present output level of about 120 million tons per year. Thereafter, expansion and new mine development would provide for an increase to a provisional target of 150 million tons annually by the year 2000. The first phase of halting the present decline of 2 million to 3 million tons per year in coal capacity was to be attained through a three-pronged attack, involving exploration, modernization, and technological advances. This provisional target, however, was to be expanded by a new "Plan 2000", presented by the NCB as a means of offsetting reduced availability of oil and gas after 1985. The new target chosen was 170 million tons per year, corresponding to the average of an estimated range of 135 million to 200 million tons in which demand would probably fall; 150 million tons of this would be mined underground and 20 million tons on the surface. At yearend a review of the Plan for Coal by the Government, unions, and NCB management indicated the possibility of severely higher costs than originally estimated owing to higher wages, original underestimates, added projects, and inflation. The cost could possibly be at least 3,200 million pounds in the period through 1985, in contrast to the 1,400 million pounds originally estimated.

About 240 coal mines were in operation in the United Kingdom in 1976, employing 246,000 persons. Average production was about 2,000 tons per working day per mine; the largest mines were in the 4,000- to 5,000-ton-per-day range. Only 9 million tons per year was won in opencast mines. Of the total production, about 20 million tons per year was coking coal. All mines

were nationalized and operated under control of the NCB, either directly or, as in the case of some opencast mines, by contractors.

Petroleum.—The year 1976 was the first in which substantial quantities of North Sea oil came ashore. Five more oilfields came onstream, for a total of 7 (out of 14 fields considered "commercial"). The 7 oilfields were producing at a combined rate of 25 million tons annually by year-end; actual production totaled 12 million tons in 1976. During the year, the United Kingdom Government decided to offer approximately 50 to 60 offshore blocks for sale. The blocks awarded will be largely in the western approaches to the English Channel, the Celtic Sea, and unexplored areas in the Moray Firth area of the North Sea. Proposed licensing terms were published in a document entitled "United Kingdom Offshore Petroleum Production Licensing—Fifth Round: A Cumulative Document." Principal proposed licensing terms were as follows: The license was to be used solely at the discretion of the Secretary of State for Energy; and the royalty rate would remain at 12.5%, although the effective rate would be higher, since costs of transporting and treating and rental fees would not be deductible against the tax value base. The document also set out guidelines on the relationship between the British National Oil Corporation (BNOC) and its colicensees. BNOC is entitled to a 51% share in all benefits and a vote appropriate to its having a 50% share. Under provisions of the act, product licenses will be awarded for an initial period of 4 years, after which licensees would be required to surrender not less than one-third of the block. After an additional 3 years, another one-third must be relinquished. Licensees might then opt to continue the license for another 30 years on the remaining one-third. The term of exploration licenses was increased from 3 years to 6 years.[3]

Taxation of North Sea oil was announced by the British Treasury in March 1976. The tax will be at a single rate of 45% on gross oil revenues from the United Kingdom's sector of the North Sea. Production of 20,000 barrels per day or less will be tax-free for 10 years. In some instances, the Government will refund the 12.5% royalty and permit a 175% tax credit on capital expenditures during the first year of production.[4]

Exploration.—Exploration for oil and natural gas was conducted onshore and offshore in the United Kingdom. The largest part of the offshore exploratory activities was in the North Sea. In addition, offshore wells (all dry) were drilled in the Bristol Channel, Irish Sea, Cardigan Bay, and West Shetland Basin. The following tabulation shows the location of the 11 onshore and offshore exploration wells drilled in the United Kingdom outside the area of the North Sea:

[3] U.S. Embassy, London. State Department Airgram A-423, June 15, 1976.

In the North Sea, 72 exploratory wells and 29 extension and delineation wells were drilled during 1976. Exploratory drilling declined 22% during 1976, compared with that of 1975. Several new discoveries were reported, the most important of which was the Beatrice Field, only 25 kilometers off the coast of Scotland in Moray Firth. In previous years, eight dry holes had been drilled in the western Moray Firth Basin. Estimates of crude oil reserves of the Beatrice Field ranged from 55 million to 71 million cubic meters (350 million to 450 million barrels).

During the year, BP commenced an active program to assess the size of the Magnus Field, the northernmost field found to date in the North Sea. The productive area was extended, increasing reserves to an estimated 63 million cubic meters (400 million barrels). However, not all results of drilling in the North Sea were favorable. The Brae discovery in the Jurassic was confirmed by one well, but two other step-outs were dry, and early estimates of reserves were lowered significantly. Two new fields found west of the Norwegian Cod Field appeared to be small.

Only four exploratory wells were drilled in southern areas of the United Kingdom's North Sea. In one, Phillips Petroleum U.K. Ltd. made a significant discovery in the lower Permian Rotliegendes sandstone west of the North Viking gasfield.

Five new oilfields, Auk, Montrose, Beryl, Brenda, and Piper, started production in the North Sea during 1976; yearend production, including oil from the Argyll and BP Forties Fields started in 1975, reached an annual rate of about 25 million tons. However, because of delays, total yearly production reached only 12 million tons (including 400,000 tons of natural gas liquids and 100,000 tons onshore) instead of 15 million to 20 million tons as was expected at the beginning of the year. Reasons for delay included damage to the platform at Auk, an accident on the offshore loading tower at Beryl, and slow drilling operations in difficult seabed conditions at Piper. Work on the Flotta, Orkney Islands, terminal continued, with completion scheduled for early 1977; the terminal will handle oil from Piper and Claymore. Another terminal, Sullom Voe in the Shetlands, was under construction at yearend; startup was set for 1978, when the facility will receive oil from the Ninian and Brent pipeline systems. The following tabulation shows pertinent information on fields in production and under development in 1976:

Field and block number	Licensees and interest in block (percent)	Date of discovery	Estimated date of startup	Estimated proven recoverable reserves (million tons)
Argyll (30/24)	Hamilton Brothers (36), RTZ (25), Blackfriars Oil Company Limited (12.5), The Trans-European Company Limited (2.5), Texaco Ltd. (24).	October 1971	June 1975	NA

• Estimate. NA Not available.

The United Kingdom's petroleum refinery capacity was about 3.0 million barrels per day (150 million tons per year) in 1976; there were 21 refineries. Whether or not this capacity should be expanded was under close examination; there were considerable differences of opinion because of present underutilization, coupled with future large increases in North Sea oil production. Expansion of as much as 22 million tons per year was under examination by the Department of Industry.

Cromarty Petroleum Ltd. received permission from the United Kingdom Highland Regional Commission in February to proceed with its planned 200,000-barrel-per-day export refinery at Nigg Point on Cromarty Firth in Scotland. Land for the site was obtained late in the year, and completion of the $300 million refinery is scheduled for 1980.

A 124-mile-long, 30-inch-diameter crude oil pipeline from the Piper offshore field to Flotta terminal came onstream in early 1976. The following tabulation shows the status of major North Sea pipelines at yearend 1976:

Major North Sea pipelines	Length (miles)	Diameter (inches)	Material conveyed	Operator	Year commissioned
Operating:					
From West Sole to Easington	42	16	Natural gas	British Petroleum Co., Ltd. (BP)	1967

Natural Gas.[5]—During 1976, about 39 billion cubic meters of natural gas from offshore fields in the United Kingdom was sold to the British Gas Corp., or approximately 98% of the country's gas requirements. The following tabulation shows natural gas production (for selected years) in the United Kingdom, by field, in million cubic meters:

	1967	1970	1974	1975	1976	Cumulative total to yearend 1976
West Sole Field	5	1,190	1,850	1,850	2,040	15,960
Leman Bank Field	--	8,080	16,190	15,620	15,920	99,950
Hewett Field	--	1,990	7,130	7,730	8,190	40,120
Indefatigable Field	--	--	5,690	6,400	6,560	28,100
Viking Field	--	--	4,850	5,610	6,180	21,620
Rough Field	--	--	--	10	520	530
Total[1]	5	11,270	35,730	37,230	39,410	206,290

[1] Data may not add to totals shown because of independent rounding in source.

All North Sea oilfields produced associated gas in various quantities, but only the Brent Field has shown sufficient quantities to justify a separate gas pipeline to the shore. In 1976 about 860 million cubic meters of associated natural gas was produced from oilfields in the North Sea; only 12% was either sold or used at fields, and the rest was flared. Under terms of production licenses, applications for flaring or reinjecting gas must be submitted for approval to the Secretary of State 2 years before actual operation starts. In 1976, seven fields had permission to flare gas, but these permits were permanent only for the Argyll and Auk Fields where the quantities of gas produced were too small to warrant investments in transportation.

[5] Secretary of State for Energy. Development of the Oil and Gas Resources of the United Kingdom, 1977—A Report to Parliament. Her Majesty's Stationery Office, London, 48 pp.

The Mineral Industry of Venezuela

By Nicholas Theofilos [1]

Venezuela's gross domestic product (GDP) at constant 1968 prices increased 7.1% to $15.8 billion [2] in 1976. The petroleum industry, dominating the economy, accounted for 30% of the GDP, 70% of total Government revenues, and 95% of the country's export earnings. Although the industry employed less than 1% of the labor force, it contributed almost 4% to total wages and salaries. In addition to these direct contributions, the petroleum industry provided a stimulus to the development of other sectors of the economy as well as to social changes throughout the country.

Export sales of crude petroleum and products totaled $8.7 billion in 1976, while local sales amounted to $390 million. The increased oil revenues gave Venezuela the highest per capita GDP in Latin America ($2,200). Venezuela's $8 billion in international reserves was also the highest in the region. The Government succeeded to a large degree in holding inflation at reasonable levels and used a portion of its oil income to provide credits and other forms of financial assistance to other developing nations.

Nationalization of the petroleum industry took effect on January 1, 1976, after many years of debate, with the termination of the 22 private oil concessions. The nationalization law had been signed on August 29, 1975, and was followed by a Presidential decree on August 30, 1975, creating Petróleos de Venezuela (PETROVEN) to administer the petroleum industry effective the beginning of 1976. In accordance with this law, compensation to each of the concession holders and participating companies, primarily U.S.-based multinational firms, was determined to be the net book value of their physical assets less certain specified deductions. Compensation payments to the companies, almost all in the form of negotiable 5-year Venezuelan Government bonds, amounted to $1.02 billion. However, about one-half of this compensation was retained by the Government in a guarantee fund, established by an earlier law, to guarantee the condition of the physical assets upon their eventual reversion to national control and to cover any remaining obligations of the companies. Deposits to this fund, representing 10% of each company's gross accumulated investment in the industry, totaled $551 million, which included some payments made to the fund prior to nationalization.

The emergence of PETROVEN and its 14 operating affiliates made this Government enterprise one of the world's largest oil groups. The company acquired 21,000 oil wells (of which 11,870 were producing), 18.3 billion barrels of oil in proven reserves, 11 refineries with a total capacity of 1.6 million barrels per day, 10,000 kilometers of oil and gas pipelines, a tanker fleet, terminals, and a work force of 23,600.

Mining, the country's second most important export sector, declined 27.1% in 1976, owing to a general contraction in steel production in industrialized countries that purchase Venezuela's iron ore. Nevertheless, the iron ore industry benefited from higher export prices and earned $279 million on sales of 18 million tons of ore.

The Government of Venezuela, working through Corporación Venezolana de Gua-

[2] Where necessary, values have been converted from Venezuelan bolivars (Bs) to U.S. dollars at the rate of Bs4.30 = US$1.00.

yana (CVG), was actively engaged in the development of a major aluminum industry that would be based upon the cheap hydroelectric power available in the Orinoco region. In anticipation of future electric power requirements for the proposed aluminum smelters, CVG was expanding the hydroelectric power generating facilities of its wholly-owned subsidiary Electrificación del Caroní C.A. (EDELCA). The creation of the aluminum production complex in Ciudad Guayana was contributing additional pressures on the region's infrastructure. Construction programs in the area included the Guri Dam expansion and major expansion of the national steel mill, as well as inauguration of several new smaller private and joint venture industries. The population of Ciudad Guayana grew from 3,800 in 1950 to 300,000 in 1976, with a current growth rate estimated at 15% to 20% per year.

The Consejo Nacional para el Desarrollo de la Industria Nuclear (CONAN) (National Council for the Development of the Nuclear Industry) was placed under the jurisdiction of the Ministry of Energy and Mines by an executive decree on November 2, 1976. CONAN expected to install the first of 14 nuclear powerplants by the late 1980's. The remaining 13 were scheduled to be constructed by the year 2000. Exploration work for uranium was carried out in the southern and eastern regions of the country. Exploration teams gathered a few tons of uranium ore which was expected to yield the first purified uranium ever produced in Venezuela. The Government was optimistic that the quantity of uranium discovered was sufficient to supply Venezuela's requirements in meeting her objectives.

PRODUCTION

Venezuela's mineral industry in 1976 continued to be dominated by the production of petroleum and iron ore. The output of crude petroleum declined slightly from that of 1975 because of the Government's efforts to conserve. An average of 2,294,000 barrels of oil per day was produced, plus 70,000 barrels per day of natural gas liquids. Iron ore production declined significantly from that of 1975, owing to a decrease in world demand for steel which, in turn, was linked to the global recession of 1975–76. The other sectors of the country's mineral industry registered mixed performance during 1976.

Table 1.—Venezuela: Production of mineral commodities

(Metric tons unless otherwise specified)

Commodity [1]		1974	1975	1976 [p]
METALS				
Aluminum, unalloyed ingot		[r] 39,200	49,700	46,500
Gold, mine output, metal content	troy ounces	16,966	18,326	15,645
Iron and steel:				
Iron ore and concentrate	thousand tons	26,424	24,772	18,140
Metal:				
Pig iron	do	545	535	427

Refinery gas [4]	do	5,504	5,283	6,807
Unspecified	do	5,268	3,634	2,734
Total	do	436,539	317,045	360,886

[e] Estimate. [p] Preliminary. [r] Revised. NA Not available.

[1] In addition to the commodities listed, lime is produced but information is inadequate to make reliable estimates of output levels.

[2] Format of table changed to show nitrogen content of nitrogenous fertilizers rather than gross weight.

[3] Includes refinery fuels.

[4] Liquid equivalent.

TRADE

Venezuela ranked as the third largest exporter of crude oil and refined products in 1976. However, for the first time in many years, Venezuela was not the single largest supplier of oil to the United States. In 1976, both Saudi Arabia and Algeria shipped greater volumes of oil into the U.S. market, as a consequence of the rapid growth in U.S. imports combined with the decline in Venezuelan exports. Direct exports to the United States averaged 727,000 barrels per day in 1976, two-thirds of which were refined products. This represented 34% of total oil exports,

a percentage that has remained relatively steady through the 1970's. Another third of Venezuela's exports, primarily crude oil, went to the Caribbean refineries (Aruba and Curaçao) for refining and transshipment to end users. About one-half of this oil, in the form of refined products, subsequently went to the United States. Thus, in total, the U.S. market absorbed about one-half of Venezuelan exports for the year.

Approximately 85% of iron ore production was exported in 1976. Although iron ore exports were 19% below those of 1975, income from export sales was 0.6% higher or $252.4 million. The United States was the market for 55% of Venezuela's iron ore exports in 1976.

COMMODITY REVIEW

METALS

Aluminum.—Aluminio del Caroní S.A. (ALCASA) was Venezuela's sole producer of aluminum in 1976. ALCASA, in 1976, produced 46,500 tons of aluminum, and consumed 850,000 million watt-hours of hydroelectric power. Expansion of the Guri Dam, combined with a growing Latin American market for aluminum, encouraged ALCASA to launch a major expansion program, including a new 70,000-ton potline. The expansion program was executed under a construction contract with Reynolds International. By the end of 1976, $87.6 million of a planned investment of $155.6 million had been spent on the project, which was scheduled for completion by the end of 1977.

Most of the additional 70,000 tons of aluminum to be produced in 1978 was to be sold in the export market. In the longrun ALCASA hoped to encourage the development of a broad variety of aluminum fabricating industries in Venezuela.

The Venezuelan Government was encouraging the development of aluminum rolling mills in the Guayana region. One U.S. firm, Southwire Co., was already involved in a joint venture project in Venezuela. Southwire owned 49% of a new company, Suramericana de Aleaciones Laminadas, C.A. (SURAL), with the remainder of the stock held by private Venezuelan interests. The SURAL plant, with an initial annual capacity of 10,000 tons of aluminum alloy rods, was to ex-

pand as the available supply of aluminum increased. The additional aluminum was expected to be supplied by Industria Venezolana de Aluminio C.A. (VENALUM), Venezuela's second major aluminum facility, which was scheduled to start production by the end of 1977.

Copper, Lead, and Zinc.—The Government was accepting bids to select two companies to participate in a project to exploit the reserves of copper, lead, and zinc at Bailadores, in the State of Mérida. The deposit was estimated to contain 3 million tons of ore grading 26% zinc, 7% lead, and 1.5% copper. Provisions were made for the formation of two mixed companies in which the Venezuelan Government would have a 70% interest. The first company was to exploit the deposit and provide concentrating facilities for the minerals, while the second company was to provide processing operations for the concentrates.

Iron Ore.—Ferrominera Orinoco C.A., a wholly-owned subsidiary of CVG, completed its first year of operations in 1976 following the reorganization of the iron ore industry in late 1975. Since the nationalization took effect on December 31, 1975, the iron ore industry functioned in an unusually smooth fashion, reflecting Venezuela's awareness of the continued need for technical and marketing assistance from the former concessionaires. In practice, there was little change in operation of the mines. The same work force and managers continued to work the 8,600 hectares in El Pao that formerly belonged to the Iron Mines Co. of Venezuela (a subsidiary of Bethlehem Steel Corp.) and the 8,093 hectares in 18 concessions in the Heres District of Bolívar State that belonged to Orinoco Mining Co. (a subsidiary of United States Steel Corporation). Forward iron ore supply contracts were signed with United States Steel and Bethlehem Steel to assure them a predetermined but declining percentage of total ore production as consumption in Venezuela increased. Similar contracts were signed with several European firms. Although the earnings from these exports were considered important and had their place in CVG budgeting for the next few years, they were not an overriding consideration. The Venezuelan Government had adopted a policy of conservation of iron ore reserves. The Government intended to hold production at current levels for the indefinite future and eventually to absorb all of the production in the expanded steel industry.

Iron ore shipments of Ferrominera in 1976, by destination, are given in the following tabulation, in thousand tons:

	Shipments
United States	9,797
Italy	1,989
Germany, West	1,892
United Kingdom	977
Spain	830
Belgium	606
France	556
Netherlands	416
Czechoslovakia	245
Poland	49
Portugal	31
Argentina	14
Domestic market	98
Total	17,500

Iron and Steel.—The State-owned CVG Siderúrgica del Orinoco C.A. (SIDOR) was in its second year of carrying out an expansion scheme that was to raise steel output from the present peak capacity of 1.2 million tons per year to 5 million tons of liquid steel per year. The expansion was the most costly program being financed by the Venezuelan Government, and it was expected to be completed by the early to mid-1980's.

The expansion will involve building a massive new steel mill alongside the existing facility. The steel plant is to be fed from nearby Government-owned high-grade iron ore mines, and powered by the Government-owned Guri hydroelectric complex on the Caroní River. The new steel project was coordinated by the State regional development agency, Corporación de Desarrollo de la Region Zuliana (CORPOZULIA), and was expected to be formally established before the end of 1977.

There were several areas of uncertainty regarding the new steel project that had to be clarified before work could begin. The two most important were financing and the absence of a foreign partner in the project. If the project is to be wholly Government owned, it seemed possible that the Venezuelan Investment Fund would be called upon to provide most of the financing. If non-Government participation is to be permitted, a substantial amount of financing might be provided by the foreign

partner in the form of equity plus supplier's credit or loans to the Government for its equity share. Several consortia, led by Japanese and Western European firms, presented proposals to the Venezuelan Government for the project as well as for the related coal, electric power, and infrastructure projects.

MINERAL FUELS

Coal.—During 1976 five private mines at Lobatera, in the State of Táchira, produced 89,200 tons of coal, a 48% increase over that of 1975. The Ministry of Energy and Mines gave CORPOZULIA permission to tap the large seams of bituminous coal near the Colombian border in the State of Zulia. Proven reserves were estimated at 780 million tons, 190 million tons of which could be mined by open pit methods. An analysis of samples showed that the coal is low ash (4% to 6%), low sulfur (0.4% to 0.8%), high volatile (39% to 40%), and not ideal for coking purposes. For the coal to be used in the integrated steelworks, as projected for the State of Zulia, it would have to be mixed with up to 70% foreign coal.

The Government was also beginning to put plans into effect to bring back into production the coal mines at Naricual near Barcelona. This area was expected to add 500,000 tons of coal per year to the country's production. Washing tests were expected to be completed by 1977. If the results are positive, the coal was expected to be utilized by SIDOR.

Petroleum and Natural Gas.—Venezuela's petroleum industry operated satisfactorily after the Government takeover on January 1, 1976. Employment totaled 23,600. Multinational companies, working under contract, provided technological and marketing expertise in accordance with policy directions given by the board of directors of PETROVEN, the holding company. All outstanding stock of this company was held by the Government. The Minister of Energy and Mines, as chairman of the company's General Assembly, sets the general policy. PETROVEN was initially capitalized at $584 million but at the end of 1976 this was increased to $2.49 billion, comprising the original capital plus the capital assets of Corporación Venezolana del Petróleo S.A. (CVP), the original State oil company.

Management of the industry was entirely in the hands of PETROVEN which controlled 14 operating companies, most of which were former affiliates of foreign oil concerns. The board of directors operated through a series of committees, each representing a major function of the industry. A board member chaired each committee, and the holding company's coordinator for that function served as its secretary.

The Ministry of Energy and Mines was charged with the responsibility of administering Venezuela's conservation program. Production of petroleum was to be held at about 85% of capacity, and crude oil prices were set in accordance with prices established by the Organization of Petroleum Exporting Countries (OPEC). The Ministry was also responsible for assigning geographical areas to the operating companies for exploration. During 1976, PETROVEN subsidiaries were limited to the concession areas originally assigned to their private predecessors.

Petroleum research was carried out by the Venezuelan Technological Institute of Petroleum. This entity was created at the time of nationalization and was given the responsibility of providing technological support to the petroleum and petrochemical industries, enabling them to reduce their dependence on foreign technology. During 1976, the Institute was working with CVP on a project in the Melones District to test in situ combustion in the recovery of heavy oils.

Exploration and the development of new production capacity were to receive priority by PETROVEN in the immediate future. Activities in this area had been stagnated in recent years by the concessionaires' reluctance to invest in view of uncertainties as to their future status and the Government's unwillingness to open up new areas for exploration. This was complicated by the lack of integrated functioning exploration groups within the industry. Another constraint on exploration and production drilling was the shortage of drilling rigs. As a result, additions to reserves attributable to new discoveries (as opposed to revisions in the amount of recoverable reserves from known fields) had fallen behind production levels.

In 1976, 44 wildcat wells were drilled compared with an average of 33 per year

for the previous 5 years. Twenty-two of these wells were successful, adding slightly over 100 million barrels to proven reserves. The only surface exploration work was seismic, which involved 38 crew months, 40% less than in 1975. Land surveys totaled 5,244 square kilometers mostly in the Anzoátegui, Zulia, and Monagas areas. Surveys in Lake Maracaibo totaled 3,359 square kilometers, and off the north coast, 2,265 square kilometers.[3] Plans for exploration activities for 1977 included the drilling of 75 exploratory wells and the extension of the seismographic program. Areas of interest for exploration, in order of priority, were onshore areas adjacent to known fields; offshore areas, including the Amacuro Delta and the Gulfs of Paria, Triste, and La Vela; and the Orinoco Heavy Oil Belt.

Crude oil production in 1976 averaged 2,294,000 barrels per day, plus 70,000 barrels per day of natural gas liquids. There were 11,870 actively producing wells at the end of the year, giving an average production of 193 barrels per day per well. In addition, there were 9,360 shut-in wells capable of production, with an estimated capacity of 300,000 to 400,000 barrels per day, almost all of which was heavy crude. A total of 285 new production wells were drilled and over 1,400 existing wells were reconditioned in 1976, with the total investment in production activities amounting to about $200 million. The distribution of crude oil production in 1976 by gravity, region, and operating subsidiary of PETROVEN, in thousand 42-gallon barrels per day, is shown in the following tabulation:

	Production	Percent
By gravity:		
Light (over 30° API)	898	39
Medium (22° to 30° API)	852	37
Heavy (below 22° API)	544	24
By region:		
Lake Maracaibo area	1,833	80
Eastern Venezuela	423	18
Other	38	2
By operating company:		
Lagoven S.A	995	43
Maraven S.A	534	23
Meneven S.A	357	16
Palmaven S.A	111	5
Other	297	13

Proven reserves at yearend were calculated at 18.3 billion barrels, about 1% below the level of a year ago. The reserves were believed to be sufficient to sustain production at the current rate for about 20 years. However, heavy gravity crude accounted for 43% of these reserves, medium for 30%, and light for 27%. Thus, emphasis was expected to be placed on the discovery of light crudes or the marketing of a greater proportion of the more abundant heavy oils.

Drilling programs for 1977 called for the completion of 350 to 450 production wells. Another major area of future investment was that of secondary recovery. Both Maraven S.A. and Lagoven S.A. were working on major steam injection projects to increase the recovery.

Natural gas production, almost all associated gas, amounted to almost 38 billion cubic meters in 1976. About 56% of this was reinjected into the oil bearing formations, 36% was sold for domestic consumption or used by the industry itself, and 8% was flared. Major projects to extract natural gas liquids from associated gas in eastern Venezuelan fields were under study. Proven reserves of natural gas were estimated to be 1.15 trillion cubic meters.

Venezuela's 11 operating refineries had a capacity of 1,554,000 barrels per day in 1976. Refinery throughput increased from 860,000 barrels per day in 1975 to 984,000 barrels per day in 1976. This represented a refinery capacity utilization of 63%. The petroleum industry faced falling gasoline production in 1976 because the refineries were originally designed to maximize production of residual fuel oil, yielding only about 20% gasoline by volume. Some flexibility in the yield was expected to be obtained from lighter gravity crudes, once these crudes become more available.

To meet the growing domestic demand for gasoline and to increase processing capacity for the more abundant heavy crudes, PETROVEN embarked on a program to upgrade its major refineries over the next 5 years. Detailed engineering was underway for a $33 million project to revamp the catalytic cracker at the Maraven S.A. refinery at Cardon. This was expected to add 14,000 barrels per day to the refinery's gasoline production by 1979.

[3] American Association of Petroleum Geologists Bulletin. V. 6, No. 10, October 1977, p. 1592.

Approval was also given to a project to add another 53,000 barrels per day in gasoline capacity by mid-1980 through the upgrading of Llanoven S.A.'s El Palito refinery at Puerto Cabello. The project, to include installation of a vacuum distillation unit, a catalytic cracker, and an alkylation unit, was expected to cost about $210 million. A much larger project involving an extensive reworking of Lagoven S.A.'s Amuay refinery, one of the world's largest, was also under consideration. Gasoline production was planned to increase by 60,000 barrels per day by mid-1982. This project was also to include additional catalytic cracking capacity as well as installation of various other units, at an estimated cost of over $600 million.

Venezuela's most important client continued to be the United States, and PETROVEN expected the relationship to continue. In 1976, the Government oil company shipped 88% of its exports (by volume) to markets in the Western Hemisphere, chiefly the United States, Canada, and Caribbean countries. Crude oils constituted about two-thirds of these exports and refined products, chiefly fuel oils, made up the remainder.

PETROVEN, which already maintained a fleet of 20 oil tankers, was planning to purchase 14 additional ships by 1982. Aside from the standard practice of replacing old ships, PETROVEN wanted to expand its tanker capacity to achieve greater flexibility in supplying new customers. The new ships would be in the 30,000- to 60,000-deadweight-ton range. PETROVEN's 1976 fleet amounted to 700,000 deadweight tons and was made up of 10 ships owned by the company and 10 under lease.

The Mineral Industry of Yugoslavia

By Roman V. Sondermayer [1]

Yugoslavia was among the most prominent producers of nonferrous metals in Europe during 1976. Lignite remained the principal fuel produced in the country. Imports of liquid fuels and high-rank coals were required to meet growing energy demand. The most prominent minerals produced were as follows, with mine production expressed in percentage of world output: Mercury, 6%; magnesite, 5%; lead, 4%; bauxite, 3%; antimony, 3%; copper, 2%; and zinc, 2%. Production of other minerals and fuels remained of only domestic significance.

Based on performance of its major sectors, 1976 was a mixed year for the minerals industry of Yugoslavia. As shown in table 1, changes in output were small and within the normal range of variations for years of recession in Europe. However, a drop in mercury output indicated more serious problems related to conditions in the mercury world market.

The GSP [2] increased 28% to $34 billion [3] in 1976. Unemployment maintained its upward trend and was 13% of the total labor force at yearend 1976 (12% at yearend 1975). Based on monthly data, inflation declined from 20% in the beginning of the year to 10% at yearend, reflecting the result of measures taken by authorities to combat inflation. The minerals industry contributed about 12.4% to the GSP and employed 249,000 persons or 5.1% of the total employment. The following tabulation shows the breakdown of employment and the share of GSP by branch of industry at yearend 1976:

	Employment (thousand)	GSP (percent)
Coal	61	1.6
Petroleum	18	1.8
Nonferrous	58	4.8
Ferrous	59	3.1
Nonmetallics	53	1.1
Total	249	12.4

During 1976, the most significant developments in the minerals industry were construction of alumina plants in Obrovac, Hrvatska (Croatia), and Zvornik, Bosna i Hercegovina (BiH); expansion of aluminum plants at Titograd, Crna Gora (Montenegro), and Šibenik, Croatia; beginning of construction of a copper mill at Bućim, Makedonija (Macedonia); completion of a new steel converter plant in Zenica, BiH; commencement of production at a new antimony mine at Kopaonik, Srbija (Serbia); beginning of platinum and palladium production at Bor, Serbia; development of lignite mines at Tamnava, Ćirkovac, and Drmno; and conclusion of an agreement between The Dow Chemical Co. (Dow) of the United States and Industrija Nafte (INA) of Zagreb, Croatia, for joint investment in a petrochemical complex situated on the island of Krk.

The minerals industry was State owned; however, investment of foreign capital in

[1] Physical scientist, International Data and Analysis.

[2] Gross social product (GSP) is an economic indicator used by Yugoslav authorities instead of gross national product.

[3] Where necessary, values have been converted from Yugoslav dinars (din) to U.S. dollars at a rate of 18 din=US$1.00.

Yugoslavia's minerals industry was allowed providing that Yugoslavia retained ownership of the deposit and controlling interest in the venture.

Mineral output in 1976 and planned targets for 1980 for the new 5-year plan are as follows:

	1976	1980
Coal ---------- million tons	36.8	58.0
Crude oil ---------- do	3.8	4.6
Natural gas ---------- 10^9 cubic meters	1.7	3.0
Bauxite ---------- million tons	2.0	5.1
Alumina ---------- thousand tons	346	1.600
Aluminum ---------- do	198	350
Copper ---------- do	137	180
Lead ---------- do	111	225
Zinc ---------- do	105	155
Nickel ---------- do	--	12
Steel ---------- million tons	2.8	3

In 1976, the railroad line from Bar, on the Montenegro coast, was completed to Belgrade, making accessible remote but mineral-rich areas in Serbia and Montenegro.

PRODUCTION

Higher output with lower use of materials and manpower remained the principal aim in the minerals industry during 1976.

The following tabulation shows output in tons per man-shift for 1970 and 1974 (latest year available):

	Underground		Opencast	
	1970	1974	1970	1974
Bituminous coal	1.3	1.2	--	--
Brown coal	2.1	2.5	6.6	9.9
Lignite	3.8	4.6	11.3	14.2
Iron ore	3.1	4.1	10.5	21.3
Antimony ore	.9	1.0	--	--
Copper ore	9.3	15.4	21.2	45.3
Lead-zinc ore	1.4	1.5	12.9	16.4
Magnesite	1.1	1.1	6.9	5.7
Asbestos	--	--	8.6	6.4
Clays	2.1	2.7	4.6	5.8

Producers of minerals directed their efforts toward modernization and expansion of existing facilities, but the industry remained a mixture of modern and antiquated, with equipment purchased in various countries. However, modern and efficient methods prevailed in petroleum exploration, production, and refining. Dual completion was used at some wells, and secondary recovery at some older fields. Chemical and hydraulic methods for stimulating gas and oil production were everyday practices.

Total [3]--do	r 72,111	75,174	79,804

e Estimate. p Preliminary. r Revised. NA Not available.

[1] In addition to the commodities listed, germanium, bentonite, kaolin, common clay, and diatomite are also produced, and tellurium may be recovered as a copper refining byproduct, but available information is inadequate for formulation of reliable estimates of output levels.

[2] As reported in official Yugoslavian production statistics; sum of actual reported gross weight for each class of fertilizer.

[3] Excludes refinery gas (10,403 million cubic feet in 1974, 11,600 million cubic feet in 1975, and an unreported quantity in 1976) as well as other materials produced by and used in the refineries as fuel.

TRADE

During 1976, Yugoslavia remained a net importer of minerals.

Imports of minerals valued at $4.0 billion accounted for 30% of total imports. Fuels, mostly crude oil and bituminous coal, were 43% of the country's mineral imports.

Exports of minerals valued $2.2 billion were 42% of total exports. Products of nonferrous metals were the largest mineral exports of Yugoslavia.

Yugoslavia's mineral trade was diversified. A large number of commodities were traded with a large number of countries, but CMEA[4] and developing countries were the principal partners. Tables 2 and 3 show details of mineral trade.

[4] (CMEA) Council of Mutual Economic Assistance comprising the following countries: Bulgaria, Cuba, Czechoslovakia, East Germany, Hungary, Mongolia, Poland, Romania, and the U.S.S.R.

Table 2.—Yugoslavia: Exports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1974	1975	Principal destinations, 1975
METALS			
Aluminum:			
Bauxite and concentrate -thousand tons--	1,611	1,283	U.S.S.R. 950; Czechoslovakia 143.
Alumina	76,333	73,845	U.S.S.R. 54,639; Czechoslovakia 15,360.
Metal including alloys:			
Scrap	4,935	6,741	Italy 4,819; East Germany 1,638.
Unwrought	69,758	71,964	West Germany 45,638; Czechoslovakia 9,692.
Semimanufactures	45,898	51,695	Czechoslovakia 20,223; Republic of South Africa 18,630; West Germany 6,660.
Antimony regulus	1,774	1,306	U.S.S.R. 1,084.
Bismuth including alloys, all forms	36	33	Republic of South Africa 15; United Kingdom 12.
Cadmium including alloys, all forms	53	65	Republic of South Africa 60.

Platinum-group metals including alloys, all forms, palladium, troy ounces	2,861	4,501	East Germany 3,858; Republic of South Africa 643.
Selenium, elemental, kilograms	34,700	NA	
Silicon	20,486	16,507	U.S.S.R. 11,641; Romania 1,849.
Silver metal including alloys, all forms, thousand troy ounces	3,581	3,694	Republic of South Africa 3,192; Czechoslovakia 474.
Tin including alloys, all forms	69	50	Austria 25; Italy 25.
Titanium oxides	8,887	13,547	West Germany 13,239.
Uranium ore and concentrate	2,043	2,015	Hungary 2,007.
Zinc:			
Ore and concentrate	1,410	7,698	Italy 7,652.
Oxide	210	37	All to Albania.
Metal including alloys:			
Blue powder	1,948	3,233	Czechoslovakia 2,903.
Unwrought	40,697	51,208	Czechoslovakia 20,166; Republic of South Africa 11,983; United Kingdom 6,559.
Semimanufactures	8,180	7,351	East Germany 3,232; Czechoslovakia 2,671; Hungary 840.
Other:			
Ash and residue of nonferrous metals	1,226	22,924	Bulgaria 17,403; Italy 2,815.
Oxides, hydroxides, and peroxides of metals, n.e.s	45	47	Netherlands 37.
NONMETALS			
Abrasives, natural, n.e.s., grinding and polishing wheels and stones	2,364	2,660	Poland 1,356; Romania 484.
Asbestos	1,735	3,259	East Germany 1,139; Albania 846; United Kingdom 483; East Germany 449.
Barite and witherite	40,830	47,732	U.S.S.R. 35,529; Hungary 12,203.
Cement	234,692	431,205	Nigeria 125,130; Libya 74,920.
Chalk	38	14	All to U.S.S.R.
Clays and clay products (including all refractory brick):			
Crude clays, n.e.s.:			
Bentonite	11,259	848	Poland 638; Libya 200.
Fire clay	18,343	5,212	Hungary 2,992; Italy 2,200.
Kaolin	724	4,765	Italy 4,757.
Products:			
Refractory (including nonclay brick)	109,779	149,952	U.S.S.R. 59,895; Poland 25,129; Romania 20,553; East Germany 17,832.
Nonrefractory	1,649	635	U.S.S.R. 258; Libya 123; Czechoslovakia 72.
Diatomite and other infusorial earth	11	NA	
Feldspar	17,448	12	All to Czechoslovakia.
Fertilizer materials, manufactured:			
Nitrogenous	6,250	5,521	East Germany 3,000; West Germany 2,521.
Phosphatic	239,806	16,744	Hungary 12,723; Bulgaria 1,489.
Other including mixed	387,471	157,219	North Korea 63,031; Hungary 52,197; Ghana 15,011.
Gypsum and plasters	NA	18	Czechoslovakia 10; U.S.S.R. 8.
Lime	NA	743	Hungary 703.
Magnesite	70,874	69,599	U.S.S.R. 25,056; Poland 12,422; Republic of South Africa 11,161; Italy 10,297.
Pyrite (gross weight)	24,327	171,920	Romania 123,320; East Germany 48,600.

See footnote at end of table.

COMMODITY REVIEW

METALS

Aluminum.—Development of new bauxite mines and construction of alumina and aluminum plants continued during 1976. The aim was to convert Yugoslavia's aluminum industry from a producer and exporter of bauxite to a processor of bauxite and exporter of alumina and aluminum metal.

Activities related to bauxite were limited to exploration in the areas near existing mines and to expansion by 0.5 million tons each of mines near Vlasenica, BiH, and Nikšić, Montenegro. New capacity at Vlasenica was necessary to assure future supply of bauxite to the new alumina plant at Zvornik, BiH, and additional bauxite from Nikšić will be necessary to meet future higher demand for the expanded Titograd Alumina Plant. Bauxite was produced along the Adriatic Sea in Croatia (Obervac), and inland in Montenegro (Nikšić) and BiH (Mostar and Vlasenica). In Serbia, bauxite was produced at Kosovo, near Priština. Energoinvest, with its mines in BiH, was the largest producer of bauxite in the country. The largest mine complex operated by Energoinvest was the Vlasenica group of mines. Yugoslavia was more than self-sufficient in bauxite and exported about 40% of its output.

Financed with credits from the U.S.S.R., construction of a 600,000-ton-per-year alumina plant at Zvornik, BiH, continued. Plans called for completion of one-half of capacity in June 1977 and of the rest in December of the same year.

Near Obrovac, construction continued on a 300,000-ton-per-year alumina plant. The plant was partly financed with loans from East Germany and Hungary. Startup was planned for 1977.

The alumina plant at Titograd, Montenegro, was the largest producer of alumina in the country contributing 54% to the total output. During the winter of 1975–76, construction started on doubling capacity at the Titograd Aluminum Plant. When completed, the plant should have an annual capacity of 100,000 tons of aluminum, 280,000 tons of alumina, and 50,000 tons of carbon anodes.

At the Šibenik aluminum plant, plans were made public to add 104 cells with an annual capacity of 35,000 tons to the existing installation. In addition, the management of the Šibenik plant announced a decision to build a secondary aluminum smelter with a capacity of 15,000 tons per year of secondary aluminum. Completion was planned for 1978. With a capacity of 75,000 tons per year, the Šibenik plant remained the largest producer of aluminum metal in the country.

Antimony.—After several years of exploration, trial production of antimony ore and concentrate started at a mine situated in Rajićeva Gora, Kopaonik, Serbia. Exploration and mine and mill construction were financed by Rudarsko Topionički Bazen Zajača (RTB-Zajača), Serbia. Production at an annual rate of 45,000 tons was to increase to 300,000 tons by 1979. Reserves in the area were between 10 million and 15 million tons. Grade of ore was not made public. The new mine is significant because if successful, imports of antimony concentrate would not be necessary in the future. RTB-Zajača, with its smelter near Zajača, Serbia, produced all the antimony metal in the country.

Copper.—Exploration at Veliki Krivelj, Serbia, beginning of mine and mill construction at Bućim, Macedonia, and startup of a copper alloy foundry at Bor, Serbia, were the major activities related to copper.

In Serbia, exploration of the Veliki Krivelj deposit was intensified, and in addition small deposits were located near Prijepolje and Kosjerić, which were low grade (1% copper) and inaccessible making production questionable.

Construction started on a mill at the Bućim copper mine in Macedonia. The mill was rated at 3.7 million tons of ore per year. Plans call for an output of 100,000 tons of copper concentrate (lower limit, 22% copper). In addition, the concentrate contains about 26 grams of silver and 1.5 grams of gold per ton. Tentatively, startup at Bućim was scheduled for 1978. Bućim, when operational, will be the first producer of copper ore and concentrate in Yugoslavia outside the Bor copper region. At Bor, a new 81,000-ton-per-year copper alloy foundry will reach its designed capacity late in 1978 or early in 1979.

The management of Bor announced a decision to build another sulfuric acid plant at the Bor copper smelter. Capacity of the plant was reported at 230,000 tons of sulfuric acid per year. Completion was scheduled for 1978.

Rudarsko Topionički Bazen Bor (RTB-Bor) was the largest producer of copper ore, concentrates, and metal in the country. RTB-Bor operated mines, a concentrator, a smelter, and an electrolytic plant at Bor, Serbia, and a mine and concentrator at Majdanpek, Serbia. The operations are about 50 kilometers apart. Concentrate from Majdanpek was smelted at Bor. Domestic output of ore and concentrate met about 95% of the country's demand in 1976.

Iron and Steel.—During 1976, efforts continued to develop additional facilities for increased production of iron ore, pig iron, and steel in Yugoslavia.

Exploration for iron ore was conducted in various parts of the country. The most promising results were in Bosnia (Vareš, Ljubija) and the western part of Macedonia. The following tabulation shows the status of iron ore reserves in Yugoslavia by region at the beginning of 1976, in million tons:

Region	Proven reserves	Total resources
Ljubija	465	1,200
Vareš, Bosnia	269	600
Vakuf-Jablanica, Bosnia	15	50
West Macedonia	114	300
Total Dinaric Province	863	2,150
Region Borjane	3.5	6.5
Region Kopaonik	3.9	8.9
Region Preševo-Prokuplje	5.5	6.5
Damjan	18.3	33.3
Pehceva	16.5	26.5
Total Serbian-Macedonia Region	47.7	81.7
Region of East Serbia	6.9	9.9

Iron content of Yugoslav ore varies between 20% and 46%, and the average was reported to be 30%. During 1976, the number of iron ore producing facilities remained the same as in 1975, and the output remained at the same order of magnitude as in the previous year. Iron ore was mined at four mines and upgraded at four concentrators, one pelletizing plant, and seven agglomeration (sintering) installations. Iron mines at Vareš and Ljubija, in Bosnia, operated by Rudarsko-Metalurški-Kombinat-Zenica (RMK-Zenica), remained the largest producers of iron ore in the country, accounting for about 76% of the total iron ore output of Yugoslavia. Production of domestic iron ore supplied about 90% of the country's demand. In the Vareš mine, new sections, when completed in 1978, should bring mine output to 2.4 million tons, about 600,000 tons more than in 1975.

During 1976, pig iron was produced at seven plants and steel at eight plants. Seven rolling mills were in production during 1976.

The RMK-Zenica remained the major producer of steel in the country with a 34% share in the total. At RMK-Zenica, a new oxygen-converter steel plant started trial production. Two converters, each with a capacity of 150 tons of steel per hour or about 1.3 million tons of steel per year, were commissioned in August 1976. In December 1976, a cold rolling mill (annual capacity 150,000 tons of rolled products) went onstream. Both additions, steel plant and rolling mill, were part of the continuous effort by Yugoslav authorities to increase domestic output and reduce imports of steel products. Domestic steel output met 70% of country's demand.

Lead and Zinc.—Smelter production capacity was in excess of mine production during 1976. Exploration for new lead-zinc deposits, commissioning of a new mine, and expansion of existing mines and mills started in the early 1970's were the essential parts of a program aimed at closing the gap.

The new Tisovik mine near Pecka, Serbia, started trial production in December 1976. Output of the mine was planned at 6,000 tons of ore per year.[5]

After 7 years of development work, the Brskovo mine near Mojkovac, Montenegro, shipped its first zinc concentrate to the zinc electrolytic plant at Šabac. The mine was rated at 500,000 tons of ore per year.

Expansion continued at mines and mills at Trepča Lece, Blagodat, Novo Brdo. When all work is completed, an additional aggregated output of 24,000 tons of lead and zinc is expected. Work in Trepča's Stari Trg mine near Kosovska Mitrovica, Serbia, was concentrated on development of levels 10 and 11 at a depth of 750 meters. Large quantities of water under pressure of 200 pounds per square inch (psi) slowed down work on both levels. Production from levels 10 and 11 is scheduled to bring output of Stari Trg mine to 1 million tons of lead-zinc ore per year.

In addition to mine expansion, the management of Trepča decided to award a contract for expansion to 70,000 tons per year by 1978 of the zinc plant at Kosovska Mitrovica to Dowa Mining and Arita Zinc Co., Ltd., of Japan. The contract value of $30 million will be paid in two installments. The first half will be made as a down payment and the balance 5 to 6 years after startup.

After several years of less than successful trials, the Trepča sulfuric acid plant started production. Output of 94,000 tons of sulfuric acid per year may be expected

[5] Yugoslav Economic Daily. Privredni Pregled-Beograd, June 18, 1976, p. 3.

if the plant continues to operate without difficulties.

During 1976 about 18 mines and 14 flotation plants were operational. Two lead smelters (Trepča-Zvečan and Mežica), and one lead refinery (Trepča-Zvečan) produced lead. In addition, one Imperial smelting plant (Titov Veles) produced lead and zinc and two zinc electrolytic plants (Šabac and Kosovska Mitrovica) produced zinc.

RMK Trepča was the largest lead-zinc producer in the country. Among other facilities, Trepča operated the largest lead and zinc mine, Stari Trg, the largest lead smelter and refinery, Trepča-Zvečan, and zinc electrolytic plant at Kosovska Mitrovica.

Nickel.—During 1976, development of a mine and construction of a ferronickel plant continued at Ržanovo near Kavadarci in Macedonia. Production of 16,000 tons of contained nickel was scheduled for 1978. Proven reserves of 24 million tons averaging 0.9% nickel were reported. Yugoslavia's Feni-Rudnici i Industrija za Nikel, Čelik i Antimon-Kavadarci, will be the operator.

Platinum and Palladium.—Yugoslavia became a producer of platinum and palladium in the fall of 1976. Platinum and palladium were recovered at RTB-Bor from sludge from the copper electrolytic plant. Output was planned at about 15 to 34 kilograms of platinum and about 100 kilograms of palladium.

Uranium.—Construction, by Westinghouse, of the first Yugoslav nuclear powerplant, Krsko (615 megawatts electrical), continued near the town of Krsko in Slovenia. Some delays in deliveries of equipment have pushed back the completion date. Work and development on the Žirovski Vrk uranium mine and yellow cake plant reportedly went according to plans.

Other Metals.—Yugoslavia also produced bismuth, cadmium, chromite, germanium, gold, manganese, mercury, selenium, and silver in 1976. Except for mercury, produced at Idria, Slovenia, output of the other metals was modest. It should be noted that economic difficulties (low mercury prices) may force closing of the Idria mercury mine during 1977. Bismuth was a byproduct of the lead and zinc operation at Trepča; and cadmium was a byproduct at Trepča and at the Zorka plant at Šabac, Serbia. The Bor complex yielded gold, germanium, and selenium as byproducts of copper. Manganese was produced in Bosnia. Trepča was the main source of silver, a byproduct of lead and zinc processing.

NONMETALS

Cement.—Output of cement ranked first in value of nonmetals produced in the country, and reached an all-time high of 7.6 million tons.

Construction of a new cement plant at Popovac, Serbia, was announced. The plant will have a capacity of 900,000 tons of cement. F. L. Smidth of Denmark was the main contractor, and completion was set for 1979. Construction continued on a 600,000-ton-per-year cement plant near Našice, Croatia, and on a 720,000-ton-per-year cement plant near Kakanj. Dalmacija Cement, with its plants at Solin near Split, was the largest producer of cement accounting for 30% of total cement output of Yugoslavia in 1976.

Clays.—*Bentonite.*—New reserves totaling 100 million tons of bentonite, situated in Slaviško Poje near Kriva Palanka, permitted the Bentomak mine to start construction of a facility for production of 40,000 tons of alkali-activated bentonite. At yearend, a new plant was near completion, and startup was announced for 1977.

A bentonite deposit was discovered at Gušica near Vitina in the Kosovo region. Reserves were reported at 73 million tons. Authorities have organized an enterprise, Bentokos, to start production of about 100,000 tons of bentonite per year.

Fertilizer Materials.—*Phosphate Rock.*—A feasibility study for development of the first phosphate mine, Lisina near Bosiljgrad, Serbia, was underway during 1976. Reserves were estimated at 100 million tons and RTB-Bor financed exploration. The study proposed an annual production of 3.6 million tons of crude ore, with an output of 900,000 tons of concentrates. Fertilizer factories at Prahovo, Šabac, and Kosovska Mitrovica, all in Serbia, would be users of concentrates from Lisina.

Lime.—During 1976 the following new lime plants went onstream: Čelinac (65,000 tons per year) and Doboj (280,000 tons per year), both in Bosnia. Construction continued on a 100,000-ton-per-year lime plant at Drniš, Croatia.

MINERAL FUELS

Energy.—During 1976, domestic low-rank coals remained the principal source of energy in the country, and Yugoslavia was dependent on imports of high-rank coals, coke, and crude oil. Table 4 shows supply and apparent consumption of energy-producing materials for 1974 and 1975.

Coal.—During 1976, about 49 coal mines were in operation in the country. However, approximately 60% of output came from four large coal operations (Kosovo, Kolubara, Kostolac, and Kreka). Brown coal and lignite comprised the bulk (98%) of Yugoslavia's coal output. Imports of bituminous coal and coke were essential for the energy supply of the country. Imports of coking coal will, in the future, increase to meet the demand of the new coking facilities scheduled for completion in 1978.

A new $19 million opencast brown coal mine, Turija, started production near Banovići in Bosnia. The mine, with an initial capacity of 1.3 million tons per year, was slated for an output of 2 million tons in 1980 and 5 million tons in 1990.

Development of the new Tamnava mine in the Kolubara Basin, Serbia, continued. When completed in 1980, the Tamnava mine will produce between 18 million and 20 million tons of lignite per year, and all mines in the Kolubara Basin will together produce 24 million tons annually.

In the Kostolac Basin, Serbia, development of a new 2.5-million-ton opencast mine, Ćirkovac, was near completion at yearend. Development of the Drmno opencast mine was slowed down and the new startup date was reported for 1982. Initial yearly capacity was planned at 6 million tons with the possibility for expansion to 9 million tons at a later date. Both mines (Ćirkovac and Drmno) were planned to deliver lignite to two power-generating plants. At yearend, one plant, a 210-megawatt facility, was near completion; and the second plant, a 600-megawatt facility, was planned.

New reserves, about 4.5 million tons of brown coal, were discovered at the Bogovina mine near Zaječar. This new reserve brought the total proven reserves at Bogovina to 7 million tons, which at the 1976 rate of production will be adequate for 20 years.

In the general area of Štavalj, near Sjenica, Sandžak Province, Serbia, discovery of about 200 million tons of brown coal was announced, but there were no immediate plans for development.

Coke.—Construction of a coking plant at Bakar continued according to plans. An underwater tunnel, 400 meters long, was completed during 1976. Equipped with a conveyor belt, the tunnel was planned to transport coal to the plant from a bulk ore port at Bakar, Croatia, which is situated on the other side of the Bakar inlet. When completed in 1977, the Bakar plant should produce 850,000 tons of coke per year. Plans exist for doubling capacity in the future.

Imports of coke started to decline reflecting 1 full year of operation of new coking facilities at Lukavac, in Bosnia. A downtrend in coke imports is expected to con-

Table 4.—Yugoslavia: Supply and apparent consumption of energy-producing materials for 1974 and 1975

(Million tons of standard coal equivalent [1])

[3] Less than 0.01 million tons of SCE.

tinue and imports of coke are scheduled to end in 1978 when the new coking plant near Bakar will be operational.

Natural Gas.—The high cost of imported liquid hydrocarbons made domestic natural gas more attractive. Construction of a large gas pipeline system continued during 1976 in Serbia and remained the major activity in the natural gas sector of the industry. When the 1,260-kilometer trunk pipeline with a capacity of 2.5 to 4.5 billion cubic meters per year is completed, it will connect the gasfield in Vojvodina with consumers in Serbia and Bosnia. Construction of the whole system was delayed and a new completion date was reported for the latter part of 1979. At yearend, 90 kilometers of the system were completed and the cement plant at Beočin will become a user of natural gas in 1977. In Croatia, construction of an 800 million-cubic-meter-per-year natural gas processing plant continued near Ivanić Kloštar. Ethane is to be piped by INA-Naftaplin to Zagreb for production of ethylene. INA-Naftaplin will operate the facilities. In Slovenia, a credit of $60 million was arranged for financing a pipeline system for transportation of gas from Austria to consumers in Slovenia. Details on the capacity and length of the system were not made public at yearend.

During 1976, domestic output of natural gas was adequate. However, in the future imports of gas from Hungary and the U.S.S.R. will be necessary to meet the demand that is being created by gasification of cities. Naftagas was the major producer of natural gas in the country and accounted for about 51% of the total output. INA's largest gasfield was Bokšić Lug in Slavonia. Two natural gas processing plants, Ivanic Klostar and Mramor Brdo, produced about 90,000 tons of butane and propane. In addition, Naftagas operated its largest gasfield near Kikinda, Vojvodina, and gas processing plants in Elemir and Mokrin with an aggregate output of about 20,000 tons of products.

Petroleum.—In 1976 domestic production of crude oil reached an all-time high of 3.8 million tons (about 75,000 barrels per day). However, about 70% of 1976 refinery throughput was imported. Iran, Iraq, and the U.S.S.R. were the principal suppliers of crude oil. INA, and Naftagas, headquartered in Novi Sad, Serbia, remained the only producers and most important refiners of crude oil in Yugoslavia. INA was by far the largest, accounting for about 70% of the country's total crude oil output. Six refineries, three operated by INA (Rijeka, Sisak, and Lendava), two by Naftagas (Novi Sad and Pancevo), and one by Energoinvest (Bosanki Brod) had an installed annual capacity of 13.2 million tons.

Exploration, Development, and Production.—During 1976 the Pannonian sedimentary basin in north Yugoslavia remained the principal area for active petroleum and natural gas exploration and development. Exploration offshore in the Yugoslav part of the Adriatic was limited to assessment of results obtained during recent drillings and preparation for further drilling. INA-Naftaplin in Croatia and Naftagas in Serbia carried out exploratory and development drilling in the Pannonian Basin. Approximately 175,000 meters were drilled by Naftaplin and about 101,000 meters by Naftagas during 1976, and new discoveries were made at Slavonija and Banat. However, further drilling will be required to assess the economic importance of the new discoveries. The stepout well in the Kikinda Field in Banat and Benicanci Field in Slavonija showed possibilities for significant extensions.

In the Adriatic, INA was preparing locations for an offshore drilling rig, the first owned and operated by Yugoslav enterprises, expected to start drilling during 1977. In the south, Yugopetrol-Adriatica (a joint venture between Buttes Gas & Oil Co., Challenger Oil & Gas Co., and Yugopetrol-Kotor) completed the first well, Juzni-Jadran 1. Casing was set at 3,300 meters and reportedly high-pressure gas zones were encountered. At yearend 1976, a decision was made to drill a second well in the area.

All of the crude oil production in Yugoslavia came from approximately 32 fields situated in the Pannonian Basin. Beničanci, Slavonija Province, Croatia, operated by INA-Naftaplin, was the largest oil producing field in the country.

One field, Palić, located near the city of Subotica, north Yugoslavia, started production in the fall of 1976. The field, operated by Naftagas, was scheduled for production of 70,000 tons of crude oil per year in 1977.

In addition, Yugoslavia carried out drilling and exploration abroad. INA was active in Syria, Burma, and Bangladesh; Naftagas in Africa, mainly Guinea.

Refineries.—Six State-owned refineries processed a total of 11.8 million tons of crude and operated at 89% of its installed capacity. Imported crude oil, mostly from Iran, Iraq, and the U.S.S.R., accounted for about 70% of the total refinery throughput. Although domestic output was far below demand, and high prices of imported crude oil burdened the economy, expansion of petroleum refining capacities remained one of the major targets for the industry.

Two new refineries, one in Koper, Slovenia, and another in Skopje, Macedonia, were scheduled for construction. However, both projects were in early stages of planning and no firm data on capacity, financing, and marketing of products were available at yearend 1976. In addition, plans were made for expansion of refineries at Rijeka (to 8 million tons annually), Sisak (to 6.7 million tons), Bosanski Brod (to 3 million tons), and Novi Sad (to 2.5 million tons). During 1976, a new lube plant and asphalt plant went onstream at the Novi Sad petroleum refinery operated by Naftagas. Capacity of the lube plant was not made public, but the asphalt plant is to produce 80,000 tons of bitumen per year.

On March 27, 1976, representatives of Dow and INA concluded an agreement for investment of about $700 million in a petrochemical complex on the island of Krk in the northern Adriatic.

The Krk joint venture is to be financed according to a new Yugoslav law regulating investments of foreign capital. INA will provide 51% of the total investment and retain controlling interest. Dow will supply the rest. In addition, Dow will introduce the latest U.S. technology for the new installations. Imported raw material will be used as feedstock, but its origin was not determined at yearend.

The new enterprise is to operate under the name DINA. DINA will be part of INA and operate under Yugoslav law. Construction started in 1976, and completion is scheduled for 1982. Final capacity of the complex will be 1.8 million tons per year of various petrochemical products.

Transportation.—Construction continued on the 1,200-kilometer crude oil trunk pipeline from Omisalj on the island of Krk, where a tanker port with storage facilities for crude oil and pumps for moving oil over the Dinaric Alps were situated, to inland refineries in Yugoslavia, Hungary, and Czechoslovakia. The pipeline will have an annual capacity of 34 million tons, when completed in 1978 or 1979.

The Mineral Industry of Zaire

By Miller W. Ellis [1]

Zaire's mineral industry was adversely affected by transport difficulties and the resulting lack of fuels and export facilities in 1976. Despite lower production of most mineral commodities, Zaire continued to lead the world in production of cobalt, germanium, and industrial diamond, and ranked sixth in copper output. The Benguela Railway remained closed throughout the year, and traffic to and from the mineral-rich Shaba Region was diverted to longer and more costly routes. Exports of Shaba's mineral products by way of the internal rail-barge-rail route to the river-seaport of Matadi were reportedly below the 1975 tonnages.

The country's monetary unit, the zaire, was worth US$2.00 until March 12, 1976, when it was equated with one Special Drawing Right (SDR) of the International Monetary Fund (IMF), then worth approximately $1.15. Zaire's inability to service its external borrowings resulted in discussions with creditor nations and arrangements for refinancing to insure continuity of projects vital for the expansion of the mineral industry.

Lack of sufficient electrical power contributed to diminished utilization of copper refining capacity at Kolwezi. The high-voltage, direct-current transmission line from Inga, on the lower Zaire River, to the Shaba copperbelt was still incomplete at yearend. A British firm was negotiating for construction of a rail link between Ilebo, on the Kasai River, and a railhead at Kinshasa to obviate river barge transport. Studies were completed for a road and railway bridge from Matadi to the north bank of the Zaire River, a railway to the Atlantic port of Banana, and larger deepwater docks at Banana for more efficient handling of large freighters and tankers.

The Zairian firm La Générale des Carrières et des Mines du Zaire (Gécamines) acounted for the country's production of cadmium, cobalt, germanium, zinc, and most of the copper and silver. Shortages of fuel oil resulted in intermittent operation of heavy mining equipment, and production of refined metal and wirebar casting was restricted by a lack of coke. Gécamines' staff was increasingly involved in negotiating and implementing arrangements for alternative export routes. Because Gécamines' products earned most of Zaire's foreign exchange, the company was allowed direct access to 45% of its foreign exchange credits, and had to assume additional responsibility for acting as purchasing and export agent on behalf of other Zairian companies. Société de Développement Industriel et Minièr du Zaire (Sodimiza), 80% owned by a Japanese consortium, operated at a loss owing to the increased cost of rail transport of its concentrate to a South African port en route to Japan.

PRODUCTION

Lack of transport and fuel caused a general decline in production of most Zairian mineral commodities in 1976. Mine production of copper was more than 10% below that of 1975, but it accounted for nearly 60% of the total value of Zaire's mineral products. Cobalt remained Zaire's second greatest foreign exchange earner

[1] Physical scientist, International Data and Analysis.

although production of metal was more than 20% lower than in 1975. Zaire's first-year offshore crude oil production of more than 9 million barrels placed this new commodity on its list of foreign exchange earners. The 1976 production of industrial diamond decreased 10%, zinc 11%, and tin 26%. Production of silver as a copper-zinc industry byproduct increased 8%. Details of mineral production are shown in table 1 and export data are listed in table 2.

TRADE

Early in 1976, the State-owned agency Société Zairoise de Commercialisation des Minerais (Sozacom) experienced difficulty in marketing copper products, and its functions were returned to the Belgian firm Société Générale des Minerais S.A. (SGM). Arrangements were made for SGM to hold 45% of sales revenue in a hard currency account in Europe, and to use these funds directly for purchases and payments authorized by Gécamines. This procedure eased Gécamines' cash flow problems and expedited delivery of equipment and supplies in Zaire. By November, proposals were made for a new agency, owned 50% by SGM and 25% each by Gécamines and Sozacom, to be responsible for marketing, purchasing, and recruitment in Europe by November 1978.

The port of Matadi handled about 237,000 tons of mineral exports during 1976, some 12% less than in 1975. The East African Railways Corporation reportedly handled 70,000 tons of copper and 25,000 tons of zinc shipped from Shaba by way of Lake Tanganyika to Dar es Salaam, Tanzania. Except for some 6,500 tons of tin and various mineral concentrates from the eastern Shaba and Kivu Regions, the remainder of Shaba's mineral exports were shipped through Zambia, Southern Rhodesia, and Botswana to a South African port.

During the early part of the year, Zairian exports through Zambia transited Southern Rhodesia en route to Mozambique ports. After Mozambique closed its Southern Rhodesian border, such exports were diverted from Bulawayo through Botswana to South African ports. The extra transport costs diminished Gécamines' income on copper metal exports and resulted in a loss for Sodimiza because of the lower unit value of concentrate (34% to 36% copper) shipped to Japan for smelting. The returning railcars were loaded with bulky imports, chiefly coke, coal, maize, and other foodstuffs needed to maintain production in the Zairian copperbelt.

The relegation by the Zairian National Railways of Sodimiza's exports to the southern route was largely dictated by Zaire's need for maximum import capacity on the return trip. The relative difficulty of transshipping concentrate to Tazara's railcars in Zambia, the incompatibility of braking systems on Zairian and Tazaran railcars, and a restriction on the number of Zambia's dual-system cars allowed to enter Zaire further mitigated against Sodimiza being allocated any of Tazara's limited capacity in excess of Zambia's high-priority requirements.

In early August, Zairian Railways announced an increase of approximately 75% in freight rates within Zaire. Both Gécamines and Sodimiza protested against the increase and negotiations were in progress at yearend. Gécamines' commodities from its industrial centers at Lubumbashi, Likasi, and Kolwezi travelled 230, 360, and 520 kilometers, respectively, over Zairian lines to the Zambian port of entry at Sakania, or more than 1,000 kilometers to river barge transport at Ilebo or to the lake steamer at Kalemie. Sodimiza's concentrate was produced at Musoshi near the railroad and the Zambian frontier, but had to travel 150 kilometers eastward over Zairian lines to the Sakania border post en route to East London, Republic of South Africa.

The most recent official information available on imports was that for 1970 which appeared in the Zaire chapter of the 1972 Minerals Yearbook.

COMMODITY REVIEW

METALS

Aluminum.—Exploitation of bauxite deposits near Sumbi, 150 kilometers northeast of Banana, was further discussed as a joint project of the Zairian Government (55%) with Alusuisse. Power from the Inga project would be used for an aluminum refinery as part of an industrial complex near projected deepwater port facilities at Banana. Zairian authorities were also reportedly negotiating with Reynolds Metals Co. of the United States for construction of a second aluminum plant in this vicinity.

Copper, Cobalt, Zinc, Associated Metals (Shaba Region).—The 1976 slump in production from the mineral-rich Shaba Region was caused by the disruption of transport facilities following closure of the Benguela Railway outlet through Angola to the Atlantic port of Lobito in August 1975. Longer and more expensive alternative routes caused shortages of diesel fuel, coke, and other commodities required for mining and metallurgical operations, and resulted in an inadvertent compliance with production limitations proposed by the Conseil Intergouvernemental des Pays Producteurs et Exporteurs du Cuivre (CIPEC) at its Lima, Peru, meeting in November 1975. The CIPEC limitations were not extended beyond their expiration date of June 30, 1976.

Transport difficulties, which were also responsible for increased costs of production and sales, coupled with depressed copper prices on the world market, drastically reduced the profitability of Shaba's mineral industry on which some 75% of Zaire's foreign exchange and about half of Government revenue depended. Gécamines, the Government-owned successor to Union Minière du Haut Katanga (UMHK) and other companies previously responsible for recovery and refining of cobalt, zinc, germanium, cadmium, silver, gold, and other byproducts, continued to dominate the industry. Shortages of diesel fuel interrupted operations at most of Gécamines' pits including those at Dikuluwe and Mashamba near Kolwezi. Late delivery of equipment contributed to delays in construction of nearby concentrating, smelting, and refining facilities as part of Gécamines' second 5-year expansion plan. Work toward completion of the high-voltage, direct-current transmission line from Inga on the lower Zaire River, vital to the expansion plan, continued during 1976.

Gécamines produced about 408,000 tons of copper, 92% of Zaire's mine output in 1976, and accounted for all of Zaire's output of cobalt, zinc, germanium, and cad-

mium, most of its silver, and part of its gold.

Zaire continued to hold a 20% interest in the Sodimiza operations near the Zambian border at the eastern end of the Zairian copperbelt. The remaining 80% was held by a consortium including Nippon Mining Co., Ltd., Sumitomo Metal Mining Co., Ltd., Mitsui Mining & Smelting Co., Ltd., Nissho-Iwai Co., Ltd., Furukawa Mining Co., Ltd., Toho Zinc Co., Ltd., Mitsubishi Metal Corporation, and The Dowa Mining Co., Ltd. Of the more than 3,600 employees, only about 150 were Japanese cadre, most of whom were Nippon employees. Sodimiza's output of copper sulfide concentrate was intended for shipment to Japan as raw material for smelting, refining, and fabrication by the Japanese industry.

Sodimiza accounted for 8% of Zaire's copper production from its Musoshi mine and 140,000-ton-per-month concentrator. Development of its Kinsenda mine continued and monthly delivery of 14,000 tons of Kinsenda ore to the Musoshi concentrator was scheduled to start in October 1977. The 1976 Musoshi concentrator output was reportedly 102,000 tons of copper sulfide concentrate containing 35.5% copper, equivalent to 36,210 tons of copper metal. These figures represent increases of 8% and 12%, respectively, over Sodimiza's 1975 production. The amount of cobalt and other byproducts in the Musoshi concentrate was not available. Sodimiza's concentrate was initially shipped to Japan through Angola to the Atlantic port of Lobito, and the returning railcars carried a substantial amount of imports to the Shaba Region. When this route was closed in August 1975, concentrate shipments were diverted through Zambia and Southern Rhodesia to the Indian Ocean port of Beira, and the returning cars brought coke, grain, and other imports to Shaba. In March 1976, the Mozambique-Southern Rhodesian border was closed and Sodimiza's concentrate was rerouted from Bulawayo in Southern Rhodesia through Botswana to the South African port of East London. Returning railcars continued to carry fuel and food vital for Shaba's industries. In respect to equivalent copper metal tonnages exported, Sodimiza required about three times the number of railcars needed by Gécamines.

Société Minière de Tenke-Fungurume (SMTF) suspended construction of its copper-cobalt mining and metallurgical complex east of Kolwezi in January 1976 because of financial difficulties following delays in receipt of fuel and equipment. The project was placed on a care-and-maintenance basis with some 850 Zairian and 30 expatriate employees at a monthly cost of about $400,000. By yearend, a reevaluation of the situation indicated that a reduction of production targets from 130,000 tons to 95,000 tons of copper cathodes per year and from 6,000 tons to 4,500 tons of cobalt per year might be envisaged at a capital cost of about $650 million in addition to the $275 million already expended.

Columbium-Tantalum, Gold, Tin, Tungsten.—Soc. Zairetain's operation near Manono in the east-central part of Shaba Region was shut down by a strike on July 19 because workers demanded a wage increase similar to one granted Gécamines earlier in the month. The Government ordered a lockout, and within a few days a broken sluice gate emptied the reservoir of water impounded to wash out the cassiterite ore during the dry season. Production could not be resumed until November after the onset of the rains had replenished the reservoir. Two of Zairetain's mines were then reopened and 1,500 of the original 2,800 workers were able to return to work, but production of tin metal and tantaliferous slag was only about 65% of that attained in 1975.

In the Kivu Region, Compagnie Belge d'Entreprises Minières (Cobelmine), a 1975 amalgamation of previously independent mining companies, and Syndicat Minière de l'Etain (Symetain) were finally consolidated into a single company, Société Minière de Kivu (Sominki). A Presidential ordinance signed March 31, 1975, officially established 20% Zairian ownership of the new company with headquarters at Bukavu and an administrative office at Kinshasa. Sominki had about 18,500 employees, 105 of which were expatriates, and was responsible for more than $20 million worth of export credits for gold, cassiterite (tin ore), columbite-tantalite, wolframite, and monazite. Some $230,000 was expended on metallurgical research and exploration for new ore.

Iron and Steel.—The Zairian Government operated a small steel plant, the Sidurna Works, at Makulu on the Zaire River near Kinshasa, which produced some 3,000 tons of steel sheet, rod, and shapes from scrap in 1974 and 1975. In early 1976, iron deposits at Banalia and Libundu were appraised, and plans were announced for their joint exploitation by German companies and the Zairian Government. The project was to operate within the International Association for the Industrialization of Northeastern Zaire. The deposits were previously reported by the French Bureau de Recherches Géologiques et Minières (BRGM), which was continuing its authorized inventory of Zaire's mineral resources outside the area allocated to Gécamines and other major mining companies.

Manganese.—Mining operations continued at a diminished rate at the Kisenge deposits near the Benguela Railway, approximately 100 kilometers east of the Angolan frontier in the southwestern Shaba Region. Société Minière de Kisenge (SMK) was Zairian owned and managed, with some 700 employees including a few expatriates. The low-unit-value ore had been exported profitably by way of the Benguela Railway, but after the closure of this export route in August 1975, all production was stockpiled. The 1976 output was about 156,600 tons, and some 550,000 tons of ore was reportedly in the stockpile at yearend. In August and September 1976, representatives of Mitsubishi of Japan were exploring possibilities for upgrading SMK's output at the mines. Later in the year SMK reportedly contracted to export 100,000 tons of ore over the southern route as soon as railcars became available.

NONMETALS

Cement.—Most of Zaire's cement was produced and consumed in the Shaba Region. Cimenteries du Shaba (Cimshaba) operated three rotary kilns at Lubumbashi and sold nearly 70% of its output to Gécamines. Other customers included Sodimiza and Constructeurs Inga-Shaba (CIS), the U.S. company partly responsible for building the electrical transmission line. Cimshaba's production was below 1975 output because of shortages of firebrick and containers. Lack of foreign exchange was partly alleviated by a $600,000 credit line with three Belgian banks, and should be obviated by Gécamines' purchase of 40% of Cimshaba's stock in December 1976. Clinker produced by Cimshaba was sold to Ciments Metallurgiques de Likasi (CML), a subsidiary of Gécamines. CML's lime and cement production was all consumed by the parent company.

The Ciments-Laçs operation at Kabimba, near Kalemie on Lake Tanganyika, was halted in October 1975 because the nearby Makala coal mine was shut down for lack of spare parts and diesel fuel. During 1976, Ciments-Laçs produced only 40,000 tons of cement but officials were optimistic that full-scale operations would resume early in 1977.

Cement plants were also reportedly planned or operating at Kinshasa and Kisangani. A new marble quarry was started near Kimpese in lower Zaire by Itenco-Marbreza Co. Some of the output was to be used by Chinese workmen in the construction of the Kinshasa "Palace of the People." Contracts for the sale of marble to neighboring countries were being sought.

Diamond (Kasai Region).—Intermittent shortages of diesel fuel caused temporary shutdowns of heavy equipment at open pit mines operated by Société Minière de Bakwanga (MIBA) in the Mbuji-Mayi area, and resulted in the lowest industrial diamond production for some 25 years. A small part of the production came from small-scale private operations, especially in the old Tshikapa fields near the Angolan frontier. Such production was sold to local buying agents. Zaire's annual industrial diamond production quota of 13.5 million carats was set by Zaire-British Diamond Distributors, Ltd. (Britmond), an affiliate of the Central Selling Organization, which has started training Zairians to sort and grade the local production in Kinshasa.

Stone.—*Ornamental.*—Malachite, the green carbonate of copper, has been used as an ornamental stone, for carvings, and for gems for many centuries. The export of malachite from "Cazembe's country" (formerly Katanga, now Shaba) was noted in 1799 and recorded in "Lacerdas Journal." Both Burton and Livingstone reported it as a trade commodity in the late 1850's, along with copper metal readily smelted from it by aboriginal metallurgists. Until 1960, malachite was the most im-

portant copper mineral in all of UMHK's mines except Kipushi, and a large quantity of malachite was profitably exported annually under strict control. During the 1960–67 post-independence disturbances, illicit export of malachite commenced on a large scale and sale of the mineral was prohibited within the country. In 1976, new regulations provided for Gécamines to transport raw malachite to three agencies in Kolwezi, Likasi, and Lubumbashi, where it was sold to approved craftsmen working in cooperatives or prepared for export. During 1976, Zairian malachite could be purchased in the United States at prices ranging from $10 to $30 per pound depending on quality and size.

MINERAL FUELS

Coal.—Although no production figures were available from La Société des Charbonnages de la Luena, 250 kilometers north of Kolwezi, it seemed probable that some coal was mined for the production of copper and cement. A new coal gasification plant was included as part of Gécamines' expansion plan. Coal from the Makala Field near Kalemie on Lake Tanganyika was reportedly used in the nearby cement plant. Coal and coke were imported from Zambia, Southern Rhodesia, and the Republic of South Africa. At yearend, negotiations were reported for the import of 200,000 tons of West German coal by way of Dar es Salaam.

Petroleum.—Crude oil production from Zaire's offshore fields commenced at yearend 1975, and more than 9 million barrels was reported for 1976, making oil Zaire's third most valuable mineral product. Three firms participated in offshore oil production: Zaire Gulf Oil Co., Japan Petroleum Zaire, and Muanda Oil Co., a subsidiary of the Belgian firm Cometra Oil. The Zairian Government retained a 15% interest in each of the concessionary firms. It was reported that some of the crude oil was shipped to the Moanda refinery near Banana, but the high pour point, paraffin, and saltwater content made it unsuitable for the local refinery. Plans to double capacity of the refinery were reported to include modifications for handling the local crude. Refinery production of about 2.5 million barrels of liquid fuels was far below local consumption, which was expected to increase as transport facilities improve and Shaba's mining industry expands. Construction of a small-diameter pipeline to carry diesel fuel from Zambia's Ndola refinery to Shaba's copperbelt was postponed for lack of financing.

Onshore oil exploration had involved an aeromagnetic survey in late 1973 by the U.S. firm L.K.B. Resources Inc., a fluvial-seismic survey by the British firm Seismograph Service Ltd., and a territorial seismic survey by a subsidiary of the French Compagnie Générale de Geophysique in 1974 and 1975, on behalf of the concessionaires Shell Centrex and Texaco Inc. Shell Centrex subsequently engaged Seismograph Service to provide a unit in Kinshasa to process and interpret the seismic data. By yearend 1974, approximately $5 million had been expended and field exploration was halted while interpretation of results continued. In mid-1976, Shell Centrex withdrew from the project for budgetary reasons and Texaco was negotiating a new agreement with the Zairian Government. Correlation of geophysical results with Earth Resources Technological Satellite (ERTS) photography indicated the possibility of potential oil deposits near Akula, near the equator some 700 kilometers northeast of Kinshasa, where field assessment was started in 1976.

The Mineral Industry of Zambia

By Miller W. Ellis [1]

Zambia continued to rank as the world's fifth largest producer of copper in 1976, and Zambia's mineral exports continued to provide more than 90% of its foreign exchange. With the gradual improvement in the international copper price, both of its major copper-producing companies, Nchanga Consolidated Copper Mines Ltd. (NCCM) and Roan Consolidated Mines Ltd. (RCM), were operating at a profit by mid-1976.

In January 1976, full emergency and austerity measures were announced because of the continued low price of copper and the transport difficulties aggravated by the closure of the Benguela Railway through Angola in August 1975. Import permits were restricted to the most essential items, and applications for the externalization of funds were approved only when foreign exchange credits became available. Only essential categories of expatriate staff could be retained or recruited. The mineral industry was given a high priority for exchange control needed to maintain production levels and to complete projects for the expansion of metal production. Imports of food and nonessential consumer goods were restricted, and domestic production of such commodities was encouraged.

On July 8, 1976, the Zambian currency (kwacha) was devaluated and was fixed in terms of Special Drawing Rights (SDR) of the International Monetary Fund (IMF) instead of the U.S. dollar.[2] This resulted in an increase in the domestic kwacha value of both exported and imported commodities. The direct effect on the mineral industry was negligible, but the local cost of imported consumer goods increased about 25%.

The Tanzania-Zambia Railway (Tazara) carried increasing amounts of Zambian exports and imports, and by July 14, when the line was officially opened, virtually all of Zambia's transport problems had been resolved.

In real terms, the gross domestic product (GDP) increased 2.4% in 1976, following a 3% decline in 1975. In terms of local currency, the increase was nearly 15%. The increase was owing to greater production by the mineral and agricultural industries.

PRODUCTION

Zambia's blister copper production increased 7% from 659,000 tons in 1975 to 706,000 tons in 1976, but production of zinc declined 21%, lead 29%, and cobalt 7%. Details of mineral production are shown in table 1.

[1] Physical scientist, International Data and Analysis.

[2] Where necessary, values have been converted from Zambian kwacha (K) to U.S. dollars at the rate of K1=US$1.4019 for 1976 and K1=US$1.5541 for 1975 as shown in International Financial Statistics. V. 30, No. 12, December 1977, p. 392.

[1] Includes leach cathodes.

[2] Chiefly contained in blister copper and refinery muds; estimated level of output for all producers; previously reported figures at a lower level did not include total national output.

[3] Refined silver and silver contained in blister copper and refinery muds.

[4] Less than ½ unit.

TRADE

The closure of the Benguela Railway because of civil unrest in Angola was followed by acceleration of work on the Tazara line. Freight- and passenger-handling facilities were completed throughout the system. Port facilities at Dar es Salaam were improved and enlarged to handle additional cargo while the Tazara roadbed stabilized to carry heavier loads and additional traffic. Zambian rolling stock was fitted with a second braking system so that it would be compatible with new rolling stock provided by the People's Republic of China.

All copper stocks within Zambia had been shipped and the backlog of imports had been cleared from Dar es Salaam before the July 14 ceremony when the Chinese Deputy Prime Minister officially handed over the Railway operation to the Presidents of Zambia and Tanzania at the Zambian junction town of Kapiri Mposhi, 160 kilometers south of the Copperbelt.

Truck routes to connect with railheads in Malawi and Mozambique were opened but were little used because of deteriorating roads and conditions for handling cargo at the Mozambique ports of Nacala and Beira.

An untarred truck route was completed from Francistown in Botswana to the Zambezi River at Kazungula, 80 kilometers upstream from Victoria Falls. Traffic was limited by the capacity of the ferry installation at Kazungula. A study of routes, rolling stock, loading, handling, and transfer capacities, and costs in respect to export and import requirements was assessed by officials of Zambian, Tanzanian, and Zairian Government agencies and mining and railroad companies. The Zambian requirements were allocated first priority for use of the Tazara route to Dar es Salaam, but RCM was also allocated low tonnages for road transport to Moatize and rail transport to the Beira harbor in Mozambique. NCCM also was to utilize a similar route through Malawi to the port at Nacala in Mozambique.

Zambia has been a net exporter of electricity since the first Kafue Gorge hydroelectric units were commissioned in 1972. With the startup of the Kariba North Bank hydroelectric station in May 1976, Zambia has been able to supply increasing industrial and export demands. Thermal power stations at most industrial centers were maintained for emergency standby capacity.

During the 5-year period 1970–74, Zambia's imports from the United States had an average annual value of about $60 million, while exports averaged less than $5.5 million. In 1975, the value of imports more than doubled, but export sales dropped to less than $250,000. This situation was dramatically reversed in 1976 when the value of imports from the United States decreased to about $60 million, and exports soared to nearly $150 million. Except for a general decline in imports during 1976, the trend of Zambia's trade relationships with other major trading partners has been relatively stable since 1970.

The value of Zambia's 1972–76 trade, in million dollars, is shown in the following tabulation:

	1972	1973	1974 r	1975	1976 e
Copper exports	814	1,092	1,303	735	965
Total exports	845	1,160	1,407	810	1,054
Total imports	628	544	787	929	657
Balance of trade (exports minus imports)	+217	+616	+620	−119	+397

e Estimate. r Revised.

The positive balances, however, do not indicate an accumulation of foreign exchange credits because of expenditures on loan repayments and overseas dividends and other disbursements. The 1975 current account deficit of more than $600 million was reduced to about $144 million in 1976.

Table 2 shows the amounts and destinations of mineral exports, and table 3 lists the amounts and sources of mineral imports.

COMMODITY REVIEW

METALS

Copper and Byproduct Cobalt.—Zambia's two major copper companies mined and treated nearly 33.7 million tons of ore with a total copper content of nearly 825,000 tons during fiscal 1976. NCCM produced approximately 17.9 million tons of ore containing nearly 500,000 tons of copper, and RCM divisions accounted for about 15.8 million tons of ore containing more than 325,000 tons of copper.

The following tabulation shows ore mined and treated and ore reserves at the various mines operated by RCM for its fiscal year ending June 30, 1976:

Mine	Ore mined and treated			Ore reserves	
	Gross weight (thousand metric tons)	Percent copper	Copper content (metric tons)	Gross weight (thousand metric tons)	Percent copper
Mufulira [1]	6,700	2.15	144,050	144,634	3.08
Luanshya [1]	4,920	1.19	58,736	69,023	2.46
Baluba [1]	1,280	2.58	33,024	64,342	2.58
Chambishi [2]	1,450	2.28	33,060	41,542	2.89
Chambishi [1]	635	2.45	15,558		
Chibuluma [1]	610	3.70	22,577	8,212	4.67
Kalengwa [2]	209	8.72	18,248	918	6.92
Kalulushi East [1]	--	--	--	5,900	4.09
Total	15,804	2.06	325,253	334,571	2.90

1 Underground.
2 Open pit.

RCM reported its fiscal 1976 production at 280,994 tons of finished copper and sales at 271,431 tons, down 3% and 6%, respectively, from the 1975 figures. The average sales price declined 12% to $1,254 per ton for fiscal 1976, but both production rate and copper prices improved during the last half of 1976. The Mufulira underground mine acounted for 45% of RCM's production. Trackless mining methods facilitated ore extraction in the western "flat-dip" area, but most of Mufulira's ore came from the eastern part of the mine where rehabilitation of workings affected by the 1970 "mud-rush" was nearly completed. A subvertical shaft system was started to extract ore below the 580-meter level in the eastern part of the mine. The total cost was estimated at about $62 million, and final commissioning was planned for about 1984. Nearly $20 million was proposed for improvements of materials-handling facilities

in the smelter complex, scheduled to be completed by early 1979.

RCM's Luanshya operation was adversely affected by poor ground conditions, resulting in dilution of ore from the Roan Antelope mine. Shortages of equipment and spare parts and a lack of skilled, experienced staff contributed to decreased output and higher production costs. An upcast ventilation shaft was completed at the western part of the mine (the Muliashi section), and surface fans were installed. The No. 5 ventilation shaft at Baluba was started, and the No. 2 shaft was deepened below the 370-meter level. Four compressors worth more than $5 million were ordered. A new rotary dryer was installed, and the converter and anode aisles were extended at the Luanshya smelter. The $7.5 million coal preparation plant was commissioned to deliver 540 tons of pulverized fuel per day.

Installation of the headframe and equipping of the 1,000-meter main hoisting shaft (No. 3) at RCM's Chambishi open pit was nearly completed, but 635,000 tons of ore was produced through continued use of trackless methods for underground mining down dip from the pit. The open pit produced 1.45 million tons of ore, and 7.22 million tons of overburden was stripped. Oxidized ore was treated in the vat leaching plant, and more than 65,000 tons of concentrates, including cobaltiferous concentrate from Chibuluma and Baluba, was treated in the roast-leach plant. Cobalt hydroxide containing 640 tons of cobalt was recovered from the leach solutions and sent to Nkana for further treatment. The electrowinning plant produced about 16,000 tons of leach copper cathodes. Sulfide concentrate was shipped to the Mufulira smelter. Interesting copper mineralization was intersected at depths of 700 to 800 meters in several drillholes located about 10 kilometers southeast of the Chambishi mine.

At Chibuluma, the No. 3 shaft was deepened, and the new No. 7 shaft at the Chibuluma West ore body was more than 600 meters deep. Shaft sinking and construction of a surface plant was resumed at the Kalulushi East ore body, 10 kilometers south of Chibuluma. More than 2.5 million tons of overburden was removed at the Kalengwa mine, and less than one-tenth of that amount of ore was recovered. The Kalengwa concentrator treated about 100,000 tons of ore, and a similar amount of high-grade ore was trucked to the Copperbelt. Low-grade ore and concentrator tailings were stockpiled for future treatment. Open pit extraction of the Kalengwa ore body should be completed in about 2 years, but there was sufficient ore stockpiled for the concentrator to operate for at least 5 years. Methods for recovering additional copper from Kalengwa tailings were being tested.

Anodes from Luanshya continued to provide most of the feed for RCM's Ndola Copper Refinery. Construction of a plant for treatment of anode slimes was completed, and operations were started by yearend. The figures for gold, silver, copper, and selenium recovery reported for 1976 probably included amounts of these metals contained in untreated stocks of tankhouse sludge.

Some 2,960 tons of cobalt was contained in the 2 million tons of ore treated at Chibuluma and Baluba, but only 640 tons was recovered as hydroxide at the Chambishi roast-leach plant. The intimate chemical and physical mixture of cobalt with copper and iron sulfides prevented recovery of more than about 30% of cobalt in the cobalt concentrate, from which both copper and cobalt were recoverable by the roast-leach process. Most of the cobalt remained in the copper sulfide concentrate and, like the iron, was incorporated in the smelter slag.

The fiscal year for NCCM, that ending March 31, 1976, was a period of depressed copper prices and increased transport difficulties. Copper production was reported at 385,414 tons and sales at 386,201 tons, down nearly 6% and 3%, respectively, from the figures reported for 1975. The average sales price received was $1,197 per ton of copper, 29% lower than the 1975 average. Ore mined and treated and ore reserves of NCCM in fiscal 1976 are shown in the following tabulation:

Mine	Ore mined and treated			Ore reserves	
	Gross weight (thousand metric tons)	Percent copper	Copper content (metric tons)	Gross weight (thousand metric tons)	Percent copper
Nkana [1]	5,047	1.59	80,247	117,354	2.40
Mindola [2]	895	2.85	25,490		
Bwana Mkubwa [2]	1,147	2.76	31,657	4,025	3.51
Nchanga [1]	2,877	3.70	106,318

Konkola [1]	1,675	3.11	52,109	122,982	3.53
Nampundwi [1]	90	1.00	899	23,083	.77
Total	17,876	2.80	499,676	552,686	3.05

[1] Underground.
[2] Open pit.

The two underground and four open pit mines of NCCM's Chingola Division produced about 9 million tons of ore. More than 22 million cubic meters of overburden was removed from the Nchanga open pit, nearly 2 million cubic meters from Chingola, and 3.6 million cubic meters from Mimbula and Fitula. The Chingola concentrator treated more than 8 million tons of the ore, and nearly 1 million tons was shipped to the Konkola concentrator. The recently commissioned tailings leach plant extracted 74,215 tons of copper from almost 7 million tons of Chingola tailings, a small amount of reclaimed oil tailings, and nearly 1.4 million tons of low-grade oxide concentrate, high-grade leach plant slimes, residues, and liquor. A second large-diameter drain was completed from the Nchanga open pit sump into the underground workings where a new $10.7 million underground pumping station was commissioned. The station replaced two older ones and was reported to have a safe capacity of nearly 120,000 cubic meters of water per day with about 40% additional emergency capacity. Subsidence and foundation movement owing to acid spillage interfered with production at the high-grade leach plant. A fifth thickener was added to the tailings leach plant at a cost of nearly $4 million.

More than one-half of the 5 million tons of sulfide ore treated at the Rokana Division concentrator came from the Mindola shaft near the northern part of the Nkana ore body. A new shaft to enhance production from this section was scheduled to commence operation in September 1977. A 250-ton-per-hour crusher and a 465-meter conveyer system were installed at Rokana's central shaft. Production from the Mindola open pit was halted at the end of January, but was resumed at a lower rate in June when copper prices improved. Waste heat boilers and gas collection systems were commissioned on the No.'s 4, 5, and 6 converters to complete installation of the $38 million sulfuric acid plant.

Development work expanded and production improved at NCCM's Konkola mine where water continued to be the major problem. The pumping rate increased to an average of nearly 375,000 cubic meters of water per day, equivalent to more than 80 tons of water per ton of ore hoisted. Treatment of Nchanga ore at the Konkola concentrator was discontinued early in 1976. Konkola's sulfide concentrate was sent to the Rokana smelter, and oxide concentrates were treated in leach plants at Nchanga.

The Nkana cobalt plant accounted for all of Zambia's production of cobalt. Nkana's 5 million tons of ore had a cobalt content of approximately 4,540 tons. Finished metal production was about 1,700 tons, including nearly 630 tons derived from cobalt hydroxide produced at Chambishi from RCM's Chibuluma and Baluba concentrates. Reopening of NCCM's Kansanshi mine, 160 kilometers west of the Copperbelt, was resumed at yearend.

The Mokambo copper mine, jointly owned by the Romanian company Geomin and the Zambian State organization Mindeco Limited, was put on a care-and-maintenance basis in July after severe flooding

delayed commencement of production in February.

Lead, Zinc, Byproduct Cadmium.—NCCM's Broken Hill Division produced and treated 360,000 tons of galena-sphalerite ore containing 7.0% lead and 18.3% zinc during its fiscal year. Finished output for that period included 21,274 tons of lead, 21,025 tons of high-purity zinc, 24,833 tons of over 98.5% zinc, 13,264 tons of sulfuric acid, and 12,900 kilograms of cadmium. No silver was produced by the Division during the fiscal year owing to plant rehabilitation and resiting of the silver cupellation furnace. During the last half of fiscal 1976, underground production of ore declined chiefly because of excavation of a subvertical shaft for extraction of ore below the 1,400-meter level. Surface plant rehabilitation included installation of a new zinc leaching process and construction of a fine coke plant to improve operating conditions and stabilize throughput of the three Waelz kilns.

Other.—Eluvial workings located 60 kilometers east of Choma and supervised by Mindeco Small Mines Ltd. produced 292 kilograms of the tin mineral cassiterite. Manganese deposits west of Mansa were investigated as a source of raw material for the manufacture of dry cell batteries. Proposals for exploitation of iron ore west of Solwezi and for operation of an oil-fired steelworks in that vicinity were being studied. The Zambian Government reportedly signed a contract for construction of a 250,000-ton-per-year sponge iron plant. The Geological Survey continued drilling to explore potential uranium ore near Siavonga on the northern shore of Lake Kariba.

NONMETALS

NCCM's Nampundwe "pyrite" mine west of Lusaka produced nearly 16,000 tons of cupriferous pyrite concentrate containing nearly 6,000 tons of sulfur and more than 700 tons of copper. The concentrate was shipped to Nkana and treated along with NCCM's sulfide copper concentrates at the Rokana smelter. Total fiscal year production of sulfuric acid by NCCM was about 288,000 tons, most of which was used in the leach treatment of Copperbelt ores. About 32,000 tons of gypsum, recovered from the Rokana cobalt plant liquor, was railed to Chilanga Cement Ltd. The Lochinvar mine and washing plant west of Monze produced 3,600 tons of gypsum. Chilanga Cement continued to supply most of the country's requirements for cement, but the amount it produced in 1976 was not reported. Quarries east of Ndola produced 565,000 tons of limestone for flux and aggregate and supplied 144,000 tons of lime to be used in metallurgical processes and building construction. A small mine near the Kariba Dam supplied more than 500 tons of feldspar and 3 tons of fluorite for glassmaking at Kapiri Mposhi. Production of amethyst declined from 32,000 kilograms in 1975 to less than 26,000 kilograms in 1976. Its sales value averaged about $28 per kilogram. Mindeco resumed emerald mining near Miku, south of Chibuluma, and recovered 17.6 kilograms of emeralds with a value of about $1,260 per kilogram.

MINERAL FUELS

Indeni Petroleum Refining Co., Ltd., imported 6,854,000 barrels of Saudi crude oil by way of pipeline from Dar es Salaam to the Ndola refinery. This supplied most of Zambia's requirements for gasoline, jet fuel, dieselene, and heavy fuel oil, but 2,840 barrels of aviation spirit for piston engine planes was imported from Iran, and nearly 15,000 barrels of lubricating oil came from various sources. Construction to double the capacity of the refinery was started, and plans for a small-diameter pipeline from Ndola to the Zairian copper belt were revived and again shelved for lack of financing. More than 750,000 tons of washed coal was produced at the Maamba colliery and transported to consumers along the railroad and to smelting centers at Broken Hill and in the Copperbelt.

THE TERRITORY OF AFARS AND ISSAS [1]

The Territory of Afars and Issas is to receive its independence from France on June 27, 1977. The Territory's economic income was based on entrepôt trade through the port of Djibouti and transshipment of goods on the Chemin de Fer Franco-Ethiopian (CFE) railroad. The Territorial budget was scheduled to increase from $32.6 million [2] in 1976 to $36 million in 1977, despite severe shortfalls in 1976 stemming from inflation and a persistent balance-of-trade deficit. Subsidies from France continued to sustain the economy, and the French pledged to provide approximately $140 million in aid annually after independence. In 1976, financial agreements were concluded with a number of Arab oil-producing countries, including Saudi Arabia which granted $10 million toward development projects. The new Republic of Djibouti is scheduled to become the 49th member State of the Organization of African Unity (OAU) and the 21st member of the Arab League, and to receive aid from their financial institutions.

The port of Djibouti and the CFE railroad constituted the Territory's main economic resources. Traffic at the port greatly

[1] Prepared by Candice Stevens, economist, International Data and Analysis.

[2] Where necessary, values have been converted from Djibouti francs (DF) to U.S. dollars at the rate of DF175=US$1.00.

increased in 1976 owing to limited access to the Eritrean ports of Massawa and Assab in Ethiopia. Approximately 2,000 ships called at the port during the year, carrying 480,000 tons of petroleum products and 380,000 tons of other freight. Nearly 75% of the trade consisted of Ethiopian imports and exports. Activity on the 780-kilometer CFE railroad, which linked Djibouti and Addis Ababa, similarly increased. A total of 200,000 tons of freight transited the railroad in 1976. Since 1959, the railroad has been jointly owned by France and Ethiopia, but negotiations were underway to transfer French interests to the Territory of Afars and Issas. Another major project, construction of a 247-kilometer highway linking Djibouti and Addis Ababa, was near completion at yearend.

Potential mineral projects in the Territory consisted of extraction of gypsum and salt from Lake Asal and construction of a cement plant at Mount Arrey near Ali Sabieh based on local limestone deposits. Legislation enacted in 1975 and 1976 was aimed at encouraging foreign investment in mineral and petroleum exploration and exploitation through providing various tax exemptions and economic incentives. Evaluation of geothermal resources in the area of Lake Asal continued in 1976 with technical and financial assistance from the Bureau de Recherches Géologiques et Minières (BRGM) (France).

[e] Estimate. [p] Preliminary. [r] Revised. NA Not available.

[1] In addition to the countries listed individually in this table, Equatorial Guinea, the Territory of Afars and Issas, the Gambia, and Upper Volta, all covered textually in this chapter, presumably produce modest quantities of crude construction materials such as clays, stone, and sand and gravel, and may produce minor amounts of other mineral commodities (most notably gypsum, lime, and salt), but output is not reported quantitatively and available information is inadequate to permit formulation of reliable estimates of output levels.

[2] In addition to the commodities listed, modest quantities of unlisted varieties of crude construction materials (including clays, stone, and sand and gravel) presumably were produced, but output is not reported quantitatively and available information is inadequate to permit formulation of reliable estimates of output levels.

[3] Sales.

[4] Limited quantities of other pegmatite minerals may also be produced, but output is not recorded.

[5] Converted from reported figures in cubic meters using a factor of 1.8 metric tons per cubic meter.

[6] Products marketed under the trade names "baylifos" and "phospal."

[7] All figures reported are sales; actual production is not reported.

BENIN (formerly Dahomey) [3]

Activity in the mining sector of Bénin in 1976 was limited to exploration and feasibility studies. The small quantities of cement and salt produced during the year made a negligible contribution to the estimated 1976 gross domestic product (GDP) of $440 million.[4] The economy continued to suffer from severe inflation, and the balance-of-trade deficit was $67.3 million. In 1976, a planning commission was established to draw up the country's first 3-year plan (1977–79), which was to include a new investment code to attract foreign capital.

Foreign aid continued to support the development of Bénin's infrastructure, the deficiencies of which constituted an impediment to the country's mineral development. The U.S. Agency for International Development (AID) provided a $12 million loan for construction of a bridge-dam complex near the port of Cotonou. In addition, a $41 million port expansion program was under consideration by a consortium of international donors headed by the International Bank for Reconstruction and Development (IBRD). Société Béninо-Nigériene de Transports Routiers was created in 1976 as Nigeria pledged to finance a more direct coastal route linking Cotonou and Lagos. The African Development Bank (ADB) made a $2 million loan to Société Nationale d'Electricité et d'Eau (SNEE) for the expansion of electrical facilities. An agreement was signed with Togo for development of the Mono River Valley and construction of a dam at Mangbeto to supply 400 million kilowatt-hours of power per year.

In November, the Comité de Recherches Géologiques et Minières convened in Cotonou to unite the activities of the members of the Entente States Council in geological and mining research. The United Nations Development Program (UNDP), which operated a mineral exploration program in Bénin for 5 years, conducted followup work on previous findings of gold, copper, iron, chrome, and nickel mineralization. The Bénin Government initiated a feasibility study of phosphate deposits that extended 20 kilometers on a north-south axis near Kandi. Another interesting deposit discovered earlier in the UNDP program was the oolitic iron ore at Loumbou Loumbou. The area was estimated to contain 250 million tons of hematite ore averaging 50% iron, and the nearby Madékali deposit was estimated to contain 40 million tons of ore averaging 58% iron. Also in 1976, Bénin and Romania signed an accord for economic and technical cooperation, particularly in the areas of mineral exploration and petroleum exploration, development, and refining.

The only oil-prospecting activity in 1976 comprised seismic surveys by the Government in a concession area previously held by Union Oil Co., whose rights were terminated along with those of five other companies in 1974. Indemnification agreements were reached with the Royal Dutch/Shell Group in 1975 and Mobil Oil Corp. in 1976, and negotiations continued with Texaco Inc., Total Petroleum Ltd., British Petroleum Co. Ltd. (BP), and Agip S.p.A. Royal Dutch/Shell remained the only foreign company operating in Bénin but relinquished part of its 1,900-square-kilometer concession area in 1976. Bénin imported approximately 2 million barrels of petroleum products per year from Algeria, Niger, Venezuela, and the Ivory Coast; distribution was by the State agency Société Nationale de Comercialisation des Produits Pétroliers (SONACOP).

The cement factory at Cotonou, operated by Société Nationale des Ciments (SONACI), registered diminishing production in 1976 owing to maintenance problems. Work started in November 1976 on expansion of the plant from a capacity of 200,000 tons to 400,000 tons per year through the addition of a new clinker-grinding unit. The $10 million cost was to be financed by the Arab Bank for Economic Development in Africa and the Bénin Government. Output was to be sold domestically and exported to Nigeria and Niger.

Société des Ciments d'Onigbolo, a joint venture of Bénin (55%), Niger (40%), and a third technical partner, was to construct a 500,000-ton-per-year cement factory in Bénin. The plant was to be located near the limestone deposits in Onigbolo and Massé in the southeastern Pobé area, where reserves were estimated at 36 million tons. Other potential limestone deposits along the Nigerian border and in Zou

Province were under examination. F. L. Smidth & Co. A/S of Denmark was contracted to do feasibility studies for the $50 million plant.

BOTSWANA [5]

The mineral industry of Botswana contributed approximately $100.2 million to the nation's 1976 GDP of $173 million [6] in current prices, compared with $72 million in 1975. Mining made up 58% of the GDP, agriculture 32%, and construction 10%. Mine production included copper-nickel matte, valued at $59.3 million; diamond, $38.9 million; semiprecious stones, $16,000; talc, $21,850; and coal, $2 million. In 1976, Botswana's trade deficit was at a record low, and mineral production showed a significant improvement. Coal production more than tripled, and diamond production decreased slightly. Minerals made up almost 70% of total exports and 19% of total imports in 1976. Mineral imports were mainly fuels, valued at $22 million.[7]

The creation of an independent currency, the pula, in August 1976 and the withdrawal from the rand monetary area was a move toward monetary independence. The pula was pegged to the U.S. dollar. This was followed by a 5% up-valuation of the pula in early 1977. The value of imports was approximately two-thirds of the nation's GDP, and almost all foreign purchases came from the Republic of South Africa, so the revaluation helped Botswana to avoid the worst of its neighbor's inflation. Inflation has been at the rate of 12% to 14% each year since 1974 in Botswana. As a member of the South African Customs Union, Botswana usually benefits from a generous revenue-sharing formula. In the 1975–76 fiscal year, however, revenue from this source fell 19%, but the drop was more than offset by the increase in diamond revenues as a result of renegotiation of the company's financial structure in 1975.

Development expenditure has been consistently increased each year and was being directed toward infrastructure improvement. Botswana received $33.7 million from the European Development Fund (EDF), $20.2 million from the United Kingdom, and $6.9 million from Norway to build roads and other development projects.[8] The official opening of the Francistown-to-Nata road was to take place in 1977. This road forms part of the all-weather Botswana-Zambia (BOTZAM) highway system, which will stretch from Lobatse in southern Botswana to Kazungula on the Zambian border.

Botswana's policy on foreign investment is flexible; agreements are negotiated on all projects and are usually worked out so that the company can get a target return. If the project does better than anticipated, the company is granted a share of the "economic rent." There is no direct policy on Government participation, but in practice the Government likes to participate on an equal basis. Foreign companies are also permitted to operate external accounts. The Bank of Botswana reported that nearly $7 million more was externalized in the form of dividends than was gained by the Government in the forms of taxes and royalties in 1976.[9]

On the eastern flank of the country, mining companies were actively evaluating coal, uranium, and gold deposits. Two consortia were looking for oil and gas in central Botswana, and Shell Oil Co. and BP were carrying out a detailed evaluation of low-grade opencast coal deposits along the eastern north-south axis. By the end of 1977, the results of an aerial magnetic survey covering all of Botswana should be known. Copper was being sought in the Kalahari Desert, where it was suspected that deposits of the Zambian stratiform type were to be found.

A West German hydrogeologist began working in May 1976 with the Geological Survey of Botswana on preparing hydrogeological maps and training local personnel. An important assignment was the estimation of groundwater reserves and the amount of groundwater recharge. Priority projects were the water supply for a cattle slaughterhouse and for a soda factory in the city of Dukwe.[10]

Mining by De Beers Botswana Mining Co. (Pty.) Ltd. (Debswana) at Orapa was being expanded from an annual capacity of 2.35 million carats to 4.5 million carats, to be completed by the end of 1978. The expansion would bring the mine's total capital cost to about $57.5 million. The output was mainly industrial stone, about 15% gem quality. At the Letlhakane property, stage 1 of the development started in November 1976 at a production rate of about 70% of the target production of 320,000 carats per year. Stage 1 was scheduled to last for about 3 years. Stage 2 would involve mining the pipes themselves, which should yield about 396,000 carats per year for an additional 13 years, the life of the current lease. The diamond material was under strict security for final treatment at the highly sophisticated extraction plant at Orapa, where X-ray sorting machines give a virtual 100% diamond recovery. There is also a final handpicking of the waste gravels at this plant. Letlhakane's capital cost will total about $25.3 million. De Beers Consolidated Mines Ltd., the parent company, experienced record profits in 1976 to which Debswana contributed $38.9 million for 2,360,945 carats produced.

De Beers Consolidated was carrying out a large-diameter drilling program on the new diamond pipe discovery at Jwaneng in southern Botswana. To provide an accurate assessment of the deposit's potential, a detailed sampling program was planned, expected to last 4 years. In the meantime, De Beers Consolidated had initiated discussions with the Botswana Government for development and mining operations. The deposit is overlain by 50 meters of sand and calcrete but was considered to have economic potential.

Botswana RST Ltd., whose Selebi-Pikwe project operated by its subsidiary Bamangwato Concessions Ltd. (BCL) has been plagued by technical and financial problems since production started in late 1973, announced results for 1976 that suggested the mine was nearly breaking even. The company announced[11] an operating profit of $372,600, compared with a loss of $1.7 million in 1975. However, after deducting interest payments the net loss for the year was $29.6 million. In view of the high capital outlay expected, the company was restructuring financial arrangements, involving, among other things, a revision of the royalty paid to the Government and changes in the sale arrangements. Under the old agreement, Botswana was receiving a fixed annual royalty of $860,000, plus 7.5% of the profits, which have not materialized. Production at the mine was 32,506 tons of copper-nickel matte. Metals returned by the refinery at Port Nickel, Louisana, in 1976 were copper, 11,927 tons; nickel, 11,878 tons; and cobalt, 132 tons. Metal sales for the year amounted to $73,647,000. The company's cash requirements were provided by loans from Anglo American Corp. of South Africa Ltd., Charter Consolidated Ltd. Group, and American Metal Climax Inc. (Amax), the principal shareholders. The total indebtedness, including accrued interest, at fiscal yearend June 30, 1977, was $301.3 million. Although all technical problems that had delayed production for Botswana RST have been identified and corrected, serious difficulties still remained as the result of depressed world markets for copper and nickel.

The Selebi-Pikwe copper-nickel deposits of eastern Botswana comprise two stratabound sulfide bodies located 9 miles apart. The dominant sulfide is pyrrhotite which occurs with chalcopyrite and pentlandite. The Pikwe ore body was being mined by both underground and open pit methods. An underground mine at Selebi was to come into production in about 3 years. The Pikwe deposit comprised three zones: A southern massive 70% sulfide zone with grades up to 2.5% nickel and 1.5% copper, enclosed in gray gneisses; a central semimassive 40% to 70% sulfide zone, associated with amphibolite; and a northern low-grade, 0.8% nickel, 0.8% copper zone of disseminated ore. Production capacity was expected to be about 180,000 tons per month, with 110,000 tons of ore from underground operations and 70,000 tons from the open pit. In the steeper northern zone at Pikwe, mining was being done by the cut-and-fill method along 80-meter-long stopes supported by pillars at 20-meter intervals. In the more flatly dipping ore zones, the ore was extracted using open stopes with post sandfill.[12] The open pit was situated in the thick northern zone of the ore body.

[11] Botswana RST Ltd., company report for 6 months ended June 30, 1977.

[12] Vallentine, R. J. Selebi-Pikwe Copper-Nickel Project at Production Capacity. Skillings' Min. Rev., v. 66, No. 27, July 2, 1977, pp. 10–15.

The concentrator was operating at a milling rate of 6,000 tons per day. The smelter, designed to produce 3,500 tons per month of matte containing 1,275 tons of nickel and 1,452 tons of copper, was commissioned in late 1973 but did not achieve design production until August 1976. The drying plant, described as the largest operating mineral concentrate spray dryer in the world, was designed to produce 69.5 tons of concentrate per hour that is simultaneously mixed with silica flux for an output of 90 tons per hour of flash furnace feed. Until May 1975, the drying plant performance was poor because of inadequate slurry storage capacity, concentrate explosions in the storage silos, and the normal difficulties associated with startup. The problem of furnace feed control remained the most serious production restriction. In 1976, there were 378 expatriate and 1,139 local mine, smelter, and administrative employees. The size of the work force was attributed. especially in the underground operations, to labor-intensive mining methods and limited worker skills, requiring a man for each activity. A training program was resulting in marked improvement, from 1.9 tons to 2.8 tons per man-shift by mid-1976. New infrastructure associated with the mine includes a new town of 20,000 people, development of coal and water resources, and the addition of railroad lines, enhancing economic welfare in not only the eastern region but the entire country.

The Morupule colliery produced 224,175 tons of coal in 1976, valued at $1.98 million, enough to meet all of Botswana's present needs. Plans for underground expansion from 25,000 tons to 40,000 tons per month were being studied. Almost all coal was sold to Botswana Power Corp. (BPC) (20,000 tons per month) and BCL (5,000 tons per month). BPC was planning to expand the Gaborone power station with a $1.15 million investment. Bagged coal was also sold for local use, which never exceeds 325 tons per month even in peak winter months.

Reserves at Sua Pan (Makgadikgadi) were estimated as follows: 28 billion tons of soda ash (Na_2CO_3), 130 billion tons of salt (NaCl), 13 billion tons of sodium sulfate (Na_2SO_4), and 4 billion tons of potassium chloride (KCl). Gulf Resources and Chemical Corp. pulled out of the project for development of these deposits, which was estimated to require an investment of nearly $175 million, excluding much of the associated infrastructure. It was said to be almost impossible to evaluate the deposit because of the vagaries of salt concentration and associated minerals, but it was thought to be commercial.

BURUNDI [13]

The mineral industry of the Republic of Burundi showed its lowest recorded annual level of activity, owing primarily to changes in the Government and the large trade deficit resulting from increased oil prices.

In 1976, mineral production consisted of 139 tons of bastnäsite, 426 troy ounces of gold, 50 tons of cassiterite concentrate, 3 tons of tungsten ore, 622 tons of lime, 2,362 tons of kaolin, and 4 tons of columbium-tantalum ore. The lime output, reported for the first time, was consumed domestically in the construction industry.

Iran remained the country's main source of petroleum products in 1976. Burundi imported about 10,800 tons of gasoline, 1,600 tons of jet fuel and kerosine, 7,000 tons of distillate fuel oil, and 1,800 tons of residual fuel oil.

The investment code of Burundi remained quite liberal and ascribed special tax and tariff benefits to foreigners who wished to participate in the economic development of the nation. Labor costs were low, and in joint venture arrangements the Government expected to provide input such as land and utilities. The Overseas Private Investment Corp's. (OPIC) political risk insurance was available for direct investment and engineering projects. A United States-Burundi agreement on investment guarantees has been in effect since 1969. The Ministry of Planning was the principal Government agency handling new investments; however, following initial contacts, most of the substantive discussions were held on an interministerial basis with the pertinent operating ministries.

In the first 5 months of 1976, a mining and petroleum industry code was estab-

[13] Prepared by E. Shekarchi, supervisory physical scientist, International Data and Analysis.

lished. The code stated that all mining activities were bound by the rules incorporated in the code, which covered prospecting, exploitation, research permits, and concession rights. Mining concession rights were limited to 25 years, with two 10-year extensions possible thereafter. Exploitation permits were for 5 years with two successive extensions possible.

Nickel deposits with estimated reserves of about 200 million tons of ore containing over 1.5% nickel remained untapped during 1976. These deposits were located at Musongate, Nyabikere, and in a 30-kilometer zone between the towns of Rutana and Mahana in the southeastern section of Burundi. Apparently, metallurgical problems with the ore hindered plans for the development of this resource. Preliminary estimates put the required finances at $800 million for various types of investments before production could begin. The possibilities of recovering other minerals such as cobalt, copper, and perhaps platinum were discussed during the year. The U.S. entrepreneur Maurice Templesman remained the prime candidate to develop the nickel deposits of Burundi.

CAMEROON [14]

The mineral industry was a minor contributor to the economy of the Federal Republic of Cameroon, which in fiscal year 1976 balanced its budget at approximately $435 million.[15] Small amounts of cassiterite, cement, gold, limestone, and marble were produced from domestic sources. Aluminum was produced from imported alumina and cement from imported clinker. Aluminum and cement exports accounted for 6% of total exports in 1976. The country's first fertilizer complex at Bonabéri near Douala came onstream at yearend. The plant was to produce complex (nitrogen-phosphate-potash (NPK)) fertilizers, ammonium sulfate, and single superphosphate (20% P_2O_5).

During 1976, the Government in cooperation with Société d'Études des Bauxites du Cameroun (SEBACAM) actively sought financing from the World Bank, other potential aid donors, and private companies to assist in developing the bauxite deposits near the towns of Minam and Martap and at Ngaoundéré. The bauxite reserves in these deposits were estimated at 2 billion tons grading 44% Al_2O_3 at Minam and Martap and 39% Al_2O_3 at Ngaoundéré. The existence of large bauxite resources in north-central Cameroon had been known since 1958.

In 1969, SEBACAM, a partnership of the Government (40%), Péchiney Ugine Kuhlmann (PUK) (45%), Vereinigte Aluminium Werke (VAW) (10%), and Kaiser Aluminum & Chemical Corp. (5%), was formed to plan the exploitation of the bauxite deposits. During 1976, SEBACAM submitted the results of the completed study of the bauxite deposits and development plans to the Ministry of Economy and Plan. Undoubtedly, significant investments would be required for development owing to the remote location and lack of transport facilities.

The Canadian International Development Agency (CIDA) funded a mineral research survey that was conducted in southeastern Cameroon. Preliminary research indicated large reserves of iron ore (hematite) in a belt extending southward from Kribi to the Río Muni border. The survey also identified manganese, thorium, and uranium mineralization and indications of gold and diamond. The UNDP began further studies to delineate the extent of the resources discovered in the Canadian program.

BRGM has studied large copper deposits between Bibémi and Maroua in northern Cameroon. The lack of infrastructure and the low world copper price in 1976 prohibited their development.

Utah Development Co. conducted further studies on uranium deposits in northern Cameroon near Poli. The deposits discovered were not considered to be of sufficient size and concentration to justify large-scale exploitation, owing to infrastructure requirements.

The Government was cognizant of the need for improving the country's transportation system and planned to invest $640 million in infrastructure during 1977–81 under the fourth development plan. Expanding and modernizing the country's

[14] Prepared by David E. Morse, physical scientist, International Data and Analysis.

[15] Where necessary, values have been converted from CFAF to U.S. dollars at the rate of CFAF-230=US$1.00.

major port, Douala, was to be completed under the plan at a cost of $120 million.

During 1976, Essence et Lubrificants de France-Société de Recherches et d'Exploitation des Pétroles au Cameroun (Elf-Serepca) drilled seven oil wells in the offshore Rio-del-Rey permit. Elf-Serepca planned to begin developing the Kolé discovery in Rio-del-Rey beginning in 1977. Crude oil production was to reach 400,000 tons per year in 1978. Exploitation of the modest natural gas field (300 million cubic meters) at Logbaba, onshore near Douala, was delayed owing to the lack of industrial consumers. Cameroon planned to build a 1.5- to 2.0-million-ton-per-year oil refinery at Limboh Point near Victoria. Details of financing and the scheduled completion date of the oil refinery were not known.

Other companies holding petroleum exploration rights in Cameroon during 1976 were Ocean Exploration Co. Ltd. (OEC) (5,300 square miles), Gulf Oil Corp. (1,094 square miles), Mobil (723 square miles), Norwegian Oil Co. Ltd.'s subsidiary Normafrique (578 square miles), and Damson Oil Co. (496 square miles).

CAPE VERDE ISLANDS [16]

The Cape Verde Islands, an archipelago of volcanic islands in the Atlantic Ocean 500 kilometers west of Dakar, had no important mineral production in 1976. The nation remained in the grip of a prolonged drought, which has persisted since the late 1960's. The Government of the young nation (independence achieved in 1975) had begun implementing comprehensive land reclamation and water conservation schemes and had instituted a program to assess the country's water resources. The Islands' leaders applied for aid from the United Nations to alleviate the critical food shortage.

CENTRAL AFRICAN EMPIRE [17]

The diamond industry, the main foreign exchange earner of the country, continued its recent downward trend, with production of only 286,000 carats in 1976. This output was 15% below the 1975 level and a 50% drop from the peak years of the late 1960's. An increase in diamond export prices offset this decline and resulted in a slight increase in export value to $14 million, or 17% of total foreign exchange earnings. The cessation of operations in February 1976 by Société Centrafricaine d'Exploitation Diamantifere, a company that was mechanizing the mining and dredging operations, was a major reason for the decline of 1976 production. Since the top-level diamond-bearing strata had been skimmed away through years of exploitation, capital investment and mechanization were required to mine lower horizons.

The exploration and evaluation work of Société d'Uranium Centrafricaine (SUC) continued during the year. SUC was incorporated by the Government of the Central African Empire, the French Commissariat à l'Énergie Atomique (CEA), and Alusuisse of Switzerland in 1975. Owing to the uranium's high phosphorus content, Alusuisse designed a new separation method that made the deposit economically viable. Alusuisse was expected to expand its feasibility study and had earmarked $3 million to $4 million [18] for the 1978 investigation. The Bakouma uranium deposit, located about 100 kilometers north of Bangassou, contains 20,000 tons of measured reserves. The inaccessibility of the deposit seemed to be the biggest obstacle to development of the mine. Total planned investment was estimated at $300 million. When in full operation, the plant was to employ 1,500 local workers.

A new magnetic anomaly discovered in late 1975 remained unexplored, although preliminary studies suggested the existence of heavy metals deposits. The United Nations and the United States, through AID, were considering an aeromagnetic study and more detailed geologic studies of the area to establish the base for possible commercial exploitation.

[16] Prepared by David E. Morse.
[17] Prepared by E. Shekarchi.
[18] Where necessary, values have been converted from CFAF to U.S. dollars at the rate of CFAF226=US$1.00.

Shell and Continental Oil Co. (Conoco) of the United States performed aeromagnetic studies and a seismologic survey to delineate possible oil structure in the northern part of the country. No drilling was reported by yearend.

Other projects in the mineral sector were under consideration and awaited financing. These included a metallurgical works producing steel at the iron deposits of Bogoin and Bembi and a cement plant at the limestone deposits of Fatima.

CHAD [19]

The mineral industry of Chad remained very small in 1976. Natron (hydrous sodium carbonate, equivalent to trona), the only mineral exported, was extracted in rough blocks by native tribesmen from saliferous basins on the northeastern shores of Lake Chad. The blocks were dried in the sun, shaped to a convenient size (average 35 kilograms), and transported to N'Djaména by camel and barge for sale. Natron was used as a salt (NaCl) substitute for human and animal consumption, to preserve meat and hide, and in soap manufacture. The 1976 natron output was estimated at 8,000 tons. Clay for the N'Djaména brickworks, salt, sand and gravel, and stone were also produced for local consumption.

The UNDP began a mineral assistance project in Chad in 1973. The project began geologic studies in a 10,000-square-kliometer area in the Mayo-Kebbi region of southwestern Chad, provided training for the staff of Chad's Geologic Service, and established a geochemical laboratory within the Service. Activities of the project have yielded evidence of gold, nickel, uranium, and complex sulfide ores. The project also provided fellowships for training personnel outside of Chad. The project experienced an 18-month delay before implementation and in 1976 was extended an additional 16 months to the end of 1977. The Director of Mines and Geology stated the "availability" in Chad of 2.7 million tons of diatomite, 500,000 tons of kaolin, 6 million tons of limestone, 6 million tons of natron, and 25,000 tons of salt.

Conoco-Tchad continued to explore for oil in Chad during the year. Oil had been discovered by Conoco-Tchad in the Kanem Prefecture north of Lake Chad and in Logone Occidental near Doba in the south. The shows were considered sufficient to warrant further drilling in both areas. The Government planned to build a 1,500-barrel-per-day topping unit at N'Djaména. The unit would be supplied with Kanem crude oil and would provide a variety of refined products. The scope of the project was limited but would be sufficient to substantially reduce the nation's total reliance on imported petroleum products.

COMOROS [20]

The Republic of the Comoros, an archipelago of islands situated in the Mozambique Channel off the southeastern coast of Africa, proclaimed its independence from France in July 1975. The three main islands are Anjouan, Mohéli, and Great Comoro; a fourth island, Mayotte, remained an overseas territory of France. The agricultural sector has consistently been the major contributor to the country's economy; mineral resources remain largely unknown and unexplored. The country's primary trade partners were Madagascar, Tanzania, Kuwait, and Saudi Arabia. In 1975–76, most major industries were nationalized, including the largest oil distributor, Royal Dutch/Shell. Petroleum products were supplied by Madagascar in 1976.

In December 1975, France terminated all economic aid (which previously amounted to $18 million [21] per year) and repatriated all French officials and technicians from the Comoros. The country's austerity budget was supplemented by foreign loans and grants. In 1976, the Comoros received $10 million in aid from the Arab Fund for Loans to African Countries. Other financial aid included $6 million from the Kuwaiti Fund for Arab Economic Development, $1 million from Libya, and $10 million from the Saudi Arabian Development Fund for

[19] Prepared by David E. Morse.

[21] Where necessary, values have been converted from CFAF to U.S. dollars at the rate of CFAF242=US$1.00.

infrastructure development. In addition, a technical and economic cooperation agreement was concluded with the People's Republic of China during 1976.

CONGO [22]

The mineral sector, dominated by the petroleum industry, continued to be a major contributor to the economy of the People's Republic of the Congo in 1976. An increase in oil tax and royalty rates was to raise the country's budget from $240 million [23] in 1976 to $254 million in 1977. Apart from the petroleum industry, the main mineral producers were the Holle potash mines at Pointe Noire and the Mpassa copper-lead-zinc mines. Both, however, suffered from mining problems in 1976, specifically, geological irregularities in the potash seam at Holle and difficulties in pillar recovery in copper production at Mpassa. The Congo also produced small amounts of natural gas, gold, and cement.

In December 1976, the Government created Société Nationale des Recherches et d'Exploitations Minières (SONAMINES) to manage and consolidate the Congo's mine and quarry operations. SONAMINES was to supervise the exploration and exploitation of all Congolese minerals and would assume the operations of Hydro-Congo, the national petroleum company, and all other mining firms. Among the projects to be transferred to SONAMINES were prospecting for uranium in the northwest near Gabon; evaluation of iron ore deposits (estimated at 304 million tons) in the Bambama, Sembé, and Mayouka Basins; and development of phosphate deposits in the lower Tchivoula and Loufica areas. In January 1976, a joint Bulgarian-Congolese company, Société des Phosphates de Congo (SOPHOSCO), was formed to exploit the deposits; production was scheduled to reach 2 million tons of phosphate per year.

The major project under the current 3-year plan (1975–77), the realignment of the Congo Ocean Railroad (CFCO), continued on schedule. Under the supervision of L'Agence Transcongolaise des Communications, the modernized railroad between Brazzaville and Pointe Noire would facilitate transport of exports from Cameroon, Chad, Gabon, and the Central African Empire. The $234 million project was to be partially financed through loans from the European Economic Community (EEC), the ADB, and the Arab Bank for Economic Development in Africa. In 1976, the IBRD approved a $38 million loan to purchase railroad equipment and increase the capacity of the port of Pointe Noire.

Petroleum production in the Congo increased 6% from 36,877 barrels per day in 1975 to 39,107 barrels per day in 1976. In 1976, the Congolese Government negotiated increased tax and royalty rates with its two producing companies. Elf-Congo (a subsidiary of France's State-owned Essence et Lubrificants de France-Entreprise de Recherches et d'Activités Pétrolières S.A. (Elf-Erap)) and Agip (a subsidiary of Italy's Ente Nazionale Idrocarburi (ENI)). As of October 11, 1976, Government revenue per barrel of petroleum was $5.49.

The greater part of production was from the Emeraude Field, owned 35% by Elf-Congo and 65% by Agip. The 1969 offshore discovery was expected to produce 100,000 barrels per day but failed to reach its goal despite continued drilling. The smaller Pointe Indienne Field produced an average of 192 barrels per day in 1976 and was scheduled to cease production in 1980.

Startup at the Loango Field, owned in equal shares by Elf-Congo and Agip, was delayed until late 1977. Fourteen wells were to be drilled from three platforms with ultimate output averaging between 40,000 and 50,000 barrels per day. A 97-kilometer, 18-inch pipeline was to link the Loango Field with the Djeno terminal, which also handled Emeraude crude. Elf-Congo and Agip also began development drilling at their other joint discovery, the Emeraude Sud Field, scheduled to begin production in 1978.

Both Elf-Congo and Agip continued exploration in their concession areas in 1976. Another consortium, Seagap, conducted seismic and magnetometer surveys in its 8,000-square-kilometer Mer Profonde permit area. Members of the group included Getty Oil Co. as operator, Agip, Phillips Petroleum Co., and Hispanoil.

Construction of the Congo's first petroleum refinery neared completion at Pointe

[22] Prepared by Candice Stevens.

[23] Where necessary, values have been converted from CFAF to U.S. dollars at the rate of CFAF242=US$1.00.

Noire. The refinery, which was to have an annual capacity of 1 million tons, would be supplied entirely by the Emeraude Field.

The Congo's natural gas production, derived from the Pointe Indienne Field, was used in the Holle potash plant. Marketed natural gas production decreased from 1.6 million cubic feet per day in 1975 to 1.48 million cubic feet per day in 1976.

Production of potash at the Holle mine, located 45 kilometers northeast of Pointe Noire, fell from 280,106 tons of K_2O in 1975 to 256,521 tons of K_2O in 1976. The mine was operated by Compagnie des Potasses du Congo (CPC), formed in 1964 to exploit the lenticular bed of sylvanite with a potash content of more than 35%. The lens covered an area of 9 square kilometers with an average thickness of 2.7 meters and an average depth of 370 meters. Reserves were estimated at several billion tons. However, technical difficulties at Holle, aggravated by a fall in the price of potash in 1976, kept output below anticipated levels.

During the year, the French partners in CPC continued negotiations with the Congolese Government for a withdrawal of shares. Interests in CPC were held by the Congolese Government (15%), Entreprise Minière et Chimique (36.125%), BRGM (36.125%), and Elf-Erap (12.75%). A statement of accord was concluded in November which envisaged the transfer of CPC to the Congolese State. France agreed to bear the cost of loan repayments and would guarantee markets for a quantity of minerals equivalent to 1 year's production. However, no final decision was made on these terms at yearend.

Other investigations have focused on the exploitation of carnallite deposits in the immediate vicinity of the existing mine at Holle. A consulting firm established with French and West German partners initiated a $6 million feasibility study in 1976. Previous work indicated that the carnallite horizon occurs as a thick regular bed unaffected by folding and could support an operation of 1 million tons of potash per year.

Production of copper, lead, and zinc concentrates by Société Minière de Mpassa was reported to have declined slightly in 1976. Copper concentrate production in 1975 was 2,181 tons grading 37.6% copper, 9.1% zinc, and 2.06% lead. Lead-zinc concentrate production in 1975 was 13,272 tons grading 2.7% copper, 37.2% zinc, 14.7% lead, and 7.5% iron.

Société Nationale des Mines de Mfouati (SONAMIF) continued development of its new base metal mining and milling facilities in the Boko Songo area, located 250 kilometers west of Brazzaville. Geological teams from the U.S.S.R. have been investigating these and other deposits in the area for a number of years and have located sufficient reserves to support a commercial mining operation. Ore reserves at Djenguilé were estimated at 300,000 tons averaging 28% lead, 9% zinc, and 4% copper. The U.S.S.R. financed the construction of a concentrator having an annual capacity of 30,000 tons of lead concentrate and 4,000 tons of copper concentrate. Startup was scheduled for 1978.

Production of gold by small independent producers in the Congo fell from 5,281 troy ounces in 1975 to approximately 5,000 troy ounces in 1976. Société Nationale des Mines de Soundi-Kakamoéka (SONAMIS), a joint venture of the Congo and the U.S.S.R., continued development of gold deposits in the Kouilou region north of Pointe Noire. Reserves at the alluvial gold deposits were estimated at 144,678 troy ounces.

Cimenterie de Loutété (CIDOULOU) continued the expansion of its cement plant from 100,000 tons to 300,000 tons per year. A clinker-grinding plant was inaugurated at Madingou with a 10,000-ton-per-year capacity. A brick company, Congobric, was established in 1976 to construct a new brick fabrication plant.

EQUATORIAL GUINEA [24]

The economy of Equatorial Guinea continued to be based on agriculture and timber in 1976. There were no changes in the oil concessions around Isla de Macias Nguema Biyogo (formerly Fernando Po) or off Río Muni Province on the mainland, nor was exploratory activity reported. Local building materials were probably utilized, but there was no indication that previously reported deposits of phosphate, iron ore, or radioactive materials were investigated or exploited during 1976. Political conditions

[24] Prepared by Miller W. Ellis, physical scientist, International Data and Analysis.

reportedly caused an increased rate of emigration of skilled expatriates from Equatorial Guinea, including some 40,000 Nigerian nationals.

ETHIOPIA [25]

The mineral sector was a minor contributor in 1976 to the economy of Ethiopia, rated by the United Nations as one of the world's 10 poorest countries. Although the country's mineral potential was believed to be excellent, it remained undeveloped except for small gold, platinum, and salt operations. Cement manufacture and refining of imported crude oil were the other major mineral activities. The Ethiopian Provisional Military Government (EPMG), which nationalized major industries and financial institutions in 1975, established State corporations in 1976 to consolidate and manage its holdings. Compensation for the nationalized companies, both foreign and domestic, was to be arbitrated by a new compensation commission. The Government required 51% ownership in all new ventures except mineral exploration and exploitation. In 1976, the EPMG budgeted a deficit of $170 million [26] for 1977 to finance development projects.

Ethiopia concluded many new technical and financial assistance agreements during the year. Soviet geological teams made a brief survey of Ethiopian mineral resources, after which Ethiopia and the U.S.S.R. signed protocols on economic and technical cooperation. The future Soviet aid commitment was estimated at $100 million. In November 1976, Ethiopia concluded scientific and technical cooperation agreements with Czechoslovakia and North Korea. Total economic assistance from the United States, traditionally Ethiopia's major economic and military supplier, was $18.6 million in 1976.

The People's Republic of China was to finance eight diesel powerplants in Ethiopia at a total cost of $12 million. In December 1976, the first 190-kilowatt plant was inaugurated at Fiche in Gojām Province. Ethiopia remained relatively unaffected by the energy crisis because two-thirds of the country's power needs are supplied by a large network of hydropower-generating facilities, with a potential for much greater future production.

Exploration and mineral assessments proceeded in 1976, primarily in Wollega Province in the western part of the country. Exploration for copper was conducted in the Kotta area of Wollega Province. After preliminary drilling, large geothermal resources in the middle and lower Awāsh Valley were scheduled for further assessment. Exploration for phosphate and radioactive minerals in Ogaden also yielded positive results but was discontinued owing to conflict in the region.

In 1976, Ethio-Nippon Mining Co., Ltd., of Japan liquidated its assets in the Debarwa copper mine and relinquished its concessionary rights. The Debarwa venture, which was originally envisaged as a 5,000-ton-per-month operation, was brought to a standstill only a few months after startup in 1974 owing to insurgent action. Located south of Asmara in Eritrea Province, the deposit was estimated to contain 600,000 tons of ore grading 8% copper. The Adi Nefas deposit, situated 10 kilometers east of Asmara, also contained substantial reserves. Only 2,000 tons of copper was exported to Japan prior to the halt in operations.

The output of the Government-owned Adola goldfields decreased to approximately 11,253 troy ounces in 1976 compared with 19,981 troy ounces in 1975. Gold from the Adola alluvial deposits, situated in Sidāmo Province in southern Ethiopia, was recovered by traditional hand methods. In 1976, exploration at the Sirgole placer gold prospect in western Wollega Province continued at a somewhat slower pace; studies were conducted to determine the most appropriate mining method—manual, semimechanized, or dredging. The Government planned to triple gold production from the Provinces of Wollega and Sidāmo.

A small amount of platinum was produced at the Government mine at Yubdo in Wollega Province. A test pitting program was undertaken in 1976 in both the eluvial and associated alluvial deposits to produce reliable reserve estimates.

Production at Ethiopia's two cement plants totaled 148,500 tons in 1976. The

[25] Prepared by Candice Stevens.

Eritrea Cement Co. plant at Massawa in Eritrea ceased operations for 2 months in early 1976 but later resumed activities. Rated capacity of the Massawa facility, opened in 1966, was 70,000 tons per year. The Addis Ababa cement plant, operated by Ethiopian Cement Corp., had an 80,000-ton-per-year capacity. Clay and limestone were quarried in Mugar Valley, located about 45 kilometers north of Addis Ababa, for production of portland cement. Approximately 8,500 tons of limestone was quarried in 1976. Additional large reserves of glass sand and limestone in Mugar Valley were under development for use in the local glass and cement factories.

Marine salt output from solar pans along the Red Sea declined to 88,000 tons in 1976. The two major saltworks in Eritrea each had a rated capacity of 100,000 tons per year. Production of Societa Saline di Massawa and Société des Salines d'Assab was mostly for export.

The route to Ethiopia's sole petroleum refinery at Assab in Eritrea was kept open, and the plant maintained a production level of approximately 4 million barrels of petroleum products in 1976. Constructed with Soviet assistance in 1967, the 14,000-barrel-per-day refinery was owned and operated by Ethiopian Petroleum Share Co. It supplied most of the country's gas and oil needs except for specialty fuels, which were imported. All crude oil was imported from Saudi Arabia. Gas rationing continued in 1976 owing to the internal security situation. The four petroleum-distributing companies—Mobil Oil East Africa Ltd., Shell, Agip, and Total—were 51% owned by the Government.

Political uncertainty in Ethiopia caused all petroleum exploration activity to cease in 1976. The Whitestone International/Louisiana Land & Exploration Co. joint venture relinquished its 100,000-square-kilometer concession in northern Ogaden during the year. Royal Dutch/Shell relinquished its 27,000-square-kilometer concession along the Eritrean coast after drilling an unsuccessful well 20 kilometers off Assab in the Red Sea. At yearend, no oil concessions were held by foreign firms.

THE GAMBIA [27]

The Gambia, a small western African republic surrounded by Senegal except along the Atlantic coastline, had a GDP of approximately $94 million [28] and negligible mineral production in 1976. The only known significant mineral deposits in the Gambia were heavy beach sands near Brufut and Sanyang in the Western Division and kaolin in the Upper River Division. Production of unrecorded small amounts of clay, stone, and sand and gravel undoubtedly took place.

The Gambia Basin Development Organization, a Gambia-Senegal cooperative, planned to construct two hydroelectric dams on the Gambia River. The proposed dam near Mansa Konko would include a toll causeway that would provide revenue for the Gambia and significantly increase communication between northern Senegal and the Casamance region of Senegal to the south of the Gambia. The dam would also limit the extent of saltwater in the river to areas below the dam, thereby increasing the amount of freshwater available for irrigation.

Geologic investigations indicated that the ilmenite, zircon, and rutile beach sand deposits in the Western Division are of a grade and quantity sufficient to justify commercial production. The Government planned to have a nationwide survey conducted to establish the existence of any other similar deposits.

The Gambia depended on imports to supply its needs of cement, fertilizer, iron and steel, and petroleum products. The Government planned to build a 1-million-ton-per-year petroleum refinery near Banjul with assistance from Middle Eastern petroleum producers.

GUINEA [29]

Guinea, a small western African nation of 4.2 million people, is well endowed with mineral resources. It has over one-fourth of the world's known high-quality bauxite reserves, 12 billion tons of iron ore, a significant but untapped diamond reserve, alluvial gold, uranium, and indications of petroleum.

During 1976, nearly all of the mineral industry of Guinea was based on the production of bauxite. The output of 10.8 million tons was 29% higher than that of 1975 and represented 14% of total 1976 world output. Alumina production during the year was 560,000 tons. Bauxite and alumina production contributed over 30% to the gross national product (GNP) and provided 80% of foreign exchange earnings. Three bauxite mines were in operation in 1976.

The Sangaredi open pit bauxite mine in northwestern Guinea, which began shipping ore in 1973, produced over 6.5 million tons in 1976 and was to produce 9 million tons per year by 1980. The mine was operated by Compagnie des Bauxites de Guinée (CBG), a consortium of aluminum producers (51%) and the Government (49%).

[27] Prepared by David E. Morse.
[28] Where necessary, values have been converted from Gambian delasis (D) to U.S. dollars at the rate of D1=US$0.4423.
[29] Prepared by David E. Morse.

The Sangaredi deposit contained over 180 million tons of bauxite grading 58% alumina, with no overburden and a minimum of waste inclusions.

In 1976, Office des Bauxites de Kindia (OBK) produced about 2.5 million tons of bauxite with an average alumina content of 46% from the Débélé deposits located 135 kilometers northeast of Conakry. The Government-owned operation began production in 1974 and was initiated with technical assistance and financing by the U.S.S.R. All of the production was exported to the U.S.S.R. during the year.

The third bauxite producer, Société d'Economie Mixte Friguia, mined over 1.8 million tons for production of alumina. The production capacity of the alumina plant was 700,000 tons per year, and the output was 560,000 tons during 1976. Friguia was owned 49% by the Government and 51% by FRIA Compagnie Internationale pour la Production de l'Alumine (Frialco), a consortium of large world aluminum producers. Friguia was studying plans to expand the capacity of the alumina plant to 1.3 million tons per year.

On July 27, Société Guinea-Arabe d'Alumine et d'Aluminum (Alugui) was established in Tripoli, Libya, at a capital cost of $2.4 billion, one-half of the capital attributed to the Guinea Government for the land allocation and mining titles. The other partners were Libya, Egypt, Kuwait, Saudi Arabia, and the United Arab Emirates. Alugui was to exploit bauxite deposits at Ayékoyé near Boké in northwestern Guinea, producing 2.1 million tons of alumina per year for export and eventually producing 150,000 tons of aluminum per year. Alusuisse was to conduct detailed exploration and feasibility studies and make preliminary designs.

Other bauxite deposits have been studied at Tougué and nearby at Dabola. Alusuisse investigated the 2,500-million-ton bauxite deposits at Tougué, and experts from Yugoslavia conducted studies on the 450-million-ton Dabola deposits. Still in the preliminary stages, an immense undertaking was planned to exploit these deposits to produce 13 million tons of bauxite and 1 million tons of alumina per year. The project would be served by a branch line to the old (1910) colonial Conakry-Kankan railroad, which was to be significantly modernized to handle increased heavy traffic.

During 1976, the major importers of Guinea bauxite were the United States (3 million tons), the U.S.S.R. (2.4 million tons), Canada (1.3 million tons), West Germany (1.2 million tons), and France (0.69 million tons). Most of the alumina produced by Friguia was exported to France and Cameroon.

Two extensive iron ore deposits were located in southeastern Guinea near the Liberian border at Mount Nimba and Mount Simandou. The Mount Nimba deposit has been studied by Swedish experts and reportedly contains over 600 million tons of hematite grading 69% iron and 2 billion tons of lower grade ore. In 1973, Société des Mines de Fer de Guiné-Nimba (Mifergui-Nimba) was set up to develop the Mount Nimba deposit. The company planned to produce 2 million tons per year from an open pit operation in 1980–81 and to expand to 15 million tons per year after the third year of operations. A 17-kilometer railroad spur connection will be built to the Liberian rail system for export of iron ore from Buchanan, Liberia. Mifergui-Nimba was owned by the Government (50%) and a group of foreign private and governmental interests (50%). In 1976, two large French steel companies purchased interests in Mifergui-Nimba, and Kaiser Engineers and Constructors, Inc., was appointed to conduct feasibility and mine-mill planning studies. The development of the Mount Simandou deposit contingent on the success of the Mount Nimba project.

In 1976, Compagnie Française des Pétroles (CFP) decided to participate in Société de Guinée des Pétroles (Soguip). After CFP acquired an interest, Soguip was owned 49% by the Government, 17.8% by Buttes Gas and Oil Co. (United States), 10.2% by Naftagas (Yugoslavia), 17.85% by CFP/Agip, and 5.1% by Japan Petroleum Development Corp. Soguip planned to conduct exploratory drilling operations in a 44,000-square-kilometer offshore block in early 1977.

GUINEA BISSAU [30]

Guinea Bissau, a small western African nation of about 800,000 people, had no important mineral production in 1976. Small amounts of sand and gravel, stone, and marine salt were produced for local consumption. The country was largely dependent on imports to supply its energy requirements. Resources of bauxite, gold, iron ore, phosphate rock, and zircon have been reported but remained undeveloped in 1976. Oil exploration had been conducted on Guinea Bissau's Atlantic continental shelf, but because of uncertainties in the Government's position concerning concessions, no activity took place during 1976.

Guinea Bissau and the U.S.S.R. signed an agreement to study the bauxite deposits in the Boe region of west-central Guinea Bissau near Lugajol, adjacent to the border with Guinea. The U.S.S.R. was to conduct a 2-year study delineating the extent and grade of the bauxite deposits. During 1975, 48 test drillings were completed in the area, and reserves of bauxite were estimated to be 500 million tons. In the late 1950's, N.V. Billiton Maatschappij of the Netherlands had determined bauxite reserves of 120 million tons including 24 million tons tested at 47% Al_2O_3. Commercial development of the Boe deposits was not expected in the near future, owing to their remote location and the lack of transport facilities.

IVORY COAST [31]

Following a difficult year in 1975, characterized by fluctuating commodity prices and a lack of demand for timber, the Ivory Coast had an excellent year in 1976. The new 5-year development plan (1976–80) presented by the Government envisaged a diversified economy, massive new investment in infrastructure, export-oriented industry, and improved mining of the substantial Mount Klahoyo iron ore deposits. A large portion of the required investment for the iron ore plant required capital investment from abroad.

Société pour le Developpement Minière de la Cote d'Ivoire (Sodemi), the Ivorian State prospecting company, conducted geological and geochemical prospecting during the year. The main targets of Sodemi's studies were cassiterite west of the Kafiné region, gold in the Lôho River Basin, and molybdenum and copper at Dyengélé.

The GDP grew at current prices from $3.4 billion in 1975 to $4.4 billion in 1976.[32] Per capita GDP increased from $510 in 1975 to $623 in 1976.

In December 1975, Société Watson became the sole diamond producer. During 1976, the company mined from its alluvial deposits near Séguéla and processed about 282,000 cubic meters of ore to produce about 60,000 carats, compared with 289,000 cubic meters and 75,000 carats in 1975. Exports of diamond decreased to about 338,413 carats in 1976, compared with 1,039,810 carats in 1975. Crude petroleum cost the country about $100 million in 1976, but the Ivory Coast recovered about one-half that amount by exporting refined products to Upper Volta and eastern Mali. Société Ivoirienne de Raffinage (SIR) processed 1.7 million tons of crude oil in 1976, most of which was imported from Nigeria, with a small portion originating in Middle Eastern countries. The Government's expansion plans called for a twofold increase in refining capacity and an asphalt production plant that would use Venezuelan petroleum and would supply the needs of the highway improvement program.

Energy production barely kept up with demand. More than 1 billion kilowatt-hours of electricity was generated during 1976, and more hydraulic energy production was planned for the future. The search for oil offshore continued during the year. Esso Exploration Inc. drilled a total of 11 wells during 1975 and 1976 and found encouraging signs of petroleum. The company planned further drilling for 1977. The consortium of Phillips/Hispanoil/Getty/Agip completed its seismic studies and brought the *Discoverer Seven Seas* drillship to the Ivory Coast to drill one hole in 1977.

The iron ore deposits found in the mountainous area 600 kilometers northwest of Abidjan remained dormant in 1976. A consortium consisting of British Steel Corp.

20%, Mitsubishi Shoji Kaisha 20%, Pickands Mather & Co. 15%, Union Sidérurgique du Nord et de l'Est de la France S.A. (USINOR) 10%, Hoogovens IJmuiden B.V. 10%, and Sodemi 5%, which was organized in 1974, delayed construction of an iron pelletization plant for another year because of the projected sluggish conditions in the world steel market and the high cost of mining infrastructure.

Installation of a third clinker grinder increased cement production to 768,000 tons in 1976. Further improvements and expansion of the Abidjan cement plant to a capacity of 650,000 tons per year by 1980 were projected. Beton-Ivoire approved the establishment in the Branco Nord region of a concrete piping production unit for the domestic market.

Gold deposits at Ity, 60 kilometers west of Man, remained undeveloped. However, a consortium was established in 1976 for its exploitation. The consortium intended early development of the mine owing to high prices for gold in the world market. Falconbridge Nickel Mines Ltd. of Canada was discussing possible financing for development of the nickel deposits in the western part of the Ivory Coast, where a mineralized zone ranging in thickness from 5 to 6 meters was reported in an area of 21 square kilometers.

LESOTHO [33]

Diamond continued to be Lesotho's only reported mineral commodity, and output in 1976 was twice that recorded for 1975. Lesotho diamonds were reported as gems only if they were individual stones valued at $230[34] or above. Lesotho diamond reported as industrial may have included small stones of gem quality. The average selling price for Lesotho's gem diamonds was about $375 per carat. All diamond was produced by local diggers, and all was recorded as exported with a total value of about $422,000. Lesotho's foreign exchange earnings of about $90 million were derived from the South African Customs Union and from remittances on behalf of some 120,000 Basotho nationals employed in the Republic of South Africa.

At the Letseng-la-Terai diamond deposit high in the Maluti Mountains of northeastern Lesotho, De Beers Lesotho Mining Co. (Pty.) Ltd. completed all housing and surface installations and an all-weather road for all-wheel-drive vehicles despite high winds and subfreezing temperatures during midyear. Pilot plant activity continued, and most sections of the full-scale plant were being tested at yearend. Systematic mining of the main K6 kimberlite ore body commenced in May. Soft weathered kimberlite was encountered to a depth of 15 meters, and preproduction mining was completed in the underlying hard kimberlite. A total of 500,000 tons of diamondiferous kimberlite was excavated and stockpiled; 300,000 tons of overburden gravel was saved for future sampling; and 250,000 tons of basalt and subeconomic kimberlite was stripped and dumped. Nearly 24,000 tons of kimberlite samples were recovered from 920 meters of development workings at the 55-meter level of a satellite deposit near the K6 ore body. Treatment plant testing was scheduled for early 1977, and full-scale production of 4,000 tons of ore per day was anticipated by mid-1977. The power supply line was supplemented by a new 88,000-volt line that was connected in August with the Lesotho Electricity Corp. power system. Adequate water was provided by a 7-kilometer, 4-pumping-stage pipeline from the Khebelu River. The cost of the new mine was estimated at about $38 million, and about 560 Basotho nationals and 100 expatriates were to be employed. The Lesotho Government holds a full 25% interest in the project and has rights to a higher percentage participation in the profits after De Beers has recovered its capital investment.

The UNDP cooperative project with Lesotho National Development Corp. and the Department of Mines and Geology reported the discovery of a large kimberlite pipe 6 kilometers east of Maseru as a result

[33] Prepared by Miller W. Ellis.
[34] Lesotho was a member of the South African Monetary Union. Where necessary, values have been converted from South African rand (R) to U.S. dollars at the rate of R1=US$1.15.

of field investigation of an aeromagnetic anomaly recorded during geophysical surveys by Canadian firms. Bulk sampling was started to determine the diamond content of the deposit. Bulk sampling of the previously known Kolo pipe was also planned to determine the potential of one of two kimberlite types found to contain possibly economic quantities of diamond.

Crushed stone, sand, and clay were produced for domestic construction purposes. Agate and other semiprecious stones were mentioned in reports, but no production statistics were available.

MALAWI [35]

The mineral industry of Malawi was a minor contributor to the nation's economy in 1976. Mineral production consisted primarily of cement, dolomite, agates, kyanite, and small amounts of sand and gravel and stone for domestic use. Mineral exploration continued on a fairly high level during the year. The Geologic Survey of Malawi was contracted to drill a carbonate deposit east of Kasungu for Portland Cement Co. (Malawi) Ltd. The deposit would be exploited to meet the needs of a new cement plant to be built in the Central Region. The Malawi Mineral Development Section of the Chamber of Mines of the Republic of South Africa completed field investigations at the Ngana coalfield northwest of Karonga and at the Chisepo iron sulfide deposit 50 kilometers northwest of Lilongwe; it also selected two areas in the Southern Region for exploratory drilling in the search for commercial apatite deposits. Eland Exploration (Pty.) Ltd. drilled a borehole at the Thuma zinc prospect 50 kilometers east of Lilongwe and two exloratory holes to investigate the geochemical-geophysical anomalies at the Chingozi ultrabasic intrusion south of Mount Mlanje.

Negotiations were begun between the Government and Lonrho Malawi Ltd. concerning the company's application for a mining lease covering the Kangankunde monazite-strontianite deposit. The deposit was reported to contain 300,000 tons of ore with 5.6% high-europium, low-thorium monazite and 18% strontianite. British Gypsum Ltd. renewed its exclusive prospecting license at the Kapirikamodzi vermiculite deposit and was granted an exclusive prospecting license covering the Kapirikadima kyanite mineralization area. During the year, a 100-ton bulk sample of kyanite was exported for testing by potential customers.

Gemstones (Malawi) Ltd. exported small amounts of agate, aquamarine, garnet, mica, and ruby corundum to gem and mineral dealers in 1976. An emerald deposit was reported in the Mzimba District late in the year.

The UNDP project "Ground Follow-up to Airborne Geophysical Surveys in Four Selected Areas" was concluded, and the restricted areas in the Nsanje, Dzalanyama, Karonga, and Rumpi Districts were reopened for mineral license applications.

The economy of Malawi continued to be strained by the high cost of imported petroleum products. Malawi imported approximately 1 million barrels of refined petroleum products at an estimated cost of $22 million [36] during 1976.

The Government applied for loans and credit from the ADB and other lenders for construction of the Nkula Falls "B" hydroelectric project. The first phase was to have a 36-megawatt output, with further development to 90 megawatts, and was to be adjacent to the existing Nkula Falls "A" project on the middle section of the Shire River.

MALI [37]

The mineral industry of Mali contributed a very small portion of the nation's 1976 GDP of $590 million [38] at current prices, which was up 11.2% over that of 1975.[39] Mineral production consisted of cement, gold, and salt. Most mineral development was in the exploration stage. Deposits re-

[35] Prepared by David E. Morse.

ported by a recent study by the Ministry of Mines included iron (approximately 597 million tons), manganese (10 million tons of 40% to 60% manganese), bauxite (880 million tons of 40% to 50% Al_2O_3), lithium (265,000 tons of 6.5% lithium), rock salt (53 million tons), gypsum (370,000 tons), limestone (22 million tons), asphalt (350 million to 400 million tons), and clay (37 million tons). Phosphates, lead and zinc, cobalt, uranium, diamond, and copper deposits had also been reported; however, most of these deposits are in extremely inaccessible regions.

Manufacturing, including handicrafts and artisans' production, accounted for 11% of the GDP. Virtually all large enterprises were owned by the State, and the remaining few had mixed ownership. In 1976, nine new plants opened, including a small private battery factory. The investment climate was reported as favorable for foreign companies, but manufacturers have been and will probably continue to be required to offer the Government a percentage ownership of 10% to 50%. In general, the basic Government of Mali Code of Investments of 1969, the Mining Code (Ordonnance No. 34/CMLN of September 3, 1970), and the Petroleum Code (Ordonnance No. 30/CMLN of May 23, 1969 (modified April 20, 1970)) are followed. The basic Code of Investments offers various incentives, mostly in the form of tax-free privileges for 5 to 10 years, to companies prepared to invest in nine areas of interest to the Malian Government, including metallurgical industries and energy production.

Total exports were valued at $123 million and total imports at $202 million, resulting in a net trade deficit. The overall balance-of-payments deficit, defined as the change in net foreign assets of the Central Bank, amounted to $33 million in 1976. As in previous years, much of the deficit was financed through the operations account with the French Treasury.

The electrical output of Mali was 76 million kilowatt-hours in 1976, which was insufficient to meet local demand. The hydroelectric powerplant at the Sélingué Dam was expected to enter production by 1980 at a rate of 44 million kilowatt-hours per year.

Mineral development in western Mali was dependent upon progress made in the Senegal River Development Organization (OMVS) programs. The regional infrastructure was to be jointly owned and managed by the three countries involved (Mali, Mauritania, and Senegal). The initial phase was estimated to cost $324.5 million and would include the Manantali Dam and powerplant; the Diama Dam, an antisalt and irrigation dam to be built in Senegal; the ports of Saint Louis and Kayes and development of the waterway; and the electrical infrastructure. Major construction work on the initial phase was expected to be complete by late 1984. OMVS activity over the past 2 years was reviewed at a meeting of the heads of state in July 1976 at Dakar, Senegal. Foreign financial commitments and loans were announced that would provide over 60% of the necessary funds for the initial phase of the major OMVS projects. West Germany pledged $60 million; the ADB, $46 million; Kuwait, $38.3 million; Saudi Arabia, $30 million; France, $18.6 million; Canada, $4.9 million; and Iran, $4 million. The three OMVS countries were to jointly guarantee the loans.

After a preliminary feasibility study of the Manantali Dam and powerplant project yielded a total estimated construction cost of $200 million, the People's Republic of China decided not to participate. The Manantali Dam was a keystone of the OMVS program and was to serve a triple purpose. By regulating an assured river flow of 300 cubic meters per second at Bakal, the dam would permit irrigation of about 500,000 hectares in Mali and year-round navigation from Saint Louis to Kayes, and the associated powerplant would produce an annual 400 million kilowatt-hours of electricity (800 million kilowatt-hours after flooding is discontinued). The dam would be 70 meters high and 1.5 kilometers long. The powerplant would have a 100-megawatt capacity and would help meet future needs of western Malian mining and industry development. The volume of stored water would be 10 billion cubic meters. A contract was signed with the Euro-African Association of Engineering Consultant Firms for engineering and design studies, which were expected to last 30 months from July 1976 to December 1978. Selection of construction firms was to take place during the first half of 1979. Construction was expected to take 5 years. The river port of Kayes will have a dry dock, a

petroleum-handling area, and facilities for transshipping from river to rail.

Approximately $6 million was allotted under the 1974–78 mineral development plan for exploration operations in western Mali. Included were plans for detailed prospecting operations and feasibility studies of the iron ore deposits (500 million tons of reserves) in the Bafing-Makana Basin; the Balé iron ore deposit (130 million tons of probable reserves at 40% to 63.5% iron), located 80 kilometers southwest of Kita; and the Djidian-Kéniéba iron ore deposit (about 12 million tons of reserves at 56% to 68% iron), located near the future Manantali Dam site. The Diamou-Bafoulabé iron ore deposit was reported as poorer in quality (150 million tons of ore with over 40% silica and 30% to 40% iron). Continued exploration and prospecting operations were planned for the bauxite at Baléa and Sitaouma, with reserves of about 400 million tons of 39% to 43% Al_2O_3. Prospecting by BRGM of France would continue for copper and associated metals in the Kayes, Nioro, and Bafoulabé regions. BRGM was reported thus far as having found a copper indication near Kayes that was not economic.[40]

The Japanese Government-financed company Power Reactor and Nuclear Fuel Development Corp. (PNC) held uranium-prospecting concessions at Tessalit and Kidal, where the company was reportedly expected to spend $4 million on exploration. Three types of uranium mineralization were reported in Mali: Granitic, with small veins averaging 0.4% U_3O_8, discovered by the Japanese near Tessalit; shale type in metamorphics (schist or argillite); and sandstone type, like the Niger uranium deposits. The shale uranium deposits occur around Araouane, and the sandstone variety occur to the south near Kidal in the Japanese concession. Seven areas of radioactivity had been located in the Kidal area, and drilling and field examinations had indicated that three of these might be commercially promising. PNC was following up with a prospecting campaign involving 35 technicians that was expected to last through 1978.

Several interesting lead-zinc and cobalt anomalies were reportedly found in an area south of Bamako by BRGM. BRGM was also prospecting near Ansongo and in the Bougouni-Sikasso region and was to do a general minerals study for Mali. The Malian Government mining organization Société Nationale de Recherches et d'Exploitation Minières (SONAREM) was also exploring around Ansongo, Kéniéba, and Sikasso. The Malians were doing geophysical surveys for massive sulfide bodies near Ansongo. Copper and manganese deposits (3.3 million tons of probable reserves at 40% manganese) were reported in the Ansongo-Gao region. Phosphate (20 million to 25 million tons at 27% P_2O_5) was reported in the Tilemsi Valley of the Adrar des Iforas area. Exploration and mapping projects for the Liptako-Gourma area adjoining Upper Volta were expected to involve investments totaling $5 million, most of which was for a geologic map and general prospecting costs. CIDA was funding an airborne geophysical survey in Mali and Upper Volta. The work was being done by Kenting Earth Sciences.

The only mining project, the gold mine at Kalana operated by the U.S.S.R. and SONAREM, had not yet started official production. Under the 1974–78 mineral development plan, three gold-mining projects were slated to be operated by SONAREM with aid from the U.S.S.R. SONAREM's contribution funds would equal approximately one-third of the Soviet aid,[41] which in 1975–77 would total $4.7 million. The first contract was signed in April 1973, followed by a technical survey by the Soviet institute Credmet. During 1975, the following program was decided upon: The first phase, lasting 2 years, would include detailed prospecting with an annual production of 25,000 tons of ore. Construction of inclined wells and cross shafts, the industrial site, and temporary workers' lodgings would be completed. The second stage would include sinking of vertical shafts and construction of permanent workers' lodgings. An annual production of 60,000 tons of ore was expected in the second phase, which would include expansion of the treatment plant and addition of a cyanidation unit. The first stage would cost approximately $5.9 million, and the total project cost was expected to be $16.6 million. Prospecting operations at the Kodiéran gold deposit situated 6 kilometers from Kalana began in 1976. Diamond prospecting

[40] Bureau de Recherches Géologiques et Minières. 1975 Annual Report (Paris). Mali. P. 54.

[41] Bulletin de l'Afrique Noire (Paris). Mining Development. Dec. 17, 1975, pp. 16540–16541.

with Soviet aid was also to resume in the Kéniéba region by 1978.

Feasibility studies for a second cement plant to be constructed near Bamako were to be done by a West German firm. The Soviet-built cement plant near Kayes continued to have technical problems. The energy cost was considered to be excessive for the amount of cement produced.

At the beginning of 1976, West German geologists explored the region between Gao and Ofalik for base metals. Apart from uneconomic manganese mineralization, no anomalies were found that would warrant a followup program.[42]

Texaco was withdrawing from oil prospecting. Murphy Oil Corp. of the United States continued petroleum exploration in its permit area of 16,250 square kilometers north and northeast of Gao. Sun Oil Co. had a permit area adjacent to and east of the Murphy area. Mali imported a total of 481,108 barrels of refined petroleum products from Senegal and the Ivory Coast in the first 6 months of 1976.

MAURITANIA [43]

The mineral sector of Mauritania, consisting mainly of production of iron ore, copper, and gypsum, was the mainstay of the country's economy in 1976. Société Nationale Industrielle et Minière (SNIM), the State industrial holding company in charge of mining operations, planned to invest $500 million [44] in the next 5 years in mineral development. The major projects were exploitation and upgrading of low-grade iron ore deposits, construction of a steelmill, and expansion of copper mining to supply a new copper smelter. Exploration continued in 1976 with promising indications for the further development of base metals, gypsum, and uranium. On October 16, 1976, a new investment code was adopted to encourage foreign investment in Mauritania; among its economic incentives were tax exemptions, guarantees against nationalization, and provisions for profit repatriation.

Output and exports of iron ore, which provided over 70% of Mauritania's export earnings and 20% of its budget, showed a substantial improvement over the 1975 figure. Exports of copper and gypsum, however, both decreased. In general, the mineral industry suffered from elevated costs owing to insufficient infrastructure, scarcities of water and power, and loss of foreign technicians. In addition, oil consumption increased 24% to 165,000 tons. To offset its adverse balance of payments, Mauritania was granted $5.5 million in standby credit by the International Monetary Fund (IMF). Also in 1976, the country received approximately $150 million in aid from the Arab oil-producing countries.

During 1976, iron ore transport from the Zouérate mining district was interrupted by the destruction of a rail link to the port of Nouadhibou. SNIM undertook the construction of a 14-kilometer bypass around Choum Tunnel to reduce the vulnerability of the 650-kilometer railroad. The new rail link was to be completed in 1977 at a cost of $1.5 million.

Construction began in 1976 on extensions to the port of Nouadhibou, scheduled for completion at yearend 1978. The $27 million project was financed by Kuwait, the IBRD, Caisse Centrale de Cooperation Économique (CCCE) of France, and the Mauritanian Government. At the same time, a deepwater port was under construction at Nouakchott, financed by the People's Republic of China. Progress was made in 1976 on construction of the Nouakchott-Néma road, a major project intended to open up the eastern part of the country. The $100 million road was financed by Saudi Arabia, Kuwait, and the United Arab Emirates. The first section, 600 kilometers in length, was to be commissioned in 1977.

Several mineral exploration programs were ongoing in 1976. Geological teams from Romania conducted research on lead-zinc and copper deposits in Adrar, phosphate in the Taoudenni Basin, iron ore in Tiris and Tasiast, and copper in Affolé. Mauritania and the U.S.S.R. signed a protocol during the year for general mineral research and geological prospecting. The Division de la Recherche Géologique of SNIM initiated studies for the preparation of a national geological map. Uranium ex-

ploration on a 165-000-square-kilometer area in the Tasiast and Dorsale Reguibat regions continued under the direction of CFP in conjunction with PUK, CEA, and Tokyo Uranium Development Co. Phosphate exploration, undertaken by BRGM and the Romanian firm Geomin, was terminated in 1976 owing to negative results.

On April 14, 1976, Morocco and Mauritania signed an agreement formally establishing their sovereignty over Spanish Sahara and providing for economic cooperation in exploitation of the Bu Craa phosphate mines. Spain, which ceded the territory of Spanish Sahara to the two countries in 1975, retained a 35% interest in the phosphate mines, where reserves were estimated at 10 billion tons. Plans called for phosphate production to reach 10 million tons per year by 1980. Mauritania and Morocco also agreed to undertake joint exploration of the mineral resources of Spanish Sahara.

Production of iron ore at Zouérate, situated in northeastern Mauritania near the Spanish Saharan border, increased from 8.7 million tons in 1975 to 9.7 million tons in 1976. The three mines, Tazadit, Rouessa, and F'Derick, were under the direction of Complexe Minier du Nord (COMINOR), a division of SNIM. All output was exported, the primary purchasers consisting of France (23%), the United Kingdom (17%), Japan (15%), Italy (13%), and West Germany (12%). Combined reserves of the three mines, where production was to be phased out by 1985, were 1 billion tons of 65% iron.

The decline in activity at the older mines was to be compensated for by exploitation of lower grade ore reserves in outlying bodies known as the Guelb deposits. Situated within a radius of 50 kilometers of Zouérate, total reserves of the Guelbs were estimated at 2 billion tons of magnetite ore averaging 38% iron. Exploitation was to begin in 1981 at an annual production capacity of 6 million tons. Approximately $300 million was to be invested in the development of the Guelb deposits between 1977 and 1986; financing was to be provided largely by the Saudi Arabian Development Fund and the Kuwaiti Fund for Arab Economic Development.

A ministeelworks was to be constructed in Nouadhibou at a cost of approximately $10 million. Initial capacity of the steelmill, which would produce rods and bars for construction purposes, was to be 12,000 tons per year. Energy requirements were to be provided by a new power station under construction at Nouadhibou.

Copper production at Akjoujt totaled 9,431 tons in 1976; the mine operated at 50% capacity owing to technical difficulties and the loss of foreign technicians. Mauritania nationalized the foreign shareholdings of Société Minière de Mauritanie (SOMIMA) and placed the copper mines under the direction of SNIM in 1975. Copper oxide ore, estimated at 2.3 million tons averaging 2.7% copper, was due to be exhausted by 1980. Exploitation of copper sulfide reserves, estimated at 13.7 million tons averaging 2.3% copper, was to begin at that time. Although copper sulfide reserves were considered less difficult to process than the copper oxide ore, new equipment for extraction and concentration was necessary.

Société Mauritano-Kowetienne des Industries Métallurgiques, a joint venture of Mauritania and Kuwait, was to complete the installation of a copper smelter at Nouakchott toward the end of 1979. The smelter was to process concentrates with a copper content of 25% and produce 30,000 tons of copper and 100,000 tons of sulfuric acid per year.

Production of gypsum at Sebkha de Ndrhamcha, located 65 kilometers north of Nouakchott, declined from 12,700 tons in 1975 to 11,200 tons in 1976. The major part of the output was exported to Senegal for use in the Société Ouest-Africaine des Ciments (SOCOCIM) plant at Rufisque. Mauritania continued to rely on imported cement, which amounted to about 70,000 tons in 1976. SNIM planned the construction of a plaster works near the gypsum deposit and solicited bids for its construction during the year. The $700,000 plant was to have an annual capacity of 11,000 tons for local distribution.

Most of the foreign petroluem companies, including Texaco, Esso, Shell, and Western Enterprises, Inc., relinquished their oil-prospecting concessions in 1975–76 owing to disappointing results. However, a new agreement was concluded in 1976 with a group consisting of Getty, Phillips, Hispanoil, and Agip for petroleum exploration in the Cap Blanc area. The 24,000-square-kilometer tract included both onshore and offshore areas south of Nouadhibou. Hispanoil was to be the operator for the con-

sortium, in which each company had a 25% holding.

L'Unité de Comercialisation des Produits Pétroliers (UCPP) was responsible for the sale and distribution of all petroleum products in Mauritania. Under the supervision of UCPP, construction continued in 1976 on the petroleum refinery at Nouadhibou. The Austrian firm Vöest-Alpine was contracted for construction of the refinery, which was to have an annual production capacity of 1 million tons of petroleum products.

MAURITIUS [45]

The mineral industry of Mauritius contributed less than 1% to the estimated 1976 GNP of $366 million [46] at current prices, up 6.9% over that of 1975. Foreign trade accounted for about 60% of the GNP.

The 1976 mineral production consisted of salt (5,500 tons valued at $269,058), lime (7,300 tons valued at $412,407), and basalt (400,000 tons valued at $1.5 million). The Mauritius Chemical and Fertilizer Industry Ltd. plant was producing 200 tons per day of a new ammonium sulfate compound, in addition to two different formulas of NPK fertilizers (17–8–75 and 17–2–25). The firm produces some 6,000 tons of fertilizer per month.

Without significant natural resources, aside from a fertile soil, Mauritius must import most raw material. The Government encouraged industrialization by a series of tax advantages and other incentives for growth. By December 1976, there were 81 factories in the Export Processing Zone (EPZ), which was started with 9 companies in 1970. Over 28,000 jobs were created in the EPZ since 1970. The Government's objective continued to be full employment, requiring 76,000 new jobs by 1980, including 47,000 in industry. Priority attention was being given to the development of export-oriented industries.

Mauritius offers a favorable investment climate to industries that are export oriented, offer high employment possibilities, and generate foreign exchange earnings. Investments are encouraged by exemption from import and excise duties on raw materials and complete exemption from payment of import duty on capital goods; a corporate income tax holiday for a minimum of 10 years and a maximum of 20 years; loans at preferential rates for the importation of raw materials; electric power at preferential rates; provision of reinforced factory buildings for use by industrialists; and an agreement in principle to exemption from income tax of those profits earned from foreign investments in Mauritius if they are not transferred but are reinvested in Mauritius.

Anticipating further growth in industrialization, the Central Electricity Board (CEB), a public corporation, was expecting to increase the electric power supply 11% per year during the next 5 years. Two new major power stations were being built at Baptistes-Guibies and Quatre-Bornes. Another station was planned for Grand River Southeast. Between 1969 and 1974, consumption increased 10% per year, owing mostly to the increased industrial growth. The European Investment Bank loaned $2.2 million to the CEB for expansion of the thermal power station at Fort Victoria. On December 3, 1976, a 6½-year, $3.4 million loan was finalized between Citibank and the CEB for the acquisition and erection of two 12-megawatt thermal generators at Port Louis. CCCE of France signed an agreement on October 18, 1976, for loaning $4.3 million to be used to construct a 12-megawatt electric powerplant in Port Louis. This was the third loan CCCE had provided to Mauritius. The Arab Bank for Economic Development in Africa granted $10 million for the Guibies reservoir and hydroelectric plant. The loan was to be repaid in 15 years at 4% interest. The new reservoir at Guibies was to have a 32-million-liter capacity and would provide water for Port Louis and the surrounding area. A hydroelectric plant of 8-megawatt capacity would also be built. An $850,000 Canadian grant was to be used to improve the Rodriguez water supply.

Mauritian trade ties remained strong with the United Kingdom, France, and India. Mauritius also worked hard in establishing firmer relations with other African countries and emerged in 1976 with the chair-

manship of the OAU. An investment guarantee agreement was concluded with the United States, and OPIC political risk insurance was made available for certain projects.

In early 1976, the Government announced that the Mauritian rupee would be linked to the Special Drawing Rights (SDR) of the IMF and no longer to the pound sterling. This step was to assure the promotion of investment and make it possible to combat inflation in Mauritius.

Under a recent agreement between the Mauritian and British Governments, two mapping projects were to produce new topographical maps of Mauritius. Maps for general planning purposes at a 1:25,000 scale would make up the first project. The second project calls for production of maps at a 1:2,500 scale for certain developed or developing coastal regions. These maps were expected to be useful for civil engineering surveys and town planners and assessors. Aerial photography for these two projects was accomplished in November 1975 by Hunting Surveys and Consultants Ltd. under a British contract.

No changes were reported in the petroleum exploration or concessions status for 1976. At last report, Texaco held all 57,000 square miles of rights. No exploratory work was performed, and there was no drilling activity. A total of 834,597 barrels of refined petroleum products was imported during the first 6 months of 1976 from Iran, Kuwait, Bahrain, the Republic of South Africa, and Madagascar.

NIGER [47]

The mineral industry of Niger, although small compared with agriculture and other industrial sectors, assumed importance in the overall economy in 1976. By yearend, Niger's uranium industry was in a very healthy state. Production of semiprocessed uranium yellow cake from Niger's single open pit mine operated by Société des Mines de l'Air (SOMAIR) steadily increased from 429 tons in 1971 to 1,722 tons in 1976, and was expected to reach 2,000 tons by 1977. Although prices for uranium were negotiated between the Niger Government and CEA, the French atomic energy authority, gross income of the uranium sector was about $83 million.[48]

SOMAIR operated the Arlit mine, 450 miles northeast of Niamey, and was the sole producer of uranium in 1976. SOMAIR is an international consortium comprising the Government of Niger, CEA, Compagnie Française des Minerais d'Uranium (France), Société Minière Péchiney-Mokta (France), Urangesellschaft mbH & Co. K.G. (West Germany), and Agip Nucleare S.p.A. (Italy). Another international consortium, consisting of Niger, France, Japan, and Spain—Compagnie Minière d'Akouta (COMINAK), established in 1976—began to develop the Akouta mine in 1976. An output of 2,000 tons per year of uranium concentrate was expected by the end of 1978. The Akouta mine is located to the southwest of Arlit and belongs to the same mineralized zone as the Arlit concession. The capital investment at the Akouta mine was estimated to be $200 million and was financed by stock sales, medium-term loans from Niger banks, and loans from participating companies. The shareholders in COMINAK were as follows: Compagnie Générale des Matières Nucléaires (COGEMA) of France (34%), Office National des Resources Minières (ONAREM) of Niger (31%), Overseas Uranium Resources Development of Japan (25%), and Empresa Nacional del Uranio (ENUSA) of Spain (10%).

Nine uranium exploration permits had been issued by the Government of Niger by the end of 1976. The Government held equity participation in all exploration permits through its agency ONAREM, but this was not required by law and was apparently negotiable. All uranium companies active in Niger were asked by the Government to help finance the $100 million Tahoua-Arlit highway. This road was to link Arlit, the uranium-rich district, to Tahoua through the Saharan section of the country and serve as a trade route through Agadez. It appeared that financial support for the road was becoming a signature bonus to be paid by companies interested in uranium investment in Niger.

At the end of 1976, the Imourarene uranium concession was organized by a

[47] Prepared by E. Shekarchi.

[48] Where necessary, values have been converted from CFAF to U.S. dollars at the rate of CFAF226=US$1.00.

consortium of COGEMA (35%), Conoco (35%), and ONAREM (30%). Preliminary investigations indicated that the Imourarene concession contained 70,000 tons of uranium; the consortium expected to begin production late in 1981.

Another mineral activity of Niger was the placer mining operation of Société Minière du Niger (SMN) that produced about 128 tons of tin concentrates in 1976. Total earnings from the tin operation were reported at $1.5 million. Tin deposits were located about 50 kilometers northeast of Agadez. The Government of Niger established a mixed enterprise, Société Nigerienne du Charbon (SONICHAR), to develop a 4.5-million-ton coal deposit in the Air Mountains. The principal purpose of the project was to provide steam-generated electric power for the SOMAIR and COMINAK uranium mines with the potential to service two additional mines. Total cost of the SONICHAR coal mine and generating plant was put at $90 million. By the end of 1976, the project had run into several problems resulting from lack of coal-mining expertise, overall planning of the generating plant, and transportation.

In October 1976, a major breakthrough in meeting Niger's growing energy needs occurred when a high-tension line began carrying cheap hydroelectric power to Niamey from the Kainji Dam in Nigeria. Under terms of a 1974 accord, Nigeria will provide Niger with 30 megawatts annually for 20 years.

Petroleum prospecting, which began in Niger following independence, involved Djado's sedimentary basins in the extreme northeast of the country in 1960–65, the Talak Basin to the west of the Air Mountains in 1965–70, the western Niger River Basin in 1970–75, and the Niger section of the Lake Chad Basin from 1970 to the present. During 1976, no fieldwork was undertaken, since most of the data gathered earlier were being reevaluated by foreign firms. Only five wells were drilled as a result of all the exploration, and petroleum was struck at only one well, near Lake Chad. Texaco was reevaluating this find, and no firm decision on the operation was made by yearend.

The phosphate deposits discovered by ONAREM at Tapoa and Tahoua remained in the development stage. The latest estimate given by ONAREM for Tapoa's reserves was 250 million tons of 23% P_2O_5, which required beneficiation before marketing; material from Tahoua could be classified as mineral ore.

REUNION [49]

The economy of Réunion, an island in the Indian Ocean approximately 640 kilometers east of Madagascar, remained largely agricultural in 1976. Mineral exploration has been limited to general geological surveys conducted by BRGM. In 1975–76, BRGM conducted ground water surveys in the Galets plains area and near Saint-Denis, the capital. It also completed electromagnetic surveys of selected regions of Réunion, which was an overseas territory of France.

In 1976, Réunion imported goods valued at approximately $460,000 [50]; 54% came from France. Import traffic increased 47% over the 1975 level owing to increased imports of petroleum products. Exports totaled $85,000 in 1976, with 58% of the goods going to France; sugar accounted for 80% of Réunion's exports. The country's major development projects, financed largely by France, consisted of infrastructure improvements including road construction, electrification, and port expansion at Pointe des Galets.

RWANDA [51]

Rwanda's mineral production increased in both quantity and value during 1976 and earned more than 15% of the country's foreign exchange. Cassiterite (tin ore) was responsible for about 60% of the value of the mineral industry and was Rwanda's second largest source of foreign exchange. The Economic Community of the Countries of the Great Lakes (CEPGL), linking Rwanda and Burundi with Zaire as a common marketing unit, was unable to relieve transport difficulties for the landlocked

[49] Prepared by Candice Stevens.
[50] Where necessary, values have been converted from French francs (F) to U.S. dollars at the rate of F4.9=US$1.00.
[51] Prepared by Miller W. Ellis.

country because of congestion on Zaire's road-barge-rail routes to Atlantic ports. Closure of the Kenyan-Ugandan border in July stranded a number of Rwandan transport vehicles in both countries and halted shipments of exports and delivery of imported motor fuel supplies. The acute shortage of fuel for mining equipment and transport vehicles was alleviated by loans from Burundi and Tanzania, but traffic by way of Tanzania was intermittent because of poor road conditions between the Isaka station on the Tanzania railroad and the Rwandan frontier at Rusumo Falls on the Kagera River. Except for air transport, the most dependable route for Rwanda's trade was by road through Burundi to Bujumbura on Lake Tanganyika, by lake steamer to Kigoma, Tanzania, and by rail across Tanzania to Dar es Salaam on the Indian Ocean.

Société Minière du Rwanda (SOMIRWA), owned 49% by the Rwandan Government, controlled about 90% of Rwanda's mineral industry. Compagnie Géologique et Minière des Ingenieurs et Industriels Belges (Géomines), with a 51% interest in SOMIRWA, was responsible for mining operations. Production of gold and beryl was more than double the 1975 output. Only small increases were recorded for cassiterite and wolframite, which were the second and fourth most valuable of Rwanda's export commodities. Production of columbite-tantalite declined slightly. Most of Rwanda's minerals were marketed by SOMIRWA to Société Générale des Minerais (SGM) in Belgium.

Geochemical and radiometric exploration by the United Nations continued during 1976. Abnormal concentrations of lead-zinc and tungsten were found in soils at several localities, and abnormal radioactivity was recorded near Butare in the southern part of the country. Drilling was started to evaluate tin-bearing alluvium and old tailings in the Nyabarongo Valley. SOMIRWA and Géomines participated in exploration drilling and in studies to improve recovery of Rwanda's minerals. Construction of a tin smelter at Kigali was planned.

Expanded utilization of methane gas from Lake Kivu was studied jointly by Rwanda and Zaire. A local brewery consumed 159,120 cubic meters of methane produced by the pilot extraction plant.

Building materials, including sand and gravel, clay, and brick, were undoubtedly produced and consumed in Rwanda, but reliable data as to the quantity and value were not available.

SAO TOME E PRINCIPE [52]

The two-island Democratic Republic of São Tomé e Principe became the smallest of Africa's independent nations in July 1975. Agriculture continued to be the chief industry and cocoa the main export commodity. Financial assistance, grants, loans, and training facilities were offered by a number of nations during 1976, but Portugal provided small ships and appeared to continue as the nation's chief trading partner despite emigration of most Portuguese nationals following nationalization of plantations and reallocation of land to indigenous families.

Of volcanic origin and with 1 to 7 meters of rainfall annually, the islands had fewer than 80,000 inhabitants, mainly farmers and fishermen, in a total area of 1,000 square kilometers. There was no activity in the offshore oil concessions surrounding the islands, but extensions of exploration permits were reportedly being renegotiated by Ball and Collins (Oil and Gas) Ltd. during 1976. Excavation of stone and clay for local building material was probably the country's only mineral activity.

SENEGAL [53]

The most significant mineral production in the Republic of Senegal in 1976 was phosphate rock and derived fertilizer products. A small amount of construction materials, sand and gravel, limestone, and cement was also produced for local consumption. Notable developments during the year were the implementation of capacity expansion programs by the Senegalese petroleum refinery, the start of aluminum

[52] Prepared by Miller W. Ellis.
[53] Prepared by E. Shekarchi.

phosphate mining, and the inauguration of the Dakar Free Trade Zone (DFTZ) in early 1976. Senegal actively sought foreign investment that matched local priorities. An attractive investment code offered tax and other concessions for foreign investors, and the legislation was supported by Senegal's record of equitable treatment of investors since its independence in 1960.

A number of manufacturing firms in ceramics, semiconductors, petrochemicals, and fertilizers, both foreign and domestic, showed interest in establishing factories in the DFTZ. Some of these manufacturers moved into the early stages of construction in 1976 and expected to start production in early 1978.

The objectives, on a priority basis, of the fifth 5-year plan (1977–81) were full production at the Tobène phosphate mines, construction of a phosphoric acid and phosphate fertilizer plant, expansion of the Pout clinker and cement plant, enlargement of the Thiès foundry, and establishment of a small steel-rolling mill for production of rods and sheets.

The main mining activity was centered upon production of phosphates by two companies, Compagnie Sénégalaise des Phosphates de Taiba (CSPTI) and Société Sénégalaise des Phosphates de Thiès (SSPTH). The performance of both firms, which were 50% Government-owned, was affected by poor world markets for phosphate in 1976, causing production, tonnage, and exports to remain static. Production by CSPTI of 1.6 million tons of calcium phosphate was slightly lower than its 1975 record, and export sales declined to only 1.3 million tons. Production of aluminum phosphate by SSPTH reached 208,000 tons in 1976, of which 147,000 tons was exported. The company's total export was about 1.4 million tons. Recipients of Senegalese phosphates, in order of tonnage, were France, the United Kingdom, Greece, and the Netherlands. Estimated reserves at the CSPTI concession, 240 kilometers north of Dakar, were given at 100 million tons grading 65% P_2O_5, while SSPTH's reserves were given at 50 million tons grading 30% P_2O_5.

The Governments of Senegal and Iran continued to study their proposed $500 million[54] phosphate/oil-refining joint venture initiated in 1975. The partnership company, Société Irane Sénégalaise des Pétroles et des Mines (IRANESCO), was considering construction of a $200 million oil refinery at Kayar, north of Dakar, with some 3 million tons per year of crude oil to be supplied by National Iranian Oil Co. The IRANESCO agreement called for Iran to buy 1.0 million to 1.5 million tons of Senegalese phosphates per year. The investment included $200 million for development of a new phosphate mine, $100 million for expanded deepwater port facilities, and a nitrogen fertilizer plant at Dakar. The inter-Governmental agreement stipulated that Senegal must obtain financing for the infrastructure, while Iran was to finance the refinery and part of the mine development. A World Bank team reviewed the project during 1976, but by yearend no firm commitment had been made.

Iron Ore Mines of Eastern Senegal Co. (MIFERSO), organized in 1975, studied the Falémé iron ore deposits in the eastern Kédougou-Saraya district during 1976. MIFERSO's partners were Fried. Krupp Hüttenwerke AG of West Germany, 24%; BRGM of France, 24%; Kanematsu-Gosho Ltd. of Japan, 24%; and the Senegalese Government, 28%. By the end of 1976, available information indicated that reserves of the Falémé ore body were 400 million tons with a 47% iron content. Also, it was concluded that further feasibility studies should be conducted in 1977 to decide on the economics of mining in a remote region of the country with no infrastructure. The Government of Senegal initiated a feasibility study for development of beach sand deposits along the coast of Senegal during the year. Apparently, these sands contained a high percentage of titanium and zirconium minerals. Also, a marble company was organized to develop marble deposits in extreme southeastern Senegal near Kédougou. In 1976, Senegal imported 80% of its domestic marble consumption from abroad. The new company envisages a marble production large enough not only to satisfy domestic requirements but also to export to neighboring countries.

Nine years ago, about 100 million tons of crude oil was discovered offshore the Senegal coast. However, the crude was so heavy that development of the deposit at the time seemed uneconomic. Recent technological developments in the oil industry and the similarity of this crude to that obtained in Venezuela led the Government

[54] Where necessary, values have been converted from CFAF to U.S. dollars at the rate of CFAF226=US$1.00.

of Senegal to enter into a new agreement with a Venezuelan oil company to reevaluate the economics of Senegalese offshore oil. Offshore oil exploration continued 50 kilometers north of Dakar, where Chevron Oil Co. planned tentatively to drill in early 1978. Reportedly, natural gas in quantities equal to 30,000 tons of fuel was located near Cap des Biches in Senegal's Cap Vert region. The Government of Senegal was planning to pipe this gas to a thermal powerplant in the near future. The oil refinery at M'Baô near Dakar processed about 696,000 tons of petroleum imported from Nigeria, Dubai, Algeria, and elsewhere. The products were used primarily for domestic needs.

The country's sole cement plant, owned and operated by SOCOCIM at Rufisque, operated at full capacity during 1976. However, because of high demand by the construction industry, the Government of Senegal imported cement from other African producers at a rate of 10,000 tons per month. To overcome this shortage, Government geologists located a limestone deposit with ample reserves near Pout, just 30 kilometers east of Dakar. The production from this deposit was earmarked as feed for a second cement plant, which the Government planned to build near the limestone deposit. The capacity and cost of this plant were not available.

SEYCHELLES [55]

The Seychelles, a cluster of 92 islands in the Indian Ocean about 1,000 miles east of the African coast, became an independent state on June 29, 1976. The islands, which had a population of 58,000, had been a British colony for 166 years and had been under French rule for 40 years before that. The only minerals produced in the past were coral rock, phosphate rock, and guano. Oil exploration was only recently being considered.

Services relating to tourism accounted for nearly two-thirds of the 1976 national income of the Seychelles. Agricultural and industrial production accounted for only one-fourth of the GNP, estimated at about $25 million for 1976. The Government's recurrent expenditure for 1976 was just under $13.7 million, and the country ended the year with a credit balance of approximately $55,000.

The first 5-year development plan (1977–81) was expected to be announced in detail in 1977. The plan was expected to call for a diversification of the economy in order to reduce dependence upon imported goods. Development of natural resources, construction of electric powerplants, and improvement of the road network were also expected to be major projects. Financing for these plans would require large sums of money. Some loans were already forthcoming from the United Kingdom, France, and the ADB. The British Government promised an interest-free loan over 25 years of about $16 million,[56] to be used in part for the La Gogue Dam, which would alleviate water shortages on Mahé, the principal island. The dam was to be finished in 1979.

The only port was Victoria, financed and built by the United Kingdom and opened for use on March 1, 1975. The port had a

[55] Prepared by Janice L. W. Jolly.
[56] Where necessary, values have been converted from Seychelles rupees (SR) to U.S. dollars at the rate of SR1=US$0.137.

handling capacity of 150,000 to 200,000 tons and a pier 215 meters long. Total traffic was only 92,000 tons in 1975, of which no more than 7,000 tons represented export traffic. Imports for the same period were valued at $13.4 million.[57] Mineral fuels accounted for 20% of all imports.

The Seychelles rupee (SR) was pegged to the pound sterling by a fixed parity (SR1 = 7.5 British pence) and thus experienced the same fluctuations as British currency. There was no foreign exchange control.

The country's investment code was very flexible, the corporation tax was only 35%, and the personal income tax could not exceed 35% of gross income. The Seychelles, located at the crossroads of Middle Eastern petroleum traffic, hoped to attract more foreign capital and become a privileged place to invest and deposit funds.

Upon gaining independence, the Seychelles immediately published petroleum legislation paving the way for exploration. Bids were accepted for 60 offshore blocks during 1976. Negotiations for exploration rights were started by Burmah Oil Co. Ltd. of the United Kingdom, Siebens Oil and Gas Co. Ltd. of Canada, and Oxoco International of the United States. No previous oil prospecting has been done in the Seychelles.

Many of the islands in the Seychelles group contain deposits of guano. In 1976, 5,580 tons of guano,[58] valued at $151,776, was produced for export. Assumption Island, a 2,700-acre coral island in the Aldabra group in the western part of the archipelago, contains extensive deposits of guano that accumulated as a product of bird life on the islands prior to human occupation. The deposits occur on the surface of the land and in pits and hollows, where the material was carried by rain. The pit guano is fairly uniform in composition, carrying a high percentage of phosphorus and only small quantities of iron oxide, alumina, and limestone. The surface guano is more variable, with calcium carbonate frequently in high concentration.

SOMALIA [59]

The mineral industry of the Somali Democratic Republic, confined to production of small amounts of salt, meerschaum, tin, and local building materials, played a minor economic role in 1976. Although the emphasis in the ongoing 5-year development plan (1974–78) was on agricultural development, provisions were made for construction of a cement plant and a petroleum refinery. Of the plan's total expenditure of $620 million,[60] 19% was to be devoted to the industrial sector and 25% to infrastructure requirements. However, the plan lagged in its investment schedule owing to inflationary effects on the economy, a balance-of-trade deficit of $126 million in 1976, and insufficient foreign aid and investment.

Foreign aid remained essential to Somali development, and the 5-year plan was dependent on outside assistance for two-thirds of its financing. Major donors in 1976 were the United Nations, the EDF, the People's Republic of China, and the U.S.S.R. Aid from the Arab oil-producing countries increased to approximately $100 million. The United States resumed a modest aid program to Somalia in mid-1976; U.S. exports to Somalia also increased, from $2 million in 1975 to $9.6 million in 1976.

A major infrastructure project, construction of a 1,000-kilometer north-south highway along the Ethiopian border, was near completion. The strategic road was built with the financial and technical assistance of the People's Republic of China. Somali port facilities were being improved by construction of a deepwater port at the capital, Mogadiscio, financed by the EDF and the IBRD. A major Soviet economic aid project, construction of a $27 million dam in Fanole to provide hydroelectric power for the Lower Juba region, was postponed during the year. Somalia's second diesel powerplant was under construction in Balad by the Italian firm Meccaniche Lombarde.

The UNDP continued its long term mineral exploration program in Somalia. Several mineral occurrences were scheduled for in-depth study. Kaolin in the southern areas of Bur Qalin and Bur Dur and the northern areas of Dubato and Qoljeid was to be surveyed and mapped in 1977. Test drilling was to continue at the sepiolite (meer-

schaum) and bentonite deposits in the central El Bur area. Molybdenum and copper mineralization in the northwestern Seinat area (Erigavo District) was to be mapped and delineated.

In December 1976, Somalia concluded an agreement with the U.S.S.R. for mineral exploration in the northwestern area. The $10 million program was to consist of a general geological survey of 3 to 4 years' duration covering 13,500 square kilometers. Prospecting would focus on iron ore and tin deposits in this area.

Wyoming Mineral Corp., a subsidiary of Westinghouse Electric Corp. (United States), was negotiating a joint venture with the Somali Government for exploitation of uranium deposits. Previous exploration by the UNDP indicated that the Wabo uranium deposits in southern Mudugh Province contained approximately 5,000 tons of uranium oxide ore averaging 0.07% U_3O_8. The El Bur region in central Somalia, 250 kilometers west of Mogadiscio, was estimated to contain total reserves of 2 million tons of uranium oxide ore averaging 0.12% U_3O_8. Negotiations in 1976 centered on the formation of a tripartite mining consortium, including an Eastern European country, to exploit the deposits.

Somalia's first cement plant near the northern port of Berbera was to be commissioned in 1977. Financed by North Korea, the $12 million plant was to have an annual capacity of 100,000 tons. Gypsum deposits in the Berbera region were estimated at 7 million tons; limestone and clay materials for the cement plant were also available in the area.

A small amount of salt was produced by solar evaporation at the production facility at Hafun in northeastern Somalia. Development of salt production was to proceed in the coastal areas of Merka, Chisimayu, Zeila, and Berbera.

Construction of Somalia's first petroleum refinery, to be located near Mogadiscio, began in mid-1976. The 10,000-barrel-per-day refinery was to produce petroleum products for both local consumption and export. The Iraqi Fund for Foreign Development financed most of the cost of the refinery, scheduled for completion in 1978. In 1976, Somalia imported approximately 1.4 million barrels of petroleum products, primarily from the U.S.S.R. and Iran.

Unsuccessful petroleum exploration caused a number of groups to relinquish their concessions in 1976. Conoco, as operator for a consortium including Royal Dutch/Shell and Agip relinquished its prospecting rights in March 1976. Earlier in the year, the group had spudded the Garad Mare I well in its 42,000-square-kilometer concession in the Indian Ocean. Burmah Oil Somalia Ltd. relinquished its 20,000-square-kilometer onshore concession in southwestern Somalia, and Deutsche Texaco AG relinquished its permits for both onshore and offshore tracts. The only active prospecting group at yearend was Elf-Exxon, which held an 18,500-square-kilometer area centering on the Hafun Peninsula. The group drilled and abandoned the Guardofui I well at 11,028 feet off the northern coast in 1976, and no other strikes were reported.

SUDAN [61]

Although the mineral industry played a minor role in the economy of Sudan in 1976, the year was marked by intensified exploration for petroleum and other minerals. The country embarked on a concerted effort to develop its diversified but unexploited resource base in an attempt to revitalize its low-growth economy. In 1976, Sudan's production of cement, chromite, gold, gypsum, magnesite, manganese, mica, petroleum refinery products, and salt made a small contribution to the GDP of approximately $3.6 billion.[62] The economy was plagued by an inflation rate of nearly 20%, a budget deficit of $330 million, and a balance-of-trade deficit of $450 million. But promising new developments were evidenced in an accelerated petroleum prospecting effort in south-central Sudan, major Japanese investments in the chrome industry, new contracts for asbestos and uranium exploration, and potentially commercial discoveries of iron ore, copper, gypsum, mica, and base metals.

The new 6-year development plan (1977–82) proposed a total spending level of $6.5

[61] Prepared by Candice Stevens.

[62] Where necessary, values have been converted from Sudanese pounds (£S) to U.S. dollars at the rate of £S1=US$2.50.

billion and an annual average growth rate of 7.5%. The plan relied on foreign financing for 52% of its revenues. The Arab Fund for Economic and Social Development mounted an ambitious plan to expand the Sudanese economy and develop the country as a source of food for the Arab world. The Arab countries planned to invest $5.7 billion in Sudan over the 10-year period 1976–85; equivalent investment in a second phase (1986–2000) would focus on infrastructure modernization. In 1976, Sudan received a total of $296 million in foreign aid from Western nations (52.5%), Arab nations (15.5%), the U.S.S.R. and Eastern Europe (15.5%), the IBRD (11.5%), and the ADB (5%).

Sudan and the United States reestablished diplomatic ties in 1976 after a hiatus of 9 years. The U.S. agency AID put into motion a $10 million to $20 million assistance program, and the Sudanese-American Council for Cooperation was established to aid investors and encourage closer economic ties. In 1976, U.S. exports to Sudan totaled $106 million as the United States moved up to second place among Sudan's nonpetroleum suppliers. Sudan actively sought investment from other countries through the passage of the Development and Promotion of Industrial Investment Act. This legislation emphasized investment incentives such as tax exemptions, favorable tariffs, privileged freight rates, and full remittance of profits and capital for foreign companies under certain conditions.

The potential for Sudanese mineral development was to be increased by national investment plans to overcome problems caused by inadequate infrastructure. The Sudan Railway was to undergo a 6-year modernization program. Construction of the new port of Sawakin, which would raise the capacity of Sudanese ports to 6 million tons per year, was to begin in 1977. The French firm Société des Grands Travaux de Marseille was awarded a $26 million contract for construction of the 280-kilometer Jonglei Canal between Juba and Malakal in southern Sudan. In addition, 1,600 kilometers of new roads were under construction by the People's Republic of China (300 kilometers), West Germany (200 kilometers), Yugoslavia (200 kilometers), Italy (300 kilometers), and the Sudanese Public Works Corporation (600 kilometers), with financing from a variety of sources. The most significant section was the 750-kilometer all-weather road from Port Sudan to Khartoum, to be opened in 1978.

Mineral exploration was active in Sudan in 1976, when a number of new prospecting agreements were concluded. Hunting Geology and Geophysics Ltd. (United Kingdom) was to undertake mineral surveys over 30,000 square kilometers of southern Sudan. The $590,000 program was to follow a reconnaissance survey carried out by the company throughout southern Sudan in 1976 which identified a number of target areas for further exploration. The focus was to be on metallic minerals as well as industrial minerals such as limestone, asbestos, clay, and talc.

In August 1976, Sudan signed a protocol with the U.S.S.R. for the continuation of its exploration program of 75,000 square kilometers on the Red Sea coast. Manganese and iron ore deposits along the coast were to be evaluated in a 2-year period. A French technical team was to commence a 3-year feasibility study of the resources of the Red Sea region in 1977. France would bear all costs of the project which would assess the commercial potential of gold, chrome, iron, and magnesium deposits. The Red Sea coastal area was also the focus of a study by the United Nations Revolving Fund for Natural Resource Exploration. Among the United Nations projects to be continued in the next 2 years were feasibility studies of iron ore and manganese deposits and an evaluation of copper deposits at Hofrat en Nahas.

Saudi Arabia and Sudan engaged in joint exploration for zinc, copper, lead, and silver on the Red Sea bed under the auspices of the Saudi-Sudanese Commission for the Exploitation of Red Sea Resources at a cost of $45 million. In September 1976, Preussag AG (West Germany) was contracted to conduct detailed studies of the Red Sea deposits. The Saudi firm Arabian Geophysical & Surveying Co. (ARGAS) and the French firm Compagnie Générale de Geophysique were collaborating on the development of techniques to exploit and process the metals.

Johns-Manville Corp. (United States) and Gulf International Co. continued exploration for asbestos in the Jibal and Qala en Nahl areas. Licenses were granted in 1976 for prospecting on 10,000 square kilometers in Blue Nile and Kassala Provinces for a 1½- to 3-year period. Initial exploration by the Sudanese outlined 20

million to 60 million tons of reserves. If commercial deposits were indicated, the three parties were to form a joint venture for the mining and marketing of asbestos fiber.

Uranium exploration by Agip in southern Darfur and Bahr el Ghazal Provinces yielded positive results in 1976. Deposits in the vicinity of Hofrat en Nahas were estimated to contain 10 million tons of copper and uranium ore. Agip and the Sudanese Government were negotiating a joint venture to exploit the deposits at yearend. In 1976, Wyoming Mineral received a uranium exploration permit for 290,000 square kilometers in southern and northern Darfur Province. Essex Minerals, a subsidiary of United States Steel Corp., was also engaged in uranium exploration in Sudan. The Sudanese Government invited bids for uranium prospecting in other permit areas.

Chromite production in the Ingessana Hills in southeastern Blue Nile Province was reported at 22,000 tons in 1976. The deposits were mined by the Government-owned Ingessana Hills Mines Corp. and the privately owned Blue Nile Chromium Ltd. The State planned to invest $2.5 million to double the annual output of its operation by 1978.

During the year, the Sudanese Government concluded an agreement with the Japanese firms Mitsubishi Corporation and Japan Metals & Chemicals Co., Ltd., for development of chrome deposits in the Ingessana Hills area. A 1-year, $1 million feasibility study was to be undertaken in early 1977 to determine if the reserves could support a 200,000- to 300,000-ton-per-year mining program. The Japanese were to finance all costs of the feasibility study in return for exclusive exploitation rights. The $50 million contract provided for the potential establishment of a joint venture owned 51% by Sudan and 49% by the Japanese companies. The Japanese would have the right to 49% of the production and first option to the remainder. A further element of the contract was the possible construction of a ferrochrome industry in Sudan, to be determined after receipt of the feasibility study.

Cement production in 1976 fell to a new low of 130,000 tons owing to technical difficulties at Sudan's two cement plants. Ambitious development plans caused imports of cement to increase to 77,000 tons in 1975 and 98,000 tons in 1976. Under joint venture projects involving Sudanese, Kuwaiti, West German, Danish, and British investments, the two existing cement plants were to be enlarged and a third factory constructed. Maspion Cement Corp., situated at Atbara in Northern Province, was to undergo an increase in capacity from 225,000 tons to 500,000 tons per year. Nile Cement Co. at Rabak was to reach a production capacity of 120,000 tons per year by 1977. The third cement plant, which was to produce 500,000 tons per year by 1980, was under construction at Derudeb in Kassala Province.

Approximately 18,000 tons of gypsum was mined for use in cement manufacture and the construction industry. Red Sea Gypsum Mining Co. reported the discovery of a deposit containing 250,000 tons of high-quality gypsum in the Nibr Ayit area in 1976. Feasibility studies were to be conducted on this and other deposits in the coastal area north of Port Sudan.

An experimental project to mine mica was established in the Shereik area of Northern Province in 1974. Initial production totaled 550 tons in 1976, and plans for expansion of the mining operation were discussed.

Two gold-mining pilot projects in Irkawit and Gebeit in the Red Sea Hills were to be put into operation by the Government in 1977. In 1976, approximately 300 troy ounces was obtained from the mines and smaller alluvial deposits in the southern Yei, Nabari, and Thingaita River areas. The possibility of reopening the gold workings in the Serakoit region was under study by the British firm Robertson Research International Ltd.

In July 1976, Sudan acquired a 50% interest in Port Sudan Petroleum Refinery Shell and BP (Sudan) Ltd. Shell and BP loaned the Government 78% of the $2.1 million purchase price. The 26,000-barrel-per-day refinery produced 8.0 million barrels of petroleum products in 1976. Almost all crude oil was imported from Iraq.

A second refinery was under construction at Port Sudan as a joint venture between the Sudanese Government and the Saudi firm Triad Naft Co. Ltd. The 200,000-barrel-per-day refinery was estimated to cost $250 million. The new refinery project also involved laying an 815-kilometer, 8-inch pipeline linking Port Sudan and Khartoum. Owing to technical problems, the pipeline would not be opened until late 1977. The

pipeline was being built by Südrohrbau GmbH & Co. of West Germany and McAlpine Services & Pipelines Ltd. of the United Kingdom. Parsons Brown International of Lebanon was the consulting engineer. Initial capacity of the pipeline was to be 600,000 tons per year, later to be expanded to 850,000 tons per year. The pipeline was designed to supply petroleum products to the interior and thus free fuel-carrying rolling stock on the Port Sudan-to-Khartoum Railway.

All petroleum exploration licenses in Sudan were transformed into production-sharing contracts providing for a Government share of between 70% and 80% of oil production. Chevron Overseas Petroleum Inc., a subsidiary of Standard Oil Co. of California, and Texaco Sudan Inc. were the operators for various partnerships. Chevron-Texaco continued seismic work in its 29,000-square-kilometer area on the Red Sea coast. In 1975, Chevron-Texaco acquired a 75% interest in the 2,500-square-kilometer concession of American Pacific International Inc. The Bashayer IA well was completed in February 1976 at 2,787 meters as a gas discovery; it tested 9.5 million cubic feet per day of gas at a depth of 1,860 meters.

Chevron-Texaco acquired a 75% interest in the Ball and Collins concession, which covered 17 blocks with a total area of 13,600 square kilometers onshore and offshore in the area north and south of Port Sudan. In August 1976, a gas strike was made in this concession 25 kilometers offshore. At yearend, the Sudanese Government and Chevron-Texaco were negotiating the commercial development of the offshore gas discoveries.

Chevron also held exploration licenses for 516,000 square kilometers of area in the south-central part of the country. Seismic surveys were underway in 1976, and the exploration program was to be intensified with the initiation of airborne magnetic surveys, gravimetric surveys, and surface drilling. Sudanese Resources Development Corp., a subsidiary of OEC, had its rights to a 14,500-square-kilometer offshore tract canceled in early 1976.

SWAZILAND [63]

Swaziland's mineral industry contributed approximately 13% to the 1976 GDP of $218 million.[64] Asbestos and iron ore dominated mine production, comprising 94% of the total value of mineral sales. Minerals produced were asbestos ($15.9 million), iron ore ($10.8 million), coal ($1.4 million), granite ($348,000), kaolin ($22,000), barite ($16,000), and tin ($13,000). In the past 5 years, the mineral sector has declined in relative importance in the Swaziland economy, and its once dominant position has been taken over by agriculture and forestry. The contribution of iron ore and asbestos to export value fell from 33% in 1970 to approximately 14% in 1976. Iron ore mining was to cease at the end of 1977, and kaolin and barite operations closed down during 1976. Coal, the country's third most important mineral, was expected to be a primary revenue earner during the 1980's. Exploration in 1976 focused on coal and diamond.

A feasibility study was being conducted on extending the Swaziland Railroad to Richard's Bay in the Republic of South Africa for general imports and exports, especially the export of coal. The country has been dependent on a single rail outlet to Maputo in Mozambique through which 80% of Swaziland's exports passed. The new $40 million rail link would integrate Swaziland with the South African railroad and facilitate the opening of a new coal mine and expansion of the fertilizer factory. The Swaziland Electricity Board announced plans to develop an independent domestic power supply at a cost of about $46 million. The thermal power project was to have a capacity of 1,500 magewatts, based on expanded production from the Mpaka coal district.

Production of iron ore at the Ngwenya mine, situated 25 kilometers northwest of Mbabane, declined from 2.2 million tons in 1975 to 1.9 million tons in 1976. Approximately 1.7 million tons was exported to Japan under a 3-year contract due to expire in March 1978. Mining of iron ore at the Ngwenya open pit operation was scheduled to cease in November 1977 upon depletion

[63] Prepared by Candice Stevens.

[64] Where necessary, values have been converted from Swaziland emalangeni (E) to U.S. dollars at the rate of E1=US$1.15.

of the ore body. Shipments of stockpiled fines were to continue until 1979. The Swaziland Government held a 20% interest in the mine, which was operated by Swaziland Iron Ore Development Co. Ltd., a subsidiary of Anglo American Corp. of South Africa Ltd. The evaluation of Swaziland's low-grade iron ore resources continued during the year as the Government sought partners in a joint venture to exploit and upgrade the low-grade deposits. Total iron ore reserves were estimated at 576 million tons with an average iron content of 34%.

Asbestos production at the Havelock mine, located at Bulembu in the northwest, increased from 37,600 tons in 1975 to approximately 39,300 tons in 1976. The underground mine had a capacity of 2,800 tons of ore per day and 120 tons of asbestos per day. Shareholders in the Havelock mine were the Swaziland Government (40%) and Turner & Newall Ltd. (United Kingdom) (60%). During 1976, Lonrho Ltd. (United Kingdom) relinquished all rights to its asbestos exploration concession situated adjacent to the Havelock mine, owing to a lack of positive findings.

In 1976, production of coal by Swaziland Collieries Ltd. at Mpaka in eastern Swaziland decreased to 126,000 tons from the 1975 level of 127,000 tons. Swaziland entered the European coal market in 1976 with the export of 27,000 tons to the Netherlands. A decrease in local demand for coal was further offset by increased sales to Mozambique and Kenya. The Government attempted both to encourage greater domestic use of coal and to secure long term markets abroad. It was anticipated that the projected thermal power station would consume 15% of proven coal reserves.

Swaziland's coal resources in the low veld have been actively explored for several years by independent concerns holding mineral exploration licenses and by the Government's Geological Survey and Mines Department. It was estimated that Swaziland's coalfield, which extended 150 kilometers in a north-south direction between Bordergate and Pongola, contained 224 million tons of anthracite. Among the companies holding exploration concessions were Shell Coal (Swaziland) Ltd., Johannesburg Consolidated Investment Co. Ltd. (JCI), and Anglo American.

Swaziland Barytes Ltd. produced 369 tons of barite in 1976, compared with 200 tons in 1975. At yearend, the company declared bankruptcy, leading to the closure of the mine, situated in the northwestern Londosi River Valley. The Government commenced negotiations with IMCO Services, a subsidiary of Halliburton Co. (United States), for reopening the mine. Proven reserves were 25,000 tons of barite, with estimated reserves of 300,000 tons within the lease area. The thickness of the barite vein ranges from 3 to 7 feet. A pilot plant with a 2,000-ton-per-month capacity consisting of gravity-separation and flotation facilities, operated in 1976.

Production of kaolin at the Mahlangatsha opencast mine, which was closed in mid-year, decreased from 2,260 tons in 1975 to 989 tons in 1976. The Swaziland Government, which acquired the mine from Kaolin (Swaziland) Pty. Ltd. in 1974, continued its evaluation of a new kaolin body near the old mine. Operations at Mahlangatsha, situated northeast of Sicunusa, were indefinitely suspended pending further prospecting and a general reappraisal of the operation.

Small tin and gold operations were taken over by the Government in 1976. Approximately 2.6 tons of tin concentrate was produced at the eluvial tin mine at Sinceni in 1976. All output was exported to the Republic of South Africa. West Germany provided equipment and personnel to explore the extensions of the cassiterite mineralization in the Kubuta area. An experimental gold-leaching plant at Forbes Reef was established by the Government in 1976. Production of gold for the year was 118 troy ounces.

Approximately 51,500 tons of granite was produced at the Van der Meer quarry and sold for use in the domestic construction industry. During the year, Koor Industries Ltd. of Israel announced plans to establish a ceramics factory in Swaziland at a cost of $2.3 million.

Expansions were planned for Swaziland's single fertilizer plant at Matsapa, constructed by National Process Industries (Pty.) Ltd. of the Republic of South Africa, which was commissioned in 1975. Operated by Swaziland Chemical Industries, the plant manufactured chemical fertilizer from ammonia and phosphoric acid imported from Iran. The $3.8 million expansion was to provide the fertilizer plant with its own bulk-blending and granulation units. The plant's 20,000-ton annual output was

marketed in Swaziland and the Republic of South Africa.

A technical team from the United Kingdom initiated a feasibility study for a petroleum refinery in Swaziland. A $58 million refinery was envisaged with production for both domestic use and export. As part of the study, the crude oil docking facilities at Maputo, Mozambique, were examined. In 1976, Swaziland imported approximately 680,000 barrels of petroleum products.

De Beers Consolidated continued diamond prospecting in its three concession areas totaling 260 square kilometers. Bedded deposits near Ehlane in northern Swaziland were shown to contain stones of extremely small size not considered of commercial value. Similarly, disappointing results were obtained from preliminary sample drilling of kimberlite pipes at Dokolwaya.

TOGO [65]

Mining and export of phosphate rock remained the most important mineral activity of Togo. During 1976, Togo's export earnings from phosphate rock accounted for almost one-half of its total export value. About 2 million tons of phosphate was exported during 1976, and with the current expansion underway, the Government was projecting higher exports in 1977. Phosphate mines were nationalized in 1974 when prices in the world market tripled. With the collapse of this high-priced market in late 1975, Togo's export earnings from this source decreased. Nevertheless, during 1976 the phosphate industry returned to a normal condition and was envisaged to remain strong in 1977.

The phosphate industry was controlled entirely by Compagnie Togolaise des Mines du Bénin (CTMB). Operating mines were located near Hohotoe, about 25 kilometers from the Bight of Bénin, where the phosphate ore occurs in rocks of Eocene age with a thickness of 2 to 5 meters, overlain by 6 to 25 meters of sand and clay. The reserves of crude ore were estimated to exceed 100 million tons. A beneficiation plant near the mine utilized saltwater because of the lack of freshwater in the region.

In 1975, Office Togolaise des Phosphates (OTP), the Government office that sells CTMB's rock, undertook to decrease its dependence on sales to its three traditional markets, France, the Netherlands, and Belgium, by cutting the volume going to these countries and seeking new markets and other customers. As 1975 was a year of reduced demand, the first half of the plan was fulfilled easily, but OTP encountered considerable difficulty in finding new customers that year. Total sales for 1976 were more than 2 million tons, however, and during the first 9 months, OTP diversified its market by sales to Poland (220,000 tons), Yugoslavia (109,000 tons), and Romania (24,000 tons).

By the end of 1976, Uranerzbergbau GmbH & Co., a West German-based uranium firm, had succeeded in organizing a company to carry on further feasibility studies and perhaps development work on uranium deposits in the Lama Kara region of northern Togo. The Togolese Government initially held 10% of the company stock, with the option to increase to 30% in the future, and the remaining 90% was to be shared equally by Uranerzbergbau and Wyoming Mineral of the United States. Since the mineralized zone of uranium in Togo extends beyond the border on the east into Bénin, the company planned to expand its exploration activity to Bénin during 1977. The uranium found in Togo, unlike that of the Canadian deposits, lacks associated elements such as gold and graphite. Total investment reportedly would amount to about $10 million [66] at the first development stage.

On December 1, 1976, the first stone of the Togo-Ghana-Ivory Coast clinker plant known as Ciments de l'Afrique de l'Ouest (CIAO) was laid by the Togolese Government. The construction site, 80 kilometers northeast of Lomé, is next to a limestone deposit. After several feasibility studies, limestone was found suitable as a feed material. The plant will have an initial capacity of 1.2 million tons of clinker per year, with a provision to double the capacity in the future. The clinker will go to four large cement plants in Ghana and the Ivory Coast and to one plant in Togo. CIAO and the accompanying infrastructure, such as the rail link to the port of Lomé,

[65] Prepared by E. Shekarchi.

[66] Where necessary, values have been converted from CFAF to U.S. dollars at the rate of CFAF226=US$1.00.

were to cost about $280 million. Production was expected to begin in the early 1980's.

The third 5-year plan for 1976–80 was introduced during the year. An average annual growth rate of 8% was envisaged for the economy during this period. Priorities assigned in this plan were overcoming water problems with improvements in irrigation and hydroelectric systems, rural development and industrialization, and improvements in mining infrastructure such as the port of Lomé, railroad linkage, and road transportation.

The unsuccessful bid of Union Carbide Corp. to search for petroleum in Togo was replaced by one from OEC, also a U.S. firm, in 1976. OEC was to review the old data accumulated by Union Carbide and start a new seismic survey both onshore and offshore Togo. The company was to concentrate its efforts on the remote northern section of the Volta River Basin onshore and within a 200-mile limit offshore. Apparently, the terms of financing provided for an initial 50–50 sharing of production costs by OEC and its partner, Sodeco Togo. OEC, which will be operator for the exploration program, will hold a 90% interest in the non-Government share of production. Sodeco Togo, a Togolese company, will hold the remaining 10% interest.

Construction of a 20,000-barrel-per-day petroleum refinery at Lomé continued on schedule during the year. The refinery will use 1 million tons of Nigerian and Libyan crude oil per year. Owing to the cash flow problem of Togo, the Libyan Government was apparently allowed to purchase 40% of the shares in the refinery during 1976. The refinery and accompanying infrastructure were built by a British firm and cost about $86 million.

UGANDA [67]

The mineral industry of Uganda was a minor contributor to the country's economy during 1976. Mining activity appeared to continue the downward trend that began in 1970. Information was not available on many sectors of Uganda's economy, but mining probably contributed less than 1% to the GDP, or about $12 million [68] in 1976.

Copper retained its position as the dominant metallic product, despite a continued decline in output. Copper metal exports fell to 5,400 tons, a 31% drop from the 1975 level and approximately one-third of the 1970 level. Production of beryl, bismuth, cassiterite, columbite-tantalite, and wolframite continued on a small scale by private investors. Exports of cassiterite were reported at 20 tons during 1976. Production of apatite for fertilizer manufacture was estimated at 5,000 tons. Cement output declined to 87,600 tons, 11% below the 1975 production and 42% below the 1974 production. The reduced cement output was probably a result of the Government's reduced investment expenditures.

Uganda continued to enjoy a positive trade balance during 1976. Total exports increased 30% in value to $348.3 million; the contribution from mining fell from 4% to 2% of the total value. Imports dropped 17.3% to $165.1 million; petroleum products and metals contributed over 25% of the import cost. Exports of nonmineral products, chiefly coffee, provided the overall positive trade balance.

UPPER VOLTA [69]

Upper Volta is one of Africa's least industrialized nations. The manufacturing-industrial sector accounts for less than 10% of the GNP, which was estimated at $644 million [70] for 1976 in current prices. Minerals were expected to be extremely important for Upper Volta's economic future. In addition to the manganese in the Tambao region, a marble deposit was under exploitation and there was potential for development of cement, gold, copper, nickel, bauxite, phosphates, stibnite, lead-zinc, and perhaps uranium. The overall investment climate was rated as very good. The Upper Voltans had a liberal investment code which granted tax and customs exemptions (up to 25 years in certain cases) and tariff protection, eased foreign currency restrictions, and guaranteed arbitration. As in many other developing nations, a policy designed to increase Upper Voltan control of vital domestic business and financial activities was being pursued. Upper Voltans were required to own at least 51% of the stock in large enterprises.[71]

Voltanization of the capital of industrial firms was outlined in an ordinance of October 30, 1975, which gave foreign firms 2 years to conform. Set at a minimum of 51% in sectors considered priority (banking, insurance, electricity, water supply, distribution of motor fuels, and shipping) and 35% in other sectors, the Voltanization was distinguished from a State takeover in that it may be achieved through the National Deposit and Investment Fund by either private individuals or legal entities under private law. Once the value of shares had been determined, they were offered by the banks to the private sector. If no private source of capital was available, the Fund for Voltanization of Capital was to buy the remainder of the shares, even though the Government might put them on the market subsequently. Among the petroleum-distributing companies, BP preferred to be bought out completely.[72]

Mining experts of the Autorite de Developpement Integre de la Region du Liptako-Gourma (an area which includes Mali, Niger, Togo, and Upper Volta) met in Ouagadougou on September 16, 1976. Their recommendations included establishing a mining research program, including provisions for making a geologic map; exploration for and evaluation of manganese deposits in the area; exploration and evaluation of northern Malian Precambrian

[72] Informations d'Outre-mer (Paris). Voltanization of Firms' Capital in 2 Years. V. 24, No. 274, Oct. 13, 1976, p. 7.

sediments and the vanadium- and titanium-bearing magnetites of Oursi in Upper Volta; and an integrated economic study of cement and phosphate needs and production availability of the region.[73] The four countries agreed that better transportation was required to accelerate development and that a policy supporting this sector would be pursued.

The total construction cost of the Tambao railroad project represented a commitment of $113.9 million and was financed by France ($23.4 million), the EDF ($17.9 million), Japan ($15.2 million), West Germany ($15.1 million), the Kuwaiti Fund for Arab Economic Development ($14.1 million), the ADB ($12.5 million), the Arab Bank for Economic Development in Africa ($11.2 million), and Upper Volta ($4.5 million). The principal financiers—representatives from the Ivory Coast, Italy, the World Bank, the European Investment Bank, and the Abidjan-Niger Railway Administration, and the private partners of Société Minière de Tambao (SOMITAM)—were to hold their third conference for the coordination of financial sources for the Tambao railroad in Brussels on January 21, 1977. At this conference, progress reports on the project were to be submitted by Upper Volta, Canada, the Abidjan-Niger Railway Administration, and SOMITAM. Pledges were expected to be made by the Ivorian Government concerning the implementation of port construction in Abidjan and by the Canadian Government concerning the water supply for the mine site. A final decision on the Tambao manganese mine was to be made by the private partners of SOMITAM when the feasibility report is published in June 1977. All agreements were to be finalized by September 1977, at which time it was hoped that work would begin on all projects.

Established on July 16, 1975, with registered capital of $450,000, SOMITAM had as its shareholders Upper Volta (51%), Tamco Company of Japan (30%), Exploration und Bergbau of West Germany (9%), Union Carbide of the United States (7%), and Société de Tambao Manganese of France (3%). The Upper Voltan share was held by two semipublic agencies (the National Deposit and Investment Fund and the National Development Bank (NDB)) 0.5% each and the Government of Upper Volta 50%. The private shareholders were to buy the mine production according to their holdings; thus Japan would take 61.2%, West Germany 18.4%, the United States 14.3%, and France 6.1%. The Government reserved the right to buy a maximum of 10% per year of the production, or 62,500 tons per year based on the expected eventual production of 625,000 tons per year. The deposit contained approximately 13 million tons of manganese oxide averaging 54.5% manganese and 13 million tons of 48% carbonate ore. Feasibility studies were still in progress at yearend.

The General Office for the Tambao Projects, which since 1974 has had the overall responsibility for bringing the Tambao project to production, was also seeking to establish a cement works at Tin H'Rassan. The Tin H'Rassan deposit contained approximately 56 million tons of limestone. The cement plant project was to be financed by a loan from the People's Republic of China. China was conducting a feasibility study of the plant, to be completed by early 1978. The plant was expected to start operation by early 1981. China was also to finance the Tambao-Tin H'Rassan road.

The marble quarry at Tiara was being exploited by Compagnie Voltaique d'Exploitation Minière (COVEMI). Approximately 50 tons of marble block was extracted and exported to the Ivory Coast in 1974 and 1975. The company anticipated extracting 20,000 to 25,000 tons of material per year. COVEMI received a medium-term loan of $535,700 from the NDB, and development was expected to begin by June 1977.[74]

Études Techniques et Realisations, an engineering subsidiary of France's Charbonnage de France Chimie, and Upper Volta Direccion des Mines et de Géologie (DMG) were undertaking an evaluation of the phosphate rock deposits at Kodjani and Aloub Djouana in eastern Upper Volta. The object of the study was to assess the viability of commercial exploitation. The initial budget for the study was $20 million. Preliminary estimates indicated about 250 million tons with an average of 30% P_2O_5. The Arly deposit was the smallest, with around 4 million tons of 27% to 33% P_2O_5. The deposits around Kodjani and Aloub

[73] Industries et Travaux d'Outre-mer (Paris). Upper Volta. V. 24, No. 274, October 1976, p. 731.

[74] Zoma, E. Upper Volta, The Industrial and Mining Situation. Afrique Industrie Infrastructures (Paris). June 1, 1977, pp. 42–45.

Djouana each were estimated at 100 million tons or more. The oolitic phosphate-bearing rock was friable, with little or no quartz and mostly pellets. Open pit mining was being considered.

Studies were being carried out by Société de Recherche Minière (SOREMI) on reopening the Poura gold mine by 1978. Production had ceased in 1966. Good recovery rates by the cyanide process resulted from preliminary tests. In 1976, the Government's share in SOREMI was increased from 34% to 51% through an increase in capital. The original capital of $2 million was distributed as follows: The Government 34.1%, Mining and Chemical Co. 32.4%, BRGM 22.9%, Consultancy and Development 7.5%, and other 3.1%. The workable reserves for the quartz vein were estimated at 15 tons of gold ore averaging 0.48 troy ounce per ton, and those for the old mine dump were estimated at 0.4 tons of gold ore averaging 0.04 troy ounce per ton. Development investment was expected to include draining of the mine, construction of a treatment plant and other buildings, and purchase of surface equipment.

A joint Government-United Nations exploration team reported a lateritic nickel find 7 kilometers from the railroad south of Ouagadougou. The nickel mineralization covered a 6-square-kilometer area of the Boromo greenstone belt. One drillhole intersected 2.5% nickel over a 14-meter distance. Drilling was continuing.

Copper deposits in the region of Gaoua were being investigated by the UNDP. Deposits estimated at 40 million tons with 0.8% copper and 0.06 troy ounce of gold per ton had been located. Geochemical sampling, geophysical testing, and drilling were in progress. The UNDP project was forecast to last 4 years (1976–79) and require a total investment of $3.4 million.

Other deposits being investigated included lead near Gan, lead-zinc at Garango, bauxite in western Upper Volta, and diamond and gold in the Comoé Basin.

CIDA was funding an airborne geophysical survey in Mali and Upper Volta. Covering 205,000 line-kilometers, the survey was expected to be completed by May 1977, using three Kenting Earth Sciences digital survey system units in three aircraft.[75] A West German geophysical advisory group from Bundesanstalt für Gewissenschaften und Rohstoffe (BGR) carried out geoelectric soundings above the phosphate deposit of Aloub Djouana to find ground water horizons, and suggested suitable well sites. In western Upper Volta, near Banfora, a magnetic survey was carried out by BGR to back up the search for diamond-bearing ultrabasite.

BAHAMAS

The Bahamian economy weathered the worldwide recession of the last few years better than most developing countries. This was mainly owing to the ties between the tourist industry of the Bahamas and the U.S. economy. The mineral industry played a minor role in the country's economy. The chief mineral exports included an increasing amount of petroleum products from the country's 500,000-barrel-per-day refinery, steel pipe, salt, and aragonite.

A 60,000-barrel-per-day desulfurization facility was completed by Bahamas Oil Refinery Co. (BORCO) in Freeport. The project included vacuum gas oil desulfurization, hydrogen and sulfur recovery, steam generation, water desalinization, and offsite facilities.

The transshipment terminal of BORCO operated at about 75% capacity. The Burmah Oil Co. Ltd. transshipment terminal, which is jointly owned with Bahamas Development Corp., was having its best year since it opened 2 years ago.

Bahamas Cement Co., a totally owned subsidiary of United States Steel Corp., was expected to cease operations by 1977. The decision to close was owing to underutilization of the plant for the past 2 years during the construction slump in its primary market, Florida.

Morton Salt Co. and Diamond Crystal Salt Co., two of the largest salt producers in the Bahamas, exported about 1.3 million tons of salt to the United States, mostly for chemical use.

[e] Estimate. [p] Preliminary. [r] Revised. NA Not available.

[1] In addition to the countries listed individually in this table, Bermuda, Grenada, and St. Lucia presumably produced crude construction materials (clays, sand and gravel, and stone), but output is not reported and available information is inadequate to make reliable estimates of output levels.

[2] In addition to the commodities listed, mineral output may also include other crude construction materials (clays, sand and gravel, and lime), but data on such production are not collected and available information is inadequate to make reliable estimates of output levels.

[3] In addition to the commodities listed, gypsum, iron ore, manganese ore, pyrite, and salt, all produced in significant quantities prior to the termination of publication of official statistics, presumably were produced during the period covered by this table, but available information is inadequate to make reliable estimates of output levels.

[4] Data are for years ending June 30 of that stated.

[5] Includes nickel content of nickel oxide and nickel fonte in addition to metallic nickel and ferronickel.

[6] Export figures; all production is presumed to be exported.

[7] Presumably salt is also produced, but output is not reported and available information is inadequate to make reliable estimates of output levels.

[8] Consumption figure.

[9] Figure reported in thousand cubic meters.

[10] Included in gasoline.

[11] Less than ½ unit.

[12] In addition, limited quantities of byproduct sulfur from natural gas may be produced.

BARBADOS

The economy of Barbados had a real growth of 6% during 1976. The mineral industry played a minor role, with only small amounts of crude oil, quarry products, and other construction materials produced mostly to meet domestic demand.

General Crude Oil Co. of Houston, Tex., the only operator in Barbados, was continuing negotiations with the Government for exclusive offshore rights. No wells were drilled during 1976, but average daily output from the Woodburne Field increased to 400 barrels from 338 barrels in 1975. General Crude also produced 350,000 cubic feet per day of natural gas, which it sold to a local company.

BERMUDA

The principal mining activity in Bermuda was the production of small quantities of coral sand, dimension limestone, and crushed limestone. All of this was used to meet domestic demand.

Petroleum consumption was very low owing to the restricted number of motor vehicles permitted to operate on the islands.

CUBA

The mineral industry of Cuba during 1976 was essentially based on the very large nickeliferous laterite deposits in the north of Oriente Province in the eastern part of the country. Other important metallic products included cobalt as a byproduct of the nickel industry and chromium. A variety of nonmetallic minerals were mined, including about 1.7 million tons of gypsum for use by the cement industry. Almost all of the country's energy requirements were met by imported petroleum. To alleviate the energy problem, the Council for Mutual Economic Assistance (CMEA) [2] announced plans to assist in building a nuclear powerplant in Cuba.

Nickel mining was based on operations at Nicaro and Moa, where expansion was planned from the combined current capacity of 36,000 tons per year to about 47,000 tons per year by 1980, and eventually to 150,000 tons per year. The first stage of expansion was being largely financed by the U.S.S.R., and the remainder of the program was expected to be financed by funds earned by the nickel industry, whose output is almost all exported. The second stage was scheduled to include a new 30,000-ton-per-year nickel-cobalt oxide plant at Punta Gorda, about 2 miles east of Moa, where reserves were believed to be sufficient to support an operation for more than 50 years. The laterites there have a lower alumina content than those of the Nicaro area (6% to 7% as compared with 10%), and a higher recovery (80%) was anticipated since the plant would be operated with modern equipment.

About 70% of the oxide and sinter produced at Nicaro was exported to CMEA countries. It is claimed to be superior to comparable products from Canada and elsewhere, in that copper content is lower. It is also claimed to have advantages over other ferronickels in terms of its content of chromium, phosphorus, sulfur, and cobalt.

The Government's efforts to find additional petroleum reserves resulted in the discovery of two fields along the northern coast east of Havana, bringing the total number of oilfields in Cuba to 10. But the addition to the country's reserves was modest, because like the older fields dating back to 1881, the new fields were serpentine-plug fields with initially encouraging flows and little long-term potential. Crude oil output thus remained at about 3,000 barrels per day. Commercial gas production, which began in 1971 and reached nearly 2 million cubic feet per day in 1974, began to fall.

Cuba's current 5-year plan called for expansion of existing refineries and the start of construction of a new one. Refinery output was about 120,000 barrels per day, compared with 72,000 barrels per day in 1958, the year before the advent of the Castro regime. The refining facilities included what were formerly Exxon Corp.'s 36,500-barrel-per-day Belot plant and Royal Dutch/Shell's Havana refinery. Since the Government takeover, both plants have been included in Havana's Nico Lopez refinery.

El Cobre's Mina Grande operation achieved a milestone in 1975, mining over 1 million tons of copper ore. A sizable vein of copper between Santiago de Cuba and Camagüey was reported to have been discovered. Development was expected to begin in 1977.

A 100,000-ton-per-year stainless steel plant was planned under the terms of a mutual cooperation agreement with Canada. It was expected to come into production in the mid-1980's and would consume 4,000 to 5,000 tons per year of nickel oxide. During 1976, Cuba imported all of its iron ore requirements.

DOMINICAN REPUBLIC

In 1976, there were no major changes in the mineral industry of the Dominican Republic. The Government continued its policy of gaining more favorable terms for the country in concessionary contracts signed with foreign firms for exploration and exploitation of minerals. The only significant mining concerns were those operated for export by Alcoa Exploration Co., Falconbridge Dominicana C. por A., and Rosario Dominicana S.A.

Alcoa's wholly owned mine at Cabo Rojo shipped 517,000 tons of bauxite to its processing facilities at Point Comfort, Tex. The company's contract with the Dominican Government expired December 31, 1976. Pending a new agreement, however, Alcoa continued to operate under the terms of the previous contract.

Falconbridge Dominicana, owned by Falconbridge Nickel Mines Ltd. of Canada (65.7%), Armco Steel Corp. (17.5%), the Dominican State Enterprise Company (CORDE) (9.5%), and minority stockholders (7.3%), was praised by the President of the Dominican Republic for its contribution to the country. In 1976, 56 million pounds of nickel was shipped, compared with 52 million pounds in the previous year. Production, however, fell short of the plant's 68-million-pound annual capacity, and one of the three electric furnaces used in the production of ferronickel remained shut down throughout 1976 owing to reduction in demand. Although the company had exploration rights to 38,000 hectares in addition to the 10,000 hectares currently mined, it planned to divest itself of some of that land in 1977. This would be in line with a policy of gradually shrinking the territory to which Falconbridge Dominicana maintains exploration rights under the 1969 pact.

Rosario Dominicana had its first full year of operation at the Pueblo Viejo gold-silver mine. Producing 414,000 troy ounces of gold and 907,000 troy ounces of silver in 1976, the Pueblo Viejo mine merited the superlatives describing it as the largest open pit gold mine and the fifth largest gold mine in the world. Operations were complicated by numerous modifications being made to the plant to improve efficiency and increase precious metal recovery. Negotiations in regard to the adjacent Los Cacaos concession and additional participation by the Government in Rosario Dominicana lasted the entire year. An agreement was achieved on December 15, 1976, by which Rosario Resources Corp. and Simplot Industries Inc. each sold 15,600 shares of the capital stock of Rosario Dominicana to the Central Bank of the Dominican Republic at book value. This represented a reduction in Rosario Resources' ownership from 40% to 27%. Simplot Industries also ended up with a 27% share, and the remaining 46% was controlled by the Government. Under the terms of the agreement, Rosario Resources, discoverer of the mine and prime mover in its development, was confirmed to have operating responsibility for the mine. Another important provision of the agreement cancelled the tentative Los Cacaos accord, owing to the low grade of the ore body and the soaring costs of a proposed mill expansion at Pueblo Viejo. Reserves of oxide ore at yearend 1976 were 23.5 million tons averaging 0.129 troy ounce of gold and 0.767 troy ounce of silver per ton. The underlying sulfide geologic reserves remained unchanged at 21.1 million tons grading 0.115 troy ounce of gold and 0.839 troy ounce of silver per ton, 1.40% zinc, and 0.14% copper. There is as yet no proven method of profitably processing these sulfides at present metal prices. A research program for metal recovery from the sulfides was continued throughout the year at the Pueblo Viejo laboratory and five metallurgical laboratories in the United States and Canada. The second stage of the tailings dam was under construction to provide sufficient additional capacity to safely store cyanide tailings from the processing of oxide ore.

Negotiations between the Dominican Government and five oil companies for exploration concessions were a major development in 1976. Las Mercedes de Petrolera of Venezuela was close to signing a contract for exploration in the region around the city of Azua on the Caribbean coast, where oil was known to exist.

The Dominican Republic became virtually self-sufficient in cement by yearend 1976. Cement capacity was expected to reach 42 million bags annually in the near future, making the country a net exporter of cement.

HAITI

The principal mining activity in Haiti continued to be in bauxite, carried out by Reynolds Haitian Mines, Inc. Although Reynolds considered its Miragoâne operations to be marginal, the company still produced and exported about 660,000 tons of bauxite in 1976. Negotiations for a new bauxite mining contract were in progress at yearend. The impasse was caused by an attempt by the Institut Nacional des Ressources Minerales (INAREM) to increase the tax rates significantly, which surprised Reynolds who expected a quick agreement on the terms of the contract.

Société Minière de Haiti S.A., a subsidiary of Kennecott Copper Corp., signed an agreement with the Government of Haiti to explore, initially for metal sulfide ores, in the Limbé District on the northeastern coast of Haiti.

The Haitian subsidiary of Peñarroya S.A., a French concern, instituted an exploration program adjacent to the Kennecott property, and was also involved in diamond drilling to delineate an ore body. The company negotiated an agreement with the Haitian Government whereby a 40% participation would be reserved for the Government in any commercial development resulting from the exploration work.

The Government and Southern Cross Petroleum Co. of the United States signed a contract for the exploration, production, and marketing of petroleum. The contract called for four wells to be drilled offshore, the first within 1 year. The revenue was to be split between INAREM (60%) and Crux, Ltd., the wholly owned subsidiary of Southern Cross that was to operate the project (40%).

JAMAICA

The general election of 1976, resulting in the success of the People's National Party, clarified some investment uncertainties and led to endorsement of the policy of greater Governmental participation in the affairs of the bauxite and alumina industry. Declining exports caused a record high balance-of-trade deficit, and labor problems impeded production. Revenue derived from the operations of the five North American companies engaged in mining and refining in Jamaica fell during 1976 to $132 million, compared with $158 million in 1975.

The alumina plant of Alcoa Minerals of Jamaica, Inc., was shut down for two 3-month periods during 1976. Labor disputes caused Alcoa to suspend operations from mid-February to early May. Two months later an explosion at the plant caused the second shutdown. The plant was reopened in October and operated at one-half of capacity the remainder of the year.

During 1976, the Government continued its negotiations with the mining companies for the purchase of a 51% interest in their assets. In October, an agreement was signed between Alcoa and the Government to form a joint bauxite and alumina venture to be known as Jamalco. Under the 40-year agreement, Alcoa will sell to the Government a 6% interest in its mining and refining assets and all of its mining and nonoperating landholdings. Collectively, this was estimated to represent a transfer of 51% of Alcoa's assets on the island. In addition, the joint operating concern would enjoy a reduced bauxite levy rate of 7.5% compared with the general rate of 8.5%. At the end of 8 years, a new rate would be negotiated. Negotiations for a similar partnership between Kaiser Bauxite Co. and the Government were also completed, due to take effect in February 1977. Agreements with Reynolds Jamaica Mines Ltd. and Alcan Jamaica Ltd. had not been concluded at the end of 1976.

The alumina plant and mines of Revere Jamaica Alumina, Ltd., were closed down in August 1975 and remained closed throughout 1976. Revere initiated a suit against the Government challenging the validity of the bauxite production levy as applied to Revere, and sought confirmation that its mining lease remained valid. Revere also filed a claim with the Overseas Private Investment Corp., a U.S. Government insurance agency, under the expropriation provisions. Neither of these actions had been resolved by yearend.

During 1976, Hungarian Aluminium Corp. completed a feasibility study of a new alumina plant in Manchester Parish. Negotiations were begun with the five North American companies for transport rights of bauxite and alumina on behalf of the newly formed Jamaican Merchant Marine. Construction of the joint Jamaican-Mexican 150,000-ton-per-year aluminum smelter to be constructed in Mexico was expected to commence in early 1977 with production coming onstream by 1983.

The Government established a new organization to oversee all aspects of petroleum refining and associated industries in Jamaica. The new organization, to be called the Petroleum Company of Jamaica Ltd., was a merger of National Oil Corp. and Luana Development Company. The new company's primary tasks were to implement plans to set up an 80,000-barrel-per-day refinery near Luana, in southwestern Jamaica, and to incorporate under Government management the existing 32,000-barrel-per-day Esso West Indies Ltd. refinery, which the Government planned to take over.

MARTINIQUE AND GUADELOUPE

During 1976, the mineral industry of Martinique continued to be centered around the production of marine salt, fertilizers, and cement, all of which were consumed domestically. Clays and construction aggregates were also mined for domestic consumption. Martinique's petroleum refinery, S.A. de la Raffinerie des Antilles, at Fort-de-France, had a capacity of 11,000 barrels per day. The principal refinery products were gasoline and residual and distillate fuel oil. Almost 40% of the petroleum products were exported.

The economy of Guadeloupe was in a depressed state, but subsidies and transfer payments by the French Government alleviated the situation. The mineral industry of Guadeloupe consisted of construction aggregates for domestic consumption. No official statistics for these products were reported in 1976.

NETHERLANDS ANTILLES

The petroleum industry continued to play a major role in the economy of the Netherlands Antilles. Thus, the slow recovery of most Western nations from the recession of 1974–75 had an adverse effect on the country's economy. The Government remained convinced that the lack of natural resources in the country makes it imperative that more industry be attracted to provide a firm economic base for the area. Thus, it was making every effort to attract more industry and to protect such industries once they were established.

Petroleum products from the two 500,000-barrel-per-day refineries on Aruba and Curaçao normally account for about 90% of the country's international trade. During 1976, however, owing to the conditions in the international oil market, neither refinery was producing at capacity. It was estimated that the Shell Curaçao N.V. refinery operated at 50% capacity, and Exxon's Lago refinery on Aruba operated at 60% capacity. According to company officials, the U.S. energy programs operated to the disadvantage of the two refineries, because they could not compete successfully in the U.S. market with Hess Oil Virgin Islands Corp. at St. Croix, which was treated favorably as a domestic U.S. refinery. The Shell Curaçao refinery in particular maintained only 15% of its former U.S. market at the end of 1976 and was experiencing substantial losses and reduced output. However, the oil transshipment terminals were flourishing. An oil storage facility was also being constructed on St. Eustatius.

Preliminary exploration for possible petroleum deposits was conducted off the coast of Saba by Marathon Oil Co. Contracts were signed with a consortium for further exploration off Saba as well as offshore between Aruba and Curaçao. The consortium, known as the Seagap Group, was composed of Getty Oil Co. (operator), Phillips Petroleum Co., Hispanoil, and Agip S.p.A.

TRINIDAD AND TOBAGO

The economy of Trinidad and Tobago registered a real growth of almost 5% in 1976. On May 28, the Trinidadian and Tobagan dollar's (TT$) traditional link with sterling was severed and substituted with a tie to the U.S. dollars at the rate of TT$2.40=US$1.00, an effective devaluation of 20% from the historical exchange rate. The new link with the U.S. dollar was expected to provide an element of stability for businessmen trading with the United States and other nonsterling countries.

Although Trinidad and Tobago did not have a formal development plan, the Government's development strategy was broadly defined. With the added revenues generated by the post-1973 petroleum price increases, the Government intended to develop oil- and gas-related basic industries. A fertilizer plant scheduled to come onstream in 1977 was expected to double the country's existing capacity. The feasibility of building a liquid natural gas plant was also under study. Other projects at various stages of planning included a methanol plant and an aluminum smelter.

Reversing the trend of recent times, petroleum output fell slightly during the year, from an average of 215,000 barrels per day in 1975 to 212,000 barrels per day in 1976. The decline was attributed to a severe fire in the processing area of Amoco's Galeota Point terminal in southeastern Trinidad where the onshore facilities for receiving marine crude were located, causing a 2-week shutdown of operations. There have been no significant oil discoveries in Trinidad and Tobago since Amoco discovered the Teak, Somaan, and Poui Fields in 1972. Amoco, which produced more than half of Trinidad and Tobago's petroleum, expected production to begin to decline soon. The Trinidad Northern Areas Ltd. consortium, consisting of Texaco Inc., Trinidad and Tobago Oil Co. Ltd. (Trintoc), and Tesoro Petroleum Corp., had the second largest share of petroleum production. During 1976, the companies lifted an average of 49,000 barrels of oil per day. As a result of the tax cut on petroleum products enacted in 1976, the major oil companies were expected to increase their investment in secondary recovery techniques.

Natural gas began to replace petroleum as Trinidad and Tobago's major mineral resource. Gas production rose to 375 million cubic feet per day, 11% above that of 1975. Offshore exploration during the past 15 years yielded substantial gas reserves, which in 1976 were estimated at 9 trillion cubic feet, twice the previous year's estimate. Texaco made a gas discovery off the eastern coast on a 305,000-acre block but was awaiting Government assurance that the gas would be available for export before it begins development.

The proposed direct-reduction steel plant of the newly formed Iron and Steel Co. of Trinidad and Tobago at Point Lisas received a setback in 1976 with the withdrawal of Kawasaki Steel Corporation and Mitsui & Co., Ltd., both of Japan, which had 11.5% and 5% interests, respectively, in the venture. Consequently, planned capacity was cut back from an annual 1.2 million tons to 450,000 tons. Also, the pipeline that was to bring in natural gas for use as a reductant was behind schedule, leaving some doubt as to the proposed startup date of 1978.

BELIZE

The only mining activity in Belize during 1976 involved the production of construction aggregates, which were used domestically. A comprehensive ordinance regulating mineral prospecting and mining was proposed during the year. Under the ordinance, which would supersede all grants and titles, ownership and control of all minerals except petroleum would be vested in the Government.

Exxon Corp. entered into an agreement with three oil companies to achieve a majority interest in nine oil prospecting leases covering 1 million acres, mostly offshore Belize. The agreement was with Weatherford International Inc. which had 30% interest in the leases, Ajax Petroleum Co. with 40% interest, and Canadian Superior Oil Ltd. with 24% interest. A new entity, Esso Ventures Inc., was established to be responsible for conducting extensive geophysical operations and drilling an exploratory well offshore Belize.

e Estimate. p Preliminary. r Revised. NA Not available.
[1] In previous chapters, crushed rock and rough stone was reported as "Other" stone. The figures were erroneously reported in metric tons rather than in cubic meters.
[2] Total clay production for 1976 was 96,375 metric tons.
[3] Exports.
[4] From lead and zinc concentrates.
[5] Quantity reported as 45,128 cubic meters.
[6] 1975 and 1976 totals exclude an amount reported in volumetric units at 8,000 cubic meters.

COSTA RICA

In 1976, the economy of Costa Rica exhibited strong signs of recovery from the stagnation of 1975. Gross domestic product (GDP) real growth was calculated to be approximately 6%.

On November 12, Aluminum Co. of America (Alcoa) formally withdrew from its agreement with the Costa Rican Government to develop the bauxite deposits in the Boruca region after deciding that the economic feasibility of mining the deposits was marginal at best. However, Alcoa and Martin Marietta Aluminum, Inc., were exploring the possibility of constructing an aluminum smelter in Costa Rica to use imported alumina. The fate of the smelter depended upon successful financing for the Boruca hydroelectric project, which would supply the electricity.

Mining of gold and silver at Bulora Corp. Ltd.'s Libano mine continued. In 1976, 9,645 troy ounces of gold and 1,608 troy ounces of silver were produced.

United Hearne Resources Ltd., a Canadian company, took an option on 625 acres containing the Santa Clara mine from Barranca Corp., also of Canada. Trenching, diamond drilling, and bulk sampling confirmed earlier studies of a large low-grade gold-silver deposit grading 0.10 troy ounce of gold per ton.

Most of the country's electricity generation was hydroelectric, with the remainder coming from thermal stations using imported fuel. The Instituto Costarricense de Electricidad (ICE) was studying the possible development of geothermal energy in the Province of Guanacaste. Financing was to be partially provided by the Inter-American Development Bank.

In November, work started on a new cement plant at Colorado de Abangares. Financing was being provided by Spain. Production, to start in July 1979, was expected to be about 1,300 tons per day.

Other:			
Liquefied petroleum gas ---do---	225	99	Mainly from Panama.
Naphtha ---do---	(3)	(3)	All from United States.
Paraffin ---do---	r 55	17	West Germany 9; Taiwan 3; United States 2.
Petroleum ---do---	8	1	Mainly from United States.
Unspecified ---do---	353	103	Do.
Total ---do---	r 1,959	2,995	
Mineral tar and other coal-, petroleum-, or gas-derived crude chemicals	1,480	2,010	United States 1,569; Netherlands Antilles 437.

r Revised.
1 Metal oxides and hydroxides are excluded because they were reported inseparably from metal salts and other compounds.
2 Excludes an amount valued at $250.
3 Less than ½ unit.

EL SALVADOR

The gold operations of Canadian Javelin Ltd. and Commerce Group Corp. of the United States in eastern El Salvador constituted the principal mining activity of the country. Minas San Cristobal S.A., Javelin's subsidiary, operated the Montecristo mine, where mill capacity was being expanded to 200 tons of ore per day. The company also consolidated several small gold-silver mines. Ore from these operations was being trucked to the Montecristo mill.

Commerce Group's San Sebastián mine, 30 kilometers east of the Montecristo mine at Santa Rosa de Lima, produced about 8,000 tons of ore grading 0.35 troy ounce of gold per ton. A 100-ton-per-day cyanidation plant was operating on the property. Geologists provided Commerce Group with favorable reports on the potential of the area, and the company was seeking partners to help finance its exploration program.

In 1975, El Salvador became the first country in Central America to utilize its geothermal resources; by 1976, the capacity of the Los Ausoles geothermal power station had doubled to 60 megawatts. This

accounted for about 20% of the total power generation capacity of the country. The development of its geothermal resources together with the well-developed hydroelectrical power has enabled El Salvador to become less dependent on fossil fuels to produce electricity.

GUATEMALA

In 1976, the rate of real growth of the gross national product (GNP) in Guatemala was 10%, significantly higher than the 1% growth of 1975. In February, Guatemala was hit by an earthquake, damaging many villages and taking many lives, but other than manageable infrastructure losses, productive capacity was only lightly affected. The long-term outlook seemed promising in 1976, with the discovery of commercial quantities of petroleum and the commencement of nickel production.

In 1976, Guatemala became the first Central American oil-producing country. Shenandoah Oil Corp. and Basic Resources International S.A. invested about $50 million in exploration and the drilling of four wells at the Rubelsanto structure in the Petén area. The four shallow wells were producing light-gravity oil with flow rates of up to 4,800 barrels per day. The pay zone was thin dolomite in the Cretaceous Coban Formation.

Shenandoah Guatemala Inc. expected that in early 1977 the Guatemalan Government would give it clearance to lay a 120-mile, 12-inch pipeline to connect its Rubelsanto oilfield with an eastcoast tanker terminal.

Production from the large lateritic nickel deposits in northeastern Guatemala was scheduled for the first quarter of 1977. The initial output rate was expected to be about 28 million pounds of nickel per year in the form of 75% nickel matte. The deposits were developed by Exploraciones y Explotaciones Mineras Izabal S.A. (Exmibal). Exmibal, formed in 1960, was owned 80% by International Nickel Co. of Canada Ltd. and 20% by Hanna Mining Co. of the United States.

Minas de Oxec, S.A., a subsidiary of Basic Resources International, operated the Oxec copper mine, west of Lake Izabal. Approximately 300 tons of ore was being milled per day, producing 15,000 tons per year of copper concentrate for sale to Rio Tinto-Patino S.A. Reportedly, nickel and magnesite also occurred within the concession area held by Basic Resources International.

Several areas of lead-zinc-silver-copper mineralization have been prospected near Chiquimula in recent years by Minos de Oriente S.A. (Minorsa), a subsidiary of Lacana Mining Corp., which was formed in Toronto in 1975. If mine development is undertaken, production is expected to be about 10,000 to 15,000 tons of ore per year. Reserves were estimated to be about 1.8 million tons.

HONDURAS

The El Mochito mine of Rosario Resources Corp. was the only operating mine in Honduras during 1976. Mineral exploration during 1976 was restrained as private companies awaited promised changes in the prohibitive tax law passed by the Government in December 1975.

Record tonnages, good grade, and excellent reserves made 1976 one of the best years in overall metal production for the El Mochito mine. The mine produced 321,059 tons of ore and the mill processed 320,812 tons containing 9.68 troy ounces of silver and 0.007 troy ounce of gold per ton, 7.26% lead, and 8.38% zinc.

Production at El Mochito for 1976 is shown in the following tabulation:

	Silver (troy ounces)	Gold (troy ounces)	Lead (metric tons)	Zinc (metric tons)	Cadmium (pounds)
Lead concentrates	2,254,422	1,258	19,326	3,152	--
Zinc concentrates	772,373	582	1,798	21,830	509,000
Dore bullion	156,891	191	--	--	--
Total	3,183,686	2,031	21,124	24,982	509,000

Source: Rosario Resources Corp. 1976 Annual Report. P. 5.

A Canadian aid program was underway to assist the Honduran Government in the organization of its mineral development effort and mining legislation. Experts in mining, geology, and claims registry were stationed in Honduras; experts in mapping procedures, tax matters, petroleum geology, coal exploration, and energy policy were to make short advisory trips to the country.

Table 6.—Honduras: Exports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1974	1975	Principal destinations, 1975
METALS			
Antimony ore and concentrate, gross weight [1]	255	562	United States 279; Japan 160; Belgium-Luxembourg 123.
Iron and steel metal including alloys, all forms:			
Scrap	9,722	40	Guatemala 15; Mexico 15; United States 10.
Other	1,428	1,139	Guatemala 585; Costa Rica 223; Belize 152.
Lead:			
Ore and concentrate, gross weight [2]	35,655	35,794	Mainly to United States.
Metal including alloys, all forms	--	215	All to Guatemala.
Silver:			
Ore and concentrate, gross weight	[3] 11	--	
Metal including alloys thousand troy ounces	230	132	All to United States.
Zinc:			
Ore and concentrate, gross weight [4]	46,623	52,462	United States 36,061; Japan 9,980; Netherlands 5,250.
Metal including alloys, all forms	--	210	All to Belgium-Luxembourg.
Other: Ash and residue containing nonferrous metals	234	1,002	Mexico 608; Guatemala 211; Netherlands 131.
NONMETALS			
Cement	29,558	101,243	Ecuador 48,152; Nicaragua 14,640; Belize 10,855.
Clays and clay products (including all refractory brick):			
Crude	2	14	All to Nicaragua.
Products	16	67	Guatemala 48; United States 18.
Fertilizer materials, manufactured:			
Nitrogenous	162	--	
Phosphatic	1	--	
Potassic	44	--	
Lime, hydraulic	--	1	All to Guatemala.
Salt	1,634	465	All to Nicaragua.
Sodium and potassium compounds: Soda ash	--	28	All to Guatemala.
Stone, sand and gravel:			
Dimension stone, crude and partly worked	11	31	Mainly to Nicaragua.
Other, including quartz	2	[5]	All to Nicaragua and Guatemala.
Other: Building materials	3,644	1,505	Mainly to Panama.
MINERAL FUELS AND RELATED MATERIALS			
Petroleum refinery products:			
Gasoline ---thousand 42-gallon barrels	--	4	Mainly to Jamaica.
Kerosine ---do---	--	7	Belize 5; Jamaica 2.
Distillate fuel oil ---do---	--	4	All to Jamaica.
Residual fuel oil ---do---	1,322	1,186	Dominican Republic 600; Panama 338; United States 152.
Lubricants ---42-gallon barrels---	341	231	Belize 121; Paraguay 58; Costa Rica 52.
Other:			
Liquefied petroleum gas ---do---	6,771	4,080	Belize 3,159; Guatemala 650.
Pitch, resin, asphalt, and coke from petroleum ---do---	2,503	1,613	Mainly to Belize.

[1] Antimony content was 223 tons in 1974 and 326 tons in 1975.
[2] Lead content was 22,827 tons and silver content was 2,995,885 troy ounces in 1974; lead content was 28,377 tons and silver content was 1,885,160 troy ounces in 1975.
[3] Silver metal content was 14,075 troy ounces.
[4] Metal content was 18,390 tons of zinc, 638 tons of lead, 113 tons of cadmium, and 711,631 troy ounces of silver in 1974 and 22,254 tons of zinc, 810 tons of lead, 123 tons of cadmium, and 617,166 troy ounces of silver in 1975.

NICARAGUA

Mining at one time played an important role in Nicaragua's export sector, but has been declining during the past 20 years. In 1976, only two mining operations were in full production, although exploration continued at a third. Mining accounted for less than 1% of Nicaragua's GDP and employed about 5,000 workers.

Although Nicaragua has a generally favorable tax structure and no history of industrial nationalization, only three large North American companies operated in the country during 1976. American Smelting and Refining Co. (Asarco) and Rosario Resources held 51.8% and 36.2% interest, respectively, in Neptune Mining Company, which operated the Vesubio lead-zinc mine, the second largest lead-zinc mine in Central America after the El Mochito mine in Honduras. The startup of the Vesubio mine in the early 1970's assured continuation of mining in a district that has been confronted with rising production costs and declining gold ore reserves.

Neptune's mill treated 165,681 tons of sulfide ore averaging 0.10 troy ounce of gold and 0.6 troy ounce of silver per ton, 0.8% lead, 0.5% copper, and 9.1% zinc; and 34,749 tons of gold ore averaging 0.21 troy ounce of gold per ton. Assured and probable sulfide reserves at yearend 1976 were estimated to be 1,049,554 tons of ore grading 8.61% zinc, 1.15% lead, 0.46% copper, and 0.11 troy ounce of gold and 0.96 troy ounce of silver per ton. Gold ore reserves were increased by 32,336 tons to 87,681 tons with a grade of 0.32 troy ounce per ton.

Noranda Mines Ltd. of Canada held a 60.5% interest in Empresa Minera de el Setentrion, the most important gold producer in Central America. In 1976, production totaled 111,584 tons of ore averaging 0.44 troy ounce of gold per ton. The Panteon vein was the main source of the ore. At yearend 1976, proved reserves totaled 160,572 tons of ore grading 0.5 troy ounce of gold per ton.

Exploration for petroleum by Union Oil Co. and Chevron Oil Co., both of the United States, resulted in no significant discoveries. Nicaragua's only refinery was

owned and operated by Esso Standard Oil S.A. Ltd., a wholly owned subsidiary of Exxon Corp. The installed capacity of the refinery was 21,000 barrels per day. The crude oil was imported from Venezuela.

Table 8.—Nicaragua: Exports of mineral commodities

PANAMA

For the second consecutive year, the economy of Panama had a real growth rate of about 2%. Economic policy-making was a major concern during 1976, with the national development plan for 1976–80 being made public. One of its objectives involved an ambitious public-sector investment program for both specific projects (copper, cement, and hydroelectrical power) and general infrastructure development.

In February, the Panamanian Legislative Council approved the two proposed contracts between Cerro Colorado Development Corp. and Texasgulf Inc. for exploitation of the Cerro Colorado copper deposit. An adit, started in April, was driven 460 meters into the deposit. Bulk samples from the adit were being used for pilotplant test work and for comparison with diamond drill core assays. About 35 additional diamond drillholes were completed to provide further information on grade, geology, structure, rock strength, and overburden. More than 150 holes had previously been drilled into the deposit. The final geologic report was scheduled to be completed by October 1977. Brown & Root, Inc., of the United States and Seltrust Engineering Ltd. of the United Kingdom were providing engineering services for the concentrator, roads, port, smelter, and related facilities. Additional studies on marketing, financing, training, and the environment were progressing.

Panama's only refinery, Refineria Panama S.A., a subsidiary of Texaco Inc., operated at 70% capacity during 1976, processing about 80,000 barrels of oil per day. The crude oil, imported from Ecuador, Venezuela, Saudi Arabia, and Nigeria, represented about one-fourth of Panama's total imports of $784 million in 1976. Of the crude oil imported, 37% was used directly for light products, mainly gasoline. The residues and heavy products were exported or sold to ships passing through the Panama Canal.

Northville Industries Corp. of the United States and the Panamanian Government were negotiating for the formation of a company to build and operate a large crude oil transshipment terminal at Puerto Armuelles on the Pacific coast. The terminal was to be designed for offloading tankers too large to pass through the Panama Canal. The oil is to be transferred to storage tanks and then to smaller tankers for transport through the Canal and ultimate delivery to the refineries on the U.S. gulf coast and east coast. Completion of the terminal was scheduled for 1978.

A geothermal energy program was being jointly conducted by the Government agency Instituto de Recursos Hidraulicos y Electrificacion and the Government/Texasgulf copper enterprise, Cerro Mining Development Corp. Concentrated efforts were centered in the Chiriquí and Veraguas Provinces, which had been determined as the most potentially profitable sources of geothermal energy.

The Mineral Industry of Other Areas of the Far East and South Asia

BANGLADESH [1]

Following a year of great uncertainty, the political situation in Bangladesh improved during 1976. The major problem for Bangladesh remained the high birth rate and crowded conditions. Bangladesh had the highest population density of any agrarian country—over 80 million people in a land area of 144,000 square kilometers, 65% of which is considered arable.

The Government, with considerable foreign assistance, was actively encouraging voluntary family planning, and set a growth rate target of 2% per year or less. However, even if the growth rate was reduced to the target level immediately, the population of Bangladesh would nevertheless nearly double within 20 years.

Bangladesh enjoyed 2 consecutive years of excellent harvests which helped to stabilize prices. While the increased food production lowered import levels, the goal of food self-sufficiency was not reached. Moreover, food production increases did not keep up with the population growth, and grains and other staples will continue to be imported for some time.

The gross domestic product (GDP) stood at $4.87 billion [2] in fiscal 1976,[3] showing an encouraging 11% increase in real terms over that of fiscal 1975. The cost-of-living index (fiscal 1970=100) dropped to 380 in fiscal 1976 from 408 in fiscal 1975. The wholesale price index dropped from 454 to 338 during the same period.[4]

The Government began to return businesses taken over in 1972 to private ownership, reserving only the three major industries—jute, textiles, and sugar—for Government ownership. The Government was endeavoring to promote private and foreign investment in an effort to increase industrial output. Industry presently accounts for 10% of the GDP, and most activities are related to the processing and manufacture of jute products.

As a result of a stringent fiscal stabilization program, the high inflation rate of recent years was curbed, strict credit ceilings were imposed, and the budget was held nearly in balance in fiscal 1976. The trade deficit, however, continued to be a

burden to Bangladesh, although it fell from $1 billion in fiscal 1975 to around $884 million in fiscal 1976. The deficit was financed by grants and loans from many foreign countries and international financial institutions. Export earnings increased 6% to about $380 million in fiscal 1976. Minerals played virtually no part in export revenue; raw jute and jute products accounted for over 80% of total exports. Imports dropped 10% to $1.27 billion in fiscal 1976. The dominant imports were foodstuffs and petroleum.

The search for oil and gas in Bangladesh continued throughout 1976 with mixed results. Six foreign companies were operating at the beginning of the year: Union Oil Co. of California, Atlantic Richfield Company, and Ashland Oil (Bangladesh) Co. of the United States; Superior Oil Company of Canada; Bengal Oil Development Corp. of Japan; and INA-Naphthalin of Yugoslavia. During fiscal 1976, these firms in addition to Toila Sandhanee Co. (TSC), the operational subsidiary of the Government-owned Petrobangla Oil Co., conducted surveys and drilled at seven onshore and offshore locations. TSC's onshore drilling was at Begumganj in Noakhali District and Hijia-Muladi in Barisal District. Both wells showed positive signs of natural gas. Further testing was to be conducted to determine the potential of the structures.

Offshore, INA-Naphthalin drilled one hole to 13,400 feet in its concession early in the drilling season but ran into unusually high pressures after hitting gas and was forced to seal and abandon the well. In December, the company joined with Texas Pacific Oil Co., Inc. (a 20% partner) to test the formation again. The drilling was scheduled for completion in late February 1977. Bengal Oil capped its first hole in March, and a second well was abandoned in June after hitting noncommercial gas at 14,500 feet. Union was forced to stop drilling at its first site because of unstable bottom conditions. Union contracted for a new rig and operations were scheduled to resume after the monsoon ended, probably in November at the earliest. Atlantic Richfield began drilling its first well in January and abandoned it as dry in April.[5]

In an effort to encourage and expedite the pace of oil exploration, Petrobangla called for bids in July on newly opened concession areas covering over 105,000 square kilometers onshore and 8,300 square kilometers offshore. Both areas were to be contracted under production-sharing agreements. In addition, the Government announced that it would consider joint-venture arrangements within its own reserve area of 26,000 square kilometers around Dacca.

Natural gas production increased modestly during 1976 to around 1 billion cubic meters. Development of the seven proven gasfields continued, with four presently being exploited on a commercial scale—Titas, Habiganj, Sylhet, and Chhatak. Development work was underway at the Titas Field to increase production to 4.25 million cubic meters per day (150 million cubic feet per day) by mid-1977. The distribution network from the Titas Field was to be expanded to the greater Dacca area and several nearby cities by eventually laying 1,400 additional kilometers of gas distribution pipeline. Initial work on the project was begun in 1976 with funds from a loan from the Asian Development Bank. Work began on a pipeline to supply the large tea plantations of the Laskerpore Valley with about 28,000 cubic meters per day (1 million cubic feet per day) of gas from the nearby Habiganj Field.

The Government planned to establish an integrated ammonia-urea fertilizer plant at Chittagong. Planned capacity was 1,000 tons per day of ammonia and 1,730 tons per day of urea. The plant would draw gas through a 200-kilometer pipeline from the field being developed at Bakrabad in Barisal District. The pipeline would have the capacity to service other industries in the Chittagong area as well. The Chittagong area consumes about $48 million worth of imported petroleum fuels per year.

The 1.5-million-barrel-per-day Eastern Refinery Ltd. at Chittagong, the country's only refinery, operated satisfactorily during the year after a complete overhaul in late 1975. The plant had operated well below capacity in the past few years. The 1976 output was estimated at 1.2 million tons, all from imported crude oil. The imported crude oil, costing about $175 million in 1976, included 600,000 tons from the

[5] U.S. Embassy, Dacca, Bangladesh. State Department Airgram A-85, Aug. 6, 1976, pp. 1-7.

United Arab Emirates, 400,000 tons from Iran, and 200,000 tons from Saudi Arabia.[6]

Aside from natural gas production, the mineral industry contributed very little to the overall economy of Bangladesh. In 1976, cement production more than doubled the prior year's output to 219,000 tons, and nitrogenous fertilizer output quadrupled. However, salt production declined 25%.

Plans were made for the development of a limestone mine and construction of a 1-million-ton-per-year cement plant at Jaipurhat in Bogra District. The project was estimated to cost about $200 million and was to get underway when suitable financing could be arranged.

The Bangladesh Atomic Energy Commission began exploring for uranium and thorium in December 1976 in the sedimentary rocks of Sylhet District and the placer sands of Chittagong District.

[e] Estimate. [p] Preliminary. [r] Revised. NA Not available.

[1] In addition to the countries listed, Nepal, covered textually in this chapter, presumably produces a variety of crude construction materials such as clays, stone, sand and gravel, and possibly cement, but production statistics are not available and general information is inadequate to make reliable estimates of output levels.

[2] In addition to the commodities listed, a variety of crude construction materials such as clays, stone, and sand and gravel presumably were produced, but production statistics are not available and general information is inadequate to make reliable estimates of output levels.

[3] For years ending June 30 of that stated.

[4] Gross production is not reported; marketed output is reported in lieu of estimating gross output because the quantity vented, flared, or reinjected is believed to be small.

[5] For cement production only.

[6] In addition to the commodities listed, iron ore and lead-zinc ores were mined in the past and the country produced pig iron, crude steel, and smelter zinc at its industrial facilities, but the status of these industries under prevailing conditions is not sufficiently clear to permit preparation of reliable estimates of output levels. Similarly, no data on output of crude construction materials are available and no reliable basis for estimation is available.

[7] Based on import statistics of the U.S.S.R. and Japan.

BRUNEI [7]

Oil and natural gas were the only significant minerals produced in Brunei in 1976, and the value of export shipments of these fuels accounted for a very favorable monetary return for this small country of less than 200,000 population. Total revenues of the Brunei Government were $520 million [8] in 1975 and were expected to reach $670 million in 1976. Government earnings were derived mainly from taxes, royalties, and dividends from oil and natural gas production. A minor amount was derived from the sale of natural rubber and timber. In 1976, recurring Government expenditures were estimated at $207 million and additional expenditures for development projects were estimated at $57 million. Thus, the Government stood to have a surplus of around $400 million for 1976. The total consolidated revenue fund surplus, accumulated mostly during the past decade, was more than $1,250 million.

The Government assumed 50% ownership of Brunei Shell Petroleum Co. Ltd. (BSP) after revision of the sultanate's Petroleum Mining Act in 1975. Moreover, the Government was reportedly negotiating an increase of its 10% interest in Brunei Liquefied Natural Gas Co. (BLNG) and was attempting to attain equity in the Shell-Mitsubishi-owned marketing company.

Although no figures were available, the 1974–75 inflation rate of 12% was believed to have been reduced substantially in 1976 by new Government price control measures.

Plans for diversifying the Brunei economy did not progress significantly during the year. No decision was reported by yearend on the establishment of an oil palm plantation that had been proposed as an alternative to setting up a large pulp and paper mill at Kuala Belait. While both projects could be undertaken, this would involve committing all available land in the Ulu Belait area, much of which is now a forest reserve. A feasibility study on a Government-approved fertilizer plant was completed during 1976, but by yearend no decision was reported to start construction.

BSP, operating under the new 50/50 ownership with the Government, produced

[7] Prepared by Gordon L. Kinney.

[8] Unless otherwise specified, values have been converted from Brunei dollars (B$) to U.S. dollars at the rate of B$2.48=US$1.00 in 1975 and B$2.39=US$1.00 in 1976.

over 200,000 barrels per day of crude oil during 1976. Production was from one onshore oilfield (Seria) and four offshore fields. Production from the Champion Shoals Field increased around 90% to 46,000 barrels per day in 1976. The large increase was attributed to the completion of repairs on an offshore platform damaged by a well blowout in late 1974. Fairley Field production increased about 25%. Output from Champion Shoals and Fairley accounted for most of the 13% overall increase in crude oil production during the year. Total crude oil production in 1976 was 74 million barrels valued at $965 million, nearly 23% higher than the 1975 value. Crude oil reserves were estimated at 1.83 billion barrels at yearend 1976.

Seismic surveying activity increased during the year, with a total of 15 crew-months compared with 4 crew-months in 1975. Twenty-six offshore development wells struck oil and four struck gas in the Southwest Ampa, Fairley, and Champion Shoals Fields. In addition, there were five successful oil wildcat wells and two gas discoveries.

Gross production of natural gas increased 27% in 1976. Marketed gas output totaled 7.46 billion cubic meters, an increase of 41% over that of 1975. The value of production of natural gas liquids nearly doubled to $60 million.

All of the marketed natural gas was processed at the BLNG plant at Lumut. Shipments of liquefied natural gas (LNG), all to Japan, totaled 4,836,000 tons in 1976, valued at $468 million.[9] Natural gas reserves were estimated at 177 billion cubic meters at yearend 1976.

The 5-million-ton-per-year BLNG plant operated at nearly design capacity during 1976. All five liquefaction lines operated satisfactorily throughout the year. The plant had had technical and break-in problems since the first line began operating in 1973. There were compressor and turbine malfunctions, and in addition, fouling of the cooling water system caused serious heat transfer problems. Repairs and modifications were made and design improvements were incorporated into units installed later. As a result, overall plant efficiency was improved considerably, downtime was reduced, and the energy required to produce 1 ton of LNG was reduced about 20%. The Lumut plant was the first LNG facility in the Asia-Pacific area and the largest operating plant in the world at yearend.

CAMBODIA (KAMPUCHEA)[10]

With the fall of the Lon Nol Government on April 17, 1975, a regime headed by Khieu Samphan was installed, and a political, economic, and social reorganization of the country began. On January 5, 1976, a new constitution was adopted and the country was officially renamed Democratic Kampuchea. The constitution provided for the election of a 250-man representative assembly every 5 years, with the assembly electing an administration to implement the laws and political policy laid down by it. Also, a three-man State presidium headed by the President was to represent the country in foreign affairs. General elections were held on March 20, 1976, and the representatives to the new assembly were announced 24 hours later. Subsequently, Khieu Samphan was officially made head of state and Pol Pot was named prime minister.

No meaningful statistical data were available on Cambodia's visible trade during 1976. Presumably, the People's Republic of China and other countries provided credit and financial assistance through shipments of iron and steel products, heavy equipment and machinery, and replacement parts, as well as technical assistance to rebuild and restore Cambodia's small and limited manufacturing industries. Assistance in the form of medical supplies, foodstuffs, fertilizers, and agricultural materials was probably also provided to help solve the country's health and nutrition problems.

No official data on mineral production were issued by the Cambodian Government during the year. However, the value of mineral production probably contributed very little to the overall economy of the predominantly agrarian country. The only significant operation is the mining of phosphate rock which is ground and processed for use as a fertilizer. Phosphate rock was

[9] Value was converted from Japanese yen (Y) to U.S. dollars at the rate of Y296.55=US$1.00.
[10] Prepared by Gordon L. Kinney.

reportedly mined at Tuk Méas (10°40′ N, 104°34′ E) in Kampot Province, and Môngkól Borei (13°28′ N, 103°10′ E) and Phnom Sampou (13°02′ N, 103°06′ E) in Battambang Province. A plant to grind the ore was located at Tuk Méas, with a design capacity of 12,000 tons of P_2O_5 content per year. The plant, which had been out of operation since 1970, was operating during 1976 at a very small fraction of its former output.

Cambodia also produces gold, gem stones, salt, nonmetallic construction materials, and cement. In December 1976, a cement plant at Châkrei Ting (10°42′ N, 104°16′ E) near Kampot was reportedly reopened.

Other mineral occurrences in the country include bauxite, coal, copper, iron, lead, manganese, and silver. Transportation problems and lack of investment funds prevented the development of commercial deposits of bauxite beyond the planning stage. In the north, there is high-grade iron ore, but reported reserves of only 2.5 million tons and very limited transport facilities presently preclude the economic development of the deposits.

There was no domestic production of crude oil or natural gas, and the old 12,000-barrel-per-day petroleum refinery at Kompong Som has probably not been reactivated. The plant was damaged during the civil war and the equipment was mothballed. Reopening of the plant would require a considerable financial outlay and foreign technical assistance.

No petroleum exploration was reported by the Cambodian Government during the year. Exploration by foreign companies in the country was probably not permitted, and the offshore concessions granted by the former government to French and Canadian companies remained inactive since 1975.

HONG KONG [11]

Hong Kong's GDP in 1976 was estimated at $8.8 billion [12] at current market prices compared with $7.2 billion in 1975. In terms of constant 1966 prices, the GDP in 1976 was $4.8 billion, a real growth of about 15% over that of 1975. The British crown colony relied almost wholly on foreign raw materials to meet the needs of its population and industries. Light manufacturing dominated the local economy, and aside from tourism, business conditions in Hong Kong were dependent on sales and shipments of export goods. Production of textiles and clothing, electronic articles, plastic products, watches and clocks, and other consumer accessories, in that order, accounted for over 80% of the value of the colony's total domestic export.

Total trade during 1976 was $17.3 billion, up $4.4 billion from that of 1975. During the year, domestic exports were valued at $6.7 billion and reexports at $1.8 billion. Exports of manufactured goods and articles constituted 82% of the total value of exports, machinery and transport equipment 15%, food 2%, and other 1%. Principal export destinations were the United States, West Germany, the United Kingdom, Japan, Canada, Australia, and others, in that order. Total imports in 1976 were valued at $8.8 billion, comprising the following, in billion dollars: Manufactured goods and articles, 3.8; machinery and transport equipment, 1.6; food, 1.4; and other, 2.0. Imports of petroleum and petroleum products in 1976 were valued at $528 million. Sources of Hong Kong's imports were as follows, in percent: Japan, 21.6; the People's Republic of China, 17.9; the United States, 12.3; Taiwan, 7.1; Singapore, 5.8; and other, 35.3.

The total value of mine output of minerals excluding aggregates and cement was $764,915 in 1976. Production of 50% iron ore concentrate was 37,058 tons, constituting about 76% of the total mineral output value. The iron ore was mined at Ma On Shan in the New Territories, and the magnetite concentrate was shipped to Japan. Owing to the lower tenor of the ore body and economic considerations, the mine ceased operation in April 1977. Output of quartz and feldspar was higher in 1976 than in the previous year, while clay and kaolin production decreased 12%. About 70% of the kaolin was exported to Japan and most of the feldspar to Taiwan. All of

[11] Prepared by E. Chin, physical scientist.

[12] Where necessary, values have been converted from Hong Kong dollars (HK$) to U.S. dollars at the rate of HK$4.905=US$1.00.

the quartz output, as well as some of the feldspar and kaolin, was consumed locally.

At yearend 1976, there were eight quarries operating in Hong Kong, two of which were Government run. The Cha Kwo Ling quarry, the largest unit, had a capacity of over 1.5 million tons per year, followed by the Shek O quarry with 1.0 million tons per year. The dominant rock type is granite. Annual consumption of rock aggregate was estimated to be between 7 million and 8 million tons, and that of marine sand dredged from the sea bed, 1 million tons. Local output supplies about 25% of the total demand.

Green Island Cement Co. operated a 790,000-ton-per-year cement plant at Hung Hom, Kowloon. The company imports cement clinker and grinds the clinker to produce finished cement for the local construction industry. Green Island announced plans to relocate its cement plant and expand its annual capacity.

During 1976, the People's Republic of China supplied Hong Kong with about 300,000 tons of refined oil products, compared with about 250,000 tons in 1975. Fuel oil dominated the deliveries, but gas, diesel fuel, aviation turbine fuel, kerosine, and lubricants were also included. Imports from the People's Republic of China accounted for about 7% of Hong Kong's total oil needs. The colony is dependent on imported fuel, particularly refined oil, for its energy requirements. However, Shell Oil Co. proposed the construction of a 200,000-barrel-per-day refinery on Lamora Island.

Under the mining ordinance, the ownership and control of minerals is vested with the Crown. The land officer is empowered to grant mining leases, while the commissioner of mines is empowered to grant mining and prospecting licenses. At yearend 1976, there were three mining leases, nine mining licenses, and one prospecting license in effect.

LAOS [13]

The first full year of the People's Democratic Republic of Laos saw little economic progress. The rate of inflation rose steadily and was probably the worst of any nation in the world during 1976.[14] The Lao kip (K), with no stabilizing foreign backing, began the year at K4,000 to the U.S. dollar. Six months later, its value had fallen to K14,000 to the U.S. dollar. The Government declared a currency exchange at midyear; new currency was issued and the inflationary pressure on the kip was lessened. The Government's official exchange rate, however, did not realistically reflect true market prices, and upward pressure on the kip resumed.

The flow of foreign goods, imported through Thailand, was tightly controlled to stop the drain on valuable foreign exchange. By yearend 1976, Thai imports had been reduced to only the most essential items and replacement parts which could not be made domestically. Most of the private merchants in Vientiane were forced to close as it became impossible to make a profit under the prevailing conditions.

Reconstruction and expansion of the road network continued to be a major goal of the Lao Government, but results were modest. The road network was so poor that surplus rice produced in the southern provinces could not be efficiently moved into the northern and central provinces, where rice had to be imported. The poor state of the roads was aggravated by the with-

[13] Prepared by Gordon L. Kinney.
[14] Far Eastern Economic Review. Asia 1977 Yearbook (Hong Kong). Dec. 21, 1976, pp. 212–218.

drawal in 1975 of U.S. aid which formerly provided nearly all of the road maintenance funds. Dissidents operating in the highlands harassed the road repair units and slowed construction progress.

Expansion of the Nam Ngum hydroelectric station got underway during the year. Plant capacity is to be increased from 30 megawatts to 110 megawatts when the project is completed, with the increased output to be mostly exported to Thailand. Laos earned about $1 million per year by selling Nam Ngum power to Thailand. The second small hydroelectric powerplant in Houaphanh Province in northern Laos was completed in April. The plant was to supply power to the industries in the Samtay District. Total installed generating capacity in Laos was about 55 megawatts at year-end 1976.

The mineral industry continued to be a minor factor in the Lao economy. The only important mineral production was again that of tin concentrate. The mines were located at Phon Tiou, about 80 kilometers north of Thakhek. They were reportedly managed by the French firm Société d'Études et d'Exploitations Minières de l'Indochine, but no production figures were available for 1976. Presumably production remained similar to that of previous years at over 500 tons of tin-in-concentrate.

A consortium of Japanese and U.S. companies that was interested in developing iron ore deposits in the Plain of Jars in Xieng Khouang Province has apparently lost interest in the venture, and there were no further developments during 1976.

Developing the rich potash deposits that were explored during 1974–75 has also been put off, pending better economic conditions. The deposit is one of the best in Southeast Asia but would have required a large capital investment for mine, processing plant, and infrastructure before production could begin.

A salt mine was opened in January in Kong hamlet, Thoulakhom District, Vientiane Province. Production in the first quarter of 1976 was reportedly 1,000 tons. Refined salt was consumed for domestic needs locally and in nearby provinces.

Laos produced no crude oil or natural gas during 1976. Its fuel needs were met by modest imports of petroleum products from Thailand.

MONGOLIA [15]

In 1976, the Mongolian People's Republic entered the first year of its sixth 5-year plan which envisioned converting the country from an agrarian society to an industrial-agrarian economy. To implement the process of industrialization, the major goal of the sixth plan was to begin a program of extensive electrification of the country. Plans were made to supply electrical energy to new industrial sites and areas and to the main economic regions. The power system of Mongolia was to be linked to power grids within the U.S.S.R., thereby affording several important advantages: The reliability of electrical energy would be enhanced; funds, fuels, and materials would be available for expenditure on other projects; and the use of more powerful equipment would be made possible.

The overall volume of capital investment in the national economy under the sixth plan would nearly double that of the prior plan. As a result, the national fixed production capital would increase about 80%, with that for agriculture increasing about 50% and that for industry more than 200%. During the sixth plan, the country's labor resources would be increased by about 100,000 persons, and the labor force involved in material production would increase about 14%. Two-thirds of the gain in national income was to be obtained through a 24% increase in labor productivity. The gross industrial output and the gross agricultural output were to increase 62.9% and 30%, respectively, over those of the previous 5-year period.

In 1976, total Governmental expenditure was estimated at $847 million, distributed between the State budget ($532 million) and local budgets ($315 million). The allocation of expenditures by sector was as follows, in million dollars: Social and cultural services, 365; national economy, 335; defense, 103; administration, 40; and unspecified, 4. Total Government spending in 1977 was projected at $940 million. Planned expenditures for 1977 include $168 million for trade, supplies, and services, $90 million for agriculture, $46 mil-

[15] Prepared by E. Chin.

lion for transport and communications, and $41 million for industry. The nation's gross industrial production in 1977 was projected to increase 6% over that of 1976. The growth rate of industrial production was expected to speed up in the last 2 years of the sixth plan when the Erdenet copper and molybdenum mine complex goes into operation.

Coal mining is Mongolia's foremost mineral industry. During 1976, production of lignite and brown coal was estimated at 2.6 million tons and anthracite and bituminous coal at 200,000 tons. About 74% of the country's coal output came from open pit mines, with the bulk of the production from coal mining areas in Nalayha, Sharyn Gol, and Chuluun. The Government envisaged the development of the Tavantolozy coal deposit in South Gobi Province which may have up to 1 billion tons of reserves. The coal is apparently suitable for use in ferrous and nonferrous metallurgy. A large open cast mine complex capable of producing 10 million tons of high-quality coking coal per year reportedly could be established at the deposit. In addition, plans were underway to develop a coal deposit at Baga Nuur into a 2-million-ton-per-year mine by 1980.

About 300,000 tons of fluorspar was produced from a mine at Berhin in 1976. Output from this mine constituted about 7% of total world production of fluorspar. A large expansion program was slated for the Berhin mine under the provisions of the sixth plan.

Output of tungsten from the Burentsogt mine and from a scheelite deposit on Hayrhan Mountain ranges between 100 and 200 tons of concentrates annually. Estimated output of other mineral products was as follows, in tons: Gypsum, 25,000; lime, 40,000; and salt, 11,000. During the year, the cement plant at Darhan produced about 160,000 tons of cement.

Most of Mongolia's trade is with the U.S.S.R. Mineral imports include coal, coke, petroleum, and semimanufactured steel products for structural applications. Tungsten concentrates and metallurgical-grade fluorspar were the major minerals exported. Output of gypsum, lime, and salt was presumably all domestically consumed. A small oil refinery at Dzüün Bayan produced kerosine and residual fuel oil.

Mongolia is a member of the Council for Mutual Economic Assistance (CMEA). Other members are Bulgaria, Cuba, Czechoslovakia, East Germany, Hungary, Poland, Romania, and the U.S.S.R. Cooperation among the members includes joint geological research, providing special credits including funds from the CMEA International Investment Bank, and promoting the efficient use of resources. The CMEA was planning a joint development project for coking coal in Tavan-Tolgoi, Shazingol, Nalaikha, and other locations in Mongolia. Additionally, the CMEA was conducting studies on the construction of a smelter to utilize material from a copper mine and concentrating plant at Chagan Suburga, and another smelter based on a tungsten-molybdenum deposit at Ugodzir.

Development of the copper-molybdenum deposit at Mt. Erdenetun-obo is the major industrial project in north-central Mongolia near the Selenga River.[16] The copper-bearing ore zone was described as massive, measuring 25 kilometers long by 2.7 kilometers wide. Preliminary drilling indicated that the ore-bearing zone extends to a depth of 500 meters. Four other copper-bearing zones were reportedly found in the area. Total copper ore resources in the area were estimated at 1 billion tons containing approximately 9 million tons of copper. Because of this extensive mineral resource, the Government of Mongolia decided to build a modern city rather than a mining settlement. In addition to the mine and ore-dressing facilities, plans for Erdenet city included a carpet-making plant and a woodworking plant. By 1979, four apartment blocks would be completed to house some 15,000 people. Six additional apartment blocks were planned for construction to accommodate an additional 15,000 people by the 1980's. Five secondary schools, a boarding school, and a mining college were scheduled for construction, as well as a library, automobile service shop, sports center, and other public amenities.

The main highway to the principal western cities of Mongolia runs through Erdenet. The city is also serviced by a recently built railroad and high-voltage power transmission lines. Water from the

[16] Mongolia (Ulan Bator). City at a Copper Mountain. No. 6, 1976, pp. 16–21.

Selenga River was diverted by a pipeline to Erdenet. When completed in 1980, it was estimated that the annual industrial output value at Erdenet would be 40% more than the country's total industrial output in 1975, through the production of possibly 15 million tons of copper-molybdenum ore.

NEPAL [17]

Agriculture accounted for about two-thirds of Nepal's estimated $1.8 billion [18] GDP in fiscal 1976,[19] employing over 90% of the 13 million people. The mining, manufacturing, construction, and transportation sectors of the economy together accounted for about 8% of the GDP. Mining alone accounted for less than 0.1%. Actually, Nepal has no mineral, fuel, power, or other industries of consequence by world standards.

Economic growth continued to be slow during the year, with the modest gains nearly cancelled by the 2.5% annual population growth. The Government of Nepal, with considerable foreign assistance, continued to expand its development activities. The main thrust has been toward improving the infrastructure. The first motor vehicle road in Nepal, from the Indian border to Katmandu, was opened just 25 years ago. Road construction has been a major goal of the Government since then, with the total mileage of motor vehicle roads nearly double that of 1969. Several highway projects were underway which will furnish the first east-west highway links across the country when completed. One of the most ambitious projects was the 407-kilometer Pokhara-Surkhet highway through the rugged Himalayan foothills. The road was being built with over $75 million in Chinese economic assistance. Opening of hitherto inaccessible areas to motor vehicles will facilitate mineral exploration.

Development of the vast hydroelectric potential of the country also ranked high on the Government's list of priorities. The total installed hydroelectric capacity was about 34,000 kilowatts at the beginning of 1976. Currently under construction about 30 kilometers southwest of Katmandu was the Kulekhani hydroelectric system. First-stage capacity was planned at 32,000 kilowatts with an additional 26,000 kilowatts to be installed after first-stage completion. This will be the largest powerplant in the country at its scheduled completion in 1980. Other major projects were also underway or in the design stage. With no fossil fuels currently being produced in the country, the hydroelectric expansion and accompanying irrigation facilities will be an important factor in future industrial and economic development.

The United Nations Development Program (UNDP) was assisting in a systematic exploration program that will cover three 8-month field seasons. The $2 million cost will be shared by the UNDP and the Nepalese Government. The basic program was to introduce sophisticated exploration techniques and establish continuing geological programs in the country. A 15,000-square-kilometer area in central Nepal was selected to inaugurate the program, which was organized in 1975. Writing of a modern mining code was also part of the program, and a draft of the new legislation was completed in 1976.

A new Department of Mines and Geology was formed in July 1976 from the former independent Mines Office and the Department of Irrigation and Geology.

Nepal's cement production nearly tripled as the Himal cement plant completed its first full year of operation in fiscal 1976. The plant operated at about 60% of its 50,000-ton-per-year design capacity, turning out over 29,500 tons valued at $1.8 million. The value of the cement was several times the combined value of all other mineral production in Nepal in 1976. The Himal plant did not have sufficient capacity to supply the country's present 160,000- to 170,000-ton annual demand for portland cement. The planned 260,000-ton-per-year Hetauda cement plant project received a $39.5 million loan from the Asian Development Bank to cover the foreign exchange component of the $59 million total cost. The Bank approved the loan in November 1976. The additional capacity should make Nepal independent of expen-

[17] Prepared by Gordon L. Kinney.
[18] Where necessary, values have been converted from Nepalese rupees (NRs) to U.S. dollars at the rate of NRs12.5=US$1.00.
[19] The Nepalese fiscal year is the year ending July 16 of that stated.

sive imported cement when the new plant opens in 1981.

It was reported that the Nepal Mining Co. had begun development of the Ganesh Himal zinc mine at Lari, 56 kilometers northwest of Katmandu. A road was under construction to the property. Shaft sinking was expected to be completed in 1979. A 25,000-ton-per-year concentrator was planned to be completed in 1981. The company was reportedly 50% Nepalese owned and 50% jointly held by an Indian and a U.S. firm.

The Department of Mines and Geology, in conjunction with an Indian company, was conducting a feasibility study on a 50,000-ton-per-year electrothermal steel plant. The plant would be based on the Phulchoki iron ore deposit 26 kilometers southeast of Katmandu. The 3.6 million tons of ore reserves are probably adequate for the project and limestone is also available nearby. However, the proposed use of wood charcoal as the reductant would deplete the local Nepalese forest resources and would be highly labor intensive and expensive.

Nepal produced no mineral fuels in 1976 and was totally dependent on imports for its petroleum needs. Imports rose slightly in 1976 to a total of 79,100 tons. The petroleum products imported were jet fuel and kerosine (34,600 tons) and fuel and diesel oils (36,500 tons). The U.S.S.R. supplied nearly the entire amount through an exchange arrangement with India.

SINGAPORE [20]

Singapore achieved a 9% economic growth rate in 1976, with the gross national product (GNP) reaching an estimated $5,886 million [21] in current prices. The real growth rate was closer to 7%, which was the general level that Government planners expected for 1977. Once one of Asia's star performers, the Singapore economy was entering a phase of consolidation and slower growth than in the late 1960's and early 1970's, although the growth was still well above the average for developing countries. The slowdown began with the international oil crisis, which is understandable in view of the special importance of petroleum activities to the economy. The prolonged slump in several leading industries, such as petroleum refining, oil rig construction, shipping, and shipbuilding, which was partly caused by the sluggish economies of Japan, Western Europe, and the United States, appeared to be ending in late 1976.

Until a few years ago, Singapore, with a population of only 2.3 million, could have been described as a nation of import-export merchants. Entrepôt trade was still the dominant part of the economy in 1976, with services (including the hotel and restaurant trade) accounting for about 70% of the GNP, and total foreign trade amounting to 270% of the GNP. However, petroleum-related activities, advanced technology in manufacturing industries, and financial and communications activities have steadily gained ground. The value of manufacturing rose 11.5% to $1.37 billion and that of construction rose 13% to $489 million in 1976. Foreign investments have played a significant role. Combined foreign and domestic plant and equipment investment for Singapore was $1.13 billion in 1975 and $1.08 billion in 1976.

The petroleum industry, posting a sharp increase in output, was by far Singapore's most important manufacturing component in 1976. Oil refineries were upgrading their processing facilities, and the projected Sumitomo Chemical Co., Ltd., petrochemical complex, if launched, would provide some stimulus to the industry.

The electronics industry boomed. Foreign demand for electrical and electronic goods sparked a large increase in investment, and three-fourths of all new manufacturing jobs were in the electronics industry.

Shipbuilding and repair activity declined nearly 10%, brought about mainly by the reduced level of regional oil exploration. The ship repair sector, however, recovered in the second half of 1976 as many shipyards turned to heavy engineering work, such as construction of offshore structures for oil activities and engineering fabrication for powerplants, chemical plants, and

[20] Prepared by K. P. Wang, supervisory physical scientist.

[21] Where necessary, values have been converted from Singapore dollars (S$) to U.S. dollars at the rates of S$2.45=US$1.00 in 1976 and S$2.39=US$1.00 in 1975.

harbor facilities. Singapore has been the world's fourth largest port for several years.

Alongside the progress in industry, trade, and tourism, Singapore made headway toward becoming a major international financial center through development of its Asian dollar market, gold market, and secondary money market. Plans were underway to create a gold exchange, similar to the Winnepeg Exchange, involving both spot and future contracts based upon certificates of gold deposits issued by authorized banks. This gold exchange, initiated by the Singapore Chamber of Commerce Rubber Association, was expected to be operational by yearend 1977. With regard to trade, Singapore's foreign reserve position improved from $3.13 billion at yearend 1975 to $3.37 billion at yearend 1976.

PRODUCTION

In 1976, Singapore produced about $2,517 million worth of petroleum products by processing $2,243 million worth of crude oil with about 3,350 workers, thereby earning $274 million in value added.[23] In 1975, output was $1,989 million, input was $1,736 million, and value added was $253 million. Residual fuel oil ranked first in tonnage, followed by distillate fuel oil, jet fuel, gasoline, kerosine, and lubricants, in that order. The refining industry had not recovered from the loss of the Vietnamese market and the reluctance of Japan to buy its refined oil. However, refining capacity utilization increased to 55% in 1976. Singapore had been producing over 2.3 million cubic yards of granite annually in recent years; in 1976, output increased to 3.3 million cubic yards.

Singapore's mineral economy shows a pattern of processing foreign raw materials (and/or intermediate materials) and domestic scrap into finished products. More than 1 million tons of cement was produced for the sixth consecutive year to sustain high levels of construction, but the principal raw material was actually imported clinker. The 230,000 tons of ingot steel produced in 1976 was from scrap; Singapore also imported much larger tonnages of steel products and semimanufactures, some of which was converted to additional downstream products. The country's statistics show that value added for cement in 1976 was $23 million; concrete products, $9 million; other nonmetallic minerals, $13 million; iron and steel, $22 million; and nonferrous metals, $5 million. The country's mineral production statistics are shown in table 1.

TRADE

Singapore's total foreign trade came to $15.78 billion in 1976, compared with $13.40 billion (revised) in 1975 when the Singapore dollar was worth slightly more. Exports (f.o.b.) rose 25% to $6.64 billion, and imports (c.i.f.) rose 14% to $9.14 billion in 1976. The trade deficit was more than offset by income from services such as tourism, banking, insurance, and shipping, and by capital inflow from abroad. In fact, a net balance-of-payments surplus of $293 million was registered in 1976. These figures do not include trade with Indonesia.

Singapore's most important trading partner in 1976 was the United States, with exports of $0.98 billion and imports of $1.21 billion, 14.8% and 13.2%, respectively, of the totals. Japan was second, with exports of $0.68 billion and imports of $1.47 billion, followed by West Malaysia with imports of $1.05 billion. Other important trading areas included Hong Kong, the United Kingdom, Australia, West Germany, East Malaysia (Sabah and Sarawak), Thailand, the People's Republic of China, France, the Netherlands, and Italy.

In terms of commodity groups, Singapore's most important exports in 1976 were machinery and equipment (25.3%), mineral fuels (23.3%), crude inedible materials (16.4%), manufactured materials (8.2%), food and live animals (5.8%), and chemicals (3.7%). The most important imports were mineral fuels (27.4%), machinery and equipment (25.9%), manufactured materials (14.6%), crude inedible materials (9.0%), food and live animals (8.3%), and chemicals (5.0%).

The entrepôt nature of Singapore's economy is self-evident in these trade figures, and petroleum occupies a special position. In 1976, Singapore imported 21.3 million tons of crude oil and 6.2 million tons of refined oil, and exported 13.0 million tons of refined oil. Most of Singapore's crude oil imports came from Kuwait, Saudi

[23] Monthly Digest of Statistics (Singapore). V. 16, No. 6, June 1977, p. 17.

Arabia, and Iran. Its sales of refined oil went primarily to other Asian countries or for bunkering, in addition to the domestic market. Singapore's 1976 oil import bill was about $2.57 billion, but its refined oil exports were worth $1.58 billion, and monies earned from bunkering were sizable also.

Table 4.—Singapore: Exports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1974	1975	Principal destinations, 1975
METALS			
Aluminum:			
Bauxite and concentrate	1,030	450	Taiwan 400; Thailand 50.
Oxide and hydroxide	962	4,319	Mainly to Malaysia.
Metal including alloys:			
Scrap	(1)	2,512	Mainly to Pakistan.
Unwrought and semimanufactures	3,190	732	Mainly to Malaysia.
Chromium oxide and hydroxide	28	16	Do.
Cobalt oxide and hydroxide	(2)	1	All to Malaysia.
Copper:			
Sulfate	220	183	Mainly to Malaysia.
Metal including alloys:			
Scrap	(1)	4,471	Pakistan 2,319; Japan 615.
Unwrought and semimanufactures	1,408	1,804	Mainly to Malaysia.
Iron and steel:			
Roasted pyrite	1	--	
Metal:			
Scrap	1,945	1,539	Taiwan 781; Netherlands 706.
Pig iron, ferroalloys, similar materials	7,685	7,702	Mainly to Malaysia.
Steel, primary forms	15,676	8,448	Do.
Semimanufactures:			
Bars, rods, angles, shapes, sections	65,099	55,848	Malaysia 42,133; Brunei 10,278.
Universals, plates, sheets	82,904	41,631	Mainly to Malaysia.
Hoop and strip	1,949	1,161	Do.
Rails and accessories	6,126	2,081	Do.
Wire	3,378	2,785	Malaysia 2,066; Brunei 516.
Tubes, pipes, fittings	44,599	74,484	Brunei 39,918; Malaysia 6,709.
Castings	680	762	Malaysia 481; United States 124.
Total	204,735	178,752	
Lead:			
Ore and concentrate	2	21	India 13; Pakistan 7.
Oxides	19	51	Mainly to Malaysia.
Metal including alloys:			
Scrap	(1)	627	Malaysia 275; Taiwan 175; Thailand 100.
Unwrought and semimanufactures	1,073	646	Mainly to Malaysia.
Manganese:			
Ore and concentrate	2,404	2,808	Malaysia 920; Kenya 773; Sri Lanka 389.
Oxides	44	61	Mainly to Malaysia.
Mercury, 76-pound flasks	17	13	Malaysia 11; Brunei 2.
Nickel metal:			
Scrap	(1)	255	Belgium-Luxembourg 100; Switzerland 48; Netherlands 36.
Unwrought and semimanufactures	44	35	Malaysia 28; Thailand 6.
Platinum-group metals and silver:			
Waste and sweepings, kilograms	25,690	721	United Kingdom 450; Australia 144.
Metals including alloys:			
Platinum-group, thousand troy ounces	108	84	Mainly to United Kingdom.
Silver, do.	308	75	Do.
Thorium ore and concentrate, kilograms	NA	1,414	All to Burma.
Tin:			
Ore and concentrate	1,629	2,343	Spain 821; U.S.S.R. 800; Mexico 558.
Metal including alloys:			
Scrap	(1)	71	Denmark 39; United Kingdom 32.
Unwrought and semimanufactures	661	596	Malaysia 177; Taiwan 134.
Titanium:			
Ore and concentrate	--	7	All to Bangladesh.
Oxides	537	416	Mainly to Malaysia.
Tungsten:			
Ore and concentrate	80	13	North Korea 10; United Kingdom 3.
Metal including alloys, all forms	NA	246	Mainly to Malaysia.

See footnotes at end of table.

Table 4.—Singapore: Exports of mineral commodities—Continued

(Metric tons unless otherwise specified)

Commodity	1974	1975	Principal destinations, 1975
METALS—Continued			
Zinc:			
Ore and concentrate	100	20	All to Malaysia.
Oxides and peroxides (except hydroxides)	17	110	Malaysia 46; Kenya 28; Hong Kong 21.
Metal including alloys:			
Scrap and blue powder	(1)	287	Taiwan 125; Japan 116.
Unwrought and semimanufactures	3,702	2,202	Malaysia 1,181; Thailand 890.
Other:			
Ores and concentrates of base metals, n.e.s. (excluding iron and magnesium)	104	3	All to Malaysia.
Ash and residue containing nonferrous metals	7,014	4,717	Malaysia 2,208; Hong Kong 1,309; United Arab Emirates 501.
Oxides, hydroxides, peroxides of metals, n.e.s	51	33	Mainly to Malaysia.
Metals including alloys, all forms:			
Scrap, nonferrous	7,443	(3)	
Metalloids	18	35	All to Malaysia.
Alkali, alkaline earth, rare-earth metals	11	15	Do.
Base metals including alloys, all forms, n.e.s	88	1,251	Iran 600; Netherlands 460.
NONMETALS			
Abrasives, natural, n.e.s.:			
Pumice, emery, natural corundum, etc	94	63	Pakistan 29; Malaysia 26.
Grinding and polishing wheels and stones	285	155	Malaysia 113; Philippines 14.
Asbestos	3,150	1,670	Malaysia 1,012; Vietnam 290.
Clays and clay products (including all refractory brick):			
Crude:			
Kaolin	244	144	Taiwan 100; Malaysia 43.
Other	5,715	11,837	Philippines 2,975; Brunei 2,138.
Products:			
Refractory (including nonclay bricks)	749	1,372	Mainly to Malaysia.
Nonrefractory[4]	6,075	4,529	Malaysia 3,030; Brunei 1,272.
Diamond:			
Gem, not set or strung—value, thousands	r $2,259	$8,186	Mainly to Hong Kong.
Industrial ——do——	$455	--	
Feldspar and fluorspar	4,366	1,529	Mainly to Malaysia.
Fertilizer materials:			
Crude:			
Nitrogenous	r 7	2	All to Malaysia.
Phosphatic	17,959	33,467	Malaysia 24,023; Burma 8,125.
Manufactured:			
Nitrogenous	28,808	21,845	Mainly to Malaysia.
Phosphatic	11,166	6,324	Burma 3,800; Malaysia 2,498.
Potassic	182,968	134,740	Mainly to Malaysia.
Other, including mixed	113,636	17,623	Malaysia 13,468; Pakistan 3,826.
Ammonia	469	336	Mainly to Malaysia.
Graphite, natural	55	130	Taiwan 50; Malaysia 39.
Gypsum and plasters	815	357	Malaysia 248; Thailand 61.
Lime	3,813	2,375	Malaysia 1,532; Brunei 700.
Magnesite	81	58	All to Malaysia.
Mica, all forms	105	314	Philippines 100; Burma 77.
Pigments, mineral:			
Natural, crude	774	69	Mainly to Malaysia.
Iron oxides, processed	364	102	Do.
Precious and semiprecious stones, including synthetic, except diamond value, thousands	$1,177	$1,124	Hong Kong $853; Japan $142.
Salt	12,153	12,408	Malaysia 6,496; Brunei 4,851.
Sodium and potassium compounds, n.e.s	r 14,839	7,938	Mainly to Malaysia.
Stone, sand and gravel:			
Dimension stone	571	1,961	Malaysia 1,061; Brunei 891.
Dolomite, chiefly refractory grade	16	--	
Gravel and crushed rock	9,435	18,241	Brunei 16,700; Malaysia 1,478.
Limestone	416	212	Mainly to Malaysia.
Quartz and quartzite	(2)	2	All to Malaysia.
Sand, excluding metal bearing	3,413	1,179	Malaysia 758; Brunei 270.

See footnotes at end of table.

Unspecified ---do---	1,755	2,874	Malaysia 1,915; Iran 378.
Total ---do---	30,746	36,038	
Mineral tar and other coal-, petroleum-, or gas-derived crude chemicals	327,615	5,955	Taiwan 2,530; Japan 1,370; Australia 1,211.

r Revised. NA Not available.
1 Scrap, if any, is included under "Other scrap, nonferrous."
2 Less than ½ unit.
3 Totals exclude quantity valued at $287,126.
4 Listed under individual metals.
5 Totals exclude bricks of baked clay valued at $943,914 in 1974 and $957,268 in 1975.
6 In addition to the products listed, liquefied petroleum gas valued at $255,194 in 1974 and $235,957 in 1975 was imported.

COMMODITY REVIEW

Metals.—*Iron and Steel.*—Singapore's steel imports were about 1 million tons in 1976, 1.2 million tons in 1975, and 1.4 million tons in 1974, with Japan by far the leading supplier. About two-thirds of the steel imports from Japan consisted of shapes, plates, pipe, and tubing. The steel ingot produced locally, which amounts to about 200,000 tons annually, is derived from scrap. The ingot along with imported materials is then made mainly into rolled semimanufactures.

Reportedly, there were 14 small iron and steel establishments in 1976, employing about 1,400 workers. Only two steel producers were of consequence, National Iron and Steel Mills Ltd. (NISM) and Malayan Iron & Steel Mills Ltd. NISM's plant at Jurong has electric furnaces, merchant bar mills, and a wire rod mill which together turn out more than 200,000 tons of steel products annually. Malayan Mills' facilities are considerably smaller than those of NISM. NISM and Japan's Mitsui & Co., Ltd., have a joint venture called Eastern Wire Manufacturing Co.

Nonmetals.—*Cement.*—Singapore had six cement and cement additive establishments in 1976, employing about 620 workers and realizing $22.8 million in value added from an output of $69.6 million and an input of $46.8 million.[23] Virtually all are grinding operations, relying on imports of clinker. In 1976, Singapore's imports of such clinker were 1,579,758 tons; 1,133,931 tons came from Japan and 354,000 tons from the Republic of Korea and Taiwan combined. In 1975, 1,318,575 tons was imported; 682,866 tons came from Japan and 344,492 tons from the Republic of Korea. Output of finished cement corresponded closely to the amount of clinker imported. Singapore's imports of finished cement were only about 70,000 tons in 1975 and 20,000 tons in 1976. The value of construction averaged about $430 million annually during 1974–76, which represented about 6% of the GNP. One of the large construction jobs in progress was the new Changi airport.

Three older cement plants can be identified—Asia Cement (Singapore) Pte.

[23] Page 19 of work cited in footnote 22.

Ltd.'s 420,000-ton-per-year plant at Jurong, Singapore Cement Manufacturing Co. (Pte.) Ltd.'s 320,000-ton-per-year plant (location unknown), and Pan Malaysia Cement Works Ltd.'s 260,000-ton-per-year plant at Jurong. Ssangyong Cement Industrial Co. Ltd. of the Republic of Korea purchased a $32 million, 600,000-ton-per-year clinker grinding system from Fuller Company for its joint-venture plant in Singapore.[24] This pollution-free plant with a 4,000-horsepower finish grinding mill and in-plant dust collectors started operations during late 1976. Ssangyong's partners included the Development Bank of Singapore and Afro-Asian Shipping Co. Pte., Ltd., both headquartered in Singapore.

Mineral Fuels.—*Petroleum.*—Singapore's program to sharply expand oil refining capacity to a level of about 1 million barrels per day of throughput was completed in 1976. Only Rotterdam, Netherlands, and Houston, Tex., have larger petroleum refining complexes than Singapore. Shell Eastern Petroleum Ltd. completed expansion of its refinery on Pulau Bukom Island to 550,000 barrels per day, making this operation the world's second largest single refinery after another of Shell's refineries at Rotterdam. Esso Singapore Pte. Ltd. completed expansion of its refinery at Pulau Ayer Chawan to 230,000 barrels per day in 1976. Mobil Oil Singapore Pte. Ltd. had completed a 180,000-barrel-per-day refinery at the Jurong Industrial Estate and was planning a $23 million project to boost gasoline production. Singapore Petroleum Co. Pte. Ltd. and BP Refinery Singapore Pte., Ltd., operated two smaller refineries. The sharp increase in oil prices and the subsequent worldwide recession had cut down severely on the demand for Singapore's fuel oil. At year-end, the country's refineries were embarking upon a program to redesign facilities to enable them to handle lighter crude oil and produce more distillates such as automotive diesel oil and kerosine. Singapore's refineries had been designed for the high-sulfur crudes of the Middle East, and some redesigning was contemplated in this area also.

Many international oil companies working in Southeast Asia have established headquarters in this small country. Singapore has become an oil logistics center in the Pacific, with various kinds of seafaring oil exploration and development barges and equipment being built, assembled, and serviced here. Thus, slackening of oil exploration in Indonesia during 1976 affected Singapore's economy adversely. Shipping activity was so heavy that the Singapore Parliament had cause to deliberate a Civil Liability (Oil Pollution) Act recently. A floating oil storage terminal had been built by a consortium of U.S. firms not long ago. Another dimension to Singapore's oil enterprise was the expected construction by Sumitomo of the long-delayed $850 million petrochemical (mainly ethylene) complex on Pulau Ayer Merbau.[25]

SRI LANKA [26]

The agriculturally based Sri Lankan economy was adversely affected by severe drought in the 1975 and 1976 growing seasons. The 3.6% real growth in the GNP in 1975 slipped to about 3.0% for 1976 when the GNP reached $2.86 billion.[27] The return of normal rainfall toward yearend 1976 led to prospects of greatly expanded agricultural output in 1977. A real increase of about 4% in the GNP was predicted for 1977.

The balance-of-trade deficit improved from nearly $202 million in 1975 to $84 million in 1976. In local currency, exports were about the same in 1975 and 1976, whereas imports declined about 15%. In 1976, exports amounted to $588 million and imports to $642 million.

The Government's budgetary position deteriorated during 1976, with increased expenditures causing a record high deficit of $424 million. This deficit amounted to 38% of total expenditures and nearly 15% of the GNP. It is difficult to gage true inflation rates for Sri Lanka because of the

[24] Rock Products (Chicago). April 1977, p. 94.

[26] Prepared by Gordon L. Kinney.
[27] Where necessary, values have been converted from Sri Lankan rupees (Cey Rs) to U.S. dollars at the rate of Cey Rs7.05=US$1.00 in 1975 and Cey Rs8.43=U.S.$1.00 in 1976.

Government's weekly free rice distribution and widespread subsidized services. The actual inflation rate in 1976 has been variously estimated at between 10% and 30%. The 20% unemployment rate continued to be a major problem despite Governmental programs to create jobs. A Central Bank survey in 1975 indicated that almost 1 million people were unemployed, and the 1976 figure was apparently higher.[28]

One of the major growth areas in the economy was the mineral sector, which contributed about one-third of the real increase in the GNP during 1976. Mineral output value was about $62 million for the year, or a little over 2% of the GNP.

Sri Lanka has been known for its precious and semiprecious gems since ancient times. The value of gems produced rose sharply in 1976, registering $39 million. Measured in current rupees, the increase was about 50% over that of 1975. Gems accounted for 65% of Sri Lanka's reported 1976 mineral production value. Virtually all of the country's gems are exported. In the past, most of the gems were smuggled out of the country with no benefit to the Government. Of late, the Government offered various tax and financial inducements to private dealers to use the State Gem Corp. for exporting gems legally, and these actions have significantly lessened smuggling activities.

Cement was a strong second in output value for 1976, accounting for $18 million or 30% of the total. Over 425,000 tons of finished cement was produced in 1976 from the Kankesanturai and Puttalam cement plants and the Galle clinker grinding plant.

Graphite has long been one of Sri Lanka's major mineral products and the second ranking mineral export. Production from the two active mines—Bogala in Kegalla District and Kahatagaha-Kolongalla[29] in Kurunegala District—totaled 8,290 tons in 1976, a more than 30% decrease from that of 1975. Exports increased to over 8,000 tons valued at $2 million. Japan, the United States, and the United Kingdom received the major share of the exports. The Bogala mine accounted for about 60% of the total production and has been credited with having proved reserves of 52,000 tons. At the current rate of production, Bogala's reserves and resources would last for about 10 years.

Two new mines were under development—Rangala in Kegalla District and Ragedara in Kurunegala District. Commercial production was expected to begin at Rangala in 1979; Ragedara will require several additional years to start production. Each mine is designed to produce 1,200 tons per year of graphite when in full operation.

Combined production of all of the lesser minerals was worth only $5 million in 1976. China clay, feldspar, mica, quartz, and salt showed significant gains. Ball clay, limestone, ilmenite, monazite, rutile, and zircon outputs all declined from those of 1975.

Reduced output of ilmenite, rutile, and zircon was a temporary condition. Ceylon Mineral Sands Corp. was constructing an integrated concentrating complex at Pulmoddai with a capacity to process 200,000 tons per year of raw sand. The Pulmoddai deposit reportedly contained 4 million tons of beach sand assaying 70% to 72% ilmenite, 8% to 10% zircon, 8% rutile, 0.3% monazite, and 1% sillimanite. There was no titanium-based industry in Sri Lanka to utilize the ilmenite or rutile, but the Government was undertaking a feasibility study on its establishment.

Geophysical prospecting and core drilling continued during the year at an iron ore deposit located at Seruvilla in Trincomalee District. In addition to the iron, sulfide mineralization analyzing 1% to 3% copper was confirmed. Thus, drilling was continuing to ascertain the tonnages of both the magnetite and sulfide ores. The presence of sulfide mineralization could complicate development of the deposit for iron ore, even if the ore bodies explored should prove to be of commercial size and grade.

Construction of an apatite crushing plant at Eppawala began during the year, where reserves have been reported at 25 million tons of phosphate rock averaging 33% P_2O_5. Geological investigation of a serpentine deposit continued in the Udawalawa area in the southeastern part of the island. The Government was interested

[28] U.S. Embassy, Colombo, Sri Lanka. State Department Airgram A-65, Sept. 13, 1977, pp. 1-10.

[29] The Kahatagaha and Kolongalla mines were linked up underground and operated as a single unit following nationalization of the graphite industry in 1971.

in the serpentine because of the possibility of using it in conjunction with the Eppawala phosphate rock for production of fused magnesium phosphate fertilizer. Since 1973, small amounts of apatite have been ground locally for direct application to crops like tea, rubber, and coconut.

Marathon Petroleum Sri Lanka, Ltd., spudded the first offshore oil exploration well in Sri Lanka's waters in June 1976. The 2,400-meter well, which turned out to be dry, was in a State-held block in Palk Bay north of Mannar Island. Marathon drilled a second well in September at a new site about 40 kilometers north of the first well and on a separate geologic structure. It also turned out to be a dry hole and as a result, Marathon reportedly decided to withdraw from its production-sharing contract covering a 7,000-square-kilometer concession area. No other firms drilled offshore Sri Lanka during 1976.

The country continued to depend totally on foreign crude oil for its needs. Imports in 1976 were nearly 1.5 million tons valued at $129 million. Saudi Arabia and Iran supplied the crude oil for refining at the Sapugaskanda refinery. Construction began on the country's first urea fertilizer plant in 1976. The 300,000-ton-per-year plant, to be located at Sapugaskanda, is designed to use naphtha feedstock from the adjacent refinery. Also in conjunction with the refinery, the country expects to build its first nylon plant. A contract was signed in late December with Japanese firms for the construction of the more than $30 million plant.

VIETNAM [30]

On April 25, 1976, general elections were held in the north and the south to choose a common national assembly. On July 2, 1976, the newly elected assembly, meeting in Hanoi, declared the formal reunification of the country, officially designated as the Socialist Republic of Vietnam, with Hanoi as the capital city. Old administrative divisions were revised and the number of provinces was revised to 35. There were 249 deputies elected from the northern provinces and 243 deputies elected to represent the southern provinces.

The value of exports from Vietnam reportedly totaled $227 million in 1976, up about 6% from that of the previous year, while the value of imports at about $831 million was down about 29% from the 1975 level.[31] The trade deficit in 1976 was about $604 million. Although conditions in 1976 cannot be compared with those in previous years owing to the different economic systems, it was apparent that Hanoi succeeded in reducing the 1975 trade deficit probably by more than one-third.[32]

The second 5-year plan (1976–80) was finally approved at the end of 1976, making it effectively a 4-year plan. The plan seeks to increase the GNP 18% in 1977. Other targets include a 20% growth in the industrial sector and a 16% increase in the dominant agricultural sector by 1977. Emphasis swung away from the heavy industry sector to the agriculture industry, light industry, and sectors that would support agriculture, especially electrical power and the road network.

Although agricultural output reportedly increased about 20% in 1976, it was still not sufficient to meet the country's needs. A United Nations report estimated a food deficit of 1.2 million tons of rice and 150,000 tons of wheat during 1976. Hanoi was forced to buy food from Burma and the U.S.S.R. and also foodstuffs valued at $35 million from the United Nations World Food Program. Poor growing conditions, drought, and floods combined to reduce expected gains in 1976. Agricultural improvement programs were pursued throughout the country during the year. Old canals were repaired and dredged and 16 large irrigation projects were started in the south. Fallow land was reclaimed and 500,000 hectares of Mekong delta land was reportedly put under double cropping.

Reconstruction and expansion of the electrical power network continued as rapidly as equipment became available. Much of the improvement in electrification was directly associated with the drive to increase agricultural output. About two-thirds of the electricity generated in the north was produced in plants fueled by north Vietnamese coal. The total capacity

[30] Prepared by Gordon L. Kinney.
[31] Trade with the People's Republic of China is not included in these figures.
[32] Asian Wall Street Journal. V. 2, No. 22, Sept. 30, 1977, p. 3.

of irrigation pumping stations powered by electricity was reported at 219 megawatts at yearend 1976. Additional power was consumed by electric pumps used to aid in dewatering more than 86,000 hectares of cropland. Over 5,000 kilometers of electrical power distribution lines were directly serving agricultural purposes. Electrical power for agricultural enterprises increased nearly 50% over the 1975 supply, whereas total national output of electricity rose only 20%.

Other electrical power developments included restoration of the Da Nhim hydroelectric plant near Da Lát and its high-voltage powerline network. The plant supplies electricity to the Ho Chi Minh City (Saigon) grid and to Nha Trang. Capacity of the Ninh Bình thermal powerplant in Ha Nam Province was reportedly increased to 100 megawatts. Initial construction began in 1971, but this plant was damaged during interim hostilities. The Uong Bi thermal powerplant and distribution lines were under priority reconstruction and expansion; its capacity at yearend 1976 was 98 megawatts.

Geological and engineering studies for the 1,664-megawatt Da River hydroelectric project near Hoa Binh were nearly completed and preparatory work prior to construction had begun. When completed, this would be the largest hydroelectric station in Southeast Asia. The U.S.S.R. was providing economic and technical assistance for the project which could be completed in a decade.

Vietnam's largest single reconstruction project of 1976, involving 70,000 workers, was completed in December when trains began running between Hanoi and Ho Chi Minh City. This marked the reopening of the entire 1,730-kilometer coastal railroad, which was virtually destroyed by years of military action. The Government publicized the event as a tangible example of the reunification of the north and south. In addition, 80 kilometers of track was rebuilt from Kep to Uong Bi in Quang Ninh Province to transport coal to the thermal powerplant at Uong Bi.

Vietnam has not been a major world producer of any mineral products, although output of anthracite, apatite, and cement is of some consequence. Data on production are difficult to obtain and seldom specific. The available figures are often stated in terms of percentage increase over an unstated or unknown base period. The more important minerals exploited in 1976 were coal, tin, chromite, iron, apatite, and zinc. Small amounts of gypsum, salt, antimony, gold, copper, limestone, clay, and glass sand were also produced. Cement and brick were both produced from local raw materials.

COMMODITY REVIEW

Metals.—*Antimony.*—Local antimony ore was refined at a new processing plant, completed in April 1976, in the north. The plant appeared to be the first of its kind in the country.

Chromite.—The only known production of chromite occurred at Co Dinh in Thanh Hoa Province. No details are available on the operation, although production reportedly exceeded the 1976 target. About 8,000 tons of ore was said to have been mined during the first 11 months of 1976.

Iron and Steel.—Iron ore apparently was mined at 11 locations in Vietnam during 1976. The Trai Cau mine was the principal iron mine supplying the nearby Nyuyen steelworks. Rated at 200,000 tons annually of finished steel plates and rods and producing roughly this tonnage in 1976, the Nyuyen iron and steel complex was scheduled to be expanded about 50% by 1980. Three furnaces of the Nyuyen complex were reportedly repaired with Chinese technical aid, and a 20,000-ton-per-year coke plant was apparently working satisfactorily. The Gia Sang and Luu Xa rolling mills were units of the Nyuyen complex. The Gia Sang mill was completed in 1975 with East German aid, and the new 120,000-ton-per-year Luu Xa mill located about 5 kilometers from Gia Sang was not yet fully built by yearend 1976. A 50-meter-high dam was under construction at Nui Coc to supply water to the steel complex and surrounding area.

The Government was planning a new 460,000-ton integrated steelmill which would include a small blast furnace, two 30-ton converters, a continuous casting mill, a bar mill, and an angle rolling mill. Japan, the People's Republic of China, the U.S.S.R., and France were interested in supplying components to the project. Since recent emphasis was on agricultural production rather than heavy industry, im-

plementation of these plans may well be delayed.

Vietnam did not produce enough steel to satisfy its needs, necessitating imports from various sources, primarily the U.S.S.R. and Japan, and secondarily the Netherlands, Sweden, and Eastern Europe. The People's Republic of China may also have furnished small tonnages of unfinished steels.

Other.—Tin was mined at Cao Bang and reportedly also at Vinh and Viet Tri. The Government was planning to increase tin output during the current 5-year plan. Estimated production of tin-in-concentrate was 300 tons in 1976. Approximately 80 tons of tin metal was exported to the U.S.S.R. in 1976.

Zinc ore, produced at the Cho Dien mine, was refined at a small smelter (with perhaps a 10,000-ton-per-year capacity) at Quang Yen.

Nonmetals.—*Brick.*—Vietnam uses domestic clay deposits to produce its own brick and tile for its growing construction needs. Efforts were being made to increase production throughout the country. Two new 20-million-brick-per-year kilns were completed during 1976. In addition, at least four new kilns of unknown capacity were completed, and twelve were scheduled for completion in 1977. Production was reported at 2,400 million brick in 1976, compared with 1,700 million brick in 1975, a 41% increase. Planned output for 1977 was 3,200 million brick. The overall value of building materials produced in 1976 reportedly rose 64% over that of 1975.

Cement.—Vietnam produced about 730,000 tons of cement during 1976 and planned a 13% increase in the 1977 output. There were two plants with 300,000-ton-per-year rotary kilns operating in 1976. One was at Haiphong and the other was at Hà Tiên in the extreme southwestern corner of the country. Additionally, several small plants supply local needs.

The second 5-year plan, ending in 1980, envisaged increasing Vietnamese cement output to 2 million tons. The U.S.S.R. was to furnish aid in constructing plants at Binh Son and Thanh Hoa, and the People's Republic of China was scheduled to help build another at Phu Ly near Hanoi. However, the only project known to be underway was a 1-million-ton-per-year plant at Hoang Thach (21°02′ N, 106°35′ E), being built jointly by companies from Japan and Denmark for over $66 million. The contract was signed in late 1976, and the plant was due to be completed in 1978.

Fertilizer Materials.—Production of chemical fertilizers continued to have a high priority, to support the drive for higher agricultural yields. No clear breakdown of production by type was officially reported, although some fragmentary data were available. The Lam Thao superphosphate plant turned out 170,000 tons during 1976, despite problems with its supply of pyrite. The capacity of the plant was rated at 200,000 tons per year.

An apatite mine at Lao Cai has long been the principal producer of crude phosphate in Vietnam. Annual output of Lao Cai presumably has been over 1 million tons; much of this is exported to the People's Republic of China and elsewhere. Domestic markets include the Lam Thao plant, the newly reopened Hai Hung apatite grinding works, and a new phosphate works at Van Dien. A grinding section was being added to the Lao Cai mine in 1976, under a priority expansion program.

The status in 1976 of the Ha Bac nitrogenous fertilizer plant at Bac Giang was uncertain. The plant, built in 1965 with Chinese aid, was subsequently damaged during the hostilities. Reconstruction and expansion of the plant began in June 1973, and equipment testing and trial production reportedly began in August 1976.

Lime.—The second 5-year plan called for a large increase in lime production, especially for use in fertilizer manufacture. The tonnage of lime produced in 1976 may be between 1.4 million and 1.7 million tons. At least two new lime kilns were completed during 1976; the largest may have a capacity of 20,000 tons per year. A goal of 2 million tons was set for 1978 with 1.6 million tons going to the agricultural sector. Most of the lime was produced in the north, causing supply problems for the heavily agricultural southern provinces. Reopening of the railroad to Ho Chi Minh City, however, should facilitate moving the lime to the south.

Mineral Fuels.—*Coal.*—The Government was trying to increase coal production as rapidly as finances and available equipment would allow. During 1976, a goal of 10 million tons was set for 1980;

all phases of development, production, and distribution were simultaneously emphasized so as to achieve the 1980 target.

Gross coal production for 1976 was reported by the Government to be 1.6 times the 1965 level. The Vietnamese claimed that the 1975 target of 5.3 million tons of coal was surpassed, and that output in 1976 had risen about 10%. A target of 6 million tons was set for 1977. The Vietnamese reported in 1976 that overburden removal at open pit coal operations was to be increased 29% in 1977. This stripping rate would significantly increase the output from several existing mines within the next few years.

The heart of the Vietnamese coal industry was still the Hon Gai anthracite combine with open pit mines called Deo Nai, Ha Lam, Cao Son, and Ha Tu, as well as underground operations, to tap reserves of several billion tons. The Hon Gai Colliery Design Institute reportedly had completed blueprints for 18 projects, including 9 coal pits, 2 coal ports, various coal beneficiation and transportation facities, and small coal mines.[33] Apparently the Cao Son mine was being expanded with Soviet aid to more than 2 million tons annually. A Japanese company was helping to build a coal calcining plant for Hon Gai. A new 600,000-ton-per-year coal combine called Mao Khe in Quang Ninh Province was also in the process of substantial expansion. Bac Thai was mentioned as a new mining area that might be supplying coking coal for iron and steel manufacture. Vietnamese engineers designed a new 350,000-ton-per-year colliery at Khe Chan (probably at 21°05′ N, 107°05′ E) in Quang Ninh Province, scheduled to start construction in 1977.

Part of Vietnam's anthracite is exported; in 1976, about 700,000 tons went to Japan alone. The Japanese were bargaining for a doubling of supply in 1977, but actual shipments probably will be under 1 million tons.

Petroleum and Natural Gas.—No petroleum or natural gas was produced in Vietnam in 1976. Offshore oil strikes of possible commercial value were made by a Shell-Cities Service consortium in 1974 and by the Mobil group in February 1975. Interest in renewing exploration was therefore high on the part of both the Government's Oil and Natural Gas Commission and several foreign oil companies. The Government did not have the expertise to continue exploration, but Vietnamese officials were also hesitant about signing production-sharing agreements with profit-oriented foreign firms. The year was mostly spent by the Government in negotiating, visiting, and learning, while the groundwork was being laid for resuming exploration under Vietnamese terms.

However, there were some tangible accomplishments. The French Compagnie Générale de Geophysique (CGG) working under contract to the Vietnamese Government began exploration survey work off the southern coast of Vietnam in March 1976. The French Compagnie Maritime d'Expertises (COMEX) reportedly signed an agreement to develop the port of Vung Tau into a major offshore oil development support base. Norwegian interests reportedly won the first new drilling rights with a contract to drill six exploration wells off the southern coast. Negotiations by several countries and companies were continuing at yearend.

AFGHANISTAN [1]

The mineral industry of Afghanistan improved substantially in 1976 as asbestos production was begun and feasibility studies were made of possible copper and iron and steel industries. The remarkable event of the year was the introduction of Afghanistan's 7-year economic and social development plan which covered the years 1976–82. The 7-year plan established ambitious goals for a gross national product (GNP) annual growth rate of 6.3% during its duration. To achieve this target, large increases in expenditures for economic development were programed in virtually every sector of the economy. Foreign assistance, in particular, was expected to finance a large share of new development projects.

The major components of the plan were the development of transportation (highways and railroads), oil and gas exploration, construction of a copper smelter to exploit the copper deposits near Kābul, and development of an iron and steel industry to exploit the rich iron ore deposits in the central part of the country. Exports during the plan period were to continue to be principally agriculture products and natural gas to the U.S.S.R.

The 7-year plan briefly outlined the role of the private sector in the development of the economy. The plan foresaw a mixed and guided economy, with those industries requiring small investment and simple technology left to the private sector and large key industries owned and operated by the public sector. The plan stated that a list of industrial activities was to be prepared in which the participation of domestic and foreign investors would be outlined. The Afghan investment law in 1976 limited foreign ownership of industries to 49%.

Tricentrol International Ltd., the United Kingdom-owned oil, gas, and minerals company, was granted prospecting rights by the Afghan Government to look for hydrocarbon possibilities in a 33,000-square-kilometer area of northwestern Afghanistan. Tricentrol was to submit its reports to the country's National Oil Institute by mid-1977.

Natural gas maintained its position as Afghanistan's most important export commodity in 1976. Total production of 3 billion cubic meters was reported for the year, of which 2.5 billion cubic meters was exported to the U.S.S.R. as part of an agreement signed in 1975 and the re-

[1] Prepared by E. Shekarchi, supervisory physical scientist, International Data and Analysis.

mainder was used in domestic power production. Export earnings from natural gas were approximately $45 million.[2] Production of coal and talc increased 2% and 50%, respectively. Hydraulic cement production increased 19% in 1976. Afghanistan's Ministry of Mines and Industries awarded a $50 million contract to a U.S. consortium consisting of Fuller Company (Pa.), Fischbach & Moore, Inc. (Tex.), and Oman Construction Co. Inc. (Tenn.). The contract called for construction of a 1,600-ton-per-day cement plant in the Kandahār region. The unique turnkey project was to include geological and techno-economic studies, supply of all equipment, erection, installation, civil works, and initial training. Upon completion of the plant, scheduled for the second quarter of 1979, a Fuller startup team was to assist in running the plant while training Afghan personnel. It was estimated that as many as 600 new jobs would be created during the construction period alone. The completed plant will provide many quarrying, operation, and management jobs.

Barite production in 1976 remained at the same level as in 1975. The Sanglau barite mine was again the primary source while the Farinjal deposit remained dormant, owing to transportation problems. A total of 13,000 tons of asbestos production was reported for the first time from Afghanistan. The details of mine location, type of asbestos, and reserves were not available by yearend.

[2] Where necessary, values have been converted from Afghanis (Af) to U.S. dollars at the rate of Af45 = US$1.00.

[1] In addition to the commodities listed, crude construction materials such as common clays, stone, and sand and gravel presumably are produced, but output is not recorded quantitatively and general information is inadequate for formulation of estimates of output levels.

[2] Data are for years beginning March 21 of that stated.

[3] Excluding gas used for gas lift.

[4] Includes gas reinjected to reservoirs, if any.

BAHRAIN [3]

During 1976, petroleum and natural gas were the major mineral products of Bahrain, an archipelagic sheikdom in the Persian Gulf between the Qatar peninsula and Saudi Arabia. Bahrain's oil revenue increased from $280 million [4] in 1975 to about $334 million in 1976, owing to increases in both price and production. The petroleum industry continued as the keystone of the Bahraini economy, with receipts from this source accounting for about 73% of total Government revenue during the year. The Awali Field in south-central Bahrain, the main island, produced 21.3 million barrels in 1976 and 20.8 million barrels in 1975, compared with the 25-million-barrel average for peak production years 1972–74. The Abu Safah Field, located in the Persian Gulf north of Bahrain and shared with Saudi Arabia, produced 37 million barrels in 1976, a 68% increase over that of 1975 but well below the 44 million barrels of 1974.

Although oil exploration continued both onshore and in the Persian Gulf, no new discoveries were made during the year. Bahrain remained an important oil refining center and processed about 58.8 million barrels of Saudi crude in addition to all production from the Awali Field. Throughput at the 250,000-barrel-per-day Awali refinery averaged 219,200 barrels per day in 1976, a 2% increase over the 215,500 barrels per day processed in 1975.

The Bahrain Petroleum Co., Ltd. (BAPCO), a subsidiary of the California Texas Petroleum Corp. (Caltex), had controlled the petroleum industry in Bahrain since the 1930's. In 1974, BAPCO and the Government reached an agreement by which the Government acquired 60% ownership of BAPCO's oil and gas production facilities. The Government announced its intentions to eventually achieve 100% participation and in 1976 established the Bahrain National Oil Co. (BANOCO) to administer its share of BAPCO and to manage domestic marketing of petroleum products. Caltex retained full ownership of the Awali petroleum refinery. The Abu Safah oilfield was administered by the Arabian American Oil Co. (Aramco) and revenues from the Field were shared equally by the Governments of Bahrain and Saudi Arabia.

The production of natural gas, controlled by BAPCO, increased 6.0%, from 7.87 million cubic meters per day in 1975 to 8.34 million cubic meters per day during 1976. Bahrain's natural gas reserves in the Khuff and Arab zones were estimated at 270,000 million cubic meters. About 38% of the natural gas production was used to fuel the country's aluminum smelter, 28% was used to maintain pressure in the Awali oilfield, 21% was consumed by the producer, and 13% was used for the commercial production of electricity.

Without any new oil discoveries since 1963, and faced with oil depletion in 15 to 20 years, Bahrain was attempting to diversify its economic base. The Sitra 120,000-ton-per-year aluminum smelter that commenced operations in 1971 continued as a successful venture and was owned 77.9% by the Government, 17% by Kaiser Aluminum & Chemical Corp., and 5.1% by Breton Investments. Aluminium Bahrain Ltd. (ALBA) operated the smelter above rated capacity and produced approximately 122,100 tons of aluminum metal in 1976, 5,800 tons more than the 1975 output. The aluminum smelter received alumina feedstock from Australia and exported aluminum ingot to Japan, the People's Republic of China, Iraq, Brazil, and Argentina. A Government-owned aluminum extrusion plant, the first on the Persian Gulf, was nearing completion near the ALBA smelter during 1976. The $12 million, 3,000-ton-per-year plant was to come onstream in 1977. It was designed by Swiss Aluminium Ltd. (Alusuisse) and was equipped with a 2,000-ton Schloemann Siemag AG press from West Germany, Tanner Companies anodizing facilities from the United States, and extrusion dies manufactured in the United Kingdom. Vereinigte Aluminium Werke (VAW) of West Germany was studying the feasibility of an aluminum rolling mill in Bahrain that would use rolling slab from the ALBA smelter.

Construction of a major dry dock and shipyard facility at the southeastern end

[3] Prepared by David E. Morse, physical scientist, International Data and Analysis.

[4] Where necessary, values have been converted from Bahrain dinars (BD) to U.S. dollars at the rate of BD1=US$2.551.

of Muharraq Island was in full swing during 1976. The $200 million venture, known as the Arab Shipbuilding and Repair Yard, was sponsored by the Organization of Arab Petroleum Exporting Countries (OAPEC) and was to be in operation by 1978. The single dry dock was to be capable of accommodating vessels of up to 500,000 deadweight tons and was of prime importance to the OAPEC-sponsored tanker fleet of the Arab Maritime Petroleum Transport Co.

Bahrain and Saudi Arabia planned to build a cement plant in eastern Saudi Arabia. The 6,000-ton-per-day facility would be financed 75% by Saudi Arabia and 25% by Bahrain, and its output would satisfy Bahrain's cement needs and part of Saudi Arabia's.

Improvements were scheduled to relieve congestion at port and transport facilities at Mina Sulman, Bahrain's only major port. In June 1976, a contract was awarded to three French companies to build six new deepwater berths, transient sheds, and open storage areas at Mina Sulman. The handling capacity of the port was to be increased 30% and storage areas would be doubled with the completion of the expansion work scheduled for 1979. During 1976, as in previous years, about one-third of the goods traversing the docks at Mina Sulman were destined for other Persian Gulf States, principally Saudi Arabia. A causeway linking Bahrain and the Saudi mainland was to be built with Saudi financing at a cost of $250 million.

JORDAN [5]

The mineral sector contributed approximately 15% to Jordan's GNP of $1.5 billion [6] in 1976. Phosphate mining and cement production were the country's only major industries based on local mineral deposits. Other mineral production was confined to refining of imported crude oil and mining of small amounts of gypsum, clay, lime, marble, and salt. Production of mineral commodities in Jordan in 1976 is reported in table 1.

Jordan's ambitious 5-year plan (1976–80) scheduled a total expenditure of $2.4 billion, of which 25% was allocated to the

[5] Prepared by Candice Stevens, economist, International Data and Analysis.

[6] Where necessary, values have been converted from Jordan dinars (JD) to U.S. dollars at the rate of JD0.332=US$1.00.

industrial and mining sector. Approximately $270 million was to be expended on expansion of phosphate operations and development of a domestic fertilizer industry. Other projects included the production of potash from the Dead Sea, construction of additional cement plants, and expansion of the Zarqa oil refinery. Potential commercial deposits of copper, manganese, uranium, and vanadium were to be further explored and studied.

The country's chronic trade deficit increased to $816 million as imports continued to outweigh exports. Phosphate was Jordan's most important export accounting for 39% of total export earnings. As in past years, budget support from other Arab countries and the United States, in addition to large remittances from Jordanians working abroad, contributed to an overall balance of payments surplus. Foreign aid from Arab States totaled $230 million in 1976. During the year, Jordan and Syria initiated several economic and technical cooperation projects, including the coordination of development plans and the granting of mutual tariff and customs exemptions. Among the joint organizations created were the Jordanian-Syrian Industrial Co., the Joint Industrial Free Zone Co., and the Jordanian-Syrian Ground Transport Co.

Phosphate production increased from 1.35 million tons in 1975 to a record high of 1.8 million tons in 1976. Exports increased from 1.1 million tons in 1975 to 1.65 million tons in 1976, going to the following destinations: Western Europe (23%), Eastern Europe (39%), Asia (35%), and Africa (3%). Despite increased exports, revenues dropped to about $55 million owing to lower phosphate prices. In November 1976, Jordan entered into an informal association of phosphate producers which sought a means of coordinating exports and promoting higher prices. Under the 5-year plan, phosphate production capacity was to be increased from 2 million tons to 7 million tons per year by 1980. Reserves were estimated at 2.5 billion tons.

Jordan had estimated reserves of 200,000 to 300,000 tons of uranium-associated minerals and nearly 1 million tons of vanadium-associated minerals. Discussions were in progress with foreign firms regarding the separation and processing of the uranium and vanadium ores.

The Jordan Phosphate Mines Co. Ltd., in which the Government held 82% interest, operated two major mining operations. The El Hasa mine, 200 kilometers north of Aqaba, had proven reserves of 200 million tons. Production was to be increased from 1.2 million tons to 2.4 million tons per year from the opencast mine, and a 1.8-million-ton-per-year underground operation was to be developed at that same location. Taylor Woodrow Construction Ltd. (United Kingdom) was contracted for the expansion of the beneficiation plants at El Hasa which produced a 75% tricalcium phosphate (TPL) product. A smaller expansion project was scheduled at Ruseifa, 15 kilometers northeast of Amman, to increase production capacity from 800,000 tons to 1 million tons per year. Excavation began in 1976 on a third mine at Shīdiyah, 130 kilometers northeast of Aqaba. Reserves were estimated at 230 million tons of phosphate at this location.

The Jordan Fertilizer Industry Co., which was to construct a $325 million phosphate fertilizer complex in Aqaba, contracted Spie-Batignolles S.A. (France) as general manager of the project. The complex, to be completed in 1980, was to produce 1,800 tons per day of sulfuric acid, 1,000 tons per day of phosphoric acid, and 2,000 tons per day of monoammonium and diammonium phosphate. In 1976, Agrico Chemical Company (United States) withdrew its 25% interest in the project and negotiations were ongoing for a replacement. Other major shareholders were the Jordanian Government (25%), Jordan Phosphate Mines (25%), and the International Finance Corp. (5%). Discussions were being held with the Petro Chemical Industries Co. (Kuwait) regarding a joint venture for a $30 million ammonium phosphate project in Jordan.

The Arab Potash Co., owned 51% by the Jordanian Government, 40% by the Arab Mining Co., and 9% by other Arab countries, sought financing for its Dead Sea potash project. Jacobs Engineering Co. (United States) continued its feasibility study of the project which was to process carnallite, produced by solar evaporation of Dead Sea brines, to yield 1 million tons per year of potash. Production was to begin in 1981 and increase to 1.2 million

tons per year by 1984 and 10.7 million tons per year by 1990. Reserves of potash in Dead Sea waters were conservatively estimated at 2 billion tons. Total cost of the project, which was to include a 200-kilometer railroad to ship potash to the port of Aqaba, was approximately $425 million. The first stage was to be financed by the Jordanian Government ($3 million), the U.S. Agency for International Development (AID) ($6 million), and the International Bank for Reconstruction and Development (IBRD) ($1 million).

The Jordanian Cement Co., which operated Jordan's only cement plant near Amman, produced 533,000 tons of cement in 1976. Increasing construction requirements in Jordan prompted plans to expand cement capacity. The Amman plant was to double its capacity from 600,000 tons to 1.2 million tons per year. Romania and Jordan were to cooperate on the construction of a 1-million-ton-per-year cement plant near Aqaba. The Jordanian-Syrian Industrial Co. conducted exploration for limestone in southern Jordan as the basis for a joint-venture, 1-million-ton-per-year cement plant.

The Department of Petroleum Affairs was established in 1976 to supervise exploration activities. The Filon Corp. (United States) carried out photogeological and seismic surveys in its 8,000-square-kilometer concession area on the eastern bank of the northern Jordan River. Under its 1975 contract, Filon was to drill at least 15 wells and undertake survey work at an initial cost of $1.6 million. The firm was to bear all exploration and development costs and receive 35% of production revenues in the case of commercial discovery. The only other petroleum exploration was conducted by the U.S.S.R. under a mutual cooperation pact.

The Zarqa refinery, situated 25 kilometers from Amman, produced approximately 8 million barrels of petroleum products in 1976. Less than 500,000 barrels was exported to Lebanon and Syria with the remainder consumed locally. Romania's Industrialexport was awarded a $190 million contract to expand capacity of the refinery from 24,000 barrels to 60,000 barrels per day. Expansions to the refinery, operated by the State-owned Jordan Petroleum Refinery Co., Ltd., were to be completed in 1978. In March 1976, Jordan reached an agreement with the Trans-Arabian Pipe Line Company (TAPline) regarding the price of crude supplies to the Zarqa refinery. Prices were raised from $3.50 to $11.50 per barrel. Saudi Arabia agreed to make up the higher crude oil price for the first 2 years and also agreed to pay Jordan's outstanding debt of $115 million to TAPline. During the year, the prices of petroleum products in Jordan were raised by an average of 20%.

Expansion of the Zarqa refinery was expected to satisfy local demand until 1980. To meet future requirements, Jordan planned a second refinery as a joint venture with Romania. The 60,000-barrel-per-day refinery was to be supplied by crude oil transported by TAPline from Saudi Arabia.

The Jordanian Natural Resources Authority (NRA) renewed the agreement with the Bureau de Recherches Géologiques et Minières (BRGM) of France for copper and manganese prospecting. BRGM estimated reserves of copper in the Wadi 'Araba region at 65 million tons. The French firm Sofremines was conducting a study of appropriate mining techniques for exploitation of the deposits at the rate of 10,000 tons per day. The Wadi 'Araba region also contained proven reserves of 1.5 million tons of manganese ore with estimated reserves of 5 million tons. Details of the grade of copper and manganese ore were not available at yearend.

LEBANON [7]

Lebanon's economy and small mineral industry, which consisted primarily of cement manufacture and petroleum refining, were seriously affected by the 19-month civil war which began in early 1975. Industries and banks were closed for most of 1976 and the annual inflation rate was close to 70%. At yearend, the Board for Reconstruction and Development was established and entrusted with drawing up a general reconstruction plan; proposing relevant economic, financial, and social policies; preparing a budget; and proposing legislation to assist the reconstruction effort. Other measures intended to revitalize the economy included the establishment of an organization to guarantee bank deposits at Lebanon's 74 private banks and to guar-

[7] Prepared by Candice Stevens.

antee local and foreign investments against noncommercial risks arising from the war. Top priority was given to repairing the financial center of Beirut and reequipping port facilities and other infrastructure. An $800,000 [8] grant from the United Kingdom was to finance a study by the United Kingdom firm Peat, Marwich, and Mitchell on the repairs needed at Beirut port, previously one of the busiest trading centers in the Middle East.

The civil disturbances resulted in both physical and financial damage to Lebanon's petroleum industry. During the year, the Higher Oil Committee was formed to supervise all oil imports, exploration activities, and the operations of Lebanon's two refineries. Shortages in the normal supply of oil products owing to the disruption in deliveries from Lebanon's refineries prompted the Government to increase the price of gasoline 76% to 79%. For most of the year, petroleum products and liquefied petroleum gas were imported from Saudi Arabia and Kuwait to the southern port of Sidon. The suspension of operations by many of Lebanon's oil distributing companies in 1976 was prompted by a combination of factors, including heavy damage to facilities, high labor costs, the difficulty of securing imports, and Government price regulation. Mobil Oil Lebanon Inc., the country's oldest petroleum company (established in 1919), and Esso Standard Near East discontinued business operations in August 1976. The Government subsequently established the Administrative Custodians Committee to supervise the companies' marketing and distribution of petroleum products. Shell Oil Co. and British Petroleum Company Ltd. (BP) pulled out later in the year after selling the share capital in their joint-venture marketing company to local employees. Total Liban Ltd., a subsidiary of Compagnie Française des Pétroles (CFP), relinquished 51% of its company valued at $3.2 million to local interests.

The nationalized Tripoli refinery in northern Lebanon ceased operating in March 1976 with the expiration of the supply agreement with the Iraq National Oil Company (INOC). At that time, Iraq began the diversion of its Kirkuk crude through the new strategic pipeline to export terminals on the Persian Gulf rather than by pipeline through Syria and Lebanon for export from Mediterranean ports. The Tripoli refinery reopened in December 1976 at 25% of capacity after Lebanon imported 350,000 tons of Kirkuk crude from Iraq. The oil, priced at $13.55 per barrel, was shipped by tanker from Basra port on the Persian Gulf. At yearend, advantages in both logistics and price led Lebanon to negotiate for the import of Saudi light crude for feedstock for the refinery. Logistically, the closure of the INOC pipeline and the necessity of importing Iraqi crude by tanker made the Saudi oil more easily available. In addition, following the inception of the Organization of Petroleum Exporting Countries' (OPEC) two-tiered price structure in January 1976, Iraqi crude (priced at $14.25 per barrel) was relatively more expensive than Saudi crude (priced at $12.49 per barrel). Some minor technical modifications would be required to enable the Tripoli refinery, which had a capacity of 30,000 barrels per day, to process the Saudi oil.

Lebanon's other refinery at Zahrani just south of Sidon terminated production in June 1976 following heavy damage to facilities. Earlier in the year, the refinery was supplied by limited deliveries of Saudi crude transported by TAPline. Although owned by the Mediterranean Refining Co. (Medreco), which in turn was owned by Caltex and Mobil Oil Corp., the 17,500-barrel-per-day refinery was taken under Government sequestration in 1973 following a price dispute with TAPline. The Medreco refinery resumed operations at half of capacity in November 1976, utilizing old stocks of crude oil as feedstock, and began supplying the local market with petroleum products in December 1976. At yearend, the Lebanese Government concluded an agreement with TAPline for deliveries of Saudi light crude at a price of $12.49 per barrel to the Medreco refinery to begin in January 1977. Payments were to be made on a quarterly basis with approximately $12.5 million due on April 1, 1977, for 1 million barrels of crude oil to be delivered during the first quarter. At the same time, the payment of the Lebanese Government's debts for past crude oil shipments, estimated at $123 million, was suspended indefinitely.

[8] Where necessary, values have been converted from Lebanese pounds (£L) to U.S. dollars at the rate of £L2.27=US$1.00.

Petroleum exploration, which had been conducted on a modest scale in Lebanon since 1947,[9] was interrupted in 1976. Lebanese Decree 10537 of July 1975 authorized the Government to invite companies to bid for offshore acreage under production-sharing terms and to review all existing prospecting rights. However, both the bidding and review of permits were necessarily postponed during the year. Onshore rights were previously held by Compagnie Libanaise des Pétroles (CLP), Shaheen Oil Co., and Abdeni Oil Co.; offshore rights were held by a group composed of Shaheen, Oxoco (UK) Limited, and Invent Inc.

OMAN [10]

Oil continued to be the foundation of Oman's economy, accounting for 99% of the exports and 70% of the GNP, estimated at $1.8 billion [11] at current prices. Petroleum production increased 7% in 1976 and Government revenues derived from petroleum increased 25% to nearly $1.3 billion. The Government was seeking to develop northern Oman mineral deposits, including copper, asbestos, limestone, chromite, iron ore, phosphates, and coal.

The 5-year development plan (1976–80), the first ever issued in the sultanate, highlighted the need for tight budgets and slower growth until the end of the decade as petroleum output was expected to decline. Resources for the plan were to be derived from oil revenues ($6.5 billion), customs and taxes ($4.6 million), and loans and grants ($1.2 billion). Oil revenues were expected to be 25% lower by 1980 than they were in 1976. Funds were to be shifted from infrastructure projects to rural development and revenue generating projects such as mining, manufacturing, and agriculture. Side effects of the economic slowdown caused by slackening in large infrastructure projects included a sharp drop in the Matrah port congestion, a decrease in inflation from 80% in 1973 to 15% in 1976, and an expected decline in the foreign work force.[12]

The Oman Development Bank was launched, with shareholding scheduled to be by the Government (40%), foreign financial interests (40%), and the Omani public (20%). There were only three exceptions to the rule that all businesses in Oman be operated by local companies—Government contractors, banks, and the technical professions.[13] Although there was a choice of five types of enterprises that could be established with foreign capital, experts were recommending either a joint stock enterprise following a standard format or a limited liability enterprise with a restricted number of shareholders. The Omani stake was expected to be at least 35% for most businesses and no joint operation was eligible to buy land. Corporate income tax was on a sliding scale from 5% to 50% of gross profits. A 5-year tax holiday was allowed to companies that were either wholly Omani owned, involved in industry, or considered to contribute to the national economy and have a capital of at least $290,000. In addition, there was a 5% maximum payroll tax and a customs duty of 2%, but no personal income tax or exchange control regulations for companies with 50 or more employees. On September 9, 1976, the Omani Government signed an agreement that authorized the Overseas Private Investment Corp. (OPIC) to provide insurance for U.S. investors and contractors operating there.

Plans were being formulated for the establishment of the Oman Cement Co., to be owned 60% by the Sultanate of Oman and 40% by the Kuwait Cement Co. The plant would produce cement at a rate of 1 million tons per year. It was hoped that the plant would start production before 1980. The Government cancelled a deal with Associated Portland Cement Manufacturers Ltd. (APC) of the United Kingdom to establish a cement plant near Muscat. The cancellation was decided because of disagreement with APC

on terms for the supply of gas and other utilities.

Except for sand and aggregate, Oman was totally dependent on foreign construction material. Oman imported about 300,000 tons of cement in 1976. Steel and cement represented about 40% of the recorded imports.[14] Although the price of cement locally increased only 6% between March 1974 and March 1976, the costs for labor increased 15%. The labor element in construction costs was reported to be as high as 78% on buildings. The bulk of the workforce was made up of expatriates, mostly from the Indian subcontinent for the basic grades and from Europe and the United States for the managerial staff. The construction industry accounted for 77% of the jobs in the private sector.

The development of the Sohar copper mining and smelting complex was to require a 200-kilometer natural gas pipeline to be laid from Ghabar to Sohar. The copper deposits were estimated to contain at least 20 million tons of copper ore averaging 2.1% copper. Extraction, refining, and development were expected to cost over $150 million. A joint venture (to be known as the Oman Mining Co.) between the Omani Government (51%), Prospection Ltd. of Canada, and Douglas B. Marshall Exploration of Houston, Tex., was to develop the deposit. Loans of $223 million and $420 million, largely representing external capital from Saudi Arabia and Abu Dhabi, were being utilized both for Dhofar development and the Sohar copper project. Exploration and other technical services had been undertaken by Prospection Ltd. No firm date for startup of operations had been announced, but the fact that most of the capital had been arranged suggested that work would begin soon. More drilling was required to complete feasibility studies. Some reports suggested that there were up to six other known copper deposits in the area. Three underground mines were visualized as supplying 3,000 tons of ore per day to a central processing complex. The mineralized area was located 40 kilometers inland from Sohar, a fishing town in northern Oman. The deposits were described as geologically similar to those in Cyprus, which were associated with pillow lavas of the Troodos Massif.

Petroleum Development (Oman) Ltd. (PDO), controlled 60% by the Omani Government and 40% by Shell, CFP, and Participations and Explorations Corporation (Partex) (Portugal), was the country's only petroleum producer, producing an average of 365,558 barrels per day in 1976 from nine fields, up 7% over that of 1975. The majority of the production (52%) came from the Fahud-Natik (discovered in 1964) and Yibal-Shuaiba (discovered in 1962) Fields. Oman was not a member of OPEC, but was following the price increase by adding $1.05 per barrel, effective January 1977. During 1976, the Omani Government took a vigorous role in negotiating prices with Shell by raising taxes and royalties on equity of crude oil to 80% and 20%, respectively, thus making the rates about the same as those of other Persian Gulf countries. Omani blended crude oil (35° API gravity) was selling at $11.70 per barrel in 1976. In the first 6 months of 1976, the chief importers of Omani crude were Japan (39.7%), the Netherlands (18.8%), the United States (15.7%), and Canada (10.7%). France, the United Kingdom, Singapore, Italy, West Germany, and Trinidad also imported crude petroleum from Oman.

Petroleum reserves in northern Oman were expected to be nearly depleted in 20 years. Petroleum production was expected to start declining in 1977. In an effort to balance the expected oil production decline, PDO had plans to spend $200 million to $250 million on development of the Dhofar area now that the conflict was at an end. Reportedly, proven reserves in this area could provide at least 30,000 barrels per day, the minimal economic recovery level. In an effort to increase exploration efforts in Dhofar, the Government was inviting bids on about 25,000 square miles on a production-sharing basis.

Test wells drilled at Amal, Nasir, and Marmul Fields in the Dhofar area revealed significant reserves of heavy to medium oil (24° API gravity), but commercial recovery was expected to be difficult. Not only do the fragmented oil-bearing strata in Dhofar present problems in development, but the oil would apparently have to be piped over steep cliffs to a marine pumping station that would be vulnerable to severe summer monsoon

[14] Financial Times (London). Government Cuts Back. July 21, 1976, p. 24.

weather. PDO expected that any oil produced would be costly and command a lower market price than light crude oil from the north.

During 1976, 39 wells were completed in Oman, down from the 53 completed in 1975. Of these, 29 tested oil, 7 were dry, and 3 were suspended. The Royal Dutch/Shell Group as operator for PDO drilled six of the wells that tested oil, abandoning four. Three of these were in the Dhofar area, one was northeast of Fahooud, and two were in central Oman. Sun Oil Co. drilled and abandoned one well off the east coast of Oman, south of the Gulf of Masira. Elf-Aquitaine and the Sumitomo group were drilling off the northern tip of Oman in the Strait of Hormuz. Elf-Aquitaine had changed its conventional exploration permit for Cape Musandam into a production-sharing agreement. Essence et Lubrificant de France—Entreprise de Recherches et d'Activités Pétrolières (Elf-ERAP) struck light oil at depths of 12,000 feet in the Strait of Hormuz, northwest of Cape Musandam, early in 1976. A U.S. independent company, Quintana Overseas International (owned by Marshall Exploration), leased the Sunaina Field in northern Oman and was to start drilling in 1977.

The Italian companies SNAM Progetti S.p.A. and Saipem S.p.A. (subsidiaries of Ente Nazionale Idrocarburi (ENI) announced the acquisition of a $32 million turnkey contract for construction of a 20-inch diameter, 331-kilometer long natural gas pipeline from the Yibal Field in the Fahud area in north-central Oman to the capital city of Muscat. The project was expected to be completed by early 1978. The Abu Dhabi Fund for Arab Economic Development was loaning $15 million, the Kuwaiti Fund for Arab Economic Development, $25 million; Saudi Arabia, $20 million; and the Arab Fund for Economic and Social Development (AFESD), $20 million toward the $94 million total expected cost to construct the pipeline. The gasline was to serve industrial projects of the 5-year plan such as a projected 2,000-ton-per-day fertilizer plant, a cement plant, and power-generating and water-desalination plants. According to a recent Government study, Oman has sufficient natural gas reserves to sustain a production of 12 billion cubic meters per year for 20 years.[15]

Under consideration were a $30 million topping plant and a 30,000-barrel-per-day oil refinery. The refinery was expected to cost $130 million, but Oman's annual imports of refined products were at a rate of over $100 million.[16] In the first 6 months of 1976, Oman imported 420,000 barrels of gasoline, 200,000 barrels of jet fuel, 600,000 barrels of distillate fuel oil, and 2.4 million barrels of residual fuel oil from Iran; and 25,000 barrels of gasoline, 28,000 barrels of jet fuel, and 40,000 barrels of distillate fuel oil from Saudi Arabia. Similar amounts were imported in the second half of the year. The sole importers of refined products in Oman were Shell and BP.

QATAR [17]

Fueled by substantial oil revenues, the economy of Qatar was developing at a rapid pace. Qatar's oil income of $2.1 billion [18] comprised over 50% of the 1976 GNP estimated at $4 billion at current prices. The Government was attempting to conserve oil resources with 25% of the possible production shut in and the production ceiling lowered to 475,000 barrels per day on January 1, 1976. Oil reserves were expected to last about 25 years, but reserves of natural gas were expected to have potential for hundreds of years after the oil runs out. The Government acquired 100% control of oil production during 1976 and early 1977.

The Government actively encouraged foreign investment, especially for industrial projects. There was a legal requirement that all local companies must have 51% Qatari ownership, although exemptions could be obtained by special decree. Imported equipment and material were exempt from duties and industrial ventures were entitled to a 5-year tax holiday.

[17] Prepared by Janice L. W. Jolly.
[18] Where necessary, values have been converted from Qatar riyals (QR) to U.S. dollars at the rate of QR3.9391 = US$1.00.

There were no personal income or municipal taxes. Government assistance was also available through capital participation, long-term interest-free loans, or provision of free land.

Economic cooperation between Qatar and France had increased with the signing in December 1975 of agreements providing Banque de France with $150 million for joint petrochemical project financing—one in Qatar at Umm Said and the other in France at Dunkerque. An Anglo-Qatari trade agreement was signed in July 1976 providing for establishment of a joint committee to stimulate the involvement of United Kingdom firms in Qatari development projects and training programs. Finland also participated in discussions aimed at developing intergovernmental cooperation.

Electricity generating capacity was approximately 801 megawatts in 1976. Qatar was largely dependent on desalinated water both for drinking and industrial consumption. There were occasional water shortages, but additional desalination plants were to be built, along with new powerstations projected to meet the needs of the country within 3 years. Doha's heavily congested six-berth port was being expanded and contracts were awarded for construction of eight berths at Umm Said to service the industrial area. Further port studies recommended 20 additional berths.

The absence of a technically or administratively trained indigenous population resulted in heavy reliance on foreign labor, and the lack of an established infrastructure or industrial base created bottlenecks for the economy. Foreign labor was supplied principally from other Arab countries, India, Pakistan, and Iran. There were shortages of both skilled and unskilled labor in all areas of the economy, a factor that has slowed industrial development.

Imports from the United Kingdom, Japan, the United States, and West Germany formed more than 50% of Qatar's total imports. Total 1976 imports were valued at $835.5 million. The 1976 figure was more than twice that of 1975 ($407.5 million). The U.S. share dropped from 12.5% to 7.8%, and Japan replaced the United Kingdom as the leading supplier with 28.3% of Qatar's imports in 1976.

Startup of Qatar Steel Co.'s 400,000-ton-per-year direct-reduction steelworks was set for February 1978. Although feed was to be imported, the plant was to use local natural gas as fuel and reductant, using the Midrex process. The Taisei Corporation of Japan and the Jung Woo Development Co. of the Republic of Korea were jointly building the steelworks. The steelworks at Umm Said was owned as a joint enterprise between the Qatari Government and Kobe Steel, Ltd., and Tokyo Boeki Ltd. of Japan. Kobe Steel, with a 20% interest, was supervising the project. When completed, the Midrex direct-reduction module will consist of two 70-ton electric arc furnaces, two 4-strand continuous billet casters, and a bar mill, and will produce rebars for the construction industry. Iron ore and pellets will be imported from Australia, Brazil, and Sweden. Some scrap will also be imported.

A third furnace for cement production was being built with a capacity of 100,000 tons per year, and a fourth plant at Umm Bab with a 900-ton-per-day capacity was planned for 1978. Newell Dunford Engineering Ltd. was given a contract to supply a complete lime calcination plant at Umm Bab for the Qatar National Cement Co. Ltd. Consultant for the project was Henry Pooley Atkins of Epsom, the United Kingdom. Hydraulic cement valued at $8.6 million (171,503 tons) was produced in 1976 and 208,800 tons of cement was imported. A prefabricated concrete factory was to be constructed by several West German companies.

Drilling in Qatar during 1976 resulted in the completion of 15 wells—4 yielded oil, 4 yielded gas, 1 was dry, 2 were suspended, and 4 were service wells. Total footage was 115,500 feet. At yearend, there were three wells in progress. There were six rigs operating in the country, two offshore and four onshore. The high price of crude oil made it possible for the Holcar Co. to begin production at a rate of 10,000 to 20,000 barrels per day from three offshore wells in 1977. The wells were on a 7,500-square-kilometer tract relinquished as noncommercial by the Japanese Qatar Oil Co. in 1973. In wildcat activity, Holcar Petroleum, an independent U.S. company, began exploration of the former Japanese tract. The Wintershall group was exploring its concession off the

northern tip of Qatar. Two wildcat wells were completed—one was an oil discovery and the other a gas discovery with oil shows. The offshore El Bunduq oilfield, straddling the boundary between the United Arab Emirates and Qatar, was expected to reach its full productive potential of 30,000 barrels per day; the well started production in February.

Petroleum production in 1976 averaged 495,000 barrels per day, up 13.9% over that of 1975. This figure includes the 20,000-barrel-per-day production of the El Bunduq Field which was shared with Abu Dhabi because the Field straddles the boundary. The remaining quantity was produced about equally by Shell-operated offshore fields and the Qatar Petroleum Company Ltd. (QPC)-operated onshore Dukhan Field. Of the offshore fields, Bul Hanine was the largest, averaging 141,000 barrels per day.

Under terms of an agreement signed on September 16, 1976, the Government took over the remaining 40% interest in the assets of the onshore producing company QPC. QPC was previously owned by BP, Royal Dutch/Shell, and CFP, each originally with 23.75%; Exxon and Mobil (Near East Development Corp.), each with just under 11.88%; and Partex with 5%. Compensation amounted to about $30 million. The Government company would be called the Qatar Petroleum Producing Company (QPPC). The former private owners were to establish Dukhan Service Co. Ltd., a company for management and operational services. The companies' service fee was to be 15 cents per barrel of oil produced, indexed to the price of Dukhan crude. This was reportedly the first service fee indexing arrangement in the Middle East. The Qatar arrangement was pegged at 1.266% of the crude oil price, which was $11.848 per barrel of Dukhan crude.[19] Under a 5-year contract, the companies were entitled to restricted liftings of 130,000 barrels per day with 60 days' credit. This compares with the 170,000 barrels per day allowable under the 1976 equity and buy-back arrangements. The onshore Dukhan Field, discovered in 1940, was producing at a rate of 225,000 barrels per day.

The Government was still to negotiate terms for the takeover of offshore operations by the Shell Company of Qatar Limited (SCQ) in which 80% of the foreign interests were held by Shell and the remainder by Italy's ENI. SCQ's three offshore fields, Idd El Shargi (discovered in 1960), Maydan Mahzan (discovered in 1963), and Bul Hanine (discovered in 1970), were producing about 245,000 barrels per day. The negotiations, expected to be concluded in February 1977, were to take longer with Shell because of the more exacting technical and operational requirements of the offshore operations and the need for substantial further exploration and development work. Shell was expected to receive a higher service fee, indexed to the price of Qatar Marine crude, which was to also apply to natural gas liquids when the projected natural gas plant was completed in 1979.

A decree was issued October 16, 1976, establishing the Qatari Petroleum Production Authority (QPPA) within the Qatar General Petroleum Corp. (QGPC), to be headquartered in Doha, to oversee petroleum production. The QPPA was to be independently budgeted. The decree was issued as part of the administrative revisions brought about by the complete nationalization of oil resources by the Government.[20] Marketing was controlled by the State oil company QGPC which was formed in 1974 in anticipation of the takeover.

OPEC held a meeting in Doha on December 15–17, 1976, at which Qatar and 10 other countries decided to increase the price of marker crude 10% from $11.51 per barrel to $12.70 per barrel as of January 1, 1977, and 5% to $13.30 per barrel as of July 1, 1977. The prices of all other crudes were to be increased by the same percentages. Saudi Arabia and the United Arab Emirates decided to raise their prices 5% only. Qatar was also a member of OAPEC, a group of 10 Arab States that functions to coordinate projects (oil-tanker groups, special funds, etc.) among the Arab producing States.

Universal Oil Products Management Services of the United States was carrying out a market survey and feasibility study for the construction of the new oil refinery in Qatar. The study was to determine the capacity, expected to be between 50,000

[19] Oil and Gas Journal Newsletter. Nov. 1, 1976, p. 1.
[20] U.S. Embassy, Doha, Qatar. State Department Airgram A-27, Nov. 1, 1976, p. 1.

and 80,000 barrels per day. Cost of the refinery was estimated at $150 million. The refinery was to serve mostly local needs. The National Oil Distribution Co. refinery at Umm Said had a capacity of 9,150 barrels of crude oil per day. Petroleum refinery input for 1976 was 1,964,869 barrels of crude oil.

Qatar Gas Co. let a $70 million contract to the Japanese companies Mitsubishi Corporation and Chiyoda Chemical Engineering & Construction Co., Ltd., for building the 7.3-million-barrel-per-year natural gas liquids plant (NGL–2) at Umm Said. The plant was to produce 5 million barrels per year of propane and butane and 2.3 million barrels per year of gasoline, and was scheduled to come onstream in 1979. A gas-gathering network to service NGL–2 totaling some 290 kilometers was already under construction by ENI's subsidiary Saipem under a $23 million contract let in April 1975. This would be the second natural gas liquids plant in Qatar.

The first natural gas liquids plant at Umm Said (NGL–1) utilized gas from the Dukhan Field. It was completed in 1975 and consisted of a gas-gathering and initial processing plant at Fahahil near the Dukhan Field; a 12-inch diameter, 60-mile long pipeline to move the liquids to Umm Said; facilities for delivery of dry gas to various industrial plants and utilities; and the fractionation plant and export facilities at Umm Said. Exports were mainly to Japan. Design gas-processing capacity was 340 billion cubic feet per day. Production capacity was 20,000 barrels per day of propane, 8,000 barrels per day of butane, and 4,000 barrels per day of pentanes. Besides fueling local industries, the dry gas provided feedstock for Qatar Fertiliser Co.'s (QAFCO) plant. In 1976, 64,382 tons of liquefied petroleum gas (from natural gas only), 118,486 tons of propane, and 110,356 tons of butane were produced.

QAFCO's fertilizer plant, owned 70% by the Government, 25% by Norway's Norsk Hydro AS, 3% by the United Kingdom's Power-Gas Ltd., and 2% by Hambros Bank Ltd., was completed in 1973. Export oriented, this project had a planned output of 900 tons per day of ammonia and 1,000 tons per day of urea. In 1976, Mitsubishi and Chiyoda received a $19 million contract from QAFCO for an additional 1,000-ton-per-day urea plant for the Umm Said complex. Based on Stamicarbon B.V.'s technology, the new plant was due to come onstream by mid-1978, together with a new 300,000-ton-per-year ammonia plant. Costain Process Engineering Ltd. of the United Kingdom was to build the new ammonia plant under a contract worth $15.6 million, and Norsk Hydro was to manage and operate the plant and market the products.

Natural gas liquids from NGL–2 would be used for a new petrochemical plant planned by Qatar Petrochemical Co. (QAPCO), an enterprise owned 80% by the State, 15% by Charbonnages de France Chimie (CDF Chimie), and 5% by another French company, Gazocean. Contracts for this complex were recently let for $200 million to the French company Cie. Française d'Etudes et de Construction Technip to build a steam cracking unit for production of 280,000 tons per year of ethylene, and for $80 million to the Belgian company Coppee-Rust S.A. for a unit to convert the ethylene to 140,000 tons per year of low-density polyethylene and other products. Due for completion in 1982, the enterprise will also include a transport company in which the Government will have 60% interest and Gazocean, 40% interest. CDF Chimie will operate the plant and handle marketing. Gazocean will ship about half of the output to France in liquid form. The remainder will either be transformed into low-density polyethylene locally or used in other downstream products.

The huge offshore gasfield discovered by Shell was located northeast of the Qatar peninsula in the Khuff formation of the northwest Dome area and was estimated to have reserves of over 100 trillion cubic feet. These new gas reserves were expected to provide the base for an important future natural gas liquids and petrochemical export trade.

SYRIA [21]

Although increasing petroleum revenues contributed to the growth of Syria's gross domestic product (GDP) to nearly $6 billion [22] in 1976, Syrian involvement in the civil disturbance in Lebanon had an overall adverse economic effect. An average annual inflation rate of more than 30% and the presence of a large refugee population put pressure on Government-controlled food and fuel prices, leading to a 60% increase in the price of gasoline. The draft budget for 1977 was $4.6 billion, of which $1.8 billion was allocated for general expenditures and $2.8 billion for development projects. Approximately $330 million was to be devoted to oil and mineral resource development, which included continued petroleum exploration, a general geophysical survey covering 24,000 square kilometers, and the completion of fertilizer, cement, and refinery projects already under construction. In addition, the Romanian firm Geomin finalized a $600,000 agreement to prospect for industrial minerals for construction purposes.

In 1976, Syria continued its policy of diversifying its trade and aid partners and of cultivating new sources of finance and technology other than the U.S.S.R. and Eastern Europe. Financial assistance totaling $355 million was received from Arab oil-producing countries in 1976, and loans of $750 million were expected in 1977. Eastern Europe dropped from its position as Syria's largest trading partner, accounting for less than 16% of imports and 20% of exports in 1976, while Western Europe had more than a 50% share in both the import and export markets. Petroleum was Syria's largest export earner, accounting for about 65% of total revenue, while phosphate exports contributed 2% of revenue. Overall, Syria suffered a balance of trade deficit of approximately $600 million in 1976 owing to large imports of capital equipment and machinery needed for development projects and defense.

[21] Prepared by Candice Stevens.

[22] Where necessary, values have been converted from Syrian pounds (£S) to U.S. dollars at the rate of £S3.90=US$1.00.

Several new economic measures were introduced since 1974 in the effort to attract foreign private and government investment in Syria's development program. These provisions included tax incentives for private investors, the liberalization of foreign exchange controls, bilateral treaties guaranteeing investments against nationalization, allowances for the repatriation of up to 50% of company profits, and the establishment of six new free zones in Adra, Tartus, Aleppo, Latakia, Damascus, and Deraa-Ramthā.

Syria's 5-year plan provisionally accorded high priority to the development of both transportation and electricity generating power. In 1976, Syria had 6,920 kilometers of asphalt-covered roads in addition to 1,126 kilometers of other surfaced roads; considerable resources were to be devoted to improving and expanding this network. The major ports of Banias, Latakia, and Tartus, which experienced a large increase in traffic in 1976 owing to the closure of Lebanese ports, were to be expanded and modernized. The Yugoslav firm Pomgrad was awarded a $19 million contract for the Latakia port expansion, which involved the construction of a 710-meter breakwater to increase the port's capacity from 1.6 million tons to 3 million tons per year. Technoexport (U.S.S.R.) was also preparing studies for the installation of additional piers and other facilities to be completed in 1979.

A vast rural electrification program and the full commissioning of the Euphrates Dam powerstation were to raise Syria's power generating capacity to about 2,500 megawatts by 1980. East Germany donated $51 million to the rural electrification program, which included 300-megawatt stations at Banias and Muhradah and a 180-megawatt steam turbine plant at Qutnah. In addition, the U.S.S.R. was to supply three powerstations of 100 megawatts each. Two turbines had yet to be commissioned at the Euphrates Dam station which was to have a total capacity of 800 megawatts. The $325 million dam, completed in 1974 with U.S.S.R. financial and technical assistance, was to provide the bulk of Syria's electricity in the next few years and the basis for an extensive irrigation program.

Syria's petroleum production increased from 65.9 million barrels in 1975 to approximately 70 million barrels in 1976. Proven commercially recoverable reserves were 1.75 billion barrels in five fields: Suwaidiyah, Karatchuk, Rumailān, Djubissa, and Olayan. The Suwaidiyah Field was the largest with over 1 billion barrels of reserves. The Djubissa Field, situated 40 kilometers south of Al Hasakah, came onstream in mid-1975. The new Olayan Field, in the extreme northeast of the country, started production in mid-1976 at an initial rate of 10,000 barrels per day. A 300,000-barrel-per-day capacity pipeline carried crude oil from the five fields by way of Homs, where a small volume of oil was taken off for refining, to the Tartus export terminal on the Mediterranean Sea.

Although Syria produced more crude oil than it could use domestically, its single refinery at Homs was not equipped to refine the high-sulfur Syrian crude oil without blending it with light Iraqi oil. However, the supply of Iraqi Kirkuk crude ceased in April 1976 when Iraq diverted its oil exports southward through a new pipeline to the Basra terminal on the Persian Gulf instead of to the Mediterranean ports of Banias in Syria and Tripoli in Lebanon. This followed a failure to agree on new levels of transit fees payable to Syria by INOC and on the cost of crude oil which Iraq formerly supplied the Homs refinery at a preferential rate. In 1975, an average of 900,000 barrels per day of crude oil transitted the INOC pipelines, which had a capacity of 1.4 million barrels per day, earning Syria nearly $150 million in transit dues. Oil transit revenues in 1976 were minimal owing to the closure of the INOC pipelines and the failure to reopen the TAPline, which closed in February 1975.

The capacity of the Homs refinery was expanded during the year from 2.5 million tons to 5 million tons per year and a new lubricating oil plant was planned. Despite the purchase of 200,000 tons of oil from Saudi Arabia and a gift of 100,000 tons of oil from Abu Dhabi, the Homs refinery did not operate at full capacity in 1976 owing to the loss of Iraqi crude. A new refinery under construction at Banias by Romania's Industrialexport was to undergo a modification of its refining process from a mixture of 80% Iraqi crude (36° API gravity) and 20% Syrian crude (25° API gravity) to a mixture containing 50% Syrian crude. The original $297 million

contract provided for the construction of a 6-million-ton-per-year refinery to be completed in 1977. A supplemental agreement concluded in 1976 provided for the study, design, supply, and installation of equipment required for the processing modification and delayed startup until 1978.

Syria's attempt to engage international firms in oil exploration met with unsuccessful results in 1976. Approximately 50,000 square kilometers of area onshore and offshore was opened to international bids under production-sharing or service-contract arrangements in 1975. Contract provisions included recoverable company costs from 40% of production, negotiable production-sharing ratios, minimum exploration commitments, and competitive signature and production bonuses. Although a U.S. consortium consisting of Tripco Petroleum Co., Reserve Oil & Gas Co., Drillamex (a subsidiary of American Express Company), and City Investing Co. acquired a 4,500-square-kilometer offshore block, it relinquished the acreage in May 1976 after completing seismic surveys. Similarly, Chemokomplex of Hungary withdrew its bid for an exploration tract in central Syria. The only remaining foreign interest was Rompetrol of Romania which was prospecting on a 9,350-square-kilometer onshore tract in the northeastern part of the country.

The Syrian Petroleum Co. (SPC), the Government concern responsible for production and exploration, continued prospecting in five blocks totaling 25,000 square kilometers in the northeast, the southwest near Damascus, the northwest south of Aleppo, and the south-central areas of the country. In the past 2 years, SPC discovered four new oilfields of varying size: The Tishreen near the Djubissa Field, the Habari in the Aleppo block, and the Salhié and Gebebeh in the extreme northeast. In 1976, the SPC was active in wildcat drilling employing Rompetrol and a Yugoslav firm as contractors and receiving technical assistance from the U.S.S.R.

The major part of Syria's natural gas production, estimated at 60 billion cubic feet annually, was flared in 1976 as in previous years. During the year, the SPC invited bids on a $40 million project to gather and process associated gas from the Suwaidiyah, Karatchuk, and Rumailān oilfields. The project, which was to be completed in 1978, included gas-gathering lines, trunklines, compressor stations, processing units, and supporting facilities. Production would consist of liquefied petroleum gas for home use, light gas fuel, industrial solvents, and sulfur. In addition, the Syrian Union of Engineering and Chemical Industries (UNICHEM) invited bids for prospecting for sulfur in the Al Jazīra area in northeastern Syria.

The production of phosphate decreased from 857,000 tons in 1975 to approximately 511,000 tons in 1976. Syria's three principal phosphate mines, Khunayfis and Sharqīyah A and B, were situated in the central part of the country about 50 kilometers south of Palmyra. About 40% of the production was exported, primarily to the Eastern European countries of Romania, Bulgaria, and Czechoslovakia.

In 1976, Cremer and Warner (United Kingdom) was contracted to act as technical adviser to the Syrian General Establishment of Chemical Industries (GECI) on all fertilizer projects. Three new fertilizer plants were to supplement Syria's single facility at Homs, which had a capacity of 110,000 tons of ammonia per year. Creusot-Loire Entreprise (France) was managing contractor for a nitrogen fertilizer plant under construction at Homs that was to produce 1,000 tons of ammonia and 1,050 tons of urea per day. The plant was due for completion in 1979. Industrial-export completed basic construction on a 1,400-ton-per-day triple superphosphate plant at Homs. The $180 million plant was to begin production in 1977. Industrialexport was also the contractor for a second triple superphosphate plant that was to be built in Deir el Zour in the northeast and have a capacity of 1,000 tons per day.

The exploitation of iron ore deposits in three areas of the country was under consideration by the General Establishment for Geology and Mineral Resources. Reserves at Rājū, 97 kilometers northwest of Aleppo, were estimated at 60 million tons of ore containing 31% iron; reserves in the Al Qadmūs region west of Damascus were estimated at 20 million to 30 million tons of ore containing 25% to 30% iron; and smaller deposits at Az Zabdānī were estimated to have an iron content of 30% to 35%. In 1976, approximately 3,400 tons of

ore was sent to North Korea for testing and feasibility studies.

The production capacity of the iron and steel complex at Hama was to be increased to 300,000 tons of product per year. An iron rod factory with an annual capacity of 110,000 tons of rod was recently installed. A metal pipe factory, which was to produce 20,000 tons of pipe per year, was under construction by Demag AG (West Germany). A sponge iron smelting factory was under construction by Brown Boveri Co. (United Kingdom). Studies were also being conducted regarding the construction of an iron plate unit and a factory to manufacture sheet steel.

PEOPLE'S DEMOCRATIC REPUBLIC OF YEMEN [23]

The mineral industry of the People's Democratic Republic of Yemen (PDRY) made a significant contribution to the 1976 GNP estimated at $200 million.[24] Mineral activity was limited to the production of salt and the refining of imported crude petroleum, but these commodities accounted for nearly 80% of total export value. The goals of the 5-year plan (1974–78), which scheduled a total expenditure of $225 million, included the intensification of oil and mineral exploration and the development of industries using local raw materials. An investment of $19 million was earmarked for mineral resource development in 1977, a 30% increase over 1976 expenditures in this sector. Both the Government and foreign companies were to continue oil and mineral prospecting, technical studies for a cement industry were to be conducted, and a salt factory was to be reopened.

In 1976, an agreement was concluded for the Government takeover of the nation's sole refinery operated by BP Refinery (Aden), Ltd. BP was to remain as operator for the refinery, which was to come under official Government control on May 1, 1977. Although the refinery was operating at 25% of its rated capacity of 160,000 barrels per day, it provided approximately 80% of the industrial output of PDRY. Built by BP in 1954, the refinery processed crude oil imported from Qatar, Kuwait, the United Arab Emirates, and other Arab States. In 1976, PDRY established diplomatic relations with Saudi Arabia and sought economic aid to finance the upgrading of the refinery as well as a source of crude oil.

Petroleum exploration continued under the production-sharing arrangements offered by the Government in 1975. Siebens Oil & Gas Ltd. (Canada) was to spend $14.5 million on drilling two wildcat wells in its 17,553-square-kilometer concession area in southern Socotra Island and its offshore area. In 1976, the company spudded a wildcat well, 1 Samhah, 113 kilometers southwest of Socotra Island in 380 feet of water. The U.S.S.R. firm Technoexport continued exploration in its 10,000-square-kilometer tract of the Thamud area. The South Yemeni Algerian Petroleum Co. (SYAPCO), a joint exploration company founded in 1971 by the Yemen National Oil Co. and the Algerian firm SONATRACH, was liquidated in 1976.

The Government also planned to expand its petroleum exploration program in 1977. A central administration was established within the Oil and Minerals Organization to supervise and coordinate all prospecting activity. In 1976, aerial surveys covering 10,000 square kilometers were conducted, seismographic surveys of the Ras Fartak area were completed, and exploratory wells were drilled in the Thamud region.

The country's large salt industry declined after 1970 owing to the loss of foreign markets. Salt production at the State-owned General Salt Organization facilities at Khawr Maksoir near Aden was chiefly for local consumption. The capacity for producing unrefined marine salt from the evaporation of seawater was rated at 80,000 tons per year. In June 1976, work was initiated on the reconstruction of a salt factory with assistance from the People's Republic of China.

Hunting Geology and Geophysics Ltd. (United Kingdom) was contracted for a second year of mineral exploration by the Board of Petroleum and Minerals. The $1.7 million contract was to involve prospecting and drilling of copper occurrences in the Maahir-Ghabar area, 50 kilometers

[23] Prepared by Candice Stevens.

[24] Where necessary, values have been converted from Yemeni dinars (SYD) to U.S. dollars at the rate of SYD1 = US$2.90.

southwest of Mukalla, and the investigation of heavy minerals in beachsands along the coast. In 1976, the use of geological mapping, geochemistry, and geophysics resulted in the identification of four main targets in the copper area for further drilling. Sampling was in progress to confirm preliminary estimates of the ilmenite, zircon, and rutile content of beachsands in five zones. Mineralogical and geochemical laboratories were set up in Mukalla for the training of Yemeni personnel.

The Government was to continue its magnetic and radial surveys of the western region and its geological survey of iron and titanium resources in the Wadi Mikayris region.

Nearly 25% of the expenditures in the 5-year plan was allocated to infrastructure development. Electricity generating capacity was to increase 80% by the construction of two powerstations in Aden and one in Mukalla with a total capacity of 80 megawatts. PDRY and the Yemen Arab Republic (YAR) received a loan from the AFESD to help finance a 150-kilometer road linking Aden to Ta'izz in the YAR. Improvements in port facilities at Aden were to be made under the auspices of the AFESD and IBRD. Aden was once one of the world's largest oil bunkering ports but after the closure of the Suez Canal in 1967, this activity declined and has not resumed despite the reopening of the Canal. Renovation and modernization of the port was expected to cost $17.4 million. During 1976, negotiations were conducted with Saudi Arabia regarding the construction of an oil terminal on the Hadhramaut coast to be linked by transpeninsular pipeline to Saudi and other oilfields in the region.

YEMEN ARAB REPUBLIC [25]

The mineral industry of the Yemen Arab Republic (YAR) was a minor contributor to the nation's economy during 1976. Mineral industry activity was limited to the production of cement, the mining of salt, and oil exploration in the Red Sea. The nation's economy continued to expand at a modest rate despite an inflation rate of 35% during the year. The balance of

[25] Prepared by David E. Morse.

trade deficit increased by $100 million [26] to approximately $350 million in 1976. Remittances from Yemenis working abroad more than offset the trade deficit and the YAR had a positive net balance of payments for the year.

The large-scale expansion of the As Salif port, completed during 1976, had suspended for the most part rock salt exports since 1973. Prior to that time, exports of rock salt from open pit operations at As Salif had averaged 70,000 tons per year. The new modern facilities were able to export rock salt at a rate of 1 million tons per year. The Government planned to produce chlorine, hydrochloric acid, and caustic soda, utilizing rock salt as feed.

The country's only cement plant at Bājil, near the nation's major port of Hodeida, continued to operate below its 50,000-ton-per-year capacity. A large portion of the YAR's cement needs was met by imports during 1976. A second cement plant with a 300,000-ton-per-year capacity was planned for the Hodeida area although financing and contractual agreements had not been arranged by yearend.

No oil was produced in the YAR during the year and petroleum products had to be imported. A Royal Dutch/Shell affiliate drilled an exploratory well in its 10,000-square-kilometer offshore Red Sea concession area during 1976. The Government announced plans to build a petroleum refinery at As Salif, one of the best natural harbors on the Arabian Peninsula, and to construct a petroleum products pipeline from the refinery to the capital, San'a, on the 8,000-foot central plateau. During 1976, petroleum products had to be transported by tanktruck to San'a, which added significantly to the cost of fuels in the central region.

ECUADOR

Ecuador's real gross domestic product (GDP) increased 6% in 1976 despite persistent shortages of electrical power and essential fuels, which caused factory slowdowns and shutdowns. Petroleum export earnings, which made up more than 50% of total export value in 1976, totaled $565 million, a 9% increase over those of 1975.

A new 60,000-barrel-per-day oil refinery at Esmeraldas was scheduled to go on-stream in mid-1977, operating entirely on Ecuadorean crude. Corporación Estatal Petrólera Ecuatoriana (CEPE) started construction of a 600-kilometer network of product pipelines which was scheduled to be completed in 1977 to coincide with the completion of the refinery.

The Government was considering increasing the legally required production rate of 210,000 barrels per day to 240,000 barrels per day, starting in 1977, to offset the increasing domestic demand. To attain and maintain such an increase, large-scale exploration in the El Oriente region would have to be resumed. Petroleum produced in the El Oriente region was being piped 350 miles across the Andes to the coast at Balao. Reserves in the area were thought to be sufficient for at least 12 years at current production rates. Most of the oil produced there was by the CEPE-Texaco Inc.-Gulf Oil Corp. consortium. CEPE, in conjunction with an Argentine counterpart, planned to drill in new areas of the El Oriente jungle. CEPE also conducted a seismic study of 3,500 square kilometers on the Continental Shelf.

On June 21, 1977, Gulf ceased payments to Ecuador for the crude oil it lifted, placing the money in a special interest-bearing account pending settlement of several complaints against the Government. The Minister of Natural Resources had opposed Gulf's case for improved operating terms and had transferred the domestic marketing operations to State ownership.

At the La Plata mine, operated by Cia. Minera Toachi and Outokumpu Oy of Finland, annual output was scheduled to increase to 1,500 tons of copper, 3,000 tons of zinc, 4,823 troy ounces of gold, and 51,441 troy ounces of silver, all in concentrates, which were to be exported to Finland for smelting. Ore reserves were estimated at 180,000 tons.

A steelplant with an annual capacity of 400,000 tons was planned in the Posorja area, south of Guayaquil. The plant was scheduled to go into operation in 1981.

Uranerzbergbau GmbH, a West German company, was granted permission by the Government to start preliminary investigations for uranium prospecting.

e Estimate. p Preliminary. r Revised. NA Not available.

[1] In addition to the commodities listed, a variety of crude construction materials (common clay, sand and gravel, and stone) undoubtedly are also produced, but output is not reported and available information is inadequate to make reliable estimates of output levels.

[2] Gem and industrial diamond production are estimated based upon a reported total production.

[3] Data represent exports.

[4] Reported volumetrically as 59,183 cubic meters.

[5] Reported as 26,000 tons.

FRENCH GUIANA

Minor quantities of gold, clay, sand and gravel, and crushed stone were produced in French Guiana during 1976 for local consumption.

The Bureau of Geological and Mining Research continued its survey of mineral resources. The survey reports were being made available to firms that had indicated an interest in the development of minerals in the country.

Development of the bauxite deposits, which have been known for a long time, was still not economically feasible under present world prices because of their low quality.

GUYANA

The Government-owned Guyana Bauxite Co. Ltd. (GUYBAU) experienced reduced bauxite and alumina production during 1976. However, the reduced production was offset by price increases, particularly for calcined bauxite, which accounted for over half of the bauxite exported from Guyana. Nevertheless, earnings for the bauxite industry and output of the country's main agricultural commodities were below the 1975 level, factors which caused a setback in the country's economy. The western industrial countries remained Guyana's major export markets for bauxite and alumina. In 1976, the United States purchased 34% of Guyana's calcined bauxite shipments and 37% of its dried bauxite exports.

The Government of Guyana actively promoted the concept of a common denominator unit within the membership of the International Bauxite Association (IBA) to cover sales of alumina and metallurgical-grade bauxite. This followed the promising initial performance of Guyana's composite currency unit (CCU), based on a basket of four internationally traded currencies, which had originally been devised for its own calcined refractory-grade bauxite.

Guyana's development plan centered around the bauxite industry. The Government planned a hydroelectric project on the upper Mazaruni River to be accompanied by construction of a large aluminum smelter. The Government expected to use power generated at Mazaruni to displace the country's total dependence on petroleum for power. The cost of the project was estimated at $120 million and was to be financed 52% by Guyana and 24% each by Trinidad and Tobago, and Jamaica.

As part of an effort to attract foreign private investment, the Government of Guyana was preparing an investment code to be released in 1977. During 1976, private investment was tolerated, but major projects were to be in partnership with the Government. Generally, the Government required majority participation, control of exports and imports, and eventual management control.

PARAGUAY

Cement is the most important mineral produced in Paraguay (155,000 tons in 1976). Sizable resources of nonmetallic minerals (marble, limestone, kaolin, talc, and gypsum) are known to exist in undetermined quantities, but they were produced only for domestic consumption. Small iron ore, manganese, and copper deposits exist in eastern Paraguay, but there were no known plans to exploit them.

The Government and Anschutz Corporation of the United States signed an agreement for the exploration of a concession area covering 168,000 square kilometers in eastern Paraguay. The 7-year agreement allowed exclusive exploitation of metallic and nonmetallic minerals, including radioactive and precious metals.

The search for petroleum in Paraguay was shifting into high gear, with five exploratory wells scheduled to be drilled in early 1977 by Texaco Paraguay, Inc., and Chaco Exploration Co.

The mammoth Itaipu hydroelectric project under construction jointly by Paraguay and Brazil employed 15,000 workers, 85% of whom were Paraguyans. The project brought about $100 million in foreign exchange to Paraguay in 1976, part as payment for Paraguyan goods and services and part as capital transfers.

A second proposed hydroelectric project at Yacyretá, to be built in conjunction with Argentina, was contingent upon financing. If financed, work is scheduled to begin late in 1978. Completion of these dams should provide Paraguay with relatively cheap hydroelectrical power, with some of it available for the export market.

[1] In addition to the commodities listed, Paraguay reports imports of "precious stones and metals" totaling 3 metric tons in 1974 and 2 metric tons in 1975.

[2] Less than ½ unit.

SURINAM

Surinam began its first year of independence with a generally depressed bauxite industry and a stagnant economy. Bauxite shipments both by Aluminum Co. of America's (Alcoa) wholly owned subsidiary Suriname Aluminum Co. (SURALCO) and the Royal Dutch/Shell-owned NV Billiton Maatschappij Suriname declined more than 10% from the 1975 level. The decline was attributed to the multiyear contracts that the companies had with their customers and the long rainy periods which made mining difficult.

Negotiations between the Government and Billiton brought a quick agreement on the Government's bauxite levy for 1976. Despite Billiton's plea for financial relief, the agreement continued the levy at the same rate as in 1974 and 1975. However, the Government did not insist on bauxite production guarantees from Billiton as it did in the case of SURALCO. SURALCO guaranteed a minimum total bauxite production of 8.4 million tons during the 3 years of the agreement.

The Government's program to develop an integrated bauxite-to-aluminum project was underway with the partial completion of a railroad line connecting the deposits in western Surinam with the port of Apoera on the Corantijn River. The Government-owned company Grassalco was to be the developer.

Despite negative results throughout the year, interest in petroleum exploration remained alive. Esso Standard Oil Co. began new seismic and geophysical investigations offshore with much optimism.

The Government of Surinam and Placer Development Ltd., a Canadian company, signed an agreement for further exploration in the Brokopondo District where gold had been mined previously. The Government was taking steps to encourage domestic entrepreneurs to get involved in small-scale mining.

As part of its import substitution effort and to meet local demand for building materials, the Government decided to establish a brick industry in the Para District. The factory, with a proposed capacity of 30,000 to 50,000 brick per day, was to create an additional 100 to 150 jobs.

The Government continued to seek external financing for the multimillion-dollar Kabalebo hydroelectric project, which was to be principally financed by development aid from the Netherlands.

The Norwegian firm A/S Ardal og Sunndal Verk, owner of a process for extraction of iron from lateritic bauxite ores, sent a mission to Surinam early in 1976 to investigate the feasibility of a local iron and steel industry.

Table 5.—Surinam: Exports of mineral commodities [1]

(Metric tons)

Commodity	1974	1975	Principal destinations, 1975
Aluminum:			
Bauxite	3,320,140	2,170,031	United States 1,952,000; Canada 113,303; West Germany 54,098.
Oxide (alumina) and hydroxide	1,111,417	1,056,368	United States 441,618; Norway 236,835; Netherlands 218,475.
Metal including alloys, all forms	33,816	25,039	United States 11,837; West Germany 8,011.

[1] Compiled from import statistics of selected trading partner countries.

URUGUAY

Uruguay's modest mineral industry experienced a further disappointment in 1976 with the failure of exploratory offshore drilling for petroleum. The GDP, however, increased 4% (in 1961 prices), following many years of little or no increase.

The Administración Nacional de Combustibles, Alcohol y Portland (ANCAP), which had a monopoly on the import, refining, and distribution of hydrocarbons and the manufacture of cement, was under consideration to have some of its uneconomic functions transferred to the private sector. This would be consistent with the Government's policy of reversing the trend of nationalization that was predominant in the last 50 years.

South African technical assistance was provided to explore coal deposits in the three northeastern departments along the Brazilian border. These deposits were thought to be an extension of occurrences that had been previously exploited on the Brazilian side of the border. They were discovered in the 1920's but had not been mined in Uruguay because of their slaty nature and high sulfur content.

BRITISH SOLOMON ISLANDS

The British Solomon Islands Protectorate continued developmental work on bauxite deposits on the Islands of Rennell and Vaghena. A feasibility study was completed by Mitsui Mining & Smelting Co., Ltd., and Pacific Aluminum Ltd. (a subsidiary of Conzinc Riotinto of Australia Ltd.), and negotiations with the Government were in progress. The Government will receive a 25% share if the project is realized. It was estimated that the Islands contain 60 million tons of bauxite with an alumina content of 45% to 50%.

[1] These areas undoubtedly produce crude construction materials (common clays, sand and gravel, and/or stone) in addition to the listed commodities, but output is not reported and information is inadequate to make reliable estimates of output levels.

[2] Exports.

[3] Nickel-cobalt content of metallurgical plant products, plus nickel-cobalt in exported ores.

CHRISTMAS ISLAND

Phosphate rock and dust remained the only mineral commodity produced on Christmas Island during 1976. The commercial history of the Island, located in the Indian Ocean 2,600 kilometers northwest of Perth, Australia, dates from 1900. As of yearend 1976, some 24.3 million tons of phosphate had been produced in the Island's history.

Owing to strong demand in Malaysia, output of phosphate rock increased about 8%. The 1.4 million tons produced was valued at about $80 million.

The base rock of the Island is volcanic and is covered by coral limestone that forms an irregular pattern of pinnacles. The coral limestone is covered by phosphate in beds averaging 6 meters in depth. There are three basic grades of phosphate, ranging from 25% to 36.5% P_2O_5. The average grade of phosphate exported ranges from 32% to 35% P_2O_5.

FIJI

Gold and river sand and gravel were Fiji's principal mine and quarry products. In 1976, these products accounted for $11.7 million,[2] or 88% of the total mineral value of $13.3 million. Quarried stone and coral sand contributed $1.1 million, and other minerals supplied the remaining $0.5 million.

Gold, silver, and tellurium were produced by Emperor Gold Mining Co. Ltd., a wholly owned subsidiary of Emperor Mines Ltd. The company produced 65,757 troy ounces of gold, 19,773 troy ounces of silver, and 1,109 kilograms of tellurium during the year. The average price of gold fell to $131.61 per troy ounce; Emperor Gold Mining consequently recorded a net loss of $884,530. The company gave serious consideration to closing down the whole operation because of the unfavorable economic conditions. The Emperor Gold Mining mine was Fiji's largest employer, and every effort was made to postpone the decision; at yearend, no decision on the future of the mine had been reached. Measured reserves were estimated at 1.3 million tons averaging 0.3 troy ounce of gold per ton.

Production of river sand and gravel nearly doubled that of 1975. Output of both coral sand for cement manufacture and limestone also increased substantially.

Diamond drilling by Emperor Mines near the Old Misty mine, south of Nandi, proved to be disappointing and the prospecting license was relinquished. Preliminary results of stream-sediment and soil-sampling surveys at Mount Kasi on Vanua Levu Island were encouraging, however, and an additional license was obtained. Emperor Mines was seeking partners for a joint venture to continue exploration in this area.

An exploratory drilling program carried out in the Tavua Basin and Nasivi Delta areas of Fiji by Anglo Pacific Exploration Ltd., Mount Isa Mines Ltd. (MIM), and Emperor Gold Mining established that the overall gold content of the alluvium was not economical.

NAURU AND OCEAN ISLAND

The Republic of Nauru and Ocean Island (the latter a member of the Gilbert and Ellice Islands Colony) lie just south of the equator, halfway between Honolulu, Hawaii, and Melbourne, Australia. Nauru's per capita income of $22,500 in 1976 was the world's highest. Phosphate rock remained the sole mineral produced on both islands, and the total output was exported.

The combined phosphate rock output of 1.2 million tons was 43% below that of 1975, owing to decreased demand in Australia and New Zealand. Income from the phosphate rock, which averaged 83% P_2O_5, totaled more than $130 million in 1976.

A calcining plant operated by Nauru Phosphate Corp. began production during the year. The plant treated surface rock previously not exported because of low phosphate content. Capacity of the two calciners in the plant was approximately 400,000 tons of P_2O_5 per year.

NEW CALEDONIA

The French island territory of New Caledonia, about 1,600 kilometers east of Australia's Queensland coast, continued as one of the world's major nickel producers. The political and administrative organization of New Caledonia, located at the capital city Nouméa, was headed by a high commissioner, a territorial assembly, and a council of government. In France, the territory was represented in Parliament by one deputy and one senator.

Nickel operations were dominated by Société Métallurgique le Nickel (SLN), a subsidiary of the French Imétal S.A. and Elf-Aquitaine groups. SLN produced garnierite ores from several mining centers on the island. Some of the company's output was shipped as ore directly to Japanese smelters when demand was strong. However, most was shipped to SLN's Doniambo smelter at Nouméa.

The local territorial assembly passed legislation improving the fiscal position of mining companies on the island. The legislation imposed a 50% tax on industrial and commercial profit but abolished the heavy export tax. Because of a more favorable tax structure and increasing demand for nickel, SLN announced a $200 million[3] expansion plan.

TRADE

Exports of minerals, mainly nickel ore, ferronickel, and nickel-cobalt matte, were valued at about $360 million in 1976, compared with $371 million in 1975. Exports of nickel ore, mainly to Japan, increased from 2.5 million tons in 1975 to 2.7 million tons in 1976. The average grade of exported nickel ore was 2.38% nickel plus cobalt. Exports of ferronickel and matte during the year totaled 51,490

[3] Where necessary, values have been converted from New Caledonian francs (CFPF) to U.S. dollars at the rate of CFPF86.14=US$1.00.

tons of nickel content—38,169 tons in ferronickel and 23,759 tons in matte. More than 75% of the ferronickel and 50% of the matte was shipped to France. The remaining ferronickel was shipped to the United States, Japan, and Australia. Of the remaining matte, the United States was the principal recipient, followed by Japan, Canada, and Finland.

COMMODITY REVIEW

Chromite.—Output of chromite by Société de la Tiébaghi was 9,537 tons, more than four times the 1975 output. Most (9,105 tons) was exported, mainly to Japan. The ore contained 45.7% Cr_2O_3 and 0.8% moisture.

An exploration program for chromite by International Nickel Co. of Canada Ltd. (INCO), through its French subsidiary Société de la Tiébaghi, continued. INCO reached an agreement with Compagnie Minière Dong-Trieu and Compagnie Financière de Paris et des Pays-Bas on the terms of an exploration program and feasibility studies. The 18-month program, which was expected to cost around $4 million, started at the end of 1976. If it proves economically viable to reopen the mine in the prospect area, the property could be brought into production by 1980.

Nickel.—Nickel ore production dropped 11.5% below that of 1975. SLN, with operations at four main mining centers on the island, remained New Caledonia's principal ore producer. Its main mining areas were Népoui and Kouaoua. Nickel output was limited by the capacity of the Doniambo smelter, located at Nouméa, which was about 85,000 tons per year of nickel contained in ferronickel or matte. This level was achieved only by utilizing the old blast furnace section and the newer electric furnaces. The company planned to increase output to 100,000 tons per year at an estimated cost of $200 million. The first $40 million would be expended in 1977, and the full program would be completed in 1981. Nickel ore production at two of SLN's mining centers would be substantially expanded. Output at Népoui, the largest, would increase to around 2 million tons per year. At Kouaoua, ore production would be increased to 1.2 million tons per year, twice the current output. Ore from Népoui was shipped to a central ore-transfer point, then carried portside by a 13-kilometer-long belt conveyor. The conveyor had a capacity of 800 tons per hour and would easily handle the expanded tonnage. Reserves at both Kouaoua and Népoui were considered sufficient to support the projected expansion program.

In addition to the SLN expansion, there was the Compagnie Française d'Entreprises Minières Métallurgiques et d'Investissements (COFREMMI) program in the northern part of the island. Originally a subsidiary of Patino N.V., COFREMMI was owned 90% by the French Government agency Bureau de Recherches Géologiques et Minières (BRGM). COFREMMI was involved in feasibility studies for a $150 million project on garnierite deposits at Tiébaghi, Poum, and Ile Cert. The program was to produce 40,000 tons per year of ferronickel. Initially it was anticipated that COFREMMI would complete the feasibility studies before inviting other overseas mining companies to participate in a development scheme; however, in late 1976, other companies were asked to submit metallurgical appraisals.

NEW HEBRIDES

Manganese remained New Hebrides' only mineral product. Output by Cie. Française des Phosphates de l'Oceanie at the Forari manganese mine on Efate Island declined slightly from that of 1975. The ore was upgraded to a 42% manganese concentrate which was exported, mainly to Japan. The past 10 years' production and export data are as follows, in tons of contained manganese:

Year	Production	Exports
1967	27,658	27,948
1968	21,306	17,432
1969	--	--
1970	5,948	11,057
1971	5,811	5,776
1972	10,942	14,548
1973	12,674	10,840
1974	19,871	17,225
1975	19,538	18,340
1976	19,320	NA

NA Not available.

PAPUA NEW GUINEA

One year after national independence, Bougainville Copper Ltd.'s copper mine at Panguna remained the only significant mining operation in Papua New Guinea. Exploration was widespread, mainly for copper but also for other minerals such as nickel, chrome, bauxite, molybdenum, and petroleum. Limestone and sand were produced for local use and gold was produced in the Bulolo-Wau area. With slightly higher copper production, the total mineral value increased to around $258 million.[4] Copper prices, however, remained at the depressed levels of 1975, despite a brief midyear rally. The average price of gold was higher, but there was no change in the price of silver. The country's gross national product (GNP) was estimated at $1.2 billion, of which mineral output accounted for 21%.

A contract between the Government and OK Tedi Development Co. was concluded along the general lines of the renegotiated

[4] Where necessary, values have been converted from Papua New Guinea dollars (K$) to U.S. dollars at the rate of K$1=US$1.26.

Bougainville Copper agreement. An agreement was also reached with seven major U.S. oil companies conducting exploration in the Gulf of Papua. The policy included a basic income tax on oil and gas production to be paid to the province in which the oil was located. The Government indicated that an additional profit tax to oil producers would be equal to 50% of after-tax cashflow. No additional profit tax would be charged for natural gas, but the Government would take a free participation share equivalent to a royalty of 8% to 16%, depending on production.

The Mineral Resources Stabilization Fund was set up through which would pass all income accruing to the Government from major natural resource projects. The aims were to insure an even flow of income to the Federal budget and to insulate the economy from price fluctuations in the world market.

COMMODITY REVIEW

Copper.—The Panguna operation accounted for 61% of total export earnings of $431 million in 1976. Bougainville Copper, the operating company, was owned by Conzinc Riotinto (53.6%), the Government (20%), and public shareholders (26.4%). The company was incorporated in 1967, and production and export of copper concentrates began in 1972. The Panguna ore body was worked by open pit methods and the concentrates were slurried and pumped to the port of Anewa on the east coast of Bougainville Island, a distance of 25 kilometers.

In 1976, the mill treated 32.23 million tons of ore and produced 596,833 tons of concentrate containing 175,806 tons of copper, 20,222 kilograms of gold, and 45,387 kilograms of silver. Sales totaled 179,081 tons of copper, 20,494 kilograms of gold, and 46,065 kilograms of silver. Contract shipments to Japan were curtailed during 1975 and 1976, but the company was able to sell all of its production. Bougainville Copper announced that it would spend $12 million over the next 2 years to build a tunnel into the nearby mountain range to drain the open pit mine. The multi-million-dollar tunnel project was part of an overall efficiency plan being carried out by the company's engineering, operational, and work-force divisions. The mine was approximately 300 meters below the level of the nearby river system, and mine drainage was becoming increasingly difficult. The tunnel would run for 7 kilometers under the surface and emerge at a point where gravity would allow the water to drain into the river system.

Carpentaria Exploration Co. Pty. Ltd., a subsidiary of MIM Holdings Ltd., was developing a porphyry copper prospect in the Sepik River area with a consortium of Japanese companies comprising Sumitomo Metal Mining Co., Ltd., The Dowa Mining Co., Ltd., and Marubeni Corporation. The consortium could earn a 40% interest by spending $5 million on exploration and other work over a 5-year period. Reserves were estimated at 366 million tons of ore averaging 0.45% copper. The deposit is located in a very remote region.

The Government negotiated an agreement with Broken Hill Pty. Co. Ltd. (BHP) to form a consortium to complete the investigation at OK Tedi and study the economics of the whole project. The consortium reportedly comprised BHP (30%); Amoco Minerals Ltd., a subsidiary of Standard Oil Co. of Indiana (25%); and four West German metal processors (25%). The remaining 20% would be taken by the Government under an equity credit arrangement. Feasibility studies were scheduled for completion in January 1979, and if a mine is developed, it would be in operation by 1984.

Exploration work continued on the Yandera copper prospect, initially investigated by Kennecott Exploration Pty. Ltd. BHP, through its wholly owned subsidiary Dampier Mining Co. Ltd., agreed to spend $1.2 million to acquire a 61% interest in the project. Initial drilling indicated the presence of ore averaging 0.46% copper and 0.12% molybdenite.

On Manus Island, porphyry copper ore was being explored by a joint venture of Exoil N.L. (70%) and Transoil N.L. (30%). Buka Minerals N.L. was investigating copper, gold, zinc, and molybdenum deposits in New Britain. Nickel prospects of 1.1% nickel were being investigated by Eastern Pacific Mines Pty. Ltd., which engaged Carpentaria Exploration for surface mining.

Petroleum.—United States, Japanese, British, and Australian companies con-

tinued the search for crude oil and natural gas, but no commercial discoveries were made. Esso Australia Ltd.'s first well in the Gulf of Papua was dry, but Esso planned to spend another $10 million on a second well in the swamp between Gulf and Western Provinces. Both Cities Service Co. and Gulf Oil Corp. planned exploration in the Southern Highlands. The Government wanted the oil companies to intensify exploration activities.
