The libraries provide public access to a wide range of material, including online exhibits, digitized collections, archival finding aids, our catalog, online articles, and a growing range of materials in many media.

When possible, we provide rights information in catalog records, finding aids, and other metadata that accompanies collections or items. However, it is always the user's obligation to evaluate copyright and rights issues in light of their own use.

U. S. GEOLOGICAL SURVEY
FIELD SECTION BOOK

No. 45.

July and August, 1885.

Vermillion Lake Country, Minnesota

R. D. Irving

10185-10190, 9734-9799, 8565-8709

Survey of the Pre-Cambrian Rocks of the N. W. States.

INSTRUCTIONS.

1. Ordinarily at least two pages of this book will be devoted to one section. On the left hand page place a map of as much of the section as has *actually been seen*. Denote rivers, lakes, marshes, etc., by the usual topographical signs. Denote the ledges of rock, when no structure is made out, by cross-hatching, making the cross-hatching cover as nearly as possible the areas occupied by the exposures. If the rock is a massive one, but still more or less plainly bedded, use the same sign with a dip arrow and figure attached, showing the amount and inclination of the dip. Denote slaty or other very plainly bedded rocks by lines running in the direction of the strike, with figures and a dip arrow attached as before. In all cases where there is the least doubt about the true bedding directions, indicate it by a query. To each exposure on the face of the map attach the number of the specimen representing it. In mapping the section count each of the spaces between the blue line as 100 paces, and twenty of these spaces as one mile, or 2,000 paces. Usually the southeast corner will be placed at the bottom of the page, or at the first black line above the bottom of the page, and at the right hand side. If, however, for any reason, it is desirable to show portions of an adjoining section, the southeast corner may be shifted up, or the map may be turned around and the north placed at the left hand side of the page.

2. On the right hand page place the notes descriptive of the exposures. Begin in each case with the number of the specimen, placing the number on the left hand side of the red line, after which give in order on the right of the same red line the position of the ledges as reckoned in paces from the southeast corner of the section, and the dip and strike when observable, for instance: 4025 | 250 N., 300 W., *Strike, N. 6° E., Dip, 50° E.* Then follow with as full a description of the ledge as possible.

3. The ruling of the left hand page is also arranged so that a smaller scale can be used. Each one of the black lines may represent a section line and the red lines quarter sections and "forties." The scale of the maps may thus be reduced, if desirable, to two inches to the mile (the ordinary town plat scale.)

4. Collect a specimen from each separate ledge of rock, or wherever there is a change of rock on any one ledge. In case of trips made on foot or in canoes, for long distances, neighboring ledges, unquestionably of one kind of rock, need not be sampled, the position and extent of the ledge being marked on the map, with a note that it is of a rock identical with specimen so-and-so. Under the same conditions small sized samples, trimmed to a uniform size of $2 \times 2 \frac{1}{2} \times \frac{1}{4}$ inches will be allowed, but in all other cases *large sized specimens*, trimmed to a size of $3 \times 4 \times 1$ inches, must be selected, in accordance with $\frac{1}{2}$ 3, chapter IV, p. 44, Regulations of the U. S. Geological Survey. In all cases collect chips for slicing. All specimens are to have numbers painted on them, in white on a black background, in the field.

5. On the last twenty-five pages of the book give, as may seem desirable, a general account of the examination of the region mapped in the previous pages, correlation of observations, sketches, cross sections, etc., etc.

6. Forward this note book, as soon as filled, as registered mail matter, to R. D. IRVING, U. S. Geologist, Madison, Wis.

Magnetic Dec. in the U. S.
Appendix No 13 Report for 1882.

Vermillion Lake Region
Minnesota

July - August 1885
R. D. Irving.

9734 - 9799

8564 - 8709

names write under spec. nos. as determined by
study of thin section - except when word "lites"
is used - when macrosc. only.

July 28 1885

3

10,187

at A. white quartzite with pebbles
flattened - also slate bands irregu-
lar - abruptly terminating, but trend-
ing on the whole E-W. Dip high N.
See Merriam's notes also.

10,188

10,189

10,190

Note how immensely these
rocks are squeezed

9734

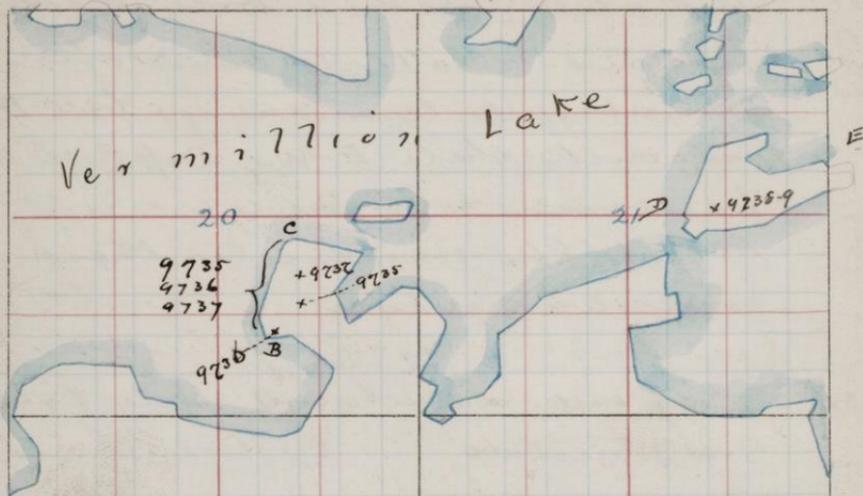

See opp. map. Dark colored slaty rock
E-W structure

10,185

white quartzite - see Merriam's notes

10,186

Speckled grey quartzite - see Merriam

fractured apart; and again in entirely detached fragments in the corner rock. Are these the result of the brecciation? or genuine pebbles? I think undoubtedly the former. Here, towards the end of the point are no less than three belts of the banded slaty iron y rocks. These masses are lens-shaped. At least we think the lens shaped terminus gone. They are irregular in the extreme; often complicatedly brecciated.

9735- slate from this point, from a place where the bedding was horizontal. shows cleavage and bedding lenses

9736 Brecciated ^{slate and quartzite} ~~cherty beds ferruginous~~ from here

9737 Banded cherty ferruginous material from here

Note that slate and quartzite are here inter-banded just as in the Animikie series - the only difference being the folding, cleavage, brecciation. Merriam has further specimens from here

July 29/885

5

9235
9236
9237

Point BC, sec. 20. Landing at B we found slates and quartzites strangely jumbled, and brecciated; probably all the result of squeezing. Coarser layers alternate with thin slaty ones, and slaty cleavage is beautifully shown. Indeed the whole series of this part of the lake owes its E-W structure or $E 10^{\circ} S$ to $S 10^{\circ} N$ structure to slaty cleavage. The bedding, as shown by beautifully marked laminations, is now with the cleavage, or vertical, and again slightly to the N or S of the cleavage, and again horizontal. So we have even in the short distance along the point BC of opp. map, several folds, very closely appressed. Even on a horizontal, or approximately horizontal surface, there is often an appearance like this:-

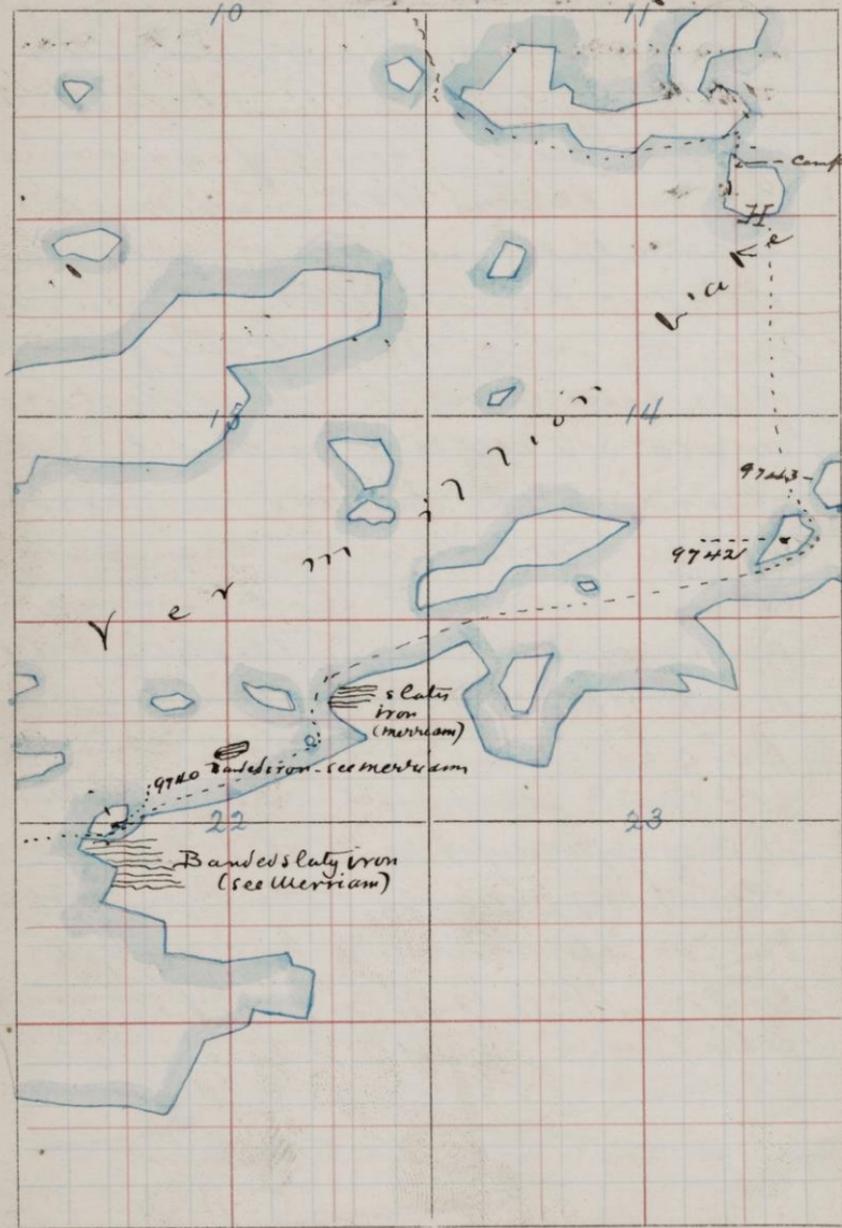

The lines show slate in sharp bends in the coarser rock, and again slaty layers

6 Vermillion Lake

T. 62

R. 15

9738 Pebbles and boulders from the coarse conglomerate of island DE map on p. 4. Are they quartz porphyry?

9739 Pieces broken from the cherty iron masses of the great conglomerate of the island DE. Note that they are largely silicified black slate

9740 Supposed massive rock from small island - see map p. 6 - Is it a quartz porphyry? and the source of the pebbles 9738?

9741 The conglomerate of the island DE (map p. 4 - Same as 9738 - Chewing matrix.

9742 See map p. 6 - Is it a massive quartzite?

9743 (Treat as local doubtful) see map p. 6 - Full of interlacing white quartz veins, several inches wide, orange when.

T.

R.

See map p. 6.

Vermillion Lake

9

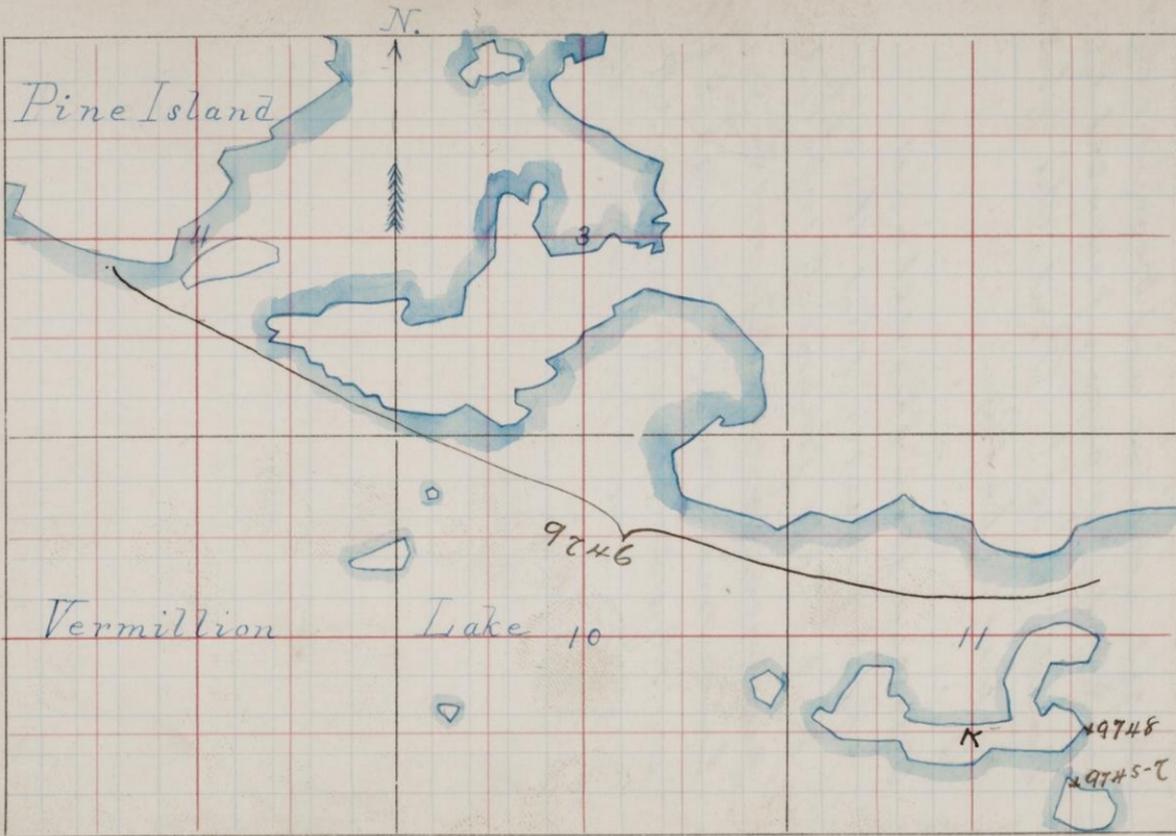

9744

Island H. map p. 6 - shows a highly schistose and brecciated slate rock. Dip of apparent sedimentary bands E 30°! But the rock is jumbled badly.

9745

Breccia from this island.

Is it possible that the apparent slate fragments indicate an unconformity with a lower green schist series? Or are they simply the result of queering and brecciation in this slate itself?

Pine Island

N.

3

4

9746

Vermillion

Lake 10

11

K

9745

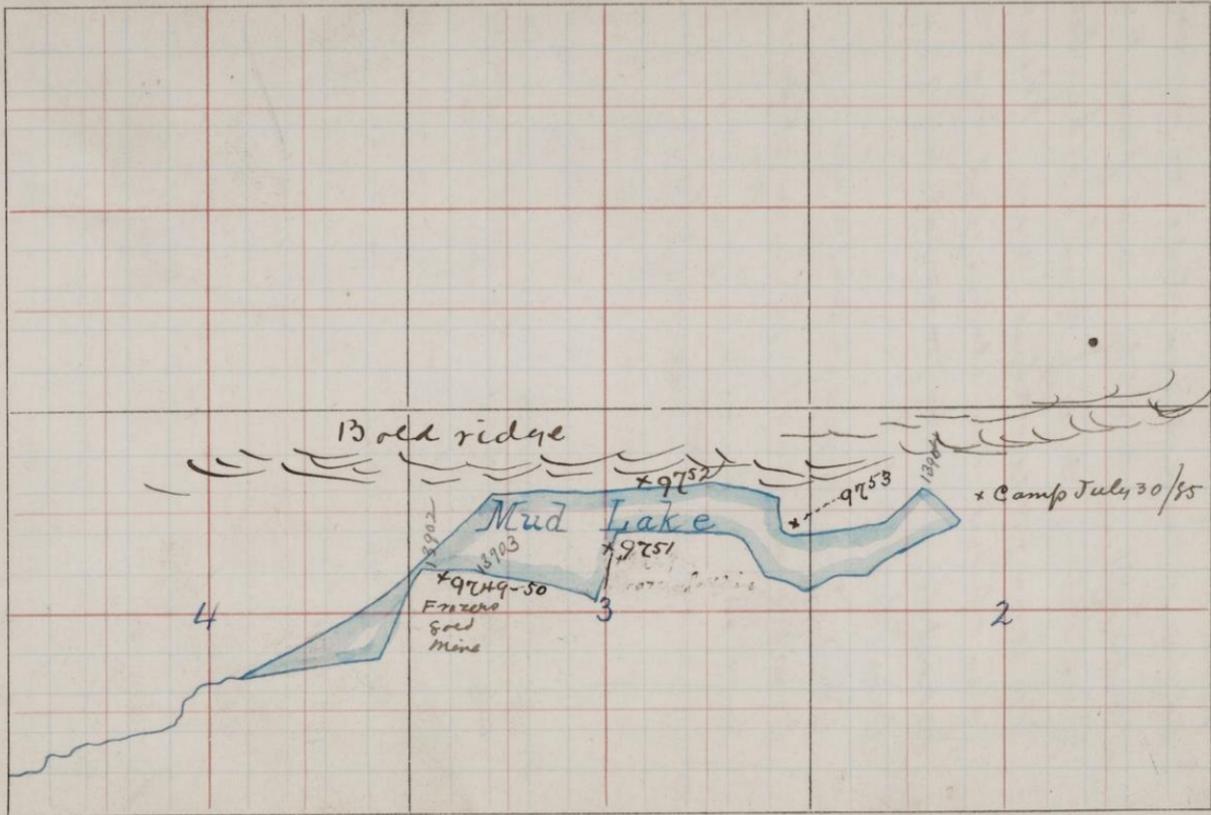

9745-2

July 30 / 85

11

- 9746 Specimens from along the north shore of Vermillion Lake in Sections 11, 10 & 4, 62 15W. and from E end Pine Island in Sec. 4. Do they belong to a lower "green-schist" series. They are often whitish, non-slaty, but highly schistose. Are the fragments in 9745 from these slates?
- 9747 Some large fragments contained in 9745 from the island H. They are squeezed look into this.
- 9748 Rock of island K. seems to be an acid rock. Has it furnished the pebbles 9747

See Merriams notes and specimens for further information

Mud Lake

13

9249 South side Mud Lake SW. No. 3
62 14. A crystalline rock. Fraser
"gold mine". Is it a quartz-propylite?
The source of pebbles in the conglomerates
of Millin Lake etc?

9250 Same place as 9249 and more represen-
tative
Q. propylite

9251 Forms rounded and jointed masses
on the south side of Mud Lake -
on the west side of the Horns point
on the south side of the Lake. N. side SW. 1/4
N.E. 1/4 3, 62, 14. Is it fragmental?
or cherty? or grey-cracked. Dark grey
very dense, chert like.

9252 On north side Mud Lake rises a bold
ridge of rock, 100 feet high, a
continuation of that north of
Millin Lake? and of Pine Island.
Where we sampled it it is a jointed to
schistose rock much decomposed - that
with calcite seams. The specimen
is from the lake then No. N.E. 3 62

T.

R.

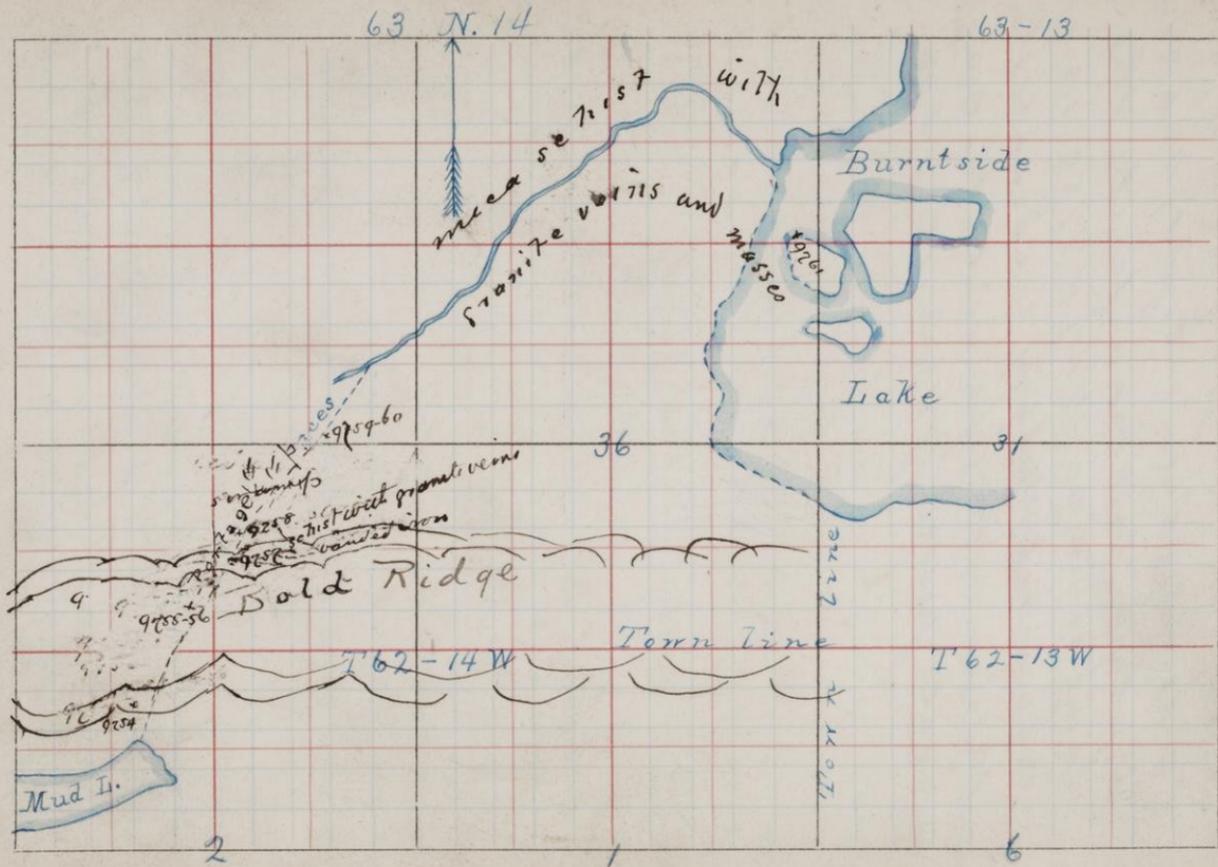

The image shows a page of graph paper with a grid of small squares. A vertical red line runs down the center, and several horizontal red lines run across the page. The page is divided into two columns by the central vertical line. The left column is labeled 'T.' and the right column is labeled 'R.'. The grid is empty, and the page is otherwise blank.

Mud Lake

15

9753

From point NW 1/4 of N.S. of 3, west
side Mud Lake - highly schistose
in places, but manifests the
same rock as 9749 & 9750 - i.e. is
a quartz porphyry, undoubtedly,
the rock which furnishes the conglom-
erate pebbles of Vermillion Lake

July 31 1885

17

- 9754 Portage from Mud to Burnt-side. Where first strike the bold ridge which runs along the west side of Mud Lake on this portage. Rounded masses of greenish grey mixed medium grained crystalline rock. Contains a dark greenish (hornblende?) ingredient.
- 9755 About 25 rods west of 9754 on winter road. A granite like rock or a granitic porphyry? Seamed with great quantities of white quartz.
- 9756 A fine grained greenish-grey fine grained fragmental rock. Nearly in contact with 9755 on the East - junction runs S-S-N.W. Broken down to angular fragments.
- 9757 A few steps further north (say 25) to banded ferruginous material - no other rock in immediate vicinity.
- 9758 about 10 rods beyond ^(n.s.) 9757 - at foot of ridge this at south side of ramp. 200-300 steps wide. At west side this ramp has dark-colored rock with granite

Specimen
9754

Specimen
9758

Burnside Lake 19

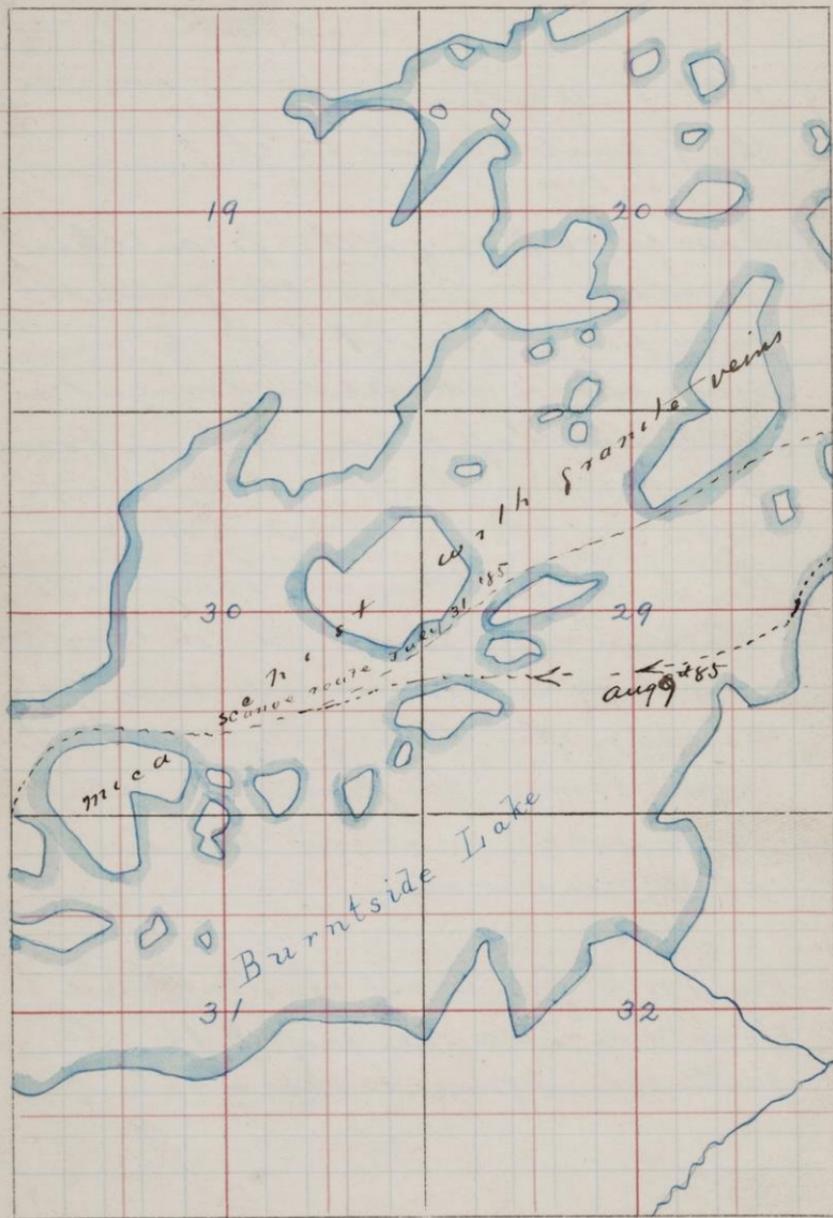

Veins

- 9759 is this dark colored rock
9760 the granite veins in it.

Does 9756 belong to the "green schist formation"? and is the granite 9755 intrusions in it? Is the iron rock here in the Alder formation? Or does it lap around it in some way?

From the end of the Point into Burnside the vein rock shows often in large and even cliffy exposures on the sides of the marshy valley through which this little stream runs. The granite is often in large areas making the hills & cliff pink or red.

- 9761 Veined rock from island near entrance to Burnside Lake. See map p. 16. A dark colored gneiss or mica schist.
Garnetif. mica sch.

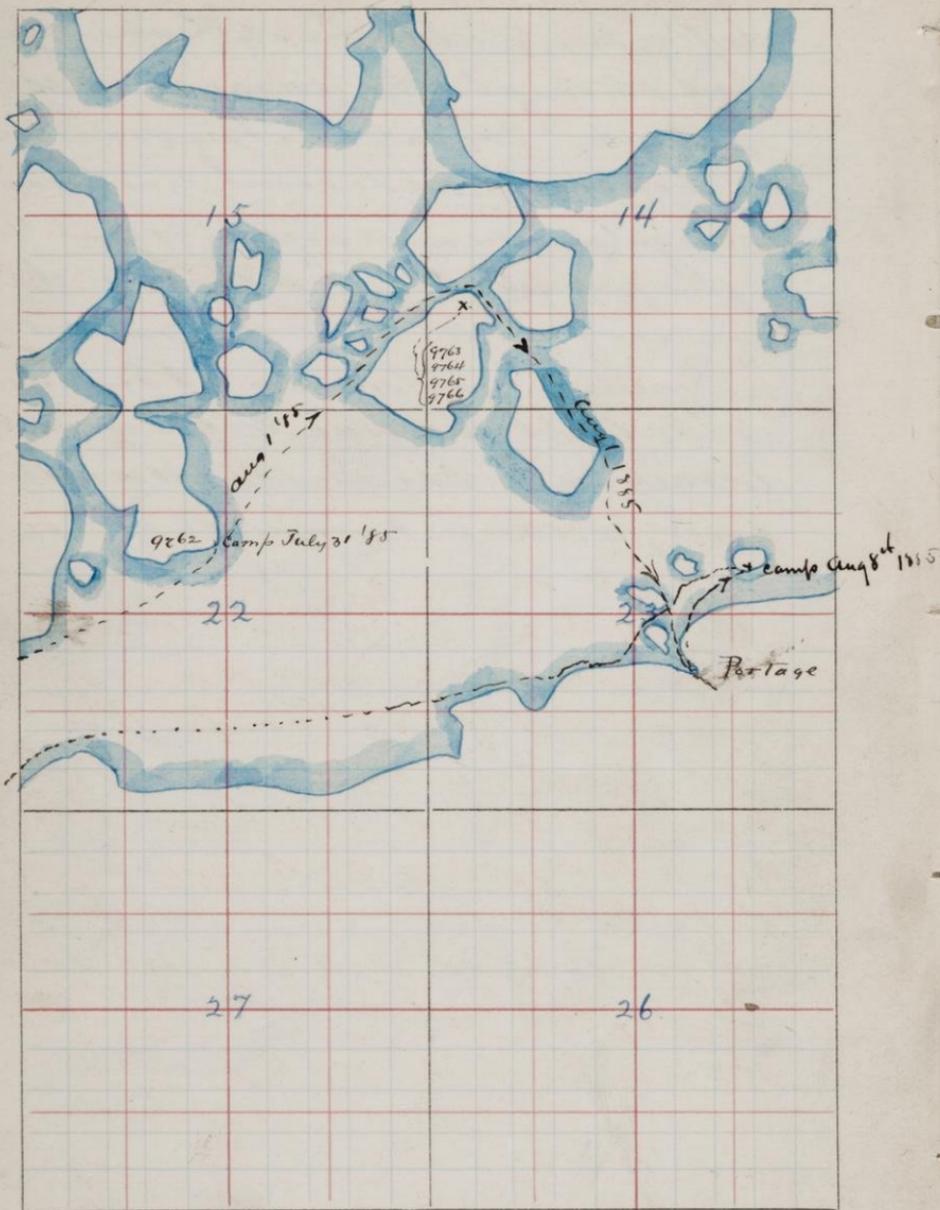

Beerside Lake 211

our course through Beerside Lake to Postage into Long Lake was all through the same coarsened Schist. The intersecting granite is in thin seams, wide veins, and broad irregular areas acres in extent. Also a fine-grained granite intersects the coarser granite. Often the granite varies much in coarseness. Beyond both butts the granite according to Merriam becomes the prevailing rock, or the only rock.

22

T. 63

R. 13

Burntside Lake 23

9262 Granite from South end of island
S 84 W. 22 to 13 W. Has finer
grained granite veins. All of this
part of the island is granite - no
schist in sight.

August 12th 1885.

Followed along among islands on
west side Burntside Lake. Granite
prevails. In two or three islands
show much schist or gneiss and veins
of granite intersect it and each
other in the most intricate manner.
Veins are wide and narrow,
coarse and fine, contorted
with the schist and again
crossing the contortions. There
seem to be three intrusions as
to form: -

- 9263
1. Wide belts of a dark color-
ed granitic rock
 2. Granite veins following the
contortions but again after leaving
them.
 3. Veins wide and narrow,
irregularly branching and cur-

9264

Burntside Lake 25

ving and crossing the veins
2.

Probably the masses 1 should
come in order after 2.

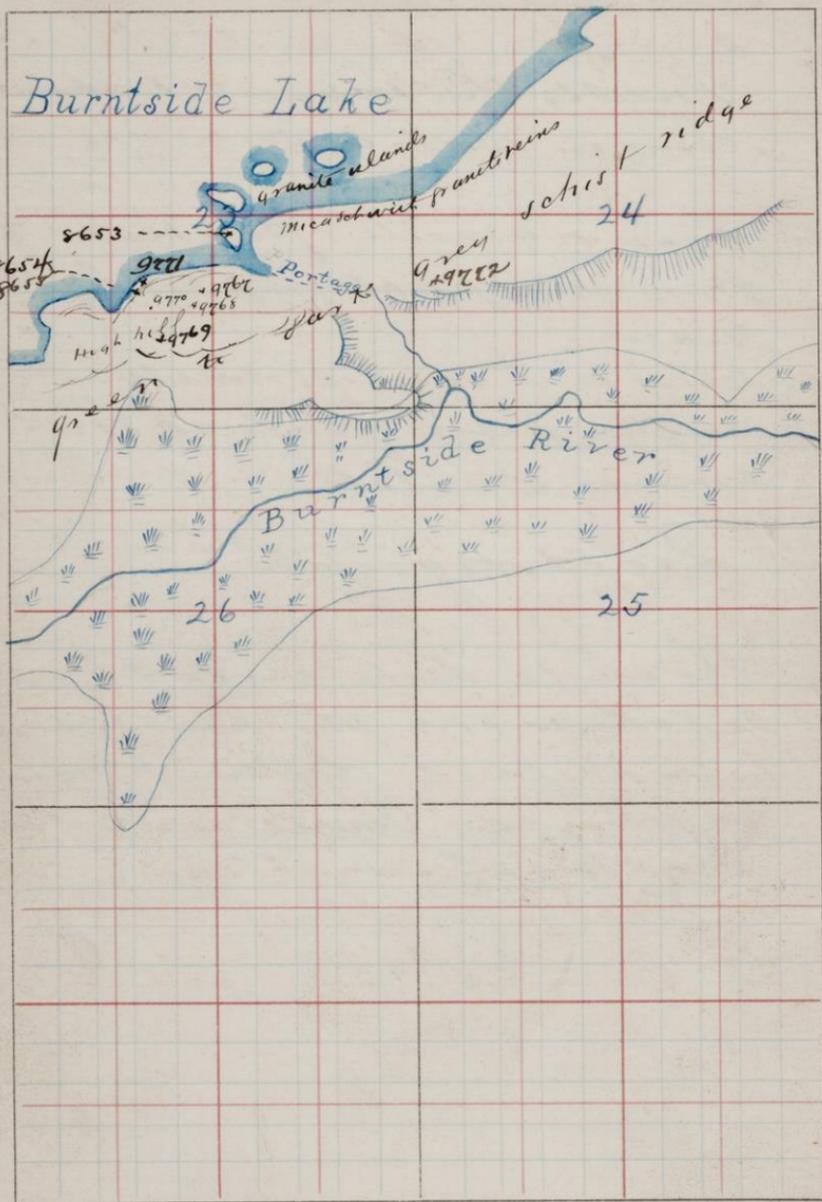

9764 coarser granite from veins 3
from area photographed by Mer-
riam.

9765 schist with vein of granite

9766 another piece of schist with
crossing veinlets.

See photographs -

The whole display on Burnt-
side Lake - i.e. the west side
is manifestly different from
anything on Vermillion Lake
The True Laurentian?

5

Burntside Lake 27

As one approaches the pass-
sage for Burntside Lake to
Burntside River, the numerous
islets are mainly granitic. But
the high knobs on the mainland are
dark colored thin, laminated
micaceous or hornblende-schist,
probably identical (save as to
greater thickness of laminae,
continuity of laminae and
less interruption with punctate seams)
with the schists on the west side
the lake?

9767 chippings from this schist
H.B. Sch.

9768 Certain seams parallel to the
thin lamination of this schist
appear to be irony weathering
brown. The interiors of the seams look
as if magnetite bearing. Are they
the same as the iron on the passage
Burntside? They seem to be
by the way at about same geol
horizon. See again same
thing at outlet of Hall's Lake
infra.

See map. p. 26.

In Brownside Riv. we run along the south side of a broad ridge, which is the Eastern continuation of that crossed on the portage from Vermilion to Brownside, or rather, Mead to Brownside.

9772. Specimens collected by Finch on south side of this ridge. See map. They are like the fusing schists with ferrug. material. but granite veins run all through to south side of this ridge. Some veins quite coarse granite.

Numerous white quartz veins
traverse this rock across and parallel
to the laminae. Often also the
white quartz appears in lenses
 $\frac{1}{2}$ " to 1" thick, one to several feet in
length. Also in irregular nests
and seams of large size.

Granite veins also occur and in
excess in size and frequency as one
great north. They are faulted ~~and~~ often.

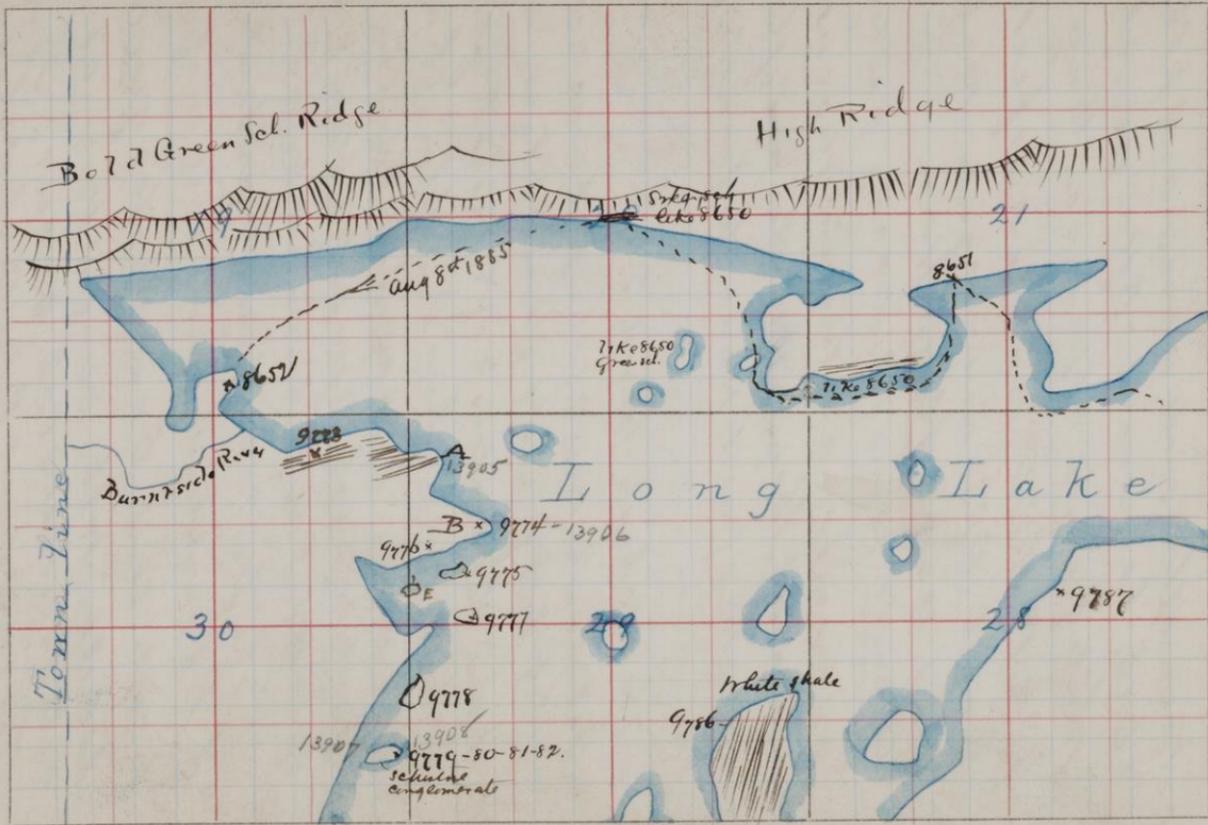

9769 Shows these granite veins - the smaller
ones.

These schists trend E-W.

9770 Interbedded iron schist - same as
9768 but from a different place

9771 Near the water edge much of the
schist is rather lighter than
the rest. It seems plainly to
be a mica sch. An outcrop of
mica sch. interbedded here?

The portage from Burntside
L. to Burntside River (see map p 26)
is quite short. On it rocks quite
similar to the banded iron above
its associated sch. occur. But
this iron is not like that of the iron
series itself.

31

Long Lake. Aug 1/885

9773 greenish chloritic schist dense highly schistose - laminated ~~by~~

The same green schist runs quite around to A. map. p. 30 making large exposures.

9774 At Bhowers after crossing bay the rock is entirely different - schistose - white - felsitic like.

9775 from island - greenstone? } See map. p. 30

9776 shaly.

Island E is like 9776

9777 Sand-colored rock. is it greenstone?

9778 A grey schistose quartzite from island - near West line S 67° 4 29 63 12W.

9779 From next island south - About 1/4 mile - Schistose Conglomerate with white weathering pebbles quite analogous to the Vermilion Lake Conglomerate. Schistose structure ENE

See map p. 30

9780 white pebbles from this Conglomerate
Is not 9774 the parent rock of
these pebbles?

No schistose or green schist pebbles
seen

9781 From this Conglomerate showing
structure like an x line rock!
But manifestly a part of this
Congl. Holes No. x Es?

This conglomerate forms the
west side of the island. The west
side for a little distance is a
shale or schist. Is it not like some
of those on Vermillion?

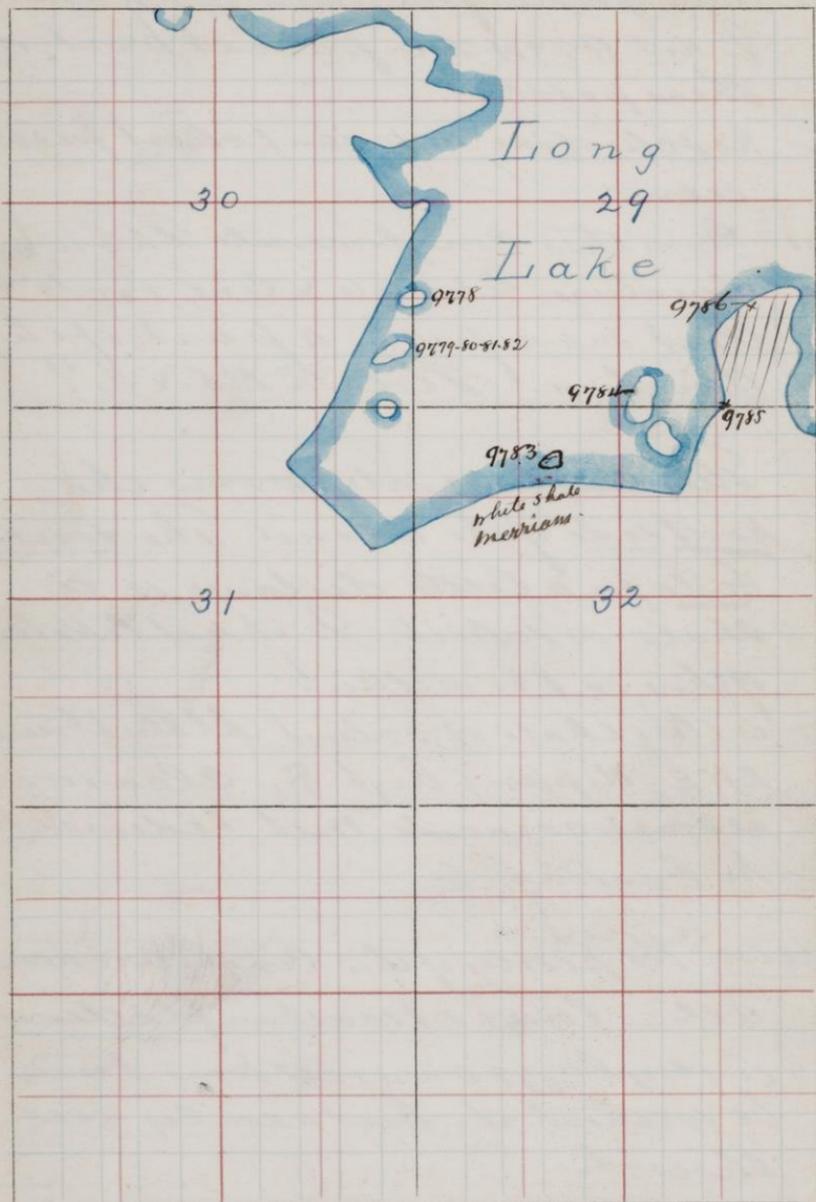

9782 is this shale or schist. Slaty structure
ENE dipping high S. Cleavage
seems to coincide with sedimenta-
tion banding

Mem. The pebbles of this Congl. are nearly
all - large + small - flattened
A very large one in some times
be without it - but nearly all
show it.

34

T. 63

R. 12

Longlake

35

9783 Greenish sch. from island N. 20° E map.
retic foliaceous structure

9784 Red shelly rock - dip with high.

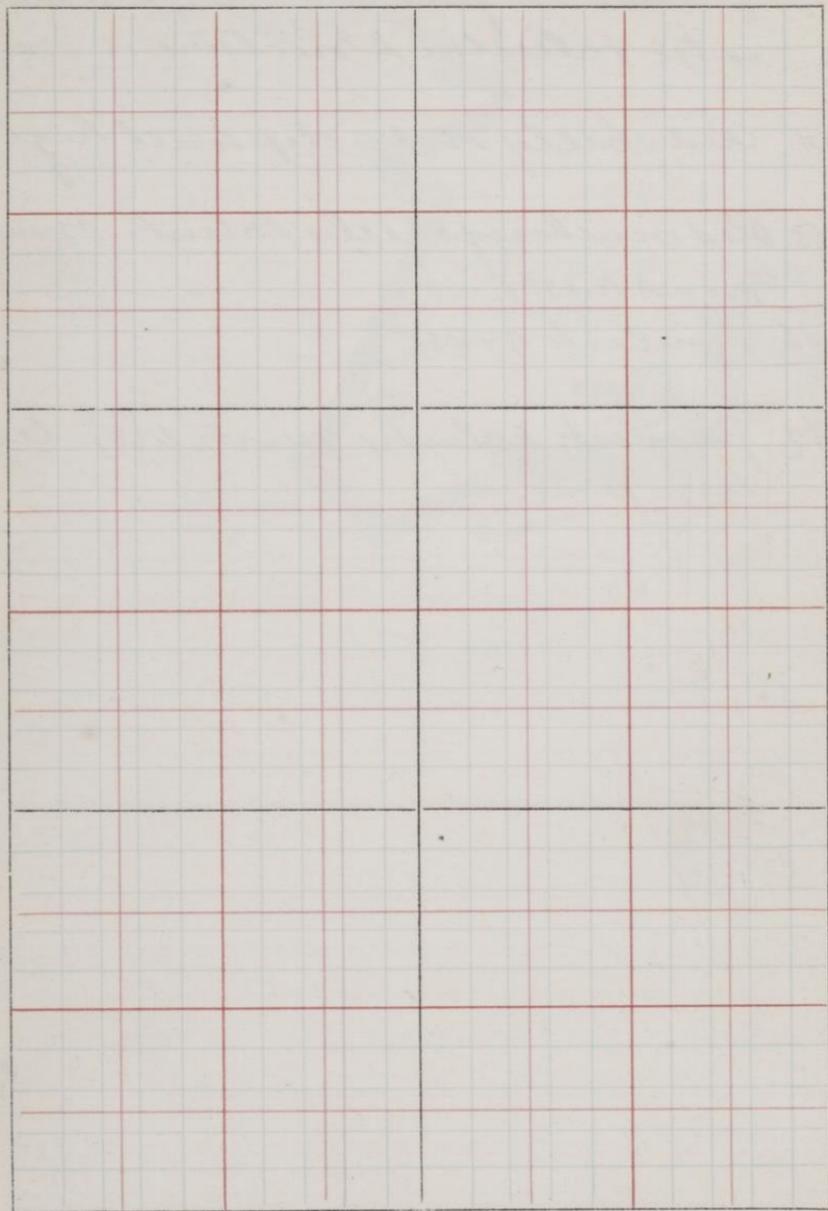

9785 Red weathering shelly schist. crumby
Trend N. 15° E

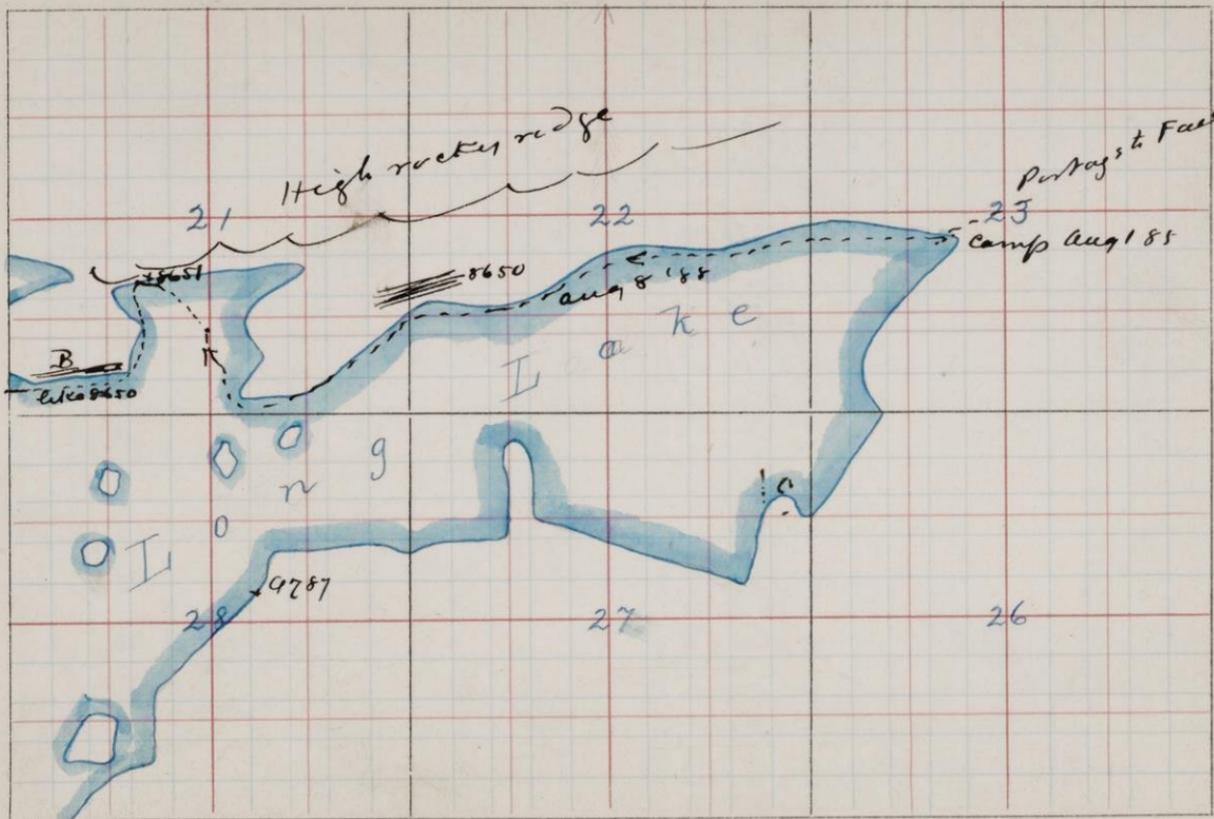

9786 Similar to 9785

9787 Greenish schist, quartzite (?) see
map. p. 38.

R.

38
 Long Lake
 T. 63
 R. 12

See p. 95

Falls Lake

41

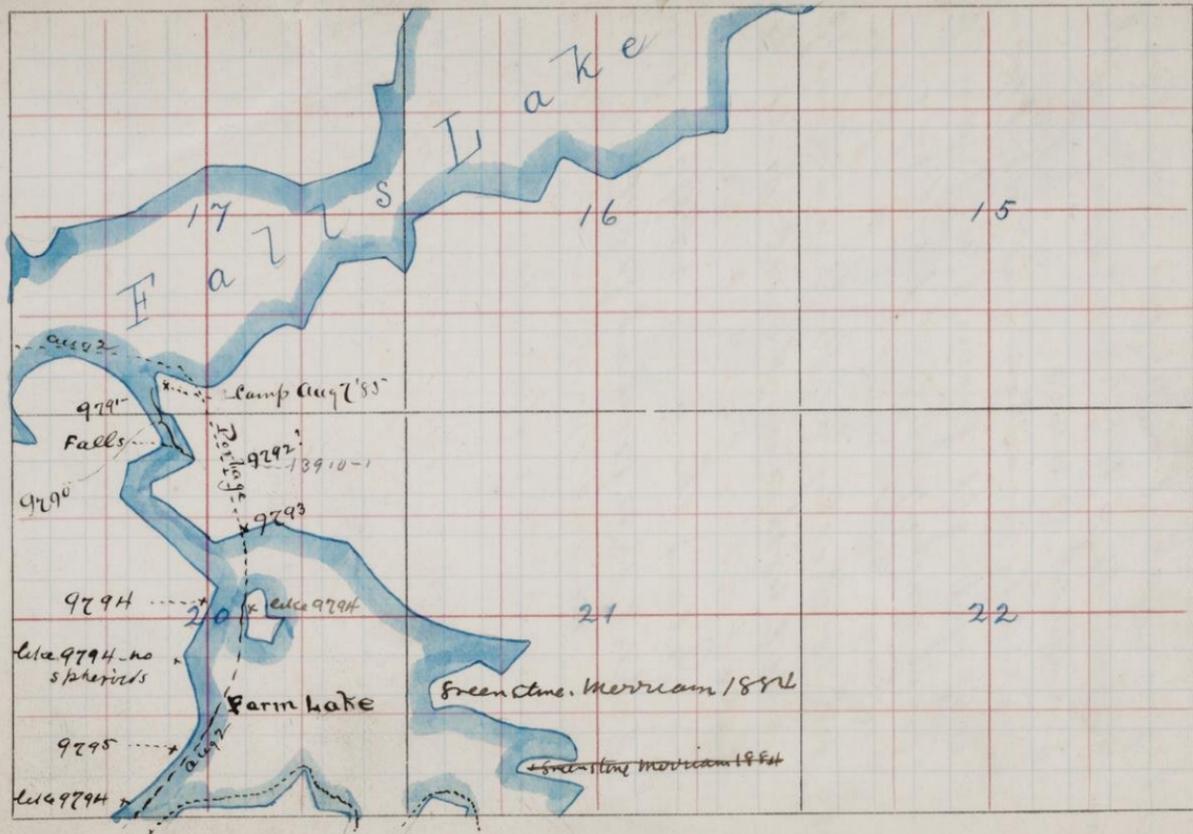

Aug 7 1885

9788 green schist schistose structure
dipping high to S. containing thin
granitic seams

The weathering is at times
a very bright green (not an epi-
dote green)

9789 white shelly hydromicaceous (?)
rock like that on South side Long
Lake.

Island the same as 9788, green
schist. (or greenish gray)

42 Falls and Farm Lakes
 T. 63
 R. 11

9790 Falls of Falls Lake. Greenish schisty rock. Specimens taken along from mouth of River up to Falls.

See Photos

9791 A phase of 9790 at mouth of the river -

9792 Ferruginous material picked on Portage by Daniels. In place? See also Merriam's notes. This portage over a high ridge? 150 feet above Falls Lake.

9793 In masses at South end portage Falls to Farnes Lake note the spheroidal weathering. This rock is eventually in place.

9794 This spheroidal weathering, often bright green, rock also shows at centers Sec. 20 in large structureless cliffs - also on Island opposite

9795 A light grey massive, crystalline rock quite unlike 9794. "Greenstone"

T.

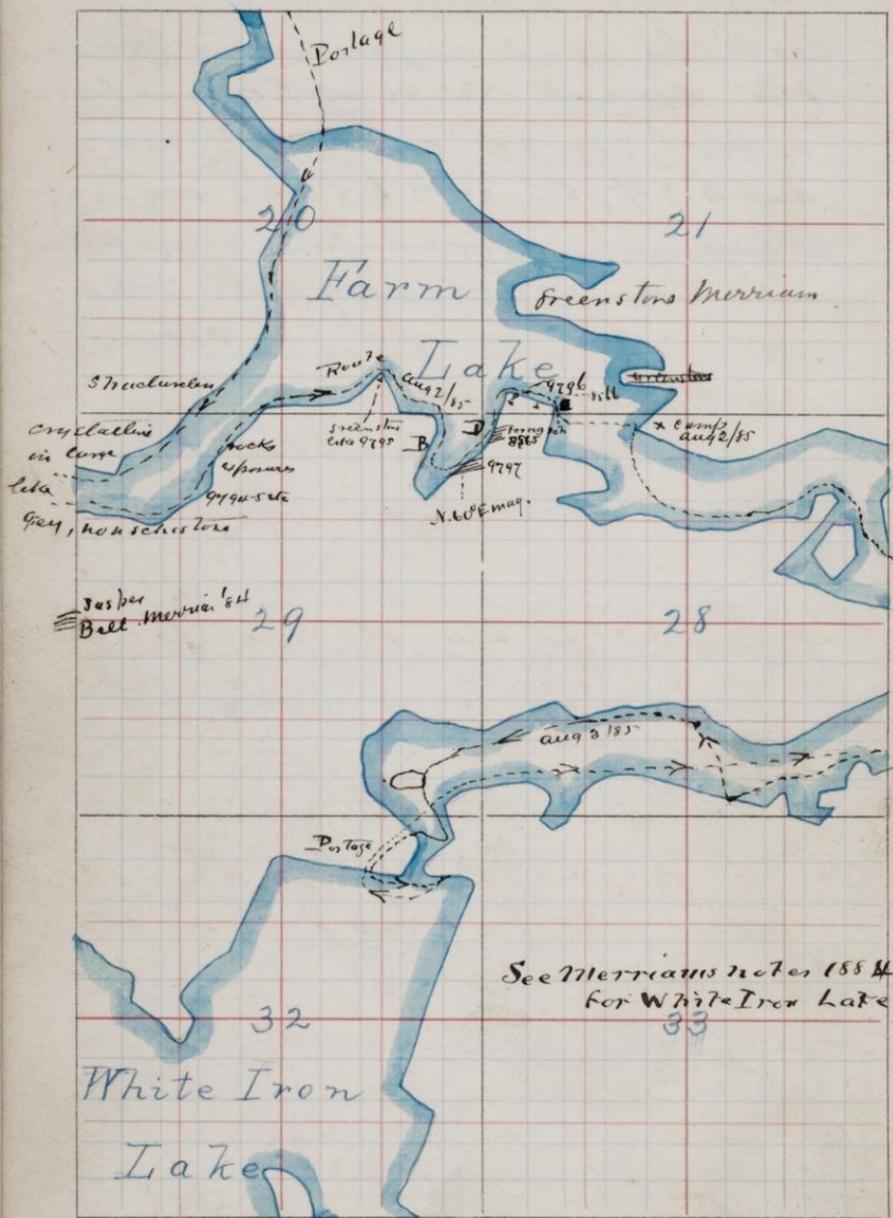

R.

See map p. 46

Harvey Lake

45

All the rock exposures around
the street area of Harvey Lake
in S.W. $\frac{1}{4}$ Sec. 20 and N.W. $\frac{1}{4}$ Sec. 29
and N.E. $\frac{1}{4}$ Sec. 30 - 63-11- are
fractureless greenstone - non-chit-
one. Like 9795 or 9794. The
exposures are large. Colors
dark grey to green.

What is the relation of Greenstone and Irons on this lake?

Farwell Lake

47

9796 greenish? or Quartzite?

B the same rock occurs at B.

9797 schistous - Structure N. 60° E magnetic

Glauconitic all about here - 1.5
south side of the lake N. 10° E magnetic
Meridian.

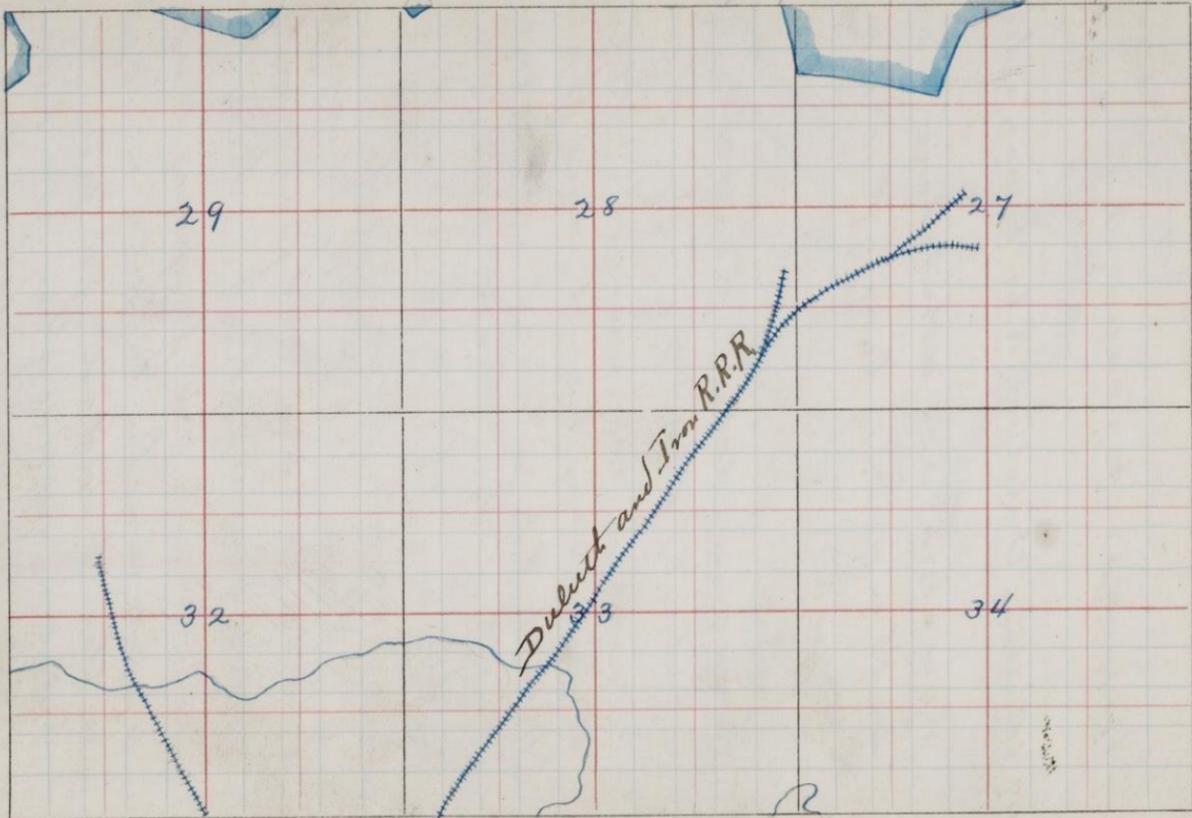

8565 Ferrous schist. Dark colored
Por. sch
schistosity parallel to 9797. This is
dolomitic or calcareous!! It is
at times very hard and finely
mass fractured. Partly
part of Dr. Beech notes
Meridian 1884 on west side
29 - same township.

8567 highly calc. hb. greenish. sh.
8568 found like 8567, part
merely fine quartz - there run
into 8567? the iron translucent.

From D to E the shore shows
broken ledges and fragments of
ferrous schist. Near to E
the fragments are jaspery and
apparently in place banded.
is this banded jasper

material - i.e. schist - run along
White Iron Lake southward one
third mile from the outlet
after which the lake is all in granite
~~to head and beyond.~~

Island H. Farewell Lake. Map. p.
50, shows most singular and
confused occurrences.

8576 Mic. #6. Sch. is a rock at times quartzite like (8576)
and again gneiss-like or mica schist like (8577)

8577 Mic. #6. Sch. This rock is penetrated by

8578 Ab. Grn. coarse hornblende granite in veins and
large masses; also by

8579 Grn. por. fine grained felsitic granite veins $\frac{1}{2}$ " to 6" to 18"
wide. These cut the coarse granite
White quartz veins also intersect the schist.

But much of 8576 and 8577 appears on
surface wonderfully like a congl.
ornate! The singular thing being that every
apparent pebble, except some of black quartz, is of a
kind identical with the veins intersecting
the same rock!! In some cases at
least the seeming pebbles are but branches of a vein
thus: - ~~black quartz~~ which is coarse granite pebble

connected with all traces of the same material
We persuaded ourselves that the pebbles
were really not true fragments - some
of them are sharply angular.

See photos

Portage to Wind Lake 75

Aug 5/85 continued

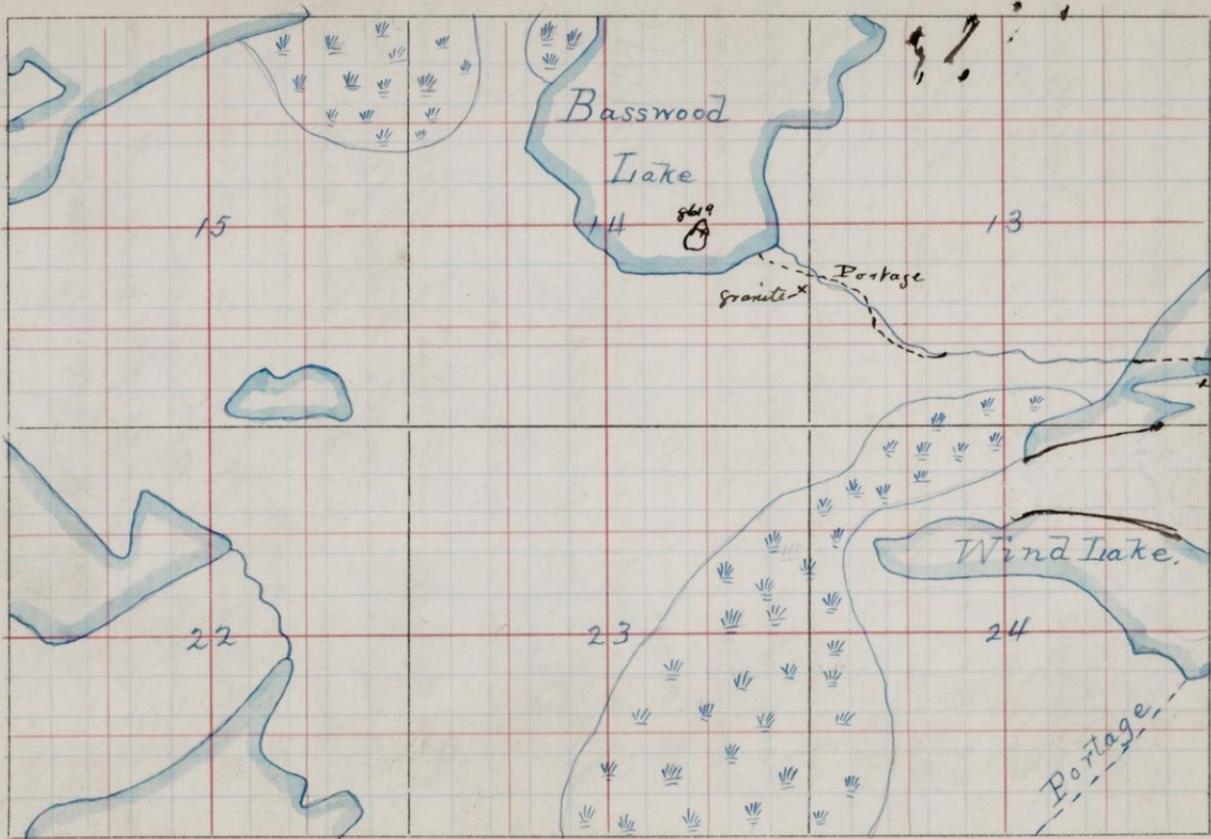

On the portage from Murrel to Wind Lake - 200-300
steps from mine, on high rocks, is a most
singularly confused looking conglomerate(?)
holding masses of banded gneiss material
as like the banded iron, also Jasper
pebbles and granite pebbles. The banded
material is in large masses and lying
in one case at least, in a single
bed, but with a strange strike S. 55- N. W.

- 8611 represents the banded cherty material
- 8612 the conglomerate
- 8613 A piece of the associated schist apparently
holding a granite pebble.

8614 } associated rocks nearby.
8615 }

This conglomerate ~~is not~~ ^{is not} at all compa-
rable to that on the trail from Jasper
to Moore. That is a true ordinary
conglomerate; this a breccia schist
contorted. The whole appearance
is confused & schistose -
