Total expenditures increased 10.4% to 14.7 billion won in 1978 and were planned to increase 17.3% in 1979. Expenditures in the mining industry increased 22% in 1978 over 1977 and were expected to be 1.4 times the 1978 outlay in 1979. Expenditures during 1979 in the chemical industry sector was to be 1.3 times the 1978 level; in the construction industry, 1.1; and in the machinery industry, 1.2.

Industrial growth in 1978 was reported as 117%, and investment for mining as 122% more than 1974. Substantial growth in other economic sectors was claimed for electric power, steel, construction, cement, and chemical fertilizers. In 1979, the Budget called for increasing further the 1978 accomplishments and reducing the cost of industrial production construction by 4.3% from the 1978 level. The construction target for the industrial sector in 1978 was reported as 2,914 projects. However, of the 12 major industrial facilities to be constructed in 1978, the only plant believed to be completed as planned was the Ponghwa chemical plant.

To date, there has been no commercial discovery of oil or gas in North Korea. To supplement indigenous coal mining and hydroelectric power generation, the country uses oil imported from China and the U.S.S.R.

PRODUCTION

The Government of North Korea does not publish mineral production data for external dissemination. Production data, given in Table 1, denotes a relative order of magnitude of the country's output of fuels, minerals, and metals. Output by the minerals sector (all mineral industries are state-owned) was estimated to comprise about 20% of the country's gross national product.

North Korea produces a variety of mineral commodities.[3] Mineral output of coal, graphite, lead-zinc, magnesite, magnetite, and tungsten are significant by world standards. It is a medium-size producer of steel in the Orient. Apatite, barite, copper, gold, talc, and other metals and minerals also are produced. Petroleum and natural gas have not been discovered.

Table 1.—North Korea: Estimated production of mineral commodities

(Metric tons unless otherwise specified)

Commodity[1]	1976	1977	1978[p]	1979[p]
METALS				
Aluminum, ingot, primary	10,000	10,000	10,000	10,000

Coke ... do	2,500	3,000	3,500	3,500

[p]Preliminary. [r]Revised.

[1]In addition to the commodities listed, a number of other mineral commodities apparently are produced, but information is inadequate to make reliable estimates of output levels. These include (but are not limited to) antimony, arsenic (in arsenopyrite), asbestos, beryl, bismuth, boracite, kaolin (china clay), chromium, cobalt, columbite, germanium, indium, lithium minerals (lepidolite), manganese ore, mica (phlogopite), molybdenite, monazite, nickel and/or ferronickel, selenium, tellurium, titanium minerals (ilmenite and rutile), zircon, and a variety of crude construction materials including miscellaneous clays, glass sand, building sand, stone (crushed and dimension), and gravel.

[2]Includes granulated iron.

TRADE

All of North Korea's trade transactions are conducted by Government corporations. The state does not disseminate official data on foreign trade. Information on apparent mineral trade, given in Tables 2 and 3, are derived from countries which publish commerce data.

Exports of the leading mineral and metal commodities have included iron ore, pig iron, steel semimanufactures, lead and zinc, tungsten, cement, magnesite, and talc, compared with imports of chromium, manganese, coke, and mineral fuels. North Korea's main trading partners were China, Japan, and the U.S.S.R., not necessarily in that order. Other trade partners have included Australia, Canada, Israel, New Zealand, countries of Europe, and member nations of the Council of Mutual Economic Aid.

In 1978, North Korea's foreign debt was estimated to be $2 billion.[4] Payment of large purchases made earlier in the decade were lagging or in apparent default. Terms for repayment were renegotiated during 1978-79, notably with Japan. Other major creditors were China, the U.S.S.R., and several West European countries. Because of its lack of foreign reserves and ballooning trade debt, imports during 1978-79 were believed to be substantially lower than the level of imports in 1974, estimated to be $1.1 billion.

COMMODITY REVIEW

METALS

Iron and Steel.—Because of the Government's ambitious program for overall industrial modernization and construction of new facilities, development of the iron and steel industry was a vital part of the last 6-year plan ending in 1977. Mine output capacity of iron ore is around 10 million tons annually. The largest mine, which is at Musan, had been expanded from 5.5 million tons per year to 6.5 million in 1978. Improvements and expansion of the mines at Komdok were also believed to be completed in 1978.

The capacity for crude steel output was around 4 million tons per year. Annual production capacity for the Kimchaek and Nampo steelworks were 1 million tons each. Additionally, Nampo was reportedly to be enlarged to 3 million tons per year sometime during the current economic plan period. Kanson Steelworks has an annual capacity of 700,000 tons, with the remainder of North Korea's output capacity from Hwangae, Kaech'on, Puryong, Pyongyang, and Songjin.

Nonferrous Metals.—The principal nonferrous ore mined in North Korea is lead-zinc from mines at Komdok and Songch'on. The country produces lead and zinc metal for domestic consumption as well as for exports. Some ore is exported, however, primarily to Japan. Refined copper is produced from imported and indigenous ore. Domestic requirements for aluminum are met by metal imports, which provide feed to small remelting and alloying facilities. North Korea's output of tungsten is significant, producing annually about 4% of the world tungsten supply. The country produces small quantities of other metals, but information is lacking or inadequate to make reliable estimates of output levels.

NONMETALS

Cement.—The 1978-79 Central Budget called for a substantial increase in investment for housing and especially for industrial construction and public transportation utilities projects. The 1978 Budget claimed a 32% gain in expenditures for capital investments for the cement industry over the 1977 level. Raw materials for making cement are abundant in North Korea, and annual cement production capacity ranges around 8 million tons. Under the current development plan, North Korea's cement production was to reach 12 to 13 million tons per year by 1984.

Fertilizers.—North Korea produces a variety of chemical fertilizers; current output is probably around 2.5-3.0 million tons per year and was projected to reach 5 million tons per year by 1984. The United Fertilizer plant at Hungnam was the country's largest producer and was adding new facilities for manufacturing carbide, sulfuric acid, and caustic soda.

Magnesite.—North Korea is well known as a producer of magnesite, and current annual output capacity is around 2 million tons per year. The country's largest mine is at Tanch'on, which produces both dead-burned and caustic calcined grades of magnesia for refractory and chemical uses. The installation of a 110-meter rotary furnace at Tanch'on was expected to be completed in 1979. The output of magnesia was for domestic consumption as well as for export.

MINERAL FUELS

Coal.—Although North Korea has large reserves of coal and produces around 45 million tons per year, petroleum and natural gas have not been discovered. Domestic demand for petroleum has been met through imports of Taching oil from China and from the U.S.S.R. Chinese oil is processed at Nam Hung, while Soviet imports of crude are processed at a refinery on the east coast.

The country's most important mineral and fuel source is coal. Both anthracite, used for space heating and electrical power generation, and metallurgical-grade bituminous coal are produced. Under the current development plan, coal production was originally to reach 100 million tons by 1984 but was revised to 70-80 million tons. The target for 1977, the last year of the past plan, was 50-53 million tons.

Output from north Hamyong Province had been expanded in line with the expansion of steel production at Kim Chaek. Metallurgical-grade coal is produced in large quantities at Yonghung, Kukdong, Yangjong, Aoji, and Kogonwon. Anju Consolidated coal mine was to be modernized and expanded in 1979 to double the 1978 output. New coal mines were reportedly being developed in Tokchon, Kangdong, Kangso, and Kowon.

The Mineral Industry of the Republic of Korea

By E. Chin[1]

During the fourth 5-year Economic Development Plan, the gross national product (GNP) of South Korea was projected to grow at an average annual rate of 9.2% between 1977 and 1981. In current prices, the GNP reached $47.4 billion[2] in 1978, compared with $35.2 billion in 1977. GNP in 1979 was $61.1 billion. In constant 1975 prices, the GNP in 1979 was $30.7 billion, a real growth of 7.1% over that in the previous year, and a growth of 10.9% for the 1977-78 period. In 1978, per capita GNP reached $1,242, an increase of $298 over that in 1977. By sector, output by Korea's primary industry decreased by 2.3%, while the mining-manufacturing and tertiary industries grew by 19.1% and 14.6%, respectively.

At current market prices, the value of input to GNP in 1979 by agriculture, forestry, and fishing was $12.6 billion ($5.8 billion in 1975 constant prices); mining and quarrying, $0.8 billion ($0.4 billion); manufacturing, $16.6 billion ($10.0 billion); and all other, $31.1 billion ($14.5 billion).

Except for coal, tungsten, graphite, and limestone, South Korea's raw materials part of its manufacturing industries is unimportant. On the other hand, individual refining and metal facilities belonging to the various mineral industries are often modern and large by world standards. In real terms, mining output decreased by 0.2% in 1979; it had grown by 2.3% in 1978, and by 9.0% in 1977. Coal mining increased by 0.3%, while metal mining decreased by 6.8%. However, other mining increased by 3.1%. The growth in the manufacturing sector was 12.2% in 1979, compared with 23.7% in 1978 and to 20.4% in 1977. By sector, the growth in light industry was 14.5% in 1978, and in the heavy and chemical industry, 24.8%, compared with 9.5% and 19.5%, respectively, in 1977. In the heavy and chemical industry sector, output of industrial chemicals grew by 15.4% in 1978; petroleum and oil derivatives, 9.9%; and primary iron and steel products, 20.2%.

While South Korea is an industrialized country, its economy is about one-twenty-fifth the size of Japan's GNP. Other than coal, zinc ore, limestone, aggregates, and other nonmetallic minerals, South Korea is dependent on imports of oil, minerals, and other raw materials to sustain the output of its manufacturing sector. Presently, the value of manufacturing is about 18 times the value of indigenous extraction of minerals and fuels, and this ratio can be expected to increase with further development of its export-oriented industries.

Wholesale prices rose 18.7% in 1979 and 11.7% in 1978, compared with 9.2% in 1977, while consumer price increases were 18.3%, 14.4%, and 10.2%, respectively. The advance in prices was attributed to a poor harvest of food grains as a result of poor weather and a concomittant increase in demand for food commodities; supply shortages for some major manufactured goods; and the rise in cost of imports of major raw materials, particularly fuels. Overall prices of imported goods increased by 26.6% in 1979, while the price of export goods escalated by 17.4%.

During 1979, exports totaled $15.1 billion and imports, $20.3 billion. Overall trade for South Korea in 1978 totaled $27.7 billion, comprised as follows: exports, $12.7 billion and imports, $15.0 billion. Commodity exports in 1978 were $210.6 million in excess of the $12.5 billion export target set by the Government at the onset of the year. To boost export sales and to help reduce the trade deficit, the Government concluded trade agreements with the Philippines on April 14, 1978, and with Upper Volta on October 10, 1978. A trade, economic, and technical cooperation agreement with Sierra Leone was concluded on May 12, 1979. In addition, there was a series of governmental and nongovernmental economic and trade meetings held during the year with Australia, Austria, Belgium, Brazil, Canada, Denmark, Finland, France, the Federal Republic of Germany, Greece, Indonesia, Italy, Japan, Mexico, the Netherlands, New Zealand, Norway, Saudi Arabia, Spain, Sweden, Switzerland, Taiwan, and the United States.

The Government continued to support local export industries by promoting deferred payment on exports and establishing fair order for export transactions. Moreover, effective on April 1, 1978, 25 foreign currencies were added to the list of legal tenders, increasing the total number to 44. During the year a total of $2.14 billion in the National Investment Fund and in foreign exchange lending funds was released to support export industries. Presently, the Government has designated 12 Korean firms as general trading companies in the country, and in 1978, these companies accounted for exports of $3.9 billion.

On May 1, 1978, 133 items were freed from import restrictions. By liberalizing 151 import items during the year, the number of automatic-approval import items increased from 561 at yearend 1977 to 712 at the end of 1978. Almost all of the hitherto import-prohibited items were virtually transferred to the import-restricted category or to the automatic-approval category.

During 1978, import duties on 48 items (including steel sheets and batteries) were made eligible for installment payments. Additionally, the tariff rates on cement and 18 other items were reduced, and these items were placed in the category of items subject to elastic tariff rates for imports.

In 1978, 11 foreign banks opened branch offices in South Korea, bringing the total of foreign banks with branches in the country to 30. In addition, seven other foreign banks opened representative offices in the country. The number of overseas branches of Korean banks increased by 8 during the year to 15, and overseas representative offices rose by 6 to 18.

South Korea became the second country in East Asia (after Japan) using nuclear power generation with startup operation of the Kori plant in July 1978. The Governments of South Korea and Japan exchanged instruments of ratification on the joint exploration of the continental shelf lying between the two countries on June 22, 1978. During 1978, there was dedication of 14 large-scale plants at industrial sites throughout the country, construction and expansion of 18 large plants, and ground breaking for construction of 10 new plants. A chronology of other notable events in 1978 follows: January 1, the Ministry of Energy and Resources was inaugurated; February 16, the Government adopted a series of guidelines for gradual import liberalization; February 19, the Economic and Social Commission for Asia and Pacific reported that South Korea recorded the highest growth rate in 1977 among developing countries; April 30, the Government proclaimed a 12-mile limit of territorial waters; May 6, site formation was completed for the Yochon petrochemical industry complex; July 1, the Environmental Preservation Law went into effect; October 5, the Nature Preservation Charter was promulgated by the Government; November 16, the first meeting of the Korea-Japan Joint Committee for development of the continental shelf was held in Seoul; and December 3, the third-phase expansion project of Pohang Iron and Steel Company was completed.[3]

During December 1978, the Asian Development Bank (ADB) approved two loans totaling $41 million for minerals and related projects in South Korea. A $33 million loan for project expansion was obtained by five research institutes, to be repaid over 12 years after a grace period of 3 years at an annual interest rate of 7.7%. The recipient institutes included Standards, Shipping and Oceanography, Machinery and Metals, and Energy Management. An $8 million loan was given to the Korean Research Institute of Geoscience and Mineral Resources with the same terms of repayment.

PRODUCTION

South Korea is a major world producer of anthracite, graphite, kaolin, pyrophyllite, talc, and tungsten. Other mineral commodities mined locally include copper, iron ore, fluorspar, lead, zinc, limestone, and salt. The overall mining production index in 1979 was 112.2 (1975=100), compared with 105.3 for metallic minerals and 154.7 for nonmetallic minerals. The coal production index for 1979 was 103.1.[4] In addition, South Korea produces primary metal from imported ores and concentrates, such as aluminum, copper, and iron and steel. Domestic production of limestone is significant, about 22 million tons, and is used primarily in cement manufacture. The domestic capacity to produce cement is around 16.0 million tons. About three-quarters of the cement production is consumed locally with the remainder exported.

There was no domestic production of oil and natural gas. In addition to local coal and hydro and nuclear power generation, Korea imports crude petroleum and coal to meet its energy demand. The production index for oil refining in 1979 was 154.4 (1975=100), an increase of 8.0% from the previous year. South Korea's total oil refining capacity at yearend 1978 by three companies was 580,000 barrels per day, compared to 435,000 barrels per day at yearend 1977. The principal petroleum refinery products during the year were bunker oil, diesel oil, naphtha, gasoline, and heavy oil, in that order.

Sales of domestically produced minerals and metals to foreign markets were estimated to be over $80 million in 1978. By value, the leading mineral export commodities included tungsten ($37.9 million), talc ($9.0 million), agalmatolite ($6.5 million), kaolin ($5.2 million), lead ore ($4.2 million), and graphite ($3.6 million).

TRADE

During 1979, total trade reached $35.59 billion ($15.06 billion for exports and $20.33 billion for imports). The value of imports of mineral products was $4.18 billion of which mineral fuels and related products accounted for $3.77 billion. Exports of mineral products were only $254 million in 1979. The major export categories were textiles ($4.2 billion), base metals ($1.8 billion), mechanical and electrical equipment ($2.0 billion), and vehicles and transport equipment ($1.1 billion).

Overall trade for the Republic of Korea in 1978 was close to $27.68 billion; the value of imports was $14.97 billion, compared with $12.71 billion for exports.[5] By area, exports to Far East and Middle East countries were valued at $5.2 billion; to North and South America, $4.6 billion; Europe, $2.4 billion; Africa, $0.3 billion; Oceania, $0.2 billion; and other, $0.3 billion. By far the largest individual export destinations were the United States, $4.1 billion; Japan, $2.6 billion; and Hong Kong, $0.4 billion. By commodity classifications, exports of textiles were $3.7 billion, by far the largest category, followed by mechanical and electrical machinery and appliances, $1.4 billion; animal and vegetable products, $1.2 billion; and exports of base metals and articles, and vehicles and associated transportation equipment, each category valued at $1.1 billion. The value of exports of mineral products was $267.8 million, and for chemicals $312.7 million.

Imports by area in 1978 were as follows in billion dollars: Far East and Middle East countries, $9.3; Europe, $1.7; North America and South America, $3.4; Africa, $0.4; and Oceania, $0.6. Imports of mechanical and electrical machinery and appliances were the largest categories by value ($3.8 billion); receipts of mineral products were $2.7 billion; and base metals and semimanufactures, $1.7 billion. Imports of petroleum during 1978 alone were valued at $2.2 billion.

COMMODITY REVIEW

METALS

Aluminum.—All of the country's output of primary aluminum was by one company, Aluminium of Korea Ltd. (Koralu), at its plant in Ulsan. Koralu, a 50-50 joint venture of the Korean Industrial Bank and Pechiney Ugine Kuhlmann (Pechiney), has an annual production capacity of 18,000 tons of aluminum metal. The plant uses Soderberg anodes and receives all of its electric energy from the thermal powerplant of Korea Electric Co. Ltd. Koralu imports alumina for its smelter requirements. South Korea's demand for aluminum was estimated around 150,000 tons per year. Korean Industrial Bank was negotiating with Pechiney for possible expansion of the Ulsan smelter to 40,000 tons per year capacity or for the construction of a 100,000-ton-per-year smelter at Onsan by 1983. The latter smelter would use alumina from India and would be designed for eventual expansion to 200,000 tons per year capacity.

Copper.—Production of copper concentrate in 1978 was almost 5,000 tons. The Kumpuk copper mine at Kyunsang Nando accounted for the bulk of the Nation's copper ore output. In 1979, imports of copper ores and concentrates totaled 128,809 tons, of which 78% was supplied by the Philippines. Close to 75% of the total producton in 1978 of electolytic copper was by the Changhang smelter, owned by Korea Mining & Smelting Co. Ltd., which has an annual capacity of 37,700 tons of metal.

An 80,000-ton-per-year smelter-refinery was constructed by a consortium of United Kingdom, Belgian, and Finnish interests at the nonferrous metals industrial complex at Onsan. Construction was completed in 1978, and commissioning of the $184 million smelter-refinery was in early 1979. Onsan Copper Refinery Co. Ltd. is owned 50% by the Korea Development Bank, with the remaining equity held by three private companies. Onsan Copper will produce cathode copper, sulfuric acid, gold, and silver. The smelter-refinery was designed for further expansion to 100,000 tons per year and is a Mechim-designed, Outokumpu-type flash smelter, using Hoboken equipment.

Iron and Steel.—Mine production of iron ore approached 500,000 tons in 1979. Almost half of the domestic mine output was from the Yangyang mine in Kangwon Province, operated by Dai Han Iron Mining Co. Ltd. Domestic mine production constitutes less than 20% of South Korea's requirement for iron ore. In 1979, South Korea imported 6.64 million tons of hematite, mostly from Australia and India, and 0.75 million tons of magnetite, primarily from Peru and India. Imports of coking coal totaled 4.2 million tons and were supplied mostly from Australia, Canada, and the United States, in that order.

Pohang Iron and Steel Co. (Posco), with an annual production capacity of 5.5 million tons of steel, dominates South Korea's iron and steel industry. The other producers were independent producers such as Dongkuk Steel Mill Co., Inchon Iron Works Co., Kuckdong Steel Co., and Pusan Iron and Steel Co.

Posco, the only integrated steel operation in the country, completed its third-stage expansion in early December 1978, bringing its crude steel capacity up to 5.5 million tons per year. Posco's facilities included three blast furnaces; one steelmaking plant with three 100-ton converters and one with two 300-ton converters; and continuous casting hot-rolling, cold-rolling, blooming, and slabbing mills.

A fourth-stage expansion is planned whereby Posco's crude steel output will reach 8.5 million tons in the 1980's. Construction in the fourth phase will include blast furnace No. 4, a second hot-rolling mill, and No. 2 continuous-casting mill.

Lead and Zinc.—Young Poong Mining Co. Ltd. (Young Poong) is the largest lead and zinc producer in South Korea, operating mines at Yeonhua, Boonpyong, and Ulgen. Young Poong produces all of the country's output of lead concentrate and almost all of the total output of zinc concentrate. Lead metal output, around 7,200 tons, was all by the Changhang smelter of Korea Mining and Smelter Co. Ltd. Young Poong operates a zinc refinery at Sokpo. Korea Zinc Co. completed the construction of a 50,000-ton-per-year refinery at Onsan and is owned principally by Young Poong Co. (44.4%), Young Poong Mining Co. (20.5%), and the International Finance Corp. (20.81%). The zinc concentrates, hitherto exported to Japan, would be treated at the new facility. Imports of zinc ores and concentrates were only 42,600 tons in 1979, mostly from Australia. In addition to zinc, the Onsan refinery has the annual capacity to produce 100,000 tons of sulfuric acid and 300 tons of cadmium metal. The estimated cost of the smelter was $100 million, which included ore storage facilities, roaster (350 tons per day), and casting shop. Another 10,000 tons of zinc refining capacity was expected to be added in 1981. During 1978, ground was broken for the construction of Young Poong's 50,000-ton-per-year lead smelter at the Onsan Nonferrous Metal Industrial Complex. Completion of this project was planned for 1980.

Tungsten.—South Korea's production of tungsten concentrate (70% WO_3) was from ores averaging 0.8% to 1.9% WO_3. The Sangdong mine of the Korea Tungsten Mining Co. Ltd. produced about 90% of the country's tungsten output. The remainder of the output was by Chungyang Co., San-Nae mine; Okbang Mining Co. Ltd., Wol-Ak mine; Ssang, Daewha mine; and other small operations. The mill at Sangdong has a capacity to process 2,000 tons of ore per day; the concentrate produced is shipped to Korea Tungsten's plant at Taegu where it is processed to produce tungsten powder, carbide, and ammonium paratungstate. South Korea's producton of tungsten constitutes about 8% of the total world output.

Other.—Bismuth concentrates were produced as a byproduct of tungsten processing by Korea Tungsten Mining Co. Ltd. The bulk of silver metal output was by the Changhang smelter of Korea Mining and Smelting and the Boonyong operations of Young Poong Mining. Close to 65% of the country's output of gold metal was from Korea Mining's Changhang smelter. Mine production of other metal values during the year included minor amounts of antimony, arsenic, manganese, molybenite, and tin.

NONMETALS

Cement.—Cement production was by seven companies in 1979. Ssangyong Cement Industries Co. Ltd., the largest cement manufacturer, produced about one-third of the country's total output, followed by Tong Yang Cement Co. and Hanil Cement Manufacturing, which accounted for another third of the country's capacity; the remainder was produced by Sung Shin Cement Co., Hyundai Cement Co., Asia Cement Manufacturing Co., and Koryo Cement Co.

Total industry kiln capacity at the end of 1978 was estimated at 19.0 million tons. Under the fourth 5-year plan, domestic production was expected to reach 23 million tons by 1980. Ssangyong Cement completed the expansion of its Tonghae plant from 2.2 million tons to 5.6 million tons in 1978 and planned further expansion to 8.82 million tons. Sung Shin Cement was completing the expansion of its plant at Tanyang to increase capacity from 1 million tons to 2.1 million tons. Additionally, Tong Yang Cement began the expansion of its plant to more than double its annual output capacity, from 2.6 million tons to 5.4 million tons.

During 1979, South Korea exported close to 1.4 million tons of cement clinker, primarily to Singapore, Hong Kong, and Bangladesh. Shipments of portland cement totaled 1.1 million tons, with Thailand, India, and Iran, in that order, as the principal destinations.

Fertilizer Materials.—Total industry capacity to produce chemical fertilizers is about 1.5 million tons per year, of which nitrogen nutrients account for close to 55% of the total. Currently, domestic consumption is on the order of 900,000 tons per year. The major fertilizer manufacturers in South Korea included Chinhae Chemical Co. Ltd., Hankook Caprolactan Co. Ltd., Korea General Chemical Corporation (State-owned); Kyunki Chemical Co. Ltd., Mamhae Chemical Corp., Posco, Pugnong Chemical Co. Ltd., and Yong Nam Chemical Co. Ltd. During 1979, exports of urea totaled 291,000 tons, mostly to the Philippines and Sri Lanka; fertilizers containing nitrogen, phosphorus, and potassium, 378,000 tons, 61% of which went to Turkey and Iran; and fertilizers containing nitrogen and phosphorus, 166,000 tons, mostly to Iran, Pakistan, and Turkey. The increase in exports of nitrogen fertilizers was due to the startup of Namhae Chemical Co.'s large operation at its major fertilizer complex in Yeochem in February 1977.

Other.—Owing to increased activity in construction and export, cement production increased almost 8% in 1979. Production of agalmatolite and talc increased significantly in 1979. Production of other nonmetallic minerals during 1979 included marine salt, amorphous graphite and crystalline graphite, feldspar, fluorite, diatomaceous earth, asbestos, barite, and andalusite.

MINERAL FUELS

Coal.—Under the Government's energy supply-demand program (1977-81), the average increase in coal demand was set at 9.1% annually. The consumption of anthracite was projected to increase from 23.8 million tons in 1978 to 27.2 million tons in 1979. However, anthracite production during the year was only 18.1 million tons. Imports of anthracite in 1979 totaled about 2,100,000 tons, mostly from the United States, United Kingdom, and unknown sources, in that order. To encourage growth in coal production, the Government's program called for investing 335.9 billion won, including $152.3 million in foreign exchange funds, in the coal mining industry during the current 5-year plan.

Virtually all of the country's production was domestically consumed, primarily for space heating. The estimated anthracite consumption pattern was as follows in percent: general consumers, 91.7%; powerplants, 3.5%; industrial establishments, 4.3%; and other, 0.5%. The Government-owned Dae Han Coal Corp. (DHCC) produced 26% of the country's anthracite output. The major mines worked by DHCC are Jang Seong (the largest), Do Gye, Ham Baeg, Hwa Sun, and Eun Seong. Consolidated coal mines produced about 4 million tons, and the remainder of the output during the year was by small-scale private mines. Total coal reserves in South Korea were estimated to be 1,434 million tons, mainly in Yeonweol, Janseong, Daechen, and Whasom. DHCC holds about 25% ownership of the total reserves, with the remainder in private hands.

Petroleum.—There is no domestic production of oil or natural gas in the Korean Peninsula. South Korea imports all of its oil requirements, mostly in the form of crude petroleum, principally from Saudi Arabia with lesser amounts from suppliers such as Iran and Kuwait. At the end of 1978, South Korea's total oil refining capacity by three refineries was 570,000 barrels per day. Korea Oil Corporation (KOCO) operates an oil refinery with a daily refining capacity of 280,000 barrels at the Ulsan Petrochemical Industrial Complex. The 60,000-barrel-per-day refinery of Kyong-In Energy Company is at Inchon. Honam Oil Refinery Company operates its 23,000-barrel-per-day refinery on the south coast of Yosu.

During 1978, KOCO completed an expansion project to increase its daily refining capacity by 65,000 barrels. Work was virtually completed on the construction of a new 60,000-barrel-per-day refinery at the nonferrous metals industrial complex at Onsan. Construction on this refinery, which is a joint venture between the Ssangyong Business Group and Iranian interests, began in October 1976. Kyong-In expanded its daily capacity at Yosu from 160,000 barrels to 230,000 barrels in 1979.

Most of the petrochemical plants in operation are located at the Ulsan Petrochemical Industrial Complex and at the Yochon Petrochemical Complex. In 1978, a 60,000-ton styrene monomer plant and a 25,000-ton styrene butadiene resin plant were dedicated at Ulsan. Construction of three petrochemical plants, including a 350,000-ton ethylene plant, was underway at Yochon. Additionally, ground was broken in 1978 for construction of a 100,000-ton caprolactan plant at Yochon.

The Mineral Industry of Kuwait

By Candice Stevens[1] and Phyllis A. Lyday[2]

The petroleum sector accounted for approximately 70% of the gross domestic product (GDP) of Kuwait, estimated at $13.7 billion[3] (April 1977-March 1978). During 1978 and $15.6 billion (April 1978-March 1979), Kuwait evidenced the third largest per capita GDP in the world. With the development of Kuwait's major oilfields completed years ago, the Government focused on projects for gathering and processing associated natural gas. Petroleum refining, petrochemicals, and other downstream operations were given high priority in development plans. The current 5-year development plan (1977-1981) projected allocations of $16.6 billion. The major expenditure was to be on infrastructure development—roads, housing, water, and electricity—for a population growing at the rapid rate of 5.5% per year. During 1979, petroleum provided 95% of all Government revenues. Kuwait continued to invest large amounts of oil revenue surpluses, which amounted to approximately 75% of foreign exchange earnings, in U.S. dollars during 1979.

Kuwait continued its large foreign aid program through the Kuwait Fund for Arab Economic Development (KFAED, established 1961) and the Arab Fund for Economic and Social Development. Total allocations through 1979 for the KFAED were approximately $2.0 billion representing over 130 individual loans. In 1978, the Saudi-Kuwaiti Permanent Joint Committee for Coordination and Development of Industrial Cooperation was formed to supervise joint ventures in petroleum coke, cement, and possibly the petrochemical and iron and steel industries. A railroad project linking the United Arab Emirates to Europe via Iraq, Syria, and Turkey had entered the planning stage in April 1979. British Rail's consultant, Transmark, was to work out a feasibility study to fix the railroad itinerary. Plans were made during 1979 to merge Kuwait Petrochemicals Industries Co. (KPIC), Kuwait Oil Co. (KOC), Kuwait National Petroleum Co. (KNPC), and the Kuwait Oil Tankers Co. (KOTC) into a single corporation headed by the oil ministers.

PRODUCTION AND TRADE

In 1978, Kuwait was the fourth largest producer of petroleum in the Middle East including Kuwait's share of production from the partitioned Neutral Zone. Kuwait's 3 refineries had a total capacity of 594,000 barrels per day of refined petroleum products. Other mineral production included small amounts of fertilizer materials and cement. Mineral production in Kuwait is given in table 1.

Kuwait had a balance-of-trade surplus of approximately $7 billion in 1978 owing to large petroleum exports. Three foreign oil companies lifted most of Kuwait's export crude oil and in 1978, boosted their offtake to the maximum allowed under their contracts. Allotments were to Shell Oil Co. (360,000 barrels per day), British Petroleum Ltd. (BP) (450,000 barrels per day), and Gulf Oil Co. (Gulf) (500,000 barrels per day). Japan was Kuwait's largest customer taking 27% of exports.

In 1978, Kuwait exported refined petroleum products primarily to the Far East (45%) and other Arab countries (23%). Again Japan was the largest single buyer taking 15% of exports. Kuwait also exported a small amount of chemical fertilizer.

COMMODITY REVIEW

METALS

Aluminum.—During 1978, proposals were under study by the Aluminum Extrusion Company for the construction of a plant to produce 6,000 tons per year of aluminum products for domestic use. The $15 million facility would process imported aluminum.

Iron and Steel.—Kuwait Metal Pipe Industries Co. produced spiralweld steel pipes for agricultural and petroleum usages at its works in Safat. Capacity of the plant was 16,000 tons of 20-inch pipes, 30,000 tons of 2 1/2-inch pipes, and 100,000 tons of 48-inch pipes per year. The company was planning to expand the product range to include 40,000 tons per year of galvanized steel sheets. Kuwait Metal Pipe Industries Co. was also considering the construction of a plant to produce 15,000 tons per year of copper rods and wire.

Kuwait Iron and Steel Co. (KISC) issued tenders for the construction of a direct-reduction steelworks at Shuaiba in 1974. However, the project, which was to have a capacity of 400,000 tons per year, was subsequently abandoned. In 1978, KISC conducted studies for a smaller plant to produce rods and bars for construction purposes.

A joint venture was formed during 1979 between Ron River (30%), a subsidiary of Rugby Portland Cement of the United Kingdom, and Mohammad Abdel-Muhsin Kharafi. The venture known as the Kuwaiti Steel Reinforcement Co. will manufacture steel reinforcements for the construction industry.

NONMETALS

Cement.—Kuwait Cement Co. (KCC) held a 45% interest in the Saudi-Kuwaiti Cement Co. which was to construct a 2-million-ton-per-year cement plant in the partitioned Neutral Zone. The plant was scheduled for completion in 1981. Kuwait's cement imports were approximately 700,000 tons per year during 1978 and domestic cement demand was expected to increase rapidly owing to growing construction activity.

Fertilizer Materials.—KPIC produced urea and ammonia products at its facility at Shuaiba. Production capacity of the plant, which began production in 1966, was 660,000 tons of ammonia, 900,000 tons of urea, 130,000 tons of sulfuric acid, and 165,000 tons of ammonium sulfate per year. Production was primarily exported to the Persian Gulf states and Eastern Asia. The Government acquired all shares of KPIC, formerly owned by BP and Gulf, in 1973.

The Government completed feasibility studies for three other petrochemical complexes to be located in Shuaiba. A 333,000-ton-per-year ammonia plant was to begin production in 1981. Total cost of the facility was estimated at $110 million. The Government was looking for partners for a $900 million aromatics complex. Annual production capacity was to be 284,000 tons of benzene, 86,000 tons of paraxylene, and 60,000 tons of orthoxylene. A proposed $580 million olefin plant was to have an annual production capacity of 350,000 tons of ethylene, 135,000 tons of ethylene glycol, 130,000 tons of low-density polyethylene, and 325,000 tons of styrene. Negotiations were continuing with Romania regarding the construction of a joint venture petrochemicals facility on the Black Sea coast.

Kuwait and Bahrain signed an agreement to set up a 50-50 joint venture between KPIC petrochemical firms and the Bahrain's National Oil Co. (BANOCO). The plant was estimated to cost $368.4 million and produce 1,000 tons per day each of ammonia and methanol. Production will be exported primarily to South Asia and China.

MINERAL FUELS

Natural Gas.—Approximately 3% of total gas production was used in power generation and desalination plants, 25% was utilized by the oil companies, 9% was reinjected in oilfields, and the remainder was flared. Natural gas reserves in Kuwait and the partitioned Neutral Zone were estimated at 1,065 billion cubic meters.

Exploration continued for nonassociated gas, which would provide a source of energy for electricity and desalinated water production independent of oil production. In 1978, a test well was drilled in Burgan Field to a target depth of 20,000 feet, but a fire at 9,000 feet prevented further drilling. Deep drilling was to be resumed in other areas to explore the Persian Khuff Zone which underlay Kuwait's oilfields. At yearend 1978, Kuwait began negotiations with Saudi Arabia for rights to exploit the large nonassociated gas deposits in offshore Dorra Field located in the partitioned Neutral Zone. At yearend 1979, no further details were available.

Kuwait produced liquefied petroleum gas (LPG) at its fractionator at Mina al-Ahmadi refinery. A new facility to produce 3.6 million tons per year of gas liquids officially opened at Shuaiba in early 1979. Production was to consist of propane, butane, and natural gasoline. As the facility was designed to utilize more natural gas than was being produced, Kuwait initiated discussions with Saudi Arabia regarding the use of associated gas from the Khafji Field in the Neutral Zone. Sales contracts for the purchase of LPG for a 10-year period were concluded during 1978 with Shell Oil Co. (200,000 tons per year), Idemitsu (440,000 tons per year), and Bridgestone Liquefied Gas Ltd. (500,000 tons per year) and during 1979 with Marubeni (120,000 tons per year). In general, the Government's target has been to have around 50% of the LPG contract volumes moving in Kuwaiti tankers. During 1979, KOTC took delivery of 3 72,000-cubic-meter gas carriers and had one carrier on order.

Petroleum.—Petroleum production reached a peak of nearly 3.3 million barrels per day in 1972 but thereafter the Government placed a production ceiling of 2 million barrels per day on the major oil producers. During 1979, Kuwait announced plans to cut oil production by 500,000 barrels per day before 1985. Petroleum reserves were reported by the Government at 72 million barrels including the Neutral Zone. Kuwait's petroleum reserves were the third largest in the world after the U.S.S.R. and Saudi Arabia.

Production from the fields operated by KOC averaged 1.9 million barrels per day in 1978. Previously owned by BP and Gulf, KOC was nationalized by the Government in 1975. BP and Gulf continued to operate facilities and provide technical assistance in exchange for a discount on crude oil liftings. KOC began production in 1938 with the discovery of Burgan Field, which proved to be one of the world's largest. The major producing KOC fields were Burgan, Magwa, Ahmadi, Umm Gudair, North Kuwait, and Minaqish.

In the Neutral Zone, the offshore concessionaire for both Kuwait and Saudi Arabia was the Arabian Oil Co., Ltd. (AOC, Japan). AOC production in 1978 was from the Khafji and Hout Fields. Output was evenly divided between Kuwait and Saudi Arabia. AOC planned to increase production to 450,000 barrels per day by yearend 1979 to meet increased Japanese demand. The onshore concessions of American Independent Oil Co. (AMINOIL) were acquired by KOC in April 1978. Production was from the South Fuweis and South Umm Gudair Fields.

Kuwait produced approximately 400,000 barrels per day of refined petroleum products from its 3 refineries in 1978. Total production capacity was about 600,000 barrels per day. Domestic consumption of refined products averaged 30,000 barrels per day. The oldest and largest refinery, located at Mina al-Ahmadi, was operated by KOC. Production capacity was 250,000 barrels per day but the plant was operating at half capacity in 1978. Plans were approved during the year to modernize the refinery at a cost of $300 million. No further details were available by yearend 1979. The Government-owned KNPC operated the Shuaiba refinery during 1978 with a new lube-oil blending unit of 540 barrels per day capacity and a new hydrocracker of 42,000 barrels per day capacity.

The Kuwait Government was considering several joint venture refinery projects, most notably with South Korea, Oman, and Ras al-Khaimah, a member of the United Arab Emirates. Kuwait's support of a $700 million oil refinery on the Indonesian island of Batam will depend upon the result of a feasibility study. Kobe Steel (Japan) had a contract to build a $20 million oil gathering center with basic engineering provided by the Bechtel Corp. (United States). KOTC signed letters of intent with Japanese yards for four 80,000-deadweight-ton tankers worth $100 million. Two vessels will be built by Mitsubishi Heavy Industries and two by Sasebo Heavy Tankers. The four tankers are scheduled for delivery in 1981-82. KOTC had 10 crude carriers in operation with a total capacity of 2,130,000 deadweight tons by yearend 1979. The Government took over the 51% share of KOTC still in private hands during 1979 by payment of $145.6 million.

The Mineral Industry of Liberia

By Phyllis A. Lyday[1]

In 1978, the Republic of Liberia maintained a world rank of 11th in both iron ore and diamond production. The contribution of mineral exports to the nation's gross domestic product (GDP) of $744 million[2 3] (at current prices) was 70% in 1978, compared with 43% in 1977. Real GDP grew 1.6% based on 1971 constant prices.

Notable events for 1978 included reestablishing oil refining production subsequent to a 20-month shutdown, obtaining loans to expand output capacity and transmission of the Bushrod Thermal Power Plant, receiving commitments from eight industries to locate on the Liberian Industrial Free Zone on Bushrod Island, and signing a long-term trade agreement between the Liberian Government and the Federal Republic of Germany to provide agricultural products in exchange for the preparation of port facilities and roadbuilding equipment. The Liberian Government continued to encourage exploration and mining by foreign companies.

The public sector of Liberia depended heavily upon foreign aid for infrastructure necessary for mineral development. During 1978, loans for projects included upgrading the St. Paul-Bomi Hills river highway and a hydro scheme study of the Mano River. At yearend 1979, Liberia's debt was $653 million. The debt-servicing rate of 11% was creating a financial strain and Liberia was advised by the International Monetary Fund to reduce its development expenditure.

Liberia Electric Corp. (LEC) was in a grave financial state during 1979. LEC was heavily indebted to overseas institutions and Liberian Refining Company (LRC), which were demanding payment.

During 1979, Liberia had the world's largest merchant fleet; shipping was Liberia's third most important source of income. Liberian shipping was threatened by the United Nations Conference for Trade and Development (UNCTAD), which had initiated phasing out flag of convenience ships, such as the 26,000 vessels carrying 80 million tons, which were registered in Liberia.

Mifergui-Nimba Co. (MIFERGUI), a Guinean company, continued its basic 1976 transportation agreement with Liberian American-Swedish Minerals Co. (LAMCO). LAMCO's railroad was the only means to transport for overseas shipment the high-grade iron ore from deposits at Sempete and Pierre-Richard, Guinea. A feasibility study of the transguinean railroad was completed by MIFERGUI during 1978.

PRODUCTION AND TRADE

Liberia's iron ore production, valued at $274.4 million in 1978, contributed about 37% to the GDP and represented 60% of total export values. The United States continued as Liberia's largest trading partner, importing 25% of Liberia's total exports during 1978. Despite increases in world production of steel, the European steel market remained depressed. Several Liberian iron ore mines operated below capacity in efforts to prevent large layoffs despite financial losses incurred during 1978 and 1979. The Government continued to encourage Liberianization of the workforce.

Liberia was adversely affected by the prolonged world recession, which resulted in price reductions in the steel industry, and the decline of the U.S. dollar, which left the country less able to buy equipment and machinery. Liberian companies raised prices of iron ore 8% at yearend 1978. The depressed iron ore market, along with uncertainty about future recovery, led to deferral of investments for new projects, cutbacks in production, and closure of some mines. Trade deficits continued, and the growth rate of the economy slowed in 1978 from the previous average of 5%. The European Community Commission, executive body of the European Economic Commission, transferred $10.5 million to Liberia during 1979 under the Lome Convention's Stabex system to compensate for a drop in revenues from iron pellet exports during 1978.

Diamonds valued at $30.3 million contributed 6% to the value of total exports in 1978, which was a 41% increase over the value of 1977 production. Speculation in the diamond market produced a 30% increase in the price of diamonds during 1978. In recent years, mines have operated at a loss as a result of adverse conditions in the world diamond market. The buoyant world demand for diamonds in 1977 was expected to have a favorable impact on Liberian production and exports in the future.

COMMODITY REVIEW

METALS

Gold.—During 1978 and 1979, the price of gold per troy ounce quadrupled. No overall gold production figures were available for 1978 and 1979 as gold mining on a small scale was restricted to Liberians. During 1978, licenses were awarded to 20 companies for prospecting and 16 companies to mine gold, including the following companies and individuals with U.S. interest: Delta Engineers Inc. for a gold-diamond deposit in Grand Cape Mount County; Bently International Trading Co. for areas in Grand Gedeh, Sinoe, and Maryland Counties; and Bruce Clayman for areas in Grand Gedeh and Maryland Counties. Discovery Oil Ltd. announced plans to set up a pilot plant to process gold from its Dougbe Creek property on concession number 2. The assay report showed 6.85 troy ounces of gold and 1.7 troy ounces of silver per ton of ore. Clayco Petroleum Corp. owned 80% of a gold concession area with the Government where preliminary exploration proved the existence of gold-bearing gravel. During 1978, the Liberian Minister of Land and Mines proposed to license gold brokers and dealers for the purpose of encouraging the mining and production of gold.

Iron Ore.—Liberian American-Swedish Minerals Co. (LAMCO) was the largest iron ore company in Liberia, accounting for 60% of iron ore mined in 1978. LAMCO was owned by an equal partnership between the Liberian Government and Liberian Iron Ore Limited (LIO). LAMCO (75%) operated LAMCO Joint Venture Operating Co. (LJV) in a partnership with Liberia Bethlehem Iron Mines Company (25%); LAMCO depended wholly upon LJV for its income. In 1978, for the first time, LAMCO operated at a net loss of $16.8 million, compared with a net profit of $9.3 million in 1977. At midyear 1979, LAMCO was still operating at a loss.

Shipment of iron ore, primarily to Europe, increased despite reduced production, because of the reduction of iron ore stockpiles at Buchanan. A 265-kilometer railroad transported the ore from Mount Nimba to Lower Buchanan, LAMCO's port on the Atlantic, where the ore was shipped or stockpiled. The completion of a permanent crushing station at Buchanan, at a cost of $5.6 million, allowed the stockpile of wash lumpy ore to be reduced at yearend 1978 from 2.8 million to 1.7 million long tons. Because of LAMCO's temporary change in market demand from washed lumpy ore to ore fines, the stockpile was expected to be eliminated during 1979 and 1980. Production at the Nimba and Tokadeh mines was 9.3 million tons of ore during 1978.

A total of $9.1 million was spent by LAMCO on property equipment in 1978, compared with $26.4 million in 1977. Capital expenditures for 1979 were estimated at $14 million. Cost eliminated by discounting the pellet plant and by write-offs of related materials and supplies at Buchanan were offset by higher employment cost.

Production at the Nimba mine near the border of Guinea was slower during 1978. Reserves of iron ore were estimated at 115 million tons with an iron content of 63% as of yearend 1978. Proven and minable reserves were estimated at 92 million tons.[4]

Production at the Tokadeh Mine, located 18 kilometers west of the Nimba Mine, was 161,000 tons of run-of-mine ore for customers requiring a high-silica type of material. Reserves of iron ore were estimated at 220 million tons with an iron content of 53%.[5]

Exploration continued on the Liberian side of the Mount Nimba concession areas, which included Mounts Tokadeh (50% Fe), Gargra (54% Fe), Yuellinton (54% Fe), Beeton (49% Fe), and Nimba/Gabhn (65% Fe), and had reserves estimated in million long tons of 219, 104, 76, 18, and 102.5, respectively.[6] It has been estimated that proven iron ore reserves of 535 million tons, having an average iron content of 51%, 438 million tons of minable reserves, and 260 million tons of product exist in the Mt. Nimba areas.[7] During 1978, LAMCO spent $743,000 on exploration as compared with $874,000 during 1977.

A retroactive agreement between LAMCO and the LAMCO Mine Worker's Union cost LAMCO $595,000 and $1 million during 1978 and 1979, respectively. Total cost of the agreement was estimated to be $6.4 million, which included $2.5 million in housing renovation. During 1978, LJV employed 4,546, of whom 54% were Liberians. The Government rejected an LJV proposal and requested the company to file a new proposal to increase the number of Liberians employed at the mine. During 1979, the new proposal demanded by the Government would increase the work force to 70% Liberians. Training programs continued, and about 600 persons participated during 1978. A cooperative program whereby employees could buy their own houses was begun in 1979.

Bong Mining Co. (BMC) was the second largest iron ore producer in Liberia. It accounted for roughly 30% of iron ore mined in 1978. BMC was owned by the Liberian Government (50%), Finsider International S.S. (16.25%), and steel companies from the Federal Republic of Germany through its manager and coordinator Exploration und Bergbau GmbH (33.75%). Production at the BMC open pit mine, located in the Saladea District west of Bong County, was 15 million ton of crude ore in 1978 at capacity level. Reserves of remaining iron ore as of December 1977 were 350 million tons with an average iron content of 38%.[8] Geological investigations of Zaweah II and Bong Peak were continuing to prove the 124 million tons of probable reserves. Of the three new mines planned, at least two were postponed until after the 1980's. BMC's austerity program in progress was plagued by labor discord. BMC reported in September 1977 that it had 3,306 employees, including 380 expatriate staff.

National Iron Ore Co. Ltd. (NIOC) accounted for roughly 10% of iron ore output in Liberia. The low-grade iron ore at Mano River had proved difficult to upgrade. The ore was carried over 77 kilometers of railway, built around 1962, to the now closed Liberian Mining Co. Ltd. (LMC) mine at Bomi Hills. The ore was then carried over a 68-kilometer section of railroad which had carried ore to Monrovia since 1951 and was in a dangerous state of disrepair. It was estimated that it would cost up to $3 million to repair or $7 million to replace the St. Paul River bridge. Plans were being made to raise additional financing of $9 million to improve the performance of the mill, renovate the railroad, and purchase additional tracts to increase haulage capacity. NIOC was experiencing financial difficulty during early 1979 and was expecting several loans to secure the company.

Liberian Iron and Steel Co. (LISCO) had a promising project at Wologisi, which was located 216 kilometers from the coast in the northwestern county of Lofa. American Metal Co. Ltd. (AMAX) was originally expected to take part, but announced its withdrawal from the project in 1978. Kawasaki Steel Corp. leads the consortium with C. Itoh & Co., Nisshho Iwai Co. Ltd., Marubeni Corp., and Tomen. The consortium seeks less extensive concessions in return for Government financing of infrastructure. Japan International Corp. Agency (JICA) concluded the exploitation technical study. An investment of $350 million in infrastructure was expected to be required. The mine was scheduled for production of 10 million tons per year of high-grade pellets of 66% iron content in 1983. The ore was to be pumped through slurry pipelines to the coast.

LMC, which ceased production in 1977, decided in 1978 not to try and reclaim the assets to which the Liberian Government laid claim. LMC requested a new concession area at Bie Mountain, about 24 kilometers west of its former Bomi Hills site.

During 1978, Metallurgical and Engineering Consultant Ltd., a subsidiary of Steel Authority of India, concluded a feasibility study concerning an integrated iron and steel plant to process iron ore into pig iron, billets, and rolled products.

Uranium.—A contract to undertake a program of airborne spectrometric surveys for exploration of uranium deposits was awarded by the U.S. company, Western Enterprises, Inc., to Hunting Geophysics Ltd. A target area of 13,000 square kilometers of the 65,000-square-kilometer concession area must be defined within the first 3 years of exploration to keep the concession.

NONMETALS

Barite.—Senwein Mining Co. (SMC), a wholly owned Liberian company, signed a concession agreement with the Liberian Government to mine barite in the Gibi Territory. SMC was expected to enter into a joint venture with Petkon Corp. of Norway.

Cement.—Production of ground clinker by Liberia Cement Corp. continued on Bushrod Island and was the sole source of cement in Liberia. Cement production was 132,488 tons valued at $7.5 million during 1978. During March of 1979, cement prices went up 19% to $3.40 per bag.

Diamond.—During 1978, 40% of the diamond mined in Liberia was estimated to be of gem quality. Production of diamond was confined to the alluvial deposits of the River Lofa Valley in the Saniquellie and Bahn Districts. The major diamond mining areas were Grand Cape and Mount Lofa Counties. In 1978, 1,396 diamond prospecting licenses were issued. Estimates of total undiscovered world resources for 1977 showed 25 million carats in Liberia.[9]

MINERAL FUELS

Liberia Refining Company (LRC) suffered a 20-month shutdown after a fire in December of 1976. Refined products were imported during 1977 with the local market consuming about 13,000 barrels per day. During 1978, LRC was managed by Resources Development Services Inc. of Bloomfield, N.J., which was a subsidiary of Combustion Engineering Inc. Processing of crude began in August 1978, and production averaged 9,000 of the maximum capacity of 15,000 barrels per day. Production increased to 14,000 barrels per day during March 1979. Rationing of mineral fuels was in effect during early 1979 after the refinery reported losing $2 million per month in gasoline subsidies. Gasoline prices went to $1.50 per gallon in June 1979. The Government made a contract with Consolidated Petroleum Industries Inc. (CPI) to expand LRC to 65,000 barrels per day contingent upon securing a government-to-government petroleum agreement. In March of 1979, the Saudi Arabian company Petromin agreed to furnish 4.1 million barrels of oil annually to LRC. Exploration of the Liberian continental shelf revealed oil deposits, but further exploration was necessary to determine if commercial quantities exist.

The Mineral Industry of Libya

By Phyllis A. Lyday[1] and Candice Stevens[2]

The petroleum and gas sector contributed 56% to Libya's gross domestic product (GDP) estimated at $19.8[3] billion in 1978. Libya has maintained an average annual growth of its gross national product of 19% since 1970. Almost all Government revenues and foreign exchange earnings originated in the fuels sector. Petroleum production spurred an increase in per capita income to $6,500 per year in 1978 and 1979, ranking Libya among the top 15 countries in the world. With a population of only 2.3 million, a primary problem was the lack of skilled labor.

Approximately 35% of Libyan oil production was by foreign companies with foreign participation allowed only in the fuels sector. Since 1973, the Government has proceeded with a policy of progressive nationalization of foreign interests in the country, such as manufacturing, transportation, communication, utilities, and banking. The Libyans did not nationalize the oilfields completely because they needed foreigners to push exploration and to promote enhanced recovery. A Government reorganization in 1978 created the Secretariat of Heavy Industries and the Secretariat of Light Industries to replace the previous secretariats of industry and minerals.

In 1978 and 1979, development activity was structured around the 1976-80 "transformation" plan where investments exceed $31 billion including $6 billion for industry, mining, and hydrocarbons. A major concern was boosting oilfield recovery rates by means of secondary and tertiary recovery methods and maintaining overall productive capacity of 2.5 million barrels per day. Other goals were increased gas exploration and the development of downstream operations in refining and petrochemicals.

The first phase of construction of Misratah port, part of the iron and steel complex, was completed in 1979. Work included two breakwaters, a 750-meter platform for container ships up to 11 meters draft, and a 180-meter berth. The work was completed by Projekt Ivan Multinovic (Yugoslavia) under a $66 million contract signed in February 1973. The project consultant was Rendel, Palmer, and Tritton (United Kingdom). Phase two, a $77.7 million contract, will be continued by the same firms. Phase one of construction of Derna port has also been completed. Other projects in the infrastructure area included a $35 million contract to Hamilton, Ontario-Westinghouse Canada Ltd. (Canada) to supply and install three 17,300-kilowatt gas turbine generator powerplants, transformers, and electric switch gear; a $20 million contract to Energoinvest (Yugoslavia) to supply a 30-kilovolt and 10-kilovolt transformer station and a 30-kilovolt long-distance powerline; a contract to Astaldi Estero (Italy) to construct an airport south of Benghazi; a contract to Devcon International Corp. (United States) to build a 100-kilometer parallel highway and railway that will run to the Tunisian border. The state-owned Imatran-Vima (Finland) was negotiating with the U.S.S.R., which was in overall charge of the project, to build a 400-kilowatt nuclear powerplant in Libya.

During 1979, Kuwait and Libya established a joint Arab investment and banking company with a capital of $1 billion, half to be provided by both countries. The company was intended to strengthen the Arab presence in international finance markets.

In July 1979, the Government changed its payment policy and informed foreign companies that payment terms for oil would be changed from 60 days to 30 days. The government also asked petroleum companies to pay their royalties on a 30-day basis effective August 1, 1979. The Government continued to negotiate exploration and production sharing agreements with various countries and companies. Libya began a policy of ending the crude buying contracts against foreign operators that did not produce adequate secondary, and if necessary tertiary, oilfield recovery programs during early 1980. On December 16, 1979, the Libyan Minister of oil announced plans to decrease production by approximately 400,000 barrels per day beginning on January 1, 1980. The cutback will be effected by production allowables, Sarir Field being the heaviest proportional decrease.

PRODUCTION AND TRADE

Libya's petroleum production averaged about 2 million barrels per day for the last 4 years. Libya's 725-million-barrel annual production during 1978 and 1979 made the country the second largest producer in Africa and the ninth largest producer in the world. The price of the high-quality Zuetina crude at yearend 1978 was $13.90 per barrel and at yearend 1979 was $34.72 per barrel. Libya also produced refined natural gas, artificial fertilizer, and cement. Mineral production is given in table 1.

Libya's balance-of-trade surplus declined from $4.5 billion in 1977 to $3 billion in 1978 owing to large imports of goods and services for its development program. Libya exported nearly 1.8 million barrels per day of crude oil in 1978 earning $8.9 billion in revenue. During 1979, exports to the United States from Libya reached $5.3 billion, and imports from the United States reached $468 million. The United States was Libya's largest customer, receiving 43% of oil exports during 1978. Other prime destinations were Italy (23%) and the Federal Republic of Germany (11%).

In 1978, Libya began exports of ammonia (70,000 tons) to Greece, Spain, and Italy and of methanol (150,000 tons) to the Netherlands, Spain, Turkey, and Italy. During 1979, Libya ranked fourth among liquefied natural gas (LNG) exporters, exporting to Italy and Spain. Under the 5-year plan, exports were expected to increase 8% per year and imports 5% per year leading to a balance-of-payments surplus of $2.5 billion by 1980.

The first example of a joint industrial venture between the Gulf States occurred during 1979. Kuwait and Bahrain signed a joint venture agreement to form a new company, the Bahrain-Kuwait Petrochemical Industries Co. to produce ammonia and methanol from Bahrain's abundant supplies of natural gas. The plant, expected to be onstream by 1985, was to be built at Sitra, Bahrain. The products were to be exported mainly to South Asia and China. Other trade agreements included a cooperative agreement to establish joint companies between Libya and Sudan, especially in the field of metallurgy, and a cooperative agreement guaranteeing Greece 3 million tons of crude oil for a 5-year period and 120,000 tons per day of ammonia for an unspecified period.

[e]Estimate. [p]Preliminary.

[1]In addition to the commodities listed, a variety of construction materials (sand and gravel, crushed stone, brick, and tile) is produced, but available information is inadequate to make reliable estimates of output levels. Natural gas liquids are also produced but are blended with crude petroleum and are reported as part of that total.

[2]Includes gas reinjected into reservoirs, if any.

COMMODITY REVIEW

METALS

Aluminum.—The General Organization for Industrialization was planning a $1 billion aluminum complex for the Zouare port, 100 kilometers west of Tripoli. For operation, Libya was to supply the natural gas and Yugoslavia was to supply the bauxite ore. The complex was to include a refining plant, a power station, and an oil coke plant.

Iron and Steel.—Feasibility studies for the construction of an iron and steel complex at Misurata, 205 kilometers east of Tripoli on the Mediterranean coast, were under consideration by the Libyan Government during 1978. Preliminary work began on the site in October 1979. The estimated cost of the project was $1 billion. Plans called for the construction of a direct reduction steel mill and continuous casting and rolling mills for long and flat products.

Design capacity of 2.5 million tons per year and an initial production of 1.25 million tons per year were planned. The complex was to eventually process iron ore from the deposits at Wadi Shati, located near Sebha in the province of Fezzan. Reserves were estimated at nearly 795 million tons of 50% iron ore.[4] The construction of the necessary infrastructure was estimated at an additional $1 billion. A railroad link with the coast was considered a major cost factor in development of the iron ore deposit. Energy for the plant will be supplied by natural gas piped from the Marsa Brega Oilfields some 400 kilometers to the east.

Uranium.—Exploration for uranium mineralization was being conducted with the assistance of France. A tract in the Kufra area of the Libyan interior desert within the border area of the disputed Aouzou strip was under study. A 200,000-square-kilometer tract in the Muzzuq area (Fezzan) was also under study. In the meantime, Libya received 258 tons of uranium for its developing nuclear program from Niger's French supervised mines.

NONMETALS

Cement.—Cement production capacity in Libya reached 5 million tons per year in 1978. The Benghazi/Hawari cement plant, built by HKD Industrienlagen A.G. (West Germany), was one of the large industrial complexes of Libya. Humboldt Wedag was the equipment supplier, with Prospective Engineering Gestion acting as consulting engineer at the Benghazi plant. The five clinker production lines had a total production capacity of 2 million tons per year. The Hawari facility, on a site adjacent to the Benghazi plant, contained a two-kiln, 1-million-ton-per-year operation which was placed onstream in September 1978. The Central National Organization for Industrialization awarded a turnkey contract to Fives Cail Babcock (France) to construct the second 1-million-ton-per-year cement plant during 1978. Compagnie de Ciments de Suk el Khamis began cement production in June 1977 at a location south of Tripoli with a capacity of 1 million tons per year. Production capacity of the cement plants in Libya with production capabilities planned to begin by 1979 were as follows:

Location	Operator	Start-up date	Capacity (tons per year)
Homs I	National Cement Co.	1968	1,000,000
Al-Homs II	Do.	1978	1,000,000
Benghazi	Libyan Cement Co.	1971	1,000,000
Hawari	Do.	1978	1,000,000
Suk el Khamis	Suk el Khamis General Cement Co.	1977	1,000,000

MINERAL FUELS

Natural Gas.—Libya produced approximately 650 billion cubic feet of natural gas in 1978, 20% of which was flared. Natural gas reserves were estimated at 29,000 billion cubic feet during 1978. Domestic consumption of natural gas accounted for approximately 15% of the nation's total energy consumption. Natural gas usage was expected to increase to 160 million cubic feet per day by 1980.

Esso Standard Libya Inc. continued its development drilling program at the Hateiba gasfield, located north of Nasser Field. Facilities were under construction to produce and deliver 240 million cubic feet per day of non-associated gas to Esso Standard's LNG plant at Marsa el Brega.

In 1978, Nasser Field was the main supplier of associated gas to the LNG plant. Production capacity of the plant was 345 million cubic feet per day. Esso Standard contracted with Snam Progetti, a subsidiary of Ente Nazionale Idrocarburi (ENI) (Italy), for the sale of approximately 245 million cubic feet per day and with Enagas (Spain) for the sale of 110 million cubic feet per day. In 1978, the Libyan Government was negotiating with Esso Standard and its buyers for a price increase over the base price of $1.62 per million British Thermal Units (Btu) agreed upon in 1975. At yearend 1979, LNG exports from the Marsa el Brega plant were $3.20 per million Btu.

Other events pertaining to natural gas during 1978 and 1979 included the following: Azienda Generale Italiani Petroli S.p.A. (AGIP), a subsidiary of ENI, was studying ways to pipe gas to Italy from a major find offshore of Tripoli; Libya considered the possibility of using Malaysia's LNG tankers for transporting Libyan gas; Greece and Libya examined the possibility of building a joint natural gas-based plant in Libya to manufacture ammonia for Greece; and Occidental of Libya agreed to sell its interest in Libyan National Methanol Co., a small liquid petroleum gas (LPG) plant, to the Government.

Petroleum.—Petroleum production increased from 1.99 million barrels per day in 1978 to 2.1 million barrels per day in 1979. Production has been reduced since the record of 3.67 million barrels per day in 1970 to conserve resources. Domestic consumption of crude oil was about 23 million barrels per year. Libya's petroleum reserves were estimated at 25 billion barrels. Libya ranked seventh in production among the members of the Organization of Petroleum Exporting Countries.

As a result of the participation and nationalization measures initiated in 1973, Libya nationalized British Petroleum, Amoseas, Bunker Hunt, Shell, Texaco, and Atlantic Richfield Oil Co. assets. Complex negotiations between 1973 and 1975 led to exploration and production sharing agreements (EPSA) between the Government and the eight remaining oil companies, with the Government acquiring a majority share in most ventures. During 1979 the NOC reported cutbacks which averaged 25% to 50% of non equity crude because of overcommitments of crude to third parties by the Government. The Government was pressuring all producers to produce every possible barrel of oil during 1978 and 1979. At yearend 1979, 13 new EPSA contracts were to be finalized. Total commitments for exploration by foreign companies over the next 5 years reached $1 billion. The EPSA sharing patterns vary, according to the prospects of the acreage concerned, 75% to 85% in favor of the Government.

Oasis, which included Continental Oil Co. of Libya, Marathon Petroleum Libya Ltd., and Amerada Hess Corp., was the country's largest producer with output of 680,000 barrels per day in 1978 and 720,000 barrels per day in 1979. The main producing fields of the Oasis group were Gialo, Defa, Waha, and Bahi.

The two subsidiaries of the state-owned National Oil Corp. (NOC), Arabian Gulf Exploration Co. (AGECO) and Umm al-Gawabi, averaged 509,000 barrels per day in 1978. AGECO planned to increase production of the Sarir Field and exploit the Mussalla Field, located northwest of Sarir, to achieve a combined production capacity of 800,000 barrels per day by 1980. A new pipeline was to link the fields to a refinery and terminal at Ras Lanuf via the Nafoora/Amal line. NOC was also planning to develop new fields in the Hamada al-Hamra plateau in western Libya. A contract was awarded to Enterprise (French) to construct a 450-kilometer-long, 18-inch-diameter pipeline to link the new fields to the Zawiyah refinery at a cost of $166 million. Initial output of the field was to be 60,000 barrels per day rising to 120,000 barrels per day. Construction of the pipeline was expected to be completed during 1981.

Occidental Petroleum Corp. (Oxylibya) had an average daily production of 355,000 barrels in 1978. Production from fields in which Oxylibya held a 49% interest averaged 341,000 barrels per day, and the field in which the company held 19% interest produced 14,000 barrels per day. Under the latter agreement, Oxylibya conducted all exploration at its own expense and initially paid 19% of development costs and received 19% of production free of taxes and royalties. The Intisar Field, which reached an 85% recovery rate owing to a new gas injection scheme, accounted for almost all Oxylibya production. The production of crude from Oxylibya's three new fields, Zella, Aswad, and Sabah, began in December 1978. They were linked through Mobil Oil Co.'s pipeline to the terminal at Ras Lanuf. A new well in the Fidda Field tested at about 4,000 barrels per day and contained an estimated 100 million barrels of oil reserves. The field is in an area where Occidental receives 19% of the net income.

AGIP produced 140,000 barrels per day from its single Abu Tiffel Field. The field was linked by pipeline to the export terminal at Zuetina. In May 1978, AGIP negotiated a $250 million 5-year loan with the Libyan-Arab Foreign Bank for increasing its petroleum activities in Libya. In February of 1979, AGIP struck oil in the Mediterranean near Tripoli. AGIP initiated planning for the development of several large offshore finds in the area. CJP Offshore was awarded the contract to design a preliminary drilling and production platform. Actual development of the deposits depended upon the settlement of a dispute between Libya and Tunisia over rights to explore and develop oil in the offshore area bordering both nations. Elf-Aquitaine was also drilling in an offshore concession which adjoined the territorial waters of Tunisia.

Exxon Oil Co. had two petroleum production-sharing agreements with the NOC, Esso Standard (49% Exxon, 51% NOC) and Esso Sirte (24.5% Exxon, 63.5% NOC, 12% Grace Petroleum Corp.). Combined production of the two companies in 1978 was 147,000 barrels per day.

The Amal Field, and to a lesser extent the Ora Field, accounted for Mobil's production of 90,000 barrels per day in 1978. Mobil operated under a production-sharing agreement with the NOC and Gelsenberg AG. During the year, the company was reported to have made several onshore discoveries that could more than offset any decline in future production.

Total (France) relinquished two onshore concessions in 1978 but retained its offshore acreage. The relinquished areas were the 28,500-square-kilometer Hamada tract and the 23,000-square-kilometer Mizeraq tract.

Refining.—Libya produced 35 million barrels of refined petroleum products in 1978 consisting of 40% fuel oil, 30% gas oil, 15% kerosine, and 10% gasoline. Six new refineries have been constructed in Libya since 1970, and three more are planned. Domestic consumption in 1978 totaled 25 million barrels. Production capacity of Libya's seven refineries was approximately 140,000 barrels per day in 1978, distributed as follows:

Refinery	Operator	Capacity (barrels per day)
Zawiyah	NOC	120,000
Nafoora	Amoseas	2,000
Marsa Brega	Esso Standard	8,000
Amal	Mobil	2,000
Intisar	NOC	2,000
Zuetina	Do	3,000
Dahra	Oasis	2,400

The NOC plant at Zawiyah accounted for more than 85% of total production. Commissioned in 1971, with a production capacity of 40,000 barrels per day, the plant was expanded to a capacity of 120,000 barrels per day in June 1977. The Zawiyah refinery supplied most of Libya's oil product requirements with some surplus for export. It employed 700 people, 86% of which were Libyan nationals. Plans were under development to expand production capacity to 180,000 barrels per day by the early 1980's.

The location of the new 220,000-barrel-per-day refinery, to be built by Snam Progetti for the Zavia Refinery Co., was changed from Tobruk to Ras Lanuf. The refinery was to process crude oil from the Sarir and Misla Fields to be completed by 1981. Two other facilities were to be constructed by the early 1980's: A 400,000-barrel-per-day refinery at Zuetina and a 220,000-barrel-per-day refinery at Misratah. When completed, the new refineries would give Libya about 1 million barrels per day of refining capacity.

Petrochemicals.— Sekisui Chemical Co., Ltd. (Japan) undertook an 18-month study to help formulate a petrochemical production policy for the Government. The petrochemical complex at Marsa Brega was progressively coming onstream during 1978 with a $190 million ammonia plant with an initial production capacity of 330,000 tons per year and a methanol unit with a production capacity at 330,000 tons per year. A urea plant was to come onstream in Marsa Brega in 1979. Construction was by Foster Wheeler Italiana (Italy). In midyear 1978 a $150 million contract was awarded to Snam Progetti by NOC for a second 330,000-ton-per-year ammonia plant at Marsa Brega.

A large chemical complex was scheduled to begin production at Abú Kammásh near the Tunisian border. Annual production capacity was to comprise 60,000 tons of polyvinyl chloride, 50,000 tons of caustic soda, and 8,000 tons of liquid chlorine. An additional facility based on the large salt beds around Abú Kammásh was to produce 120,000 tons per year of salt. Construction was by a West German consortium led by Salzgitter Industri bau GmbH.

Three other facilities were under consideration by the Libyan Government. Belleli Industrie Meccaniche (Italy) won a contract for a 330,000-ton-per-year ethylene-based petrochemical complex using naphtha cut from the refinery as feedstock. A synthetic fibers plant was to be built at Ras Lanuf and a 100,000-ton-per-year ethylene dichloride plant was proposed for Abú Kammásh.

The Mineral Industry of Madagascar

By David E. Morse[1]

Madagascar, the world's fourth largest island, is predominantly an agricultural country with over 80% of the population employed in the agriculture sector. Agriculture contributed over 30% to the nation's gross domestic product (GDP) and accounted for 90% of material exports in both 1978 and 1979. The country's industrial sector was mainly directed at food processing and textiles with small segments dealing in timber, cement, fertilizers, and assembly of cars, bicycles, and radios. The mining industry continued to be a minor contributor to the nation's economy but, as in many developing nations, an important contributor to exports earnings.

Madagascar's major mineral products in 1978 and 1979 were chromite, flake and lump graphite, and phlogopite mica. A wide variety of gem and ornamental stones were also produced mainly for export. Unreported amounts of crude construction materials (clays, sand, stone, and gravel) were also produced for local use. Madagascar had significant resources of nickel, bauxite, iron, coal, bituminous sandstone, ilmenite, zircon, and rutile that were not being exploited in 1978 and 1979. The country has barely begun to realize its mineral potential, both from the exploration aspect and from the point of view of exploitation.

The current development plan, 1978-80, is aimed at increasing food production, reducing unemployment, and developing industry. An annual growth rate in real terms of 5.7% was projected for the duration of the plan, but the long-term goal was an average annual increase of 6.2% in the GDP to the year 2000. The 1978-80 plan provided for investments totaling $1.06 to $1.26 billion[2] to be spent on improving agricultural productively, building schools, processing minerals such as nickel and chromite, constructing roads, and completing of two new hydroelectric power schemes one at Andekaleka-Rogez on the Vohitra River and the other on the Namorona River.

PRODUCTION AND TRADE

Production statistics are given in table 1.

In 1978 and 1979, Madagascar continued to be an important world supplier of quality lump and flake graphite and also of phlogopite mica. Chromite exports valued at nearly $19 million in 1978 and 1979 primarily went to Japan and France. Petroleum products were exported to Comoros, Réunion, and Mauritius. Primary mineral imports were cement, iron and steel products, and crude petroleum. The Government continued its policy to restrict imports to minimize the materials trade deficit, which was $63 million in 1978 and an estimated $78 million in 1979. The latest available mineral trade statistics are given in tables 2 and 3.

COMMODITY REVIEW

METALS

Chromite.—A significant and unexplained drop in chromite output was recorded in 1978 and continued through 1979. The state-owned Kromita Malagasy operated the nation's only chromite-producing mines at Andriamena and Befandriana Nord in 1978 and 1979 with most of the output exported to France and Japan. The Government planned to build a 30,000-ton-per-year ferrochrome plant which was to come online in 1982 and use power from the Adekaleka-Rogez hydro-power scheme.

Iron Ore.—A program of drilling, prospecting, and chemical analysis was conducted on the Soalala iron ore deposits in 1977. Further investigations of the Soalala deposits were begun in 1979 by Italsider S.p.A. of Italy. The deposits are located on the island's west coast approximately 150 kilometers south of Majunga and were estimated to contain 300 to 400 million tons of ore.

Other.—No progress on developing the Manantenina bauxite deposits, the Tsaratanana chromite deposits, or the Ambotavy nickel deposit was reported in 1978 or 1979. No developments in exploiting heavy beach sand concentrations near Tamatave and near Ft. Dauphine on the east coast were announced in 1978 or 1979.

NONMETALS

Cement.—E.S. Cement d'Antsirabe awarded a contract to Loesche GmbH for the construction of a new 115,000-ton-per-year cement plant that was scheduled to come onstream in 1981. Madagascar's only operating cement plant at Amoania was not able to supply the nation's requirements, although it operated near capacity in both 1978 and 1979.

Fertilizer Materials.—In December 1978, Ze-Ren, a joint venture of the Madagascar Government and N-Ren International of the United States, began construction of the island's first fertilizer facility. The 100,000-ton-per-year ammonia-urea plant site was located at Tamatave near the nation's only oil refinery, which was to supply naphtha as feedstock for the fertilizer facility's ammonia plant. Completion was scheduled for late 1980.

Graphite.—The graphite industry in Madagascar has remained essentially unchanged for several decades. Quality flake and lump graphite is produced from highly weathered metamorphic rock that typically contains 2% to 7% graphite. Simple washing near the mines upgrades the product to 60% to 65% carbon as graphite concentrate. The concentrate, after removal of lump, is further upgraded by grinding, flotation, washing, and drying. Major gangue materials are clays and quartz. Madagascar contains one of the world's largest graphite-bearing horizons. Any significant increase in output depends on the Government's perception of the industry because the present operators were unable or unwilling to invest in new facilities, owing to previous nationalizations of other mining operations and lack of capital.

Mica.—The phlogopite mica-mining district is located in a triangular area of southeast Madagascar near Fort Dauphine. Mica exports of over 1,000 tons in 1978 and 1979 were approximately 15% splittings, 1% or less block, and over 80% scrap or waste. Major importers were Japan, the European Economic Community, and the United States.

MINERAL FUELS

Coal.—In July 1978, Madagascar's Ministry of Economy and Commerce contracted the Polish state-owned company Kopex to complete an economic and technical study on mining coal from the Sakoa formation in south central Madagascar. Sakoa reserves had been reported at over 60 million tons of bituminous coal with a 17% ash content. Total Sakoa resources were estimated to be nearly 1,000 million tons of high-ash non-coking coal.

Petroleum.—Madagascar produced no crude oil in 1978 or 1979 but continued to import and refine petroleum for its own needs and export products to neighboring Indian Ocean island nations. Output of the Tamatave oil refinery was well below the facility's 11,500-barrel-per day-capacity owing to Government import restrictions.

Uranium.—Officials from the National Military Office for Strategic Industries (OMNIS) and the United Nations Development Program (UNDP) signed a protocol agreement, for uranium exploration and exploitation in March 1979. Under the terms of the agreement, Madagascar was to provide services buildings, vehicles, and transport, and the UNDP was to provide the scientific staff and training for OMNIS personnel.

[2]Where necessary values have been converted from Malagasy Francs (FMG) to U.S. dollars at a rate of FMG230=US$1.00 in 1978 and FMG214=US$1.00 in 1979.

The Mineral Industry of Malaysia

By Edmond Chin[1]

During the 1960-78 period, Malaysia's economic growth averaged 6.4% per year; and by the end of the period, the gross domestic product (GDP) had reached $10.1 billion.[2] The GDP in 1979 was estimated at $10.9 billion, distributed as follows, in million dollars: Mining and quarrying, 545; agriculture, forestry, and fishing, 2,725; construction, 436; manufacturing, 2,071; and other industries, 5,123.[3] [4]

From 1960 to 1970, the mainstays of the mining sector were bauxite, iron ore, and tin. However, the gradual exhaustion of known reserves resulting from mining and the absence of significant new mineral deposits, caused the production of metal ores to decline annually. The most significant declines have been in bauxite output and, especially, iron ore output. Despite favorable prices, mine output of tin has generally declined since 1970. Offsetting the declining output of tin and other minerals, however, were discoveries of new oil wells that were brought into production beginning in the early 1970's. By 1978, output of crude petroleum totaled 218,000 barrels per day compared with 18,000 barrels per day in 1970.

The other components of Malaysia's primary industrial sector are palm oil, rice, rubber, and timber. By tonnage, timber is the largest component of the sector, but in terms of annual growth in output, palm oil leads with an average annual growth rate of 19%. Since 1960, the value added of the manufacturing sector grew at the rate of 11.5% per year, compared with the rate of 5.2% for the agricultural sector. Manufacturing enterprises consisted largely of the electronics, textile, and footwear industries and the processing of agricultural products.

Growth in the construction sector has been at 7.7% per year since 1960. Attempts were being made to develop poorer regions of the country and to quicken the pace of implementing construction in the public sector. Particular attention was directed toward infrastructure development for roads, railways, ports, electricity, and water.

Malaysia's external trade continued to be the most important aspect of its economic activity, with the value of exports and imports each accounting for nearly one-half of the gross national product. Presently, trade duties account for one-third of the country's total Federal Government revenue and over 60% of total indirect taxes. The composition of external trade has changed significantly during the last two decades. Export earnings from rubber and tin accounted for about 69% of the total export value in 1960, but by 1978, these two products accounted for only 33% of the total value. By contrast, the combined share of palm oil, timber, and petroleum exports increased from 11% of the total export value to 39% over the same period. However, manufactured goods were the leading export earner, accounting for 21% of the total export value. The composition of Malaysia's gross exports is given in the following tabulation, in percent of total value of exports:

Sector	1960	1965	1970	1975	1978
Agricultural	66.1	54.5	59.2	52.8	50.6
Minerals	22.2	30.0	25.9	22.6	25.6
Tin	14.0	23.1	19.6	13.1	11.8
Petroleum	4.0	2.3	3.9	9.3	13.2
Other	4.2	4.6	2.4	.2	.6
Manufactures	8.5	12.2	11.9	21.4	21.2
Other exports	3.2	3.3	3.0	3.2	2.6

There has been a trend in Malaysia toward less reliance on imports of consumer goods and toward increased imports of intermediate and investment goods. The share of consumer goods in total imports fell from about 47% in 1960 to 22% in 1978. During this same period, imports of intermediate goods rose from 28% to 45%, and imports of investment goods rose from 17% to 31%.

The consumer price index (CPI) for Peninsular Malaysia reflected an inflation rate of 1% per year throughout the 1960's. However, price stability was disrupted in 1973 and 1974 by imported inflation averaging 14% per year. Domestic prices stabilized during the 1975-78 period, when the CPI averaged 4.2% annually.

PRODUCTION

On the basis of value, production of crude petroleum was Malaysia's most important mineral commodity. By the second quarter of 1979, production reached 25.8 million barrels, due mainly to higher output from the Pulai, Tapis, and Bekok Oilfields off the shore of Peninsular Malaysia. Crude oil output was small by world standards, however; it amounted to less than 1% of the total world output.

Malaysia is the world's largest producer of tin, accounting for about 25% of the world's output. Metal output of tin in 1978 and 1979 came from the Butterworth and Penang smelters. Production of tin-related minerals included significant quantities of ilmenite, monazite, and zircon. Small quantities of columbite, gold, scheelite, tantalite, wolframite, and xenotime were also produced as tin byproducts. The number of tin-producing operations in 1978 totaled 936, of which 833 were gravel pumps, 53 dredges, and 50 were other types.

Bauxite was produced by one operation in Peninsular Malaysia. Copper was produced by the Mamut Mine in Sabah. There were 8 iron ore operations, and china clay was produced by 13 operations in Peninsular Malaysia. In addition, Malaysia produces small quantities of antimony, barite, kaolin, and manganese.

Malaysia's natural gas production is associated with its crude oil production. Only an estimated 20% of the gas is utilized; the rest is flared.

[e]Estimate. [p]Preliminary. [r]Revised. NA Not available.
[1]All production is from Malaya unless otherwise specified.
[2]In addition to the commodities listed, a variety of crude construction materials (clays, sand and gravel, and stone), salt, and fertilizers are also produced, but output is not reported and available information is inadequate to make reliable estimates of output levels.
[3]Estimates based on exports of copper concentrates.
[4]Reported figure.
[5]Based on export figures.
[6]Includes small amounts of tin from the smelter in Singapore.
[7]Includes production from Malaya and Sarawak.

TRADE

The bulk of Mayaysia's total export earnings was derived from exports of products of the agriculture, forestry, and fishing; mining and quarrying; and manufacturing sectors. Malaysia exports over 95% of its total production of rubber and tin, over 85% of its production of palm oil and petroleum, nearly 60% of its log and timber production, and about 20% of its manufacturing output. These products account for about 95% of the value of total exports. Total exports in 1978 were estimated at $7.8 billion, compared with $6.2 billion for imports.

Tin was the country's fifth largest export earner in 1978 after rubber, timber, petroleum, and palm oil, in that order. Tin exports accounted for almost 12% of the total exports in 1978. Although tin exports had declined in tonnage, the value of tin exports had increased as a result of the increases in tin prices. From 1960 to 1978, the average price of tin increased about fourfold, from $3,000 per ton to $13,000 per ton.

The prominence of petroleum in Malaysia emerged in the 1970's when oil exports increased from $92 million in 1970 to $388 million in 1975 and to $1.03 billion in 1978. These large increases in exports resulted from increased production from wells along the east coast of Peninsular Malaysia and in offshore Sabah and Sarawak. Because of the rising price of oil, petroleum was expected to become Malaysia's single largest export commodity, by value, by 1980.

Japan was the major importer of Malaysian products, with receipts totaling $1.7 billion, and was followed by the United States ($1.4 billion) and Singapore ($1.3 billion). Collectively, these countries comprised 66.5% of Malaysia's total export value. Malaysia's major import sources were Japan ($1.4 billion), the United States ($0.9 billion), Singapore ($0.5 billion), and the Netherlands ($0.5 billion).

Aside from petroleum, the largest growth in imports was in manufactured goods, followed by metal products, construction materials, agricultural products, and miscellaneous machinery. The growth of these imports reflected the current trend favoring imports of semimanufactures and investment goods over imports of consumer goods. More specifically, it reflected Malaysia's emphasis on economic development through investments in agriculture, construction, manufacturing, and infrastructure.

COMMODITY REVIEW

METALS

Aluminum.—Bauxite was produced by the Telok Ramunia Mine in Johore State, operated by Southeast Asia Bauxite Sdn. Bhd., a subsidiary of Alcan. Annual mine output has decreased from the 1-million-ton level of the 1969-73 period to about two-thirds this level in 1978. Mine production has been diminishing annually owing to lower grade ore. Ore reserves at Telok Ramunia were estimated at about 10 million tons. Because Malaysia lacks both alumina and smelter facilities, its bauxite production was exported; as in previous years, the bauxite output was exported to Japan.

The Sabah and Sarawak State governments have been encouraging the construction of smelter facilities at Labuan Island and Bentulu, respectively. Because of increased oil production, up to 80% of the associated natural gas from Malaysia's offshore oilfields was flared rather than utilized. The proposed smelter at Labuan would use natural gas for generating electrical energy, and natural gas from the Bentulu field might be used initially for an aluminum smelter in Sarawak.

Copper.—Overseas Mineral Resources Development Sabah Bhd. produced copper concentrate grading 28% copper from the Mamut porphyry copper mine in Sabah, on the northern end of Borneo Island. This concentrate is shipped to Japan for smelting and refining. The ore mineral at Mamut is composed primarily of chalcopyrite with molybdenite, galena, and sphalerite. Copper mineralization occurs in the potash-rich adamellite porphyry intrusion as well as in the wall rock (serpentinite and clastic sedimentary rocks). Mamut has an estimated ore reserve of 179 million tons of 0.476% copper and about 0.5 grams per ton of gold.

Iron Ore.—Annual mine production of iron ore has declined to about 300,000 tons in recent years. Iron ore was mined from relatively small deposits by eight operations in Panang, Johore, Perak, and Kedah States, all of which are in Peninsular Malaysia. Production in Panang accounted for about one-half the total output. Although deposits of high-grade ore are known to exist in Malaysia, none contain sufficient reserves to support profitable mining.

Tin.—Malaysia continued to be by far the largest world producer of mine tin and tin metal in 1978 and 1979. Of the 1978 mine tin output, 54% was from gravel pumping operations; 32% was from dredging; 5% was from open casting; 2% was from underground mines; and the remainder was from various small operations. During 1978, there was a total of 936 active mining operations, comprised as follows: gravel pumps, 833; dredges, 53; open cast, 22; and others, 28. Workers employed by Malaysia's gravel pumping operations made up 66% of the world tin industry's total labor force.

Employment by other types of tin-producing operations was as follows: dredging, 8,700 persons; open casting, 1,500 persons; underground mines, 1,900 persons; and others, 1,600 persons.

Despite high prices (M$1,822 per picul at the beginning of 1979, compared with the average price of $1,743.19 per picul during 1978), total tin production continued to show an overall downward trend. Aside from production in 1977, the output in 1978 was the lowest since 1965.

To encourage new production, the tin industry petitioned the Government to revise the tax policies that applied to tin mining. It was estimated that the Government received up to 80% of the mining companies' profits through taxes. Affecting the industry were direct taxes, including export duties and taxes on tin profits, income, and development; and indirect taxes such as sales tax, import duties, and a surcharge on imports.

Because of increased profitability, tin stealing and smuggling has increased since 1977. In 1978, 3,247 piculs of tin ore valued at $5.5 million was seized from smugglers, compared with 2,626 piculs worth $3 million in 1977. The value of export duty payable on the ore seized in 1978 was estimated at $1.1 million. The Government was expected to review and evaluate the Tin Control Regulations of 1977 in light of the increase in tin theft and smuggling.

Land alienation, conversion, and renewal is a State matter. However, export duty is paid to the Federal Government, and the State receives only a small percentage of the duty along with annual land fees. As a result of this arrangement, the States have been reluctant to allocate land for mining ventures. A committee of representatives of the Federal and State Governments was reviewing the draft of a National Mining Code to streamline procedures governing prospecting, the issuing and renewal of leases, and the conversion of mining land.

Malaysia Mining Corp. (MMC), formerly London Tin Group, accounts for about 30% of the country's tin concentrate output and is one of the world's leading tin producers. MMC, which is owned 71.35% by Pernas Securities and 28.65% by Charter Consolidated, has individual holdings in 13 Malaysian tin mining companies. Pernas Charter Management, general manager of all of MMC's companies, including two in Thailand, operated 35 dredges in Malaysia. MMC arranged to sell tin directly to consumers, after smelting on a toll basis, rather than to the Penang Tin Market. Also, MMC was preparing to establish a Commodities Exchange in Kuala Lumpur, was possibly interested in becoming directly involved with smelting, and was actively negotiating joint ventures in various States with established mining companies.

Companies operating tin-producing dredges were as follows: Ayer Hitam, three dredges at its mining leases south of Selangor; Berjuntai, seven dredges in Kuala Selangor; Kamunting, two dredges near Taiping; Malayan Tin, five dredges near Kampong Gajah in Perak; Southern Kinta, two dredges in Bernam, Selangor, and one in southern Kanipar in Kinta Valley; Southern Malayan, six dredges in Tanjong Tualang in Kinta Valley and Batang Padang, Perak; Tronoh Mines, two dredges in Ayer Kuning, Perak; Bidor Malaya Tin (51% owned by Tronoh Mines), four dredges in Bidor, Perak; Penghalen, one dredge in Kinta Valley in Perak; Petaling Tin, two dredges in southwest Selangor; and Tanjon Tin, one dredge in Kinta Valley in Perak. Kinta Kellas also operated a dredge and an open-cast mine in Kinta Valley. Goping has open-cast, hydraulic, and gravel pumping operations in Ipoh, Perak; and Idris Hydraulic uses gravel pumping hydraulic operations in Ipoh. Pahang Consolidated operates the only underground lode mine in the country on the east coast of Peninsular Malaysia. As of July 31, 1978, ore reserves at this mine were estimated at 500,000 tons at an average grade of 1.3% tin.[5]

Titanium.—Ilmenite, an iron-titanium oxide, is a major mineral obtained as a byproduct of alluvial tin mining. Malaysian ilmenite assays about 53% TiO_2, but higher grades (up to 65% TiO_2) have been recovered at Sungkai, Perak and Petaling, Selangor. Exports of ilmenite, all from West Malaysia, totaled about 187,000 tons in 1978.

Other Metals.—Other minerals recovered from tailings of dredging operations included columbite, scheelite, zircon, and the rare-earth minerals, monazite and xenotime. In addition to small quantities of wolframite concentrate recovered as a byproduct of alluvial tin operations, the major source of tungsten production in Malaysia was a wolframite lode in Panang. Gold was recovered as a byproduct of tin dredging operations at Batang Padang and Kuala Lumpur, and from small-scale mining operations in the Raub area and the Bau District in Sarawak. During 1978, 11 operations were mining gold; 7 were in Sarawak, and 4 were in Peninsular Malaysia.

NONMETALS

Cement.—Cement production in 1978 increased by about 24% over the 1977 level of production. Malaysia's largest cement producer was Tasik Cement Bhd. in Ipoh, which has an annual output capacity of 1.04 million tons. Other cement producers were as follows, with capacity expressed in thousand tons per year: Associated Pan Malaysia Cement Sd. Berhad, 900; Cement Industries of Malaysia Sd. Berhad, 400; and Malaysia Industrial and Mining Corp. Berhad, 60.

Fertilizer Materials.—Domestic production of nitrogenous phosphatic and potassic fertilizers totaled about 327,000 tons, and 20 companies contributed to the total. Three of these companies accounted for about 35% of the total output. In order to meet the domestic demand for fertilizers, an equivalent quantity of fertilizers was imported in 1978; imports consisted mainly of potassic fertilizers, urea, and composite, complex, and compound fertilizers. The major suppliers of fertilizer materials were the Christmas Islands, Canada, the Federal Republic of Germany, Japan, and the United States.

Other Nonmetals.—Crushed rock was produced primarily in Selangor, Johore, Panang, and Perak. Crushed granite, most of which was used for road metal and concrete aggregate, accounted for 68% of total production. The remainder was predominantly limestone, of which about 50% was used for road metal and concrete aggregate, 40% was used for cement manufacture, and 10% used for for various specialty applications. Almost all of the output of sand and gravel was used as concrete aggregate; and Perak, Tohore, Penang, and Pahang were the major producing States.

Kaolin production remained at 32,000 tons per year. Mine output came from 13 operations, all in Peninsular Malaysia. Part of the output was consumed locally by the ceramic, paint, rubber, plastics, and pesticide industries; the remainder was exported to Japan and Singapore. Domestic ball clay, obtained mostly from alluvial tin mining operations, was used with kaolin for manufacturing wall, floor, mosaic tiles, sanitaryware and tableware. Common clay mined locally was used primarily for drainage and sewer pipes, flower pots, and similar uses.

Output of quartz sands and powder was primarily from sand deposits in Johore and from tin tailings operations. Most of the quartz was used locally by the glass and ceramics industries, and some was exported. Barite production was wholly from the Tasek Chini deposit in Pahang.

MINERAL FUELS

Petroleum and Natural Gas.—At the beginning of 1979, Malaysia's proven reserves of oil were estimated at 2.8 billion barrels.[6] Oil production by 3 companies in 1978 averaged 196,500 barrels per day and was from 154 producing flow wells. Output by Esso Malaysia from the Pulai, Tapis, and Tembungo fields averaged 32,700 barrels per day; Sarawak Shell produced 94,100 barrels per day from the Bakau, Baram, Baronia, Fairley-Baran, Tukan and West Lutong fields; and Sabah Shell produced 69,700 barrels per day from the Samarang field. The largest producing fields to date have been Baram, discovered in 1973 (cumulative production of 91.2 million barrels); followed by West Lutong (84.6 million barrels since 1966); Miri (79.7 million barrels since 1911, but now shut in); Baronia (59.9 million barrels since 1967); and Samarang (54.6 million barrels since 1972).

Because of disputes involving estimated reserves and projected development costs, Conoco withdrew from its concession in Sotong, and its acreage was relinquished to Petronas Carigali, the exploration-drilling arm of Petronas, the national oil company. Carigali was expected to begin drilling in 1980, individually or with a partner, on the old Conoco concession. Seven wells were planned, three for appraisal and four for exploration.

Natural gas reserves in Malaysia was estimated at 17 trillion cubic feet as of January 1, 1979. Presently, all natural gas output is associated with oil production. Only about 20% is captured, and the remainder is flared. However, Shell was developing gas reserves to feed a $1 billion liquefied natural gas (LNG) project in Sarawak. Beginning in 1983, 850 million cubic feet per day of LNG is to be exported to Japan.

The Mineral Industry of Malta

By Roman V. Sondermayer[1]

During 1978-79, Malta produced only limestone and salt. Modest demand for fuels, lime, cement, fertilizers, diamonds, and metals was met through imports.

The major event related to minerals was the organization of Enemalta Corp., which was established by an Act of Parliament-Act XVI of 1978. Enemalta took over responsibilities of the Electricity Board and the Gas Board of Malta. The new organization is in charge of all energy-related activities in Malta including production of electricity and distillation of sea water. In 1979, the possibility of building a petroleum refinery on Malta was examined together with the Government of Libya, which showed interest in financing the project. However, at yearend 1979, no agreements on the refinery project were announced.

PRODUCTION

Table 1 shows the latest trends in production of minerals in Malta. The industry was mostly made up of small family-run enterprises.

Table 1.—Malta: Production of mineral commodities

Commodity and unit of measure	1976	1977	1978[p]	1979[e]
Lime thousand metric tons	27	32	28	30
Limestone[e] [1] thousand cubic meters	962	802	850	900
Salt metric tons	290	797	600	500

[e]Estimate. [p]Preliminary.
[1]Figures represent reported production plus an estimate for quantitatively unreported output.

TRADE

Malta depended on imports of a number of mineral commodities but all in small quantities.

Fuels were major import and export items; bunkering was the principal category of exports. Foreign mineral trade is shown in table 2.

The Mineral Industry of Mauritania

By Candice Stevens[1]

The production and export of iron ore, Mauritania's main export commodity, rebounded in 1979 after falling to low levels in 1978. The rise of the Mauritanian economy began with the start of iron ore production in 1963, and the decrease in iron ore production in 1978 caused an overall economic decline. Adverse world market conditions, depletion of the older deposits, and local conflict prompted the decrease in iron ore output and reduced the contribution of the mineral sector to 21% of the gross domestic product (GDP) of $515 million.[2] For similar reasons, the copper operation at Akjoujt closed down in 1978. In that year, Mauritania suffered a large balance of trade deficit, a balance of payments deficit of $80 million, and a total foreign debt burden of $750 million.

The country's primary development projects were the exploitation of low-grade iron ore reserves, the construction of a deepwater port at Nouakchott, and the completion of the Nouakchott-Nema road. In an effort to stabilize the economy, the Government enacted measures to reduce imports by 20%, reschedule foreign debts, cut Government expenditures through an austerity budget, and revive the private sector. A new investment code adopted in 1976 included economic incentives for private enterprise such as tax exemptions, guarantees against nationalization, and provisions for private repatriation. In 1978, Mauritania received a loan of $13.7 million from the International Monetary Fund (IMF) to help offset the drop in the country's export earnings.

The Société Nationale Industrielle et Minière (SNIM) was the Government's holding company in charge of most mining operations. In 1978, the Government offered for sale 49% of the stock in SNIM to obtain financing for the iron ore project. At yearend 1979, new shareholders included the Arab Mining Co., the Islamic Development Bank, Morocco, Kuwait, Iraq, and Libya. SNIM was also relieved of its operating responsibilities for the Nouadhibou petroleum refinery and the Akjoujt copper mine in the attempt to solidify its economic foundation. SNIM registered a loss of $16 million in 1978 but reported an improved financial situation in 1979.

PRODUCTION AND TRADE

The production of Mauritania's major mineral commodity, iron ore, declined greatly in 1978 owing primarily to disruptions in the supply route and low world prices, but normal production levels were reinstated in 1979. Less than 3,000 tons of copper was produced in 1978 and the mine was closed in midyear. Gypsum production evidenced an increasing trend as operations were expanded.

Mauritania's balance of trade deficit increased to $176 million in 1978 when mineral exports were at low levels. Mineral exports typically account for about 73% of total export value. Iron ore exports fell to 6.5 million tons in 1978 but increased to about 9 million tons in 1979. In 1978, iron was exported to France (34%), Italy (22%), other Western European countries, and Japan. In 1979, Mauritania concluded an agreement with Japan to export 1.4 million tons of iron ore during the year. All copper production was exported primarily to France and Spain. Gypsum production was exported to Senegal. In 1978, Mauritania imported about 3,000 tons of fertilizer, 52,000 tons of cement, and 200,000 tons of refined petroleum products.

Table 1.—Mauritania: Production of mineral commodities

Commodity[1] and unit of measure	1976	1977	1978[p]	1979[e]
Copper, mine output, metal content ---------- metric tons--	9,431	7,640	1,773	--
Gold ---------- troy ounces--	22,120	28,000	8,000	--
Gypsum ---------- metric tons--	11,195	10,176	13,438	13,600
Iron ore and concentrate, gross weight thousand metric tons--	9,644	9,794	6,934	8,000
Rare-earth metals: Monazite concentrate, gross weight[e] metric tons--	100	100	100	100
Salt, marine[e] ---------- do----	1,000	1,000	1,000	1,000
Silver ---------- troy ounces--	31,572	[e]26,000	19,000	--

[e]Estimate. [p]Preliminary.

[1]In addition to the commodities listed, modest quantities of unlisted varieties of crude construction materials (clays, stone, and sand and gravel) presumably are produced, but output is not reported quantitatively and available information is inadequate to make reliable estimates of output levels.

COMMODITY REVIEW

METALS

Copper.—Mining at the Akjoujt copper deposit ceased in May 1978 owing to financial losses caused by low copper prices and technical difficulties at the mine. Losses in 1977 were reported at $13 million. Reserves of copper oxide ore were almost depleted. Exploitation of copper sulfide reserves was postponed owing to the financial difficulties of SNIM. Reserves of copper sulfide ore were estimated at 14 million tons averaging 2.3% copper. Original plans called for mining 120,000 tons of sulfide ore per year and the construction of a new flotation plant. Plans for the construction of a copper smelter at Nouakchott were also canceled.

Iron Ore.—In 1978, iron ore production fell to its lowest level since the nationalization of the industry in 1974. With the resolution of the local conflict situation and an increase in world prices, output increased in 1979. Exploitation of the iron ore deposits in the Kedia d'Idjil range near the city of Zouerate was under the direction of the Complexe Minier du Nord (COMINOR), a division of SNIM. The older mines, Tazadit, Rouessa, and F'Derick, had an annual production capacity of 11.4 million tons per year. Reserves were expected to be depleted by 1985.

Mauritania's major development project was the exploitation of low-grade iron orebodies known as the Guelb deposits. More than 25 Guelb deposits, containing magnetite ore with a content of 38% iron, were within a radius of 50 kilometers of Zouerate. Exploration was focused on the deposits of El Rhein and Oum Arwagen, with combined reserves of 400 million tons. A pilot plant was erected at Zouerate in 1974 that produced magnetic and oxidized sinter feed with 64% to 66% iron through autogenous grinding and dry magnetic separation. A feasibility report prepared by Société de Cooperation Minière et Industrielle (Socomine) (France) in 1975 scheduled the startup of the El Rhein deposit and the first section of a benefication plant in 1981. The startup of the Oum Arwagen deposit and the second stage of the plant was to follow in 1988. Annual production capacity was to be initially 6 million tons rising eventually to 12 million tons. Production was to be transported and shipped by way of the existing 650-kilometer rail link to the port of Nouadhibou. Socomine, which was awarded a contract for supervision of the Guelbs project, issued tenders for the supply of equipment for mining, materials handling, and civil engineering in 1978.

Almost all financing was secured for the first stage of the project estimated to cost $500 million. SNIM was to contribute $43 million. The remainder would be financed by an international consortium of donors led by the International Bank for Reconstruction and Development (IBRD) ($60 million), Saudi Arabia ($60 million), and Kuwait ($40 million).

A ministeelworks began production in Nouadhibou in March 1979. Capacity of the steelworks was 12,000 tons per year of raw steel and 36,000 tons per year of rolled steel. Studies were in progress by Kobe Steel Ltd. (Japan) on the construction of an iron ore pelletizing plant at Nouadhibou. The $130 million plant was to be operated by Société Arabe d'Industries Metallurgiques (SAMIA), a joint venture of Mauritania and Kuwait.

Uranium.—The uranium exploration program in the northern Tasiast and Dorsale Reguibat regions was suspended in 1978 owing to conflict in the area but the program resumed at yearend 1979. Prospecting has been carried out since 1975 by Compagnie Francaise des Petroles (CFP) in conjunction with Pechiney Ugine Kuhlman, the Commissariat à l'Energie Atomique (France), and the Tokyo Uranium Development Co.

NONMETALS

Gypsum.—Production of gypsum increased at Sebkha de N'Drahamcha, located 65 kilometers north of Nouakchott. Gypsum was contained in high-grade, fine-particled sand grading 94% $CaSO_4$ and less than 0.3% NaCl. Output was exported to Senegal for use in the Société Quest-Africaine des Ciments (SOCOCIM) plant at Rufisque. SNIM hoped to diversify the gypsum export market upon the completion of the new deepwater port at Nouakchott.

As part of an $8 million credit received from the International Development Association (IDA), consulting services were to be provided to study the feasibility of establishing a gypsum plaster brick industry. The construction of a plaster works was to alleviate Mauritania's dependence on imported cement with locally made brick. It was also reported that SNIM was conducting a feasibility study of a 150,000-ton-per-year cement plant.

Salt.—Studies were being conducted by the Compagnie pour Etudes Techniques et Economiques (COMETE) (France) for the exploitation of the Sebkha N'Drahamcha salt deposits. The deposits were estimated to contain 11 million tons of salt. Annual production capacity was expected to be 30,000 tons per year.

MINERAL FUELS

Petroleum.—Approximately 100,000 tons of petroleum was refined at the Nouadhibou refinery, completed in June 1978. After this test run, the refinery was closed owing to crude oil supply problems and the necessity of instituting technical modifications to meet safety requirements. Constructed by Voest Alpine (Austria), annual production capacity of the refinery was 1 million tons per year. Output was originally to supply domestic requirements (300,000 tons per year) with the balance destined for European markets. Negotiations were being conducted with Algeria in 1979 for technical assistance in making the refinery operational.

Exploratory drilling for petroleum was to be undertaken by the Seagap Group, a consortium including Hispanoil, Phillips Petroleum Co., and Shell Oil Co. The group held a 24,000-square-kilometer concession including both onshore and offshore areas near Nouadhibou. Elf-Acquitaine (France) acquired a concession area offshore Nouakchott in 1979 and was to commence exploration in 1980.

The Mineral Industry of Mexico

By Doris M. Hyde[1]

Mexico's economy has shown significant growth. The 1978 gross domestic product (GDP), at constant 1960 prices, was $92.4 billion,[2] an increase of 7% over 1977. In 1979, the GDP was estimated at $120 billion and represented the highest growth rate in 10 years. Growth was stimulated by increased private and public investment and increased consumption. Higher inflation accompanied Mexico's economic growth—rising 17.5% in 1978 and 18.2% in 1979.

There has been a sharp increase in the demand for goods and services and, consequently, import levels increased dramatically. In 1979 the total value of imports was more than double that for 1977. The total export value also doubled in this 2-year period; but in spite of an almost quadrupling of crude oil export value, the trade deficit grew from about $1.5 billion in 1977 to $3.2 billion in 1979.

Mexico's mining industry produces 18 metallic and 28 nonmetallic minerals. Ten of these, copper, coke, fluorspar, gold, iron, lead, manganese, silver, sulfur, and zinc, represent about 93% of the value of total mineral production. In 1979 mineral production accounted for 1.3% of the GDP, compared with 1.1% in 1978. Investments in the mineral sector under the "Alliance for Production" have reached approximately $1.28 billion and in 1980 an investment of about $775 million is expected.

An inadequate railroad transport system and insufficient port capacities adversely affected both internal and external movement of material in the petroleum and the mineral industries. Mining companies found it necessary to move concentrates by more costly and slower truck transport. Additional railroad equipment came into service by the end of 1979 as part of a modernization program promised in 1978. The Government has also initiated measures to upgrade port facilities.

Government Policies and Programs.—The new mining taxation and subsidy law, which became effective January 1, 1978, combined the previous production and export taxes into a simplified production tax based on the mineral content of the ore or concentrate. The tax varies with the mineral produced: 9% on the official value of gold, silver, and sulfur; 4% on coal, iron ore, and manganese; and 7% on all other minerals. A 2% per annum reduction or subsidy of the value of minerals produced is allowed if the money is reinvested in exploration or mineral development during the same calendar year. An additional reduction of 1% is allowed to small producers whose annual gross mineral sales are less than $1 million. A 75% subsidy of the general import taxes on machinery, equipment, parts, and replacements, was granted to mining concerns that import these items when they are not manufactured in Mexico. This latter subsidy requires prior approval of the Finance and Public Credit Secretariat. Concession taxes were set at $1.33 per hectare for nonmetallic minerals and $2.65 per hectare for metallic minerals. The exploration tax was set at $0.44 per hectare per year.

The mining industry has benefited from the new mining tax law, and it was reported that additional changes are under consideration to further simplify mining operation and investment.

In November 1978, the Consejo de Recursos Minerales joined with the United Nations Institute for Training and Research to hold the First International Conference on Small-Scale Mining of the World. Nearly 70 countries were represented at the meeting in Mexico. A small-scale mining company, by Mexican law, is one which produces a gross income under $880,000 annually. These small operations are considered important from the employment aspect since they are less capital intensive and cover a wide geographic area. In many instances they have provided the preliminary work for what eventually became large operations.

Late in 1978 the Government placed the entire nuclear industry under a single agency, the Comisión Nacional de Energía Atómica (CNEA). CNEA will have the ultimate responsibility over research, production, and marketing. Under CNEA's control are the Instituto Nacional de Investigación Nuclear (ININ), the research division; and Uranio de Mexico (Uramex), the division responsible for supervising exploration and exploitation. The bill that established CNEA also stipulated that no uranium could be exported until a 15-year nuclear energy program for Mexico had been submitted and approved.

PRODUCTION

In 1978, Mexico easily maintained its position as the world's leading producer of silver. Contrary to expectations and despite price incentives, silver production fell in 1979. Gold output also declined in 1979. The production declines were attributed to lower grade ores and not to inactivity at major installations. Decreased 1979 production of manganese was offset by increases in dollar values.

The mid-1979 opening of the La Caridad copper mine was reflected in the substantial increase in 1979 copper production over that of 1978. As the mine progresses toward full development, copper production in 1980 is expected to more than double that of 1979.

Mexican mercury producers were not able to take full advantage of an improved mercury market in 1978-79 due to the disorganization resulting from operators working small scattered deposits. These deposits have a limited productive life and present little opportunity to adjust production to demand. Many operations had ceased when the mercury market fell to unprofitable levels in 1976.

Petroleum production gains were impressive in 1978-79, but fell somewhat short of earlier predictions. Crude oil production from the Northern Zone during 1978 increased over that of 1977; but in 1979, production fell below the 1977 level. This same production pattern was true for the Central Zone. It was in the Southern Zone that large production increases were sustained in 1978-79, especially in the Comalcalco, El Plan, and Gulf of Campeche areas. Natural gas production increased in all three zones during 1978-79, with the Southern Zone predominating. Natural gas flaring was reduced to 6% in 1979. As new gas-processing plants and pipelines come on-stream, flaring is expected to drop to about 3% of production in 1980.

[e]Estimate. [p]Preliminary. [r]Revised. NA Not available.
[1]In addition to the commodities listed, lime, pumice, and additional types of crude construction materials are produced, but output is not reported and available information is inadequate to make reliable estimates of output levels.
[2]Reported figure.
[3]Sb content of ores for export plus Sb content of antimonial lead and other smelter products produced.
[4]Calculated white As equivalent of metallic As content of products reported.
[5]Bi content of refined metal, bullion, and alloys produced indigenously, plus recoverable Bi content of ores and concentrates exported for processing.
[6]Calculated from reported Fe content on the basis of ore containing 66.67% iron.
[7]Calculated from reported Mn content of mine production on the basis of ore containing 36% manganese.
[8]Estimates by the International Tin Council.
[9]Excluding that for cement production.

TRADE

Petroleum continued to dominate Mexico's export trade. In 1978 petroleum exports contributed about 30% to the $6.2 billion value of total exports, and in 1979 it accounted for an estimated 45% of the $8.9 billion total value. About 96% of all petroleum exports consisted of crude oil. The United States has remained the major importer of Mexican oil. Throughout 1978-79 Mexico continued to diversify its future petroleum export market, successfully using oil as a means of obtaining favorable technological and industrialization cooperative agreements.

After almost 2 years of price negotiations, Mexico agreed to sell 300 million cubic feet per day of natural gas to the United States with export to begin in January 1980. The price, $3.625 per thousand cubic feet, represented a substantial boost to the Mexican export economy as it is tied to world petroleum prices and subject to a quarterly review.

In 1978 the value of nonfuel mineral exports was about $510 million. Exports to the United States accounted for 60% of this value. In 1979 nonfuel mineral export value increased to $789 million. Silver, zinc, lead, sulfur, and fluorspar minerals remained the leading mineral exports in 1978, representing 48% of total value. Despite decreased silver export volumes, its steadily rising price during 1979 was the major reason for the increase in the overall nonfuel mineral export value for that year.

Imports of nonfuel minerals in 1978 reached $417 million, a 68% increase over the 1977 value. Increased imports of aluminum, iron, and copper accounted for about 85% of the value difference. In 1979 Mexico's mineral import costs increased to an estimated $513 million.

Commodity	1977	1978	Principal destinations, 1978
METALS			
Aluminum metal including alloys, all forms	51	(1)	All to United States.
Antimony:			
Ore and concentrate	3,387	4,871	United States 3,104; United Kingdom 1,767.
Metal including alloys, all forms	143	384	Brazil 191; United States 160; Netherlands 31.
Arsenic trioxide, gross weight	3,244	2,802	United States 2,364; Brazil 417; Australia 15.
Bismuth metal including alloys, all forms	331	187	Belgium-Luxembourg 145; United States 40; Netherlands 1.
Cadmium:			
Intermediate metallurgical products	3	--	
Metal including alloys, all forms	961	759	United States 597; United Kingdom 55; Netherlands 28.
Chromium: Chromite	--	4	All to Costa Rica.
Cobalt, intermediate metallurgical products	--	8	All to United States.
Copper:			
Ore and concentrate	995	569	Do.
Copper sulfate	420	1,011	Brazil 632; United States 294; Honduras 33; Japan 25.
Metal including alloys, all forms	12,885	960	Japan 897; United States 56; Peru 5.
Iron and steel:			
Ore and concentrate	802	1,015	Guatemala 545; United States 400; West Germany 70.
Metal:			
Scrap	1,745	315	United States 281; France 34.
Pig iron and similar materials	150	43	All to United States.
Sponge iron, powder, shot	192	7,127	Japan 6,547; United States 294; Venezuela 186.
Ferroalloys	26,619	3,331	NA.
Steel, primary forms	2,985	1,152	Mainly to United States.
Semimanufactures	15,786	14,119	United States 13,656; Venezuela 250; Guatemala 64.
Lead:			
Ore and concentrate	9,965	11,108	All to United States.
Oxides	34,692	37,470	United States 21,513; Venezuela 6,993; Colombia 1,650.
Metal including alloys:			
Scrap	137	44	All to United States.
Unwrought	77,574	75,438	United States 41,702; Italy 14,126; Japan 8,763.
Semimanufactures	574	330	United Kingdom 167; West Germany 78; Canada 28.
Manganese ore and concentrate	257,213	198,509	Japan 76,959; France 55,016; United States 30,613.
Mercury 76-pound flasks	13,870	6,278	Brazil 2,804; United States 2,790; Argentina 303.
Molybdenum metal including alloys, all forms kilograms	91	--	
Nickel metal including alloys, all forms do	1,485	2,380	Guatemala 2,282; Nicaragua 98.
Selenium, elemental	52	30	United Kingdom 14; United States 10; Brazil 6.
Silver:			
Ore and concentrate thousand troy ounces	942,504	941,539	All to United States.
Metal including alloys, all forms do	23,126	26,472	United States 14,893; United Kingdom 5,484; Belgium-Luxembourg 3,071.
Tin:			
Ore and concentrate	--	61	United States 60; Peru 1.
Metal including alloys, all forms	--	1	NA.
Tungsten ore and concentrate	407	437	United States 427; Netherlands 10.
Zinc:			
Ore and concentrate	140,914	125,520	West Germany 59,080; United States 57,077.
Oxide	9,972	11,274	United States 10,688; Canada 158; Guatemala 153.
Metal including alloys, all forms	106,144	104,666	United States 51,038; Brazil 28,506; Venezuela 5,428.
NONMETALS			
Abrasives, natural	505	142	United States 110; Guatemala 30.
Asbestos	(1)	55	Mainly to Canada.
Barite and witherite	122,204	98,227	All to United States.
Clays, crude:			
Bentonite	9	23	Mainly to United States.
Fuller's earth	16,419	14,558	Brazil 5,517; West Germany 2,043; Colombia 1,209.
Kaolin (china clay)	(1)	53	Guatemala 50; Haiti 2.
Other	387	574	Guatemala 170; Colombia 138; United States 80.

See footnotes at end of table.

Table 2.—Mexico: Exports of mineral commodities —Continued

COMMODITY REVIEW

METALS

Aluminum.—The high cost of aluminum production held back primary aluminum smelter expansion and was mainly responsible for Mexico's 1978 withdrawal from participation in the proposed joint Mexico-Jamaica Jalumex aluminum smelter project planned for Coatzacoalcos near Veracruz.

Mexico lacks domestic bauxite reserves and must import alumina. In 1979, Industrias Peñoles S.A. de C.V. began testing machinery for a process to extract alumina from nepheline syenite. The proposed project cost was estimated at $600 million and if proved economically feasible would supply at least 300,000 tons of alumina per year.

Peñoles' nepheline syenite reserves are estimated at 3 billion tons, located in the Sierra de San Carlos Mountains in the State of Tamaulipas. About 10 tons of ore produce 1 ton of alumina. Tailings from the alumina extraction process can be used to produce soda ash, potassium, sulphate, and cement.

Cobalt.—In late 1979, Roman Corp. of Canada decided to continue development on Blythwood Mining Co.'s cobalt-gold-silver property located in the State of Sonora. The additional $400,000 investment will bring total cost to $800,000. Diamond drilling was in progress and final feasibility studies were expected to be completed by the end of 1979.

Copper.—Initial production from Mexicana de Cobre, S.A.'s La Caridad copper mine in the State of Sonora was delayed until June of 1979, about 12 years after the project was initiated. The mine was designed to produce 600,000 tons per year of 32% copper concentrate. Concentrate is trucked to the railhead at Nacozari where it is then shipped to port facilities at Guaymas.

Project costs, estimated at $600 million in 1975, have been revised upward to about $1 billion, including the mine, concentrator, molybdenum recovery plant, smelter, refinery, and infrastructure. A 180,000-ton-per-year smelter and a 150,000-ton-per-year refinery are scheduled to come onstream by late 1982. The smelter and refinery sites are located near the Caridad airport, about 40 miles northeast of the mine.

Gold.—In 1978, the Comisión de Fomento Minero, the State mining development agency, announced plans to renovate the Pinzon Dorado gold mining operation. The mine, located in the State of Guerrero, has not been operational for about 30 years. By 1980 the mine is expected to produce 32,000 ounces of gold annually and employ around 200 persons. The Pinzon Dorado operation would be the only Mexican mine worked exclusively for gold.

Iron Ore.—Recoverable reserves of iron ore contain about 225 million tons of metallic iron. Potential reserves have been estimated at about 57 million tons of metallic iron.

In 1978, it was estimated that maximum mining capacity equaled about 15 million tons of ore annually. The ore beneficiating capacity in 1978 was estimated at about 13 million tons annually. In 1978 Mexico was the third most important producer of iron ore in Latin America after Brazil and Venezuela.

Exploration for additional reserves continued as well as investigations to secure foreign sources of iron ore. In 1979 it was reported that Mexico may obtain iron ore from Brazil in exchange for crude oil.

Iron and Steel.—In September 1979, the three State-owned or controlled integrated steel companies were formally merged into one holding company, Sidermex. Two of the companies, Altos Hornos de Mexico S.A. (AHMSA), and Siderúrgica Lazaro Cardenas Las Truchas, S.A. (SICARTSA), are fully State-owned, and the Government holds a 44% controlling interest in the third company, Fundidora de Monterrey, S.A. The three companies remain separately managed but all other administration including planning, coordination, production, finances, and marketing have been under Sidermex control since January 1978. Improvements through Sidermex control were evident in 1978-79 as output increased and financial losses decreased.

In 1979 both private and State-owned steel industries were involved in expansion programs. Tubos de Acero, S.A. (TAMSA), planned a 6-year, $650 million investment to double steel output. Hojalata y Lamina S.A. (HYLSA), has scheduled $750 million over 5 years to increase steel production from 1.5 million tons to 2.5 million tons. Sidermex had a multibillion dollar program underway designed to bring installed capacity to 11.7 million tons of steel by 1982. Sidermex envisions a production capacity of 24 million tons of steel by 1990.

In 1979 Mexico accounted for 43% of the total sponge iron production in Latin America. This represented a decrease from Mexico's share of 63% in 1978 because of increased production in Argentina, Brazil, and Venezuela. Mexico was the only producer of sponge iron until 1973, when Brazil began production.

Natural gas as an energy source figures prominently in iron and steel expansion planning. About two-thirds of Mexico's future steel industry will be on the east coast, convenient to both ports and large gas pipelines.

Lead and Zinc.—In 1978, subsidiaries of the newly formed holding company Grupo Industrial Minera Mexico, S.A. (GIMMSA), jointly obtained a $200 million loan from a consortium of nine Mexican, Canadian, and United States banks, including the Bank of America.

Industria Minera Mexico, S.A. (IMMSA), the largest of GIMMSA's subsidiaries, planned to use $120 million of the loan to help finance the completion of the 113,000-ton-per-year electrolytic zinc refinery at San Luis Potosí. Construction work on the refinery resumed in 1979 with initial shipments to start near the end of 1981 and reach full capacity in 1982 or 1983. The plant will also refine almost 1,400 tons per year of cadmium metal. By 1983, zinc concentrate production was expected to be sufficient to supply both the new refinery and the Nueva Rosita refinery, and still provide over 100,000 tons per year for export.

The remaining $80 million of the GIMMSA loan was allocated to the other subsidiaries for a general program of modernization and expansion of existing mines and plants during the period 1978-81. The loan represented the largest unsecured and unguaranteed private sector loan in Mexico's history.

Manganese.—In 1978, La Compañía Minera Autlán S.A., one of the principal ferroalloy producers in Latin America, acquired the manganese alloy plant of Airco Alloys, Inc. in Mobile, Ala., United States. The purchase took place through Autlán's subsidiary, Autlán Manganese Corp. Autlán's manganese deposits at Molando, near Tampico, will provide material for use in Alabama as well as in its Mexican operations.

Molybdenum.—Minera Frisco, S.A. de C.V., a holding company with nine subsidiaries, became wholly Mexican owned in 1978 when investors purchased the 30% interest held by Union Corp. of England. The company announced that it planned an investment of $23 million to develop Mexico's first molybdenum mine at Cumobabi in Sonora, south of the Cananea and Caridad copper mines. Plans called for a mine production of 600 tons of ore per day in 1980, increased to 1,200 tons per day by 1981. Total reserves from several orebodies were estimated at 10 million tons averaging 0.25% of molybdenum. Capacity ore production of 1,200 tons per day would yield about 2 million pounds of molybdenum per year.

Mexicana de Cobre's molybdenum recovery plant has been scheduled for completion by late 1981. it will produce about 2,000 tons per year of molybdenum sulphide from the La Caridad copper project.

Silver.—Uncertain world economic conditions coupled with increased industrial consumption and coin mintage stimulated both the demand and price for silver in 1978-79.

This favorable silver market enabled many small and medium-sized mines to open or expand operations. The larger silver producers continued exploration and development work on new and old properties, increasing ore reserve estimates, initiating new mining projects, and expanding production facilities at others.

In late 1979 construction began on the old Real de Angeles open pit mine expansion project at Zacatecas. This deposit, with a present estimate of 59 million tons of ore reserves, is owned by Minera Real de Angeles, S.A. de C.V., a joint venture of the Comisión de Fomento Minero (33%), Minera Frisco S.A. de C.V. (33%), and Placer Development Ltd. (34%). The ore averages 2.4 ounces per ton of silver, 1% lead, 0.9% zinc, and 0.015% cadmium.

First production from the mine has been scheduled to begin by the end of 1981 or early 1982. Planning included a 10,000-ton-per-day concentrator to come onstream in 1982, by which time it was estimated that 7 million ounces of silver per year would be produced. Lead production was forecast at 31,000 tons per year, zinc production at 26,000 tons, and cadmium production at 415 tons per year. Given the present ore reserves estimate and proposed mining rate, the mine has a life expectancy of 17 years. Initial investment was estimated at nearly $150 million. Total investment could eventually reach $250 million and employ 500 workers.

Uranium.—Reports on Mexico's uranium reserves have not always been consistent. The Mexican Government official estimate as of the end of 1979 included 8,823 tons of proven reserves and approximately 150,000 tons of potential reserves. Most deposits are all located in northern Mexico, especially in the State of Chihuahua. Other deposits have been located in the States of Nuevo Leon, Sonora, and Durango. Active exploration was underway in many areas since it was estimated that only about one-tenth of Mexico has been surveyed for radioactive minerals.

A 3,000-ton-per-day mill has been planned for the Las Margaritas Mine near Villa Aldema at an estimated cost of about $33.7 million. The yield from about 900,000 tons per year of ore was calculated to be between 800 tons and 1,000 tons of uranium oxide.

NONMETALS

Cement.—Production of cement during 1978-79 failed to keep up with demand and spurred plant expansion programs. The Government estimated new cement construction and expansion programs would produce at least 20 million tons per year by 1982. In 1979 total plant capacity reached 15.6 million tons per year from 28 active plants, of which 25 were independent and 3 were cooperatives.

The Government introduced an incentive program for cement producers which are majority Mexican-owned. These incentives included a subsidy of up to 75% of ad valorem duty on imports of capital goods and equipment not available locally. Some firms may claim accelerated depreciation for certain productive equipment and installations.

Fertilizer Materials.—In 1979 Roca Fosforica Mexicana, S.A. de C.V. (ROFOMEX), a State-operated company, began construction on a 5,000-ton-per-day concentrator at the new phosphate mine at San Juan de la Costa in Baja California. The mine was expected to come onstream in 1980. Ore reserves were estimated at about 50 million tons. The open pit mine will evolve into an underground mine using the room-and-pillar technique. Annual concentrate production was expected to reach 750,000 tons with a maximum P_2O_5 content of 31%. The plant will also produce 200,000 to 300,000 tons per year of ground phosphate rock for direct application. Capital investment was estimated at $60 million.

Basic plant engineering and exploration work preparatory to exploitation continued on the low-grade Santo Domingo phosphate deposits also located in Baja California. Ore reserves were estimated at 1,450 million tons. Initial production has been scheduled for 1982 at 1.5 million tons per year of concentrate. By the mid-1980's concentrate production is expected to be 4.5 million tons per year. Capital investment for the operation was expected to be $60 million.

Ventures of this nature are encouraged by the Government to lessen the need to import minerals available domestically. At full production, the San Juan de la Costa project should decrease phosphate imports by 50% with self-sufficiency expected when the Santo Domingo plant comes onstream. When the Santo Domingo project is fully developed, around 1986, phosphate should become available for export.

Fluorspar.—In 1978, increased domestic consumption and the onset of Canada as an important importer due to its cessation of fluorspar production aided Mexico's depressed fluorspar industry to a small extent. Total production was about 69% of installed capacity and companies refrained from expansion programs. In 1979, demand increased but producers were not able to take full advantage of improved markets due to the persistant rail transportation problems.

MINERAL FUELS

Coal.—It was reported that Mexico's total coal reserves now amount to 2 billion tons, three-fourths of which are located in the State of Coahuila. The steel and metallurgical industries utilized about 95% of all coal consumed in Mexico and electric powerplants use about 3% to produce 4% of the total electricity generated. New coal-fired electric plants are under construction, and by 1986 coal-fired plants could account for 10% of total installed generating capacity.

Coal production has continued to increase but not enough to satisfy the growing domestic demand. The loss of foreign exchange due to increased coal and coke importation is expected to be offset by the increased export of end products and the decreased import of steel products as their domestic manufacture is initiated.

Petroleum.—By the end of 1979 the official Petróleos Mexicanos (Pemex) estimate of proven reserves was 45.8 billion barrels of crude oil, natural gas liquids, and natural gas equivalents, a 14% increase over 1978 estimates. Probable reserves were estimated at 45.0 billion barrels and possible reserves (including both proven and probable) were placed at 200 billion barrels. Increased reserves can be attributed primarily to the Southern Zone, the Chicontepec Paleocanal in the northern part of the State of Veracruz, and the Sabinas Basin in Coahuila. Exploration was ongoing or planned for all onshore and offshore areas in Mexico where studies indicated the possibility of hydrocarbon deposits.

On June 3, 1979, an exploratory well in the Gulf of Campeche, the Ixtoc 1, went out of control spilling crude oil; some of which ultimately was carried northward to the United States coastline. It was estimated that about 3 million barrels of crude oil escaped. Capping efforts were on the verge of completion and complete cessation of the spill was expected early in 1980.

In Mexico's Southern Zone, crude oil production from the Gulf of Campeche was initiated in mid-1979. By the end of December production amounted to about 240,000 barrels per day. Crude oil production from the Southern Zone represented 87% of total national production. About 70% of total natural gas production in 1979 came from the Southern Zone.

Prior to 1975, the shallower formations of the Chicontepec Area in the Central Zone were regarded as having minimal production potential and were bypassed in favor of deeper production. In 1978, after a lengthy reexamination of old records and the drilling of new test wells, these Tertiary layers of alternating sand and shale were believed to contain as much as 100 billion barrels of oil. Pemex development plans included almost 16,000 wells to be drilled on 2,285 sites over a period of about 13 years.

In 1979 construction was completed on what has been described as the largest diameter gasline laid to date in the Western Hemisphere. A 48-inch pipeline was extended northward for 683 miles from Cactus, in the Reforma Zone, to San Fernando where it was decreased to 42-inch-diameter pipe for 155 miles to Monterrey. Line capacity is 2.7 billion cubic feet of gas per day. Another 74-mile branch of 42-inch-diameter pipe was nearly completed from San Fernando to Reynosa to link up with U.S. transmission systems.

At the end of 1979 Mexico had nine oil refineries in operation. The Tula refinery came onstream in 1978 and the Cadereyta and Salina Cruz refineries were operational in 1979. Total crude oil refining capacity at the end of 1979 equaled almost 1.4 million barrels per day.

The Mineral Industry of Morocco

By Janice L. W. Jolly[1]

Mineral Production in Morocco contributed about 6% to the value of the Nation's 1978 Gross Domestic Product (GDP) of $12.9 billion[2] at current prices. By 1979, Morocco was entering its third year of tight Government fiscal and monetary policies designed to restore balance to the economy. Investment in the industrial sector (excluding the priority areas of phosphate and petrochemicals) dropped from $497 million in 1977 to $265 million in 1978. Low prices for phosphate rock and the unrest in the Sahara continued to plague the economy. Even so, the mineral industry continued to receive priority Government funding. Several loans and other financing were arranged during 1978-79 for the continued phosphate mine expansion and development of phosphate processing. Morocco eventually hoped to process 30% of its phosphate production. Prospecting for new cobalt reserves was active, and plans for a new calcination kiln were being studied. The Government continued to improve and expand Morocco's ports, including new facilities at Jorf Lasfar, Agadir, TanTan, El Aaiun, Boujdour, and Tarfaya. A new port was also under construction at Nador as plans for expansion of the iron and steel industry were proceeding. Plans were also continuing for the expansion of the lead foundry at Oued El Heimer and for a new smelter at Meknes. Uranium prospecting continued, and plans for the recovery of uranium from phosphate rock were being finalized. Discovery of oil in the Taza Region was giving new impetus to petroleum prospecting. Negotiations for an agreement were also nearly concluded with Occidental Petroleum of the United States for the development of Morocco's extensive oil shale deposits as well as for oil exploration and phosphate sector development. The Bou Skour copper mine was closed.

In 1978, Morocco undertook strict measures to reduce the trade imbalance. Investment authorization was reduced by about 30%, thereby reducing the need for imports of capital goods such as industrial equipment and construction materials. A more modest 1978-80 development plan was designed to conserve foreign exchange. Import restrictions and licensing were placed on numerous items, and firms were required to make a 25% 6-month deposit for all imported goods. This retrenchment policy had a marked effect on the commercial trade deficit for 1978, and also produced some dislocations in the domestic economy. The Government policy of reduced investment spending was expected to continue through 1980 along with slower expansion of the money supply and continued import restrictions.

The Moroccan Investment Code offered inducements to firms prepared to accord local partners at least half ownership plus board chairmanship. In such priority sectors as mining, 100% foreign ownership was authorized, while still permitting foreign firms to profit from code incentives. To encourage the eventual decentralization of Moroccan industry, even more favorable investment terms were available to firms willing to locate their operations outside the dominant Casablanca-Rabat industrial area. Also, for any new investments in excess of $7.7 million, advantages in addition to those specified by the code could be negotiated with the Government.[3]

A commission was studying the possibility of constructing new roads between Morocco, Bou Craa, and Mauritania. About $800 million was to be spent on a new road between Marrakech and El-Aaium for use in transporting phosphate concentrates. Feasibility studies were expected to be finished by 1980. The Soviet Union was also building a new road from Meskala to Essaouria for phosphate transport. In the long term, the Government of Morocco expected to complete its portion of the Transafrica Highway, which links Tangier with Dakar, Senegal. This highway will pass through Agadir, Tarfaya, El Aaiun, Guelta Zemour, Mijilic, Zouerate, Atar, Akoujt, and Nouakchott.

Morocco was a member of the Arab Organization for Mineral Resources (AOMR), which held its fourth meeting in Mohammedia on February 24, 1979. Formed in 1972, the AOMR also included Jordan, the United Arab Emirates, Saudi Arabia, Kuwait, Iraq, Mauritania, and the Palestine Liberation Organization. Tunisia, Sudan, and Qatar had applied for membership.

The Moroccan National Economic Development Bank (BNDE) secured several loans for industrial and mineral development from the international banking community during 1978 and 1979. These included a $7.25 million loan from the Abu Dhabi Fund for Arab Economic Development (FADEA), a $200 million loan from Canada, $300 million from seven banks, headed by Bank of America International Ltd., $53 million from Japan, $2 million from the OPEC special fund, and $150 million from Midland Bank. The World Bank also approved a $25 million loan to assist in an integrated small industry development program.

PRODUCTION AND TRADE

The mining sector registered an overall increase in production for both 1978 and 1979, but production of certain minerals declined. Iron ore production for both years continued to be affected by the slump in the world iron ore market. Production and exports of anthracite, pyrrhotite, fluorite, and barite improved in 1978, compared with 1977, while copper, lead, cobalt, zinc, and manganese production remained at somewhat similar levels. The first 6 months of 1979 saw an increase in both production and exports of copper, lead, zinc, barite, pyrrhotite, and silver. Both fluorspar and barite experienced slight decreases in mine production as a result of slower markets. Manganese production remained at about the same level as in 1978 with exports increasing slightly. Mineral production, excluding petroleum, natural gas, and cement, was valued at $701 million in 1978.

Phosphate production and exports for 1978 increased by 9% in volume, but the decline of the U.S. dollar, in which phosphate contracts were written, and a continued weak world phosphate market caused receipts to fall from 1977 levels. In 1978, a total of 17.3 million tons of phosphate rock was exported to Spain (16%), France (12%), Belgium-Luxembourg (8%), Poland (6%), Italy (5%), and other European countries. U.S. phosphate rock imports from Morocco increased sharply owing to Beker Industries' contract with Morocco to purchase material for phosphoric acid production. Exports to the United States were 923,800 tons in 1978, placing the United States in sixth place among Morocco's customers. Mainland China was the largest importer of Moroccan fertilizer in 1978. The value of phosphate rock exports was estimated at $508.5 million for 1978, compared with $536 million for 1977. Phosphate rock exports formed 25% of the 1979 export value, compared with 32% of the 1978 total export value.

Total exports were valued at $1,565 million and total imports were valued at $3,100 million for 1978. The 1978 foreign trade deficit was about 40% lower than in 1977. Total exports for the first 6 months of 1979 were valued at $918 million compared with $820 million for 1978. Crude petroleum imports were valued at $314 million for 1978 and $206.5 million for the first 6 months of 1979. Energy imports formed 80% of local consumption. The U.S. share of Moroccan 1978 imports increased to form 12.9% of the total, while the U.S. share of exports was 2.8%. On July 6, 1979, Morocco signed a 5-year commercial agreement with the Soviet Union. The Soviet Union was one of Morocco's leading trade partners with a two-way trade reaching $75 million. This new agreement followed the 1977 Soviet agreement for Meskala phosphate development.

COMMODITY REVIEW

METALS

Cobalt.—Morocco produced about 6% of the world's total cobalt. The Bou Azzer mine, operated by the Compagnie de Tifnout-Tiranamine (CTT), produced 7,805 tons of cobalt concentrate in 1977, 8,719 tons in 1978, and 6,798 tons in 1979. The cobalt sulfide concentrate ranges from 10% to 14% cobalt. Despite higher prices for cobalt, CTT was not expected to expand production beyond about 11,000 tons in the next few years because of limited reserves. However, prospecting was active and the expectation of proving new reserves was high. CTT was planning to construct a calcination kiln which would process the cobalt concentrate at Bou Azzer. The concentrate was being sent to France for final processing. CTT was owned 63% by Omnium Nord Africain (ONA) and 37% by Bureau de Recherches et de Participation Minières (BRPM).

Copper.—Feasibility studies were continuing for the construction of a copper smelter and refinery at the port of Agadir, although the austerity budget for the 1978-80 3-year plan allotted no funds for construction. The smelter, a project of the Fonderie Marocaine de Ciuvre (SOFOMAC) company, was to have a 30,000-ton-per-year capacity. The Arab Mining Company, financed by 12 Arab nations, planned to invest in 25% of the project. Development at the Bleida copper mining project by the Société Minière de Bou Saffer (SOMIFER) was also progressing. The Bleida mine was to have a mine output of about 200,000 tons of copper ore per year. A concentrator would produce about 16,000 tons per year of copper concentrates. Low copper prices in 1977, combined with poor ore grade, brought about the closing of the Bou Skour copper mine, operated by Ste. des Mines de Bou Skour. The Bou Skour had been the second largest copper producer.

Iron and Steel.—Morocco's iron ore resources of about 142 million tons were distributed in 10 small deposits. Near Nador in northern Morocco there were the Qiukchane, Setolazar, and Mellilia deposits; in central Morocco, there were the Bou Azel and Bou Guergour (near Katfara), Tourza (near Quarzazate), Air Amar (near Wadizam), and Kettara deposits; in southwestern Morocco, there were the Ait Ahmane and Tachilla deposits (near Agadir). The Nador pellet plant of Société d'Exploitation des Mines de Rif (Seferif) had a capacity of 850,000 tons per year but had never exceeded 500,000 tons per year. All of the pellet plant production, which uses Quikchane ore, was exported. Exploitation of other deposits depended upon whether Société Nationale de Sidurgie (SONASID) plans for domestic steelmaking developed. The plan to build a steel plant at Nador—a project in the books since 1948—was given the final go-ahead in late 1979. The $82 billion cost was to be spread over 7 years. A new port to service the iron and steel industry of Nador was under construction by the Romanian enterprise Contransimex. The new Nador port was expected to have an annual average traffic of 2 to 2.5 million tons by 1985.

The Moroccan company Sidema started up a new steel plant for reinforcing bars in Tangier, with 60,000-ton-per-year capacity. Sometal's reinforcing bar plant, started in 1971, produced 45,000 tons per year from imported billets. About $9.3 million was also to be spent for an iron plant at El Jadkja. This would be established by a new company, Metalam, in which Intemaxim of Lichtenstein had a minority interest.

Lead and Zinc.—The Draa Sfar lead-zinc mine, located 15 kilometers northwest of Marrakech, was officially opened in December 1978. The mine was to process 81,000 tons of crude ore per year, yielding 3,000 tons per year of lead concentrate and 7,500 tons per year of zinc concentrate. The Draa Sfar mine was an old mine which had been reactivated after new reserves had been proven. Two important ore bodies were discovered. The first contained reserves of 335,000 tons, containing 3.17% lead, 6.1% zinc, and 300 grams of silver per ton. The second had reserves of 280,000 tons with 6.7% zinc and 0.4% lead. The 1978 lead concentrate output of the Compagnie Minière de Toussit (CMT) reached 72,150 tons in 1978, compared with 60,392 tons in 1977. CMT exploited the Beddiane and Oued Mekta mines of Oujda Province. Exploitation of a million-ton silver-lead deposit began in 1979 at Sidi Lahcen, located near Oujar. The deposit was to yield 6,500 per yield of silver-lead concentrate and to be mined by the Arab Mining Company. The company's capital was shared by Morocco, Saudi Arabia, Jordan, Sudan, Libya, and Iraq. The Arab Mining Company was also to develop the Zgounder deposit near Quarzazate. Plans were continuing for the expansion of the lead foundry at Qued El Heimer and for the new smelter to be built near Meknes.

Tungsten.—On December 14, 1978, Morocco's BRPM signed an agreement with the West German company Klockner under which it will explore tungsten deposits at Azegour, located in the Marrakech area. The terms of the agreement included an expansion program to prove reserves and the possibility of setting up a joint venture with BRPM and Klockner as partners. The agreement also provided for cooperation with regard to exploration and exploitation of uranium in Morocco.

Uranium.—Several uranium occurrences had been located in the Upper Atlas. A Japanese mission was carrying out a 3-year exploration project in the Upper Moulaya region, where drilling had uncovered encouraging signs of uranium mineralization in 1977. Another discovery was made by the BRPM in the Imintanout Circle, south of Chichaoua. Negotiations for the construction of a plant at Safi to recover uranium from phosphoric acid continued during the year.

NONMETALS

Cement.—Local cement consumption estimated at 3.5 million tons for the year, decreased during 1978 as demand from the construction industry slowed. At the end of August, consumption was estimated at 2,376,000 tons, down 30% for the same 1977 period. There was also a reduction in cement imports, which at the end of August were down by about 28.5%. Imports were expected to continue to decline as several new Moroccan plants came onstream. The Cimenterie de l'Oriental plant (1.2 million tons' yearly capacity) at Oujda came onstream in late 1979. The new company was to be called Cimenterie Maghrebine (CIMA). A new facility was also built for Asement de Temara S.A. near Rabat (690,000 tons' yearly capacity) with the first phase of 360,000 tons completed during the second quarter of 1979 and the final startup by 1982. The Blue Circle Group's Consultancy Services was contracted to establish the feasibility of and to construct a new million-ton cement plant at Casablanca Sud. A new 760,000-ton-per-year plant was also to be built at Fgih Bin Salah in the Tadlu area. Morocco's cement production target was 7.6 million tons by 1982.

Phosphate Rock.—Morocco's Office Cherifien des Phosphate (OCP) was proceeding ahead with plans for a major expansion of phosphate mining and processing, designed to reinforce the country's position as the world's largest exporter of phosphate rock. Several loans were secured during 1978-79 as progress continued toward this goal. In 1979, OCP negotiated a loan for $200 million from a consortium of European, Arabian, and Japanese banks, but without any specific project in mind. The World Bank approved a loan of $50 million for construction of the Maroc Phosphore II phosphate processing plant. The project was cofinanced by a loan of $13.7 million from Poland and would need an overall investment of about $124.4 million. Late in 1978, a medium-term Eurocurrency loan of $150 million was granted to OCP by a consortium of 36 international banks, led by the Banque Marocaine du Commerce Exterieur (BMCE). This loan was to finance new projects at Ben Guerir and Khouribga. Under development, the open cast mine at Benguerir was to come onstream in 1980 with a capacity of 600,000 tons per year; by 1984, it was to produce 2 million tons per year of phosphate rock at the Maroc Phosphore II plant. OCP was installing a Krupp-built impact jaw crusher at Ben Guerir, the largest of its kind in the world and capable of processing 800 tons of rock per hour. At Khouribga, Recette IV was to be developed as an open pit mine, producing 2.6 million tons of phosphate rock per year by 1981, and increasing to 3.9 million tons per year by 1982. Current production capacity of the Khouribga-Casablanca area was about 16 million tons per year with a treatment capacity of about 19 million tons per year. In 1978, 14,461,000 tons of phosphate rock was produced at Khouribga, and 4,812,000 tons was produced at Youssoufia.

OCP also obtained a $100 million loan from the international financial market for phosphate processing at Safi. It was to be used to finance equipment at the Qued Zem complex and for an extension to Maroc Phosphore I, raising the capacity to 660,000 tons of phosphoric acid. Polimex-Cekop of Poland was to have a $26.4 million contract to equip the sulfuric acid unit at Safi. The contract was a barter deal with OCP under which Poland was to import phosphate rock. In 1978, OCP's phosphoric acid capacity at Safi was 850,000 tons per year. When the fourth line of Maroc Phosphore I and the Maroc Phosphore II project are completed in 1980, this capacity will rise to 1.5 million tons per year. The European Investment Bank (EIB) was to lend Morocco $52 million for building the phosphate rock port at Jorf Lasfur, 80 kilometers south of Casablanca. A new major fertilizer complex, Maroc Phosphore III, will also be developed at Jorf Lasfur. The first stage, producing 1,500 tons per day of phosphoric acid from Khouribga phosphate, will begin in 1983. This output will be doubled to 3,000 tons per day by 1985. The first phase also includes washing and drying facilities for 3 million tons per year of phosphate rock, to be obtained from Sidi Hajjaj.

Geological studies were underway at the Meskala-Essouira phosphate deposits as well as studies for a new port at Cap. Sim. The new port was to be built after Jorf Lasfar has been completed. Much of the production from the Meskala area was destined for the Soviet Union, under a major cooperation agreement signed in 1977. Studies were continuing on the deposits at Sidi Hajjaj. The first stage of production, with a capacity of three million tons per year, was scheduled to begin in 1983.

Western Sahara.—Although shipments of phosphate rock from the Bu Craa Mine stockpiles had resumed by the fourth quarter of 1977 and continued to be delivered by heavily guarded convoy to the coast, the mine itself had not started production. The 100-kilometer conveyor belt connecting the mine to El Aaium processing facilities was also inoperative. By 1979, with exhaustion of ore stocks at the mine, all movement of phosphate rock to the coast ceased, as did exports of crude concentrate. At yearend 1979, there were no plans to resume production at the mine in the near future, despite predictions made earlier in the year that the mine would open by late 1979. The mine had been closed for nearly 4 years by Polisario guerilla action following Spain's 1975 handover of the territory to Morocco and Mauritania. Raids had been made repeatedly on the conveyor, and a total of 6 kilometers of belt had been completely burnt out at five separate sections. Two of the 10 control stations were also damaged. Germany's Krupp Industries had agreed to repair the belt after initially declining to send technicians into the troubled area. In 1978, Fosfatos de Bu Craa (Fosbucraa) expected most of the approximately 450,000 tons of concentrate produced to be exported. The first cargo of 55,000 tons for the Zen Noh Company of Japan left El Aaiun in March 1978. Sales were primarily to Spain and Japan, both established consumers of Bu Craa phosphate rock, while deliveries were also made to Germany, France, Finland, Hungary, and Lebanon.

Sulfur.—The Iranian unrest of 1978 had an indirect influence upon Morocco's supply of sulfur, affecting the fertilizer and chemical industries. Morocco imported most of its sulfur from Poland, which produced it through gas received from the Soviet Union, which in turn had its gas supply cut off from Iran. As a result, Poland's exports of sulfur to Morocco were cut back by 25%.

MINERAL FUELS

Bituminous Shale.—A wide-ranging agreement with Occidental Petroleum of the United States for cooperation in the development of the Moroccan oil shale deposits was signed in early 1979. Occidental was to develop Timadhit oil shale to produce 50,000 barrels of oil per day by an in situ process. A $30 million feasibility study was first to be carried out over a period of a year. A 60-ton oil shale shipment was sent to Laramie for testing in late 1979. Five sites had been selected by Occidental for in situ test retorting. A Soviet-supported, oil-shale-fired, electric power facility was also planned for completion by 1985. In 1978, studies by three firms (Deutsche Babcock and Klockner of Germany and Energoma Shexport, U.S.S.R.) established the shale to be characterized by self-sustaining combustion. An ash content of 70% and a low heat capacity raised questions as to the economic viability of the deposits.

Coal.—An estimated 44.5 million tons of lignite was discovered at Oued Nja as a result of the Moroccan Bureau de Recherches & de Participations 1977 exploration program. Charbonnages Nord-Africaines (CNA) increased their capacity and market for coal by 6% per year during the period 1973-77. With the opening of a new pit (No. 5) at the anthracite deposits of Jerada, CNA further increased production by about 2% in 1978. Anthracite-fueled electric plants furnished about 32% of the national energy needs. Prospecting for new reserves continued at Jerada.

Natural Gas.—Gas production from the Essaouira basin and from Mechra bel Ksiri in the Rhaarb basin increased, while Douar production declined. Average gas output in 1978 was about 7.9 million cubic feet per day, compared with 8.3 million cubic feet per day in 1977.

Petroleum.—In an attempt to reduce dependence on petroleum imports, there has been an increase in oil exploration. The BRPM was spending more on petroleum research than on prospecting for other mineral resources. Seven agreements for petroleum exploration had been signed in 1978 and 1979, two on land and five offshore. A consortium that included Phillips Petroleum Co., the Italian company AGIP, British Petroleum (BP), and Getty Oil, working with BRPM, was operating off Essaouira, while BP and Phillips held permits off El Aaiun. In 1978, Phillips signed an agreement with BRPM to prospect for oil in the Guercif and Missour areas, where BRPM had already completed geological and geophysical surveys. Occidental Petroleum signed a petroleum exploration contract on September 14, 1979. The accord was for an area west of Agadir and the Souss. An agreement was also signed with Elf Aquitaine Morocco Corporation for offshore exploration and exploitation of discoveries made at Fes and Taza and of a deposit of natural gas in the same region.[4] Discovery of oil in the Taza region was announced in late 1978 in the Raob Basin, northeast of Rabat. The U.S. National Science Foundation was reported to have found evidence of a major oilfield off the coast of northwest Africa, in samples obtained from 5,000-foot drillholes in 12,000 feet of water with the

Glomar Challenger ship, 90 miles off Cape Tafelney.

The Société Nationale des Produits Pétroliers (SNPP) reported the domestic products market experienced a demand increase of 8.5% in 1978, the same rate as in 1977. The needs of the market were supplied 74% by local refineries; the remainder was imported in the form of refined petroleum products. This situation changed in 1979 when the expansion of the Société Anonyme Marocaine de l'Industries du Raffinage (SAMIR) refinery was completed. The refining potential of 80,000 barrels per day was expected to be sufficient to supply over 90% of the country's needs. Morocco received a $35 million loan from a consortium of Arab and foreign banks to expand the oil refinery, located near Mohammedia, about 12 miles south of Casablanca. Oil imports had been growing at the rate of 10.2% per year between 1970 and 1976.[5]

Nuclear Energy.—Morocco was to buy a nuclear reactor (100-kilowatt capacity) from the U.S. firm General Atomic. The reactor was to be used in the Atomic Studies Institute of Rabat, which opened at the end of 1978 to permit training and research for the technicians who will supervise the future thermonuclear station in Morocco.

The Mineral Industry of Mozambique

By Miller W. Ellis[1]

Mozambique's mineral industry has left an incomplete record since the Government of the People's Republic of Mozambique (GPRM) became independant from Portugal in 1975. Because most of the expatriate population had departed before the new government took over, it was necessary to call on technical experts from the Eastern European countries to set up new governmental departments. These officials were expected to supervise research work, to train all staff, and to produce mineral commodities. The economic directives of the third Frelimo Party Congress of February 1977 contained regulations intended to insure that the economic community would not stagnate. Property left for 90 days reverted to the state without compensation. Businesses were taken over by the workers or operated by a state-appointed administrative committee. Basic commodities were procured and distributed by state agencies which replaced retail shops in some areas. Major industries were supervised by the Council of Ministers, and most of the banks were nationalized with compensation promised, as were the larger mines and the oil refinery. The nationalization of a Mozambican firm producing galvanized roofing and pipe, and of four mining companies including a potential fluorspar producer, was announced in August 1979. The Mozambique Glass Company, which operated in the Matola industrial district of Maputo and had recently installed a new furnace, was nationalized in October 1979.

In 1978 the Republic of South Africa finally abandoned its fixed price per troy ounce for gold (equal to $42) in favor of the world market price. This substantially reduced the amount of gold paid to Mozambique and other neighboring countries as deferred wages and benefits for their emigrant nationals employed in South Africa's mines. Mozambique's loss of revenue was estimated at about $100 million. In 1977 Mozambique's chief port of Maputo (formerly Lourenço Marques) handled nearly 12 million tons of export freight of which 6 million tons were from the Republic of South Africa. In mid-1978 the GPRM negotiated an agreement providing for the Republic to double its exports through Maputo by 1985. In order to provide increased facilities Mozambique borrowed a number of South African Railway's locomotives, arranged to purchase other locomotives as well as forklift trucks, and was to build a second coal loading facility to handle the output of a new mine in the northern Transvaal. The railroad on both sides of the border was equipped with centralized traffic controls, heavier rail, and additional ballast in order to carry two to three times the amount of freight to Maputo.

A 35-member delegation from the German Democratic Republic arrived in Mozambique on July 4, 1978, and subsequently signed agreements to assist with mineral exploration, supervise coal and metal mining, and build textile and truck factories and high-tension powerlines. They undertook to provide technical assistance in toolmaking, metallurgy, agriculture, and fishing, and to train Mozambicans technically.

In July 1979 a Mozambican trade delegation visited Brazil to cement economic ties between the two countries, and to negotiate with Petróleo Brasileiro S.A. (PETROBRAS) for petroleum research in Mozambique. The following month a large delegation from Siderúrgica Brasileira S.A. (SIDERBRAS) commenced investigating the use of

Brasilian technology in the extraction of Mozambique's iron ore reserves for Brazil's iron industry.

During a 5-day visit to Iraq in December 1979, Mozambique's head of state signed a joint communique in which Iraq pledged to compensate Mozambique, as a poor developing country that has a petroleum contract with Iraq, by granting a long-term interest-free loan equal to the surcharges on petroleum imposed from June 1979 to the end of the year.

PRODUCTION AND TRADE

Mozambique's deteriorating economic situation reflected its unbalanced trade as shown by its soaring imports. Among the sparse statistics available were those in the following table:

Balance of payments estimates

(In millions of United States dollars)

	1975	1976	1977	1978	1979[e]

Source: Government of Mozambique, quoted in United Nations General Assembly. Report of the Economic and Social Council, August 16, 1979.

In 1979 the GPRM appeared to be seeking more trade and investment from the West, including the Republic of South Africa. South African contractors were hired to expand the coal loading facility at Maputo. It was claimed that 85% of Maputo's export traffic originated in the Republic and generated $12 million per year in transit fees for Mozambique.

The Republic of South Africa continued to purchase the 1,200-megawatt output of the Cabora Bassa dam on the Zambezi River at a cost estimated at $4 million per month in 1978 but increasing to about twice that by the end of 1979. The funds were paid to Hidro-electrice de Cabora Bassa (HCB), which was controlled 85% by Portuguese and 15% by Mozambique interests and was responsible for paying off the outstanding European and South African creditors. By 1992 all such debts should be repaid and the ownership of the installation and all foreign exchange income accruing to it will belong to the GPRM.

COMMODITY REVIEW

METALS

Copper.—Early in 1978 the GPRM reactivated Lonrho's Edmundian copper mine near Manica, across the border from Umtali, Rhodesia-Zimbabwe. A loan of $600,000 from the Bank of Mozambique paid wages for a staff of 298 and purchased necessary supplies. In January 1978, 460 tons of chalcopyrite concentrate with about 130 tons copper content was sold to the German Democratic Republic (GDR). At a nearby mine, 28 miners were producing an average of 6.4 ounces of gold per month.

The Soviet Union and the GPRM signed an agreement in March 1978 authorizing the Soviet Enterprise Techniexport to make a 3-year study of the mineral resources in the Tete, Nampula, and Zambezia districts, involving some 60 Soviet experts with $500,000 worth of research equipment. Studies of bauxite, coal, copper, nickel, gold, pegmatite, and syenite deposits were scheduled to start in October 1978.

The Secretary of the German Democratic Republic State Ministry of Geology also signed an accord on June 22, 1978, for supplying German Democratic Republic technicians to operate copper and gold mines in the Manica district. Subsequently the delegation of July 4, 1978, signed an agreement covering mineral exploration in the Manica and Zambezia districts, but details of the Manica copper-gold projects were not revealed.

Iron and Steel.—At the request of the GPRM, the Swedish Aid Authority was investigating the iron ores of the Honde area in central Mozambique as the basis for a domestic iron and steel industry. Production of Mozambique's Cifel steel foundry increased in 1978, but the industry was plagued by shortages of skilled workers.

MINERAL FUELS

Coal.—On May 12, 1978, the GPRM nationalized the country's only coal mine at Moatize and its owner, Companhia Carbonifera de Mozambique (CCM), because of the lack of safety precautions and in order for GPRM to control this key sector of the economy. Frelimo Congress Law established that mineral rights and subsoil were state property and no indemnification was required therefore. The law also provided that other terms for indemnification may be set at a future date if not nullified by the behavior of the former owners toward the state, the mine property, and/or its records. The Portuguese-Mozambican group Enterposto owned 46% of CCM, ISCOR of South Africa reportedly owned 26%, and 5% was state controlled. Mining operations were restarted in May 1978 under the direction of technicians from Romania and the German Democratic Republic. CCM employees were absorbed into the new Mozambican National Coal Company known as Carbomoc. An accord confirming East German assistance for the Moatize coal mine in Tete Province was signed on June 22, 1978, and a 35-member delegation led by the German Democratic Republic Minister of Coal and Energy arrived on July 4, 1978, and signed new agreements to provide men and equipment to operate the Moatize colliery, and to export part of the product to the German Democratic Republic. In April 1979 the GDR revealed that the GPRM had overestimated the amount of high-grade coal at Moatize, and the production schedule of 2.5 million tons for 1980 was judged too high.

Petroleum.—Empresa Nacional Petróleos de Mozambique's (Petromac's) major facility in the Matola industrial district of Maputo continued as the country's only petroleum refinery. The staff of 600, including Romanian technicians, failed to achieve Petromac's production goal of 570,000 tons throughput for 1978, but had planned to increase throughput and to export refined products in 1979. The company acquired a 10,000-ton oil tanker in May 1978 and named it the Matchedje. The 5-year old ship, reportedly of Japanese origin, was scheduled to haul fuel to Mozambique ports and to earn foreign exchange by carrying international freight.

The Mineral Industry of the Netherlands

By William F. Keyes[1]

The Dutch economy was again one of Europe's stronger economies during 1978 and 1979, but it was linked more closely than ever before to foreign trade, rather than to domestic growth. In June 1978, the Dutch Government introduced Economic Blueprint 1981, which established a framework for balanced economic growth into the 1980's. The central conclusion was that Government spending during the past decade was beginning to adversely affect the country's economic health, and the Blueprint called for a reduction of 10 billion guilders[2] in planned budget increases during the 1979-81 period. The Blueprint focused on four goals: reduction of unemployment to 150,000 workers (3.8%), a drop in inflation, a reduction in labor income by 1% annually, and maintenance of purchasing power and social benefits for the average worker. These proposals evoked considerable discussion, and in 1979, there was some realignment of priorities in order to favor lower income groups. One major criticism was that the Blueprint failed to call for restructuring the economy toward high technology, which will be essential after 1985 when foreign natural gas sales are expected to begin to decline.

The major mineral resource of the Netherlands is its large onshore reserves of natural gas, and a key element in the Government's economic policy has been to prepare for eventual depletion of these reserves. Steps taken by the Government have included the initiation of gas imports and preparations for greater use of imported coal and nuclear power. A decline in natural gas exports and a rise in imports converted the 1-billion-guilder current account surplus of 1977 to a half-billion-guilder deficit in 1978, but a 0.6-billion-guilder surplus was registered in the first 7 months of 1979. In other areas of the minerals and metals sector, the country's major steelmaker had a profitable period, but still faced declining world markets, upon which it is dependent; and the large petroleum refining industry operated at well below capacity while also facing a decline in vital export markets.

PRODUCTION

The heavy industry production index rose slightly between 1977 and 1978 (1970=100), from 127 to 128, and continued on a moderate increase in 1979, but the minerals production index declined from 213 in 1977 to 196 in 1978. The two major components of the minerals production index were the natural gas index, which declined from 292 to 267 in the same period, and the index of other minerals, which declined from 93 to 92. Production of minerals in recent years is given in table 1.

TRADE

The Netherlands lives by trade; its merchandise exports equal two-fifths of the total gross national product. It imports large quantities of raw materials, including all energy sources except natural gas and some petroleum, and reexports the processed forms of many of these to its major customers. The Netherlands' customers are chiefly other members of the European community, and the greatest share of Dutch exports is purchased by the Federal Republic of Germany. The United States and the Netherlands are major trading partners and are also currently the largest direct foreign investors in each other's territory. Leading U.S. minerals exports to the Netherlands are nonferrous metals, coal, and petroleum coke. The United States imports from the Netherlands important quantities of petroleum products, iron and steel semimanufactures, copper metal, and diamonds. Minerals trade between the two countries is almost balanced at about half a billion dollars each way. The Netherlands' minerals trade is reported in tables 2 and 3.

Gold thousand troy ounces	727	850	Switzerland 380.
Iron and steel:			
Ore and concentrate, except roasted pyrite	147,631	11,671	West Germany 6,572; France 1,811; Italy 1,442.
Metal:			
Scrap thousand tons	926	1,190	West Germany 700; Belgium-Luxembourg 231; Spain 109.
Pig iron and ferroalloys[1]	17,464	16,637	Germany 9,887; France 5,114.
Steel, primary forms thousand tons	1,539	1,708	West Germany 486; United States 306; United Kingdom 134.
Semimanufactures:			
Bars, rods, angles, shapes, sections	465,029	537,501	Belgium-Luxembourg 109,369; West Germany 100,215; United Kingdom 40,679.
Universals, plates, sheets thousand tons	1,628	1,625	United Kingdom 284; United States 257; West Germany 217.

See footnotes at end of table.

Table 2.—Netherlands: Exports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1977	1978	Principal destinations, 1978
METALS —Continued			
Iron and steel —Continued			
Metal —Continued			
Semimanufactures —Continued			
Hoop and strip	97,903	119,052	West Germany 75,307; Switzerland 10,177; Belgium-Luxembourg 6,586.
Rails and accessories	30,619	39,702	West Germany 21,184; Italy 7,781; Pakistan 4,988.
Wire	53,667	54,665	France 14,973; West Germany 11,108; Belgium-Luxembourg 9,646.
Tubes, pipes, fittings	334,362	553,138	West Germany 117,097; Venezuela 84,744; Belgium-Luxembourg 44,030.
Castings and forgings, rough	9,255	12,450	Belgium-Luxembourg 6,763; West Germany 4,240.
Lead:			
Ash and residue	4,179	3,945	Belgium-Luxembourg 2,893.
Oxides	578	3,841	Italy 2,967.
Metal:			
Scrap	39,874	32,825	West Germany 12,817; Demark 8,801.
Unwrought	14,953	21,722	West Germany 12,725; Belgium-Luxembourg 2,020; U.S.S.R. 2,398.
Semimanufactures	1,622	2,213	Belgium-Luxembourg 759; Norway 108.
Magnesium metal including alloys:			
Scrap	1,972	1,687	United States 1,165.
Unwrought and semimanufactures	r2,589	4,590	West Germany 2,815; United Kingdom 1,193.
Manganese:			
Ore and concentrate	31,557	37,452	West Germany 7,157; Belgium-Luxembourg 4,213; Iran 4,067.
Oxide	51	8	NA.
Mercury 76-pound flasks	1,856	1,993	West Germany 836; Indonesia 129; Belgium-Luxembourg 129.
Molybdenum:			
Oxide	1,609	1,621	Austria 1,079.
Metal including alloys, all forms	187	153	Belgium-Luxembourg 101; West Germany 18.
Nickel:			
Matte, speiss, similar materials	681	2,568	West Germany 1,478; France 329; Sweden 286; India 231.
Oxide and hydroxide	137	273	West Germany 66; France 55; Sweden 53.
Metal including alloys:			
Scrap	1,795	1,845	West Germany 602; United Kingdom 424; Sweden 241.
Unwrought	1,968	3,246	United Kingdom 1,895.
Semimanufactures	2,680	338	Sweden 111; West Germany 65; Spain 23.
Platinum-group metals, all forms thousand troy ounces	r46,607	37,843	Switzerland 6,471; United States 3,982; Japan 3,904.
Selenium, elemental	37	6	France 3; Poland 2.
Silver metal including alloys, all forms thousand troy ounces	15,868	892,703	West Germany 489,846; France 125,050.
Tellurium, elemental and arsenic	27	17	France 16.
Tin:			
Oxide	6	--	
Metal including alloys:			
Scrap	698	549	United Kingdom 320; West Germany 174.
Unwrought	1,758	1,274	West Germany 618; United Kingdom 472.
Semimanufactures	692	691	West Germany 365; Belgium-Luxembourg 108; Spain 34.
Titanium:			
Ore and concentrate (ilmenite)	10,460	940	Norway 514; Belgium-Luxembourg 100.
Oxides	24,444	10,228	West Germany 1,638; France 1,755.
Metal including alloys, all forms	109	135	Italy 72; United Kingdom 35.
Tungsten:			
Ore and concentrate	864	1,260	West Germany 559; Czechoslovakia 291; U.S.S.R. 258.
Metal including alloys, all forms	220	243	Belgium-Luxembourg 114.
Zinc:			
Ash and residue	10,679	12,887	West Germany 4,171; Belgium-Luxembourg 3,953; France 2,362.
Ore and concentrate	15,142	3,200	Belgium-Luxembourg 2,109; Italy 1,066.
Oxide	7,829	10,484	Belgium-Luxembourg 1,730; West Germany 1,607.
Metal including alloys:			
Scrap	6,053	6,352	France 2,664; Belgium-Luxembourg 1,807; West Germany 1,023.
Dust (blue powder)	1,979	2,821	NA.
Unwrought	109,219	123,205	United Kingdom 49,958; West Germany 27,329; France 12,508.

See footnotes at end of table.

Table 2.—Netherlands: Exports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1977	1978	Principal destinations, 1978
METALS —Continued			
Zinc —Continued			
Metal including alloys —Continued			
Semimanufactures	3,449	5,615	West Germany 3,300; Belgium-Luxembourg 630; Switzerland 374.
Zirconium ore and concentrate	17,311	839	West Germany 512; France 168.
Other:			
Ores and concentrates	22,850	24,265	Italy 4,711; United Kingdom 4,451; West Germany 4,422.
Base metals including alloys, all forms	2,859	3,542	West Germany 2,532; France 334; United Kingdom 202.
Ash and residue containing nonferrous metals	6,260	9,663	West Germany 3,716; Belgium-Luxembourg 2,729; United Kingdom 1,297.
Oxides, hydroxides, peroxides of metals	442	130	NA.
NONMETALS			
Abrasives, natural, n.e.s.:			
Pumice, emery, natural corundum, etc	8,027	7,835	Norway 1,606; Thailand 1,268; United Kingdom 973.
Dust and powder of precious and semiprecious stones, including diamond thousand carats	1,089	1,026	United Kingdom 524; West Germany 113; Belgium-Luxembourg 107.
Grinding and polishing stones	3,218	3,357	West Germany 790; United Kingdom 765; Australia 188.
Asbestos	255	393	West Germany 258.
Barite and witherite	103,708	94,774	United Kingdom 60,976; Norway 17,140; West Germany 13,993.
Borates, crude, natural	341,025	338,960	West Germany 80,078; France 65,017; United Kingdom 48,947.
Cement	335,247	412,319	West Germany 159,800; Belgium-Luxembourg 142,676.
Chalk	17,332	29,886	All to Belgium-Luxembourg.
Clays and clay products:			
Crude:			
Bentonite	17,107	23,839	Belgium-Luxembourg 11,034; France 3,421; United Kingdom 3,206.
Kaolin	71,194	84,085	Belgium-Luxembourg 73,436; West Germany 7,023.
Refractory	3,386	3,372	West Germany 2,100; Belgium-Luxembourg 904.
Other	1,098	1,060	West Germany 334; Nigeria 252; Belgium-Luxembourg 187.
Products:			
Refractory (including nonclay brick)	32,189	24,979	West Germany 8,952; Belgium-Luxembourg 3,097; France 2,697.
Nonrefractory	736,402	756,645	West Germany 539,084; Belgium-Luxembourg 172,248; France 19,089.
Diamond, excluding dust and powder:			
Worked:			
Gem carats	443,663	599,552	Belgium-Luxembourg 326,208; United States 106,438.
Industrial do	33,201	6,753	United States 5,995.
Unworked:			
Gem thousand carats	626	249	Israel 147; Belgium-Luxembourg 49; United States 32.
Industrial do	4,152	1,065	United States 252; Belgium-Luxembourg 208; Israel 130.
Unsorted do	1,832	1,085	Israel 476; Belgium-Luxembourg 182; United Kingdom 179.
Diatomite and other infusorial earth	294	520	Belgium-Luxembourg 226.
Feldspar, fluorspar, leucite	3,135	6,441	West Germany 2,324; Belgium-Luxembourg 1,909; Finland 1,208.
Fertilizer materials:			
Crude:			
Phosphatic	75,915	66,605	West Germany 62,961; Ireland 2,407.
Other	96,281	78,167	Belgium-Luxembourg 61,526; West Germany 14,681.
Manufactured:			
Nitrogenous thousand tons	2,588	3,089	United States 672; India 633; Brazil 440.
Phosphatic (including Thomas slag)	186,616	236,734	West Germany; 9,003; France 117,725; Belgium-Luxembourg 38,947.
Potassic (K_2O content)	518	487	Belgium-Luxembourg 200; Oman 130; Nigeria 79.
Other, including mixed	985,853	952,517	France 363,973; United Kingdom 94,213; West Germany 88,178.
Ammonia, anhydrous thousand tons	720	698	Belgium-Luxembourg 291; Ireland 109; United Kingdom 101.
Graphite, natural	191	594	West Germany 530.
Gypsum and plasters	1,902	2,366	Belgium-Luxembourg 797; United Kingdom 473.

See footnotes at end of table.

Table 2.—Netherlands: Exports of mineral commodities—Continued

(Metric tons unless otherwise specified)

Commodity	1977	1978	Principal destinations, 1978
NONMETALS—Continued			
Lime	3,431	4,711	West Germany 2,460; Saudi Arabia 1,249.
Magnesite	29,981	33,554	West Germany 17,109; France 5,560.
Meerschaum, amber, jet	2	--	
Mica	831	713	Oman 225; West Germany 213.
Pigments, mineral, including processed iron oxides	3,464	4,648	West Germany 2,485; United Kingdom 614; France 548.
Precious and semiprecious stones, except diamonds kilograms	2,633	3,771	West Germany 3,557; Belgium-Luxembourg 143.
Salt thousand tons	1,988	1,891	Belgium-Luxembourg 514; West Germany 510; Sweden 375.
Stone, sand and gravel:			
Dimension stone:			
Unworked and partly worked	4,614	4,318	West Germany 3,015.
Worked	6,033	11,984	West Germany 8,734; Belgium-Luxembourg 2,592.
Dolomite	11,527	10,463	West Germany 7,627; Belgium-Luxembourg 1,269.
Gravel and crushed stone thousand tons	r4,088	3,226	Belgium-Luxembourg 2,921; West Germany 302.
Limestone	371	23	NA.
Quartz and quartzite	9,943	11,395	West Germany 8,259; Belgium-Luxembourg 1,702.
Sand, excluding metal bearing thousand tons	9,553	8,767	Belgium-Luxembourg 8,380.
Sulfur:			
Elemental	17	57	Belgium-Luxembourg 54.
Sulfur dioxide	1,378	--	
Sulfuric acid	156,944	156,981	Belgium-Luxembourg 37,326; Spain 37,100; Portugal 21,734.
Talc and steatite	2,785	3,674	Belgium-Luxembourg 847; Saudi Arabia 718; Italy 608.
Other:			
Slag, dross, and similar waste, not metal bearing:			
From iron and steel manufacture thousand tons	r56	36	West Germany 23; Belgium-Luxembourg 6.
Other do	74	78	Belgium-Luxembourg 34; West Germany 8.
Unspecified do	187	--	
MINERAL FUELS AND RELATED MATERIALS			
Asphalt and bitumen, natural	48	51	NA.
Carbon black	84,454	72,555	France 35,463; West Germany 16,065; Belgium-Luxembourg 9,916.
Coal and briquets:			
Anthracite and bituminous coal	462,415	485,013	Luxembourg 241,304; West Germany 227,679.
Briquets of anthracite and bituminous coal	13,093	3,376	Belgium-Luxembourg 3,164.
Lignite and lignite briquets	1,279	1,452	All to Belgium-Luxembourg.
Coke and semicoke	726,521	731,593	Belgium-Luxembourg 275,929; United States 157,683.
Peat, including peat briquets and litter	112,592	123,689	Belgium-Luxembourg 67,144; West Germany 26,888.
Gas:			
Manufactured	289	220	Belgium-Luxembourg 171; West Germany 38.
Natural million cubic feet	1,999	1,840	West Germany 852; France 372; Belgium-Luxembourg 360.
Hydrogen, helium, rare gases	r23,235	24,225	West Germany 11,589; Belgium-Luxembourg 7,132.
Petroleum:[2]			
Refinery products:			
Gasoline thousand 42-gallon barrels	73,244	67,905	West Germany 41,560; United Kingdom 8,433.
Kerosine do	23,010	20,632	West Germany 10,739; United Kingdom 2,319; Denmark 2,181.
Distillate fuel oil do	105,074	100,941	West Germany 63,408; Belgium-Luxembourg 11,071; Denmark 5,256.
Residual fuel oil do	122,744	106,267	West Germany 16,520; United Kingdom 12,995; Luxembourg 9,437.
Lubricants do	3,898	4,331	Belgium-Luxembourg 804; United Kingdom 517; West Germany 353.

See footnotes at end of table.

Table 2.—Netherlands: Exports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1977	1978	Principal destinations, 1978
MINERAL FUELS AND RELATED MATERIALS —Continued			
Petroleum[2] —Continued			
Refinery products —Continued			
Other:			
Liquefied petroleum gas thousand 42-gallon barrels	4,212	3,048	Belgium-Luxembourg 1,786; Portugal 435; West Germany 217.
Mineral jelly and wax do	[r]763	740	West Germany 256; United Kingdom 218; Morocco 48.
Petroleum coke and pitch do	2,380	2,179	West Germany 667; Denmark 485; Norway 389.
Bituminous mixtures do	385	443	West Germany 119; Nigeria 116; Sweden 75.
Unspecified do	2,104	3,253	West Germany 930; Denmark 618; Belgium-Luxembourg 287.
Total do	[r]337,814	309,739	
Mineral tar and other coal-, petroleum-, or gas-derived crude chemicals	445,940	543,669	West Germany 253,208; United Kingdom 113,241; Belgium-Luxembourg 54,859.

[r]Revised. NA Not available.
[1]Includes spiegeleisen, sponge iron, shot, grit, pellets, and ferromanganese.
[2]Includes bunkers.

Table 3.—Netherlands: Imports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1977	1978	Principal sources, 1978
METALS			
Aluminum:			
Bauxite	141,242	151,521	Greece 148,250; Guyana 2,813.
Alumina	536,564	570,330	Surinam 208,378; Greece 197,269; France 126,915.
Metal including alloys:			
Scrap	29,850	30,515	West Germany 15,629; Belgium-Luxembourg 4,202; United States 2,400.
Unwrought	162,304	145,508	Norway 74,161; West Germany 43,942.
Semimanufactures	92,230	93,683	West Germany 38,683; Belgium-Luxembourg 18,643; France 11,861.
Antimony:			
Oxide	897	1,059	Belgium-Luxembourg 360; Bolivia 298; United Kingdom 249.
Metal including alloys, all forms	128	126	China, mainland, 32; Turkey 20.
Arsenic oxide and acid	200	--	
Beryllium metal including alloys, all forms	3	3	All from West Germany.
Bismuth metal including alloys, all forms	55	52	Belgium-Luxembourg; Japan 8; Mexico 8.
Cadmium metal including alloys, all forms	59	55	Japan 31.
Chromium:			
Chromite	26,440	6,398	Mozambique 5,668.
Oxide and hydroxide	608	784	West Germany 454; U.S.S.R. 244.
Metal including alloys, all forms	75	81	Japan 35; France 27.
Cobalt:			
Oxide and hydroxide	274	387	Belgium-Luxembourg 204; United States 119.
Metal including alloys, all forms	17	78	West Germany 39; United States 16.
Columbium and tantalum	2	3	NA.
Copper:			
Copper sulfate	3,479	4,603	Belgium-Luxembourg 2,154; France 1,268; U.S.S.R. 918.
Oxide and hydroxide	882	884	West Germany 520; Norway 163.
Metal including alloys:			
Scrap	14,588	7,580	West Germany 3,668; France 1,318; United Kingdom 1,258.
Unwrought	52,309	28,021	Poland 5,905; U.S.S.R. 5,176; West Germany 4,388.
Semimanufactures	87,802	91,628	West Germany 38,552; Belgium-Luxembourg 33,207; France 7,283.
Germanium metal including alloys, all forms	([1])	1	All from West Germany.
Gold[2] thousand troy ounces	754	1,148	United States 411; United Kingdom 262; Switzerland 160.
Iron and steel:			
Ore and concentrate, except roasted pyrite thousand tons	6,921	5,578	Brazil 1,768; Liberia 865; Canada 773.
Metal:			
Scrap	113,035	166,359	Belgium-Luxembourg 77,979; West Germany 39,658; United Kingdom 28,326.
Pig iron[3]	r49,309	50,805	Brazil 15,264; West Germany 13,815; France 6,579.
Ferroalloys	48,643	48,771	Norway 17,596; France 11,099; West Germany 5,622.
Steel, primary forms	290,870	292,384	Norway 128,240; Spain 77,147; West Germany 36,988.
Semimanufactures:			
Bars, rods, angles, shapes, sections thousand tons	1,309	1,332	West Germany 487; Belgium-Luxembourg 459; France 113.
Universals, plates, sheets do	1,060	1,024	Belgium-Luxembourg 392; West Germany 374; Japan 69.
Hoop and strip	196,977	193,307	West Germany 136,236; Belgium-Luxembourg 32,301; France 11,633.
Rails and accessories	38,914	45,660	West Germany 25,694; France 16,221.
Wire	110,497	107,642	Belgium-Luxembourg 57,112; West Germany 38,730; France 6,087.
Tubes, pipes, fittings	572,792	749,007	West Germany 490,977; France 121,845; Belgium-Luxembourg 43,455.
Castings and forgings, rough	15,103	18,652	West Germany 9,435; Belgium-Luxembourg 6,902.
Lead:			
Oxide	9,922	8,513	West Germany 5,768; Belgium-Luxembourg 2,581.
Ash and residue	r2,755	3,157	West Germany 1,797; United Kingdom 426.
Metal including alloys:			
Scrap	16,706	10,882	West Germany 6,726; Belgium-Luxembourg 1,777.
Unwrought	r60,685	59,918	Belgium-Luxembourg 16,989; United Kingdom 13,723; Australia 10,600.
Semimanufactures	4,539	4,921	Belgium-Luxembourg 3,160; West Germany 1,243.

COMMODITY REVIEW

METALS

Aluminum.—ESTEL N.V., the Dutch-West German steel combine that controls Holland Aluminium B.V., operator of the smelter at Delfzijl in northeast Netherlands, announced its intention in 1979 to join with Kaiser Aluminum and Chemical Corp. of the United States to merge the two firms' aluminum smelter and fabricating facilities in Europe. ESTEL had become the sole owner of the smelter when Hollandse Metallurgische Industrie Billiton withdrew in 1977. ESTEL also controlled 61.5% of Sidal N.V., an aluminum fabricator based in Belgium, and its share was scheduled to increase to 100%. Early in 1980, further talks on the merger were postponed until the end of 1980.

Iron and Steel.—For the first time in 3 years, the major Dutch steelmaker, Hoogovens IJmuiden B.V., moved out of the red in 1978 and 1979, as sales—especially to the United States and other foreign markets—increased. Consequently, national steel production rose from 4.9 million tons in 1977 to 5.6 million tons in 1978 and to about 5.8 million tons in 1979. ESTEL N.V., of which Hoogovens was a part, continued to show an overall deficit, but this deficit was declining late in 1979.

Hoogovens nevertheless continued to lose competitiveness in the developing world steel market. Factors that forecast a decline in ESTEL's sales in the next few years—and were grounds for concern according to ESTEL's chairman—were the strong Dutch guilder, which was sustained by the Netherlands' large exports of natural gas; the high labor and materials costs in the Netherlands, which was in part a result of the social legislation of recent years; and the development of cheaper (or subsidized) steelmaking facilities in secondary export markets.

In addition to Hoogovens, with its single steel plant at IJmuiden on the coast west of Amsterdam, one other firm, NFK-Staal B.V., a subsidiary of Thyssen of the Federal Republic of Germany, produced less than 10% of the national total steel output in an electric steel plant at Alblasserdam, near Rotterdam.

Lead.—The 45,000-ton-per-year secondary lead smelter of Hollandse Metallurgische Industrie Billiton (HMIB) at Arnhem was required by new environmental regulations to decrease lead emissions to a maximum of 35 kilograms per 24 hours, which was half the previous limit. Billiton expected the modification to take at least a year to complete and also expected it would be expensive, although no exact cost was released. In 1978, HMIB announced that it would be forced to close its vanadium plant because it was unprofitable (see Vanadium).

Vanadium.—The vanadium plant of Hollandse Metallurgische Industrie Billiton was closed about January 1979. The plant, at the Billiton secondary lead smelter in Arnhem, had treated vanadiferous slag from the Republic of South Africa, but had lost an annual average of 1.5 million guilders over the previous 4 years.

NONMETALS

Limestone.—Ground limestone for industrial, construction, and agricultural purposes is produced by two firms headquartered in Maastricht: Ankersmit's Chemische Fabrieken B.V., which operated plants at Maastricht and Winterswijk with a total grinding capacity of up to 2 million tons per year; and CV Nekami Kalk, which operated plants at Margraten in the Netherlands and Seilles in Belgium, each with a grinding capacity of 400,000 to 500,000 tons per year.

Sulfur.—Construction of a $16.5 million sulfuric acid plant was planned by Climax Molybdenum Co. The plant would recover sulfur in emissions from Climax's molybdenum conversion plant in Rotterdam, and completion was expected by 1981.

MINERAL FUELS

Coal.—Early in 1980, a Government memorandum on the use of coal in the Netherlands was presented to Parliament. The memorandum recommended increasing the share of coal in Dutch energy supplies from the present 1.6% to 20% (or 40% of all electricity generated) by the year 2000. Coal imports would thus increase from 1.5 million tons currently to 26 million tons, since the Dutch mines are uneconomic and all have been closed since 1974. Plans were to decrease the share of electricity generated by natural gas and oil from the present 80% to 20%, and, if politically feasible, to develop nuclear energy for the remaining 40%. Plans also called for placing emphasis on combined cycle use of gasified coal and on fluidized-bed combustion; both are as environmentally acceptable as conventional coal combustion with stack scrubbers.

Three coal gasification projects were being studied in the Netherlands: a semicommercial plant announced by Royal Dutch Shell for Moerdijk, south of Rotterdam, which is expected to use the Shell-Koppers process to supply a 140-megawatt powerplant; an experimental gasification plant to be completed by the Rotterdam Municipal Power Company (GEB) in 1980; and a plant to produce low-calorie gas—for blending into the Dutch distribution system for natural gas—to be built by Nederlandse Gasunie N.V., the monopoly gas distributor, in the Eemshaven area in the northeast part of the country.

Natural Gas.—According to the Gas Marketing Plan submitted to the Ministry of Economics by the Nederlandse Gasunie N.V. (the sole distributor), proven natural gas reserves were 1,677 billion cubic meters on January 1, 1979, and total reserves were 2,271 billion cubic meters, of which about 1,900 billion cubic meters was onshore. Although reserves had declined slightly in 1978, total reserves for 1979 were 223 billion cubic meters more than the yearend 1974 reserves total. Reserves at the largest field, Slochteren, were estimated by the State Geological Service in mid-1979 to be 150 billion cubic meters more than the former estimate, or about 1,700 billion cubic meters. Deliveries of gas by Gasunie also declined by 5% in 1978, to 90 billion cubic meters, as foreign consumers rescheduled their deliveries. Part of the decline in Gasunie's deliveries may also have been a result of the recently changed official policy, which now is aimed at reducing gas use in heavy industrial processes and electric-generation plants. In a status report to the Dutch Parliament, the State Geological Service noted that the recent decline in reserves will be difficult to reverse or even stabilize and recommended extending exploration to parts of the continental shelf that are now off limits, as well as to geological layers below 9,000 feet.

The Netherlands had contracts for a total of 141 billion cubic meters of gas to be obtained from foreign sources, which in effect would extend domestic reserves. These contracts included 61 billion cubic meters from Norway, to be delivered over the next decade through the undersea pipeline to Emden; and 80 billion cubic meters of liquefied natural gas (LNG) from Algeria, to be delivered during a 20-year period starting in 1984. The Algerian LNG was originally expected to be landed at Maasvlakte, near Rotterdam, but in August 1978 the Dutch Cabinet revised its earlier plan and approved the selection of Eemshaven, near Delfzijl in the north, as the site. Although the Government discussed its decision to establish an LNG terminal with the Federal Republic of Germany and Belgium, the European community as a whole did not take part in these discussions, since no European energy policy had yet been established. The facility is expected to be capable of processing 4 billion cubic meters of LNG annually. The Eemshaven site would cost an estimated 190 million guilders more than the alternative at Maasvlakte, but the Government considered it more advantageous because it would aid a depressed area that would otherwise require financial support. Also, the Government had experienced difficulty in attracting other industry to Eemshaven.

Production of natural gas offshore continued to increase but was only a small part of the Dutch total, which included production from the huge Groningen Field. The Noordwinning consortium, a group of American and European companies led by Pennzoil Nederland Co., started production in 1978 from the F structure (Rotliegende) in concession bloc K13, at a rate of 1 billion cubic meters per year. In the same bloc, the A structure (first tapped in 1976) and the B structure (1977) yielded about 900 million and 600 million cubic meters, respectively. The total production rate from the Dutch continental shelf is therefore about 2.5 billion cubic meters per year. A 120-kilometer pipeline from the offshore field reaches the coast near Callantsoog, south of Den Helder, and ends in Balgzandpolder, where the gas is treated and delivered to Gasunie. A fourth natural gasfield was being developed on the E structure in bloc K13, with a potential of another 1 billion cubic meters annually by 1980.

Petroleum.—All refineries continued operating well below capacity (which totaled about 93 million tons per year). In most cases, the refineries operated at between 60% and 65% of capacity. The Netherlands' refineries were principally constructed to serve the export market from the complex around Rotterdam, and this market continued to be very competitive.

BP Nederland N.V. completely closed its 320,000 barrel-per-day refinery at Rozenburg near Rotterdam during April and May 1978, except for essential maintenance. Shell Nederland B.V. replaced one of its large distillation units with a smaller one nearby, at its Pernis (Rotterdam) refinery (530,000 barrels per day). Esso Nederland B.V. at Europoort, Rotterdam (176,000 barrels per day), Mobil Oil B.V. at Amsterdam (125,000 barrels per day), and Gulf Oil B.V. at Rozenburg (76,000 barrels per day) were also in a precarious position. Late in the year, the Total Nederland N.V. refinery at Flushing (150,000 barrels per day) announced plans to discontinue operations. The other two Dutch refineries were Chevron Petroleum B.V. at Pernis (300,000 barrels per day) and the small Smid & Hollander B.V. refinery at Amsterdam (7,000 barrels per day). The total domestic capacity for crude distillation (before Shell's alteration) was thus, by one reckoning, about 1.6 million barrels per day.

The Nederlandse Aardolie Maatschappij B.V. (NAM), owned 50% by the Government and 25% each by Shell and Exxon, was the only crude oil producer in the Netherlands. NAM continued efforts to boost production, particularly in the Schoonebeek Field near the Federal Republic of Germany border, which produced 60% of the domestic total. A 175-million-guilder 6-year NAM program was aimed at almost doubling daily production to about 5,000 tons by 1981.

The Mineral Industry of New Zealand

By Charlie Wyche[1]

New Zealand's most significant mineral activity in 1978 and 1979 was the production of construction materials, including limestone, sand and gravel, aggregates, and clay; and the value of this production was higher than that of any of the country's other mineral products. Coal, iron sands, natural gas, and a small quantity of gold and silver accounted for virtually all the remaining mineral value. Several prospects, including gold, molybdenum, and asbestos, were being investigated and could contribute to New Zealand's mineral value in the early 1980's.

Natural gas operations and associated condensate production could play an increasingly important role in New Zealand's future energy program. The offshore Maui gasfield began production in late 1979, and development continued at the onshore Kapuni gasfield. A comprehensive policy concerning private oil and gas exploration was announced in 1979, and the mining industry subsequently increased its exploration activity significantly. New Government-sponsored exploration was also being initiated.

Imports of crude oil and refinery products supplied about one-third of the national energy requirements. Planned development of coal, natural gas, hydroelectric power, and geothermal power was expected to reduce petroleum imports to 20% to 25% of the total energy requirement by 1990. In 1978, geothermal steam at the Wairakei power station generated 5.5% of New Zealand's total electricity.

The number of conflicts between mining and conservationist interests over environmental issues declined in 1978 and 1979. The conservationists believed current environmental requirements were inadequate and wanted a total restriction on exploration and mining in certain areas. Government agencies proposed no new or enlarged reserved areas, such as national parks or wilderness areas, in 1978 or 1979.

PRODUCTION

The value of New Zealand's mine and quarry output for 1978, including metals and nonmetals but not mineral fuels, was $150 million,[2] or 0.9% of the country's $16.7 billion gross national product (GNP). The estimated mineral production value for 1979 was slightly higher, at $153 million. There were no significant production shifts noted between 1978 and 1979. Values of the most significant minerals produced during 1978 were as follows (in thousand dollars): Sand and gravel ($51,873); coal ($45,658); iron sand concentrate ($22,000); limestone for agriculture, roads, cement, and other industries ($12,400); gold ($1,700); clays for brick, tile, and pottery ($1,600); salt ($689); serpentine ($600); and silica ($583).

The establishment of a $60 million nickel smelter at Bluff in Southland was being considered. It was proposed that nickel ore from New Caledonia would be used as feedstock for the smelter. The plans have been discussed with Government officials, and feasibility studies were being conducted.

Residual fuel oil do	7,795	7,093	5,668	6,500
Other do	674	780	600	650
Refinery fuel and losses do	1,704	939	695	700
Total do	27,393	24,552	21,712	23,450

[e]Estimate. [p]Preliminary. [r]Revised.
[1]Reported figure.
[2]Average 57% Fe.
[3]Includes crushed rock for building aggregate, roads, and ballast.
[4]Excludes carbon dioxide component of natural gas, which is reported separately.
[5]Includes field condensate.

TRADE

According to the Department of Statistics at Wellington, principal mineral exports during FY 1978 (the fiscal year ending June 30, 1978) were aluminum and aluminum alloys (valued at $107.9 million) and iron ore and concentrates ($24.1 million). For FY 1979, the export value of aluminum and aluminum alloys rose (to $153.0 million), as did the value of iron ore and concentrates ($25 million).

Crude petroleum, partly refined petroleum, and petroleum refinery products dominated New Zealand's mineral imports. Imports in these three categories were valued at $437.5 million in FY 1978 and at $472.4 million in FY 1979. Iran remained the principal import source, but Kuwait and Saudi Arabia were also significant suppliers. Imports of iron and steel, mainly semimanufactures, totaled $152.4 million in FY 1978 and $194.3 million in FY 1979. Large quantities of phosphate rock from Nauru, sulfur from the United States, and alumina from Australia were also imported during 1978 and 1979.

The Government planned to export up to 250,000 tons of coal annually from the Buller coalfield in the northwest area of Southland, beginning in the early 1980's. This trade, estimated at $10 million annually, would constitute the country's first major coal export of recent times. Probable customers were Japan, South Korea, Taiwan, Hong Kong, and Singapore. Another proposal, for the sale of $30 million of coking coal to Japan, was deferred.

Table 2.—New Zealand: Exports of mineral commodities[1]

(Metric tons unless otherwise specified)

Commodity	1977	1978	Principal destinations, 1978
METALS			
Aluminum:			
Bauxite and concentrate	232	53	Netherlands 35; Belgium-Luxembourg 17.
Metal including alloys:			
Scrap	1,953	1,540	Japan 1,483.
Unwrought	2,599	114,659	Japan 106,250; Hong Kong 5,358.
Semimanufactures	858	1,522	Australia 463; Singapore 258; United Arab Emirates 167.
Copper:			
Ore and concentrate	98	613	China, mainland, 500.
Metal including alloys:			
Scrap	493	800	Australia 672; United Kingdom 128.
Unwrought and semimanufactures	1,316	1,951	Singapore 634; Malaysia 355; Thailand 276.
Iron and steel:			
Ore and concentrate thousand tons	2,223	3,079	Japan 3,036.
Metal:			
Scrap	2,161	1,391	Japan 1,026.
Pig iron, spiegeleisen, sponge iron, ferroalloys	174	4	All to Indonesia.
Ingots, blooms, billets, sheet bars	866	15,688	Venezuela 15,091; Philippines 480.
Semimanufactures:			
Bars, rods, angles, shapes, sections	16,140	34,797	United States 15,435; Canada 13,897.
Universals, plates, sheets	27,537	41,574	United States 28,723; Papua New Guinea 3,116.
Hoop and strip	11	21	Fiji 15.
Wire	5,572	6,631	United States 4,696; Canada 644.
Tubes, pipes, fittings	1,091	1,018	Fiji 307; Papua New Guinea 162.
Castings and forgings, rough	75	139	Australia 129.
Total	50,426	84,180	
Lead:			
Oxides	386	55	Taiwan 54.
Metal including alloys:			
Scrap	347	481	West Germany 188; Japan 188.
Unwrought and semimanufactures	204	240	Australia 146; Fiji 53.
Magnesium metal including alloys, all forms	10	3	West Germany 2.
Platinum-group metals and silver:			
Ores and concentrates	4	7	United Kingdom 6.
Metals:			
Platinum-group troy ounces	1	56	NA.
Silver do	276	1,423	Fiji 619; Australia 257.
Zinc metal including alloys:			
Scrap and blue powder	1,550	910	Japan 462.
Unwrought and semimanufactures	279	146	Taiwan 100; Australia 23.

[6]Excludes quantites valued at $1,108 in 1977 and $222 in 1978.

COMMODITY REVIEW

METALS

Aluminum.—The Government of New Zealand and New Zealand Aluminium Smelters Ltd. (NZAS) agreed to terms that increased electric power rates 4.5-fold in April 1978. These rates, which were continued throughout 1979, had an adverse effect on NZAS' expansion plans. The Bluff smelter, which is located near the tip of Bluff Harbor's Tiwai Peninsula, had a capacity of 150,000 tons per year. Plans to expand its capacity to 220,000 tons per year were deferred, following the levy of increased electrical rates on the company.

Gold.—Mine production of gold declined slightly in both 1978 and 1979 from that reported for the past several years. Kanieri Gold Dredging Ltd. produced some 6,000 troy ounces of gold in 1978 from 2.7 million cubic meters of gravels dredged from the Taramakau River near Kumaru, South Island. The year was a difficult one for the company because of machinery breakdowns, labor shortages, escalation in costs, and delays in deliveries of replacement parts. Litigation over purchases of adjoining lands, delays in the issue of a mining license, and disagreements over water rights also caused problems. The grade of the alluvial gold mined by Kanieri was among the lowest gold grades in the world. All gold from the Kanieri operation was purchased by the Government. Because of the sharp rise in gold prices in 1979, companies were conducting prospecting and exploration activities on both the South and North Islands.

Mineral Resources (New Zealand) Ltd. continued exploration throughout 1979 at the Martha mine, Waihi, North Island. Mine dumps at Union Hill were being worked, and bulk samples were evaluated. Blackwater Gold Ltd. and Carpentaria Exploration Co. Pty. Ltd. continued testing ore extensions at a former property of Blackwater Mines. Amoco Minerals New Zealand Ltd. received a prospecting license for the Monowai gold area.

Iron Sands.—Output of iron sand concentrate by the two producing companies (New Zealand Steel Mining Ltd., a wholly owned subsidiary of New Zealand Steel Ltd., and Waipipi Ironsand Ltd.) again reached record high levels during 1978 and 1979. New Zealand Steel produced steel and mined iron sands through its subsidiary, New Zealand Steel Mining; Waipipi only mined iron sands. Expansion of iron sand production capacity was completed by New Zealand Steel Mining and Waipipi; and expansion of New Zealand's only steel-producing plant, which was operated by New Zealand Steel, was expected to be completed in 1980.

Waipipi Iron Sands produced some 2.2 million tons of concentrate at Waverly during 1978 and some 3.0 million tons in 1979. Waipipi exported most of its output under a 10-year contract with the Japanese steel industry. It was estimated that the current mine output can be sustained for about 14 years.

New Zealand's iron sand reserves of more than 5 billion tons far exceeded any foreseeable domestic requirements. Also, the world's greatest potential reserves of titanomagnetite deposits are located on the west coast of North Island.

Steel.—New Zealand Steel produced iron sands at its Waikato North Head deposit for use in its direct-reduction steelmaking plant at Glenbrook. The plant at Waikato North Head was designed to produce 200,000 tons of concentrate annually, but in 1978 its annual capacity was expanded to 250,000 tons. Some 150,000 tons of raw steel was produced during 1978, and around 200,000 tons was produced in 1979. This figure was expected to increase to about 750,000 tons annually within 10 years. A cold-rolling mill and coat line for plain and galvanized sheet steel were being considered. Long-range plans included a new melt shop, continuous slab facilities, and more direct-reduction kilns.

Other Metals.—In 1978 and 1979, the Department of Scientific and Industrial Research continued its investigation of black heavy-metal beach-sand deposits on the west coast of South Island. These sands contain ilmenite, monazite, zircon, and gold.

Amoco Minerals was granted prospecting licenses on Ceromandel Peninsula, North Island, and began conducting airborne magnetometric surveys in search of base metals. Otter Minerals Exploration Ltd., in partnership with Gold Mines of New Zealand Ltd., continued exploration in Nelson Province and a drilling operation on D'Urville Island. Gold Mines of New Zealand Ltd., a partnership of Australian Anglo American Corp. Ltd. and Amoil New Zealand Ltd., remained active in the Raukumara, East Cape, and Kaikoura regions.

NONMETALS

Asbestos.—Chrysotile asbestos occurs at several deposits in the serpentines at Nelson and Otago on South Island, but there was no mining in New Zealand in 1978 and 1979. A deposit found in the northwest Otago (along the Pyke River) by Asarco Exploration Co. of Canada Ltd. was found not to be of commercial value.

Phosphate.—Research carried out by the New Zealand Oceanographic Institute in 1978 and 1979 indicated the presence of under sea phosphorite nodules varying in diameter from 10 to 150 millimeters. Most of the deposits were found in water from 400 to 500 meters deep, and none were found at depths less than 200 meters. The phosphorite occured mostly within an irregular east-west belt that was up to about 16 kilometers wide and extended along the crest of Chatham Rise, which runs 1,300 kilometers east of Banks Peninsula, South Island. The $P_2 0_5$ values for the phosphorites generally range between 18% and 24%, and the highest recorded content was 27.7%.

Sulfur.—Fletcher Mining Co. Ltd. continued excavation of a pit in the Taupo area of North Island to provide information from which to develop economic data for an open pit sulfur operation. The intention was to mine the ore by open pit methods and extract the molten sulfur by using hot water under pressure, followed by sulfur recovery using a solvent. The sulfur reserve is contained in mixed pumice and was estimated at 6 million tons.

Other Nonmetals.—In 1978 and 1979, serpentine was produced at Propio and the North Cape, North Island; and Lee Valley, Collins Valley, and Mossburn, South Island.

Sand and gravel production from several new rock quarries near Nelson, South Island, reached full capacity in 1979. Quarry activity for sand and gravel and various stone was high, particularly near cities.

MINERAL FUELS

Coal.—New Zealand produced 2.2 million tons of coal in 1978 and some 2.8 million tons in 1979, from about 70 mines in various fields on North and South Islands. Nearly 75% of the production was from open pit mines. There was an increase in production from private mines in both 1978 and 1979, and development work on three new coal mines was on schedule. Prospecting for new deposits on both North and South Islands continued in 1978 and 1979. Investigations on North Island were mainly in the Coramandel District, between the Huntly and Maramarua fields. On South Island, investigations were being carried out in the Nelson-Westland and Central Otago Districts.

The Government removed the Energy Resources Levy from underground coal mine production on June 1, 1978. The levy had been $2 per ton for other than South Island lignite and $1.50 per ton for South Island lignite.

A new Coal Mining Bill introduced into Parliament was being examined by Parliament's select committee on commerce and mining. The Coal Mining Bill would give the Government much more control over all private coal mining, but would not involve it in taking over the ownership of land or coal mines. Under the new proposals, all coal mining activity would be licensed by the Minister of Energy.

The Department of Mines' 5-year coal exploration program estimated recoverable coal reserves at 1.2 billion tons. Measured reserves of coal totaled 210 million tons. The exploration program started in the eastern part of the Southland lignite field in Mataura Valley, South Island, and was scheduled to continue in the Waikato area, North Island, and in the area of the west coast deposits of South Island.

Natural Gas.—Natural gas and some condensate were produced at the Kapuni offshore field in 1978 and 1979; and gas was supplied to Auckland, Wellington, and to the New Plymouth and Stratford power stations. Also, a proposed ammonia-urea fertilizer plant that would use Kapuni gas was being studied.

Construction of the first production platform by Shell-BP-Todd Oil Services Ltd. for the Maui offshore gasfield was being completed. Drilling of the first production well began in early 1978, and the first gas from Maui began flowing ashore in early 1979. Maui gasfield reserves were estimated at 150 billion cubic meters of gas and 75 million barrels of condensate.

Recently, the New Zealand Government announced a delay in the construction of a second production platform in the offshore Maui gasfield. The postponement was related to the Government's decision to seek to use the gas in the production of methanol. The delay beyond the proposed completion date of 1983 was expected to add greatly to both the capital cost of the project and the unit cost of gas produced.

Petroleum.—The Government announced a comprehensive petroleum exploration policy in 1979. In instances where the Government accepts a company's petroluem exploration proposal, the Government would retain the right to acquire a 51% interest in the discovery in exchange for a 40% contribution to the exploration costs. Smaller contributions to exploration costs by the Government would entitle it to a lower share of the venture. Should either party to such an arrangement decide not to contribute to the costs of a particular well, the remaining party or parties could proceed on a sole-risk basis. In the event of a discovery, the parties contributing to the cost of drilling would be permitted to recover 600% of their expenditure as a prior charge against first production. Royalties to be paid to the Government on oil found were set at 12.5% of the sale value. The price of indigenous oil was raised to that of world crude oil.

New Zealand's only important known oil resources were in the Maui and Kapuni natural gasfields. Production by Shell-BP-Todd Oil Services (in equal partnership with the Government) increased significantly over that of recent years. A light crude oil, or condensate, was produced as a joint product with natural gas.

Shell-BP-Todd signed an agreement with the Government of New Zealand to undertake a $40 million, three-well oil search of the western tip of North Island. Drilling was expected to commence in mid-1980. New Zealand Petroleum, a local exploration firm in which Triton Oil of Dallas (United States) has an interest, also revealed plans to resume its oil search off the southwest coast of South Island.

Production of liquefied petroleum gas at Kapuni reached a record high in 1979, but market demand still exceeded supply. An extraction plant was planned to strip liquefied petroleum gas from the Maui gas stream, but was not expected to be operational until 1981. Proposals from distributors to import liquefied petroleum gas from Australia were under consideration by the Government and were expected to be approved in early 1980. The problem of excessive demand resulted from the conversion to liquefied petroleum gas by several vehicle fleet operators and some industrial users following the 1978 introduction of generous tax rebate provisions for new users.

The Mineral Industry of Nigeria

By Janice L. W. Jolly[1]

The fortunes of the petroleum industry formed the cornerstone of Nigeria's economic health, providing over 90% of export earnings and from 22% (1978) to about 30% (1979) of the Nation's gross domestic product (GDP), estimated at $43 billion[2] for 1978 and about $50 billion in 1979 at current prices. Because of lower oil production and marginal agricultural growth, the Nigerian economy made little progress in 1978. Real GDP in the 1978-79 fiscal year (April-March) grew by an estimated 2.5%, in contrast to 10.8% and 9.9% in the two previous years. By yearend 1978 the Iranian oil crisis was to provide the Nigerian petroleum industry with a revived demand and new incentive and an economic recovery in 1979. For the last several years, however, steadily decreasing petroleum production and Government overspending had reduced Nigeria's total foreign reserves from $5.6 billion in 1975 to $1.9 billion at yearend 1978. Faced with continuing high inflation (never lower than 20% per year), balance of payments difficulties, and a high level of deficit financing, the Federal Military Government (FMG) applied brakes to the economy in early 1978. Government spending was slashed back, major curbs were placed on imports, and additional measures were taken to reduce liquidity and curb inflation. The immediate result for 1978 was a sharp downturn in economic activity. Petroleum output hit bottom at 1.52 million barrels per day in March 1978, down 32% from the comparable month of 1977. By 1979, petroleum production had increased to an average of 2.3 million barrels per day and successive price increases had helped to improve Nigeria's oil income considerably. Nigeria had a balance of payments surplus for 1979, compared with a deficit of about $3.6 billion for 1978.

Nigeria's financial troubles caused modification of development planning with some deferment or altering of scope of some projects. Projects already underway, even those awarded to foreign companies, were subject to close monitoring and reassessment by the new Civilian Government elected in October 1979. Projects expected to remain active included natural gas gathering systems, liquefied natural gas plants and shipping systems, petrochemical plants, fertilizer plants, port development, railroads, iron and steel plants and mills, petroleum pipelines and refineries, cement plants, and power facilities. A recent progress report on the Third National Development Plan, 1975-80, showed $6.25 billion was spent by the public and private sectors over the first 2 years of the plan period. In manufacturing, these investments had totaled about $480 million, or about 14% of the planned expenditure. The report also stressed that the continuing problems of manpower shortage had inhibited implementation of many plans. There was an acute shortage of technical personnel, and the new civilian government was planning to increase training programs.

A lack of finance caused Nigeria to go to the Eurodollar market for three very large loans. The first, signed in December 1977, was for $ 81 billion for petroleum, cement, iron and steel, port development, and smaller projects. The second, signed in November 1978, was for $750 million intended for petroleum refining, pipelines, and other projects. Early in 1979, a third loan in excess of $1 billion was also obtained from Federal Republic of Germany banks for a direct-reduction steel plant.

Nigeria remained a difficult environment for foreign investors and businessmen. Compounding the economic slump were the measures introduced to stem imports, reduce foreign exchange outflows, and restructure the ownership of the Nigerian economy. By yearend 1978, all firms that included some foreign ownership were to be in compliance with the indigenization law of 1977, which required from 40% to 100% Nigerian ownership, depending upon the business sector or the ruling of the Nigerian Enterprise Promotion Board. Agents or distributors were also to be at least 60% Nigerian, except for commission agents and distributors, who were to be entirely Nigerian. In December 1978, the FMG announced that a firm established in Nigeria after January 1, 1979, could have a liaison office for 2 years, during which period it would look for a Nigerian partner in order to formally start business operations in compliance with the investment law. Nigeria also introduced a new taxation on foreign airlines and shipping companies in 1978. The tax was set at 10% of the companies' Nigerian turnover on any cash that they remit out of the country. Attributed as a further attempt at discouraging imports, the new tax followed the scrapping of the section in the Nigerian Companies Tax Act of 1961 that exempted shipping and airline companies of countries that offered reciprocal exemption to Nigerian companies. At the same time, double taxation agreements were terminated with nine countries including the United States.[3] Corporate business taxes were increased from 45% to 50%. By yearend 1979, Nigeria had established the National Office of Industrial Prosperity to permit easier identification, evaluation, and selection of foreign technology for Nigeria. This office was to function as a corporate body with a permanent secretary from the Ministry of Finance as its chairman.

Early in 1978, Nigeria announced that it would be withdrawing all State funds from Barclays Bank of Nigeria and ordered a reduction in its foreign staff in protest at the bank's policy towards the Republic of South Africa. It was the first major step to implement Nigeria's new policy of punitive action against companies dealing with the Republic of South Africa. In 1976, Nigeria had ruled that all foreign banks operating there would have to be 60% locally owned. Along with Africanization, there was also increasing Government pressure on banks to adjust lending policies to the state's economic targets.

From late 1977 to about mid-1978, a nationwide brownout was caused by unforeseen low water at Kainji Dam and resulted in daily power shutoffs that affected industry, agriculture, and commerce. Production losses were estimated to total several hundreds of million of dollars. The Kainji Dam hydroelectric plant produced nearly 70% of Nigeria's electric power. The Ministry of Mines and Power and the National Electric Power Authority (NEPA) were reviewing long-term plans to decrease reliance on hydrofacilities and increase use of thermal power using gas and coal.

An extensive cost and design study was completed by Matthew Hall Ortech Ltd. on a national minerals and metallurgical laboratory project for the Jos Plateau State. The Nigerian Federal Ministry of Mines and Power, which awarded the contract to Ortech, was evaluating the result of the study as part of its 5-year development plan.

PRODUCTION AND TRADE

Nigeria's mineral production, excluding petroleum, was valued at $103 million in 1978.[5] Tin, columbite-tantalite, and coal were major contributors. Production and export of petroleum continued to decline through much of 1978. Nigeria's petroleum revenues in 1978 were reported as $9.3 billion compared with $10.6 billion for 1977.[6] The contribution of crude petroleum to total export value declined from 92.6% in 1977 to 91% in 1978. By 1979, however, Nigeria was benefiting from the petroleum shortage triggered by the Iranian crisis; petroleum revenues for 1979 were estimated at $15 billion. With the boost of Nigerian oil prices on January 1, 1980, from $27.26 per barrel to $30, Nigeria was anticipating even higher petroleum export returns in 1980. To alleviate the problem of overpricing that plagued Nigeria in late 1977, Nigeria had lowered petroleum prices by about 30 cents per barrel on January 1, and by another 21 cents early in April 1978. These measures, coupled with the Iranian production dropoff that occurred late in 1978, injected Nigeria's petroleum industry with new incentive and recovery in 1979. Petroleum production averaged 1.8 million barrels per day in 1978, but by December, output had reached 2.3 million barrels per day and a reduction in stocks allowed exports to reach a level of 2.5 million barrels per day. Petroleum production averaged about 2.3 million barrels per day in 1979.

The crisis in the foreign trade sector continued throughout 1978, despite the recovery of petroleum exports late in the year. Imports remained at close to $1 billion per month through the third quarter of the year despite the April 1 ban on imports. Government officials had attributed a large portion of the trade deficit to overinvoicing and other fraud. To remedy this situation, the Government announced a preshipment inspection system was to be instituted on January 1, 1979. Inspection for quantity, quality, and price standards was to be done by a Swiss firm, Société Generale de Surveillance. This procedure, along with other import measures already instituted, was expected to cause more delay and complication to the import process. The banning and licensing of imports had adversely affected wholesale and retail trades as well as Nigerian manufacturers who depended upon imported raw materials. By the second half of 1978, the import measures were beginning to take effect. For example, British exports to Nigeria, worth $208 million in July, were down to $140 million by December 1978. By yearend 1979, with imports cut back and oil production running at record levels, Nigeria appeared to be over the worst of its external foreign exchange and trade difficulties.

The United States, with a 11% share of the Nigerian import market in 1978, continued to rank third as supplier to Nigeria, after the United Kingdom (21.6%) and the Federal Republic of Germany (14.2%). Nigerian crude petroleum accounted for 13% of the total U.S. imports in 1978,[7] compared with 19% in 1977. The share of oil in United Kingdom imports from Nigeria fell from 76% in 1975 to about 38% in 1977, corresponding to the increase of North Sea oil production. United Kingdom imports of Nigerian tin rose only marginally during the same period. Nigeria was the Federal Republic of Germany's largest African export market in 1978, and its third largest source of African imports, after Libya and Algeria.[8] Since 1974, Nigeria's exports to the U.S.S.R. have decreased by about 76% in value; imports from the U.S.S.R. have increased by 250% over the same time span. Nigeria is the U.S.S.R.'s third largest African export market, after Egypt and Algeria.[9] During 1978, discussions were held with Jamaica on trade arrangements in which Jamaica would purchase tin, columbite, and coal and in return would sell bauxite and other items to Nigeria.[10]

Nigeria was considering several barter deals, exchanging oil for goods in order to conserve foreign exchange. Contracts were being renegotiated with both Yugoslavia and the Republic of Korea shipbuilders. In terms of the contracts awarded in 1977, Split of Yugoslavia was to build eight multipurpose vessels for $133 million, and Hundai of South Korea was to supply 11 cargo ships, costing $142 million.[11]

COMMODITY REVIEW

METALS

Columbite.—After an increase during 1978, columbite concentrate production slumped by 23% to 666 tons, following the suspension of operations at the Odegi mine by Vectis Tin Mines Ltd. In 1978 and 1979 the principal sources of columbite were Amalgamated Tin Mines of Nigeria, which produced over 40%, and Bisichi-Jantar Ltd., which produced between 49% (1978) and 68% (1979) of the total. Bisichi-Jantar produced 354.14 tons of columbite in 1979 compared with 329.19 tons in 1978. Gold and Base Metals Ltd. produced less than 1% of the columbite concentrates. Mining and processing continued to be influenced by rising costs exacerbated by lower tin prices early in 1978 and by the failure of columbite prices to respond to the rise in value of their tantalum content. The columbite market gained strength during 1979 largely owing to increased demand, with 1979 columbite prices at $10.30 per pound compared with $3.45 per pound in November of 1978.

Iron and Steel.—In June 1979 Nigeria and representatives of the Soviet company Vsesojuznoje Exportne-Inportnoje Tiajpromexport initialed a draft agreement for the iron and steel complex at Ajaokuta, Kwara State. Pilot mining of iron ore also started in the Itakpe Hills. Nigerian authorities were negotiating with Brazil and Liberia for the supply of up to 1.5 million tons of iron ore to be used in the direct reduction plants scheduled for construction by 1982 at Warri. A loan of $1,126 million was arranged in 1979 for financing the Warri steel project with a group of West German and Austrian banks. To be called the Delta Steel Complex, the Warri project includes a harbor and plant that will produce 1.3 million tons per year of raw steel using a Midrex direct reduction process. The direct reduction plant will be fed from a pellet plant (1.4 million tons per year) to be built by Voest—Alpine of Austria. Contracts were also signed for three rolling mills, to be situated at Oshogbo, Jos, and Katsina. Kobe Steel Ltd. of Japan (Katsina) and Eisenbau Essen Gmbh (Oshogbo), Aktiengesell Schaft (Jos), and Mannesmann Demag (Jos) of the Federal Republic of Germany were the contractors.

Tin.—Net income at Amalgamated Tin Mines of Nigeria (Holdings) (ATMN) of London dropped during 1978 and 1979. The slippage was explained mostly by the inflationary costs for mining and a lower level of production, which was only 2,020 tons tin concentrate for fiscal year 1978 and 1,870 tons in 1979 compared with 4,630 tons for the same 1977 period. The company's operating subsidiary was now 60% owned by Nigerian interests, primarily the state-owned Nigerian Mining Corporation (NMC). ATMN produced about 50% of the Nigerian tin production; other producers included Bisichi Jantar (9%), Gold and Base Metals (13%), and Exlands Nigeria (13%). Kaduna Syndicate, United Tin areas Ltd., and Vectis Tin Mines Ltd. also produced small amounts. Kaduna Prospectors was a subsidiary of Mining Investment Corporation of the United Kingdom, which had interests in tin mining in both Nigeria and Cornwall and was recently (1977) named the Selukwe Gold Mining and Finance Company. Bisichi-Jantar produced 291.4 tons of tin concentrate in 1979, compared with 347.9 tons in 1978. ATMN lost over 6 months' production in 1978 when the bucket wheel excavator in the company's new deep pit failed to cope satisfactorily with handling of overburden and the instability of the ground being worked. Even so, ATMN had demonstrated that the problems encountered in opencast mining at depths of over 150 feet were not insurmountable. A group of experts were commissioned to study possible methods of solving the mining problems encountered. The unstable ground conditions stemmed from a water-saturated sand layer located 30 feet below the surface. The consultants recommended installation of a drainage system. Prospecting of ATMN's subbasalt ore reserve areas revealed 6,000 tons of tin concentrate, which were being considered for exploitation. Gold and Base Metal Mines retained an interest in the Rirewai underground mine through its 40% holding in the Nigerian subsidiary.

Makeri Smelting Co., Ltd., operated the tin smelter at 25% of capacity during 1978 and reported a 10% drop in refined tin processed. The company installed a small secondary lead smelter and refinery which would use motor car battery cells for raw material. The lead and antimony recovered would supply Makeri's own needs for production of solder and printing metal materials. The new project would also keep the tin smelter crews employed during slow periods.

Uranium.—An agreement was signed by the Ministry of Mines and Power and the French Bureau de Recherches Geologiques et Minieres (BRGM) under the auspices of the Nigerian Uranium Company (NUMCO), for uranium prospecting in the Gombe area of Bauchi State. NUMCO was incorporated in Nigeria with NMC having 60% of the shares and Minatome of France holding 40%.

NONMETALS

Building Materials.—A new brick plant was established in Isiwo, Ogun State. The factory, owned by Patrick George and Sons Ltd., produces red brick and colored terrazzo tile. Its initial output of 45,000 brick per day was to be raised to 60,000. The industry used local raw materials, including clay and sand, for the brick, although the coloring pigment was imported. Two other similar plants were located in Anambra and Borno States.

Cement.—A number of large French banks were instructed by a Paris court to block Nigerian bank accounts because of the continued failure of Nigeria to settle a debt for cement dating from 1975. In 1975 the Nigerian Central Bank apparently issued irrevocable letters of credit for the payment, but canceled them after shipment. Subsequently, Nigeria agreed to a private settlement payment for the cement.[12]

With expansion of construction activities and the resultant growth in demand for cement, the domestic output of cement has steadily increased in recent years. Total domestic output of cement was estimated at nearly 2.5 million tons, and plans were underway for expanding existing plants and building new ones. In addition, Nigeria was to take part in a joint venture cement complex in Benin as a result of the Economic Community of West African States (ECOWAS) decision for coordinated investment within member States. Demand for cement was estimated to be nearly 7 million tons in 1978. By January 1980, because of a slump in construction projects, the Nigerian National Supply Company declared a surplus of cement and prices were reduced from $114 to $98 per ton of cement.[13] Beginning April 1, 1979, an advance deposit of 50% would be required for all cement imports.

The West African Portland Cement Company (WAPCC), a Blue Circle Group subsidiary, officially opened its second cement plant on May 5, 1978, at Shagamu near Lagos, although production had started by yearend 1977. The new plant had a 650,000-ton-per-year capacity. During the construction period, more than 30,000 tons of plant and machinery were imported, and at its peak, more than 2,000 people were employed on the project. The works at Shagamu was designed to eventually use six kilns, of which only two were installed in 1979. WAPCC's plant at Ewekoro, near Lagos, had three kilns and a production capacity of 750,000 tons per year. A loan agreement for $22.5 million was signed in 1978 for additional extension to the cement works at Shagamu. Turners Building Products Ltd. was investing $7.8 million to double their plant's asbestos cement production. A new $14 million asbestos cement manufacturing plant was established in Bauchi State with production scheduled for 1980. Sited near Gombe, the plant would be a jointly owned project including Hyderabad Asbestos of India (35%) and the Nigerian Bank of Commerce and Industry and Nigerian Industrial Development Bank. A 10% share would also be reserved for interested local businessmen.

Fertilizer Materials.—*Phosphate Rock.*—Federal Superphosphate Fertilizer Co. (FSF) produced 22,100 tons of single superphosphate in 1978, well below the plant's capacity of 100,000 tons. The low production was attributed to erratic supplies of electricity and phosphate rock. Togo was FSF's sole source of phosphate rock. The FSF plant located at Kaduna came onstream in 1975.

MINERAL FUELS

Coal.—In recent years the Nigerian Coal Corporation (NCC) had spent about $60 million on improved coal mining mechanization. NCC was then faced with a problem of finding markets for the expected increased production. Ghana was reportedly the only country importing coal from Nigeria. In 1975, coal exports went also to Egypt and the Federal Republic of Germany. Sales of Nigerian coal had been dropping since the peak production year of 1972 when 341,000 tons had been produced. By yearend 1978, NCC had on hand approximately 59,000 tons of unsold coal which had accumulated since 1976. For 1976, the unsold figure was reported at 18,485 tons, and for 1977, as 26,873 tons. The mechanization of the Enugu mines was being done since 1976 by Katowic Arebowa (KOPEX) of Poland. To date, two of the four scheduled mines were fully equipped for longwall mining.[14] Construction was also started on the Onne River coal port.

Natural Gas.—A consortium comprising Phillips Petroleum (7.5%), Shell Oil Co. (10%), Azienda Generale Italiani Petroli S.p.A. (AGIP) (7.5%), Elf-Nigeria (5%), and the Nigerian National Petroleum Corporation (NNPC) was proceeding with studies relating to the construction of a 1,600-million-cubic-foot-per-day liquefaction plant at Bonny Island. The plant would be supplied with associated gas that was being flared, as well as from gas-only fields already discovered but not producing. The project will necessitate the construction of a pipeline system in difficult terrain. The state expected to participate in the pipeline project up to 85% with a partner as yet unnamed. The Government was to also take 50% share in the shipping facilities. Contracts for purchase of the LNG were to be negotiated with several U.S. companies.

The Government was going ahead with the billion-dollar petrochemical complex at Port Harcourt which was to produce vinyl chloride monomer (VCM), polyvinyl chloride (PVC), caustic soda, chloride, high-density polyvinyl (HDPE), and low-density polyethylene (LDPE). Technimont, subsidiary of the Montedison Group, was to build the $80 million plant. Production was to begin in 1982. By yearend 1979, an agreement had been reached with Pullman-Kellogg of the United States for construction of a fertilizer complex at Port Harcourt. The $340 million complex was to produce 1,000 tons per day of ammonia, 1,500 tons per day of urea, and 1,000 tons per day of compound fertilizer (NPK). It will use nearly 1 billion cubic feet per day of natural gas. Two U.S. companies, Transcontinental Fertilizer and International Minerals and Chemical Corp, will help market the products.

Petroleum.—*Production.*—As of January 1, 1978, Nigeria held 4.3% of the Organization of Petroleum Exporting Countries' (OPEC) total crude petroleum reserves. Estimated proven recoverable reserves were given as 18.7 billion barrels. In 1979 the state-owned NNPC increased its holdings in the main producing groups to 60% and was acting as the Government's regulatory authority for the oil industry. Nigeria also nationalized all of British Petroleum's Nigerian crude oil interests. This included the 20% stakes in the Port Harcourt Refinery and Shell-BP. Development Company as well as the 60% share in the BP Nigeria Ltd. Marketing Company. Shell-BP Development Company of Nigeria was 20% owned by Shell and 80% by NNPC. NNPC was to be reorganized into several companies with NNPC serving as holding company. The five companies proposed were Crude Sales, Petrochemicals, Refineries, National Tanker Fleet, and National Gas Companies. Each company will have a chairman, board members, and general manager.

Following expiration of long-term purchasing agreements at yearend 1977, Nigerian oil production slumped to the lowest point in over six years by March 1978. Three of the largest producers were operating at only 60% of capacity. The 1978 yearly average of 2,098,000 barrels per day, down from the average of 2,098,000 barrels per day achieved in 1977. The increase began in April and continued through the year after price reductions were announced. Official price reductions helped bring about a turnaround in Nigerian oil output for 1978. Nigeria announced reductions of 21 to 23 cents per barrel on its main crudes, with second-quarter prices as follows (excluding 2 cents per barrel harbor dues): 42% API Brass River, $14.13 (down 23 cents); 37% API Forcados, $13.80; 26% API medium, $13.60. The market dislocations caused by the Iranian production dropoff in late 1978 and early 1979 were eventually to support price hikes of much greater magnitudes. By yearend 1979, Nigeria's crude oil was priced at $26.27 per barrel for Brass River Blend. Crude petroleum production was scheduled to be cut in 1980 by about 10% from earlier record 1979 rates of 2.4 million barrels per day.

Exploration.—The Shell-British Petroleum (BP) Development Company of Nigeria had three seismic teams under permanent contract and had increased seismic surveys and exploratory drilling by 40% over 1977. Gulf was employing four drilling rigs on and off shore in 1978, three of which were exploratory operations. Gulf's 1979 exploration budget was $215 million. NNPC was contracting the largest number of seismic teams with one party working in the Chad Basin,one in Anambra, and two in the Niger Delta. NNPC was expecting to offer new exploration and production licenses on areas outside the existing concessions on terms related to the situation of each area. All interested companies were to be considered, not just the operating companies.

After expiration of its contract, Japan's Nigeria Oil withdrew even though it made finds at 6 of its 18 offshore wells. Reserves in this area, estimated at 30 million barrels, were considered noncommercial under 1978-79 production terms. Italy's AGIP, the Spanish-state-owned Hispanoil, and the Crown Central oil company all signed new exploration contracts under NNPC's new terms. AGIP was to carry all risks in exchange for 50% of production from commercial finds to cover expense, investment, and profit. If this oil does not cover cost, NNPC will sell additional oil to AGIP at market price in addition to 50% of production. Hispanoil's and Crown Central's agreements were described as service contracts. AGIP was to develop its Nembe Creek discovery at an output of 60,000 barrels per day. AGIP's Utapate South discovery was also under development.

Texaco Overseas (Nigeria) tested the Funiwal-1 well at 1,007 barrels per day in the offshore block held by NNPC (55%), Chevron Oil Co. (Nigeria) (22.5%) and Standard Oil of California (22.5%). The find occurred in water 40 feet deep, 6 miles offshore. A new offshore field was also discovered by AGIP on the OML-62 area of the Niger Delta. The crude was 28.3% API from deeper levels and 20.3% API from upper levels in the Beniboye North-1 discovery well. The well tested a maximum flow of 3,100 barrels per day.

Refining.—Nigeria's new refinery at Warri started production on September 19, 1978. Constructed by the Italian company Snamprogetti, the Warri refinery was stopped temporarily in December a few months after its startup because of technical difficulties. With a crude petroleum capacity of 100,000 barrels per day, the new refinery was designed to process crude from Shell-BP's Ughelli blending station and from Gulf's Escravos terminal. A full range of products were being produced with facilities capable of producing a high proportion of light products for the local market. Refined products were to be distributed though a 3,000-kilometer network of pipelines and 19 storage facilities still under construction. Including the Port Harcourt refinery, which had a 60,000-barrel-per-day capacity, the total national refined product output was expected to be 43.8 million barrels per year. Current consumption, running at 67.5 million barrels per year was increasing at about 25% annually. The third refinery (100,000 barrels of crude oil per day) under construction at Kaduna was expected to be operational by 1980.

The Mineral Industry of Norway

By Joseph B. Huvos[1]

In 1978 and 1979, financial restrictions to improve Norway's international competitiveness were further tightened, including a wage and price freeze, reduced credit supply, reduced industry support, and reduced public spending. As a result, Norway had a trade surplus. The country's minerals industry, mainly hydropower-based aluminum, ferroalloys, copper, and zinc, remained in a slump with the exception of oil and gas, the production of which expanded, making Norway a net exporter of these commodities. In 1979, Norway's gross national product (GNP) was about $42 billion.[2] The average unemployment rate was about 1.6%.

There were only a few important events in Norway's mineral industry in 1978 and 1979. In the North Sea, production started at the Thor oilfield, and development drilling was begun at the Statfjord A platform. Oil and gas were discovered in blocks 31/2, 30/6, 34/10, 15/5, and 1/9-3. Construction was completed at LKAB's Narvik iron ore loading port and continued at Elkem's Bremanger silicon smelter. Construction started at Norsk Jernverk's Rana Gruber iron ore concentrator. Finally, a decision was made to close three more copper mines.

PRODUCTION

In 1978 and 1979, change in production of most mineral industry products was not significant, but oil and gas expanded substantially. Production of major mineral commodities in Norway in 1976, 1977, 1978, and 1979 is shown in table 1.

[e]Estimate. [p]Preliminary. [r]Revised. NA Not available.
[1]Reported figure.
[2]Less than 1/2 unit.
[3]Data represent exports.
[4]Excludes nepheline syenite, which is included under "Stone."
[5]Excludes a quantity of stone reported at 4,774,485 cubic meters.
[6]A small quantity may have been used for fuel in the fields, but there was essentially no marketed production.

TRADE

In 1979, Norway's trade deficit changed to a surplus. Exports increased substantially due to increased crude oil and natural gas production, but imports changed little. There was no change in the general pattern of Norway's mineral trade, which consisted mainly of imports of raw materials for the electric smelters and exports of petroleum and finished metals. Norway's mineral commodity trade in 1977 and 1978 is shown in tables 2 and 3.

Table 2.—Norway: Exports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1977	1978	Principal destinations, 1978
METALS			
Aluminum:			
Alumina	1	1	NA.
Metal including alloys:			
Scrap	14,704	21,520	West Germany 10,656; Brazil 4,769; Sweden 2,504.
Unwrought	555,263	630,241	West Germany 168,622; United Kingdom 130,887; United States 68,361.
Semimanufactures	43,854	56,826	United Kingdom 15,970; United States 9,739; Sweden 7,940.
Cadmium	81	97	NA.
Cobalt	677	559	NA.
Copper:			
Ore and concentrate	98,728	98,239	West Germany 67,913; Sweden 27,494.
Oxide and hydroxide	3,122	2,752	NA.
Metal including alloys:			
Scrap	2,673	4,221	West Germany 2,671; Sweden 726; Belgium-Luxembourg 396.
Unwrought:			
Unrefined	6,841	5,586	West Germany 5,586.
Refined	20,684	16,201	West Germany 4,741; Sweden 3,415; France 3,345.
Semimanufactures	2,104	1,815	Sweden 901; West Germany 436.

See footnotes at end of table.

COMMODITY REVIEW

METALS

Aluminum.—Norway's primary aluminum industry, the fifth largest among market economy countries, with capacity of about 750,000 tons per year, was under growing public pressure to halt expansion in order to save energy, despite a shortage in world aluminum supply expected in 1981-82. The key to future expansion was the Government's energy program, which was not yet finalized. At present, many expansion projects by the country's six primary producers have been shelved, although several individual projects were advanced during 1978 and 1979.

In 1979, primary metal production increased further to about 95% of capacity. Aardal og Sunndal Verk AS, Norway's biggest aluminum producer, and VEBA AG of the Federal Republic of Germany agreed to form a joint company to produce aluminum and other products in Norway. Investment costs were estimated at $65 million, with Aardal og Sunndal AS holding 60% and VEBA 40%. VEBA is an industrial group, largely owned by the West German Government, involved in electric power generation, coal, and chemicals.

The Aluminium Company of Canada (ALCAN) decided to sell its remaining 25% stake in the Norwegian aluminum producer, Aardal og Sunndal AS, to the company's majority owner, which is the Norwegian Government.

Aardal og Sunndal Verk AS decided to go ahead in expanding its Höyanger aluminum smelter from 28,000 tons to 43,500 tons per year by 1981. A second-stage expansion calls for an increase in smelter capacity to 76,000 tons per year at an unspecified date.

Norsk Hydro AS applied to the Norwegian Government for permission to expand capacity at its 120,000-ton-per-year aluminum smelter at Karmöy near Haugesund by 47,000 tons. The $1.5 million expansion is expected to take about 2 years. In 1977, the company shelved plans to build a new smelter at Glomfjord. The company decided also to reactivate the 46,000-ton-per-year expansion of its Höyanger smelter.

Ownership, location, and capacity of Norwegian primary aluminum plants are shown in table 4.

Table 4.—Norwegian producers of primary aluminum

Company, plant location	Capacity, thousand tons at end of 1979	Ownership
Aardal og Sunndal Verk, Oslo:	•	Government (75%); Alcan Aluminium Ltd., Canada (25%).

DNN Aluminium AS:		Alcoa (50%); The British Aluminium Ltd. UK (50%).
Tyssedal, Sörfjord, Odda	24	

Copper, Lead, Zinc.—The Government had plans to close three more of Norway's 12 remaining copper mines, leaving only nine because it cannot justify the annual outlay of about $20,000 per employee to keep the mines open. The surviving mines will be subsidized from the State copper fund, which is slated to receive an additional $10 million, bringing the total to about $70 million.

Some of the copper ores produced in Norway were processed at Sulitjelma Gruber's 10,000-ton-per-year copper smelter at Sulitjelma, east of Bodö; the remaining copper ores were exported, as were all domestic lead ores.

Norway's 12 complex sulfide ore mines, distributed throughout the country, were operated by 10 independent companies. The ores mined contained mostly copper, lead, zinc, and iron sulfides. Among the more important mines were A/S Sulitjelma Gruber's Fauske Mine, east of Bodö (copper, lead, zinc), Grong Gruber A/S's Röyrvik Mine near the Swedish border (copper, zinc), Folldal Verk A/S's Dovre and Kvalsund mines in southern and northern Norway (copper, zinc, pyrites), and Orkla Industrier A/S's Keldal Mine, south of Trondheim (copper, zinc, pyrite).

Det Norske Zinkkompani (Boliden AB)'s Eitrheim, Odda, 90,000-ton-per-year electrolytic zinc smelter was to be expanded to 105,000 tons per year of zinc by 1980. The plant processed all domestic and also some imported zinc concentrates.

Iron Ore.—In 1978, Norsk Jernverk's Rana Mine started construction of a new concentrating plant for its iron ores. The new plant is scheduled for completion in 1980-81.

Work was completed by the Swedish company, Luossavaara Kirunavaara AB, to expand iron ore loading facilities at Narvik, one of the world's largest iron ore shipping facilities. Capacity has been increased to 30 million tons per year. The latest expansion, completed in 1978, included pellet-screening facilities, a stacker, and a bucket-wheel reclaimer at the port's fifth berth. The port can handle ships to 75,000 deadweight tons. Other important iron ore ports in Norway were Kirkenes near the U.S.S.R. border, for loading up to 125,000-deadweight-ton ore carriers at a rate of 4,000 tons per hour, and the port of Malm on Beistadfjord, for loading of up to 35,000-deadweight-ton ships at a rate of 1,500 tons per hour.

Folldal Verk AS has concluded a long term contract for supplying 20,000 tons per year of magnetite concentrate produced as a byproduct at its Tverrfjellet metal mine located near Kjerkinn, central Norway, to the National Coal Board of the United Kingdom. The concentrate will be used for heavy-media separation of coal.

In 1978 and 1979, iron ore production did not significantly change. Norway's three largest iron ore mines were Government owned: AS Sydvaranger's Sör Varanger Mine near Kirkenes (capacity 2.3 million tons of concentrate per year), Norsk Jernverk's Rana Gruber Mine near Mo (1.2 million tons), and Fosdalens Bergverks AS's Verran Mine (510,000 tons). Privately owned AS Rödsand Gruber was located on the west coast (150,000 tons). Minor quantities of iron ore were produced also as a byproduct of ilmenite and vanadium production.

Iron and Steel.—After the bankruptcy in 1977 of Stavanger Staal AS, Norway's only stainless steel producer, located in Jörpeland, the Government decided in 1978 to establish a new company, Nye Stavanger Staal AS by granting a loan of $1 million and guaranteeing loans up to $4 million.

Norsk Jernverk has completed plans for the construction of a continuous casting plant at its Mo-i-Rana works on the west coast.

Elkem Spigerverket AS was doubling its production capacity for silicon metal to 24,000 tons per year by adding another furnace at its Bremanger smelter, located on Norway's west coast north of Florö. The $20 million plant was scheduled for completion in 1980.

Crude steel production came mainly from Government-owned AS Norsk Jernverk's Mo-i-Rana plant, Elkem Spigerverket's Nydalen plant near Oslo, and Stavanger Staal AS's Jörpeland plant. There were nine other companies in the specialty steel business at various locations.

Magnesium.—Although Norsk Hydro had earlier withdrawn from the actual mining project, it was expected to receive the output of magnesium chloride from a solution mine in the Groningen area in the Netherlands for magnesium metal production in Norway. The Dutch Government had given Billiton Delftstoffen (Holland), a subsidiary of Royal Dutch Shell, permission to exploit a large magnesium salt deposit found in Groningen.

Norsk Hydro AS's 70,000-ton-per-year Porksgrunn plant, near Oslo, was the country's only magnesium smelter.

Molybdenum.—In 1979, rapidly rising molybdenum prices prompted the Norwegian Ministry of Industries to consider reopening the Knaben molybdenum mines near Kristiansand, south Norway. The mines were closed 7 years ago.

Nickel, Cobalt, Platinum-Group Metals.—The Kristiansand refinery of Falkonbridge Nikkelverk AS, a subsidiary of Falconbridge Nickel Co. of Canada, remained the country's only producer of nickel-group metals using nickel matte imported from Canada. Production of nickel in 1978 decreased over 10%.

Titanium.—Titania AS, a subsidiary of NL Industries of New Jersey, continued to be Europe's largest titanium ore (ilmenite) producer. The Tellnes deposit, located near Hauge i Dalane on the south coast, supplied about 17% of world ilmenite production. Some byproduct magnetite concentrate and pyrite were also produced. Kronos Titan AS produced some titanium pigment at Frederickstad, on the south coast. The rest of the ore is exported.

Yttrium.—A/S Megon (Metal Extractor Group of Norway) & Co. operated a 30- to 50-ton-per-year extraction plant at Kjeller, about 12 kilometers east of Oslo, producing 99.999% yttrium oxide. Nine Norwegian companies had an interest in Megon: Elkem Spigerverket, Dyno Industries, Aardal og Sunndal Verk, Norzink, Sulitjelma Gruber, H. Bjorun, S.D. Cappelen, Norwegian Talc, and Sydvaranger. Raw material used is xenotime from the U.S.S.R., Malaysia, and Australia and Japanese rare-earth plant byproducts.

The company had a joint venture with Malaysian interests to operate a concentrator near Kuala Lumpur, producing 27 tons of 60% Y_2O_3 concentrate per year, which was converted at the company's plant in Kjeller to a purity of 99.99999% Y_2O_3, and used mainly for red phosphors in color television screens.

NONMETALS

Cement.—Norcem, Norway's only cement concern, planned to build a cement plant at Verdal at a cost of $390 to $450 million using Government support. In 1978 and 1979, the company controlled three plants totaling 2.3 million tons capacity.

Fertilizer Materials.—Norsk Hydro has signed a deal to buy 100,000 tons per year of apatite concentrate (36% P_2O_5) for 5 years from Luossavaara Kirunavaara AB of Sweden. This represents about one-quarter of the company's yearly requirements. Norsk Hydro accounted for most of the fertilizer materials produced in Norway, including ammonia capacity of 830,000 tons per year.

Norsk Hydro has started to expand its mixed fertilizer capacity by 60,000 tons to 510,000 tons at Glomfjord, west of Mo. Supplies of domestic ammonia and imported phosphate rock are expected to be available for this purpose.

Sulfur.—Seven companies operating one mine each accounted for the sulfur contained in about 300,000 tons of pyrite concentrates produced annually in Norway in 1978 and 1979.

Other Nonmetals.—A number of industrial minerals were produced in Norway in 1978 and 1979. Norwegian Talc AS prepared about 60,000 tons per year of white dolomite filler from its Hammerfall Mine in north Norway, processed at Knarrevik near Bergen. White marble was produced in the Nordmore region, northeast of Aalesund by Hustad Kalk og Marmor AS at Elnesvaagan (100,000 tons per year), Langnes Marmorbrudd at Eide (20,000 tons per year), and Visnes Kalk og Marmorbrudd AS at Lyngstad (100,000 tons per year).

Ground limestone filler was produced by Franzefoss Bruk, Hylla Kalkverk, and Aardal og Sunndal Verk AS.

Synthetic abrasive grain was produced by Arendal Smelterverk AS, a subsidiary of Carborundum Co., United States, at Arendal (37,000 tons per year), Norton AS at Lillesand (12,000 tons per year), and Orkla Exolon AS & Co. at Orkanger (12,000 tons per year).

MINERAL FUELS

Over four-fifths of Norway's energy supply (production plus imports) was domestic oil and gas, and less than one-fifth was domestic hydroelectric power. Domestic coal was insignificant. All natural gas and more than half of the crude oil produced was exported.

Norway's supply and apparent consumption of fuels and power in 1977 and 1978 are shown in table 5.

Table 5.—Norway: Supply and apparent consumption of fuels and power for 1977 and 1978

(Million tons of standard coal equivalent)[1]

	Total energy	Coal and coke	Crude oil and petroleum products	Natural gas	Hydroelectric power[2]
1977:[3]					
Production	34.1	0.5	20.3	3.6	9.7
Imports	18.5	.9	17.3	--	.3
Exports	27.3	.2	23.3	3.6	.2
Apparent consumption	25.3	1.2	14.3	--	9.8
1978:[3]					
Production	54.4	.4	36.0	8.0	10.0
Imports	15.8	.9	14.8	--	.1
Exports	36.9	.2	27.6	8.0	1.1
Apparent consumption	33.3	1.1	23.2	--	9.0

[1]Coal equivalent of 7,000 kilocalories per kilogram.
[2]Secondary included in trade.
[3]Primary energy only.

Source: Monthly Bulletin of Statistics. Central Bureau of Statistics, Oslo, Norway, No. 12, 1978; Monthly Bulletin of External Trade, Oslo, December 1979, Norway 1979; Central Bureau of Statistics.

Coal.—The Government-controlled Store Norske Spitzbergen Kullkompani AS continued coal production on Svalbard Island at a decreased rate of 378,000 tons per year in 1978 and 1979. The U.S.S.R. continued coal mining nearby at an estimated rate of 400,000 tons per year.

Petroleum and Natural Gas.—In 1978, oil and gas production rose to approximately 30 million tons of oil equivalent including exports of 13.5 billion cubic meters of natural gas. Exports of oil and gas for the same period netted $2.9 billion. In 1979, oil and gas production was expected to reach almost 40 million tons of oil equivalent, valued at about $4 billion at 1978 prices. The action of the OPEC countries in raising the price of crude oil contributed to Norway's increased oil income.

July 1978 marked the beginning of the production of crude oil from the Thor oilfield, located in block 2/4 and tied in to Ekofisk center. Thor is, after Cod, the fifth oilfield in the Norwegian sector of the North Sea to go into production; the rate of production was to be 3.5 million tons of crude oil and 720 million cubic meters of natural gas per year.

In 1978, there were two significant oil discoveries in the North Sea in the "Golden Block" at block 34/10 of the Statfjord field. There were also gas and condensate discoveries, one located west of the Sleipner field in block 15/5, and one in block 1/9-3 that was drilled with the "Ross Rig."

In 1979, Norske Shell AS made a significant gas find in block 31/2 that could be several times the size of the Frigg field, but production is not expected until the 1990's because of the depth of the water there. Gas was also found in Statoil's block 30/6. Statoil's well in 34/10 was tested at 650 tons per day from Middle Jurassic sandstone.

At the end of 1979, offshore construction work on Statfjord platform "A" had been completed, and development drilling had started. Twenty-inch casing was set in the first four wells. Statfjord development costs increased from $2.9 billion to $6.3 billion, caused partly by recent safety regulations. Production was due to start by the end of 1979.

The Petroleum Directorate was considering relaxing royalties and tax rates for North Sea oil discoveries considered marginal such as Heimdal, Sleipner, West Frigg/Northeast Frigg, Odin, and British Petroleum-Statoil and Phillips-Statoil strikes in blocks 7/12 and 1/9 in an attempt to bring them onstream as quickly as possible.

Norway was to retain full control of its oil resources while retaining membership of the International Energy Agency (IEA).

It was expected that the Government would approve test drilling north of the 62d parallel on Halten Bank, north of Trondheim, and Fugloy Bank, north of Tromsö, during spring in 1980, shortly before the beginning of the drilling season. The first exploration licenses for the area awarded in December 1979 went to three Norwegian companies, SAGA Petroleum, Statoil, and Norsk Hydro.

Location of a $4 billion petroleum refinery employing 2,100 workers, north of the 62d parallel, was the object of a study by authorities. It was found that dispersing such a facility into eight separate units would significantly increase construction and operating costs.

According to a Norwegian Government policy statement, Statoil, the Government-owned oil company, will have at least 50% of all future block allocations on the continental shelf, but Norsk Hydro AS and SAGA Petroleum AS will also be included to some extent.

The $60 million feasibility study for the pipeline project from the Statfjord oilfield to Sotra Island on the Norwegian coast was successfully completed, and cost estimates for the project were submitted.

The Mineral Industry of Pakistan

By David E. Morse[1]

Mineral production in Pakistan during 1978 and 1979 remained modest by world standards. Although Pakistan produced a variety of industrial minerals, fuels, and a few metallic ores, output was of domestic significance only. Exploration for minerals and fuels was conducted by several federal and provincial agencies; faced with limited resources and an escalating bill for imported crude oil and petroleum products, federal funding for petroleum exploration was more than four times the exploration budget for nonfuel minerals in 1978-79.

The success of the federally owned Oil and Gas Development Corp. (OGDC) in finding oil outside of the Potwar Basin in 1976, the relatively high price of crude oil on the world market, and amendments to Pakistan's tax laws specifically written to encourage foreign companies to explore for petroleum in Pakistan resulted in nine new exploration agreements between the Government and foreign oil companies in the 1977-79 period. The country's need for a significant increase in domestic output of crude oil was clearly demonstrated in 1979 when world crude oil prices escalated over 80%, which placed a severe burden on Pakistan's foreign exchange reserves.

Two federally owned, mineral development agencies, Resources Development Corp. (RDC) and Pakistan Mineral Development Corp. (PMDC), continued to operate through 1979. RDC was concerned exclusively with the development of the Saindak copper deposits, and PMDC covered all mineral fields except Saindak copper, nuclear materials, and oil and gas. In addition, Pakistan's Geological Survey conducted geologic studies and nonpetroleum mineral exploration. Three provincial governmental bodies, the Baluchistan Development Authority (BDA), the Punjab Mineral Development Corp. (Punjmin), and the Sarhad Development Board (of the Northwest Frontier Province) performed nonpetroleum exploration and development functions within their regions, often in conjunction with PMDC or through contractors. The Agency for the Federal Administered Tribal Areas held mineral responsibility for the tribal areas of Baluchistan and Northwest Frontier provinces. The Government established a gem stones corporation in 1978, which was responsible for the mining, cutting, polishing, marketing, and exclusive exporting of stones (for example, Swat emeralds and Hunza rubies).

Domestic private industry's role in the mining sector continued to be limited both by government policy and by investor caution. Government policy had been to maintain control of those industries considered essential to the economy except where foreign technology and/or capital were required. After the Martial Law Administration took over control of the Government in 1977, a new stance was taken toward industry, and some previously nationalized processing plants had been returned to private industry in 1978 and 1979. Nonetheless no sweeping changes had been announced, and private investors continued to be suspicious about new ventures, which resulted in little or no capital input from the non-Government sector in areas other than light industry and commerce.

Pakistan's domestic economy registered generally good years in both fiscal 1977-78 and fiscal 1978-79[2]. Pakistan's gross domestic product (GDP) was $17.9 billion[3] in fiscal 1978-79, a growth of 5.9% in constant 1959-60 prices. The growth of the GDP in fiscal 1977-78 was nearly 7% in constant 1959-60 prices. The growth of Pakistan's gross national product (GNP) surpassed the growth in the GDP because of the increased and substantial contribution of Pakistanis working overseas. The GNP increased 10% in fiscal 1977-78 and by 6.3% in fiscal 1978-79. Pakistan's GNP was $17,039 million in fiscal 1977-78 and $19,352 million in fiscal 1978-79.

Notwithstanding growth in the domestic economy and the over $1 billion in home remitances, Pakistan's economy was under substantial strain because of the nation's poor position in its external finances. Record trade deficits in 1977-78 and 1978-79, plus increasing debt service payments caused a significant decline in foreign exchange reserves during 1979. To decrease the federal budget deficit, which would include additional external financing, a package of new and increased taxes was instituted to raise over $500 million in additional revenue in fiscal 1979-80.

PRODUCTION

Mining and quarrying contributed 0.78% to the nation's GDP in fiscal 1977-78 and 0.82% in fiscal 1978-79. Domestic natural gas, Pakistan's most abundant fuel, was used to supply nearly 35% of the nation's commercial energy in 1978 and 1979. Crude oil output from fields in the Potwar Basin of northeast Pakistan supplied only 10% to 12% of the nation's petroleum requirements. By late 1979, crude oil production had reached 11,500 barrels per day at the Rawalpindi refinery, the only refinery in the producing area. A $31.6 million expansion program at the Rawalpindi plant got underway in 1979 to accomodate increased output from the Meyal and other nearby oilfields.

Processing mineral commodities was of importance to the economy especially by reducing the need for imported, expensive, finished goods. Pakistan's domestic cement industry had a capacity of 3.45 million tons per year in 1979. Nitrogenous fertilizers were produced utilizing domestic natural gas as feedstock, and complex fertilizers were produced from domestic and imported materials. The nation produced finished steel products from domestic and imported scrap and from imported steel. Other metals were imported and processed by the country's foundaries and forges. Two petroleum refineries near Karachi processed imported crude oil for domestic consumption.

Table 1.—Pakistan: Production of mineral commodities

TRADE

Pakistan's material trade balance continued to be highly unfavorable despite record performances in exports in both fiscal 1977-78 and 1978-79. Exports increased 14.9% in fiscal 1977-78 and 29.5% in fiscal 1978-79, primarily on the strength of the agriculture sector. Imports for the same period increased by 20.4% and 31.3%, respectively, and the trade deficit for fiscal 1978-79 rose to $1,977 million.

Pakistan's trade in mineral commodities was an important part of the deficit. Exports of barite, chromite, and petroleum products were the only significant mineral exports. Imports of petroleum and petroleum products, fertilizer materials, iron and steel products, nonferrous metals, and cement were valued at nearly $1.17 billion in fiscal 1978-79 or 32% of the value of total imports. Mineral exports were only valued at 5.5% of mineral imports in fiscal 1978-79. Pakistan planned to decrease its mineral trade deficit by increasing domestic crude oil production, by building more fertilizer plants, increasing cement capacity, and by completing a major steelmaking facility.

The following tabulation lists the value of Pakistan's mineral imports, by major group.

COMMODITY REVIEW

METALS

Bauxite.—Punjmin was investigating bauxite deposits near Khushab in the Sargodha district, Punjab, and in 1978 reported 340,000 tons of ore averaging 63% alumina and an additional 11.4 million tons at 40% alumina. Punjmin received a $1.68 million loan from the United States in 1979 to aid in determining the suitability of the Khushab ore for alumina production and for use as refractory-grade bauxite.

Chromite.—The bulk of Pakistan's chromite production came from the Zhob Valley region of Baluchistan near Muslimbagh. BDA was building a 20-ton-per-day pilot plant to test the low-grade chromite ores of the Zhob region. Government plans for chromite development near Muslimbagh included an 18,000-ton-per-year concentrator, a 15,000-ton-per-year ferrochrome plant, and a refractory brick plant.

Copper.—In 1979, PDC awarded a contract to Mountain States Mineral Enterprises Inc. of the United States to conduct a preliminary engineering and feasibility study for an integrated 12,500-ton-per-year copper project at Saindak, Baluchistan. In 1977, Seltrust Engineering Ltd. of the United Kingdom completed a preliminary feasibility study on the Saindak deposits that recommended a mine and mill project that would treat 12,500 tons per day of ore to produce 165 tons per day of copper concentrate, 250 tons per day of magnetite concentrate, and 205 tons per day of pyrite concentrate. The concentrates were to be shipped to processing facilities near Karachi for the production of blister copper, sulfuric acid, and steel billets. Additionally, small amounts of molybdenum, silver and gold were to be recovered from the concentrates at the processing facilities.

Iron Ore.—Geologic investigations reportedly discovered good quality iron ore deposits in Pakistan; 10 million tons was delineated in Dar Ghazi Khan district Punjab, 5 million tons in Chagai district Baluchistan, and 32 million tons in the Kohistan district, Northwest Frontier Province. The Kohistan deposits were discovered while prospecting for barite, and laboratory analysis of samples resulted in assays of 54% to 65% iron. Preliminary estimates of the Kohistan deposits were as high as 100 million tons, although the deposits have not been officially investigated.

Iron and Steel.—Pakistan Steel Mills Corp. continued erecting the new Pipri steelworks near Karachi. The mill's first blast furnace was to be "blown-in" in 1980 and full operation of the steel making plant was scheduled for 1981. The completed works was to have an annual capacity of 1.1 million tons of raw steel, employ 15,000 workers, and reduce the import of steel products. Port Qasim, which will handle the bulk raw material imports required by the steel mill, neared completion in 1979. Imported iron ore and coal will be unloaded from ore carriers at the port and transported directly to the steel mill by two 4.5-kilometer-long conveyor-belt systems.

In 1978, a heavy forge and foundary was completed with aid from China at Taxila, Punjab, south of Islamabad. The project was designed to produce 28,000 tons of steel ingots, 6,300 tons of steel castings, 4,700 tons of iron castings, and over 7,000 tons of other ferrous manufactures per year. The $45 million project provided employment for about 3,000 and was to save nearly $18 million in foreign exchange annually.

Molybdenum.—Reportedly, large reserves of molybdenum were discovered at Darbanchah, in the Chagi district of Baluchistan. An initial survey has been completed and a drilling program to assess the quality and extent of the mineralization was begun in 1979.

NONMETALS

Barite.—Operations at Bolan Mining Enterprise's (BME) Khuzdar, a 30,000-ton-per-year barite-grinding plant, were suspended on September 24, 1978, following a total interruption of electrical power. To avoid complete loss of production, BME made arrangements for 500 tons per month of barite to be ground by Crown Mills Ltd. of Karachi. BME, a joint enterprise between the government of Baluchistan (50%) and Pakistan Petroleum Ltd. (50%), decided to build its own source of power generation at the grinding plant. Two 250 kilovolt-ampre diesel generators were in operation early in 1979.

Cement.—Cement was in short supply in many areas of Pakistan in 1978 and 1979. Cement imports were valued at $6 million in fiscal 1977-78 and over $20 million in fiscal 1978-79. Pakistan's cement capacity in its nine operating plants was 3.45 million tons per year, and demand was projected to increase from 3.9 million tons in 1978 to 5.1 million tons in 1980. Two 300,000-ton-per-year extensions to existing cement plants were scheduled for completion in 1979: one at Javedan near Karachi was onstream in early 1979; the second near Rawalpindi was to come onstream later in the year. The State Cement Corp. of Pakistan Ltd., the managing agent for all cement companies in Pakistan, planned to increase the country's cement output by building five new cement plants and adding capacity to two established facilities. Additionally, after the Government announced that cement production was no longer closed to private enterprise, numerous proposals were received from private groups requesting approval for the establishment of cement plants in all four provinces of Pakistan.

Fertilizer Materials.—Pakistan continued to import significant quantities of manufactured fertilizers. The value of imported fertilizer materials in fiscal 1977-78 increased to $112 million and shot up to over $270 million in fiscal 1978-79. Pakistan manufactured nitrogenous fertilizer utilizing domestic natural gas and phosphoric fertilizers by processing imported materials. The country did not produce potassic fertilizers from either domestic or foreign sources but imported complex fertilizers to supply the potasium component of fertilizer consumption.

Nitrogenous.—Pakistan produced over 300,000 nutrient tons of nitrogen (N) in a variety of forms in 1978 and 1979. Domestic demand was over 600,000 nutrient tons N for the same period. Pakarab Fertilizers Ltd., a joint venture between the National Fertilizer Corp. of Pakistan (NFC) and Abu Dhabi National Oil Co., completed a $127 million expansion to NFC's Multan fertilizer plant in 1978. The expansion increased ammonia capacity by 300,000 tons per year, ammonium nitrate capacity by 350,000 tons per year, urea capacity by 12,500 tons per year and added facilities for the production of complex fertilizers. Natural gas from the Sui field was used for feedstock for the ammonia plant. NFC, with financing provided by Saudi Arabia and the Asian Development Bank, was building a 1,000-ton-per-day ammonia, 1,750-ton-per-day urea facility at Mirpur Mathelo near Sukpur, Sind.

Commissioning was scheduled for 1979, and natural gas from the Mari field was to be used as feedstock.

The Fauji Foundation was setting an ammonia-urea complex at Machi Goth near Sadiqabad, Punjab, in 1979. The $270 million project, based on natural gas from the Mari field, was to have the capacity to produce 250,000 nutrient tons of N per year.

The Pakistan Ajman Fertilizer Corp. proposed to set up a $300 million fertilizer complex on the coast near Port Qasim, Baluchistan. The facility was to use natural gas from the Sui field and imported phosphoric acid for the production of urea and di-ammonium phosphate. The project was slated for completion in 1981.

NFC planned to build a fertilizer complex at Haripur, Northwest Frontier Province, to produce 95,000 tons per year of urea based on Sui gas feedstock in one phase. A second phase was to add facilities for phosphoric acid and mono-ammonium phosphate production utilizing domestic phosphate rock from Kakul. No completion date for this project was announced by yearend 1979.

Phosphatic.—In 1978, the United Kingdom Ministry for Overseas Development approved a $3.14 million grant for PD-NCB Consultants Ltd. to conduct further exploration of the Hazara region phosphate deposits. PD-NCB completed investigations in 1977 of the Kakul deposits and began development of a 57,000-ton-per-year pilot program to supply phosphate rock to NFC's superphosphate plant at Jaranwalla. The new, 2.5-year study, was to center on Dalola and Lagarban and determine the feasibility of establishing a large-scale phosphate rock mine in the area to feed the planned fertilizer complex at Haripur.

Fluorite.—Commercial production of fluorite by the Baluchistan Development Authority commenced at Koh-e-Dilband in the Kalat District of Baluchistan late in 1978.

Salt.—PMDC started exploitation of a new salt mine at Jatuna near Khewa, Punjab, in 1978. This brought salt production capacity from the Salt Range to over 420,000 tons per year. Rock salt was also mined in the Preshawar Division, NWFP. Twenty coastal operations produced solar evaporated marine salt in 1978 and 1979.

MINERAL FUELS

Coal.—Coal was produced in all four provinces of Pakistan with the Salt Range and Makarwal coals from Sind and the Sor Range, Mach Kost, and Sharigh collieries near Quetta, Baluchistan, the major contributors to the nation's output. PMDC planned to develop the Lakra coalfield near Hyderabad to supply 1 million tons of coal per year for a planned 250-megawatt power station at Jameshoro, Sind. Sharigh coal was to be used to augment imported coking coal at the Pipri steel mill.

Natural Gas.—Over 80% of Pakistan's natural gas output came from Pakistan Petroleum Ltd.'s (PPL) Sui gasfield in east central Baluchistan. The Mari gasfield produced over 40 million cubic feet per day exclusively for the Dhakari fertilizer plant. Natural gas was also produced and recovered from oilfields in the Potwar Basin.

Petroleum.—Domestic crude oil production increased from less than 10,000 barrels per day in mid-1978 to over 11,000 barrels per day by yearend 1979, but only supplied 10% to 12% of the nation's requirements. Pakistan Oilfields Ltd.'s (POL) Meyal and Balkassar oilfields and OGDC's Toot oilfield were the major contributors to the country's output in 1978 and 1979. OGDC was committed to increasing Toot ouput to 9,500 barrels per day and completing a 10 well development program at the Dhodak field to produce 22,500 barrels per day by 1981. POL planned to increase Meyal's output to 17,000 barrels per day by 1983.

The PPL-Amoco Pakistan Exploration Co. joint venture discovered oil in 1978 in PPL's East Potwar concession area. Extensive testing on the discovery well, Adhi 5, was conducted in 1978, and Adhi 6 was spudded about 6 miles from Adhi 5 in 1979 to delineate the extent of the field. OGDL discovered oil at Dhermund 1 in 1979 and was conducting test operations at yearend 1979.

Three petroleum refineries were in operation in Pakistan in 1978 and 1979, and a fourth was under construction. Two Government-owned oil refineries near Karachi processed imported crude oil. Attock Oil Co. Ltd. (AOC) processed domestic crude at its Rawalpindi facility near Islamabad. AOC planned to increase the Rawalpindi capacity by 20,000 barrels per day to accommodate the increasing output from the Toot and Meyal oilfields and the anticipated production from the Adhi discovery. Crude oil was to be shipped by pipeline to Multan where a new 40,000-barrel-per-day oil refinery was being built.

The Mineral Industry of Peru

By L. Nahai[1]

The Peruvian economy after 2 years of declining aggregate output in 1977 and 1978, recovered in 1979 and was forecast to grow about 1.6%. The reversal in the decline of the gross domestic product (GDP) and the improved international reserve position resulted from the 1978 stabilization program. However, the high inflation rate persisted, about 74% in 1978 and 67% in 1979.

The mineral sector showed a 13% increase in the first half of 1979, primarily because of increased petroleum production; the manufacturing sectors showed evidence of a mild recovery in the same period. The mineral industry accounted for 9.4% of GDP in 1978 and 10% in 1979; mineral exports accounted for about 50% of total exports in 1978 and 45% in 1979.

Government Policies.—There has been a gradual shift in Government policy regarding the development of Peru's many known and explored deposits. The Government is more willing to have foreign capital participate in mineral development. The magnitude of the required capital is such that Peru's own resources cannot meet the need. As a result, many of the mineral projects include some degree of foreign participation. (See Development Plans.) The more favorable attitude to foreign capital participation is illustrated by legislation passed to encourage mining of placer gold. Also, modifications were made in the mining law to provide incentives for the industry.

In 1976, the Government established a 15% export tax that was later increased to 17.5%. In September 1977, copper producers were exempted from the tax owing to low prices, and in May 1978, zinc producers were also exempted until April 1979. In December 1979, zinc producers were exempted from the tax until April 1980. However, the tax was reintroduced for medium-size copper and zinc producers.

Decree-laws were issued in December 1979 authorizing Petróleos del Perú (Petroperú) to renegotiate its existing production contracts with Occidental Oil Co. and Belco Petroleum Corp. The Government also published guidelines to govern existing and future oil contracts (See Petroleum). The Government signed a scientific agreement with the Federal Republic of Germany under which geologists will evaluate the petroleum prospects of the Marañón River basin.

As of January 1, 1979, the Instituto de Geología y Mineria (INGEOMIN) and the Instituto Científico Tecnológico Minero (INCITEMI) were merged into Instituto Geologíco Minero Metalúrgico (INGEMMET).

Development Plans.—Both Empresa Minera del Perú (Minero Peru) and Empresa Mineral del Centro del Perú (Centromín) have a number of plans for expanding production in existing mines and plants and developing large known deposits. As is shown by the tabulation that follows, implementation of these plans require substantial capital not available to the two State-owned companies. As a result some of the projects, such as the expansion of the Ilo copper refinery and La Oroya zinc refinery have had to be postponed. However, since the Government is now more willing to be associated with foreign capital, it is expected that some of the plans will be realized in the next few years. For example, private capital will play a role in the development of the Tambo Grande polymetallic deposit and La Granja copper-molybdenum deposit as well as the Bayóvar phosphate mine and fertilizer complex.

Project	Principal development plans and description	Current status	Estimated investment (millions)
CENTROMIN			
Cobriza Mine	Expansion of mine production from 2,600 tons of ore to about 10,000 tons of ore per day and a new 10,000 -ton-per-day refinery to produce 200,000-ton-per-year concentrates with 25% copper.	Postponed in 1978, but work resumed in 1979 and to be completed in 1982.	$181.3
Refinery at La Oroya, 184 kilometers east of Lima.	Expansion from 70,000 to 90,000 tons-per-year for zinc and 58,000 to 73,000 tons for copper; new lead sinter plant.	Plant expansion in abeyance, but work on modernization of the zinc refinery was carried out. The sinter plant project expected to start in 1980.	78
Mine water treatment at Cerro de Pasco.	To replace cement copper precipitation with a solvent extraction/electrowinning plant.	Basic engineering test work completed; on site work started and expected to be completed in 1980.	18
Toromocho, 140 kilometers east of Lima.	To develop a mine to produce 35,000 tons of ore per day.	Feasibility study.	
Cerro Pasco Mine	Expansion of mine production from 6,300 to 8,000 tons per day.	To be executed in the 1979-83 period.	
MINERO PERU			
Cerro Verde - Stage II Phase I mine, located 24 kilometers SW of Arequipa.	Expansion of mine and concentrator to produce 200,000 tons of concentrate annually (60,000 tons of copper).	Proposals have been made by Italian, Japanese and West German companies.	285
Ilo copper refinery, 5 kilometers from Ilo port.	Expansion from 150,000 to 225,000 tons per year of cathodes.	Postponed to 1981.	
Antamina copper-zinc located in northern Peru in Province of Huari, Department of Ancash.	Development of mine to produce 50,200 tons of copper, 27,000 tons zinc, 487 tons of molybdenum, and 21 tons silver.	Work being done in association with Geomim of Romania which has submitted feasibility study.	326
Zinc refinery at Cajamarquilla, 25 kilometers east of Lima.	Construction of refinery to treat 200,000 tons of concentrate and produce 100,000 tons of zinc. Byproduct will include 355 tons per year of cadmium	Construction by "Sybetra" of Belgium progressing and expected to be completed in 1980.	215
San Antonio de Poto gold placer in Department of Puno.	Exploitation of gold placer (345-square-kilometer area).	Minero Perú will exploit the deposit.	14
Tambo Grande Pyrite	Exploration, development and mining.	Negotiation with BRGM of France; action not initiated.	
Iron pelletizing plant	Expansion.	Postponed.	
Quellaveco, located between Toquepala and Cuajone.	Develop deposit to produce 20,000 or 40,000 tons per day of ore.	Southern Peru Copper Corp. has reportedly shown interest in developing deposit.	300 (for 20,000 ton-per-day alternative)
Tintaya in southern Peru, in Province of Espinar, Department of Cuzco.	To develop the deposit of sulfide and oxide ore to produce 200,000 tons of copper concentrate for export.	Although many private companies indicated interest, the deposit will be developed by the State-owned, Minero Perú, Centromín, and Cofide.	234
Michiquillay in Department of Cajamarca.	To develop deposit to produce 394,000 tons of copper concentrate.	Feasibility study stage.	660
Bayóvar phosphate deposits and potassic brines in Sechura desert in Department of Piura in northern Peru.	To develop deposit to produce 800,000 tons of phosphate rock, phosphate fertilizers, and potassium chloride.	Feasibility study completed. Mine open, also operating a pilot plant to produce 20,000 tons of phosphate rock. INI of Spain participating.	320
SOUTHERN PERU COPPER CORPORATION			
Botifaca concentrator	To recover 3,000 short tons per year of molybdenum from Cuajone ore.	Authorization granted by the Government and construction underway in 1979.	10

PRODUCTION

Production in 1978 and 1979 was affected by labor strikes in both years. A strike at the mines of Centromín in August and part of September 1978 caused the declines in production of lead, zinc, silver, and iron ore, as shown in table 2. Copper production in 1978 did not suffer because the Cuajone was less affected by work stoppages. In 1979 both Cuajone and Toquepala had work stoppages but in general the labor situation in 1979 was calmer.

Placer gold mining increased as a result of incentives provided by the new gold law and the increase in price.

TRADE

Mineral exports in 1978 increased both in tonnage and value and, with a value of $970 million, represented 50% of all exports. Copper ranked No. 1 in export value, and silver ranked No. 2. They accounted for 42% and 21%, respectively, of the value of mineral exports. In 1979 mineral exports were valued at $1,548 million or 45% of total exports. The bulk of Peru's mineral exports is in the form of metal. However, the country still exports lead and zinc concentrates and will continue to do so even with the completion of the Cajamarquilla refinery.

In 1979, mineral exports by Minero Perú Commercial (Minpeco), the state agency in charge of marketing all Peruvian minerals, were as shown in the following preliminary data:

Commodity	Quantity (metric tons)	F.O.B. value (thousand U.S. dollars)
Refined copper cathodes	175,145.0	328,746
Refined copper bars	31,406.0	57,645
Refined copper wire rod	5,547.0	10,429
Blister copper	[1]139,613.0	247,287
Copper concentrate	[1]111,742.0	50,350
Copper cement	[1]1,784.0	2,262
Copper ores	[1]715.0	264
Total copper		696,983
Refined lead	85,531.0	95,270
Lead concentrates	[1]134,962.0	183,709
Lead ores	[1]5,861.0	2,111
Total lead		281,090
Refined silver	772.0	234,096
Refined zinc	57,292.0	38,782
Zinc concentrates	[1]693,639.0	132,420
Zinc zamac	14.0	10
Zinc sulfate	20.0	8
Total zinc		171,220
Crude antimony	102.0	204
Refined bismuth	362.0	2,001
Refined cadmium	210.0	1,173
Refined indium	3.7	1,608
Refined selenium	12.5	333
Refined tellurium	12.3	505
Arsenic trioxide	1,519.0	635
Tin concentrates	[1]2,365.0	13,711
Molybdenum concentrates	[1]2,141.0	53,365
Tungsten concentrates	[1]1,129.0	10,784
Antimony ores	[1]741.0	742
Total various products		85,061
Iron ore	[2]5,529,026.0	84,854
Total		1,553,304

COMMODITY REVIEW

METALS

Copper.—As a result of strikes, the projected production goal of 380,000 metric tons in 1978 was not achieved but was surpassed in 1979, reaching 400,385 metric tons. Production of contained copper by the principal segments of the industry in 1978 and 1979 were as follows:

	1978	1979
Total contained copper production	366,400	400,385
Principal producers:		
Southern Peru Copper Corp	283,064	291,073
Centromín (from its own mines)	25,911	p30,500
Minero Peru (from Cerro Verde Mine)	28,426	33,100

pPreliminary.

Minero Peru received renewed proposal from Klöckner Industrie Anlage of the Federal Republic of Germany and Marubeni of Japan for Phase I of the expansion program envisaged for the Cerro Verde Stage II deposit, to produce 60,000 tons of contained copper. Minero Peru also carried out negotiations in 1979 with Bureau de Recherches Géologiques et Minières (BRGM) of France, Billiton International Metals B.V. of Netherlands, and Outokumpu Oy, of Finland to develop the Tintaya copper deposit.

Centromín's plan for copper call for the expenditure $20 million in 1979, $77 million in 1980 and $70 million in 1981.[2] The funds will be used for the expansion of the Cobriza copper mine and the copper refinery of La Oroya.

The Agila copper mine at Huarás, 250 kilometers north of Lima, started production in 1978. The mine hopes to produce 10,000 to 12,000 tons of contained copper per year. The copper concentrate will be shipped by pipeline and truck to Chimbote port for export.

Gold.—With the dramatic gold price increase and the Government's reduction of taxes on private mine developers in May 1978, the gold boom initiated in 1978 continued throughout 1979, especially in the placer gold area of Madre de Dios in the southeastern jungle region. The Banco Minero del Perú, which has the monopoly on all gold trading in Peru, increased its purchases from 90,295 ounces in 1978 to 113,022 ounces in 1979.

Over 50% of gold production is from Centromín's La Oroya refinery and the company retained its No. 1 position as Peru's gold producer. The remainder of the production is from placers and the small Ocoña lode gold mine in the Department of Arequipa. Gold production by Centromín, by sources, in 1978 and 1979 were as follows:

	1978	1979
In ores and concentrates	12,860	17,008
In blister	16,075	12,057
Refined	32,183	42,857
In placer gravels	46,008	50,412
Total	107,126	122,334

The Madre de Dios area accounted in 1979 for 90% of placer gold, which was the largest single source of Peru's gold production. Although, in this area a few modest producers are active, the bulk of the gold is produced by many individual entrepreneurs who work with hand tools and small water pumps and sluices. Peruvian and United States interests who own the Roberto 24 concession, on the Madre de Dios River north of the Island of Laberinto, were in the development stage of removing the overburden. They were planning on a medium-size mechanized operation of around 100 cubic meters per day. In addition, a group of Swiss and Peruvians were carrying out exploration in the Huepetue and Colorado Rivers with the idea of eventually setting up a completely mechanized operation, probably with dredges. Another Peruvian-United States group is exploring with very encouraging results, in the Puquibe River, which will probably turn out to be a large operation.

The Government-owned Centromín continued its exploration between the Madre de Dios and Inambari Rivers with encouraging results. Existence of a gravel horizon with gold, tin, and chromite has been established.

The only other large gold mining project is San Antonio de Poto in Puno in the far south, which Minero Perú was planning to develop through a special mining company with local and foreign investors. However, negotiations with Oro Sur, a company formed by private Peruvian investors, and St. Joe Minerals Corp. fell through when the Government reintroduced a 17.5% export sales tax, which caused St. Joe to reconsider any new investment plans. Minero Perú has now decided to develop the project alone and has contracted SIMA, the Peruvian Navy Industrial Service, to evaluate the cost of raising a dredge that sunk back in 1972 when the concession was being worked by Natomas Co. of California.

In addition to gold placer mining, there are several small underground operations, some of which have now become feasible owing to the present price of gold. The old Cochasayhuas gold mine in Apurímac and the old Sucuytambo, now known as "Nora Maria," in Arequipa, containing silver and gold, are currently being reactivated. Moreover, the Arias group, which controls a large number of mines in the country, is interested in opening a new gold prospect in the Pataz area, 300 miles north of Lima in the mountains, Department of La Libertad, east of the Marañón River. It calls for an investment of $3 million, which includes the installation of a 200-metric-ton-per-day mill, the opening of a 35-kilometer access road, and the acquisition of electric diesel power and mine equipment. The company expects the new mine to go into production in about 2 years.

Because "non-traditional" exports, in this case jewelry, were given export subsidies, domestic sales, mainly to jewelers for fabrication and export, increased. Exports of gold bullion, therefore, decreased in 1979 from 89,121 ounces valued at about $16,956 million in 1978 to 49,100 ounces worth $13,024 million in 1979. Gold shipments in 1979 went entirely to Venezuela and the United States.

Iron Ore.—During 1979, the State-owned Hierro del Peru, the only iron ore producer, obtained a number of loans for buying trucks, desalinization units for improving the quality of the pellets produced, and has plans to buy additional equipment in 1980. By yearend, the company started production of pellets using fresh water from two desalinization units. Hierro del Perú's production by categories was as follows, in dry long tons:

	1978	1979
Pellets	2,102,530	1,755,900
High-grade sinter feed	1,457,880	1,922,430
Pellet feed in slurry form	506,090	521,458
Pellet feed in filter cake form	777,200	1,158,370
Total	4,843,700	5,358,158

Iron ore exports in 1979 totaled 5,513,772 dry long tons; of which 2,365,940 went to Japan and 1,249,470 went to the Republic of Korea; smaller quantities were shipped to the United States (491,140 dry long tons) and a few other countries.

Lead and Zinc.—Centromín, the dominant lead and zinc producer of Peru, accounted for about 38% of zinc and 42% of total lead production. Centromín's main investment in its lead-zinc operations was the modernization of the La Oroya refinery. The strike against 15 medium-size mining companies resulted in a production decline by this sector of the industry in 1978.

Activities in the private sector of the industry included the construction of a new 1,800-metric-ton-per-day concentrator by Cía. Minera Milpo S.A., which started operation in August 1979, the expansion of ore production from 460 to 750 metric tons per day in the Alianza lead/zinc deposit located in Ancash, the expansion of Cía. Mínera San Ignacio de Morococha S.A.'s mine from 1,500 to 2,000 metric tons per day of ore, and the development of the Contoga zinc deposit of Sociedad Minera de Gran Bretaña S.A. to produce about 200 tons per day of ore. These expansion plans have contributed to the production increase noted in 1979. Promotora de Negocios Mineros Perú S.A., 71% owned by Milpo, completed geological and feasibility studies of the Colladare polymetallic prospect.

Molybdenum.—The major molybdenum producer in Peru is Southern Peru Copper Corp. from its Toquepala Mine, which in 1979 produced 1,980 metric tons of molybdenite containing 1,787 metric tons of MoS_2, a substantial increase from the 1,216 metric tons MoS_2, in 1978. Cía Minera Turmalina, a small operation in northern Peru, produced about 30 metric tons of concentrates containing 24 metric tons of molybdenite, making a total of 1,811 metric tons of molybenite in 1979.

Cía. Minera Turmalina is currently exploring the Ricrán molybdenum deposit in the central mining district (Department of Junín). Amax Exploration, Inc., of Denver, Colo. has obtained an option on the Pashap copper-molybdenum deposit located in the Province of Huaylas, Department of Ancash in northern Peru, having initiated a drilling program in 1979. The deposit was previously explored in 1973.

Molybdenum production should be increasing considerably starting in 1980 if the Cuajone molybdenum concentrator currently under construction goes onstream by mid-1980 as scheduled.

Silver.—Silver exports in 1978 and 1979 valued at $207 million and $394 million, respectively, ranked second in value in Peruvian exports; the 1978 exports accounted for 11% of all exports by value. Centromín, the largest producer (20.4 and 25.5 million ounces in 1978 and 1979, respectively), was followed by Cía. de Minas Buenaventura S.A. (4.35 million ounces in 1979), and Minas de Arcata S.A. (1.8 million ounces in 1979). Buenaventura owns four mines: Julcani and Huachocolpa in the Department of Huancavelica in Central Peru; Orcopampa in the Department of Arequipa; and Uchucchacua, 120 kilometers northeast of Lima. The company completed expansion at the Uchucchacua Mine in 1979. The companies operating Huarón and Alianza mines and Cía. Minera Milpo S.A., listed among the lead zinc producers, were other important silver producers.

The high silver prices increased exploration and production. Primary examples are reactivation of the Salpo silver deposit near Quiruvilca; exploration of the "El Extrano" lead-silver-zinc deposit in Ancash Department and the Auquichani silver deposit on the continental divide near Lima; start of production in 1979 at the Farallón polymetallic mine; and the reactivation (in 1977) of the old Cacachara lead-silver mine.

Cía. Minera Condesa S.A., one of Buenaventura's subsidiaries, acquired an important group of mining concessions close to the town of Huachocolpa, in the Department of Huachocolpa southeast of Lima, containing mineralized veins with high silver content. Moreover, Condesa in association with Cía. Minera Caudalosa S.A., and Cía. Minera Castrovirreyna S.A. are participating in the Cía.. Minera Chonta S.A., which was formed recently to develop the Rublo Mine in the Huachocolpa region.

Tungsten.—In addition to Centromín, Peru's principal tungsten producer from the San Cristóbal Mine, and Fermin Malaga Santolalla e Hijos Negoc. Minera, which produces tungsten from the old Pasto Bueno Mine, Soc. Minera Regina S.A. produced 150 tons of tungsten concentrate (67% WO_3) from the Regina Mine, which the company has started to develop. The Regina Mine is located in southern Peru, northeast of Juliaca. Soc. Minera Puquio Cocha S.A. also recovered tungsten from tailings accumulated over 30 years from a copper concentrator. Small tonnages were produced by Tungsteno Peruano S.A., a Canadian firm operating a small deposit in Ancash, and Cía. Minera Turmalina. Production by companies in 1978 and 1979 was as follows, in metric tons of WO_3 content:

	1978	1979
Centromín	424	363
Malaga Santolalla	196	192
Small producers	114	160
Total	734	715

NONMETALS

Barite and cement were the principal nonmetallic commodities produced in Peru. The status of the industry and producers was unchanged from that of 1977. Expansion of the Pacasmayo cement plant of Cementos del Norte Pacasmayo S.A. to increase capacity from 1,000 to 3,000 tons per day has been completed and is reflected in the higher production in 1979.

Fertilizer Materials.—*Nitrogenous.*— The refineries of Petroleos del Peru produce urea by processing refinery gases. Urea production since 1975 was as follows, in metric tons:

Year	Quantity
1975	47,506
1976	100,289
1977	117,955
1978	112,860

Phosphatic.—The National Institute of Industry of Spain completed a feasibility study of the Bayóvar phosphate. The study envisages a $300 million investment to produce the following, in tons per year:

Phosphoric acid	213,000
Sulfuric acid	588,000
Potassium chloride	200,000
Triple superphosphate	358,000

MINERAL FUELS

Coal.—The world energy situation stimulated interest in coal in Peru in recent years. In early 1978 the Government created a commission to draft plans for utilizing the country's coal resources. One of the conclusions of the energy symposium in June 1979 was that an entity should be chosen to evaluate and promote the development of Peru's coal resources for domestic use and export. It is hoped to increase the contribution of coal to the total energy supply from the present level of 0.5%.

Developments in the coal industry during 1978 and 1979 were as follows: Centromín in 1978 reopened the old Goyllarisquizga deposit and reportedly started a modest production in 1979. A coal-washing plant with a daily capacity of 300 tons is also being installed. Centromín plans also to start exploration and diamond drilling for coal in the Jatunhuasi area, located in Cachi 45 kilometers northwest of Huancayo, and planned to do some diamond drilling to locate coking coal.

Minero Perú's coal activities were concentrated on the Alto Chicama anthracite seams. The anthracite would be used for the 480-megawatt powerplant to be built by KOPEX-Universal, a Polish-Swiss consortium working on the project. The consortium submitted its feasibility study in November 1978.

Empresa Siderúrgica del Perú (Siderperú) is exploring the Oyon area with means to install a coking plant. Within Siderperú's short term expansion program, it is considering a direct-reduction furnace and a thermal power station using anthracite coal from the Santa Valley in northern Peru.

Private industries were also active. Combustibles Solidos S.A. was reported to have contracted to export 80,000 tons of anthracite from the Santa Valley region, with the first shipment to start in 1979. The coal would come from the Ancos Mine and small producers in the area.

Petroleum and Natural Gas.—Two new oil contracts were signed in 1978, one with Occidental Petroleum Co. to exploit heavy crude in Block 1-B adjacent to Occidental's existing fields (Block 1-A) in the eastern jungle. The second contract was with Occidental and Bridas S.A. of Argentina for secondary recovery in a cluster of 11 fields in the Lobitos-El Alto/Los Organos area on the west coast. Secondary recovery from these fields is expected to reach 38,000 barrels per day by 1984. The major event in 1979 was a publication by the Government of guidelines to govern existing and future oil contracts with foreign companies, and tax regimes applicable to all contracts. The guidelines set limits on areas of exploration and number of blocks a company may explore. These contracts would be either service contracts or operations contracts to be valid for a maximum of 30 years (exploration and exploitation). The contractors will be compensated for their services by Petroperú either in a negotiated amount of cash, in cash according to volume and value of production, or in crude in an amount proportional to the volume of production.

Production.—The increase in crude production in 1978 resulted from the completion of the northern spur pipeline linking Occidental's fields in the eastern jungles to the Trans-Andean pipeline (completed in 1976). Production in 1979 increased again as a result of expansion by Occidental's field in the jungle area and of increased secondary recovery in the coastal fields. By yearend 1978, the Trans-Andean pipeline was transporting 125,000 barrels of crude per day. In 1978, the jungle fields, with an average daily production of 92,000 barrels, accounted for 61% of output followed by the coastal fields (20%) and the continental shelf (19%). Corresponding 1979 figures were 67% for the jungle (128,782 barrels per day), 18% for the coast (34,539 barrels per day), and 15% for the continental shelf (28,325 barrels per day).

The producing companies were as follows:

Company	Fields	Production (thousand barrels) 1978	1979
Occidental	Eastern jungle area	23,492	38,756
Petroperú	Eastern jungle and the Talara coastal fields.	21,298	18,685
Belco	Offshore fields in blocks Z - 1A and Z - 2A.	10,287	10,339
Occidental Bridas[1]	Secondary recovery in Lobitos and El Alto/Los Organos area.	1,114	2,171
Total		55,191	69,951

[1]Started operation in April 1978.

The northeastern and central jungle fields continued as dominant producers.

	Production (thousand barrels) 1978	1979
Northeastern fields:		
Occidental	23,492	38,756
Petroperú	9,513	7,784
Central fields:		
Petroperú	521	466
Total	[1]33,527	47,006

[1]Total may not agree because of rounding.

Reserves.—By yearend 1978, proven reserves under development by the above companies were reported to total 715 million barrels divided as follows: Occidental-350, Petroperú -305, and Belco-60.

In addition, Royal Dutch Shell carried out technical studies on a jungle area in the Marañón basin, Sun Oil Co. showed interest in the central Ucayali basin, and MAPCO and Petroperú held preliminary discussions on secondary recovery.

Consumption and Trade.—Peru consumed 120,428 barrels per day of petroleum in 1978 and 126,016 in 1979. Crude exports in 1978 and 1979 were 10.7 million and 19 million barrels, respectively. The total value of crude and byproducts exports nearly tripled from $192 million in 1978 to $719 million in 1979. Peru also imported petroleum products: 2,144,000 barrels in 1978 and 17,755,000 in 1979, with f.o.b. values of $34.5 million and $16 million, respectively.

To keep petroleum product prices in line with international levels, the Government increased prices in 1979. In local currency these price increases were 30% to 50% above the 1978 levels. However, because of the depreciation of the sol, the increases in dollar prices were close to 10%. Gasoline costs about 90 cents per gallon; prices for some of the other products in U.S. cents were domestic kerosine-$0.10; diesel No. 1-$0.41; and residual fuel oil-$0.32.

Refining.—During 1978 and 1979, Petroperú continued operating four refineries. Crude processed by the refineries in 1978 and 1979 was as follows:

Refinery	Location	Capacity (barrels per day)	Crude processed (thousand barrels) 1978	1979
Talara	Northern Peru	65,000	20,566	20,338
La Pampilla	Lima	100,000	22,349	29,259
J. L. Diaz	Iquitos	1,400	408	403
Pucallpa	Central Jungle	2,500	579	581

In late 1979, the Ministry of Energy and Mines approved construction of a 10,500-barrel-per-day refinery at Iquitos to meet the needs of the jungle marketing area. The new refinery, which will replace the small topping plant, is scheduled to come on-stream by 1982. The plan for the construction of a 150,000-barrel-per-day refinery in Bayóvar has been postponed.

The Talara refinery produced 112,858 tons of urea in 1978 and 109,200 tons in 1979. This plant also produces carbon black, which Peru started exporting in 1979.

The Mineral Industry of the Philippines

By E. Chin[1]

The Philippines is a commodity-exporting country, earning most of its foreign exchange from exports of agricultural and forestry products, animal foodstuffs, and minerals. Despite the mounting annual trade deficit-$1.2 billion in 1978 and $1.5 billion in 1979-the gross national product (GNP) rose 22.2% from $23.9 billion in 1978 to $29.2 billion in 1979 at current market prices.[2] In terms of constant prices (1972 pesos), real growth in GNP was only 6%, from a GNP of $11.1 billion in 1978 to $11.8 billion in 1979.[3]

The mineral output value of the Philippines in 1979 was estimated at $1.3 billion, compared with $0.8 billion in 1978, representing only 4.4% and 3.3% of the GNP, respectively.[4] The value added for the production of refined minerals and metals was not included in the output value inasmuch as the bulk of the mining output is exported for overseas processing.

The minerals sector was an important component in overall trade, accounting for 28% of total export value in 1979 and 24% in 1978. In terms of imports, mineral fuels alone accounted for 23% of all imports in 1979, with receipts of base metals, 9%, and metal manufactures, 2%. Receipts of nonmetallic commodities (chemicals, fertilizers, and nonmetal manufactures) were valued at $576 million in 1979, or 9% of total imports.

There was increased production in 1979 of copper, chromite, cement, and the other major mining products except gold and nickel. The minerals sector was buoyed both by higher demand and by higher world prices for precious and base metals. Although gold prices exceeded $500 per ounce before yearend 1979, output of both primary and secondary gold was below the 1978 level of production.

Presidential Decree (PD) No. 1677 was promulgated in 1979, amending certain sections of PD 463 (Mineral Resources Development Decree of 1974). PD 1677 obligates owners of mining claims to place mining properties into production in 5 years; failure to do so would result in automatic abandonment of the mining claims. Holders of existing mining leases are required to submit a revised or updated work program and are obligated to submit proof of compliance with annual work obligations. Deviation from the submitted work plan was to be subject to approval by the Philippine Bureau of Mines. The main purposes of the Decree were to speed development of mining claims and to eliminate speculation by claim owners.

In September 1979, the President of the Philippines proposed the acceleration of its industrialization program, which encompassed 11 major projects totaling $6 billion. Objectives envisioned in the program included the establishment of 12 industrial export processing sites during the next 5 years to earn up to $500 million annually, introduction of tariff reforms to promote free and competitive trade, creation of new industries, modernization of existing industries, and financial assistance for small- and medium-size firms. Projects related to the mining sector included construction of an aluminum smelter, a copper smelter, an integrated steel mill, and a phosphate fertilizer plant, expansion of the cement industry, and establishment of two downstream petrochemical projects.

Philippine 1979 energy needs were estimated at 91.9 million barrels of oil equivalent (BOE). Imported petroleum accounted for 81.4%, or 74.8 million BOE, of the consumption in 1979, down from 81.5 million BOE in 1978. Configuration of domestically produced energy was as follows: Petroleum, 10% (9.2 million BOE); hydropower, 6.4% (5.8 million BOE); geothermal, 1.5% (1.3 million BOE); coal, 0.8% (0.7 million BOE); and other, 0.01% (0.006 million BOE). Geothermal production in 1979 was 223 megawatts and was scheduled to double in 1980 to about 480 megawatts. Three 60-megawatt hydropower units of the Argus River project in Mindanao came onstream in 1979. No other major hydroelectric projects were slated for completion in the Luzon grid until 1982.

Petroleum import cost was $1.4 billion in 1979 and was expected to exceed $2 billion in 1980. Because of difficulties at the Nido field near Palawan Island, petroleum production stabilized at a flow rate of 40,000 barrels per day (bpd), dropping, however, at the end of the year to 21,300 bpd. The Nido field was opened in April 1979 and was to be followed by the development of the Cadlao and Matinloc fields in 1980.

The Philippine Bureau of Mines projected an average annual growth rate of 13.3% for the mining sector during 1980-85. Copper mining and beneficiating was to remain the largest contributor and was to reach a growth rate of 16% as new mines and expansion programs became operational in 1980. Gold production was to parallel the trend for copper with metallic output targeted to reach 1 million ounces in 1983. The ratio of traditional mineral commodity exports to total export was to decrease to 14% by 1983, in line with the national effort to promote exports of manufactured goods rather than raw materials. The Bureau of Mines was to provide guidance and coordination of all Government efforts in mining exploration and development down to the local level. Additionally, it will conduct geologic surveys; expedite the granting of mineral rights; provide geologic, mining, and metallurgical research assistance; and monitor information to promote and foster exploitation.

Under the authority of Presidential Decree No. 1654, the Philippine Bureau of Mines was renamed the Bureau of Mines and Geo-Sciences effective December 14, 1979.

PRODUCTION[5]

The Philippine Bureau of Mines estimated the total value of mineral production at $1,288 million in 1979, compared with $823 million in 1978. The large increase in value was attributed to the rise in prices for major mineral commodities rather than to a significant increase in quantity output. The value of metal mining output in 1979 was $852 million ($564 million in 1978), and for nonmetallic minerals, $436 million ($259 million in 1978).

The Philippines is the largest producer of copper in the Orient, and the value of output of ore and concentrate totaled $468 million, or 38% of the total output by the mining sector. Production of cement was valued at $282 million, followed by gold, $141 million; nickel, $112 million; sand and gravel, $86 million; cobalt, $67 million; and chromite, $39 million. Production of other metal values in 1979 included silver ($15 million), molybdenum and zinc ($4 million each), and lead ($2 million). In the nonmetallic sector, salt production in 1979 was valued at $19 million and silicon sand, $4 million.

Coal production increased 38% in value from $6 million in 1978 to $8 million in 1979. Beginning in 1980, it was expected that petroleum production would be an increasingly significant input for the minerals sector.

[e]Estimate. [p]Preliminary. [r]Revised. NA Not available.
[1]In addition to the commodities listed, the Philippines produces platinum-group metals as byproducts of other metals, but output is not reported quantitatively and no basis is available to make reliable estimates of output levels.
[2]Reported figure.
[3]Includes unspecified earths.

TRADE[6]

Total trade in 1979 was $10.7 billion compared with $8.1 billion in 1978. Exports increased 35%, reaching $4.6 billion in 1979. The Philippines is well known for its exports of forestry and agricultural products. Shipments of coconut oil during the year were valued at $740 million; followed by logs and lumber, $341 million; and sugar,

$212 million. For mineral commodities, the value of exports of copper concentrates totaled $440 million; followed by gold, $103 million; chromite, $22 million; and cement, $13 million.

The value of imports increased from $4.6 billion in 1978 to $6.1 billion in 1979. Receipts of mineral fuels and related materials alone totaled $1.4 billion in 1979. Imports of base metals were $532 million; metal manufactures, $128 million; and nonmetallic manufactures, $47 million. Imports of chemical products and fertilizers in 1979 were $441 million and $88 million, respectively.

Table 2.—Philippines: Exports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1976	1977	Principal destinations, 1977
METALS			
Aluminum metal including alloys, all forms	1,795	843	Japan 366; Indonesia 238; Hong Kong 134.
Chromium: Chromite ore and concentrate	378,104	432,937	United States 159,319; Japan 74,616; Sweden 67,049; United Kingdom and northern Ireland 53,125.
Copper:			
Ore and concentrate	956,558	1,011,105	Japan 749,244.
Metal including alloys:			
Scrap	1,305	930	Taiwan 586; Japan 246.
Matte	8	2	All to Belgium-Luxembourg.
Unwrought and semimanufactures	--	36	All to Taiwan.
Gold:			
Bullion thousand troy ounces	140	94	All to United Kingdom and northern Ireland.
Metal, rolled, unworked or partly worked do	395	419	Japan 283; United States 68.
Iron and steel:			
Ore and concentrate thousand tons	836	1,983	All to Japan.
Roasted pyrite do	34	56	Taiwan 42; Japan 11.
Metal:			
Scrap	80	369	Hong Kong 220; Japan 149.
Pig iron, ferroalloys, similar materials	7,304	4,778	Japan 2,229; Thailand 1,646; Malaysia 540.
Semimanufactures:

COMMODITY REVIEW

METALS

Aluminum.—The Government of the Philippines was negotiating a joint venture agreement with Reynolds Aluminum Co. for a 50-50 equity in the construction of a $450 million aluminum smelter in Claveria, Misamis Oriental, Northern Mindanao. The proposed plant, to be operational in 1985, would have an initial installed capacity of 70,000 tons per year of metal, to be expanded later to 140,000 tons. Site selection was based on dependable hydroelectric power, good roads, and shipping facilities in the Phividec area. A separate agreement was to be negotiated for the power requirements to be supplied by the hydroelectric projects from the Polangui and Agus Rivers.

Exploration by the Bureau of Mines has delineated bauxite reserves in the Samar area between 65 and 100 million tons. Detailed geologic work was being conducted at Samar as well as research by the Bureau of Mines and Reynolds to extract and upgrade the bauxite, containing 40% to 50% Al_2O_3. The Leyte-Samar area has abundant geothermal energy available if alumina facilities were to be constructed there.

Chromium.—There were five producers of refractory-grade chromite in the Philippines. Consolidated Mines, Inc., accounts for 97% of the total output, followed by Pulsar Mineral Resources, Inc., 2%; and three companies for the remainder. Output of metallurgical-grade chromite was by 22 companies. Inter-Continent Mineral & Oil Corp. produces around 5,000 tons per year; G. Lluch & Sons, Inc., 3,100 tons; six companies produce 2,000 to 2,999 tons; nine companies 1,000 to 1,999 tons; and five produce less than 1,000 tons. Production of concentrates of metallurgical-grade chromite was by three companies: Acoje Mining Company, Inc., accounts for 63% of the total; Trident Mining & Industrial Corp., 25%; and the Golden Arrow Mining Co., Inc., 12%. Shipments to Japan account for about 40% of all exports, followed by the United States, 30%; Mainland China, 7; and Brazil, 5; the bulk of the remainder goes to Australia, Canada, and the Netherlands.

The Philippines ranks in the top 10 producers of chromite in the world. Reserves of chromite, estimated by the Philippine Bureau of Mines, were 13,970,000 tons distributed as follows: Metallurgical grade (12% to 52% Cr_2O_3), 6.36 million tons; and refractory grade (29% to 38% Cr_2O_3), 7.61 million tons.

Bayer A.G. of West Germany was granted pioneer status by the Board of Investments for the construction of a P87.5 million chromite processing facility on Samar Island. By obtaining pioneer status, the company was eligible for Government incentives such as tax-free capital imports, tax deferments, and high priority for financial and nonfinancial resources. The 100,000-ton-per-year plant, to be operated by Bayer's wholly owned subsidiary, Alamag Corp., will be operational by 1983.

In 1979, Acoje Mining Co. completed a $7.2 million expansion program, boosting mining and milling capacities 50%. Meanwhile, the Heidis Group and Voest Alpine A. G. of Austria completed the takeover of the ownership and management of Acoje Mining. Ferrochrome Philippines, Inc., a joint venture of Heidis and Voest, was formed to establish a $75 million ferrochrome plant at the Phividec industrial estate in Misamis Oriental. Construction startup for the 50,000-ton-per-year ferrochrome plant was planned in early 1980 and initial production by mid-1982. All of the smelter's output is to be exported, with 25% designated for the Voest Alpine group's metallurgical operations.

Cobalt.—The sole producer of cobalt in the Philippines was Marinduque Mining and Industrial Corp. Cobalt, a byproduct of nickel mining, is currently recovered in the Philippines as a mixed nickel-cobalt sulfide which is shipped to Japan for processing by Sumitomo. The National Economic and Development Authority disapproved Marinduque's proposal to construct a cobalt refining plant. The average annual cobalt recovery was about 1,200-ton-per-year.

Copper.—Twelve producers account for virtually all of the mine copper output in the Philippines. Atlas Consolidated Mining & Development Corp., the largest, accounts for 42% of total production; followed by Marcopper Mining Corp., 15%; Marinduque Mining & Industrial Corp., 10%; Philex Mining Corp., 8%; CDCP Mining Corp., 7%; Lepanto Consolidated Mining Co., 6%; Western Minolco Corp., 4%; and the bulk of the remainder by Consolidated Mines, Sabena, Baguio Gold, Black Mountain, and Acoje, in that order. In addition, copper recovered as a byproduct of zinc mining totaled around 543 tons (less than 0.1% of the national output) and was by Zambales Base Metals, Inc., and Benguet Exploration, Inc.

Atlas Consolidated, a subsidiary of A. Soriano Corp., operates one underground mine and three open pit mines in Cebu. In 1979, Atlas installed three diesel generating units with a combined capacity of 34 megawatts to insure power adequate to run its mines and mills. A sixth ball mill circuit was added at Carmen and new fines crushing equipment at the concentrator. Ore reserves held by Atlas in Cebu totaled 937 million tons, averaging 0.46% copper. Atlas is the largest producer of silver in the Philippines and recovers gold as well as molybdenum sulfide concentrates from its operations.

Marcopper Mining Corp.'s primary open pit mine and mill is in Tapian, Marinduque Island. Marcopper's ore reserve base totals

68.1 million tons of 0.58% copper. Development continued on the San Antonio mineralized zone, 4 kilometers north of the Tapian pit; ore production could begin in 1981. Marcopper is also the fifth largest gold producer and the third largest silver producer in the Philippines.

Marinduque Mining and Industrial Corp. operates the Sipalay and Bagacay Mines under a 25-year lease from the Government; the lease is renewable for an additional 25 years. Marinduque was planning an expansion of the Sipalay capacity from 18,000 tons per day to 30,000 tons per day. The company is the only nickel producer and the fourth largest silver producer in the Philippines and in also a producer of gold and molybdenum.

Four new copper mining projects were onstream at the end of 1979. Sabena Mining Co. has a production capacity of 10,000 tons per day (tpd) at its Kamanlangan project in Maco, Davao del Norte. CDCP Mining Co.'s project in Basay, Negros Oriental has a production capacity of 10,000 tpd. Sabena and CDCP were newly organized copper producing firms. Consolidated Mines began operating its 15,000-ton-per-day Ino project in Mogpog, Marinduque; and Benguet Consolidated's 17,000-ton-per-day Dizon project in San Marcelino, Zambales.

By the submission deadline of 5:00 p.m., August 15, 1979, Philippine Associated Smelting and Refinery Corporation (PASAR) received three bids for the construction on a turn-key basis of the country's first copper smelter and refinery. PASAR is composed of 11 Philippine copper firms and the Government of the Philippines. The bidding companies were Canada's SNC Ltd.; the Anglo-Finnish consortium of Davy McKee International, Selection Trust, and Outokumpo Oy; and Japan's Marubeni Corporation. The smelter-refinery contract was awarded to Marubeni, and the formal ratification was scheduled for January 14, 1980, in Tokyo. Construction cost for the copper facility, to be sited in Southern Leyte, was $250 million, including provisions for contingencies and cost escalation.

Gold.—Production of gold was by 7 primary producers and 11 secondary (byproduct) producers. Primary gold production accounts for about 25% of the total output; the other 75% is byproduct recovery from other metal mining activity. Production by the top five producers in 1979 was as follows in kilograms (figures in parentheses are 1978 output); Philex, 3,914 (5,085); Atlas, 2,996 (3,379); Benguet Consolidated, 2,703 (3,331); Lepanto, 2,368 (2,265); and Marcopper, 1,617 (2,283). Production by each of the remaining producers was less than 700 kilograms in 1978 and 1979.

Reserves of gold ore were estimated by the Philippine Bureau of Mines at 802 million tons assaying from 0.11 to 20.57 grams of gold per ton. Also there are 24 known, undeveloped gold prospects totaling around 200 million tons. Total rated ore capacity is 2.03 million tons per year. Higher prices for gold, offset the declining ore grade and high cost of production cited by producers. Production costs for primary producers were estimated to be between $4.82 and $5.78 per gram, or $150 to $180 per ounce. Gold production in the Philippines was expected to increase at an average rate of 9% per year during 1979-82.

The gold and silver refinery and mint in Quezon City of the Central Bank of the Philippines was commissioned in January 1978. The P222 million complex will print the country's currency and mint coins, and was to refine the national output of gold and silver. Designed capacity for the refinery was 600,000 troy ounces of gold (0.990 to 0.995 fineness) per year and 400,000 troy ounces of silver (to 0.999 purity) per year. However, initial installed capacity was 300,000 ounces for gold and 200,000 ounces of silver.

Gold refining by the Central Bank (CB) was mandatory, and all gold produced was to be sold to the CB. Secondary gold producers informed the CB that copper concentrates, including the precious metal values, were covered by existing smelting contracts with foreign companies. The Monetary Board then temporarily waived the requirement that gold output of secondary producers be sold to the CB at current market prices.

Iron and Steel.—Production of iron sands from beach mining operations was banned in 1976. About 100,000 tons of pyrite cinder have been produced annually from copper operations in Bataan, Buluccan, Cebu, Pangasinan, and western Samar. The status of developing the magnetite deposit in northern Lugon was unknown. Kawasaki Steel Corp. operates its 5-million-ton-per-year-capacity iron ore sintering plant in Villanueva using imported ore from Australia, Brazil, and Canada, and domestically mined limestone. Total output of the plant is shipped to Kawasaki facilities in Japan.

The establishment of an iron and steel industry, first proposed in 1965, was announced as one of the 11 industrial projects included in the major economic policy for the 1980's. The proposed integrated mill was to be built on 700 hectares of the 3,000-hectare Phividee Industrial estate in Tagaloan at a cost of $1.44 billion. Feasibility studies for the 1.5-million-ton-per-year mill were being conducted.

In early 1978, Armco-Marsteel Alloy Corp. placed into operation its steelworks in Taguig. Plant capability includes production of some 50 grades of carbon and alloy steel for forging, machinery, structural, and other high-strength applications. National Steel Corp. has two plants for production of steel products using mainly imported materials; Elizalde Iron and Steel Co. operates a cold mill and a tinplate plant; and other producers such as Philippine Blooming Mills' Mindanao Steel have remelt and fabrication facilities.

The Government announced plans for a charcoal-fired 100,000-ton-per-year pig iron plant in Currimao, Ilocos Norte. Raw material feed for the plant included iron ore to be mined in Ilocos Norte, limestone from Bacnotan Cement Co. and Northern Cement Co., and charcoal from a 10,000-hectare plantation being created by the Bureau of Forest Development near the site.

Lead-Zinc.—Production of lead-zinc in the Philippines is virtually by two primary producers. Benguet Exploration, Inc., better known for gold and silver, produced zinc from its mine in the Baguio area, Benguet, Ilocos region; and Zambales Base Metal, Inc., produced lead and zinc at its operation in Zamboanga del Sur, western Mindanao. Zambales' output is shipped to Japan, while Benguet Exploration exports to the United States.

Molybdenum.—Production of molybdenum sulfide concentrate was wholly by Marinduque Mining from its Sipalay Mine and by Atlas Consolidated from its Carmen project. Both companies recover molybdenum as a byproduct of copper mining. Exports of concentrate in 1978 were to the United States and the Federal Republic of Germany.

Nickel.—During 1978-79, nickel ore was produced by Marinduque Mining, Rio Tuba Nickel Mining Corp., and Infanta Minerals and Industrial Corp. The nickel industry is considered a priority investment by the Philippine Government which grants such incentives as tax—free imports of capital equipment, deductions for organizational and operational expenses, and accelerated depreciation schedules. Marinduque Mining, the largest producer in the Philippines, also operates the Surigao Nickel Refinery and recovers cobalt in the form of mixed nickel-cobalt sulfides. Marinduque Mining's ore reserves were estimated at 125 million tons of 1.22% nickel, 0.12% cobalt, and 38.5% iron. Marinduque Mining suffered from operational difficulties both at the mine and at the refinery. Despite a decrease in production, output value rose 30% because of higher nickel prices. The company's operations further benefited from its cobalt recovery; a tight supply worldwide resulted in a higher price for the metal.

Rio Tuba operates its mine on Palawan Island which has a rated annual production capacity of 700,000 tons, containing 11,000 tons nickel. Mine output is shipped to ferronickel smelters in Japan for processing. Rio Tuba's ore reserves were estimated at 13 million tons. Plans for installing a refining complex were deferred in 1978 because of the soft market. The remainder of the nickel production in 1978-79 was by Infanta Minerals. Acoje Mining's nickel mine was not operated during both years. New Frontier Mines, Inc., was expected to proceed with its plans for the $25 million Isabela project, which was designed to produce 6,800 tons per year of ferronickel.

Uranium.—Presidential Decree No. 1101 outlined the guidelines and incentives for the opening, processing, and refining of radioactive materials, thereby encouraging the private sector to explore and develop uranium resources. Ultrana Nuclear & Minerals Corp. and Western Nuclear Co. were to conduct uranium exploration jointly in the Mabinay area in Negros Oriental. At least $250,000 will be spent for exploration and an additional $750,000 if test results are favorable. The Philippine Bureau of Mines in cooperation with the Philippine Atomic Energy Commission was to undertake exploration activities in Larap, Jose Panganiban (Camarines Norte). Other possible exploration activities were for possible uranium occurrences in Hinabangan, Samar; Salsona, Ilocos Norte; Ayala district, Zamboanga; and Magna Rosa, Caranoan Peninsula.

NONMETALS

Cement.—Reconstruction and development of the cement industry is one of the 11 projects established under the economic policy for the 1980's. Owing to mounting domestic demand, the Government projected a deficit in the supply of cement by 1981-82. Presently there are 17 cement-producing companies in the Philippines with a rated capacity of 7.4 million tons annually. Rated capacity, however, has not been attained because of electricity supply shortfall, adverse weather, and generally widespread operating problems.

The Development Bank of the Philippines (DBP) was making available P1 billion for the rehabilitation and expansion of existing cement plants. The funds also included a coal conversion program for the industry. The DBP will select the cement firms to be included in the rehabilitation program based on the findings of a rating team studying the industry.

Local limestone is abundant, as is byproduct gypsum. The six top producing companies were Northern Cement Co., Republic Cement Co., Floro Cement Co., Island Cement Corp., Philipinas Cement Corp., and Fortune Cement Corp., in that order. These companies account for about 55% of the total annual cement production.

Other Nonmetals.—The Philippines produces about 0.5 million tons of various clays and about 15 million cubic meters of aggregates for construction materials. Close to 10 million tons of limestone is produced annually for use in cement manufacture and for industrial and agricultural uses. Output of other fertilizer materials includes phosphate rock, pyrite, and guano. Other nonmetallics produced include alumina and silica sands, silica quartz, diorite, dacite, and salt. In addition, small quantities of andesite, barite, feldspar, talc, and miscellaneous materials are produced.

The Government was studying the feasibility of establishing a $340 million chemical fertilizer facility with or without Association of South East Asian Nations (ASEAN) participation. The project would utilize 300,000 tons of byproduct sulfuric acid from the proposed copper smelter and also will have a capacity of 350,000 tons per year of phosphate fertilizers. If established, it was believed that $150 million would accrue to the country through export earnings. The Government was expected to discuss the possibility of a joint venture agreement with Agrico of the United States and International Minerals and Chemical Corp. of Canada.

MINERAL FUELS

Coal.—Production of coal in the Philippines is insignificant, less than 300,000 tons annually between 1973 and 1978. In an attempt to increase the national output, PD 972 (Coal Development Act of 1976) encouraged coal companies to pool resources to enhance the producers' financial and technical capabilities. PD 1174 further enhanced incentives offered by PD 972 by increasing the operator's maximum share in net proceeds by another 10% and by upgrading the cost recovery allowance to 90% of gross proceeds (originally 70%). In 1979, International Industrial Management and Development Corp. acquired the rights of the Malangas Mines from Maria Cristina Chemical Industries, Inc., to intensify coal production. Vulcan Industrial and Mining Corp., Sulu Sea Oil and Development Co., and Seafront Petroleum and Mineral Resources, Inc., formed Signal Consortium to undertake the $150 million development of the Semirara coal project. Equity in Signal will be distributed evenly among the three participants with an initial paid-up capital of P300 million (total authorized capital of P500 million). Signal was also negotiating long-term sales contracts with a mining company, a public utility, and two cement producers.

Petroleum.—Oil developments in the Philippines are offshore, northwest of Palawan. The only producing area was from the Nido complex with five wells. Pumping from the South Nido A-1 well was experiencing difficulty owing to a high percentage of water seepage due to oil being drawn. This well was expected to be shut down in early 1980 to stabilize the reservoir pressure. The other four wells in the Nido field were operating at an output of 21,300 barrels per day (production capacity of each was 40,000 barrels) at yearend 1979.

Production from the Cadlao and Matinloc fields offshore Palawan has not begun. American Oil Company (Amoco) originally planned to begin operations late in 1980. However, because of delays in equipment shipments scheduled for October (beginning of the monsoon season), Amoco deferred initial operations until early 1981. The Matinloc field was estimated to have reserves containing between 150 million and 700 million barrels of oil. The Matinloc 1 oil samples had a 43° API gravity, comparable to a premium Arabian light crude. Testing of oil from Matinloc 2 was being conducted. If test results were favorable, Citgo (Cities Services) was expected to accelerate the development of Matinloc together with the drilling of four or five additional wells.

The Mineral Industry of Poland

By Tatiana Karpinsky[1]

There are large reserves of coal, lignite, sulfur, copper, zinc, lead, salt, and construction materials in Poland, but the country remains deficient in crude oil, natural gas, iron ore, phosphate, nickel, manganese, tungsten, chrome, and rare earth. In 1978, the Polish mining industry produced over 540 million tons of raw materials including the principal raw building materials and over 550 million tons was extracted in 1979. In 1979, capital investment in the economy totaled 588 billion zlotys (Z),[2] a decrease of 1.5% as compared with the 1978 level. The net share of investment in the national income in 1975 amounted to 27%; in 1978, to 25%; and in 1979, to 21%.[3] In 1980 less than 18% of the national income is planned to be allocated to investment projects.

The tendency toward a faster production of consumer goods and of goods for export was maintained through 1978 and 1979, but not all targets of the plan in this regard were realized. According to Polish sources, the national income of Poland increased 2.8% in 1978[4] and about 2.6% in 1979.[5] The planned increase for 1979 was 4.9%. In 1979 industry provided 51.1% of the national income.

The economic performance in 1979 and the proposed plan for 1980 were presented by the Deputy Premier and Planning Commission Chairman. He made it quite evident that 1979 was the worst year for the Polish economy in 30 years and that prospects for the coming year, the final in the current 5-year plan period, seem even gloomier. The total value of the gross industrial production amounted to Z2,928.2 billion in 1978 and Z3,034.3 billion in 1979, compared with Z2,702.4 billion in 1977.

In 1978, the machine building and manufacturing industries contributed 28.3% to Poland's total industrial output; the fuel and power industry, 9.7%; ferrous industry, 5.6%; nonferrous industry, 3%; and nonmetallic mineral industry, 3.5%.[6] In 1978 and in 1979, planned targets were not met by the steel, copper, nitrogen fertilizers, and cement industries.

Transportation problems and energy cutbacks adversely affected some sectors of industry, particularly production of pig iron, rolled steel, copper, and cement. Winter and floods hampered railway and road transport.[7]

In 1978, employment in the mining industry accounted for 9.8% of the total labor force in the socialized industry.[8] In the first half of 1979, average employment in the socialized industry was 4,762,000 people, 11,500 fewer than in the first half of 1978.

Of the 352,700 employees in the coal industry, a total of 229,000 were working in underground mines in 1978. Employment in the iron and steel industry accounted for 173,800 workers.

In 1978 and 1979, Poland continued investing heavily in hard coal mining and developing a new hard coal basin in the Lublin and Chelm regions. Production from the Lublin Basin is scheduled to start in 1981 and by 1985 the basin is to produce 7 million tons of coal.

The country was also sinking new coking coal mines (Kaczyce, Ornontowice, and Pawlowice) in the Katowice and Rybnik basins. Development also continued on the 40-million-ton-per-year capacity surface mining operation in the Belchatow lignite region. In the current 5-year plan period (1976-80), about Z185 billion, is to be invested for the development of the coal industry, about Z34 billion above that provided for in the preceding 5-year plan.[9]

In 1978 and 1979, Poland was speeding up the development of copper mines (Rudna, Sieroszowice) and concentration plants (Glogow, Orsk). The country has started the construction of the second stage of the Katowice steel complex and was expanding the Lenin plant in Krakow, the Nowatko plant in Ostrowice, and the Bierut plant in Czestochowa. The country was also modernizing and expanding the chemical industry (Plock, Wloclawek, Pulawy, Tarnow).[10]

Major projects put into operation in 1978 included the Glogow 2 copper plant with projected capacity of 150,000 tons of refined copper per year, the rolling mill at the Katowice steel complex, additional production facilities of the plate rolling mill at the Bierut steel plant, a petrochemical plant in Plock, and seven power units and two thermal heating units at existing powerplants, having a total capacity of 1,900 megawatts.

In 1979, the following facilities were commissioned: A tower cable excavator at the Belchatow lignite mine, the section of copper rolling mill at the Cedynia foundry in Orsk, expansion of the cold rolling mill at the Lenin steel works, and a few others.[11]

Poland continued to participate in many multilateral investment projects for the production of natural gas, petroleum, asbestos, iron ore, and other products on Soviet territory. In return, the U.S.S.R. insured increased supplies of iron ore, crude oil, natural gas, and other raw materials over a period of 12 years.[12]

Among the most important Poland bilateral investment projects in 1978 and in 1979 were:

1. The sulfur ore mine at Tarnobrzeg, the copper mine at Lubin, and the Staszic coal mine in Upper Silesia, for which development credits have been given by Czechoslovakia.

2. The expansion of the Turnow I brown coal mine and the development of the new Turnow II mine, for which credit has come from the German Democratic Republic.

3. The potash salt mine in the U.S.S.R. for which the credit has come from Poland.

Government Policies and Programs.— Poland's economy is centrally planned and controlled by the Government. The final targets for the 1980 annual plan were approved by the Seym in December 1979.

The plan calls for greater supplies of consumer goods, enlargement of the economy's energy and raw material bases, strengthening of transport, decrease of investment, and further improvement in the balance of payments through a considerable intensification of exports.[13]

High priority is to be given to investments in fuel and raw materials. Outlays for the fuel and energy industry are planned to be increased 14%. The plan calls for a 3.0% to 4.2% increase in industrial production in 1980, a 1.4% to 1.8% increase in national income, and an 8.9% increase in export production.

The plan places special emphasis on increasing labor productivity, improving the organization of production processes and management in economy, economical use of financial, technical, and material resources, improvement in the quality of work, and further increasing wages and real income.

The planned mineral commodity production for 1980, in million metric tons unless otherwise specified, follows:[14]

Copper (0.425 originally planned)	0.390
Zinc	.260
Lead	.120
Crude steel	22.2
Fertilizer materials:	
Nitrogen	1.9
Phosphorus	1.1
Bituminous coal	208.0
Electrical energy billion kilowatt-hours	135.0
Cement	28.6

The coming eighth party congress will outline an action program for the 1981-85 5-year plan.

As for the foreign trade, the 1980 plan envisages balancing the trade with the market economy countries. In the 1980's, particular attention is to be paid to trade with socialist countries and especially to strengthening Poland's position on the Soviet market.

On February 27, 1979, the Presidium of the Polish Academy of Sciences established a Committee for Mineral Raw Material Economy as a part of its Geological and Mining Science Department in Krakow. The decision to establish the Committee stemmed from the need for more efficient mineral raw materials management, a problem of top priority in Poland.[15]

The first nuclear power station in Poland is planned to go into operation in 1984.

PRODUCTION

Upper Silesian coal mining continued to expand in 1978 and in 1979.[16] Despite difficulties in the first quarter of 1979 (because of unfavorable weather), the hard coal mining industry recorded production growth. The Rybnic coal area, to the south of Katowice, which is to increase its output capacity by 100% in 1980-90, continued to be the center of intense development.

Development of the rich copper deposits in the Legnica Glogow region, with loans from market economy countries' banks, continued in 1978 and in 1979. Production of copper in 1978 and 1979 was below the planned targets owing to a delay in production at the Glogow 2 smelting and refining plants.

Some production increases were reported in refined lead for 1978 and 1979, but zinc production decreased for the same time.

Crude steel production in 1979 was approximately the same as in 1978, and the planned target was not met.

Production of pig iron and rolled products was also lower than planned. Crude oil production in 1978 and 1979 could not meet national demand, which required additional crude oil imports from the U.S.S.R.

Table 1.—Poland: Production of mineral commodities

(Metric tons unless otherwise specified)

Commodity[1]	1976	1977	1978[p]	1979[e]
METALS				
Aluminum metal, primary	103,000	104,000	100,000	100,500

[e]Estimate. [p]Preliminary. [r]Revised. NA Not available.

[1]In addition to the commodities listed, antimony, cobalt, germanium, gold, a variety of crude nonmetallic construction materials, and carbon black are also produced, but available information is inadequate to make reliable estimates of output levels. Poland may also produce alumina in small quantities, but details of such an operation, if it exists, are not available.

[2]Reported figure.

[3]Includes building gypsum as well as an estimate for gypsum used in production of cement.

[4]Sums of listed commodities only; exclude products not reported individually as well as refinery fuel and losses.

TRADE

The turnover of foreign trade (exports plus imports) in 1978 increased 7% as compared with that of 1977. The value of exports was 44.7 billion foreign-exchange zlotys, or an increase of 9.8% and the value of imports was 50.9 billion exchange zlotys, an increase of 4.7%.

Turnover with the centrally planned economy countries increased 10%, and the share of this group of countries in the total value of turnover increased from 55.7% in 1977 to 57.4% in 1978. The turnover of Polish foreign trade with the Soviet Union increased 12.5% in 1978. The value of exports to the developed economy countries increased by 7.6%, and the value of imports remained approximately at the 1977 level.[17]

In 1978 and in 1979, the rates of trade increases were higher in the Polish trade with the centrally planned countries and with the developing countries than in trade with developed market economy countries, particularly with the countries of Western Europe. In 1978, the negative balance of trade was reduced to about $1.8 billion, and in 1980 an equilibrium of turnover is expected.

Polish trade with developed market economy countries is concentrated mainly in Western Europe, particularly the Federal Republic of Germany, the United Kingdom, France, and Italy. An important role is also played by trade with Austria, Sweden, Switzerland, and the United States.

In 1979 Poland signed export contracts with the Federal Republic of Germany, providing for sale of up to 80,000 tons of copper a year until 1990. Contracts for exports of smaller amounts of copper were also signed with Belgium, Italy, France, and the United Kingdom.

About 20 million tons of hard coal were sold to the market economy countries in 1979.

Poland maintained trade with developing countries. The greatest share in exports fell to the countries of Asia and in imports to the countries of Latin America.

Among branches of the Polish industry, the most important in external trade was machinery and equipment. The share of this group of commodities in total exports increased from 46.2% in 1977 to 46.9% in 1978.[18] Fuel and electric power contributed 15.6% to Poland's total exports; products of the ferrous and nonferrous industries, 6.4%; chemical products, 8.1%; and products of other industries, about 23%.

The import value of machinery and equipment accounted for 40.8% of the total imports, products of ferrous and nonferrous industries, 12.2%; chemical products, 11.7%; fuel and electric power, 12.9%; and products of other industries, about 22.4%.

Major commodities of Polish exports in 1978 were as follows:[19]

Commodity	Value of exports (billion zlotys)	Rate of growth in value in percent (1977=100)	Percent of total exports
Hard coal	5.50	6.2	12.3
Iron and steel products and semiproducts	1.30	12.0	2.9
Sulfur	.67	0.6	1.5
Copper and semi-products	.64	10.2	1.4
Petroleum products	.54	-23.3	1.2
Coke	.48	-16.6	1.1

Major commodities of Polish imports in 1978 were as follows:

Commodity	Value of imports (billion zlotys)	Rate of growth in value in percent (1977=100)	Percent of total imports
Crude petroleum	4.62	13.0	8.1
Iron and steel products	2.81	−11.8	5.3
Iron ore	1.05	−2.9	2.0
Petroleum products	1.05	4.0	2.0
Natural gas	.52	21.6	1.0
Pig iron	.51	−0.3	1.0
Phosphate rock	.49	−2.0	.9
Potash fertilizers	.47	−16.9	.9
Aluminum and semiproducts	.34	39.4	.6

In the first half of 1979 foreign trade turnover (in current prices) increased by 6.9% as compared with the first half of 1978. The value of exports increased by 10.2%, while the value of imports increased by 3.7%. Trade with centrally planned countries increased 11.5% for the same period, and trade with economy market countries increased 0.8%, with exports going up 2.7% and imports dropping 0.7%. This improved the trade balance with those countries.

Poland's accumulated negative trade balance amounted to about $15 billion in 1979.

Trade with the U.S.S.R. accounted for about 30% of Poland's entire foreign trade turnover and 60% of Poland's trade with Council for Mutual Economic Assistance (CMEA)[20] countries in 1979. Turnover in 1980 is to increase substantially over the turnover in 1979 so that total value of Polish-Soviet trade for the 1976-80 period will be almost 33 billion rubles ($49.5 billion at current official dollar-ruble exchange rate) and will also be 5 billion rubles (about $7.5 billion) higher than called for in the original plan. In 1979, imports from the U.S.S.R. made up 30% of all imports of machinery and equipment.

The U.S.S.R. covered 40% of Poland's demand for imported raw materials, including 76% of the crude oil, 100% of the natural gas, 75% of the iron ores, 88% of manganese ore, 60% of chromium ore, and 69% of potassium fertilizers.

An agreement on the 1980 trade exchange and payment between Poland and the Soviet Union was signed in Warsaw on January 4, 1980. It provides for a further increase in trade with machinery and equipment, accounting for 59.8% of exports to the U.S.S.R. Raw and primary materials and fuels will constitute 57.8% of the total imports from the Soviet Union. Planned 1980 imports from the U.S.S.R. included 13.1 million tons of crude oil, 600,000 tons of gasoline, 2.2 million tons of other refined petroleum products, 9 million tons of iron ore, 53,000 tons of aluminum, and 1.2 million tons of potash. Poland will continue to export sulfur, copper, coal, and zinc to the U.S.S.R.

In 1979, Poland signed a $550 million loan agreement with a group of international banks, including U.S. banking for general economic development. Previous loans were signed for specific investment projects. For the 1980's, Poland is planning a long-range program for increased exports.[21]

Table 2.—Poland: Exports of selected mineral commodities[1]

(Metric tons unless otherwise specified)

Commodity	1977	1978	Principal destinations, 1978
METALS			
Aluminum:			
Alumina	--	[2]6	All to United Kingdom.

COMMODITY REVIEW

METALS

Aluminum.—The aluminum industry experienced severe domestic raw material shortages and depended on imports of bauxite and alumina. Poland has signed a 10-year agreement with Yugoslavia for delivery of 1.2 million tons of alumina in the period from 1976 to 1985. Alumina was also imported from Hungary and Australia. Skawina and Konin were the principal aluminum production centers in Poland in 1978 and 1979. In the near future, they are to increase their production. The aluminum smelting plant at Skawina was Poland's largest producer of aluminum with an output of some 60,000 tons per year. The basic production facility consisted of 300 Soviet-made pots, each producing about 1.5 tons of aluminum metal in one 3-day cycle. Approximately 70% of the plant's aluminum production is used for aluminum wire and electrical cable.

Over the next 5 years (1981-85), a $50 million expansion, with emphasis on high-technology modernization, is expected to raise capacity of aluminum plants to 140,000 tons per year. Expansion does not include provisions for a sheet-rolling mill. All sheet aluminum was produced at Poland's other large aluminum plant at Konin. The Konin plant was slightly smaller than Skawina plant and it used French-licensed equipment. The Skawina plant employed some 2,500, workers including 400 engineers and technicans, in 1979. In 1978, negotiations were under way for sales of U.S. air pollution control equipment, valued at $3 to $4 million, for Polish aluminum industry.

In 1979, experimental equipment to produce alumina from the dust emitted by the Turszow powerplant was put into operation at the Wiozow chemical plant (Wroclaw Region).

Rocks highly enriched in aluminum, including bauxite layers, were discovered recently in the northeastern part of the Lublin coal basin. At three localities bauxite of economic value was found.[22]

Cadmium.—Polish smelter production of cadmium is derived as byproduct from zinc ores of domestic origin. The bulk of cadmium production is destined for export markets, principally for shipment to the U.S.S.R. and the United Kingdom.

Copper.—The 1978 plan provided for 360,000 tons of electrolytic copper to be produced, but the Glogow 2 smelting and refining plant was not commissioned on time and the planned quota was not fulfilled. In 1979 the annual plan provided for 400,000 tons of refined copper, and this target also was not met.

It is expected that the copper plants will deliver 425,000 tons of refined copper in 1980 and about 500,000 tons in 1983. About 44% of the total electrolytic copper and copper products were exported in 1979 to the Federal Republic of Germany, the

United Kingdom, Holland, France, Czechoslovakia, Romania, the German Democratic Republic, and the U.S.S.R. The continuously increasing Polish copper exports have placed Poland among the leading copper exporting countries.

In the 1978-79 period copper ore was mainly extracted from the Lubin, Polkowice, and Rudna mines, located in the Legnica-Glogow region, about 40 miles northwest of Wroclaw. A fourth mine, the Sieroszowice mine, located in the same area, was under development. The sinking of the first shaft at the mine began in July 1979. It is to be 920 meters deep and is to be put into operation at the end of 1981. When the first stage of development of the mine is completed in 1983, the mine is to produce 5,500,000 tons of ore a year. Projected mine capacities are as follows: Lubin, 7 million tons of ore per year; Polcawice, 8 million; Rudna, 12 million; and Sieroszowice, 12 to 15 million tons of ore per year.

It is expected that the Rudna mine will reach full capacity after 1980. Expansion of the Rudna concentration plant was in progress in 1978, and trial of equipment started at the end of 1979. The plant is to reach the capacity of 12 million tons of ore per year.

The first section of the ore-dressing plant at the Lubin copper mine was renovated in 1978 and its capacity increased from 4.5 million tons of ore per year to 7.5 million tons. The metal content of the concentrate also increased.

The copper ore deposits lie at a depth from 600 to 1,500 meters below the surface and consist of sulfide ores. Typical minerals are bornite, chalcocite, chalcopyrite, galena, and sphalerite. The average copper content was estimated at 1.4%. Associated with the copper are silver, lead, cobalt, vanadium, and other elements.[23] According to the Lubin officials, the known copper ore reserves are estimated to last for about 35 years at the planned rate of production. Two main smelters, one at Legnica with 88,000 tons of electrolytic copper per year and one at Glogow with 180,000 tons of electrolytic copper per year, were in operation in 1978.[24] The new Glogow 2 plant, with a projected capacity of 150,000 tons of electrolytic copper per year, was commissioned in 1978. The smelter was closed for 45 days in 1979 for routine overhaul. The Outokumpu flash-smelting technology was used in Glogow 2 plant. The next planned project of this type is to be located at Orsk, near Lubin.

In 1979 a new copper rolling mill was commissioned at Orsk, with an annual processing capacity of 100,000 tons.

Large credits from the U.S. and other Western banks have been used to finance Lubin's development. In February 1978, a 15-bank syndicate managed by Chase-Manhattan signed a $250 million loan for development of Sieroszowice mine and construction of the Orsk smelter and continuous casting wire rolling mill.

The Polish copper industry operates under the administration of the organization called Copper Combinate. Scientific research on the technology of production is led by the Cuprum Plans Office in Wroclow, Institute for Nonferrous Metals in Gliwice, and Bipromet Plans Office in Katowice. In 1978, the Polish Impexmetal of Warsaw and the Colombo SpA of Italy signed a contract for the delivery to Italy of 20,000 tons of copper over 4 years. The deal is to be financed by a $20 million credit from the Banca Commerciale Italiana to Bank Handlowy in Warsaw.

In May 1979, under a contract concluded by the Impexmetal Corporation in Warsaw with West German firms, including Siemens, Metallgesellschaft and Kabelmetall, 480,000 tons of copper is to be exported to the Federal Republic of Germany in 1979-90. At the same time the agreement of 1976 on semifinished copper products and cable was extended.

Gold.—Some gold has been discovered in western Poland, and placer mining is beginning along some mountain streams. Polish mining engineers are operating on the assumption that a concentration of 100 milligrams of gold per cubic meter of material is the minimum economic amount for a start-up of mining operations.[25]

Iron and Steel.—The Polish economy lacks most of all iron ores which are imported in large quantities from the U.S.S.R. (Krivoi Rog), Sweden (Kiruna), and Brazil.

In 1978 and 1979, iron ore was extracted in Poland from seven mines located in the Czestochow District (which gives some 80% of the total output) and in the Leczyca District.[26] Iron ore deposits in Poland are marginal, with an average metal content of approximately 30% to 35%. The Polish production of iron ore only partly meets the needs of the national demand.

In 1979, exploration of the rich magnetite iron ore deposits continued near Suwalki in the northeast of Poland.

Crude steel production in Poland in 1979 remained at the 1978 level. The plan calls for the production of 22.2 million tons of crude steel in 1980 and 25 million tons by 1985. Steel consumption for 1980 is planned at about 22 to 23 million tons. The 1990 plan for steel consumption is about 31 to 33 million tons. About 15% of the total volume of steel produced in 1979 was high-quality steel.[27]

Ferrous alloys are produced in Poland only at Siechnice and Laziska plants.

The decline in imports of steel rolled products in 1978 and 1979 was partly due to increasing production of rolled steel at the new Katowice steel complex.

The largest iron and steel plants in Poland are the Lenin steel plant in Krakow and the new Katowice steel complex, located about 40 miles west of Krakow.[28]

The Lenin metallurgical complex produced 6.7 million tons of steel, 4.8 million tons of pig iron, 4.5 million tons of rolled products, and 4.1 million tons of coke in 1979.

The general modernization of the No. 5 blast furnace, the biggest at the Lenin complex with a volume of 2,000 cubic meters, was completed in 1979. As a result, the furnace will be able to produce 4,000 tons of pig iron a day, 500 tons more than previously.

The Katowice metallurgical complex produced 4 million tons of steel and 3.1 million tons of rolled products in 1978 and 4.5 million tons of steel in 1979; about 0.5 million tons of steel, produced at the complex, was exported to the market economy countries in 1979. The large rolling mill at the Katowice steel complex was commissioned in July 1978, and the first stage of the complex was completed.

In 1979 there were two sintering machines, a blast furnace (3,200 cubic meters), two converters each with a capacity of 300 tons, and a blooming-slab mill operating in the Katowice complex. Within the next 2 0r 3 years, it is planned to put in operation two sintering lines, two blast furnaces, a third converter, four continuous-casting machines, and a 2,000 millimeter broad-strip hot rolling mill.

French specialists were cooperating in the design and construction of new types of furnaces for the 2,000 millimeter continuous hot-sheet plants at the Katowice complex in 1979.

There are no plans to increase capacity of Katowice steel complex beyond 9 million tons per year (two stages each of 4.5 million tons capacity) or to produce any products other than basic steel shapes and sheets. The share of Katowice steel complex in total domestic production of the iron and steel industry is to be as follows (in percentage):

Production	First stage	Second stage
Pig iron	33	47
Steel	21	35
Hot rolled products	16	35

The total employment at the complex, including production, maintenance, and auxiliary services, was 17,500 men in 1978.

The construction of the second stage of the transloading station for Katowice steel complex, 5 kilometers from the steelworks, was in progress in 1978 and was completed in 1979. Raw material will be shipped from the station to the steelworks along a 5-kilometer conveyor belt directly to the sintering plant. The wide-gauge (1,524-millimeter) railroad from the U.S.S.R. to the Katowice transloading station was completed in December 1979.

New installations put into operation in 1978 also included an electric steel melting shop for high alloyed grades of steel, with an annual capacity of 75,000 tons at Huta Baildon and equipment for expansion of existing heavy plate mill by 300,000 tons per year at Huta Bieruta.

In 1979, work was in progress to complete the following installations: (1) small section mill at the Nowatko plant, with an annual capacity of 800,000 tons; (2) further expansion of heavy plate mill at Bieruta by 430,000 tons per year; (3) expansion of the Tandem mill for cold-rolled sheets at Lenin complex by 400,000 tons per year.

Construction of seamless tube plant began at Siemianowice in 1979, which is designed to produce 400,000 tons of pipes per year.

Lead and Zinc.—Zinc and lead mining is concentrated in the Katowice area, where three major mines (Boleslaw, Olkusz, and Pomorzany) were in operation in 1978-79. Most of the mineralization in this region occurs in the ore-bearing Triassic dolomites.[29] Ores are generally about 250 meters deep with ground water problems. The Olkusz mine has a capacity of 4.6 million tons per year. The Pomorzany new lead-zinc mine, with designed capacity of 4 million tons per year, produced an estimated 2 million tons of ore in 1978. The mine, with a concentration plant, is part of the Boleslaw mining and metallurgical complex at Bulowina, near Krakow. The Boleslaw complex incorporates the zinc-lead ore mines, ore dressing plant, agglomerating plant, zinc refinery, lead plant, and sulfuric acid plant.

Poland's second Imperial smelting furnace was unable to come onstream as planned in October 1979; however, operation of the smelter was expected to start shortly. The smelter is to produce 52,000 tons per year of zinc and 23,000 tons per year of lead, using local concentrates.

It is planned to increase lead-zinc ore production from deposits discovered in the Olkusz-Chrzanow and Zawiercie region. In the Zawiercie region, it is planned to develop one mine with 2.5 million tons of ore per year and another mine with a capacity of 1 million tons after 1980. Two mines (Pomorzany II and Irzebionka) also are to be developed in the Olkusz-Chrzanow area. The target for 1980 calls for the production of 120,000 tons of lead and 260,000 tons of zinc.

Silver.—The largest share of total Polish primary silver production was as a byproduct of copper from the Legnica-Glogow region, about 65 kilometers northwest of Wroclaw. The balance of the Polish primary output is derived as a byproduct of lead-zinc mining.

Silver exports were expected to reach 13 million ounces in 1980, up from 9.5 million ounces in 1979. Silver hard-currency earnings equal approximately those from copper.

Other Metals.—Molybdenum, cobalt, germanium, gallium, selenium, tellurium, and rhenium are found and produced as byproducts from the polymetallic and copper ores. The Nonferrous Metals Institute in Gliwice has developed a method of obtaining rhenium from complex ore. The method is being introduced at the copper plant in Glogow.

A deposit of tin ore (cassiterite) has been found in the Sudety Mountains west of Jelenia Gora, and it is thought that exploitation will be profitable. Mining is to be started at the end of 1980.

NONMETALS

Barite.—Trials of equipment have begun at the newly built barite concentrator at Boguszow near Walbrzueh in July 1979. The enterprise, which has the only barite mine in the country, produces annually over 90,000 tons of barite, which satisfies about 60% of the national requirement. The new concentrator will make it possible to increase production substantially and to eliminate costly imports. The concentrate will have a pure barite content of 95%. Fluorite, which has never previously been produced in Poland, can also be obtained from the barite ore.

Cement.—There are 25 cement plants in operation in Poland. A new plant at Gorazdze (Opole) in the southwest went into full capacity of 2.4 million tons of cement in 1978; however, cement production in 1979 was decreased signifantly. The Przjazn II cement plant near Padom, with the capacity of 2.2 million tons of annual production, continued to be under construction in 1979 and was scheduled to be commissioned in 1980.[30] It is planned to produce 28.6 million tons of cement in 1980 by attaining full production capacity in new plants, as well as by the modernization and expansion of old ones.

Construction of new cement plants is based on supplies of machinery for the cement industry from the U.S.S.R. and the German Democratic Republic.

During the 1978-79 period, a large cement-handling center was under construction near Cigacice on the Odra in the Zielona Gora Province. This port is to greatly improve the delivery of cement, mostly from the Gorazdze cement plant, to the interior of Poland.

Fertilizer Materials.—There were five main nitrogen fertilizer plants in operation in Poland in 1978 and 1979. Over one-half of the output of nitrogen fertilizers was supplied by the nitrogen plant in Pulawy, built in 1966. Four others are located in Wloclawek, Tarnow, Chorzow, and Kedzierzyn.

Plants are concentrated in the southeastern region of the country close to indigenous supplies of gas, and further north, where Soviet gas is supplied.

Currently Poland produces more nitrogen fertilizers than it consumes. Consumption has tended to stagnate in recent years at about 1.2 million tons per year.

A new ammonia installation, with a capacity of 500 tons per day, is planned to be constructed in Pulawy to supplement the existing plant.[31]

In 1978, the Wloclawek plant, built in 1971, operated two 750-ton-per-day ammonia lines, far below its capacity. In 1978, the Creusot Loire of France was awarded a contract by the Polish Polimex Cekop to expand the plant. Reconstruction of the plant is due to start in the near future, and it is expected that it will take approximately 2 years for total production of ammonia to reach its new capacity of 1,650 tons per day. The Tarnow nitrogen plant produced about 175,000 tons of nitrogen fertilizers per year. Construction of a large ammonia plant is to begin at Tarnow (Tarnow III) in the future.[32]

The Police II 500,000-ton-per-year natural-gas-based ammonia plant was under construction in 1979. Production at this plant is scheduled to begin in the first half of 1981.

The planned ammonia-urea project, based on a coal gasification plant at Libiaz, was postponed in 1979. The plans were made for a new project based on natural gas and not on coal as originally planned. The new project at Kedzierzin will comprise a plant producing 1,500 tons per day ammonia and three 900-ton-per-day urea units. The final plans for the construction of this complex have to be made by the June 30, 1980, expiration date of the Germany credits.[33]

The Tarnolerzeg, Police, Lubon and Krakow plants producing phosphatic fertilizers were in operation in 1979. The Lubon plant produced 150,000 tons of superphosphate in 1978 and supplied 10,000 tons more in 1979. The chemical plants at Police, founded in 1969, manufactured 920,000 tons of compound fertilizers and 400,000 tons of sulfuric acid in 1978.

Construction of the Police II nitrophosphate complex began in 1976. The contract was awarded by Cekop to a West European consortium headed by Creusot-Loire of France. It is expected that the whole project will be completed in 1983 when the Police II complex will produce annually 500,000 tons of ammonia, 400,000 tons of urea, and 823,000 tons of NPK fertilizers. However, as a result of limited funds in 1978 and 1979, a number of key projects in Poland were hit by delays, including the Police II fertilizer complex.

The Poles started to build their own port on the Oder River at Police in 1978 to ship fertilizers by water transport to the interior of Poland. The first stage of construction is to handle about 1.5 million tons of goods.

Gypsum.—One of the richest European deposits of gypsum is located in Poland, in the Nida Valley. It is exploited by the Dolina Nidy mining-processing complex located near Pinczow.

Polish exports of gypsum stone run up to several hundred thousand tons a year. The main importers are Sweden, Denmark, Norway, Finland, and Hungary.

Salt.—In 1978 and in 1979 production was principally derived from salt mines and salines in Inowroclaw, Klodawa, and Wapno in the central part of Poland. The oldest salt mines in Wieliczka and Bochnia were of less economic importance. There were 12 salt mines and plants in operation in Poland in 1979, and they employed about 5,000 people. Poland's total salt reserves amounted to 43.5 billion tons. A new mine, which was under development at Moszczenica in Tarnov Province, is to replace old mines at Bochnia and Wieliczka. This mine is to go into operation in 1984 and is to produce initially about 600,000 tons of salt. Construction of the Moszczenica mine is estimated to cost Z1.9 billion. In 1979 the first shaft (Siędlec) of this mine, which is 480 meters deep, was completed, and work started on the construction of the second shaft.

In the biggest salt mine in the country, at Klodawa in Konin Province, a new level was under developmet at a depth of 750 meters. When it goes into production, the mine's output will be increased by 150,000 tons.

Sulfur.—The Grzybow mine, with an annual output of 1.5 million tons of sulfur, Jeziorko (about 3 million tons), and the Machow mine, located in the rich sulfur fields around Tarnobrzeg, were the principal contributers of sulfur production in 1978.[34] In the first two mines, the sulfur was extracted by the Frasch method. Machow is the opencast mine where the sulfur is extracted by excavators.[35] The output of sulfur in 1978 was the highest so far produced in Poland. The experimental Baszina Mine in the Preusl region produced over 24,000 tons of sulfur in 1978. Sulfur production in this mine is expected to increase to 50,000 tons per year. A new mine is planned to be developed near Baranow after 1980. In the first 2 months of 1979, Polish deliveries for both domestic and export markets were totally disrupted by severe weather conditions. Of the existing mines, only Grzybow was unaffected by the cold weather. The Machow openpit was put out of production almost through the entire 1979 year.[36] Production of sulfur at Jeziorko Mine was also declined. The rail transportation system in Poland was paralyzed by snow and ice in the beginning of 1979, and the number of sulfur shipments out of Gdansk was greatly reduced. Polish sulfur exports to the market economy countries totaled 633,000 tons in the third quarter of 1979, representing a fall of 9% from third quarter 1978 deliveries. Over the first 9 months of 1979, Polish sulfur exports to the market economy countries were down 22% to 1.47 million tons. Deliveries to the centrally planned countries were expanded, however; for the first 9 months of 1979, CMEA countries imported 1.33 million tons of Polish sulfur, an increase of 0.11 million tons over the first 9 months of 1978. The bulk of the sulfur exports is handled by the Gdansk-based State Foreign Trade Enterprise Siarkopol.

Chemadex, a Krakow-based corporation, contracted for the delivery of 3 sulfuric acid plants worth R56 million to the U.S.S.R. in 1977-78 as part of a total of 15 Polish sulfur plants to be built in the U.S.S.R. by 1980.

Under an initial contract between Poland and Occidental Petroleum of the United States, approximately $25 million worth of Florida phosphate rock will be shipped to Poland during 1980. Since Poland does not have enough sulfur available to make barter payments, Oxy has agreed to make delivery on the basis of a long-term credit. It is expected that Oxy will be able to provide a credit for additional sulfur development since all current and future prodction from existing mines has already been committed for domestic use and to foreign buyers.

MINERAL FUELS

Coal, including lignite, has been the major source of primary energy in Poland. In 1979, the total primary energy production was 229.2 million tons in standard coal equivalent (SCE), an increase of 9.8 million tons over that of 1978. Coal (lignite and bituminous) contributed 93.8%; crude oil, 0.2%; natural gas, 4.7%; and others (peat, wood, and hydropower), 1.3%. Total consumption of all types of primary energy reached 218.1 million tons SCE with coal providing 78.9%; petroleum 13.0%, natural gas 6.7%, and hydropower, peat, and wood about 4%. In 1979, the total apparent consumption of primary energy increased 5.7% over that of 1978. The energy balance for 1978 and 1979 is shown in table 4.

Table 4.-Poland: Total primary energy balance for 1979 and 1978

(Million tons of standard coal equivalent)[1]

	Total primary energy	Coal (lignite, bituminous) and coke	Crude oil and petroleum products	Natural gas	Others
1979:					
Production	229.2	214.9	.6	10.7	3.0
Imports	35.4	1.0	30.5	3.9	--
Exports	46.5	43.9	2.6	--	--
Apparent consumption	218.1	172.0	28.5	14.6	3.0
1978:					
Production	215.44	204.5	.6	10.6	3.3
Imports	32.8	1.1	28.3	3.4	--
Exports	45.9	43.0	2.9	--	--
Apparent consumption	206.3	163.0	26.0	14.0	3.3

[1]1 ton of standard coal equivalent (SCE)=7 million kilocalories. Conversion factors used are from the United Nations as follows: hard coal, 1.0; brown coal, 0.3; coke, 0.9; crude oil, 1.47; petroleum products, 1.54; natural gas (1,000 cubic meters), 1.33.

Coal.—In 1978-79, Poland continued to undertake efforts to expand coal output in order to increase exports and to ensure the maximum degree of national energy self-sufficiency. Bituminous coal production is planned to reach 207.5 million tons in 1980, 240 million tons in 1985, 260 million tons in 1990, and approximately 300 million tons in 2000.[37] In 1979, bituminous coal exports were equally divided between centrally planned economy countries and market economy countries. Poland is one of the world's largest producers of lignite, which is used mainly by local electric power stations. Lignite production is planned to reach 42 million tons in 1980, 85 million tons in 1985, 140 million tons in 1990, and approximately 250 million tons in 2000. Hard coal is located in three basins: the Upper Silesian, Lower Silesian, and Lublin.

The Upper Silesian basin produced 98% of the total hard coal output in 1978 and about the same percentage in 1979. About 60% of total Polish coal output was suitable for coking. The production of hard coal came from deep underground mines, average mining depth of which was estimated at 517 meters in 1978 and 533 meters in 1979. The average excavation depth will be approximately 600 meters by 1985. There were 65 mine administrations producing coal and 2 experimental mines in operation in 1979. The average production from one mine administration was about 9,500 tons per day. About 87% of total hard coal production was obtained from mines using the longwall system of mining. The prevailing longwall face was about 200 meters.

In 1978 the mines obtained over 150 power supports, over 240 wall cutter loaders, and over 60 heading machines. Adoption of a four-brigade (four-shifts) organization of labor began in 1978 at the mines of the Upper Silesian Basin. It is anticipated that the four-brigade system will be adopted at all coal mines by the end of 1981.[38]

Renovation and development of mines in the Upper Silesian coal basin, including the Rybnic region, continued in the 1978-79 period. Among new mines under development were the Swierclany, Suszec, Kaczyce, Czeczot, and Orantovice mines. The Swierclany mine (two shafts) began operation in December 1979. In 1980, this mine is to produce 1,600 tons of coal per day (projected capacity is 8,000 tons per day). The Suszec mine is to reach its target output of 12,000 tons per day in 1986. The first output of coal is planned for 1982. Sinking of the two shafts at the Czeczot mine, with projected capacity of 24,000 tons per day, was well advanced in 1979. First production of this mine is expected in 1983 at the depth of about 600 meters. Development of the Orantovice mine started in 1978 in the Upper Silesian field. It is expected to yield 20,000 tons per day from seams at 1,000 and 1,500 meters depth in the 1990's.

The Ministry of Mining reported that the process of expansion and overall modernization of mining enterprises will continue in the period running up to 1985. The modernization program encompasses 18 mines presently in operation. Renovation activities will include the Brzeszcze mine (targeted production growth to 16,000 tons per day), Ziemowit (to 27,000 tons per day), Lenin (to 25,000 tons per day), Halemba (to 24,000 tons per day), and other mines. The possibility of overall renovation of the Murcki, Knurow, and Debiensko mines was also studied.

To obtain the required quantity and quality of fuels by 1985, about 50 coal preparation plants are to be modernized and enlarged and 7 new ones built.[39]

Work was progressing in the new Lublin hard coal basin in 1978 and 1979. With the completion of the first stage of the project scheduled for 1990, its annual output is to be 25 million tons. Seven mines are to be developed in the Lublin Basin in the near future. The first million tons of coal was expected to be produced in 1981.

More than Z1,800 million were invested in the development of the first Bogdanka Mine in the Lublin Basin in 1979. In the past 4 years (1975-78), Z3,300 million was invested in the mine. All of the coal in the Lublin Basin will be extracted by longwall mining. The coal seams are about 1.5 to 2.0 meters thick and are comparatively flat, however, most of the deposits contain high concentrations of methane.

The Polish press reported that a coal dust explosion on October 10, 1979, at a mine at Bytom (near Katowice) resulted in the death of 33 miners and the hospitalization of 3 others. The explosion occurred at a depth of 774 meters where 43 miners were working. Another coal mining accident occurred October 3 in a mine near Walbrzych in southwestern Poland. According to a report published in Zycie Gospodarcze, seven miners perished and three were hospitalized.

Lignite is the second most important fuel for the Polish power industry.

In 1979, six lignite strip mines were in operation with a total annual average employment of about 13,000 people. Lignite deposits are located in the central and western parts of the country. The main basins are the Turoszow, the Konin, the Adamov, and the Belchatow Basin (under development). The Turnow Basin accounted in the years 1978-79 for about 61% of the total lignite production in Poland, the Konin Basin for 28%, and the Adamov for 10%.[40] About 90% of lignite was used for electric energy generation. The remainder was halved between export and heating purposes.

Three excavators were working at the site of the Belchatow opencast mine in 1979. In August 1979, the mine was 2,300 meters long, more than 1,000 meters wide, and about 80 meters deep. About 40 million cubic meters of overburden were removed at the yearend of 1978 and another 100 million tons had to be removed before the lignite could be moved. The lignite lies at the depth of 150 meters. The first stage of the Belchatow complex is to be commissioned in 1980. Belchatow is to have annual capacity of 40 million tons per year when it is fully developed. Reserves of this basin are estimated at 2.3 billion tons. The Belchatow project includes two power stations each with a generation of 4,300 megawatts.

About eight new large lignite strip mines (besides Belchatow Mine) are planned to be developed in western and central Poland in the next 20 years.

According to the Polish Central Geological Board's estimate, Poland's minable reserves in place of hard coal in categories A+B+C1+C2 amounted to about 57,500 million tons (on January 1, 1974), of which 19,600 million tons was surveyed in categories A+B+C1 (measured, indicated, and inferred) and 37,900 million tons in category C2 was classified as speculative.[41] Poland's ultimate hard coal resources are estimated at about 75 billion tons. Total lignite reserves are estimated at 36 billion, of which about 15 billion tons are recognized as economically minable.[42] Proved reserves are about 8 billion tons.

Natural Gas.—The gas production in Poland is too small to supply the national demand.

In 1978, an additional 2.8 billion cubic meters of gas were imported from the Soviet Union. A total of 4.1 billion cubic meters of gas was imported from the U.S.S.R. in 1979. Under a 20-year agreement, Poland is to receive 2.8 billion cubic meters of natural gas per year in return for the investment made in constructing the Soyuz gas pipeline. In 1980, gas imports from the U.S.S.R. will account for half of Poland's total consumption. Poland achieved good results in gas exploration. New gasfields were discovered recently in the Carpathian foothills and some in the lowland. In 1978 considerable deposits of gas, of high calorific value, were discovered in the Leszno Region. In 1979 more than half of Poland's output of natural gas came from the Zielona Gora-Leszno Region.

Prospecting for gas will continue in 1980 mainly in the same regions (Leszno and Zielona Gora) and in the Carpathian foothills. According to Polish sources, gas reserves (proved, probable, and possible) are estimated at about 160 to 200 billion cubic meters.

Work on the 380-kilometer Polish gas pipeline between the town of Police and Odolanow (Kalisz Region) was continued in 1979 and is to be completed in March 1981.

Petroleum.—The country's refineries processed about 17 million tons of crude oil. More than 80% of the imported oil came from the U.S.S.R in 1979.

Polish oil demand is expected to be 20 million tons in 1980 and 35 million tons in 1985.[43] Almost half of the national production of oil derivatives is used in transport.

In 1979 about 800,000 tons more crude than envisaged by the long-term agreement was imported in return for Poland's contribution to the development of the Soviet oil industry. Energopol enterprise in 1978 was building a 440-kilometer pipeline from Belorussia through Latvia to Lithuania and some of its pumping stations; when this project is completed Polish workers are to start work on a new oil pipeline between Western Siberia and Belorussia. In 1980 and in 1981, the extra deliveries of crude oil will probably also be about 800,000 tons.

Oil wells in the Kamien Pomorski area (Poland's Lowlands) produced about 50% of the crude oil extraction in Poland in 1978-79.[44] Production of crude oil was also concentrated in the Krosno Region in the Carpathian Mountains, where several new oil wells were drilled. Oil deposits in this region have been exploited for 125 years and are heavily depleted. Polish effort to find new oil reserves resulted in the discovery of new oilfields; however, there are not of major importance. There is no indication that Poland's own production of crude oil will increase in the next few years. Poland's recoverable reserves of crude petroleum are estimated at 6 million tons. About 40% of these reserves occur in Poland's lowlands, 40% in the Carpathian Mountains, and about 20% in the Carpathian foothills.[45]

Poland's refinery capacity in 1978 was estimated at 18.5 million tons per year. Work on the new refinery at Blachovnia in Opol Province continued in 1979. The crude oil capacity of the first section is expected to be 3 million tons per year. The 100-millionth ton of Soviet oil transmitted by the Friendship oil pipeline was refined at Plock refinery in July 1978. Plock oil refinery processed about 13 million tons of crude oil in 1979. The complex manufactured about 100 final products. Its annual output is worth over Z60 billion. Plans are to rebuild and modernize the first cracker at the Plock complex.

The Gdansk refinery supplied the first consignment of 238,000 liters of a new engine oil named Marinol CC-30 to the home market in November 1978. It is produced for use in marine diesel engines and diesel railway locomotives.

The Mineral Industry of Portugal

By Roman V. Sondermayer[1]

During 1978 and 1979, the Portuguese Government continued preliminary studies that were focused on expansion of the country's modest mineral industry. The Government saw expansion of the mineral industry as a means for creating jobs and improving the country's negative trade balance.

Only the production of tungsten and, to a certain extent, ornamental stone had some significance for the world economy. All other minerals and metals produced in the country were important only to the domestic economy.

Data on the contribution of Portugal's mineral industry to the total gross national product (GNP) were not readily available. However, recent studies estimated the share of the GNP contributed by the mineral industry's extractive sector alone at 0.5% to 1% of the total. Labor employed in mining was about 14,500 persons.

During 1978, major events in the mineral industry were the commissioning of a 10-million-ton-per-year petroleum refinery south of Lisbon and the acquisition of the Borralha mines by Beralt Tin of Portugal. Planning continued for development of the Moncorvo iron deposit in northern Portugal, and studies were conducted for the recovery of lead, zinc, and silver from pyrite in southern Portugal.

In 1979, the major industry event was the discovery of copper, lead, and zinc at Castro Verde in southern Portugal.

PRODUCTION

Portugal's mining industry was made up of a large number of operations (over 1,500), but about 95% of these operations employed less than 20 workers. Most of the large operations had some Government participation. Table 1 shows details of the country's mineral production for selected years.

A study of Portuguese mineral production was prepared.[2]

Table 1.—Portugal: Production of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1976	1977	1978[p]	1979[e]
METALS				
Arsenic, white	278	222	200	220
Beryl concentrate, gross weight	--	--	(1)	--
Columbite and tantalite concentrates, gross weight	5	3	8	5

TRADE

Portugal was a net importer of minerals, and fuels were its most expensive imports. Portugal had a negative trade balance in minerals with the United States. Tables 2 and 3 show details of this trade and Portugal's trade with other countries.

Table 2.—Portugal: Exports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1977	1978	Principal destinations, 1978
METALS			
Aluminum metal including alloys, all forms	2,716	2,921	Spain 2,589; France 134; West Germany 120.
Arsenic trioxide, pentoxide, acids	29	--	
Cobalt oxide and hydroxide	--	9	Belgium-Luxembourg 5; Spain 4.
Columbium and tantalum: Tantalum ore and concentrate	3	9	Japan 4; Netherlands 4; West Germany 1.
Copper:

COMMODITY REVIEW

METALS

Copper.—During 1978 and 1979, encouraging results from exploratory efforts were reported at a site near Castro Verde in the Neves Corvo area. Drilling activities were conducted by a group consisting of the Bureau de Recherches Géologiques et Minières of France, the French mining company Penarroya, and the Portuguese Government-owned Santiago Mining Co. The group reported the discovery of a new, complex lead-zinc-copper deposit with a high copper content. The extent of the metal reserves, however, was not made public. The area under investigation is part of the Iberic complex sulfide ore belt. (See also the section, Lead and Zinc, of this chapter.)

Iron and Steel.—During 1978, Portugal continued to plan a two-phase expansion of its steel industry. The first phase, scheduled to be completed in 1981, called for expansion of Portugal's only primary steel plant, the 700,000-ton-per-year plant at Seixal, near Lisbon. It was anticipated that the addition of a 120-ton LD converter would enable the plant to increase its output to 1 million tons per year. The second phase, scheduled for completion in 1985, called for the construction of a new integrated steel plant at Sines, further south, with a capacity of 1.8 million tons annually. The new plant was expected to have one 160-ton LD converter.

During 1979, Portuguese authorities decided to go ahead with a semis plant at Seixal, but postponed construction of the integrated steel plant at Sines and the expansion project at Seixal. These decisions were made under pressure from the European Economic Community (EEC) commission that was examining Portugal's application for EEC membership. The EEC expects new members to shelve or cut plans that do not conform to the EEC policy of modernization without expansion.

At yearend 1979, Luossavaara-Kirunavaara AB (LKAB), the Swedish iron mining company, was near completion of a feasibility study on the production of ores from the Moncorvo deposit. Based on recent reports, the Moncorvo deposit, at latitude 41°12'28N and longitude 7°10'29W, is located north of the Douro River in northeast Portugal, in hills about 800 meters above sea level. Situated 13 miles from the Spanish frontier, east of the city of Torre Moncorvo, these iron-bearing bodies of Ordovician age, strike east-northeast and dip gently south. Several north-south faults divide the deposit into separate ore bodies. The thickness of the formations varies up to 150 meters. The footwalls are schists, quartzites, and graywackes lying on a basal intrusive granite. The overlying rocks are fossil-bearing schists and limestone. Over these rocks, in turn, lie Tertiary and recent clays, gravels, and alluvial deposits. The Moncorvo deposit is connected by 14 miles of meter-gauge railroad track to Pocinho on the Douro River; and Pocinho is connected by 118 miles of standard-gauge track to Leixoes, a port on the Atlantic Coast near Oporto. The ore reserves at Moncorvo were reported at 500 million tons, with an average content of 37% iron and 0.58% phosphorus.

Lead and Zinc.—During 1978 and 1979, exploration near Castro Verdo (see also the section on copper in this chapter) resulted in the reported discovery of lead-zinc ore. Reports indicated a 6% content of metal in the ores, and most of this content was zinc.

Discovery of this complex sulfide deposit may lead to significant output of lead, zinc and copper in Portugal, providing further exploration is successful and capital for development of a mine is available.

Pyrite.—Implementation of a Government program known as Total Utilization of Pyrite had a slow start in 1978; and in 1979, the slow pace continued. The management of the pyrite mine at Aljustrel started expansion of its mining and milling facilities for complex sulfide ores containing pyrite and nonferrous metals, located near Aljustrel in Alentejo Province. Plans called for production to rise from 300,000 tons to 1.2 million tons per year. The expansion was being supported by the Swedish Government through the engineering subsidiary of LKAB International AB, which was the coordinating consultant for the operation. Boliden Metall AB, Sala International AB, and LKAB from Sweden; and Outokumpu Oy from Finland were contracted to supply know-how and equipment. The metallurgical part of the program—at yearend still in the preliminary phase of studies—called for recovery of nonferrous metals from cinder, pelletization of cinder, and use of cinder in national steel plants as a source of iron. Portugal's reserves of complex sulfide ore are mostly located near Aljustrel and were estimated at 240 million tons, of which 40 million were proven. The average grade of this ore was reported as follows: sulfur 41% to 46%, iron 39%, lead 0.9% to 1.2%, and zinc 2.2% to 3%. Two deposits were in operation during 1979; they were Aljustrel (80 kilometers east of Sines) and Lousa Caveira (36 kilometers north of Aljustrel).

Silicon.—Portugal was planning to increase its silicon output to over 70,000 tons per year by 1981, including projected increases by Milnorte S.A.R.L. and Fornos Electricos totalling about 32,000 tons. Most of the new production was expected to be exported.

Tungsten.—During the summer of 1978, Beralt Tin & Wolfram (48.2% owned by Charter Consolidated) announced that its Portuguese operating company, Beralt Tin & Wolfram (Portugal) S.A.R.L., was planning to acquire, at a cost of about $3.6 million, French interests in a tungsten mining company, Mines de Borralha. Mines at Borralha are located some 300 miles north of Beralt's existing operations at Panasqueira. In December, a new company, Minas de Borralha S.A.R.L., was incorporated, with capital of 100 million escudos (44 escudos = US$1.00), divided in 100,000 shares. Of these shares, 80,500 were owned by Beralt Tin & Wolfram (Portugal) S.A.R.L., and the other 19,500 shares were held by Sociedade Portuguesa Empreenimentos S.A.R.L.

The Borralha deposit was discovered at the end of the last century, and peak output was achieved in 1956 when over 370 tons of a ferrotungsten product was produced. A recently completed incline to the 160-meter level had a total daily hoisting capacity of 380 tons of ore and was expected to increase output of concentrates to 30 tons per month. The mine's two electric-arc ferrotungsten furnaces were capable of processing 50 tons per month of concentrates. The product is 82% WO_3 ferrotungsten, which is crushed for shipping. Exploratory work by Union Carbide continued in the Covas scheelite zone near Viana do Costelo; and in the area of Tabucao, the Belgian company Geomines, in association with a Portuguese partner, was also prospecting for scheelite. Results were promising at both locations during 1978 and 1979, but details were not available.

Other Metals.—Tin was produced in eight mines. The Montesinho, Seixoso, and Argozelo mines had the largest reserves of tin in the country (about 82% of the total); these reserves averaged 1.05 to 1.36 kilograms of tin per ton of ore. Output continued to decline during 1978, but leveled off in 1979. Gold was produced in one mine, Couto Mineiro, in Jales, near Vila Pouca de Aguiar.

NONMETALS

Cement.—Cement remained among the most important of the nonmetals produced in the country. Ten cement plants operated by three companies were in production during 1978 and 1979. The largest company was Cementos de Portugal (CIMPOR), and its 1.9-million-ton-per-year plant at Alhandra, near Lisbon, was the largest in the country.

Clays.—*Kaolin.*—Plans to increase output of kaolin in Portugal were under consideration. In Alvares, the Jeronimo Pereira Co. planned to increase production to 50,000 tons per year and possibly to 100,000 tons. The most important kaolin deposits are located in Rio Major, Alvaraes (Viana do Costelo), and Senhora do Hora (Porto).

Stone.—Portugal produced a variety of stones in areas around Vila-Vicosa-Borba-Estremos, east of Lisbon. Processing of Portuguese stone was done abroad. During 1978, however, the possibility of starting a modern stone cutting industry was examined, but no major decisions had been announced by yearend 1979.

MINERAL FUELS

Coal, mostly anthracite, remained the principal fuel produced in the country during 1978 and 1979. However, the energy demands of Portugal were almost completely satisfied by imports of liquid hydrocarbons (which were the bulk of imported fuels), high-rank coal, and coke.

Coal.—During 1978 and 1979, there was one coal mine in operation. The Pejao mine, located near Oporto in northern Portugal, was owned by the Empresa Carbonifera do Douro. It produced annually about 200,000 tons of anthracite. The nearby thermal powerplant, Central Termica da Tapada do Outeiro, consumed most of the output.

Petroleum and Natural Gas.—Portugal was not counted among the producers of petroleum and natural gas. Imports of crude oil, some petroleum refinery products, and liquefied gas were essential to meet the country's demand. Principal suppliers of crude oil were Iran, Iraq, and Saudi Arabia.

A third Portuguese refinery, located at Sines, south of Lisbon, and operated by Government-owned Petrogal, started production in the fall of 1978. This refinery was expected to initially operate at a rate of 6 million tons of crude oil per year. Later, production may be increased to 10 million tons. The Government had approved construction in 1971, and site preparation was underway in 1973. In 1974, Technik-Procofrance won the main contract for Sines. In addition to refineries, jetties for 500,000-deadweight-tonnage-tankers and 250,000-deadweight-tonnage-tankers were also completed.

At an input rate of 10 million tons per year of crude oil, annual refinery output was anticipated as follows, in tons: Sulfur 34,000, fuel gas 65,000, propane 180,400, butane 345,900, isopentane 117,500, light gasoline 118,600, chemical naphtha 623,400, platformate 952,900, kerosine 209,900, desulfurized kerosine 648,000, light gas oil 913,400, desulfurized gas oil 1,380,700, desulfurized vacuum gas oil 700,000, asphalt 128,500, pitch 416,000, and residue 3,300,000.

Uranium.—Uranium activities in Portugal were carried out by the Government through the Nuclear Energy Commission (Junta de Energia Nuclear). Mines were in operation at Urgeirica and Guarda, in central Portugal. The aggregate capacity of these installations was reported at 180 tons of U_3O_8. In addition, resources at Nisa, in upper Alentejo Province, were mentioned as the site designated for future mining. Total reserves and resources of U_3O_8 were reported at 30,000 tons of U_3O_8. During 1979, Portugal's National Uranium Co. started work on opening several deposits in known zones of mineralization. Reserves of these deposits reportedly amount to 700 tons of uranium.

The Mineral Industry of Southern Rhodesia

By Janice L. W. Jolly[1]

Rhodesia's mineral industry was anticipating a renewed opportunity for growth by yearend 1979. In May 1979, Zimbabwe-Rhodesia came into existence with the newly elected government of Bishop Muzorewa. By December 1979, the Muzorewa government agreed to step down and two months were to be spent by all parties campaigning for a new election. Following this agreement, sanctions against Rhodesia were dropped first by Britain, Australia, and the United States, and later by the United Nations. Lifting of the trade embargo was not expected to have an immediate significant effect owing to a lack of adequate transportation facilities in addition to a continued depressed investor confidence, although all sectors, and especially mining and agriculture, were expected to eventually benefit. The removal of sanctions also meant that the nation must resume servicing its external sterling debt, on which the accumulated interest payments since 1965 totaled $225 million;[2] the country remitted $75 million to $90 million annually in dividends for the first time in 15 years.

The main economic constraints for 1978 and 1979 continued to be international sanctions and the local conflict, which at more than $1.6 million per day was costing some 40% of the national budget. The gross domestic product (GDP) for 1978 was estimated at $3.3 billion. Rhodesia's GDP had a near zero real growth for 1979, but with end of sanctions, a 3% growth in real GDP was anticipated for 1980. The war had been the principal cause of economic distress; together with slack export market and prices, the war caused the economy to shrink by almost 5% per year over the past 4 years. This contrasted with the first 10 years following the Unilateral Declaration of Independence (UDI) when the economy grew at an annual rate of almost 8%.

Because of sanctions and the closed economy that followed, Rhodesia was producing many things that probably would not be competitive to those produced by modern machinery elsewhere in the world. With prospects of increased foreign competition, some local businessmen were now seeking antidumping legislation and import controls. Soon after sanctions were imposed, overseas suppliers ceased exporting mining equipment to Rhodesia. In order to expand, the mining industry looked to local engineers both for new projects and mines and for replacement equipment. The result was a wide range of materials and equipment now being manufactured locally, including such heavy mining equipment as locomotives, hoists, crushing and grinding mills, and concentrating plant equipment. One company estimated about a $500,000-per-year foreign exchange savings solely through production of steel wire ropes for scrapers and rope haulages used in both surface and underground mining.

Faced with mounting economic problems, Rhodesia devalued its dollar approximately 8% against most major currencies and about 5% against the South African rand in April 1978. It was the second devaluation in about 6 months. While a growth in sales and corporate income tax was expected, revenues from individual income taxes would decline, reflecting an increased emigration, which in 1978 was officially about 1,000 per month. In 1978, the Government introduced a 12.5% personal income tax surcharge as a defense "loan."

Employment in mining and quarrying declined about 3,000 during 1978, or by almost 5%, because of cutbacks in nickel and chromite production and security restrictions. The number of Rhodesian workers in South African gold mines was dropping and was expected to be only 8,000 by yearend 1978. Wenela (the official recruiting organization of South Africa) was expected to continue recruitment at a rate of about 10,000 workers per year for the next 5 years. At present levels of pay, workers were sending back to their homes in Rhodesia about $580,000 per month.[3]

PRODUCTION AND TRADE

After independence was achieved formally on April 18, 1980, the new Zimbabwe Government published the first official production figures to be made available to the public since UDI.[4] Based on this report, the production figures were revised on table 1 of this report for the following commodities: asbestos, gold, chromite, coal, copper (mine production), nickel (mine production), iron ore, silver, cobalt, and smelter tin. Because of late receipt of the data, however, the new figures could not be used in the 1978-1979 commodity reports appearing in Volume I of the U.S. Bureau of Mines Minerals Yearbook, with exception of the chapters on silver and chromite.

Mineral production was valued at $363.2 million in 1978 and about $432 million in 1979, compared with $341.9 million in 1977. Higher metal prices, particularly gold, helped in maintaining the record income for both 1978 and 1979. Prices for commodities such as nickel, copper, chromite, and steel remained low in 1978 (causing cuts in production and stockpiling), but generally enhanced prices for gold, silver, tin, tantalite, tungsten, lithium, coal, and emeralds accounted for the increased market realization. Most of the latter-named minerals were produced for the export market. The surge in nickel prices during 1979 gave new life to Rhodesia's ailing nickel mines, adding foreign exchange earnings of about $70 million. Cobalt production increased markedly in 1979 and exports were expected to be in the region of 50 tons per year of contained metal.[5] The security situation prevented production at some smaller mines in outlying areas.

Nonmetallic mineral products, which consisted mainly of cement and other building materials, suffered the worst downturn of all mineral products during what has been a 4-year recession for the construction industry. For 10 years, up to the end of 1974, production of this sector had been increasing at about 12% per year. Until 1979, however, there had been a steady downward trend. Seasonally adjusted figures show that output for the construction industry for the first 8 months of 1978 was 32.3% below the volume produced in the same period of 1977.[6] Construction, mining, manufacturing, and banking sections all improved in the first few months of 1979, compared with those of 1978, and statistics were indicating a dramatic upturn in the economy by yearend.

Detailed import and export information has not been available since 1965 for security reasons. In 1978, exports increased by 13% in value while imports were curtailed. In the first half of 1978, Rhodesian businessmen were being asked to make across-the-board cutbacks in import allocations by as much as 20% in many instances.[7] The cutbacks reflected difficulties in exports that were mainly attributable to international economic demands in general, rather than to sanctions alone. Continuing sanctions, however, were aggravating the situation. The Swiss Government tightened sanctions against Rhodesia at yearend 1977. In December 1978, Dutch officials seized Rhodesian chrome worth $23.4 million en route to an Austrian ferroalloys smelter.[8] It was also established that U.S.S.R. had been buying chrome from Rhodesia in contravention of United Nations sanctions. Reportedly purchased at $32 per ton, it was resold in the United States at $58 per ton.[9]

In 1979, total exports were estimated at $1,000 million and imports at $893 million. With an end to sanctions, exports were expected to increase by about 30%, but a trade deficit was also expected. Dividends and earnings of foreign-owned businesses were to remain frozen until further notice despite the end of sanctions.[10]

The railway route from Zambia and Rhodesia was re-opened by the Zambian Government in October 1978 after a 5-year closure. It was a move forced by the inability of northern and Tanzanian railways to handle vital copper exports and fertilizer and corn imports. Rhodesia refused to reopen the Kazungula ferry route, which it had destroyed in eary 1978. By June 1979, at least 600,000 tons of corn, fertilizer, and other products were being stockpiled in South African ports waiting shipment to Zambia. A series of clandestine meetings were being held between Rhodesia and Zambia in the hope of reopening road traffic.

Table 1.—Southern Rhodesia: Production of mineral commodities[1]

(Metric tons unless otherwise specified)

Commodity[2]	1976	1977	1978[p]	1979[e]
METALS				
Aluminum: Bauxite, gross weight	2,000	2,000	--	--
Antimony, mine output metal content[e]	300	300	250	250

[e]Estimate. [p]Preliminary. [r]Revised. NA Not available.

[1]For the first time in 16 years, official figures were published on output of a number of mineral commodities produced in Southern Rhodesia in the May 1980 issue of the Zimbabwe Monthly Digest of Statistics. These data covered production of chromite, cobalt metal, mine copper, mine gold, iron ore, mine nickel, mine silver, tin metal, asbestos, and coal; the availability of these data made revisions necessary in estimates for output of pig iron, crude steel, and mine tin. In addition, some company data became available on production of coke and ferroalloys for 1979 and were incorporated in this table.

[2]In addition to the commodities listed, modest quantities of unspecified types of crude construction materials (including clays, stone, and sand and gravel) were produced, but output is not reported quantitatively and available information is inadequate to make reliable estimates of output levels. Also, graphite and mica have been produced in the past and output presumably has continued, but no basis for estimates of output levels is available.

[3]Reported figure.

[4]Includes Ni content of nickel oxide and nickel fonte.

[5]Data represent only an approximate order of magnitude.

[6]Data represent sales for years ending Aug. 31 of that stated by Wankie Colliery only; additional coke is produced at the Radcliff steel plant of Rhodesian Iron and Steel Company (RISCO), but data on production there are not available.

COMMODITY REVIEW

METALS

Chromite.—A standard friability test for chromium ores was devised and reported on by Rhodesia's Institute of Mining Research (IMR).[11] The friability of chromium ore largely determined its sales potential, thus the importance of the friability factor to both miners and ferroalloy producers. The unique test devised by the IMR was a simple and economical one which expressed in percentages the commonly used terms "hard lumpy," "lumpy," "friable," "semi-friable," and "friable lumpy," and which thus more clearly indicated the potential suitability of the ores for smelting. For instance, ores with friability of less than 15% fell within the category of "hard lumpy" and were well-suited to the production of high-carbon ferrochromium. "Lumpy" ores had a friability range of 15% to 25%. From 25% to 60% friability, however, the ores fell into less definitive categories. The test was expected to have wide application in Rhodesia. Union Carbide of the United States estimated their Rhodesian chromite mine assets at $25.8 million. With removal of sanctions on December 16, 1979, the U.S. companies were expected to renew importing Rhodesian chrome and ferrochrome.

Copper.—M.T.D. Mangula announced a 60% fall in taxed profits for the 6-month period ending in April 1978. Even so, the company was expanding capacity, with the extensions at the Norah mine being completed in 1977 and at Mangula in April of 1978. For the year ending September 30, 1979, the combined production for both mines was 16,440 tons of copper, compared with 17,369 tons of copper for the same 1978 period. Ore reserves had been maintained at 17.5 million tons, but the grade had risen from 1.25% to 1.30% copper as a result of the exclusion of lowergrade areas from mining at Mangula. By yearend 1978, it was evident that a strong rise in copper prices would continue, and the country's main copper producers were reexamining the feasibility of either reopening closed mines and section of mines, or cautiously expanding production levels previously scaled down because of low prices. In November 1979, M.T.D.'s Lomagundi Smelting and Mining (Pvt.) Ltd. began construction of an electrolytic copper refinery adjacent to the Alaska copper smelter, which in 1978 had produced 26,240 tons of blister copper. The cost to build the 20,000-ton-per-year refinery was estimated at $7.6 million and was to be financed through local loans. In addition to some local fire-refining, copper refining had been carried out in South Africa. Early in 1978, Lonrho announced plans to purchase the 50% interest in the Nyaschere copper company that it did not already own. This was considered the most satisfactory solution to financial problems that had arisen. Corsyn Consolidated Mines produced copper from the Inyati and Muriel properties. For financial year ending September 30, 1978, a total of 3,553 tons of copper was produced from 256,000 tons of ore milled from both mines.

Gold.—As the price of gold moved from $160 at the end of 1977 to $185 per troy ounce at the middle of 1978 and $700 per ounce by 1979, the Rhodesian Ministry of Mines and the Chamber of Mines were actively reassessing the country's gold potential. So far some 1,300 gold mines had been cataloged. Apart from the suspected presence of many new deposits, many of the old mines appeared to offer considerable scope for redevelopment. The Ministry of Mines issued a list of all known dormant gold mines in late September 1979 as an aid to prospective small workers. A new shaft was sunk at Falcon Mines Ltd's Dalny gold mine to allow more extensive work to be carried out at deeper levels. The 2-year project was finished at yearend 1979. The Dalny also crushed and milled all the ore from neighboring mines, including the Venice. About 5,000 tons of ore from the Venice mine was processed per month at the Dalny facilities. In the financial year ending September 30, 1979, the Dalny mine produced 52,896 troy ounces of gold compared with 55,849 troy ounces for the same 1978 period. Coronation Syndicate produced about 2.2 tons of gold from its Arcturus, Mazoe, Muriel, and Maskona Kop operations and as a by product from the Inyati copper mine. Blanket Mines Pvt produced about 0.5 ton of gold from the Blanket mine. Rio Tinto announced plans to expand the Renco gold mine and indicated their Zinca platinum prospect may be developed.

Iron Ore.—The IMR was carrying out a general review of iron formations and their associated iron ore deposits throughout Rhodesia. Detailed mapping was being done in the Buchwa, Manisi, and Redcliff areas. The project also included geochemical studies of samples from the West deposit at Buchwa, the Ripple Creek and South Hill ore bodies at Redcliff, and the Rho-Iron claims at Manisi. Geophysical investigations were also done. Preliminary results of these studies were given in a recent report.[12]

Iron and Steel.—The Government was providing further subsidies to the Rhodesian Iron and Steel Company (RISCO), as well as increasing its equity stake in the group to 49.7%. Government support for RISCO over the last 3 years totaled over $130 million. The company officially changed its name to RISCO Limited, effective August 28, 1979. No. 3 furnace, closed down since February 1977, was brought back into full production in November 1978. The No. 4 furnace was shut down in April 1979 for a short period for relining and overhauling. Several modifications, including a better water cooling system and improvements to hot air and gas pipes were being made. Meanwhile, much of the additional steel produced by the two furnaces was stockpiled to cushion the effect of the closure.[13] Output from the No. 4 furnace alone in 1977 was 654,000 tons of pig iron.[14]

Nickel.—The Shangani Mining Corporation Ltd. (49% Johannesburg Consolidated Investment Co. Ltd. (JCI)) operated a nickel mine situated northeast of Bulawayo. Concentrates produced by the mine were processed by Bindura Smelting and Refining Company at its plant, located 100 kilometers northeast of Salisbury. Trial milling commenced in October 1975, and the mine began production from the open pit on March 1, 1976. The underground mine was expected to start production in early 1980. Burdened with a massive $40 million debt loan and struggling against depressed nickel prices on world markets, Shangani had experienced a loss since the mine began. In 1978, the net loss for the financial year was $3.1 million; this, brought forward, gave an accumulated loss of $8.5 million.[15] By yearend 1978, it was announced that production of ore from Shangani would be discontinued for about 6 months in 1979, but revenues would continue to be earned from stockpiled ore. By yearend 1979, financial results had been better than anticipated. Nickel prices had improved measurably and the company expected to be able to cover interest payments on loans. Production of ore from the East pit had been stepped up from 50,000 tons per month to 75,000 tons per month earlier in 1978 because pit walls were deteriorating. This action followed a production cut in November 1977 by half in an effort to cut expenses and more closely match production with sales. Operations in the East pit continued on a reduced scale until reserves were finished in April 1979.

Anglo American Corporation (AAC) was appointed secretary, technical advisor, and buyer for the Shangani Mining Corporation effective April 1, 1978. AAC provided similar services through its Salisbury office to the Rhodesian Nickel Corporation (RHONICK), which has joint smelting and refining facilities with Shangani. JCI considered a Salisbury management base would allow a more rational use of resources. JCI expected to continue its investment and representation on the Shangani Mining Corporation's board and executive committees. Rhonick assumed the name of Bindura Nickel Corporation in 1979. The company had a $29 million tax loss for the year ending April 1979.

Although lower in grade, the tonnage of ore milled at RHONICK's Trojan mine was higher for the fiscal year ending June 30, 1978, than for the comparable 1977 period, and the production of nickel in the concentrate was highest ever achieved by the mine. Underground mining capacity had been extended at RHONICK's Epoch mine so that the average production rate during the year was 35,000 tons per month. Minor plant modifications, careful operational control, and improvements in metallurgical recovery, coupled with a marginal improvement in mill head grade resulted in the recovered nickel in concentrates being 40% higher than in fiscal year 1977. At Madziwa mine, various methods to refine mining were being pursued in order to exclude as much waste as possible and increase the nickel grade above the historical 0.60%. The Madziwa ore bodies were extremely erratic and complex. Dilution of ore by waste rock resulted from the contorted ore body outlines and random distribution of ore with barren inclusions. Security commitments were also placing a very heavy load on staff at Madziwa where mine personnel were on regular standby.

Part of the brickwork of the electric smelting furnace at Bindura Smelting and Refining collapsed on Dec. 17, 1978, as a result of recent operating difficulties.

The furnace was out of commission for 8 weeks.[16]

Because of higher nickel and gold prices Rio Tinto Rhodesia showed a profit after tax of nearly $3.7 million for the 9-month period to September 30, 1979, compared with $2.2 million for the same 1978 period. Profit for the last quarter was helped by the high gold price, but the Empress nickel mine earned lower profits. Empress nickel profits dropped because of a drop in production resulting from ore processing difficulties. The Empress was a low-cost producer, but the profit margin at current prices was small. The planned major exploration program for additional nickel ore was also severely hampered by military commitments and the deteriorating security situation. The mine had proven ore reserves of 10.5 million tons with a nickel and copper content of 1.27%, giving a minimum life of 10 years.[17] A breakthrough in a metallurgical method enabling the extraction of gold, platinum, and palladium from the nickel ore was announced by the company in 1979. Rio Tinto had been working on a modified Finnish process which appeared successful. Although some initial problems were encountered, production from the new precious metals plant was expected in early 1980.

An investigation was undertaken to determine whether a ferrochromium nickel alloy, similar to austenite stainless steel, could be produced directly by smelting a composite charge of nickel silicate and chromium ores derived from the Great Dyke. The nickel silicate thus obtained and used in the initial smelting tests had a low 1.2% nickel content and was predominantly composed of silica and magnesia with some iron oxide and residual chromium. The smelting tests established the practical feasibility of the process, and it was recommended that an extensive survey be carried out to determine the nickel-bearing weathered serpentinite reserves on the Great Dyke and elsewhere. Surveys into the marketability of the alloys and the economic aspects of large-scale production were also necessary. By increasing the proportion of nickel silicate to chromium ore in the charge, it was determined that a range of alloys would be produced with increasing nickel and decreasing chromium contents.[18]

Tungsten.—Scheelite accounted for 65% of the total tungsten mineral production, but this portion was expected to diminish relative to wolframite production in the future. Although over 400 mines contributed to the national production, about 75% of the production was derived from about 5% of the mines. The R.H.A. mine accounted for most of the wolframite production from the deposits of the Wankie area. The P&O mine, in which scheelite was dominant, was a large producer in the Sabi River area near the Mozambique border. The Hippo mine was dormant but had been the largest wolframite producer in the Sabi area. The Mapani mine, adjacent to the P & O mine, produced more wolframite than scheelite and was the largest current producer of the Sabi area. At the Mapani, the ore occurred with copper, gold, and silver minerals in quartz and calcite-filled fault breccia. Scheelite often had a similar distribution to gold and was a byproduct of many gold mines; it also commonly occurred with iron, copper, and lead sulfides in low-temperature quartz veins. The Scheelite King mine, one of the largest producers, was sited in a skarn zone adjacent to the Jumbo granite, north of Salisbury. The Beardmore mine, situated near Bikita, produced about 100 tons of contained tungsten oxide in concentrates per year and was also associated with coarse aggregates of epidote, garnet, and vesuvianite in greenstone near a granite contact. The R.A.N. and Golden Valley mines, located near Bindura, were examples of gold mines rich in scheelite.[19]

NONMETALS

Asbestos.—The King mine produced chrysotile asbestos of high quality from ore bodies which were developed in serpentinized host rocks of the Fort Victoria Schist Belt of Archean age. The mine was situated 7.5 kilometers southeast of Mashaba and 40 kilometers west of Fort Victoria. Silky chrysotile fiber seams form a stockwork in three ore bodies named the Main, Western, and Central. The complex geological and structural environments in which the Gath, King, and Shabanie mines were developed have posed difficulties in the design and implementation of underground mining methods. As a result, the block cave technique was continually revised, and a code for design of block caving stopes was formulated.[20]

Bauxite.—Deposits of bauxite have been known and mined for many years in the Eastern Highlands and adjoining areas of Mozambique. Despite the small production from the Alumen Claims, Penhalonga, little exploratory work was carried out to prove the extent of reserves. The ore was being used entirely for the production of aluminum sulfate.[21]

Cement.—Sales of cement by the Salisbury Portland Cement Company, located in Salisbury, dropped 12% from 186,000 tons to 163,000 tons in the year ended November 30, 1978. The drop in cement sales was caused by a continued decline in the construction industry. Limestone for use in cement was produced by the Abadan Slate (Pvt.) Ltd. of Bulawayo, the Dodge Mineral Production Co. (Pvt.) Ltd. of Salisbury, and by the Early Worm Mining Co. (Pvt.) Ltd. in Concession.[22]

Clays.—In Rhodesia, refractory and semirefractory clays occur in the Karoo System associated with the coal measures. The main deposits of flint clays investigated are those of the Lower Sabi coalfield near Chiredzi and Chivumburu Hill. Based on available information, the minimum tonnages shown on table 2 were indicated:[23]

Table 2.—Deposits of flint clays

Area	Million tons
Dambalangwe	2.5
Sangabwe	6.0
Chipolo	1.0
Nyawagi	3.8
Gozonya	4.0
East of the Chiredzi River	16.0

An unknown quantity of flint clay also occurs between Sangabwe and Gozonya and east of Gozonya. Problems of selective mining, necessitated by the variable thickness of associated ferruginous layers, have to be overcome for economical exploitation. There is only one known kaolin deposit, the Alumens Claims, located north of Umtali. The kaolin formed as a weathering product of anorthosite.

The Rhodesian-based company G & W Industrial Mineral (Pvt.) Ltd. was mining bentonite for domestic consumption. The company was an associate of Zimro (Pty.) Ltd. of South Africa and also mined iron oxide pigments in the Gwelo District.

Diamond.—Kimberlitic Searches Ltd. continued to prospect for diamonds and met with some success in the discovery of a diamondiferous kimberlite intrusive into rocks of the Limpopo Mobile Belt near Beitbridge. The deposit was still under investigation.[24] Kimberlites were known to occur in Rhodesia at 21 localities; ten were found on the craton, two in the Limpopo Mobile Belt, and nine in Karoo rocks. These intrusions were not always diamondiferous, and had thus far been uneconomic where stones had been found. A recent Rhodesia Geological Survey article described the kimberlites of Rhodesia.[25]

Euclase.—The occurrence of euclase, a member of the datolite group of minerals, was described in a recent article by the Rhodesia Geological Survey.[26] The hydrated beryllium-aluminum silicate occurred as a low-temperature replacement of beryl in the Miami pegmatite field, located north of Karoi. Economic minerals found in the younger pegmatites of this area include beryl, mica, tantalite, and cassiterite; the quartz veins contain wolframite. Some spectacular aggregates of euclase were produced from the Last Hope, Last Hope 3, Mishek, Falls and Trim, and the Rattis mines. Most of the mineral was being stockpiled while a lucrative market was being sought. Some of the dark blue, paling to light blue crystals were transparent and of gem quality.

Magnesite.—Work was nearly complete on the $520,000 expansion project at Gatooma Magnesite, a medium-grade magnesite mine in the Midlands on the Barton Farm, which was jointly owned by the South Africa companies Vereeniging Refractories (Verref) and Cullinan Refractories. A new shaft began in December 1978, and the target date for completion of the project was October 1980. The Gatooma Magnesite mine started in 1939 as a quarrying operation, and underground work started in 1964 when Verref took over. The mine has a currently assessed life of about 12 years.[27]

Slate.—Premier Slates, a company mining slate from a quarry near Feathersone, declared the mine's product to have tremendous export potential. The market for billiard table tops alone was considered a potentially large one. Premier Slates had received an inquiry for supplying 40,000 table tops.[28]

Sulfur.—It was estimated that Anglo American Corp. Rhodesia Ltd. (Amrho) had a production capacity of 45,000 tons per year of recovered combined sulfur,[29] as a byproduct of metal and coal mining and the Iron Duke pyrite mine.

MINERAL FUELS

Coal.—Wankie Colliery (Anglo American Corp.) reported lower profits and 3,065,000 tons mined in 1978. Coal production improved in 1979 when 3,188,000 tons was produced, but demand and profits were still low. The Government agreed to allow a 10% price increase effective the first of August, 1979. Closed since October 1, 1977, it appeared that the number 4 underground colliery would remain closed for longer than anticipated, but plant and equipment were to be maintained. A lack of adequate railroad transportation had been a major constraint in coal sales. A new 1,300-megawatt power station was to be built at the Wankie mine site and would necessitate an expansion in production of coal. The coke ovens were operated at a minimum during 1978, and it was possible to reduce Wankie's large coke stockpile. Coke sales for fiscal year 1979 ending August 31, 1979, were 261,471 compared with 178,971 tons for the same 1978 period. Coke exports had proved important, since the domestic demand had slackened.[30]

Petroleum.—Sabotage, destroying 22 of 28 petroleum storage tanks in late 1978, was considered to be one of the biggest economic setbacks since the internal strife began. Located near Salisbury, the tanks were owned by Shell, British Petroleum, Total (France), Caltex, and Mobil Oil Co. Rhodesian-based oil companies distributed strictly rationed fuel that had been imported through South Africa, mainly from Iran. An estimated 17 million gallons of diesel, aviation fuel, and gasoline were destroyed in the attack.[31] The domestic price of premium gasoline increased by almost 80% during 1979 and the impact of buying oil in spot markets had affected all markets; a unit (5 liters) of premium gasoline cost $3.60 in July 1979. Rhodesia was expecting to produce enough ethanol by 1980 to provide 15% of Rhodesia's gasoline supplies. Ethanol would eventually form 15% of diesel supplies and 20% of gasoline.

Before independence, Rhodesia got most of its crude oil by pipeline from Beira, Mozambique. The oil companies shut the pipeline in December 1965 in response to sanctions law. Oil began to be delivered first by truck from South Africa and then by rail through Mozambique and more recently through South Africa. The five oil companies apparently dropped all competition and allowed the Rhodesian Government company, GENTA, to allocate business to insure that each company maintained its market share.

A new $1 million oil re-refining plant was completed by Shell and British Petroleum. Only about 16% of the oil used in the country was currently being re-refined, but it was hoped to raise this to 30%.

The Mineral Industry of Romania

By George Rabchevsky[1]

Romania in 1978-79 did not meet its production targets in national income, industrial production, agriculture, and foreign trade. The 1979 investment target was not realized, even though it was at lei 206.2 billion[2] or 5.1% over that of 1978. The industrial sector received almost half of the investments in 1978, and almost 60% in 1979. Industry continued to be a priority for development in Romania's overall planning. In 1978 and 1979 the industrial production posted a 9% and 9.1% increase, respectively, which is below the planned targets of 10.6% and 11.3%. The output was particularly below planned levels for the petrochemical industry, which was restrained by the imposed energy conservation measures, import prices, and the major accident at the Pitesti refinery. Other industrial sectors where targets were not reached included coal, steel, crude oil, and electric energy.

Wages are to be increased by 13.6% in 1978, affecting mining, oil, gas, and coke industries, as well as engineering and geological research. According to Vasile Patilinet, Minister of Mines, Oil and Geology, during the current 5-year plan the salaries of miners were increased by 38.2% and those of geology and drilling personnel by 35.9%.

Romania in 1978 incurred a sizable foreign trade deficit, primarily due to its import increases in energy and raw material needs and escalating prices. Imports grew significantly faster than exports, with petroleum accounting for a sizable part of Romania's hard currency expenditures.[3]

Despite the problems in productivity, resources availability, and energy, the 1980 Romanian plan calls for a continued rapid development of the economy, already COMECON's[4] fastest growing. Energy self-sufficiency is in the forefront of the Romanian 1980 policy. The extraction of domestic crude oil and the consumption of hydrocarbons will be frozen at present levels, while mining of coal and utilization of hydropower will be substantially increased. What crude Romania plans to import, will be refined domestically and eventually reexported to boost its hard currency needs.

In accordance with the policy of continued development of its indigenous raw materials base, the 1980 plan again envisages intensified geological research and exploration programs, maximum utilization of all domestic resources, recovery of secondary products and waste, reduced oil consumption, and more efficient utilization of metals. Coal and nuclear power are to be developed rapidly under the plan. New coal mines are to be opened, substantially boosting production over 1979. Improved secondary recovery techniques will be employed for a more efficient exploitation of the less productive oil reservoirs. The production of crude oil and natural gas will remain at approximately the 1979 level. The 1980 goals of the domestic economy as a whole are modest and more realistic than the previous aspirations. National income is planned to advance 8.8%, industrial production 11.5%, total investments 4.9% (at lei 245 billion), and foreign trade turnover 14.8% (at a new high of lei 130.9 billion). Foreign trade will continue to be promoted with all countries in all categories, emphasis put on exports of Romanian-built equipment and machinery, technical services, and refined petroleum products.

PRODUCTION

Romanian reserves of raw materials are at the point of depletion and to sustain its existing processing facilities and output, Romania continues to rely increasingly on imports of ores and mineral fuels. This pertains especially to the bauxite, iron, lead and zinc ores, and metallurgical coke. Lignite is the only mineral fuel in abundance, which is being relied on more intensly as a substitute for the generation of power, eventually replacing hydrocarbons. Cement is the only other commerical mineral with a steadily increasing production, with plentiful reserves skirting the Carpathian Chain. Reportedly, oil was discovered offshore in the Black Sea in 1979, the reserves and production, however, are as yet uncertain and have not been reported officially. Production from the Ploesti Fields can now be sustained only by secondary recovery. Thus, even though, Romania is attempting to reach self-sufficiency in energy and mineral production, no new reserves were discovered or new mines were opened in 1978-79, except coal. Conservation of resources, lowered consumption, and emphasis on mineral processing and metallurgy industries remained a national priority during the current 5-year plan.

The gross value output of ferrous and nonferrous metallurgy increased 8.7% and 5.7%, respectively, in 1978, with some plants, such as the Slatina aluminum reduction plant being expanded, even though almost 50% of the bauxite had to be imported from Greece and Yugoslavia. To streamline quality and productivity, automation is being introduced wherever possible. In 1978-79, the machine building industry grew by more than 13%. Nevertheless, a number of equipment manufacturing plants and metallurgical complexes did not fulfill the prescribed quotas or meet the expected production plans. Significant construction delays were reported by fertilizer, petrochemical, and metallurgical industries. For example, material shortages and production delays occurred at the Galati Tirgobiste and Resita Ferrous Metals Combines, the "1 May" petroleum equipment plant at Ploiesti, the Medgidia II Cement and Lime plants, and others. The delays caused shortfalls in steel and rolled products output[6].

In 1979, President Nicolae Ceausescu visited a number of mining areas, and later criticized the miners and officials for inefficiency and poor performance. As a result of that visit, Vasile Patilinet, Minister of Mines, Oil and Geology, was fired and replaced by Virgil Trofin.

Table 1.—Romania: Production of mineral commodities

(Metric tons unless otherwise specified)

Commodity[1]	1976	1977	1978[p]	1979[e]
METALS				
Aluminum:				
Bauxite, gross weight	[r]680,000	702,000	707,767	708,000

[e]Estimate. [p]Preliminary. [r]Revised. NA Not available.

[1]In addition to the commodities listed, antimony, asbestos, gypsum, and a variety of crude construction materials are produced, but output is not reported quantitatively and available information is inadequate to make reliable estimates of output levels.

[2]Reported figure.

[3]Romanian sources do not indicate whether refinery fuel is reported as a part of the listed product yields. Moreover, additional minor products may be produced but are not listed in official sources.

TRADE

Romania is a centrally planned economy country which follows a more independent economic and foreign policy within the COMECON and has attempted to cultivate commercial ties worldwide. Romania is a mineral-poor country, and has to import most of its raw materials, including oil. Iron ore, lead, zinc, and coke are all imported due to the depletion of indigenous deposits, to maintain the manufacturing plants and refineries in operation. About 40% of Romania's imports consist of raw materials and 60% of finished goods and spare parts.

Romania's primary export commodity is petroleum products, mining, and oil drilling equipment. Technical services and even investment credits have also been negotiated, especially with the developing countries. Most of the trade conducted, however, is with the advanced developing countries and those rich in natural resources. A number of joint ventures have been signed, such as the Peruvian-Romanian Anatamina Co. project for the exploration and mining of copper and zinc deposits. Reportedly, Romania and Bangladesh reached an agreement in 1979 on joint ventures in coal mining, the use of gas and petrochemicals, and oil prospecting, as part of the joint commissions for economic and technical cooperation held in Bucharest. A joint exploration program for potash-bearing brines in the Jhelum District of the Punjab Province of India was being established in 1978. Cooperative exploration projects also exist with Guinea for bauxite, and with Burundi for nickel. A joint copper exploration and production company was established in 1979 with Zambia, with a U.S. $50 million credit granted by Romania to Zambia for the purchase of Romanian-made installations and equipment. As in numerous previous agreements, however, it may be postponed or never even implemented. A joint petroleum exploration program was signed with Egypt in 1979. That year, Romania and Greece agreed to increase trade exchanges (which already registered a 64% jump in 1978 over the previous year), and also to continue cooperation in the search for oil. Bauxite has been imported from Greece for a number of years. Oil refineries and mineral processing plants have been built with Romanian assistance in Turkey, Egypt, Syria, India, Pakistan, and Yugoslavia. Romania and Yugoslavia are also involved in a number of other energy-related joint ventures, such as the construction of the Iron Gates I and II hydroelectric plants.

Increased exports have always been the goal and concern of the Romanian foreign trade policy. Trade imbalance, however, continued to persist and in 1978 the deficit amounted to a record high of lei 3.8 billion. Imports climbed 16.5% (15.1% in 1977) and exports were up only 5.5% (14.4% in 1977). The 1979 export target of 16.6% was at 18%, and import was 20% over that of 1978. Foreign trade turnover (exports plus imports) in 1979 was at lei 93.3 billion, 19.1% over that of 1978, and 1.1% over the planned target. To stimulate exports, the Romanian Government was actively seeking trade agreements and attempted to upgrade the quality of its goods and services. The emphasis on better and more sophisticated commodity production was intended to generate higher values for given amounts of materials, fuels, and energy, often accompanied by profit incentives to the plants and its employees.[7]

Romania continued to trade with the COMECON countries (46.3% of total in 1978) and, in addition to the traditional imports, crude oil may be purchased from the Soviet Union for the first time in 1980. Iron ore and potassic fertilizer were received from the U.S.S.R., coal and sulphur from Poland, and rolled steel from the German Democratic Republic. Nickel concentrate and reportedly chromite were also imported from Cuba. Overall, trade with the U.S.S.R., Cuba, and other COMECON countries decreased, while it went up 40% with China. Romania was actively soliciting trade agreements also with the African developing countries. In spring of 1979, President Nicolae Ceausescu visited many African countries, seeking imports of raw material. To establish and stimulate new sources of supplies, Romania even extended credit to many of those countries. Thus, manganese was being shipped from Gabon, and uranium may be imported from there by 1986. Discussions also centered around oil imports from Angola and Mozambique. The other African countries visited by President Ceausescu included Burundi, Liberia, Zambia, Libya, Sudan, and Egypt, during which treaties of friendship and cooperation were signed.

Most of the Romanian-processed products are bartered or exported for hard currency, which is needed for subsequent foreign purchases. Iron ore and ferroalloys are imported from India, for example, in exchange primarily for Romanian chemical fertilizers and equipment. A 1980 trade protocol was signed with Albania under which Romania will export oil drilling equipment and other machinery in return for Albanian bitumen, sulfur, crude oil, chromium ore, copper and copper products, pyrite concentrate, and consumer goods.[8] A similar goods exchange protocol was also in force in 1979.

In 1978, Romania negotiated an agreement with Canada for delivery on credit of four nuclear reactors. The agreement is of significance, since this was the first sale of a Canadian nuclear reactor to a centrally planned economy country. U.S. mineral exports to Romania in 1979 included bituminous coal and phosphates, while United States imported petroleum products such as naphthas and fuel oil from Romania. The U.S.-Romanian trade reached approximately U.S. $800 million in 1979, of which U.S. exports totaled about U.S. $445 million. Trade with the United States registered the highest increase (40% in 1978) of all market economy countries.

Table 2.—Romania: Apparent exports of mineral commodities[1]

(Metric tons unless otherwise specified)

Commodity	1977	1978	Principal destinations, 1978
METALS

COMMODITY REVIEW

METALS

Aluminum.-Romanian bauxite reserves are estimated at 50 million tons. All of the producing mines are located in the Oradea Area of the northwestern part of the country. Small reserves of low-grade ore have also been reported to exist in the Ohaba-Ponor Area, the central-southwestern part of the country. Domestic production of bauxite is insufficient, and Romania imports over 70% of its requirements, primarily from Greece and Yugoslavia.

Alumina processing capacity of Romania may be over 510,000 tons annually, and in 1978-79 the plants in Tulcea and Oradea operated almost to capacity. Romania imports only about 8% of its alumina consumption. Neither the bauxite, nor alumina are exported. Aluminum metal is produced in Slatina, the only plant in Romania. The plant was expanded and modernized recently, and in 1978 it produced for the first time a high purity aluminum. This development may eventually cut Romania's imports in the future of high purity aluminum. In 1978, the plant also began the manufacture of aluminum tube closures, and developed a new aluminum alloy for the manufacture of roller bearings.

In 1978-79, the overall performance of the Romanian aluminum industry (bauxite, alumina, and aluminum) showed only a slight progress, such as in the utilization of the inferior-quality bauxite ores at Ohaba-Ponor, and the expansion of the Slatina aluminum plant. This stagnation may continue into the forthcoming 5-year plan (1981-85). Bauxite was first mined in the Apuseni Mountains only in 1964, the first alumina produced in Oradea in 1965, and the first aluminum smelted at Slatina in 1965. By 1980 the planned production of primary aluminum and alloys is 265,000 tons. This is to be achieved following the ongoing installation of two additional potlines at the Slatina plant.[9]

Copper.—In 1978-79, Romania mined over 5.5 million tons of ore, averaging about 0.49% copper content. There may be 10 active copper mines, the higher grade ore located in the northern part of the country around Baia Mare and Rosia Montana areas of the Apuseni Mountains, and the lower grade ores located in the Moldova Noua-Rosia Poieni areas in the south. None of the ore is exported, and imports of ore and concentrates are low. Reserves in the north are being depleted rapidly and ores of the newly developed "South Banatian" copper province around Rosia Poieni and Moldova Noua, are only low-grade copper. Those deposits are directly related geologically to the Bor copper province of Yugoslavia. The Moldova Noua deposits are on the same geological trend as the old mining district of Oravita, which produces copper and molybdenun. Stratiform skarn copper deposits have been found on the Stinapari Plateau, not for from the well-known Sasca and Ciclova Montana copper skarn deposits. The recent copper mineralization discoveries of Lapusnicul Mare around Resita and just north of Oravita, also include the Liuoradja, the Moceris, and the Minis Valley mines. The copper there usually occurs as a porphyry skarn, containing a host of other minerals. In the Apuseni Mountains, for example, there are copper-molybdeum and copper-pyrite-gold, and silver porphyries, as well as some lead-zinc deposits.[10] Romania has a joint copper mining venture with Compania Minera Codemin of Chile. Gorghe Fulea, Romania's Deputy Minister of Mines, Oil and Geology, visited the Chilean Quimbo copper mine in 1979 to discuss minerals trade and the expansion of mine production.

Romanian production of smelter and refined copper metal remained practically at the same level for a number of years. To supplement domestic consumption, almost 50% of copper metal and products are imported. Romania also exports a significant tonnage of copper metal and alloys. The new Baia-Borsa Mining Enterprise established recently is expected to boost Romania's production of copper in the near future.

Gold.—The estimated production of gold by Romania has remained at the same level for a number of years. No official information or data is available on domestic production, consumption, or trade. In 1978, however, the Romanian State Council issued a decree for a stricter control over the precious metals and semiprecious stones. For example, the use of gold, even in dentistry, must now be planned annually and approved by the State Council. The precious metals covered by the new decree are the same as in the past, including gold, silver, platinum, osmium, ruthenium, rhodium, iridium, and palladium. The number of precious stones, however, was increased by more than 10, among which were included topaz, spinel, amethyst, as well as any stones with a hardness higher than 7 on the Mohs scale. Remaining on the previous list are diamond, ruby, sapphire, emerald, and pearl.[11] The purpose of the new decree is to continuously develop and increase the National Treasure, and to restore goods to state ownership, thus prohibiting the private possession of precious metals and stones, except for personal use.

Gold in Romania is probably still extracted from polymetallic porphyries in the Apuseni Mountains, and from the auriferrous and argentiferrous ores of Baia-Mare. In the Transylvania region, gold is most likely extracted also from alluvial sands.

Iron and Steel.—Production of iron ore did not change significantly in 1978-79. Most of the ore is mined in the Transylvania region, but reserves there are now of inferior quality and are being depleted. Most imports of iron ore come from the Soviet Union and India. For example, only 10% of Galati's iron ore requirement is satisfied by domestic ores. Romania imported also over 1 million tons of roasted pyrite, and exported only a small fraction of it. The only mention by the Romanian press of new iron ore mine development in 1978-79 was that of the Palas-Constanta Mine. The ore is located at a depth of 600 meters in folded strata.

Romania has a well-established iron and steel metallurgical industry, exporting small quantities of pig iron, crude steel, and steel semimanufactures. All crude steel is consumed domestically. Romania imports some pig iron, semimanufactures, crude steel, and ferroalloys.

The Galati iron and steel complex is the largest in Romania. Other major iron and steel works are the Hunedoara, Calarasi, and the Resita Complex. Romania is striving to expand and upgrade its steel production, and in 1979, 75,000 tons of stainless steel was produced. To date, Romania has not produced any ferroalloys, importing most of them from the Soviet Union, Poland, and Norway. By 1980, Romania plans to produce over 13% of alloyed steel and 52% of high-quality steel. The share of steel produced by oxygen converters is to increase to 44.2% in 1980, while the open hearth is to decrease to 37.5%; electric furnaces will constitute about 18%.[12]

In 1979, construction of a wire and a medium profile rolling mill started at Focsani in Vrancea County, approximately 70 kilometers northwest from the Galati iron and steel complex. Another wire rolling mill was under construction at Beclean in Bistita-Nasaud County, about 70 kilometers southwest of Baia-Mare. With the ongoing modernization of the Galati iron and steel enterprise, and a planned crude steel capacity in 1980 of 10 million tons, Romania expects to produce a total of 15.6 million tons of crude steel in 1980. Another developing aspect of the Romanian metallurgical industry, was the high investment in the special steel complex designed to produce Romanian-brand stainless steel sheets by the name of "Otelinox." After Galati, Tirgoviste (part of the Resita Complex) is the most important project of the Romanian iron and steel industry. By the end of the second construction stage in 1980, the production of crude steel is expected to reach a capacity of 1 million tons. The Calarasi is the newest Romanian steel works project, slated for full operation in 1981.[13] Reportedly, the first batch of steel at Calarasi in an electric furnace was produced in November 1979. According to reports, the steel output of Calarasi is to be nearly 2 million tons by 1985, and 10 million tons by 1990. Thus, the long-term crude steel plans include the expansion of domestic production to over 25 million tons by 1990, increased exports, and a decrease in imports.

Lead and Zinc.—Romania, in its 1979 annual statistics yearbook, published the production of lead and zinc for the first time.[14] The output of lead and zinc metal has been stable since 1970, with minor yearly fluctuations. In 1978-79 about 5 million tons of lead and zinc ore was processed each year, with approximately 0.67% lead and 1.20% zinc metal content. Romania also imports small amounts of lead ore and concentrate, lead and zinc oxides, and finished metal, depending on the yearly requirements. The entire output is consumed domestically.

NONMETALS

Cement.—Romania is self-sufficient in cement production. About 12 cement plants scattered throughout the country are increasing production steadily for a domestic consumption of over 11 million tons. The recently completed Tasca cement plant in Neamt County, the Moldavian Carpathians, is the largest and most efficient in Romania. It is planned to increase production capacity of the Romanian plants up to over 20 million tons by 1980.

To cut its energy consumption, Romania is attempting to curb and streamline its output of energy-intensive products. The research in the use of tuff as an admixture in cement is one such attempt. Romanian reserves of tuff amount to thousands of millions of tons, located primarily in Slanic, Vilcea, and Persani areas. Other smaller deposits occur in Salaj, Cluj, Bistrita-Nasaud, Vilcea, Ara-Severin, and Constanta Counties, providing raw materials for the construction industry. Reportedly a new technology has been developed and a plant designed for the production of cellular concrete from tuffs. In addition, the old wet-processing method is now being replaced by the dry-processing method in many of the Romanian plants, including various other energy-saving measures. In addition to the Tasca-Bicaz, the Deva cement plant was also nearing completion in 1978.[15]

Fertilizer Materials.—During the current 5-year plan, Romania has been steadily increasing the output of its manufactured fertilizers except for a slight decline in 1978. Romania manufactures all of its nitrogenous fertilizer, and exports over 50% of it worldwide. All of the crude phosphate and apatite concentrate, and manufactured phosphatic fertilizer, are imported for domestic consumption. Romania also imports all of its requirements for the manufactured potassic fertilizer. The approximate consumption of chemical fertilizers in 1978-79 may have reached over 1.5 million tons of active substances annually. Phosphate rock and potassic fertilizers are imported from Israel, the U.S.S.R., the United States, Morocco, Syria, Algeria, Jordan, the Democratic Republic of Germany, and the Federal Republic of Germany. Exports of nitrogenous fertilizer and ammonia are directed to the market economy and other countries throughout the world.

According to published reports of the COMECON countries, a Romania is second only to the Soviet Union in terms of numbers of chemical plants on hand. Romania also maintains a second position after the Soviet Union in the fertilizer industry, with a total capacity of 1,650,000 tons of ammonia and 1,269,000 tons of urea annually.

The 1980 plan envisages a production increase in the chemical industry in general, with an output of almost 4 million tons of fertilizers. In additiion to the newly expanded Turnu Magurele plant, the fertilizer combines at Bacau and Slobozia were reportedly also planned for expansion in 1980.

The production capacity of the Romanian fertilizer and chemical plants is summarized in the table below:

Plant Location	Product	Capacity (tons per year)
Arad	Ammonia	300,000
	Complex fertilizer	891,000
	Diammonium phosphate.	17,000
	Nitric acid	480,000
	Urea	420,000
Bacau (relocated from Tecuci).	Ammonia	300,000
	Complex fertilizer	891,000
	Nitric acid	480,000
	Urea	420,000
Craiova	Ammonia	300,000
	Complex fertilizer	891,000
Navodari	Phosphoric acid	20,000
	Superphosphates (single and triple).	600,000
Piatra Neamt	Azot No. 4 plant nitrogen.	140,000
	Urea	1,000
Slobozia	Urea	420,000
Tirgu Mures	Complex fertilizer plant.	891,000
	Ammonia plant (3)	300,000
Turnu Magurele	Complex fertilizer	891,000

Sand and Gravel and Stone.—In 1979, the Romanian Ministry of Mines, Oil and Geology undertook a country-wide sand and gravel and building stone reserves mapping and exploration program. An effort was made to locate the reserves for eventual mining and transport to areas of need. Thus, for example, the granite in northwestern Dobruja region could meet all the needs of the eastern Wallachia and Southern Moldavia. The known undepleted sand and gravel quarries were planned for expansion (such as Taul Rosu, Cicirlau-Maramures, and Suseni-Harghita), and new reserves were mapped (Zam-Hunedoara, Piatra, Tisei-Maramures and Tarcau-Piriul Caprei-Bacau). In the southern Moldavia, Wallachia, and Oltenia regions, sand and gravel are localized to the Danube River Valley and its tributaries, such as the Siret, Buzau, Prahova, Arges, Otr, Mures, and Somes. The Ministry also planned to examine the utilization of sand and gravel overlying the coal beds in Oltenia. Reserves of commercially usable limestone have been mapped in Dobruja and Oltenia; of scoria in the Racosul de Jos-Valea Bogatii zone; of volcanic tuff in the Transylvania region (Vilcea, Prahova, and Bacau Counties); diatomite in Patirlagele, Adamclisi, Filia, and Minis; and perlite in the Orasu Nou zone, to name only the most important reserves. The Ministry stressed that for the sake of energy conservation, those reserves located closest to the existing transportation facilities to be used first. The table below summarizes the reserves compiled for some of the building materials.[16]

Building materials	Usable reserves: Total	Usable reserves: Percent now in use	Annual consumption	Supply of reserves (years): Total	Supply of reserves (years): Now in use	Number of deposits: Total	Number of deposits: Now in use
Hard rocks (mostly granite, crushed) thousand tons	1,707,283	62.3	24,365	70	44	171	120
Ornamentals do	52,054	37.9	218	238	91	55	27
Sand and gravel thousand cubic meters	1,114,803	47.3	27,409	41	19	204	110
Scoria, tuff, diatomite thousand tons	25,235	14.8	398	634	94	10	5
Perlite, dacite do	2,052	0.8	4	513	38	12	3
Limestone (for cement) do	757,824	69.5	6,954	109	76	162	104
Miscellaneous rocks do	3,816,350	71.6	35,655	107	77	85	42

Sulfur.—All of Romania's sulfur is produced from pyrite and as a byproduct of oil processing. Romania mines some of its own pyrite, but large quantities of roasted pyrite are imported from Italy. Elemental sulfur is also imported mostly from Poland, and sulfuric acid from the German Democratic Republic and Hungary. An insignificant quantity of roasted pyrite is exported, much of it to Hungary. All of the sulfur and acid, however, are used domestically, with the consumption of sulfur growing steadily.

Most of Romania's cupreous and auriferous pyrite reserves are located in the Carpathians and in Transylvania, with some of the cupreous pyrites also occurring in the northern Dobruja region in the southeast. Reportedly, a new mining facility was put into operation at Calimani in 1979 for the mining there of the newly discovered sulfur-bearing ores.

MINERAL FUELS

Romania's primary sources of energy in 1978-79 were petroleum, natural gas, and hydropower. While the 1980 energy policy was being developed, the energy situation in 1978 worsened; Romania in 1979 did not meet its target for the production of crude oil, and was facing severe supply and price problems in crude oil imports. Even though Romania's reserves of coal and natural gas are substantial, the output of natural gas was being leveled off, and coal production grew considerably less than planned.

Romania, however, began to attach high priority to development of its electric power sector which it considers to be a prerequisite for the overall economic development of the country. The largest hydroelectric generation facilities in Romania are located on the Danube River: "Iron Gates I" and "Iron Gates II," constructed in cooperation with Yugoslavia and the Soviet Union, and "Turun Magurele" station built in cooperation with Bulgaria. The current energy policy is aimed at directing Romania's gas reserves increasingly for use as feedstock in the chemical industry, while additional power generation is to be based on low-grade domestic solid mineral fuels such as lignite and shale, and on hydro and nuclear power.

Overall, Romania consumes two to three times more power per unit of output than many of the industrialized countries, simply through excessive or inefficient usage. The ferrous and nonferrous industry, for instance, consumes about 28% more energy than France and 14% more than Sweden. The chemical industry consumes four times more than France and five times more than Sweden.[17] Industry uses over 70% of the total primary energy resources. The metallurgical industry used almost 24% and the chemical industry 35% of the primay energy in 1978-79. During the next decade, however, the industry has been directed to cut the consumption of power to 40%. To achieve energy self-sufficiency by the end of the next decade. President Ceausescu, in 1979, called for a gradual reduction of oil and other fuel imports, for the promotion of the less energy-intensive industrial branches, for energy conservation in general, for a more intense search for domestic oil, gas, and coal reserves, and for the elevation of oil extraction above its present rate of some 25% to 30%. It is estimated that at present, Romania's energy self-sufficiency stands at about 75%.

To broaden its base for hydrocarbon supply, Romania in 1978-79 continued to seek international participation in geological research, oil drilling projects, and joint ventures. In addition, Romania provided oil drilling equipment and personnel for the exploration and construction of refineries abroad.

Virgil Trofin, Minister of Energy, speaking at the 12th Congress of the Romanian Communist Party in Bucharest on November 20, 1979, reported that Romania's installed total power at present is almost 15,000 megawatts, and that 25 new power stations were commissioned during the current 5-year plan, of which 6 were fueled by coal. In 1980, hydroelectricity is to account for almost 18%, and hydrocarbons and coal is to account for 40% each of total produced power, with over 2% being contributed by solar power. According to some reports, by 2000 Romania will also become one of the most important markets in Eastern Europe for equipment and research projects dealing with solar energy.[18]

The total Romanian primary energy balances for 1978-79 are shown in the following table:

Romania: Total primary energy balance for 1978-79

(Million tons of standard coal equivalent)[1]

Year	Total primary energy	Coal lignite, anthracite, bituminous, coke	Crude oil and petroleum products	Natural and associated gas	Hydropower, etc.
1978: [2]					
Apparent consumption	83.3	17.8	22.7	41.8	1.0
Exports	10.9	--	10.3	.3	.3
Imports	18.5	5.7	12.7	--	.1
Production	75.7	12.1	20.3	42.1	1.2
1979: [2]					
Apparent consumption	83.8	20.1	20.4	42.2	1.1
Exports	11.3	--	10.7	.3	.3
Imports	19.0	5.9	13.0	--	.1
Production	76.1	14.2	18.1	42.5	1.3

[1] 1 ton of standard coal equivalent (SEC)=7,000,000 kilocalories. Coversion factors used are: hard coal, 1.0; lignite and brown coal, 0.33; coke, 09; crude oil, 1.47; natural gas, 1.33 (per 1,000 cubic meters); hydroelectric power, 0.123 (per 1,000 kilowatt-hours).

[2] Production-production table.

Coal.—In 1979, Romania reported the production of run-of-mine and washed coal, and also the output of coke. During 1978-79, Romania, however, did not reach its planned production goal.

In 1978-79, lignite accounted for 75% of total coal by tonnage, mined mostly in the Southern Carpathians, near Tirgu Jiu. The 25% or so of the anthracite and bituminous coals come from the Valea Jiului (Jiu Valley), in the Oltenia Region. Romania possesses adequate reserves of lignite, primarily used for the generation of electric power. Total coal reserves in Romania are estimated at 3,000 to 4,500 million tons. Although lignite is able to meet electric power generation requirements, coking coals continued to be imported for the metallurgical industry.

Reportedly, over 600,000 tons of metallurgical-grade coal was purchased by Romania from Canada's Kaiser Resources Ltd. in 1978. A joint agreement for the development of metallurgical coal reserves in British Columbia at Quintette (Denison Mines) was signed with Canada in 1978. Romania plans to purchase about 1.5 million tons annually of metallurgical coal over the next 20 years from the Denison Mines. Delivery may start in 1982 at the rate of about 1.4 million tons annually, and Romania expressed an interest in acquiring a 10% equity in the project.

In 1979, in addition to existing import of bituminous coal from Canada, Romania finalized its purchase agreement of 400,000 tons annually of coal from the Occidental Petroleum Co.'s subsidiary, Island Creek Coal Co. in Virginia. Additional Island Creek exports may start in 1980, initially at 500,000 metric tons. Romania also imports coal from the Democratic Republic of Germany, the Federal Republic of Germany, India, and the Soviet Union, and in the future may purchase coal from Australia.

Natural Gas.—According to Romanian plans, the production of natural gas in 1978-79 decreased from 1977, and has been leveled off in lieu of increased usage of coal as the primary energy source. Furthermore, in 1979 Romania began receiving gas from the Soviet Union through the completed Orenburg pipeline. Deliveries in 1979 by this pipeline were to total 0.8 billion cubic meters and are to increase to 1.5 billion cubic meters annually during the 1981-85 period. Although Romania's participation in the Orenburg project was somewhat less than that of other COMECON countries, the amount of gas that will be received as payment is significant, representing about 2.8% and 5.2%, respectively, of total Romanian gas production in 1979 and 1980. Romania exports a small amount of gas, mainly to Hungary. Natural gas remained Romania's most important source of primary energy production. In 1978, natural gas supplied about 50% of all electrical power produced in Romania.

The Romanian natural gasfields are over 95% pure methane, with a high heating rate. The Romanian upcoming 1981-85 5-year plan provides for a decrease in the production of methane gas to about 26.5 billion cubic meters annually by 1985. Most of Romania's reserves of natural gas are concentrated in the northwest, in the Ardeal region. Depending on sources, Romania's gas reserves are estimated to suffice for the next 10 to 20 years, at present production rates.

In addition to the newly built Orenburg gas pipeline, a pipeline feeding gas from the Soviet Union to Bulgaria already crosses Romania near its Black Sea coast. One of the Soviet's 1979 top-proirity projects was the construction of a new gas pipeline from the Shebelinka gasfield in the Ukraine to Izmail on the Soviet-Romanian border. Soviet gas deliveries are guaranteed to 1990, with an optional extension for a further 10-year period.

Petroleum.—Romania is the only significant producer of crude oil in Eastern Europe. It did not meet its goals for crude oil production, targeted at 15.1 million tons for 1978, and 14.8 million tons for 1979. In 1979 Romania imported over 50% of its crude oil requirements for domestic consumption and for export of petroleum products, on which the country's economy depends heavily. According to some reports, exports of petroleum and petroleum products represented 9% of the total exports and 14% of the total imports in 1978. Romania also participated in various cooperation projects in the petroleum sector with partners in more than 20 countries, the majority being developing countries, to insure Romania's future petroleum needs. Reportedly, Romania in 1978 imported several million tons of Iranian oil, and has been negotiating for alternative supplies from Algeria, Libya, China, Indonesia, Venezuela, Mexico, Nigeria, and Middle Eastern countries such as Iran, Iraq, and Kuwait.

One of the basic objectives of President Ceausescu's April 8-25, 1979 tour of eight African countries was to look for assured supplies of vital raw materials for Romania, most importantly oil and gas.[19] In addition to the official visits to oil-producing States, Romania in 1979 hosted the World Petroleum Congress. The congress provided another occasion for discussions with oil companies and representatives of oil-producing States about the supply problem.[20]

Romania is the only COMECON country that does not import oil from the Soviet Union. Some reports indicate, however, that Romania approached the Soviet Union for crude shipments in 1979. Those purchases would be initially small and without any long-term commitments by either side.

In 1979, President Ceausescu called for gradual reduction of imports of oil and other fuels so that self-sufficiency could be reached by the end of the next decade. To achieve this goal, a number of measures have been recommended including the search for domestic oil, gas, and coal reserves, and to raise the degree of oil extraction above its present rate of about 32%. According to Vasile Patilinet, Minister of Mines, Oil, and Geology, the recovery factor will rise to 37% in 1986, and to approximately 40% in the 1990-2000 period.[21]

In line with the program of energy self-sufficiency, of major importance in 1979 was the announced discovery of oil in the Black Sea, off the Romanian coast, by the Gloria drilling platform. Reserves and production are as yet undetermined. Another Romanian-built off-shore oil platform, Former 2, was being built in 1979 at the 1 May Works in Ploiesti. Once completed it will be sent to Galati and then will join the Gloria platform in the Black Sea.

Domestic production of refined products was interrupted in 1978, by an explosion at the Pitesti oil refinery. During the night of October 30-31, an explosion in the catalytic cracking unit caused a fire that killed nine people and injured others, and a number of installations were put out of action. The Pitesti oil refinery is part of a massive petrochemical complex that is comprised of 96 different plants, employing about 9,000 workers. The Pitesti refinery reportedly processes exclusively imported rather than domestic crude.

Negotiations were reportedly underway in 1979 between Romania and Nigeria for the continuation of construction of an oil refinery at Media-Navodari on the Black Sea coast, a project that had been delayed after negotiations with Kuwait stalled in 1978. Nigeria will eventaully supply the crude oil for the refinery. Part of the new refinery, which is specifically designed for export purposes, went onstream in 1979. The planned annual capacity of the completed Navodari refinery of 3.5 million tons is to be reached in 1982.

In 1979, a 3.5-million-ton annual capacity unit was also added to the existing Borzesti refinery. Reportedly, a total of 15 new petrochemical units were planned to be put into operation during the 1976-80 5-year plan.

Nuclear Power.—Romania continued to plan the development of its nuclear industry. In 1978, an agreement was signed with Canada for the purchase of four 600-megawatt CANDU reactors using natural uranium. The 1978 agreement was part of a plan that would eventually provide for up to 16 nuclear plants by 1990. Some of the 16 planned reactors are to be built entirely by Canada, and some by Romania under a license. The first complex of four units to be constructed in the southeastern part of the country (Olt and Cernavada) is expected to go on-line in 1985. This was the first sale of a Canadian nuclear reactor to a centrally planned economy country. Romania has also purchased a nuclear reactor from the Soviet Union with a 440-megawatt capacity for a power station that is to be completed by 1983. According to Romania's long-term plan, the power station will represent a 5.5% share in total power production in 1985 and 20% in 1990.

Reportedly, Romania in 1979 concluded a 3-year contract with Gabon providing for annual deliveries of 100 to 150 tons of uranium beginning in 1986. Romanian uranium mines will not be able to supply the needed nuclear fuel. According to some estimates, Romania has 10,000 to 20,000 tons of reasonably assured uranium reserves, and an additional 20,000 to 50,000 tons of estimated reserves. Romania's estimated annual production of uranium was 1,000 tons in 1978.

The Mineral Industry of Saudi Arabia

By Candice Stevens[1] and W. Thomas Cocke[2]

Increased oil revenues accounted for the rapid growth of Saudi Arabia's gross national product (GNP), from $5 billion[3] in 1970 to $63 billion in 1978 and to an estimated $76 billion in 1979. The contribution of the petroleum sector to the GNP had risen to about 60% by 1979. However, diversification of the economy was a top priority of the Government in the late 1970's, and large investments were made in nonpetroleum enterprises. Nonfuel minerals production was mainly for construction and industrial uses, and mineral exploration continued at a high level by both the Government and a number of foreign firms.

Two new industrial centers, Jubail on the east coast and Yanbu on the west coast, were the focus of the Government's development efforts during 1978 and 1979. By the end of 1979, $4 billion had been committed for 275 contracts for Jubail, with emphasis on creation of an infrastructure. The expansion project to raise the handling capacity of Yanbu Port to 2.7 million tons per year was completed at a cost of $340 million. The 1978-79 and 1979-80 budgets ($38 billion and $47 billion respectively) were largely devoted to finishing projects begun under the second 5-Year Development Plan (1975-79) and efforts to reduce Government expenditures and control inflation. The third 5-Year Development Plan (1980-84), with a projected budget of more than $250 billion, was expected to focus less on infrastructure development and more on industrial projects and development of human resources.

In January 1978, the Government issued new requirements for foreign investors. Saudi Arabia invited foreign and national private investment in mineral enterprises, but retained an option to acquire up to 50% interest in any such venture. Other provisions required foreign firms to have a Saudi agent or partner, limited the issuance of visas for dependents to highly skilled workers, gave preference to projects with the fewest possible employees, and required foreign contractors with more than 100 employees to provide their own housing. Housing shortages, port congestion, and staggering rates of inflation caused by the 1975-76 oil boom, were relieved by energetic Government efforts begun in 1977.

PRODUCTION

Saudi Arabia's petroleum production decreased in 1978 owing to lowered production ceilings and weak work demand, but remained second only to that of the U.S.S.R. In 1979, however, production was near record high levels, as a result of a temporary increase in the production ceiling for most of the year. The temporary increase lifted the ceiling to 9.5 million barrels per day and was effected in response to disruptions in the supply of oil from Iran. Total oil receipts were down in 1978, but rose sharply in 1979.

The Arabian American Oil Co. (Aramco) was the sole producer of oil in Saudi Arabia, except for the production shared with Kuwait in the partitioned Neutral Zone. Total oil and natural gas liquids (NGL) production in 1979 was nearly 10 million barrels per day. In December 1978, the Organization of Petroleum Exporting Countries (OPEC) decided to raise prices in quarterly increments that would have totaled 14.5%

over the course of 1979, but by December 1979, prices for Arabian light crude were $24 per barrel, or nearly double the December 1978 price. Aramco reported proven petroleum reserves of 113 billion barrels and proven plus probable reserves of 178 billion barrels. Petroleum reserves in the Neutral Zone were estimated at 3.5 billion barrels. By the end of 1979, Saudi Arabia's oil-producing capacity had risen to nearly 11 million barrels per day.

The Ras Tanura facility, operated by Aramco, was Saudi Arabia's largest producer of petroleum products and NGL, and the facility's production of these products rose sharply during 1978 and 1979. Production of cement and fertilizers also rose sharply during this period owing to the expansion of facilities. Saudi Arabia also produced small quantities of other nonmetallic minerals. Mineral production for 1978 and 1979 is shown in Table 1.

Table 1.—Saudi Arabia: Production of mineral commodities

Commodity and unit of measure	1976	1977	1978[p]	1979[e]
METALS				
Iron and steel: Crude steel ---- thousand metric tons	[r]5	[r]5	5	5

[1]Data are for the Hejra calendar year, which corresponds closely to the Gregorian calendar year.
[2]Includes Saudi Arabia's 1/2 share of production in the Kuwait-Saudi Arabia Partitioned Zone.

TRADE

Saudi Arabia's balance-of-trade surplus decreased in 1978 for the first time in several years. Decreasing oil revenues and increasing imports of goods and services combined to reduce the large trade surplus, but in 1979, the upward trend returned and petroleum receipts rose rapidly.

Saudi Arabia is the world's largest exporter of petroleum. The main recipients of Saudi crude oil were Western European countries, Japan, and the United States. The country also exported refined petroleum products and was the world's largest exporter of NGL, which was exported principally to Japan and Western Europe.

The Government embarked on a massive port-expansion program to relieve congestion at the country's crowded terminals.

The large port of Damman on the east coast was scheduled to be modernized and expanded to handle larger oil tankers. New commercial ports were under construction at Jubail and Yanbu to handle general and industrial bulk cargo and liquid products. Hyundal Construction Co. Ltd. (Republic of Korea) was contracted for work at Jubail Port and Frederic R. Harris Inc. (United States) was designated master planner for Yanbu Port. Construction by Fluor Corp. (United States) proceeded on the Ju'aymah terminal, which was expected to be the world's largest NGL export facility.

COMMODITY REVIEW

METALS

Exploration for metallic minerals on the Arabian Shield continued by a number of foreign companies under licenses granted by the Directorate General of Mineral Resources (DGMR). The French Bureau de Recherches Geologiques at Minieres (BRGM) continued its general exploration program in central Saudi Arabia. Investigation of mineral deposits in western Saudi Arabia was being conducted by the U.S. Geological Survey (USGS). Hunting Surveys Ltd. (United Kingdom) proceeded with the surveying and mapping of Eastern Province. Rio Tinto Finance & Exploration Ltd. (Riofinex), a subsidiary of Rio Tinto-Zinc Corp. Ltd. (United Kingdom), was providing an overall feasibility study on the exploitation of Saudi Arabia's mineral deposits under a 5-year contract.

In 1978, Utah International Inc. (United States) was awarded an exploration concession in the Wadi Ablah area of the Arabian Shield. The prospecting focus was expected to be on copper, lead, zinc, and gold mineralization. Fairey Surveys (United Kingdom) was awarded a $2 million contract for the preparation of geologic maps covering a 110,000-square-kilometer area of the Arabian Shield.

In 1979, Arabian Geophysical and Surveying Co. (ARGAS) was awarded a $27 million contract for mapping 400,000 square kilometers of Rub Al-Khali in the southeastern desert area of Saudi Arabia. ARGAS is 51% owned by the General Petroleum and Mineral Organization (Petromin) and 49% owned by French Cie General de Geophysique.

The 60-square-kilometer Atlantis II Deep Basin area was selected by the Saudi-Sudanese Commission for the Exploration of Red Sea Resources for the site of a pilot mining project to recover metal-bearing sediments from the Red Sea floor. In 1978, the U.S. research vessel Melville conducted a program of geological and geophysical surveys in an area of the Atlantis II Deep Basin that was estimated to contain seabed deposits of zinc, copper, silver, and other materials valued at $3.5 billion. In 1979, a mining system consisting of a vibrating suction sieve and a series of hydraulic pumps was developed and tested by Orenstein and Koppel AG, working under a contract to Preussag AG (both Federal Republic of Germany). About 3,500 cubic meters of material was recovered and stored, and construction of a pilot processing plant at Yanbu was planned.

Aluminum.—Southwire Ltd. (United Kingdom) was commissioned in 1978 for a feasibility study of a planned aluminum smelter to be located in Jubail. Design work for the smelter had been postponed in 1976 owing to delays in the gas-gathering program. The $1 billion smelter was expected to reach full production by 1986, and its projected annual production of 225,000 tons of aluminum ingot was destined primarily for export markets.

Aluminum Products Co. (Alupco) brought into production an aluminum-extrusion plant in Damman in 1978. Designed by Alusuisse (Switzerland), the plant was expected to produce 5,000 tons per year of aluminum products, mostly for domestic use. A number of small plants, with a combined capacity of 37,000 tons per year, manufactured aluminum products in Saudi Arabia. In 1978, the Government acquired a 20% interest in the smelter operated by Aluminum Bahrain Ltd. (ALBA) in Bahrain.

Copper.—After 2 years of exploratory work and drilling, evaluations of Saudi Arabia's copper deposits proved disappointing. Noranda Ltd. (Canada) reported that the Kutan deposits, located in the south near the Yemeni border, were too low in copper grade to be of economic value. Also, the Societe d'Etudes de Recherches at d'Explorations Minieres (SEREM) completed its feasibility study of copper deposits at Jabal Sayid, which is located between Mecca and Medina. SEREM determined that exploitation of the deposit, estimated to contain reserves of 8 million tons, was not commercially viable.

In 1979, the Saudi Ministry of Finance granted an interest-free loan of $11 million to the Arabian Shield Development Co. to finance underground exploration and development of the Al Masani area. Drilling has indicated significant amounts of copper, zinc, gold, and silver in two lenses with a combined strike length of 1,600 meters. Watts, Griffis, and McQuat Ltd. was appointed manager of the underground development project, and National Mining Co. was the Saudi partner in the venture. In 1978, Granges AB (Sweden) received a license to explore the Al Nagra copper-zinc deposit located 200 kilometers northeast of Medina. Petromin reserved the right to enter into a joint venture with Granges in the event that commercial exploitation is considered.

Gold.—Petromin acquired a 50% share in the exploration license held by Consolidated Gold Fields for the gold deposits at Mahd adh Dahab. Plans were for Petromin to participate in the third stage of the Mahd adh Dahab exploration program, which was expected to involve drilling and the extraction of bulk samples. Consolidated Gold Fields obtained its license in 1976 for an area of 1,600 square kilometers, northeast of Jidda. Reserves were estimated at 1.5 million ounces of gold and 5 million ounces of silver contained in 6 million tons of comparatively low-grade ore lying close to the surface. No decision on commercial production was expected to be made until 1980.

Iron and Steel.—British Steel Corp. (United Kingdom) continued its study of the Wadi Sawawin iron ore deposits located in northwest Saudi Arabia near the Gulf of Aqaba. The firm was awarded a $15 million contract in 1976 to investigate these deposits, and a final report is due in 1981. Mapping and drilling was being conducted in 1978 to verify the tonnage and grade of the Wadi Sawawin reserves, which were originally estimated at 350 million tons averaging 42% iron.

A final agreement was signed in 1978 with Korf Stahl AG (Federal Republic of Germany) for construction of an iron and steel complex in Jubail. An initial annual production capacity of 850,000 tons of steel billets was anticipated, and the complex was expected to employ the Midrex direct-reduction process, using local natural gas. The facilities were expected to be eventually expanded to 4 million tons per year. Plans were to import iron ore, pending the development of the Wadi Sawawin iron ore deposits. Construction of the $600 million complex was begun in April 1979 and was scheduled to be completed in 1982. The plant was to be owned 80% by the Saudi Arabian Basic Industries Corp. (SABIC) and 20% by Korf Stahl.

Another joint venture was concluded between SABIC (50%) and Korf Stahl (50%) for the modernization and expansion of the Jidda steel-rolling mill. It was planned that the mill's capacity would be increased to 140,000 tons per year of reinforcing bars. The mill was to use imported billets until the Jubail iron and steel complex starts up. The estimated cost of the project was $30 million.

The National Pipe Co., owned 60% by Saudi interests and 40% by Sumitomo Metal Industries (Japan), began construction of a plant at Damman that was scheduled to be completed in July 1980. The plant was expected to produce 80,000 tons per year of spiral-weld pipe.

Saudi Metal Industries began construction of a reinforcement bar plant in Damman in 1979. Production was projected at 20,000 tons per year. The $9 million plant was undertaken as a joint venture by Saudi and British interests (60% and 40%, respectively).

Uranium.—In 1978, the DGMR signed an agreement with Minatome (France) for a 3-year survey for radioactive minerals. The results of a recent aerial survey indicating several radioactive occurrences in Saudi Arabia prompted the DGMR's contract with Minatome for a more extensive study. After general surveying and mapping, Minatome was expected to undertake detailed prospecting in selected areas.

NONMETALS

Cement.—Saudi Arabia's cement consumption increased to 10 million tons in 1978, 80% of which was imported. In 1978, a 1-million-ton-per-year cement plant constructed by Skanska Cement (Sweden) opened in Yanbu, bringing domestic production capacity to 2.5 million tons per year. In 1979, Saudi Cement Co. awarded Polysius AG (Federal Republic of Germany) an $84 million turnkey contract to modernize and expand the Hofuf plant to 1 million tons per year. The third 5-Year Development Plan called for an increase in domestic production capacity to 10 million tons per year. The construction of four new plants was planned as follows:

Location	Operator	Startup date	Capacity (tons per year)
Quassim-Buredah	Quassim Cement Co	1980	730,000
Abqaiq	Saudi-Bahraini Cement Co.	1980	550,000
Neutral Zone	Saudi-Kuwaiti Cement Co.	1981	2,000,000
Rabigh	Jidda Cement Co	1981	1,000,000

Fertilizer Materials.—The Saudi Arabian Fertilizer Co. (SAFCO) initiated its own marketing program in 1978 as production continued to increase. Annual production capacity was rated at 220,000 tons of ammonia, 400,000 tons of urea, 10,000 tons of sulfur, and 20,000 tons of sulfuric acid. SAFCO's plant, located in Damman, was previously operated by Occidental Petroleum Co., and marketing was managed by its subsidiary. In 1978, SAFCO exported approximately 130,000 tons of urea to India and Pakistan. Sim-Chem (Korea) was contracted to construct a new sulfuric acid unit to increase production to 120,000 tons per year.

In 1978, SABIC reached an interim agreement with the Taiwan Fertilizer Corp. (TFC) for construction of a nitrogen fertilizer complex in Jubail that was expected to produce 1,000 tons per day of ammonia and 1,600 tons per day of urea. A feasibility study was completed in 1979, and the Pullman-Kellogg Group (United States) was awarded a $250 million contract to provide preliminary designs, engineering work, startup assistance, staff training, and to purchase equipment and materials. Completion was scheduled for mid-1982. TFC is committed to purchasing 60% of the output.

Feasibility studies on the construction of a triple-superphosphate plant in northwest Saudi Arabia were also planned. The plant was under consideration as a joint venture of Lebanon Chemicals Inc. and the Research and Development Corp. (REDEC), and annual production capacity was projected at 700,000 tons of phosphatic fertilizer.

Phosphate.—The Government embarked on a major study of transportation, water, harbor, and other infrastructure needs in preparation for the possible exploitation of the Thaniyat phosphate deposits. Granges AB continued its drilling and mapping program in a 2,500-square-kilometer area in the northwest corner of the country. Reserves in the Thaniyat district were estimated at 242 million tons of phosphate grading 24% P_2O_5. In the event of exploitation, plans were for a joint venture to be formed between the Government and Granges on a 50-50 basis. In 1979, the Government granted a license to Riofinex for evaluation of the phosphate potential of the Turaif Basin on the northern border of Saudi Arabia.

Magnesite.—SEREM continued its study of magnesite deposits at Zarghat for Saudi Arabia Magnesite Ltd. Reserves at Zarghat, located south of Jabal Said, were estimated at 1 million tons containing more than 95% magnesium carbonate and less than 2% silica. Exploration of the deposits was scheduled to begin in 1979 at the rate of 100,000 tons per year. SEREM was to obtain a 15% share in the operation.

MINERAL FUELS

Natural Gas.—Over half of Saudi Arabia's associated natural gas production was flared, and the remainder was used for oilfield reinjection, fuel for local industries, and NGL production. Saudi oil producers were increasingly utilizing reinjection, owing to the problem of water encroachment, a rising demand for fuel by growing local industries, and greater production of NGL.

Aramco continued construction of the major gas-gathering and treatment system that was contracted for by the Government. In July 1979, the NGL plant at Berri was brought up to full capacity; the entire system was scheduled to be in operation by 1984. The projected processing capacities of the various units were as follows:

Product and location	Design feed[1]	Startup date
Gas:		
Abqaiq	600 MMcfd	1973
Berri	600 MMcfd	1977
Shedgum	1,400 MMcfd	[2]1980
Uthmaniyah	1,400 MMcfd	[2]1981
Natural gas liquid:		
Ras Tanura	360,000 bpd	[2]1973
Ju'aymah	270,000 bpd	[2]1982
Yanbu	270,000 bpd	[2]1984

[1]MMcfd Million cubic feet per day; bpd Barrels per day.
[2]Projected.

Petroleum.—*Production.*—The takeover of Aramco by the Government was completed in 1979, and Aramco became a service company under contract to the Government. A new organization, the Saudi National Oil Co., was created to operate some of the existing petroleum facilities. Petromin was responsible for the marketing and distribution of petroleum products, the development of refining capacity, and Government participation in petroleum-related companies. Plans were for Aramco to continue to market the bulk of crude oil production.

Aramco operated under production ceilings set by the Government. The ceiling was set at 8.5 million barrels per day in 1978 and 9.5 million barrels per day for most of 1979. The light:heavy oil production ratio was scheduled to be increased progressively from 65:35 to 50:50 by the late 1980's. In accordance with decisions reached by OPEC, the price of Arabian light crude oil rose to $24 per barrel by yearend 1979.

Refining.—Domestic consumption of petroleum products increased to 430,000 barrels per day in 1979. Local requirements were expected to reach 700,000 barrels per day by 1984 and exceed 1 million barrels per day by 1988. Saudi Arabia planned a major increase in refining capacity to meet rapidly growing domestic demand as well as the demand from expanding export markets. Plans were for refining capacity to be distributed as follows:

Location	Operator	Startup date	Capacity (barrels per day)
Ras Tanura	Arabian American Oil Co. (Aramco).	1945	600,000
Mina Saud	Getty Oil Co. (GOC)	1958	100,000
Ras al-Khafji	Arabian Oil Co., Ltd. (AOC)	1966	30,000
Jidda	Petromin/Saudi Arabian Refinery Co. (SARCO).	1968	95,000
Riyadh	Petromin	1975	100,000
Yanbu	do	[1]1982	170,000
Do	do	[1]1982	250,000
Jubail	do	[1]1980	250,000
Do	do	[1]1980	125,000

[1]Projected.

A new refinery in Yanbu was built as an alternative to expansion of the Jidda refinery, which recently attained a production capacity of 95,000 barrels per day. United Oil Products (UOP) (United States) received a contract for expansion of the Riyadh refinery to 100,000 barrels per day by 1980. The two refineries served the domestic market exclusively.

Construction of three export-oriented refineries was planned for the new industrial centers of Jubail and Yanbu. Petromin and Shell Oil Co. planned, on a 50-50 basis, to construct a 250,000-barrel-per-day refinery in Jubail. Shell began engineering and design work for the facility in 1978. Petromin also entered into a joint venture with Standard Oil Co. and Texaco Oil Co. for construction of a 125,000-barrel-per-day refinery in Jubail; interest shares were 50%, 25%, and 25%, respectively. Mobil Technical Services Inc. was awarded a $20 million contract for engineering studies for a proposed 250,000-barrel-per-day refinery in Yanbu that would be owned on a 50-50 basis by Petromin and Mobil Oil Co. It was anticipated that the refinery would produce gasoline, distillate fuels, and fuel oil to be marketed in the United States and Europe.

The Jidda Lube Oil Refinery, which is

owned 70% by Petromin and 30% by Mobil, began production in May 1978. Its output of approximately 500,000 barrels of finished base oils was sent to the Petromin Lubricating Oil Co. (Petrolube) plant, also located in Jidda. Full production capacity of the Jidda Lube Oil Refinery was estimated at 1 million barrels per year of lubricating oil base stocks, which were previously imported.

In 1979, Petromin entered into a joint venture with Chevron and Texaco (50%, 25%, and 25%, respectively) to construct a specialized lubricating oil refinery at Jubail. The facility, which would be one of the largest in the world, was expected to produce 12,000 barrels per day of lubricating oil base stocks for domestic use and was scheduled to begin production in 1984.

Petrolube, owned by Petromin (70%) and Mobil (30%), awarded a contract to Chiyodu Construction Co. (Japan) in 1979 for construction of a lubricating oil blending plant at Riyadh. Production capacity was projected at 175,000 barrels per year and production was scheduled to begin in 1981. Plans were for base stock lubricating oils to be supplied by the Jidda Lube Oil Refinery.

A fire damaged the Ras Tanura Refinery in August 1979. About 800,000 barrels of stored products were lost, but the plant was restored to full operating capacity by September 1979.

Petrochemicals.—Methane and ethane production from Saudi Arabia's gas-gathering program was expected to provide basic feedstock for a $7 billion petrochemical industry. SABIC, in a joint venture with a Japanese consortium, concluded an agreement in 1979 to study the feasibility of a $270 million, 600,000-ton-per-year methanol project to begin in 1983 at Jubail. This brought the number of joint ventures with foreign firms for the construction of petrochemical complexes at Jubail and Yanbu to seven. Under the agreement, financing was to be divided among SABIC (60%), the equity partners (30%), and other sources (10%). A feasibility study on boosting the ethylene capacity of the SABIC-Mitsubishi petrochemical complex at Jubail to 450,000 tons per year was completed. Advantages to foreign firms included low-cost feedstocks, low equity requirements, liberal tax incentives, and crude oil entitlements. Most of the projects were still in the planning stage.

Location	Ownership	Major product	Capacity (tons per year)
Jubail	SABIC-Shell Oil Co	Ethylene	656,000
Do	SABIC-Dow Chemical Co	do	400,000
Do	SABIC-Exxon Co	Polyethylene	240,000
Do	SABIC-Mitsubishi Chemical Industries Ltd	Ethylene	450,000
Do	SABIC-Celanese Chemical Co	Methanol	730,000
Do	SABIC-Japanese consortium	do	600,000
Yanbu	SABIC-Mobil Oil Corp	Ethylene	450,000

The petrochemical plant to be constructed by SABIC and Shell Oil Co. was in the most advanced stage. The agreement for this complex was signed in November 1979, and Fluor Corp. was designated as general contractor. C. F. Braun was selected to provide engineering services for the single-stream 656,000-ton-per-year ethylene plant. Other contracts were awarded to Dravo Co. (United States), for a 377,000-ton-per-year caustic soda unit and a 454,000-ton-per-year ehylene dichloride unit; Badger Inc. (United States), for a 295,000-ton-per-year styrene unit; and C. F. Braun (United States), for a 180,000-ton-per-year ethanol unit. Approximately 250,000 tons per year of ethylene production was expected to be supplied to the polyethylene plant that is to be constructed by a SABIC-Exxon joint venture known as Saudex. The remainder of the plant's output was slated for export. The SABIC-Shell complex was scheduled to go onstream in 1982 and was expected to cost $2.1 billion, rather than the $1.8 billion that was originally estimated.

Pipelines.—Construction was proceeding on the two transpeninsular pipelines being built to carry crude oil and NGL from the Eastern Province to Yanbu. Pipe laying began on the crude oil line in December 1978 and on the NGL line in March 1979. Both projects were scheduled for completion in 1981.

The Mineral Industry of Sierra Leone

By Candice Stevens[1] and Phyllis A. Lyday[2]

The mineral sector of Sierra Leone remained in a depressed state in 1978 following the closure of the Marampa iron ore mine and the decrease in diamond production. Despite lower output, the value of diamond production increased owing to a 30% rise in prices during 1978. Diamond ($102 million),[3] bauxite ($6 million), and refined petroleum products ($60 million) contributed to the 1978 gross national product (GNP). GNP calculated on a fiscal year basis was $817 million during 1977-78 and $901 million during 1978-79. The contribution of the mineral sector was expected to increase with the start of rutile production in 1979 and the potential exploitation of kimberlite diamond pipes. During 1978, mineral exports were approximately 70% of the total exports.

During the 1977-78 fiscal year, Sierra Leone's economy suffered from an inflation rate of 30%, the largest overall budget deficit in the nation's history ($85 million), a total external debt of $205 million, and a continuing balance-of-payments deficit owing to large oil imports. During the 1978-79 fiscal year, the inflation rate of 35% and the overall budget deficit was $84 million, double that of the previous fiscal year. An additional debt burden was Sierra Leone's scheduled role as host to the 1980 Organization of African Unity (OAU) Conference. In 1978, the International Monetary Fund (IMF) granted Sierra Leone a standby loan of $30 million contingent on the implementation of a number of corrective economic measures.

During December of 1978, the Government devalued the unit of currency, the Leone, by 5% and freed it from the sterling zone by linking it to IMF Special Drawing Rights (SRD) as part of an economic reconstruction package. When President Stevens failed to implement the package suggestions, IMF postponed the standby arrangement. In July 1979, new package suggestions were agreed upon and $22 million in IMF loans to support the economic stabilization efforts were approved by IMF. The Government was to restrict foreign borrowing, reduce Government spending, limit credit extension, and institute other budgetary reforms.

A new investment code was proposed to update the Sierra Leone Development Act which governed foreign investment; the code provided for tax holidays ranging from 2 to 5 years, exemption from import duties, and incentives for profit reinvestment. Internal transport facilities were to be upgraded and the ports authority was reorganized.

The first phase of harmonization of tariffs between Liberia and Sierra Leone under the Mano River Union protocols was completed in 1978. The European Economic Community financed a French firm to conduct feasibility studies for the development of a hydroelectric scheme of the Mano River Basin. Sierra Leone Electricity Corp. planned a fifth power station at King Tom to be undertaken by ABU (Federal Republic of Germany). A German engineering firm had completed plans for a proposed highway between the capitals of Freetown in Sierra Leone and Monrovia in Liberia. The Mano River Union also established four joint work force training institutes and was planning a number of industrial projects.

PRODUCTION AND TRADE

Production of Sierra Leone's major mineral commodities, diamond and bauxite, declined in 1978-79; however, the value of mineral production increased owing to the rise in diamond prices. Sierra Leone also produced small amounts of nonmetallic minerals and refined petroleum products. The production of rutile began in 1979. Mineral productin in 1978 is given in table 1.

At the end of fiscal year 1979, Sierra Leone's balance-of-trade deficit increased to approximately $80 million owing largely to the higher price of petroleum imports. Mineral production contributed about 70% of total export value in 1978 with diamond exports contributing 66% of that figure. All bauxite was exported unprocessed to Canada and the Federal Republic of Germany. Approximately 20% of the production of refined petroleum products was exported primarily to Liberia. Sierra Leone imported 7,000 tons of fertilizer in 1978 and 1.7 million barrels of crude oil from Nigeria. The United Kingdom remained Sierra Leone's principal trading partner by supplying the bulk of manufactured imports and taking about 60% of total exports.

Table 1.—Sierra Leone: Production of mineral commodities

Commodity[1] and unit of measure	1976	1977	1978[p]	1979[e]
Aluminum: Bauxite, gross weight ---- thousand metric tons--	651	745	716	720
Diamond:				
Gem ---- thousand carats--	433	423	283	285
Industrial ---- do----	650	538	424	425
Total ---- do----	1,083	961	707	710
Petroleum refinery products:				
Gasoline ---- thousand 42-gallon barrels--	231	331	394	[2]376
Jet fuel ---- do----	109	101	102	[2]96
Kersosine ---- do----	185	199	213	[2]239
Distillate fuel oil ---- do----	407	464	501	[2]523
Residual fuel oil ---- do----	423	824	412	[2]388
Liquefied petroleum gas ---- do----	3	10	10	[2]7
Refinery fuel and losses ---- do----	29	6	43	[2]49
Total ---- do----	1,387	1,935	1,675	[2]1,678
Salt ---- thousand metric tons--	180	180	180	180
Titanium: Rutile ore and concentrate, gross weight ---- do----	--	--	--	10

[e]Estimate. [p]Preliminary.
[1]In addition to the commodities listed, a variety of crude construction materials (clays, sand and gravel, and stone) is produced, but output is not reported and available general information is inadequate to make reliable estimates of output levels. Gold may occur, but data are not available for estimating production. Sierra Leone annually refines 4,000 to 10,000 metric tons of salt from imported crude marine salt, but this is not included in the body of the table because it would represent double counting of materials credited to the country where the salt was originally collected.
[2]Reported figure.

COMMODITY REVIEW

During 1979, a comprehensive article entitled "The Geology and Mineral Resources of Sierra Leone"[4] was published which included locations and descriptions of metallic and nonmetallic minerals. A history of the exploration and exploitations of these resources and a geologic map was also included.

METALS

Bauxite.—The Sierra Leone Ore and Metal Co. (SIEROMCO), wholly owned by Swiss Aluminum Ltd. (Alusuisse) (Switzerland), had mined bauxite in the Mokanji Hills near Moyamba in southwestern Sierra Leone since 1963. Remaining reserves were estimated at approximately 25 million tons of ore.[5] In 1978, SIEROMCO renegotiated with the Government its contract to exclude Government participation in the mining venture and to increase the tax and royalty rates to be paid by SIEROMCO. A new jetty was under construction at the port of Niti from which bauxite was shipped after being transported 21 kilometers from the Mokanji Mine.

Alusuisse continued its negotiations with the Government concerning the conditions for a new bauxite mine at Port Loko. In 1978, reserves at Port Loko were estimated at 70 million tons of ore containing 47% Al_2O_3; an additonal 34 million tons was highly probable.[6] The Government was to have a 50% share in the mining venture and would receive taxes and royalties from Alusuisse after an initial 5-year tax holiday. Alusuisse was to have use of the abandoned Sierra Leone Development Co. Ltd. (DELCO) railroad from Marampa to the Port of Pepel. Production of 1 million tons of bauxite per year was to begin in the mid-1980's. An alumina plant, financed by an international consortium led by Alusuisse, was to be constructed in Pepel.

Gold.—Eurocan Ventures Ltd. (EVL) (Canada) entered into a joint venture gold agreement with Diamond Distributors Explorations Inc. (DDX) (United States). After an initial investment of $2 million for a 60% interest of a 10-square-mile diamond-gold concession, the cost of development will be prorated. DDX will maintain the diamond rights.

Iron Ore.—The Government contracted LKAB International AB (Sweden) to conduct a feasibility study for reopening the Marampa iron ore mine located in the Port Loko district. The study was to include assessment of ore reserves, evaluation of existing facilities, and prediction of potential for producing salable products. The Marampa iron ore deposits were mined by DELCO from 1933 until 1975 when the company encountered financial difficulties. Reserves were last estimated at 67 million tons of 37% iron ore. Since 1975, installations at Marampa and the Port of Pepel have been kept on a care and maintenance basis by a skeleton staff. Reserves at a second location, Tokolili, about 80 kilometers northeast of Marampa, were estimated at 124 million tons of 55% iron ore. Negotiations between the Government and Bethlehem Steel Corp. (United States) for reopening the Marampa Mine in conjunction with exploitation of the Tokolili deposit were unsuccessful.

Titanium Minerals.—Production of rutile at Gbangbama in Moyamba and Bonthe district by Sierra Rutile Ltd. (SRL) began in mid-1979. Initial production was to be at the rate of 35,000 tons per year building up to 100,000 tons per year to make Sierra Leone the world's second largest producer of rutile after Australia. Reserves were estimated at 110 million tons of black sand with a rutile content of 1.8%.[7] SRL, a joint venture of Bethlehem Steel Corp. (85%) and NORD Resources Corp. (15%), was to pay the Government a royalty of $4 per ton of production and approximately 50% of profits. Nearly $50 million was invested by SRL in machinery, equipment, and buildings. The entire output was to be exported for use in paint manufacture, glass and porcelain manufacture, and as an alloying material.

SRL acquired the Gbangbama leases from Sherbro Minerals Ltd. which liquidated in 1971 owing to problems with the dredging equipment. SRL planned to mine the rutile using a 24-cubic-yard bucket dredge designed by F.W. Payne and Son (Bickley) Ltd. and constructed by Taylor Woodrow Contract Services (United Kingdom). The dredge was to operate in a pond impounded by six dams constructed by Allgemeine Bou-Union GmbH (West Germany). A treatment plant constructed by Taylor Woodrow was to use electrostatic and magnetic separators and produce titanium concentrates containing 95% TiO_2, 1% ZrO_2, and 1% $Fe2O_3$. Taylor Woodrow was also responsible for the electrical transmission system and the expansion of the powerplant. A joint subsidiary of West German firms, Bayer A.G. and Preussag Metal, was reported to have relinquished their rutile concession in the Bradford and Rotifunk (Mogbwemo) areas of Southern Province.

NONMETALS

Clays.—The Sierra Leone clay factory with a capacity of 70,000 brick per week began production in December 1979. Four types of high-quality clay from different parts of the country are used by the factory.

Diamond.—Diamond production has been gradually declining over the past years from 2 million carats per year in the early 1970's. Approximately 40% to 55% of diamond output was gemstone. The National Diamond Mining Co. (DIMINCO) has experienced a steady decrease in output owing to the lower grade of deposits available for mining and depredation by illicit miners. DIMINCO, which held exclusive mining rights to the large Yengema Area and the smaller Tongo Area, reduced its staff and closed two processing plants in an effort to prolong its alluvial operations. Higher diamond prices in 1978 allowed the company's operations to remain viable; DIMINCO accounted for less than half of the country's diamond production in that year.

Aluvial mining by DIMINCO was expected to cease when underground mining of Kimberlite pipes in the Kono district commenced in approximately 5 years. Financing terms were under negotiation by the two major shareholders in DIMINCO, the Government (51%) and Sierra Leone Selection Trust Ltd. (49%). Plans called for diagonal shafts to be sunk on either side of the kimberlite and the reopening of treatment plant No. 6. An investment of $40 million was expected to yield a production rate of 300,000 carats per year.

The balance of diamond production was by hundreds of individual miners licensed to dig on specific plots in accordance with the Alluvial Diamond Mining Scheme (ADS), introduced in 1956 to discourage illicit digging. Licenses were issued to nationals of Sierra Leone or to firms with a Sierra Leonean majority holding for digging in 23,000 square kilometers of area outside the DIMINCO concessions. Diamonds offered for sale under the ADS increased in 1978 owing to a decrease in export duty to 2.5% for all sizes and categories dating from February 1, 1978. Prior to that date, the export duty was 7.5% on all sizes up to 14.8 carats and 2.5% for all those larger than 14.8 carats. Approximately 35% of Sierra Leone's diamond production was sold to Diamond Corp. of West Africa Ltd. (DICORWAF), a subsidiary of DeBeers Consolidated Mines Ltd. The remainder was sold to licensed buyers including Leon Templesman and Sons, Universal Mines Ltd., and Gems of Sierra Leone, all of the United States.

MINERAL FUELS

Petroleum.—Production of refined petroleum products by the Sierra Leone Petroleum Refining Co. was approximately 1.6 million barrels during 1978. The refinery, located in Freetown, was jointly owned by the Government and five oil companies: British Petroleum Co., Texaco Ltd., Shell Oil Co., Mobil Oil Corp., and Azienda Generale Italiana Petroli S.p.A. (Agip). All crude oil was imported. In 1978, the Government signed an exclusive agreement for offshore oil and gas exploration with Aracca Petroleum Co., in combination with Sundance Petroleum Co. and Oxocco Petroleum Co., for a period of 1 year.

The Mineral Industry of the Republic of South Africa

By Miller W. Ellis[1] and Charles W. Sweetwood[2]

The mineral industry continued to dominate the economy of the Republic of South Africa in 1978 and 1979 when mineral products accounted for more than one-half of the country's export value and for about one-fifth and one-fourth, respectively, of the gross domestic product (GDP). The value of mineral production increased to records of $7.9 billion[3] in a GDP of $46 billion in 1978 and $11.4 billion in a GDP of more than $57 billion in 1979. Although production of gold and diamond was virtually unchanged, the sales value of gold and diamond increased markedly both in 1978 and 1979. Together with coal, these commodities accounted for more than $6 billion in 1978 and nearly $9 billion in 1979 in mineral sales. New coal loading facilities at Richard's Bay handled nearly 2.7 million tons in 1978 and allowed total coal exports to increase from 15.4 million to 23.3 million tons from 1978 to 1979. The Saldanha Bay export facilities handled less iron ore than in 1977, but construction of a new 250-meter ore outloading pier was nearly completed. The new pier had an initial loading capacity of 6,000 tons per day and was designed to handle copper and lead concentrates from the new Phelps Dodge/Gold Fields of South Africa Ltd. (GFSA) underground mine at Aggeneys, northwest Cape Province.

Through its Industrial Development Corporation of South Africa Ltd. (IDC), the government indirectly controlled such companies as the Phosphate Development Corporation Ltd., which mined and processed apatite rock into phosphate concentrate near Phalaborwa in the Transvaal Province, and the state's Alluvial Diamond Diggings of Alexander Bay at the mouth of the Orange River. The state also maintained a controlling interest in the South African Iron and Steel Corp. Ltd. (ISCOR), which operated one colliery, two iron mines, one tin mine, one zinc mine, and two dolomite quarries, in addition to its three major steelworks at Vanderbijlpark, Pretoria, and Newcastle. Until October 1979 the state owned and operated the country's coal-to-oil synthetic crude oil ("syncrude") refineries. The syncrude facilities— operating as the South African Coal, Oil and Gas Corp. Ltd. (SASOL)— included the company's original pilot plant SASOL I and its captive Sigma colliery at Sasolburg in the Orange Free State, and the second generation SASOL II and III plants under construction near the developed Bosjesspruit coal mine at Secunda in the Transvaal.

In October 1979 the corporation became a new multisector company, SASOL Ltd., with IDC and a Konoil company holding 30% and the other 70% held by institutional, corporate, and small investors. For SASOL II the $3.0 billion total capital was from Parliamentary appropriations and the state Oil Fund, plus $585.5 million from export credits and loans. SASOL III's anticipated cost of $3.9 billion should include nearly $800 million from loans and export credit. SASOL II's coal gasification units were scheduled to start up in April 1980 and the liquification units by October 1980 at an estimated annual rate of 18.7 million barrels of syncrude from 12 million tons of coal. With the improvements already projected the capacity might reach 30 million barrels per year of syncrude. SASOL III was scheduled for commissioning as a "carbon copy" in 1982, and the Bosjesspruit colliery was being geared for a production rate of 27 million tons per year of coal by 1982.

PRODUCTION AND TRADE

The Republic of South Africa continued as the world's leading producer of chromite, gem diamonds, gold, platinum, and vanadium, and as one of the three top producers of antimony, asbestos, industrial diamond, manganese, uranium, and vermiculite. Details of mineral production are shown in table 1.

Mineral products from the Republic of South Africa continued to be a major source of raw material for the manufacturing industries of Western Europe, the United States, and Japan. Both demand and price for many industrial commodities weakened during 1978, but strengthened in 1979, in some cases to record figures. The main exception was coal, the exports of which increased both in volume and in value during both years through the new Richard's Bay coal-loading facilities. Although gold sales declined in 1979, the price of gold continued to rise throughout both years to a recordbreaking average of $307 per troy ounce for 1979. The price of gem diamonds was increased 30% by De Beers Central Selling Organization in 1978 and 17% in 1979 to gross values of $513 million and $651 million, respectively. The quantity of iron and manganese ores exported declined, but their value decreased to $190 million and $100 million, respectively, in 1978. The 1979 exports set new records for both quantity and value. Major mineral imports continued to include crude oil and alumina. Details of exports from and imports to the Republic of South Africa are shown in tables 2 and 3. Table 4 lists comparisons of the value of commodities exported and sold domestically during 1977, 1978, and 1979.

Marble	16,220	8,523	2,369	2,000
Crushed and broken:				
Limestone thousand tons	13,739	13,076	14,112	14,000
Shale do	369	267	376	400
Sulfur:				
S content of pyrite do	294	332	340	340
Byproduct:				
Of metallurgy do	91	105	100	100
Of petroleum do	27	28	25	25
Total do	412	465	465	465
Talc and related materials:				
Talc	7,039	8,095	7,487	8,000
Pyrophyllite (wonderstone)	5,784	5,109	5,159	5,000
Vermiculite	222,077	165,419	209,093	[1]191,573
MINERAL FUELS AND RELATED MATERIALS				
Carbon black[e]	43,100	45,000	40,000	40,000
Coal:				
Anthracite thousand tons	[r]2,459	2,559	2,150	[1]3,309
Bituminous coal do	74,600	82,852	88,208	[1]100,459
Total do	[r]77,059	85,411	90,358	[1]103,768

See footnotes at end of table.

Table 1.—Republic of South Africa: Production of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1976	1977	1978[p]	1979[e]
MINERAL FUELS AND RELATED MATERIALS —Continued				
Coke:				
Coke oven and beehive ---- thousand tons	4,608	5,201	4,869	[1]4,951
Gashouse, low and medium temperature[e] ---- do	110	110	110	110
Petroleum refinery products:				
Gasoline ---- thousand 42-gallon barrels	29,783	30,083	30,090	NA
Jet fuel ---- do	2,196	2,349	2,440	NA
Kerosine ---- do	3,132	3,338	3,333	NA
Distillate fuel oil ---- do	31,279	31,918	32,973	NA
Residual fuel oil ---- do	22,027	22,036	22,178	NA
Lubricants ---- do	2,228	2,262	2,240	NA
Other ---- do	8,581	8,607	7,372	NA
Refinery fuel and losses ---- do	5,561	5,624	5,700	NA
Total ---- do	104,787	106,217	106,326	112,000

[e]Estimate. [p]Preliminary. [r]Revised. NA Not available.
[1]Reported figure.
[2]Less than 1/2 unit.
[3]Includes osmiridium from gold ores, estimated at 2,500 troy ounces per year.
[4]Sales.
[5]Domestic sales plus exports. Production not reported.

Table 2.—Republic of South Africa: Exports of selected mineral commodities[1]

(Metric tons unless otherwise specified)

Commodity	1976	1977	1978
METALS			
Aluminum metal, unwrought[2]	20,400	28,300	37,400
Antimony ore and concentrate, gross weight	5,958	8,452	3,173
Chromium:			
Chromite ore and concentrate, gross weight:			
More than 48% Cr_2O_3[3]	50	3,256	--

eEstimate. rRevised. NA Not available.

[1]Because official South African trade statistics provide data only on the value of total exports of each commodity class (with no data on destinations), this table has been compiled from several sources and includes some estimates. Unless otherwise specified, data are from the quarterly publication "Minerals" issued by the Department of Mines of the Republic of South Africa (various issues 1974-78).

[2]World Bureau of Metal Statistics. World Metal Statistics, October 1979, London. 1979, 112 pp.

[3]American Consulate General, Johannesburg. Various airgrams.

[4]Exports from the Territory of South-West Africa are included in source publication, and no basis is available for distribution of this total between the Republic of South Africa and the Territory of South-West Africa.

[5]1977 data for ferroalloys are Bureau of Mines estimates. All other data are from: United Kingdom Iron and Steel Statistics Bureau. International Steel Statistics—Republic of South Africa. 1976, 1977, and 1978.

[6]Less than 1/2 unit.

Table 3.—Republic of South Africa: Imports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1977	1978	Principal sources, 1978
METALS			
Aluminum:			
Bauxite	24,033	18,119	Australia 10,506; Denmark 5,687.

COMMODITY REVIEW

METALS

Aluminum.—The country's only producer of primary aluminum, Alusaf (Pty.) Ltd., imported alumina from Alusuisse operations at Gove, Australia, and produced 76,000 tons of metal at its Richards Bay refinery where the capacity was increased from 78,000 to 85,000 tons per year in 1979. Alusaf, owned 66% by the Industrial Development Corp. Ltd., 22% by Alusuisse, 8% by Barlow Rand Ltd., 3% by Huletts Aluminium Ltd. (Hulamin), and 1% by Alcan Aluminum Ltd., produced aluminum as liquid metal and ingots for its affiliated fabricators. The adjacent Alustang (Pty.) Ltd. facility produced redraw rods and solid sector aluminum for electric cable. Hulamin produced flat and coil sheet, extrusions, cable, and paste for the paint industry at its four plants. During 1978, Hulamin contracted to use ISCOR's new $8 million coil coating line for the production of prepainted aluminum coil sheet for use in the vehicle and construction industries. Hulamin had an annual production capacity of 33,000 tons of aluminum sheet including a new facility producing 4,000 tons of thin-gage sheet for cold-drink cans at Olifantsfontein, Transvaal.

Imports of aluminum metal products, chiefly from the United States and the Federal Republic of Germany, increased from 1977 through 1979. Australia supplied most of the 18,000 tons of raw and activated bauxite required by the country's abrasives, chemicals, and refractories industries. The private-sector firm, South African Bauxite Ltd., reported 15 to 20 million tons of bauxite located in the Weza area as part of their Natal midlands reserves totaling 50 million tons at an average grade of 30% Al_2O_3. The exploitability of such bauxite was questionable.

Antimony.—Consolidated Murchison Ltd. (CML), owned 25% by Johannesburg Consolidated Investment Co. Ltd. (JCI), continued operations at its seven mines along the "antimony line" of the Murchison Range west and northwest of the Palabora copper mine. In 1978, ore and concentrate production and concentrate exports declined chiefly because of decreased demand for antimony in the battery and fire retardant industries. Both production and export of concentrates increased markedly in 1979. Local sales of antimony concentrates increased moderately to 8,832 tons. Local production of antimony oxide was halted during May, June, and July at the Antimony Products (Pty.) Ltd. plant at Gravelotte, owned jointly by Chemetron Corp. of Chicago, CML, and JCI.

Chromite.—Production of chromite increased in both 1978 and 1979, but total sales decreased to approximately $86 million in 1978 and then soared to more than $105 million in 1979. The country's chromite output was from some 17 producers operating along a number of parallel seams and bands of chromite in noritic rock of the Bushveld Igneous Complex in central Transvaal Province. Most of the mining was relatively inexpensive, because it required only shallow, underground, room-and-pillar mines and, except for the Grasvally and nearby mines, the iron-to-chrome ratio was high. Export facilities at Durban and Richard's Bay were underutilized in respect to chromite as most of the ore was handled through the port of Maputo in Mozambique.

The Transvaal Consolidated Land Exploration Co. Ltd., owned 59% by Barlow Rand Ltd., started to expand production from recently developed extensions of its Winterveld (T.C.L.) Chrome Mines Ltd. property near Steelport, north of Lydenburg. The Southern Sphere Mining and Development Co. (Pty.) Ltd., a subsidiary of Utah International, and TG Exploration Ltd. and Pandora Mining Pty. Ltd., both subsidiaries of Texasgulf Inc., were negotiating a joint venture to apply Texasgulf's new smelting technique, the Expanded Precessive Plasma (EPP) process, to unexploited chromite-platinum deposits of the Bushveld Complex.

In August 1977, Armco (Pty.) Ltd., a subsidiary of Armco Steel Corp., acquired mineral rights in the Marico District west of Rustenburg. Armco subsequently agreed with Vereeniging Refractories Ltd., a subsidiary of Anglo American Corp. and the owner of adjacent properties, for the joint operation of a new mine. Initial capacity was scheduled at 120,000 tons per year of chromite, chiefly for export to Armco Steel Corp.

Copper.—Production of copper increased marginally, and the average world market price increased slightly during 1978. In 1979 the price improved substantially but production dropped, and the value of exports soared to more than $225 million. In 1978, the Republic's reserves of copper ore were estimated by the Minerals Bureau of the Department of Mines as follows:[4]

Area	Million tons	Percent	Copper metal (Tons)
Cape Province:			
O'okiep	27.198	1.67	454,200
Prieska	48.000	1.74	835,200
Black Mountain	80.000	.80	640,000
Broken Hill	60.000	.40	240,000
Transvaal Province:			
Messina	4.300	1.37	59,000
Palabora	509.091	.55	2,800,000
Total or average	728.589	.69	5,028,400

The Merensky Reef's 1,712.5 million tons of platinum-nickel ore containing 0.08% copper was added to the above totals to yield an additional 1.37 million tons of copper metal.

The mines operated in northwest Cape Province by O'okiep Copper Co., owned 57.7% by Newmont Mining Corp., produced 1.8 million tons of ore in both 1978 and 1979, but the copper content decreased from 1.35% to 1.29% in 1979. The O'okiep smelter treated only 38% in 1978 and less than 38% in 1979 of the copper concentrate produced by Prieska Copper Mines (Pty.) Ltd., instead of the 57% handled in 1977. This shortfall accounted for O'okiep's drop in blister copper production from 43,088 tons in 1977 to 41,561 tons in 1978 and to 32,105 tons in 1979, the lowest figure reported in more than 20 years. Prieska, jointly owned by Anglo Transvaal Consolidated Investment Co. Ltd. and U.S. Steel Corp., reported increases in both ore and copper concentrate production to 3 million tons and 127,700 tons, respectively.

Messina Transvaal Development Co. Ltd. reported its fourth consecutive year of declining production and a loss of $500,000 in 1978 from its northern Transvaal mines. Ore production declined to 669,000 tons, and the copper content of its concentrate dropped to 7,300 tons. The operation was granted state assistance to accelerate new development and increase production. In 1979 Messina returned to profitability because of improved copper prices although only 610,000 tons of ore containing 1.12% copper was hoisted and milled.

Development of an underground mine to exploit the Broken Hill ore body on the Aggeneys farm in northwest Cape Province, west of Pofadder, continued by Phelps Dodge Corp. and GFSA. Production of 20,000 tons per year of copper concentrates plus silver, and larger quantities of lead and zinc concentrate was scheduled to begin in 1980.

Palabora Mining Co. Ltd. reported an increase to 27 million tons of ore milled in 1978 and 1979 at its open pit operation in northeastern Transvaal. Copper concentrate production and sales revenue increased, reflecting price improvements. Vermiculite sales rose owing to improving economic conditions, but magnetite sales dropped sharply as the last shipment of magnetite to Japan under a 10-year contract was made in September 1978. Approximately 45% of Palabora's copper was sold domestically, the balance being exported. In 1979 Palabora announced plans to increase its mining rate from 300,000 to 355,000 tons per day and to increase its pit diameter by an average of 200 meters at the surface and extend its depth by 100 meters to an ultimate depth of 774 meters. Production of the Palabora Copper Co. for 1977, 1978 and 1979 was as follows, in tons:

	1977	1978	1979
Ore and waste mined	89,480,000	90,030,000	86,214,000
Ore milled	24,864,000	27,474,000	27,077,000
Concentrate produced	307,248	330,883	296,295
Copper in concentrate	109,503	118,641	111,872
Sales:			
Copper	104,231	114,878	112,667
Magnetite	435,293	116,597	70,447
Sulfuric acid	120,615	116,759	103,139
Vermiculite	154,380	193,046	178,022
Total sales value, millions	$164	$186	$261

Gold.—The gold industry of the Republic of South Africa enjoyed the most successful and lucrative years in its history in 1978 and 1979. The reported value of production rose to new records in both years as the average sales price climbed. Production figures of the major mines or companies for 1977, 1978, and 1979 are shown in table 5.

Sources: Chamber of Mines of South Africa. Quarterly Analysis of Working Results, October-December 1978, 1979. U.S. Consulate General. Johannesburg, Republic of South Africa. State Department Airgram A-47, July 15, 1980, pp. 45 to 48.

Five of these mines accounted for more than one-third of the country's gold production and each produced more gold than the entire United States. Most of the mines produced their own bullion containing approximately 88% gold, 10% silver, and 2% base metals in bars weighing from 800 to 870 troy ounces. The bars were then delivered to the Rand Refinery at Germiston where they were assayed and purchased on behalf of the South African Government's Reserve Bank. The producing mines were paid promptly (within 5 days) by the Reserve Bank at the world market price of gold on the date of delivery.

Although the Republic of South Africa is responsible for about 60% of the world's gold output, its gold mining industry consisted of about 35 large underground operations and two major tailings retreatment plants. Most of these were controlled or managed by seven large corporations with interlocking shareholdings and extensive mineral and industrial holdings both inside and outside South Africa. These corporations were Anglo American Corp. of South Africa Ltd. (AAC), Anglo Transvaal Consolidated Investment Co. Ltd. (Anglovaal) Barlow Rand Ltd., General Mining and Finance Corp. Ltd., Gold Fields of South Africa Ltd., (GFSA), Johannesburg Consolidated Investment Co. Ltd. (JCI), and Union Corporation Ltd.

AAC's Elandsrand mine began commercial production in December 1978, 2 years ahead of schedule. Most of the output was reportedly derived from preproduction development work, and the design capacity of 180,000 tons per month of ore was reached with the installation of three autogeneous mills by mid-1979. GFSA's Deelkraal Shaft No. 1 was fully equipped to a depth of 2,037 meters, and the subvertical incline was sunk to a depth of 427 meters. The refrigeration plant, reduction works, and other major surface installations were complete. Milling on a trial basis began in December 1979.

AAC's Joint Metallurgical Scheme treated slimes from six of its mines in the Welkom area of the Orange Free State. The main facility was the rehabilitated uranium plant and flotation complex at the President Brand Mine, which had the capacity to treat 350,000 tons of slimes per month and to recover gold, in addition to uranium and pyrite for byproduct sulfuric acid. Production for both 1978 and 1979 was below expectations. The East Rand Gold and Uranium Co. Ltd. (ERGO) was formed by AAC to recover low concentrations of gold, uranium, and pyrite from old slimes and tailings dams in the Witwatersrand area of Transvaal Province. Sulfuric acid was produced by roasting the pyrite concentrated from the tailings; gold, copper, and other metals were recovered by leaching the sinter. The first uranium salts were produced in February 1978, the first charge of pyrite into the roaster of the 1,000-ton-per-day sulfuric acid plant was made in March 1978, and the first gold bullion was poured in April 1978. Production for the year included nearly 85,000 troy ounces of gold, 115 tons of U_3O_8, and 240,000 tons of sulfuric acid.

JCI commissioned the Cooke section gold and uranium treatment facilities of its Randfontein mine southwest of Johannesburg in 1978. A total of $230 million was spent on rehabilitation of the old Randfontein mine and mill and construction of the new Cooke section. The refurbished uranium plant at Millsite was operating satisfactorily at the Randfontein section, but at the Cooke section, the mill failed to reach its targeted capacity because of corrosion and mechanical difficulties. JCI was also investigating the feasibility of opening still another large mine in the Randfontein Estates area despite the possible closure of the South Roodepoort and Durban Deep mines in the vicinity.

Iron Ore and Concentrate.—In 1978, production of iron ore decreased from that of the record year 1977, which marked the startup of the Sishen-Saldanha Bay export project. Exports decreased slightly, both in volume and in value, and the quantity of iron ore sold on the local market increased to 16 million tons in 1978. The following year, new records were set in both quantity and value of production, exports, and local sales.

The Government-owned Iron and Steel Industrial Corp. Ltd. (ISCOR) was the Republic's largest producer of hematite ore from its mine in the Sishen area in northern Cape Province. In 1973, ISCOR initiated a development program which included a new mine and facilities, an 861-kilometer railroad, and a modern ore-loading port at Saldanha Bay. Production capacity at Sishen was doubled to 27 million tons of iron ore per year. Approximately 15 million tons per year was to be exported with the remainder supplied to ISCOR's steelworks at Vanderbijlpark, Newcastle, and Pretoria. ISCOR operated a second mine at Thabazimbi in northwestern Transvaal, which supplied iron ore to the Pretoria Works. The Thabazimbi operation had an annual production capacity of 3 million tons. Associated Manganese Mines of South Africa Ltd. and Consolidated African Mines Ltd. were other major hematite producers.

Magnetite ore accounted for about one-sixth of the total iron ore production in 1978 and was primarily for domestic consumption. Magnetite exports decreased in 1978 owing to the completion of several sales contracts with Japanese steel producers including Palabora Mining Company's 10-year sales contract with Kobe Steel Ltd. Magnetite was produced as a byproduct from the processing of carbonatite copper and phosphate ores, primarily by the Palabora Mining Co. and the Phosphate Development Corp. in eastern Transvaal.

Iron and Steel.—ISCOR accounted for 85% of South Africa's liquid and pig iron production and 76% of the country's output of steel products in 1978. Total liquid and pig iron production increased marginally in 1978 while output of steel ingot increased and production of steel and iron castings declined. However, higher export volume and rising steel prices increased the total value of pig iron and prime steel products from $1.2 billion in 1977 to $1.5 billion in 1978. The value of all iron and steel commodities increased during 1979 to a total value of $2.23 billion.

ISCOR reported a record loss of $84 million for the fifth consecutive deficit year ended June 30, 1978, and a moderate ($45.1 million) loss for 1979, owing largely to debts incurred for its ongoing expansion program. Production capacity of liquid steel was to be increased from 7 million tons per year to 11 million tons per year by 1982. Production capacity was allocated among the company's steelworks as follows: Vanderbijlpark, 5 million tons per year; Newcastle, 4 million tons per year; and Pretoria, 2 million tons per year.

Highveld Steel and Vanadium Corp. was the leading producer of specialty steel and products at its integrated steelworks in Pretoria. Highveld set new production and earnings records when steel sales rose 25% to approximately 632,000 tons in 1978. Production capacity was rated at 750,000 tons per year. Southern Cross Steel Co. (Pty.) Ltd. was the only producer of primary stainless steel at its Middleburg, Transvaal, facilities. Production in 1978 consisted of 5,000 tons of stainless steel finished sheet and 15,000 tons of plate increasing somewhat by 1979 when major expansion plans were announced. Approximately 50% of the output was sold locally and 50% exported. Union Steel Corp. Ltd. (USCO) completed tests for the manufacture of alloy tool and specialty steels not previously manufactured in South Africa and commenced local sales of these products in late 1978. USCO, with current assets of $45 million, reported a $4 million net profit on sales of $160 million in mild steel sections, special steels, forgings, and castings.

Ferroalloys.—The ferroalloy industry had record years in 1978 and 1979 when total production rose and export earnings increased by half to $352 million. Almost all production was exported to the steel-producing countries of the United States, Japan, and Western Europe. The most significant ferroalloys produced in terms of both importance in world supplies and export earnings were ferrochrome, used mainly in the stainless steel industry, and ferromanganese, used mainly in the carbon and alloy steel industries.

South African Manganese Amcor Ltd. (SAMANCOR) accounted for about 40% of the 1978 production of ferroalloys. SAMANCOR's facilities at Meyerton, Transvaal, produced ferromanganese, ferrochrome, and ferrosilicon. Other important producers of ferromanganese were ISCOR, Associated Manganese Mines Ltd., Highveld Steel and Vanadium Corp., and Anglovaal.

Two new producers of ferrochrome moved into full production. Consolidated Metallurgical Industries Ltd. (CMI), a subsidiary of JCI, operated its 120,000-ton-per-year plant at Lydenburg, Transvaal, at full capacity in 1978. Tubatse Ferrochrome (Pty.) Ltd., a joint venture of Union Carbide and General Mining and Finance Corp. Ltd., reached its full production capacity of 120,000 tons per year in 1979. Palmiet Chrome Corp. (Pty.) Ltd. discontinued production of low-carbon ferrochrome at its plant in Krugersdorp, Transvaal. Other producers of ferrochrome were Anglovaal and Southern Cross Steel Co. Ltd.

Manganese.—Manganese production declined in 1978 compared with 1977 output owing primarily to continued recession in the world iron and steel industry and strong competition from other manganese producers. However, the Republic of South Africa ranked second only to the U.S.S.R. in the volume of production and remained the free world's largest exporter of manganese. Approximately two-thirds of production was exported in 1978, chiefly to Japan, France, the United States, the United Kingdom, the Federal Republic of Germany, and Norway. The ferroalloy industry was the major local consumer of manganese ore. Small quantities were also sold on the local market to the chemical industry and to the electrolytic manganese plant at Nelspruit, operated by Delta Manganese (Pty.) Ltd. A decline in exports in 1978, coupled with lower prices, led to a decrease in total sales revenue in 1978, but these trends were reversed in 1979.

Important manganese occurrences were found in the Postmasburg Field, the Kuruman or Kalahari Field, and in the vicinity of the Witwatersrand goldfields. Since the early 1970's, local manganese mining capacity has greatly increased as a result of expansions to existing mines and the establishment of new mines. Capacity was further increased in 1979 when AAC brought onstream the new Middelplaats underground mine located near Kuruman in northern Cape Province. Installed capacity of the mine was scheduled at a rate of 1.1 million tons per year of manganese ore by mid-1980.

SAMANCOR was the largest producer of manganese ore with annual production capacity of about 4 million tons per year. SAMANCOR operated the large Wessels underground mine, recently expanded to a 500,000-ton-per-year capacity, and three open pits - Hotazel, Mamatwan, and Lohathla. In September 1979 SAMANCOR reportedly was importing some 20,000 tons of low (6.5%) iron, high (54%) manganese pellets from Amapa, Brazil, for blending with ore from SAMANCOR's Wessels Mine to make an acceptable feed for the ferromanganese plant at Kookfontein operated by its subsidiary, Metalloys Ltd. The results of the blend was compared with the normal production of Mamatwan ore at 7% iron and 40% manganese. Associated Manganese Mines of South Africa Ltd. was the country's second-largest producer with an annual production capacity of 2 million tons per year of ore. The main Mancorp Mine and other smaller mines were located in the Kalahari Field's Black Rock area.

During an independent study of the manganese ores of Cape Province in 1978, SAMANCOR's analysts concluded that the recoverable and salable ores of the Postmasburg and Kuruman Fields are larger and more important than had been previously estimated by the South African Geological Survey and others. Specialists from the Minerals Bureau of South Africa's Department of Mines confirmed the superior reliability of the new estimates and have suggested their use in respect of the country's proved and probable ore in situ.[5] These reserves are as follows, in tons:

More than 44% Mn	310,800,000
40% to 44% Mn	30,000,000
30% to 40% Mn	7,181,000,000
20% to 30% Mn	4,618,000,000
Total	12,139,800,000

Nickel.—Nickel production was a byproduct of platinum mining in the Merensky Reef in the prolific Bushveld Igneous Complex of the central Transvaal. Although platinum production declined slightly in 1978, improved nickel grade and recoveries resulted in a slight production increase over the 1977 level. Approximately 88% of refined nickel production was exported to captive buyers in Norway, Canada, the United Kingdom, and the United States. Local sale of nickel was primarily to the stainless steel industry.

Nickel was recovered by the refining of nickel-copper matte at an approximate ratio of 1 ton nickel to 55 troy ounces of platinum metal. Nickel production capacity of the major platinum producers was as follows: Rustenburg Platinum Mining Co. Ltd., 10,000 tons per year; Impala Platinum Mines (Pty.) Ltd., 10,000 tons per year; and Western Platinum Ltd., 3,000 tons per year. In 1978 and 1979 Rustenburg modified their plant to separate cobalt from nickel and produced about 75 tons of cobalt sulfate in 1979.

Platinum.—Although production of platinum-group metals decreased slightly from the 1977 level in 1978 and increased in 1979, the Republic of South Africa remained the world's largest producer. Higher world prices meant increased profits for the country's three platinum producers, who milled a total of 15.1 million tons and 15.9 million tons of ore in 1978 and 1979, respectively. Virtually all platinum production was exported at prices increasing steadily from $195 per ounce in January 1978 to $645 in December 1979. South Africa was estimated to have at least 50% of the world's known recoverable resources of platinum in the Merensky Reef of the Bushveld Igneous Complex.

Rustenburg Platinum Mining Co. Ltd., the world's largest producer of platinum metal, expected to raise annual production capacity from 900,000 troy ounces in 1978 to 1.2 million troy ounces in 1980. Rustenburg planned to develop the Amandelbult mine to replace output from the high-cost workings at the Union section. The country's second-largest producer, Impala Platinum Mines (Pty.) Ltd., had a annual capacity of approximately 750,000 troy ounces of platinum metal. Western Platinum Ltd., operated by Lonhro Ltd., produced platinum matte at a smaller mine near Brits.

Tin.—As world tin prices approached record levels, the country's three tin producers initiated new development plans. In 1978, the production of tin concentrate decreased marginally and the quantity exported declined, but export value increased. In 1979 there was further reduction in concentrate production and both the quantity and value of exports declined markedly. Production of tin metal, which was consumed locally, increased in quantity and in value in both years. South Africa's tin production by company for the years 1977, 1978, and 1979 was as follows, in tons:

Company	1977		1978		1979	
	Ore	Concentrate	Ore	Concentrate	Ore	Concentrate
Rooiberg Minerals Development Co. Ltd	135,437	4,563	117,792	4,523	136,460	3,975
Union Tin Mines Ltd	34,333	1,268	47,285	1,317	49,868	1,467
Zaaiplaats Tin Mining Co. Ltd	73,500	308	75,500	279	78,189	264
Total	243,270	6,139	240,577	6,119	264,517	5,706

The Rooiberg field, located 56 kilometers west of Warmbaths, accounted for more than two-thirds of the tin concentrates produced in 1978. Annual capacity was 2,300 tons of tin in concentrates, and underground mine development was in progress. Rooiberg was constructing a 2,000-ton-per-year smelter, which was expected to reduce exports of tin-in-concentrates markedly when it was commissioned in 1980.

Zaaiplaats Tin Mining Co. Ltd. was the smallest producer of tin ore and concentrate from its field extending 21 kilometers along the Makapansberg Range. Zaaiplaats operated the country's independent tin smelter near Potgietersrus, Transvaal. During the year, Zaaiplaats began a tailings retreatment project which was expected to have an output of 50 tons per year of tin.

High tin prices prompted Union Tin Mines Ltd. of GFSA to postpone the phasing out of its operation. It was reported that the company inaugurated a new development program in 1978 and 1979 to exploit additional reserves, and continue flotation retreatment of mine dumps.

Uranium.—Two new uranium reclamation projects and renewed emphasis on uranium recovery owing to increased prices led to production increases in the last few years. Approximately 15 of the more than 40 Witwatersrand gold mines recovered uraninite as a byproduct in 1978 when production of U_3O_8 from gold ores increased 18% to 4,531 tons. The average grade of gold ore treated declined marginally from 0.182 kilogram U_3O_8 to 0.175 kilogram U_3O_8 per ton of ore treated. Table 6 shows the 1977, 1978, and 1979 production of U_3O_8.

Table 6.—Republic of South Africa: Production of U_3O_8, by producer

(Kilograms)

Company or mine	1977	1978	1979
Blyvooruitzicht	199,949	292,212	285,710
Buffelsfontein	653,200	620,000	620,400
Harmony	535,820	534,839	540,925
Free State Saaiplaas	45,545	--	--
Hartebeestfontein	377,405	365,889	394,210
Randfontein	3,635	96,081	412,959
Vaal Reefs	1,016,955	1,059,851	1,273,415
West Driefontein	295,567	295,119	288,274
Western Deep Levels	167,410	183,365	199,002
West Rand Consolidated	265,559	312,914	367,512
Anglo American JMS	312,750	635,059	676,262
Palabora Copper	88,661	140,860	121,252
Miscellaneous	--	117,828	457,079
Total	3,962,456	4,672,017	5,637,000

All uranium production was exported in 1978. Most uranium producers, with the exception of Palabora Mining Co., sold their output through the Nuclear Fuels Corp (NUFCOR), a consortium of AAC, Anglovaal, General Mining, and Union Corp. Production was marketed by the Chamber of Mines of South Africa. The value of uranium exported increased from $104 million in 1977 to $245 million in 1978.

Uraninite and other radioactive minerals occurred primarily in association with gold-bearing reefs or in copper-bearing carbonatites. In 1978, reserves were estimated at 325,500 tons of U_3O_8 considering uranium as a byproduct of gold and copper processing at a base price of $30 per pound of U_3O_8 and at current operating costs.

AAC's East Rand Gold and Uranium Co. Ltd. (ERGO) came onstream in 1978 at an estimated development cost of $167 million. ERGO was to recover low concentrations of gold, uranium, and pyrite from previously abandoned slimes dams at Transvaal mines east of Johannesburg. Approximately 1 million tons per month of slimes was to be treated to recover 54% of the contained gold, 20% of the contained uranium, and 86% of the contained sulfur. Annual production was to consist of 200 tons of uranium, 225,000 troy ounces of gold, and 530,000 tons of sulfuric acid. After nearly 2 years of operation the monthly target was established at 14,725 troy ounces of gold, 16.7 tons of U_3O_8, and 37,500 tons of sulfuric acid.

AAC's Orange Free State Joint Metallurgical Scheme moved closer to full production in 1978 and 1979 when production approached the 700 tons U_3O_8 mark. Participants in the project to recover gold, uranium, and sulfur from slimes and tailings included Free State Geduld, Free State Saaiplaas, President Brand, President Steyn, Welkom, and Western Holdings mines. Technical difficulties in the treatment plant limited initial throughputs, which were expected to total 1.5 million tons per month of slimes.

Randfontein Estates Gold Mining Co. Ltd. operated by JCI, registered the largest gains in 1978 and 1979 when production increased from 4 to 96, and then to 413 tons U_3O_8 in 1977, 1978, and 1979, respectively. During 1978, the Randfontein section of the mine was reopened, and the company started producing from the new Cooke section. Anticipated monthly capacity of 250,000 tons of ore, in addition to 100,000 tons of slimes, was achieved in 1979.

In 1978, Union Corp. announced plans to develop South Africa's only mine at which uranium would be recovered as a primary product with gold as a byproduct. Beisa Mines Ltd., a Union Corp. subsidiary, was to operate the mine located in the vicinity of the Harmony property about 25 kilometers south of Welkom in Orange Free State. Ore reserves were reported to contain 0.5 kilogram of U_3O_8 and 0.225 troy ounce of gold per ton. The plant was to treat 100,000 tons per month of ore at the underground operation by 1982.

Uranium production was expected to double by the 1980's as new treatment plants came onstream and uranium exploration continued. General Mining continued construction of its new $69 million uranium plant at Stilfontein Mine. Rand Mines announced plans to construct a new uranium plant at the Merriespruit section of Harmony Mine. GFSA, AAC, General Mining, and Union Corp. continued drilling programs in Orange Free State. Apart from exploration and development in the gold and uranium bearing areas, exploration in the Karroo Desert, northeast of Capetown, was intensified. Three U.S. companies were working in this region, Esso, Union Carbide, and Newmont, as well as AAC, and JCI of the Republic. Interest was centered on channel deposits with uranium minerals in rocks of Karroo (Permian-Trassic) age.

Vanadium.—Worldwide over-capacity led to cutbacks in vanadium production by the country's major producers in 1977 and 1978. With production remaining at the 1977 level, the Republic of South Africa continued as the world's largest producer of vanadium, accounting for nearly one-half of world production. The value of vanadium production increased slightly, although prices remained at low levels in 1978. Both quantity and value increased in 1979. Production statistics combined the V_2O_5 content of several products - pentoxide, ferrovanadium, metavanadate, and slag. Virtually all vanadium production was exported, since local sales continued to be weak.

The principal source of vanadium was in the titaniferous magnetite deposits in the Bushveld Igneous Complex of central Transvaal with the most important deposits occurring in the general vicinity of Lydenburg. The country's largest vanadium producer (and the leading world producer of this commodity) was Highveld Steel and Vanadium Corp. Ltd. Highveld had an annual capacity of 12,000 tons of vanadium pentoxide with ore originating from the Steelport-Roossenekal area of the Transvaal and treated at Witbank. Ucar Minerals Corp. Ltd. of Union Carbide SA Ltd. had an annual capacity of 2,000 tons of vanadium pentoxide from its plants at Brits and Bon Accord near Pretoria. The remaining producer was Otavi Mining Co. Ltd., which produced 1,500 tons per year of vanadium pentoxide at its plant near Wapadskloof in Transvaal.

Zinc.—Zinc concentrate production from a single operating zinc mine decreased in both 1978 and 1979 but zinc prices improved substantially in 1979. Prieska Copper Mines (Pty.) Ltd., was in its sixth year of operation as a four-product mine and concentrator with recoveries of copper, zinc, lead, and pyrite. Prieska sold zinc concentrate locally to GFSA's Zinc Corp. of South Africa Ltd.

(ZINCOR), which produced 79,000 tons of electrolytically refined zinc from domestic and imported concentrates. Approximately 42,000 tons of zinc concentrate was exported under contract to Metallgesellschaft (Federal Republic of Germany) in 1978.

Zinc production was to be augmented in the 1980's by output from a new mine developed by Phelps Dodge, in conjunction with GFSA. Reserves at the Black Mountain deposit near Aggeneys in northwestern Cape Province were estimated at 38 million tons of ore containing 0.45% copper, 6.25% lead, 2.87% zinc, and 0.08% silver. Annual production capacity of the mine was expected at 1.1 million tons of ore with recoveries of 22,000 tons of copper concentrate, 132,000 tons of lead concentrate, 35,000 tons of zinc concentrate, and 2.6 million ounces of silver.

A joint venture consisting of Newmont Mining Corp. (27.5%), O'okiep Copper Co., (27.5%), and AAC (45%), postponed exploitation of their large zinc deposit near Gamsberg in Namaqualand. Reserves were estimated at 143 million tons of ore containing 7% zinc and 0.5% lead.

NONMETALS

Andalusite and Related Minerals.—The Republic of South Africa continued as the world's leading producer of andalusite and a significant producer of sillimanite. The combined value of the two commodities was approximately $12 million and $16 million in 1978 and 1979, respectively. Local sales consumed more than one-half the country's output of andalusite, but less than one-fourth of the sillimanite production was sold locally. The country's andalusite production has nearly trebled since 1970 and was expected to continue rising. Large reserves occurred in the Groot Marico-Zeerust area, the Thabazimbi area, and the Lydenburg District. In 1978, Hudson Mining Co. (Pty.) Ltd. was the largest producer of andalusite in the country and one of the largest in the world. Hudson's operation at Burgersfort near Lydenburg in eastern Transvaal had an annual production capacity of 50,000 tons per year. Other large producers were Havercroft Andalusite Co. (Pty.) Ltd. with a 36,000-ton-per-year operation near Lydenburg, and Cullinan Minerals (Pty.) Ltd. with a 12,000-ton-per-year mine at Welverdieng in western Transvaal.

Sillimanite production was notable for its high alumina content (60%) and lumpy form. Production has declined in recent years but was expected to remain constant after 1978 until available reserves were depleted. Two companies produced sillimanite in Namaqualand: Pella Refractory Ores (Pty.) Ltd. at Pella Mission and R. G. Niemoller (Pty.) Ltd. at Klein Pella.

Asbestos.—Production and exports of asbestos were well below 1977 levels owing primarily to weak world demand. The Republic of South Africa was a major source of the crocidolite, amosite, and chrysotile varieties of asbestos produced largely in the Transvaal and Cape Provinces. Cape Blue crocidolite was the country's most important variety and traditionally accounted for well over one-half of the value of annual asbestos sales. In 1978 and 1979, production and export declines were evidenced in all major categories of asbestos.

Of South Africa's 17 or more asbestos producers, three companies accounted for the majority of production. General Mining and Finance Corp. Ltd. owned two asbestos-producing subsidiaries, Griqualand Exploration and Finance Co. Ltd. and Msauli Asbes Beperk. Griqualand produced about 50,000 tons per year of crocidolite fiber from operations in the Kuruman District of Cape Province. In 1978, the company closed its Brethy Mine but maintained normal operations elsewhere. A Msauli property, with a production capacity of 85,000 tons per year at Barberton in Transvaal, was the country's largest producer of chrysotile asbestos.

Cape Asbestos South Africa (Pty.) Ltd. administered Cape Blue Mines (Pty.) Ltd. and Egnep (Pty.) Ltd. Cape Blue produced blue crocidolite at its mines in northern Cape Province. The expansion and modernization of the Pomfret Mine (70,000 tons per year) was completed in August 1978. Egnep operated the recently modernized Penge Mine (100,000 tons per year) in Lydenburg district, in Transvaal Province, which continued as the world's leading amosite producer.

Kuruman Cape Blue Asbestos (Pty.) Ltd. and Danielskuil Cape Blue Asbestos (Pty.) Ltd. were subsidiaries of Asbestos Investment (Pty.) Ltd., owned by the European Eternit Group. Kuruman produced 30,000 tons per year of crocidolite at Whitebank and 18,000 tons per year in the Postmasburg District. Danielskuil operated a 15,000-ton-per-year mine in Cape Province.

Diamond.—Overall production of diamond (gem and industrial) increased marginally in 1978 and 1979 but the output value increased substantially. This rise in value per carat reflected continued world market price increases of 30% in 1978 and 15% in 1979 implemented by the De Beers Central Selling Organization, which controlled external sales of the country's diamond production and reportedly marketed about 80% of the world's diamond per year. In 1978, the volume of diamond sales decreased, while overall value increased more than 150%. Both volume and value showed substantial increases in 1979. Table 7 shows the marketed output of diamonds in carats and the average prices per carat realized for diamonds from various sources in the Republic of South Africa.

Table 7.—Republic of South Africa: Marketed diamond output, by type and province

Type and province	1977		1978		1979	
	Output (carats)	Price per carat	Output (carats)	Price per carat	Output (carats)	Price per carat
Mine diamond:						
Transvaal	2,033,790	$12.90	1,940,755	$31.95	2,033,993	$39.60
Cape Province	3,627,912	25.22	3,593,972	44.38	3,680,787	45.58
Orange Free State	455,780	84.37	408,802	113.97	441,050	117.34
Total	6,117,482	25.53	5,943,529	45.10	6,155,830	48.75
Alluvial diamond:						
Transvaal	10,014	154.85	16,274	294.18	22,268	325.21
Cape Province	1,338,906	103.42	1,430,273	168.17	1,995,046	172.45
Orange Free State	34	434.29	23	26.00	7	261.80
Total	1,384,954	103.81	1,446,570	169.07	2,017,321	174.13
Grand total	7,466,436	34.50	7,390,099	69.37	8,173,151	79.70

De Beers accounted for approximately 93% of South Africa's diamond production and 17% of world diamond production in 1978. The largest producing mines were the Finsch Mine in Cape Province, which produced 2.63 million carats in 1978 and 2.58 million carats in 1979, and the Premier Mine in Transvaal Province, which produced nearly 2 million carats in 1978 and 2.08 million carats in 1979. Both mines were to undergo expansion of production capacity. At the Finsch Mine, output was to be increased to 3.5 million carats annually by 1980 and capacity of the treatment plant was to increase 40%. At the Premier Mine, extraction of diamondiferous kimberlite from below a 100-meter-thick barren gabbro sill was initiated in 1978. This block, which was estimated to contain 14 million tons of kimberlite, was expected to greatly extend the life of the mine. A notable event for the 1978 diamond industry was finding, studying, and cutting the 353.9-carat Premier Rose diamond. The Mouw Diamond Cutting Works (Pty.) Ltd. bought the rough stone for $4.25 million, and cut it into three top-color stones of 137.02 carats, 31.48 carats, and 2.11 carats, which were subsequently exported and sold for approximately $6.0 million. In 1979 a 74.13-carat alluvial stone of exceptional quality was found at the Alexander Bay diggings and the uncut gem sold for about $10,000 per carat.

The Namaqualand mines production increased as a result of the commissioning of the Koingnaas Mine in August 1978. The open pit alluvial deposit was expected to reach a production capacity of 750,000 carats per year by 1980. Ore reserves were estimated at 15.5 million tons.

Cement and Limestone.—The growth in domestic demand led to an increase in the 1978 production of lime and limestone which was reversed in 1979. Although domestic sales of cement declined in both years, their value increased owing to higher cement prices. Total cement production was only slightly down in 1978, but increased in 1979. Exports of all three commodities increased in 1978 with cement exports nearly doubled. In 1979 cement exports declined in both volume and value. Imports of specialty cements increased drastically in 1979, with the value of imports from France showing a tenfold increase to about $2 million, while the value of imports from the United States declined to less than $8,000.

Four major companies accounted for over 85% of domestic limestone and cement production. Anglo Alpha Cement Co. Ltd. was the country's largest cement producer from its 1.9-million-ton-per-year Dudfield plants in Lichtenburg, its smaller Ulco plant in Kimberley, and plants at Phillipi and Roodeport, as well as its 500,000-ton-per-year plant at Ouplaas, about 160 kilometers west of Kimberly. Other major producers were Pretoria Portland Cement Co.

Ltd., and Cape Portland Cement Co. Ltd.

Fluorspar.—Output of fluorspar increased to new record production levels in both 1978 and 1979 making South Africa one of the world's leading producers and exporters of this commodity. Acid-grade fluorspar, containing 97% or more CaF_2, accounted for about three-fourths of the total production in 1978 and the proportion increased in 1979. Approximately 88% of total fluorspar resources were concentrated primarily in the Transvaal, Zululand, and northwestern Cape Province. In 1978 recoverable reserves were estimated at 190 million tons of ore with an average grade of 25% CaF_2, which can be readily improved by flotation.

The largest producer of fluorspar was Marico Fluorspar (Pty.) Ltd., a subsidiary of U.S. Steel Corp. Marico produced 120,000 tons per year of acid-grade fluorspar and 50,000 tons per year of metallurgical-grade fluorspar at its operation in Zeerust, Transvaal. Buffalo Fluorspar (Pty.) Ltd., a General Mining subsidiary, was rated as the world's largest producer of acid-grade fluorspar at its mine near Naboomspruit, which had a production capacity of 150,000 tons per year. Other producers were Chemspar Ltd., a subsidiary of Phelps Dodge, Vergenoeg Mining (Pty.) Ltd., owned by Bayer AG, and Ruigtepoort Fluorspar Mines (Pty.) Ltd.

Gypsum.—Production of gypsum declined from 1977 levels as both local sales and exports decreased. Domestic gypsum consumption declined owing to a slump in the building industry. Gypsum occurred extensively in western and northwestern Cape Province, in the Kimberley district of Orange Free State, and in central Transvaal Province. Reserves were estimated at 85 million tons. The largest producer was Gypsum Industries Ltd. with an annual production capacity of 620,000 tons per year from three mines.

Phosphate.—The government-controlled Phosphate Development Corp. Ltd. (FOSKOR) accounted for most of the Republic's phosphate production from its Palabora carbonatite deposit in northeastern Transvaal. Until 1979 FOSKOR's production of concentrates containing more than 30% P_2O_5 came from three sources: (1) Its own 8% to 9% P_2O_5 ore from its portion of the carbonatite deposit it owned and mined jointly with PMC, which owned the rights to copper, base metals, precious metals, and vermiculite, but not phosphate; (2) Copper-poor overburden stripped by PMC in order to expose its copper ore; and (3) The coarse fraction of PMC's tailings, which contained apatite and other phosphate minerals ready for FOSKOR's treatment. Concurrently with PMC's major open pit expansion plan, FOSKOR has also expanded its plant capacity to 3 million tons per year and agreed to draw exclusively on PMC's piped tailings and stockpiled overburden for its future ore requirements. FOSKOR continued to sell most of its concentrate locally to Federale Kunsmis Ltd. (FEDMIS) and Triomf Fertilizer (Pty.) Ltd., both of which manufactured phosphoric acid for export. Both the 250,000-ton-per-year plant operated by FEDMIS at Palabora, and the 500,000-ton-per-year Triomf plant at Richards Bay, were producing below capacity.

Another producer of phosphate was GFSA's Glenover Phosphate Ltd. with total output of about 75,000 tons of selective mine-run and hand-cobbed ore. Reserves at Glenover's mine in Thabazinbi, Transvaal, were estimated at 10 million tons of ore with an average content of 20% to 30% P_2O_5. Ore was sold locally to Chemfos Ltd., a subsidiary of SAMANCOR. A feasibility study was being conducted on mining vermiculite as a coproduct of phosphate at Thabazimbi. SAMANCOR suspended operations at its Langebaan Phosphate works in Cape Province early in 1978 owing to escalating costs and product surpluses in its traditional marketing area. Production capacity was 250,000 tons per year of concentrate sold primarily to the local market.

Vermiculite.—Vermiculite was produced as a byproduct from the copper operations of Palabora Mining Co. in northeastern Transvaal. The Republic of South Africa was the world's second-largest producer of this commodity and accounted for about one-third of world production. Both production and sales value increased in 1978 but declined in 1979. The bulk of production was exported chiefly to the United States and Western European countries with only about 7,000 tons per year consumed locally. Palabora had an annual production capacity of about 210,000 tons per year of vermiculite from its open pit operation. Reserves were estimated at 75 million tons.

MINERAL FUELS

Coal.—Coal was the nation's second-largest mineral revenue earner after gold in 1978 and 1979, when total value increased to a new record high of nearly $1.4 billion owing to increased prices for both exports and local sales. In 1978, coal supplied approximately 70% of the country's energy needs, and total production and exports continued to expand through 1979. Coal consumption was as follows: power generation was 57%; coke production dropped from 12% in 1978 to 11% in 1979; and industry was steady during both years at 10%, as were the SASOL oil-from-coal project at 7%, and mines and local merchants at 14%. The SASOL II oil-from-coal plant consumed 1% in 1979 as certain units commenced functioning.

The Republic expected to increase coal exports to 44 million tons per year by 1985 and to expand the capacity of the Richard's Bay facility accordingly. Coal production was rapidly expanding as new mines were opened or developed, and several operating mines were undergoing expansion in 1978 and 1979. It was estimated that development expenditures totaling $1.15 billion were initiated during those years. AAC's Amcoal subsidiary commissioned the Kleinkopje colliery, located near Witbank in Transvaal Province. Kleinkopje was to eventually supply 4.7 million tons per year of coal to the local commercial market and ISCOR, as well as export markets. Amcoal's new Kriel colliery, commissioned in 1977 had a production rate of 4.5 million tons per year by mid-1979. Trans-Natal Coal Corp. Ltd., a subsidiary of General Mining and Finance Corp., started production from the Ermelo mine, which was to eventually produce 3 million tons per year of steam coal for export. Shell Coal of South Africa Ltd., in conjunction with Transvaal Consolidated Land and Exploration Co. Ltd., commissioned Rietspruit, the country's largest export colliery on March 29, 1979. Located near Witbank, Rietspruit was designed to produce 5 million tons per year of steam coal for export. The Electricity Supply Commission (ESCOM) started production at its Matla No. 1 mine in May 1978 and began stockpiling coal at the rate of 2.2 million tons per year to supply the future Matla power station. Matla No. 2 mine was to come onstream in 1981 at a capacity of 4.2 million tons per year.

Petroleum.—The Republic of South Africa imported all its crude oil requirements other than the production obtained from the SASOL I oil-from-coal plant. In 1978, imports were approximately 125 million barrels of petroleum from Iran and the Arabian Gulf states. The country's five refineries had a throughput capacity of approximately 350,000 barrels per day. Information about oil imports and refinery throughput became increasingly difficult to obtain during 1979.

Petroleum exploration continued both onshore and offshore under the direction of the Government-owned Southern Oil Exploration Corp. (Pty.) Ltd. (SOEKOR). Since 1960, SOEKOR has spent $150 million on oil prospecting with disappointing results. It was announced in 1978 that exploration onshore would cease in 1979 since it has yielded only small, uneconomic occurrences of oil and gas, particularly associated with coal in northern Natal and the southeastern Transvaal. In 1978, SOEKOR reported oil traces in the Bredasdorp Basin south of Mossel Bay and small gas occurrences in Pletmos Basin. Exploration and drilling continued offshore along the west and south coasts in 1979.

The Mineral Industry of the Territory of South-West Africa

By Miller W. Ellis[1] and Candice Stevens[2]

The mineral industry contributed approximately 50% of the value of the estimated $1.3 to $1.4 billion[3] gross domestic product (GDP) of the Territory of South-West Africa in 1978 and 1979. Although some base-metal mines were closed owing to low metal prices, diamond prices rose 30% by yearend 1978 and 13% by September 1979, and uranium production increased in both years. Two firms, Consolidated Diamond Mines of South-West Africa (Pty.) Ltd. (CDM) and Rossing Uranium Ltd., accounted for over 75% of the value of mineral output. Other important mineral exports were copper and lead, produced primarily by Tsumeb Corporation Ltd. The Territory's operating budget of appoximately $500 million was derived largely from tax revenue paid by the mineral industry.

Labor problems caused slowdowns at several mines. The Rossing uranium mine, Krantzberg tungsten mine, and Uis tin mine experienced strikes in 1978 and negotiations over pay rates at Tsumeb were settled by wage increases in January and May 1979. In 1978, a Chamber of Mines, established to replace the former Mining Association, was composed of representatives of the mining companies in the Territory. Its functions were to promote and protect the interests of the industry, attend to matters such as transport and labor, and monitor marketing exports. A Government commission was also established to investigate the feasibility of subsidies for marginal mines during periods of low prices.

In August 1978, areas previously closed in the northern part of the Territory were opened to mineral exploration. CDM initiated a detailed geological, geochemical, and airborne geophysical survey for minerals other than diamonds in the northern and eastern parts of the country. The first results of this survey, which covered Kaokoveld, Ovamboland, and the Gobabis area, were placed on open file with the Geological Survey of South-West Africa. CDM appropriated $28 million for diversification outside the diamond area. Mineral exploration for uranium and base metals was undertaken by Johannesburg Consolidated Investment Co. (JCI), Falconbridge Nickel Mines Ltd., Anglo Transvaal Consolidated Investment Co. Ltd., and Barlow Rand Ltd.

A consortium of British and South African engineering companies were studying the feasibility of constructing a Trans-Kalahari Railroad at an estimated cost of $1 billion. The 900-kilometer railroad would link Francistown in northern Botswana with the existing railhead at Gobabis in South-West Africa. Various Governments and organizations such as the United Nations have been approached with a preliminary report, and tenders have been requested. The Ruacana Falls hydroelectric scheme, which was to supply electricity to the northern half of the Territory, remained incomplete because South African engineers were denied access to the north bank of the river by Angolan authorities. The Territory was to be linked with the Electricity Supply Commission of South Africa (ESCOM) grid through a 320-megawatt power line. The status of the port of Walvis Bay, which handled over 80% of the Territory's exports, remained a subject for negotiations between the Territory and the Republic of South Africa, which has held ownership rights to the port since 1884.

PRODUCTION AND TRADE

Since the compilation of separate production and trade statistics for the Territory was suspended by the South-West Africa Administration in 1965, much of the statistical data in table 1 was derived from the annual reports of the companies operating in the Territory. Although virtually all of the Territory's mineral products were exported, specific data on exports remained unavailable and are no longer incorporated with exports reported by the Republic of South Africa. Trade statistics on some imports have been incorporated with those of the Republic of South Africa with which the Territory is a member in the South African Customs Union.

The Territory's balance-of-trade surplus was estimated at $350 million in 1978 increasing to about $450 million in 1979 chiefly owing to increased earnings from uranium and diamond exports. The mining sector's share of total export earnings increased from 68% to nearly 75% in 1979. Diamond was marketed by the Central Selling Organization of DeBeers Consolidated Mines Ltd. Uranium was sold under contract to Japan and Western European countries. Metal production from Tsumeb Corp. was transported on a 640-kilometer company-owned railroad to Tsumeb's loading facilities at Walvis Bay for overseas refining.

COMMODITY REVIEW

METALS

Copper.—The gross value of total sales of Tsumeb Corp., the Territory's principal producer of nonferrous metals, increased from $61 million in 1977 to $86.4 million in 1978 and more than $131 million in 1979 owing largely to increased copper sales and higher metal prices. The company's profits increased from $2.5 million to $12 million and to $26 million for the same periods. Tsumeb was South-West Africa's leading producer of copper, lead, and silver; a secondary producer of zinc; and the only source of arsenic and cadmium. Newmont Mining Corp. (United States) was the manager and a principal shareholder (29.2%) of Tsumeb Corp., whose other owners included AMAX Inc. (29.9%), Selection Trust Ltd. (14.2%), O'okiep Copper Co. Ltd. (9.5%), Union Corporation Ltd. (9.4%), South-West Africa Co., Ltd. (SWACO) (2.4%), and others (6.1%).

At Tsumeb, the company's largest mine located 400 kilometers north of Windhoek, 466,533 tons of ore were milled in 1978 containing 4.95% copper, 7.01% lead, and 1.68% zinc. Mine development, which had been at a reduced rate since 1976 pending improved metal prices, was accelerated somewhat but the grade declined during 1979. Tsumeb's ore reserves at yearend 1979 were estimated at 3.5 million tons containing 4.27% copper, 7.02% lead, and 1.91% zinc.

Tsumeb's Matchless mine plant, located 42 kilometers south of Windhoek, milled 110,000 tons of high-sulfur copper ore in 1978 and 115,000 tons in 1979. Reserves at yearend were estimated at 702,161 tons of ore containing 2.34% copper and 12.56% sulfur. The Kombat mill, reopened in October 1978, treated 40,510 tons of ore containing 2.23% copper and 1.66% lead from both the Kombat and Asis West deposits by yearend. The Kombat feed increased to 301,420 tons of ore with 2.89% copper and 2.31% lead in 1979. The mill feed from Asis West amounted to 17,174 tons with 3.08% copper and 0.72% lead. The nearby Asis Ost mine remained idle during the 2-year period. Reserves at yearend 1979 were:

Deposit	Metric tons	Copper (percent)	Lead (percent)
Kombat	564,700	1.65	2.97
Asis West	568,045	5.57	2.06
Asis Ost	255,386	2.83	0.67

Tsumeb Corp.'s overall copper production increased from 22,827 tons in 1977 to 29,633 tons in 1978 and decreased to 28,768 tons in 1979. Sales totaled 32,522 tons in 1978 rising to 32,707 tons in 1979 as secondary stocks at the smelter were reduced to minimum operating levels. The No. 2 smelter circuit, constructed to treat toll concentrates from the Otjihase mine, was idle throughout both 1978 and 1979 and Tsumeb received penalty

[e]Estimate. [p]Preliminary. [r]Revised. NA Not available.

[1]In addition to the commodities listed, the Territory of South-West Africa, prior to 1967, produced bismuth concentrates, cesium ore, columbite-tantalite concentrates, gold, manganese ore, molybdenum concentrates, graphite, kyanite, lime, mica, precious stones, sillimanite, and a variety of crude construction materials (clays, stone, and sand and gravel). No official statistics have been published since yearend 1966, and available information is inadequate to ascertain if production has continued and, if so, at what levels.

[2]Data for 1976, 1977, and 1978 are compiled from operating company reports for 1976-78 as follows: Tsumeb Corp. Ltd. (arsenic, mine and refined cadmium, mine and blister copper, mine and refined lead, mine and smelter silver, mine zinc, and pyrite concentrates); South-West Africa Co. Ltd. (SWACO) (mine lead, mine tin, mine tungsten, mine vanadium, and mine zinc); South African Iron and Steel Industrial Corp. Ltd. (ISCOR) for Imcor Zinc (Pty.) Ltd.'s Rosh Pinah mine (mine lead and mine zinc) and for ISCOR's own Uis mine (mine tin); General Mining & Finance Corp. Ltd. for Klein Aub Koper Maatskappy Ltd.'s mine near Rehoboth (mine copper and mine silver); and Falconbridge Nickel Mines Ltd. for Oamites Mining Co. (Pty.) Ltd.'s Oamites mine (mine copper). Data from Tsumeb and Falconbridge are for calendar years; data from other companies are for fiscal years ending June 30 of that stated.

[3]White arsenic equivalent of all arsenic products reported as being produced.

[4]Figures for 1976, 1977, and 1978 comprise reported production of Tsumeb and Oamites plus estimates for Klein Aub and Johannesburg Consolidated Investment Co. Ltd.'s Otjihase copper mine.

[5]Figures for 1976, 1977, and 1978 comprise reported production of Tsumeb plus estimates for Oamites and Klein Aub.

[6]Figures for 1976, 1977, and 1978 comprise reported production of ISCOR for Imcor's Rosh Pinah mine plus an estimate for Tsumeb (based on ore milled), as well as an estimate for SWACO for 1977 and 1978.

[7]Totals reported by De Beers Consolidated Mines Ltd. in company annual reports for calendar years; detail on gem and industrial diamond are estimates, assuming output to be 95% gem quality.

[8]Output has not been officially reported since 1966 but presumably has continued, since a number of countries record imports from "South Africa," which in total quantity considerably exceed reported output of the Republic of South Africa and presumably include shipments from the Territory of South-West Africa. Quantities given represent imports of the United States and the European Communities reported as originating in South Africa, but the reader is cautioned that a portion of the material may have been mined in Southern Rhodesia.

payments for nondelivery of concentrates. At the beginning of 1978, Tsumeb Corp. established a London sales office and commenced marketing its own products jointly with O'okiep Copper Co. Ltd. of Springbok in the Republic of South Africa.

The Territory's second largest producer of copper was Oamites Mining Co. (Pty.) Ltd., a joint venture of Falconbridge Nickel Mines Ltd. (Canada) (74.9%) and International Development Corp. (IDC) of the Republic of South Africa (25.1%). The Oamites mine, located 55 kilometers south of Windhoek, produced and milled successively 620,000 tons, 615,000 tons, and 575,000 tons of ore from 1977 through 1979. Recoverable copper output decreased 6,916 tons in 1978 to 6,231 tons in 1979 but the sales revenue increased from $13.38 million to $18.5 million during the same period. Reserves at yearend 1979 were estimated at over 2 million tons of ore containing 1.09% copper and about 0.5 troy ounce of silver per ton.

Klein Aub Koper Maatskappy Ltd., a subsidiary of General Mining and Finance Corp. Ltd. (GMF) (Republic of South Africa) produced copper/silver concentrates for its mine and mill near Rehoboth, shipped them to Tsumeb for smelting, and exported the blister to Federal Republic of Germany at a rate of nearly 5,000 tons per year. Higher prices for metals, particularly silver, accounted for the company's first dividend in several years of $0.9 million in 1978 and for a fivefold increase in dividend to $5.1 million in 1979. The Otjihase copper mine, located 27 kilometers northeast of Windhoek and owned by Johannesburg Consolidated Investment Co. Ltd. (JCI) (49%) and Minerts Development (Pty.) Ltd. (51%), remained on a care-and-maintenance basis throughout 1978 and 1979. The Otjihase plant was being maintained in such condition that production could again be resumed at short notice. Previous output consisted of concentrate shipped to Tsumeb and smelted into approximately 6,000 tons per year of blister copper.

Lead, Zinc, and Vanadium.—Tsumeb was the Territory's leading producer of lead with 33,826 tons in 1978, decreasing to 31,369 tons in 1979. Sales were 39,974 tons and 33,505 tons for 1978 and 1979, respectively. Tsumeb also produced nearly 500 tons of zinc concentrate, and byproduct arsenic and cadmium, and about 1.5 million troy ounces per year of silver. A secondary producer of lead and a major producer of zinc was the Rosh Pinah mine, located in the Namib Desert about 27 kilometers north of the Orange River. The open-pit mine had a capacity of 160,000 tons of ore per month to produce about 40,000 tons of 48% zinc concentrate and 12,000 tons of 45% lead concentrate per year. Rosh Pinah was operated by Imcor Zinc (Pty.) Ltd., a subsidiary of the South African Iron and Steel Industrial Corporation Ltd. (ISCOR).

The Berg Aukas mine, which has produced lead, zinc, and vanadium concentrates since the early 1920's, was closed because of low metal prices. Located near Grootfontein, Berg Aukas was acquired for SWACO by Kiln Products Ltd., administered by Gold Fields of South Africa Ltd. (GFSA), and partly owned (41.85%) by Anglo American Corp. of South Africa Ltd. (AAC). Kiln Products operated a kiln on the Berg Aukas property in which zinc silicate concentrate and zinc residues, bought from Berg Aukas, were roasted and converted to oxides. The zinc oxide was then sold to GFSA's subsidiary refinery, Zinc Corp. of South Africa Ltd. (ZINCOR).

Tin and Tungsten.—The Uis tin mine, located northeast of Swakopmund near Brandberg, was the Territory's major tin producer with output averaging 800 tons per year of tin metal. This massive low-grade tin deposit containing about 0.15% tin was operated by Industrial Minerals Corp. (Pty.) Ltd., a wholly-owned subsidiary of ISCOR. Mill throughput capacity was around 72,000 tons of ore per month to produce some 1,300 tons of concentrate per year containing about 64% tin. Output from the Uis mine was shipped to ISCOR's tin smelting plant in the Vanderbijlpark Steel Works in the Republic of South Africa.

SWACO brought its Brandberg West tin-tungsten mine back into production in 1975 after a hiatus of 3 years. Production averaged 200 tons of tin and 150 tons of tungsten per year and the mine operated at less than full capacity in 1978-1979. In October 1979, the Strathmore tin mine recommenced production with a staff of 50 people. Tungsten was produced by the Krantzberg mine, owned by Nord Resources Corp. (40%) and Ebco Mining Co. (60%). Located near Omaruru, northwest of Windhoek, Krantzberg's production capacity was rated at 600 tons of 70% tungsten trioxide concentrate per year but the mine has operated at less than capacity in recent years. Tungsten reserves in South-West Africa were estimated at 4,000 tons of contained tungsten metal.

Uranium.—Output from Rossing's large uranium operation near Swakopmund increased rapidly from startup in 1977 to planned output capacity by yearend 1979. Gross turnover value increased from $156 million in 1958 to $272 million in 1979, while net profits increased from $2.8 million to $26.7 million during the same period. Since the first uranium output in mid-1976, Rossing has suffered a series of design and technical difficulties in the treatment plant. Throughput was restricted by the abrasiveness of the ore which caused excessive wear in the plant. Modifications to the grinding circuit cost $100 million but have increased milling capacity to about 40,000 tons per day of ore. In May 1978, a fire in one of the treatment plant's two solvent extraction units necessitated extensive repairs and replacements. A workers' strike over wage levels at yearend 1978 caused reduced output until it was settled in 1979. The large (375 million tons) low-grade (0.4% U_3O_8) ore body was managed and partly owned by the

Rio Tinto Zinc Corp. Ltd. (United Kingdom) (46.5%) and has been worked to a depth of 60 meters over an area of about 2.5 square kilometers. It was designed for an overall size of 3 square kilometers to a depth of 300 meters with possible subsequent underground development. The other partners include IDC, GMF (South Africa), and Total Compagnie Miniere et Nucleaire (France). Contracts for the delivery of uranium oxide production through the mid-1980's were concluded during the year. Major purchasers were the United Kingdom Atomic Energy Commission, Kansai Electric Power Company of Japan, Total (France), and Urangesellschaft (West Germany).

Uranium prospecting was being conducted north and east of Swakopmund by a number of other companies. General Mining was considering a $350 million operation at the 60-million-ton Langer Heinrich uranium deposit near Tinkas. Production was estimated at 3,000 tons per year of U_3O_8, and pilot plant work needed to develop a viable alkali leach process for the secondary calcrete ore was completed during 1978. GFSA evaluated the Trekkopje uranium deposit 20 kilometers northeast of Rossing, and AAC reported substantial tonnages of uranium mineralization in its concession area. Other groups conducting uranium exploration included Falconbridge and Omitaramines (France).

NONMETALS

Cement.—The First National Development Corporation, a consortium of several South-West African firms, was to contribute $7 million toward the construction of a $35 million cement plant in Karibib northwest of Windhoek. Feasibility studies were in progress on the plant which would be the first in South-West Africa. The major investor in the plant was the South-West Africa Portland Cement Co. Ltd., owned by Pretoria Portland Cement Co. and Anglo-Alpha Cement Co., both of the Republic of South Africa. The plant was to utilize local limestone and gypsum deposits, and to begin production in 1981.

Diamond.—Diamond production by CDM, a wholly owned subsidiary of DeBeers Consolidated Mines Ltd., decreased slightly below the 1977 level in 1978 and 1979. Approximately 95% of CDM's diamonds were gemstones and CDM accounted for 22% of DeBeers' after-tax profits in 1978. The amount of gravel treated at Orangemund increased from 14.90 million tons in 1977 to 15.14 million tons in 1978 and 16.03 million tons in 1979 but the recovery grade dropped from 0.1343 carat per ton to 0.1031 carat per ton over the 2-year period. The quantity of overburden stripped at CDM's mining operation, stretched over 100 kilometers of coastal area north of the Orange River, decreased from 59 million tons in 1977 to 55 million tons in 1978 and 54.9 million tons in 1979. Modifications and improvements effected during the year to the four conglomerate treatment plants, all of which were operating at full capacity, enabled more efficient operations to be achieved. However, a fire and the failure of a bridge bearing at the bucketwheel excavator caused its availability to drop to 65% by 1979. A special effort was undertaken to establish new reserves which might extend the life of CDM's diamond operation in South-West Africa. Reconnaissance prospecting was conducted over large portions of the country. Exploration on both the beach and inland in the Sperrgebiet area below Luderitz was intensified. Work continued on the sampling of potential reserves in the central and western blocks of the diamond mining area in order to increase ore reserve information. Modifications to the sampling plant were completed in 1979 and 720,400 tons of samples were treated, 52% more than in 1978. Systematic sampling at sea was also conducted.

MINERAL FUELS

Coal.—Evaluation of South-West Africa's low-grade coal deposits continued in 1978 and 1979. Drilling was being conducted in three general areas: northeast of Etosha Pan in Ovamboland; along the Kaokoveld coast; and northeast of Aminuis along the Botswana border.

Petroleum.—All oil exploration in the Territory was under the direction of the Southern Oil Exploration Corp. (Pty.) Ltd. (SOEKOR) of the Republic of South Africa. No prospecting activity other than offshore drilling conducted by SOEKOR was reported. South-West Africa imported all of its petroleum product requirements.

The Mineral Industry of Spain

By Roman V. Sondermayer[1]

During 1978 and 1979, Spain continued to develop its mineral resources with the aim of lowering imports of raw materials and fuels and improving its trade deficit in minerals. Spain's approximate share of world output of its most significant minerals was as follows: mercury 18%, pyrite 11%, fluorspar 8.5%, potash 2.1%, steel 1.6%, zinc 1.5%, and barite 1.4%. The share of the mineral industry in the gross national product (GNP) of the country was declining as sharp increases in other sectors of the economy lowered the importance of the mining sector to below 1% of the GNP. Spain was dependent on imports for most of its petroleum, coking coal, and metals.

During 1978, the Government issued Royal Decree 1167, which expands upon provisions in Mining Development Law 6 for promoting and developing mining, prospecting, and research within the national territory. In short, producers of raw materials assigned priority under the country's national supply plan receive a rebate of up to 95% of taxes on property transfers, imports, capital gains, and other commercial and industrial activities and profits during the installation period. Furthermore, during 1979, work on the Spanish National Raw Materials Plan was completed. The plan known in Spain as Plan Nacional de Abastecimiento de Materias Primas Minerales (PNAMPM) will require the investment of 247,267 million pesetas. The State will provide 40% of planned investment and private capital the rest. The prime goal of the plan is to reduce foreign dependence on imports of mineral raw materials. Five minerals (iron, manganese, copper, zinc, and lead) will receive priority, and these minerals will account for 60% of total planned investments.

In 1978, major events of the mineral industry were the completion of an aluminum plant at San Ciprián, expansion of copper mines at Cerro Colorado, development of complex sulfide ore deposits at Aznalcollar and Sotiel, discovery of natural gas in areas in the north and south of Spain, and discovery of uranium in the provinces of Salamanca and Segovia. In 1979, major events were as follows: completion of construction of a steel miniplant near La Coruña and commissioning of the complex sulfide ore mine and plant at Aznalcollar.

PRODUCTION

Ownership of the mineral industry was both Governmental and private. The Government manages most of its companies through Instituto National de Industria (INI).

Table 1 shows changes in output of minerals during 1978 and 1979.

Table 1.—Spain: Production of mineral commodities

(Metric tons unless otherwise specified)

eEstimate. pPreliminary. rRevised. NA Not available.

[1]Reported figure.

[2]Includes recorded production of salable acid-grade fluorspar from both fluorspar mines and lead-zinc mines plus some salable acid-grade fluorspar obtained by beneficiating a portion of salable metallurgical-grade fluorspar.

[3]Includes sand obtained from kaolin.

TRADE

During recent years Spanish imports of minerals have ranged between 30% and 40% of total imports; petroleum has accounted for about 25% of total imports. Exports of minerals were about 15% of the country's total exports. Tables 2 and 3 show details of foreign trade in minerals. The United States had a positive trade balance in minerals with Spain, with a surplus of about $39 million. Coal, coke, and phosphates topped the list by value of U.S. exports to Spain. Zinc metal, quartz, feldspar, fluorspar, mica, salt, and petroleum refinery products were the most valuable imports from Spain.

Table 2.—Spain: Exports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1977	1978	Principal destinations, 1978
METALS			
Aluminum:			
Oxide and hydroxide	52	47	Portugal 19; United Kingdom 13; Argentina 11.
Metal including alloys:			
Scrap	136	219	France 94; West Germany 46; Italy 42.
Unwrought	8,860	5,838	Portugal 2,385; Japan 2,119; Hong Kong 1,001.
Semimanufactures	12,366	10,790	United States 1,886; Portugal 1,268; Cuba 1,037.
Antimony metal including alloys, all forms	262	392	Netherlands 156; United States 90.
Arsenic trioxide, pentoxide, acids	(1)	--	
Bismuth metal including alloys, all forms	6	2	All to Netherlands.
Cadmium metal including alloys, all forms	208	143	United States 79; Netherlands 51.
Chromium:			
Chromite	18	14	All to Italy.
Oxide and hydroxide	16	20	Greece 10; Colombia 6.
Copper:			
Ore and concentrate	2,637	36	All to West Germany.
Matte	575	689	Mainly to West Germany.
Copper sulfate	348	736	Mainly to United States.
Metal including alloys:			
Scrap	1,593	705	West Germany 323; Japan 303.
Unwrought	47,382	52,375	Belgium-Luxembourg 11,140; West Germany 10,453; Italy 9,824; France 9,794.
Semimanufactures	7,770	17,629	Morocco 3,231; Italy 2,505; Portugal 2,146; Iran 1,806.
Gold metal, unworked or partly worked thousand troy ounces	713	482	Switzerland 257; United Kingdom 225.
Iron and steel:			
Ore and concentrate, except roasted pyrite thousand tons	1,466	948	West Germany 424; Netherlands 227; United Kingdom 114.
Roasted pyrite ----do----	531	172	Mainly to West Germany.

See footnotes at end of table.

METALS —Continued			
Other:			
Ores and concentrates of molybdenum, tantalum, titanium, vanadium, zirconium	90	56	United States 26; Iran 12; Netherlands 8; Austria 5.
Ash and residue containing nonferrous metals	23,325	33,531	Sweden 15,048; East Germany 12,422.
Oxides, hydroxides, peroxides of metals	14,879	16,352	Kuwait 9,911; Saudi Arabia 5,000.
Metals including alloys:			
Alkali, alkaline-earth, and rare-earth metals	(1)	1	Mainly to Austria.
Pyrophoric alloys	(1)	60	All to Portugal.
Base metals including alloys, all forms, n.e.s.	3	44	Netherlands 33.
NONMETALS			
Abrasives, natural, n.e.s.:			
Pumice, emery, natural corundum, etc	1,990	2,547	United Kingdom 1,000; West Germany 867.
Dust and powder of precious and semiprecious stones value, thousands	$22	$28	Switzerland $10; Argentina $5; Mexico $4; Venezuela $4.
Grinding and polishing wheels and stones	2,358	2,468	West Germany 1,247.
Asbestos	11	33	Italy 20; Portugal 10; Mexico 3.
Barite and witherite	58,070	90,794	West Germany 52,409; Algeria 20,700.
Boron materials:			
Crude natural borates	19	401	Portugal 341.
Oxide and acid	1,120	2,986	United States 1,316; West Germany 900.
Cement thousand tons	7,517	9,830	Saudi Arabia 2,741; Nigeria 1,207.
Chalk	12,919	18,753	Algeria 8,512; Portugal 3,499; Libya 2,308.
Clays and clay products (including all refractory brick):			
Crude:			
Bentonite	40,090	37,881	Portugal 17,482; West Germany 4,500.
Kaolin (china clay)	57,720	59,802	West Germany 25,853; Italy 9,209; France 7,569.
Other	21,593	24,623	Portugal 5,409; Andorra 4,032; Italy 3,184.
Products:			
Refractory (including nonclay brick)	26,136	32,676	Egypt 6,507; Cuba 5,112.
Nonrefractory	321,084	308,085	France 78,795; West Germany 25,003; Andorra 23,681.
Cryolite and chiolite kilograms	--	50	All to Austria.
Diamond:			
Gem, not set or strung value, thousands	$232	--	
Industrial do	$66	$82	Mexico $33; Ireland $32; Belgium-Luxembourg $12.
Diatomite and other infusorial earth	2,286	1,658	Belgium-Luxembourg 447; Italy 410; United Kingdom 323; France 198.
Feldspar, leucite, nepheline, nepheline syenite	5,720	6,989	Mainly to France.
Fertilizer materials:			
Crude and manufactured:			
Nitrogenous	300,316	311,253	Belgium-Luxembourg 68,186; United Kingdom 67,149; Brazil 58,908.
Phosphatic	56,053	17,133	Brazil 10,451; Kenya 3,113; Syria 2,517.
Potassic	492,764	404,741	Portugal 53,232; Norway 52,718; United Kingdom 44,501; United States 40,200.
Other	186,708	191,892	Venezuela 63,500; Turkey 44,928; Thailand 33,941; Sri Lanka 27,500.
Ammonia	38	53	Mauritania 28; Ghana 25.
Fluorspar	200,722	193,485	United States 94,023; West Germany 35,601; Italy 30,491.
Graphite, natural	37	1	Mainly to Peru.
Gypsum and plasters	635,097	775,752	Denmark 194,323; Sweden 188,790; Finland 68,250.
Iodine	1	2	Colombia 1; Venezuela 1.
Lime	7,365	6,999	Kuwait 1,798; Algeria 1,554; Equatorial Guinea 1,541; Morocco 1,000.
Magnesite	92,936	79,029	United Kingdom 25,041; West Germany 21,692; Poland 11,246.
Mica, all forms	950	3,048	United Kingdom 2,704.
Pigments, mineral, including processed iron oxides	10,065	9,652	United Kingdom 1,399; United States 947.
Precious and semiprecious stones, except diamond:			
Natural value, thousands	$61	$141	Switzerland $105; India $13.
Manufactured do	$340	$480	Switzerland $385; United States $36.
Pyrite, gross weight thousand tons	294	242	Belgium-Luxembourg 210.
Salt and brines do	645	816	United States 419; Italy 140; Portugal 75.
Sodium and potassium compounds, n.e.s	57,501	90,033	China, Mainland, 17,060; Portugal 13,975; Brazil 9,541.

Calcareous	22,762	26,457	Italy 19,258; France 2,077.
Slate	1,597	1,648	France 1,464.
Other	56,673	79,765	Italy 58,420; France 14,737.
Worked:			
Slate	129,818	147,677	France 125,003; West Germany 10,964.
Paving stone and flagstone	109	48	All to France.
Other	16,247	20,133	West Germany 10,403; France 2,364.
Dolomite	82,374	110,304	United Kingdom 86,974; West Germany 17,750.
Gravel and crushed rock	61,489	58,085	Andorra 41,644; Morocco 15,868.
Limestone	2,000	--	
Quartz and quartzite	195,547	224,408	Mainly to Norway.
Sand, excluding metal bearing	173,366	174,217	Mainly to Andorra.
Sulfur:			
Elemental, all forms	20,615	25,953	Turkey 16,135; Algeria 8,438.
Sulfur dioxide	331	--	
Sulfuric acid	150	112	Morocco 65; France 26; Mauritania 16.
Talc, steatite, soapstone, pyrophyllite	9,608	6,128	Austria 3,000; United Kingdom 1,005.
Other:			
Crude:			
Meerschaum, amber, jet	146,468	--	
Other	365,226	508,142	France 246,684; Belgium-Luxembourg 117,909; West Germany 56,520.
Slag, dross, and similar waste, not metal bearing	43,819	74,367	Portugal 49,446; France 11,363; West Germany 10,407.
Oxides and hydroxides of magnesium, strontium, barium	360	181	West Germany 90; Canada 72; Republic of South Africa 19.
Building materials of asphalt, asbestos, and fiber cement, and unfired nonmetals, n.e.s	112,308	82,630	Kuwait 27,960; France 19,285; Nigeria 16,165.
MINERAL FUELS AND RELATED MATERIALS			
Asphalt and bitumen, natural	97	26	Mainly to Abu Dhabi.
Carbon black and gas carbon	3,843	5,081	Portugal 3,921; Algeria 843.
Coal and briquets:			
Anthracite and bituminous coal	21,967	16,395	Mainly to Belgium-Luxembourg.
Lignite and lignite briquets	135	31	All to Andorra.
Coke and semicoke	2,955	2,048	Mainly to Mexico.
Hydrogen, helium, rare gases	190	530	Italy 307; Belgium-Luxembourg 219.
Peat, including peat briquets and litter	([1])	4	All to Portugal.
Petroleum:			
Crude and partly refined thousand 42-gallon barrels	138	--	
Refinery products:			
Gasoline, including natural do	3,042	628	Morocco 189; Zaire 163; Syria 108; Andorra 63.
Kerosine and jet fuel do	907	1,683	United Kingdom 330; Morocco 180; France 160; United States 149.
Distillate fuel oil do	4,335	4,853	Netherlands 560; Morocco 460.
Residual fuel oil do	9,379	7,177	Sweden 1,616; United States 1,417.
Lubricants do	884	79	Switzerland 18; Greece 13; France 11.
Other:			
Liquefied petroleum gas do	689	30	Morocco 19; Portugal 9.
Mineral jelly and wax do	7	6	Morocco 5; France 1.
Petroleum coke do	2,528	--	
Bitumen and other residues do	355	2,808	Italy 1,105; Libya 562; Nigeria 324.
Bituminous mixtures, n.e.s do	56	319	Nigeria 177; Libya 108.
Pitch and pitch coke do	134	78	France 69; Portugal 8.
Unspecified do	21	1,970	Belgium-Luxembourg 295; Greece 87.
Total do	22,337	19,631	
Mineral tar and other coal-, petroleum-, or gas-derived crude chemicals	40,065	19,239	Netherlands 6,572; Italy 5,857; France 3,196.

COMMODITY REVIEW

METALS

Aluminum.—The aluminum plant at San Ciprián de Viñas, Province of Lugo, started trial production in December 1979. Designed capacity of about 180,000 tons per year should be reached in 1980. During 1978, through the Bank of Bilbao, the owner, Aluminio Español, S.A., a subsidiary of Empresa Nacional del Aluminio (ENDASA), Aluminio de Galicia, S.A., and others, received a loan of 95 million dollars from a consortium of international banks. The loan will be used for completion of an 800,000-ton-per-year alumina plant under construction at San Ciprián. During 1979, construction of the alumina plant at San Ciprián continued. With the San Ciprián aluminum plant in operation, Spain had five aluminum plants at yearend 1979. The supply of aluminum should exceed demand between 1980 and 1982, and the surplus will be available for export. However, after 1982 domestic demand should increase, and all domestic aluminum is expected to be consumed in Spain. With modest bauxite production and resources, Spain remained largely dependent on imported bauxite and alumina to meet the requirements of the domestic aluminum industry.

Copper.—During 1978 and 1979, the largest producer of copper in Spain, with output close to 30,000 tons of copper in concentrates, Rio Tinto Minera S.A., continued expansion of its mine and mill at Cerro Colorado, Province of Huelva. The expanded mill and mine will enable the company to produce an additional 23,000 tons per year of copper. Development of mines at Aznalcollar and Sotiel are described in the section on pyrite, as part of a large project for recovery of nonferrous metals from complex sulfide ores.

Iron Ore.—Difficulties in the domestic steel industry reflected adversely on the iron mines. However, to improve the country's negative trade balance, expansion of capacity was underway at iron ore mines, owned by various companies, in the Provinces of Granada, Huelva, Badajoz, Teruel, and Guadalajara.

Spain imported about 4-5 million tons per year of iron ore to meet its demand, or about one-half of its requirements. The expansion underway was expected to decrease the imports required to about one-third.

Iron and Steel.—The iron and steel industry of Spain had difficult years during 1978 and 1979. The apparent consumption of steel declined owing to a general slowing of capital investments, particularly in shipbuilding.

The Government of Spain was preparing long-term and short-term plans to aid the steel industry. The long-term steel policy, being finalized at yearend 1978, was expected to be based on new forecasts of consumption, a study of the structure of the steel industry, and studies of the problems of raw materials, fuels, and financing. The short-term plan envisages substantial cash aid to the country's large steelmakers, but not the restructuring which would be necessary if the industry intended to remain competitive after Spain joins the European Economic Community. During 1979, however, the plan was not approved pending further examinations by all concerned.

Cia. Española de Laminación, S.A. (Celsa) started production in a new melting shop and continuous casting facility at its San Andreas de la Barca works near Barcelona. The 80-ton Electromelt furnace was built by Guinea Hnos. The continuous casting machine is a six-strand Concast for 100- to 160-millimeter billets of 5- to 12-meter lengths. Capacity is 200,000 tons per year.

The Spanish roller, Tetracero, owned 47% by ENSIDESA, closed the Castellbisbal (Catalonia) works and was preparing to sell it. In addition, the company shut down its Seville works and was restructuring the installation at Gijon (Asturias).

The steel miniplant of Sidegasa (Siderurgica de Galicia, S.A.) was completed during 1979 at a site in Galicia situated 24 kilometers from Teijeiro, 50 kilometers from La Coruna and 54 kilometers from Santiago de Compostela. Capacity of the new plant is 307,000 tons per year of steel and 255,000 tons of rolled products, of which 80,000 tons will be wire rods, and the rest will be 50,000 tons of merchant bars and 125,000 tons of deformed reinforcing bars. Commissioning of the Sidegasa plant indicates an increase of Spain's electric steelmaking capacity.

Pyrite.—Development of the Aznalcollar complex sulfide ore deposit, in the Province of Huelva, continued during 1978, and in 1979 the mine and plant came onstream. The operating company, Andalusa de Piritas S.A. (APRISA), received from the Government special fiscal benefits for the construction of a 500,000-ton-per-year sulfuric acid plant in Aznalcollar. APRISA obtained a 95% reduction in corporate taxes and a 5-year grace period for repayment of Government loans. When in full production, Aznalcollar will produce 51,000 tons of copper concentrates (25% copper), 42,000 tons of lead (50% lead), and 98,000 tons of zinc concentrates (50% zinc) from 2 million tons of complex sulfide ores and 1.5 million tons of cupriferous pyroclastic rocks. Reports show Aznalcollar proven reserves to be about 44.5 million tons of complex sulfide ores with 0.58% copper, 1.78% lead, 3.3% zinc, and 57 grams of silver per ton of ore; and about 34 million tons of cupriferous pyroclastic rock with about 0.58% copper, 0.40% lead, and 10 grams of silver per ton of ore.

At Sotiel, Huelva, the Government-owned company, Almagrera S.A., continued exploration and metallurgical testing of about 40 million tons of complex sulfide ores. At Huelva, Aprovechiamento Integral de Piritas S.A. (AIP), owned by Union Explosivos Rio Tinto (68.5%), Compañia de Azufre y

Cobre Tharsis (24.6%), and Metalquimica del Nervion S.A. (6.9%), studied the possibility of recovery of nonferrous metals from pyrite cinder left after roasting to recover sulfur. During 1978 and 1979, the AIP work on development of a 1-million-ton-per-year pellet installation and facilities for recovery of nonferrous metals was slowed because of financial difficulties.

NONMETALS

Bentonite.—Most of the bentonite deposits were located in southern and central Spain. The largest producer was Minas de Gador S.A. (Gador), about 40% owned by Laporte Industries of the United Kingdom. Gador's main source of bentonite was a large mixed deposit containing montmorillonite clay and calcium-based absorbent clay, situated at Serrate de Nijar in Almeria. Annual production was about 36,000 tons of sodium-exchanged bentonite, 12,000 tons of activated bleaching earths, and 12,000 tons of absorbent granules. Other bentonite producers were CECA Española, which produced bentonite in Almeria, and Bentonitas Especiales S.A.-Benesa with production from deposits in the Madrid-Toledo area.

Cement.—During 1978 and 1979, no major events were reported in the cement industry of Spain. The largest cement plant was the 2-million-ton-per-year Barcelona plant operated by Uniland S.A. of Barcelona. Of total capacity (34 million tons per year of cement), Cia. General de Asfaltos y Portland, S.A. (Asland, S.A.), headquartered in Barcelona, owned approximately 14%, and was the largest producer of cement in the country.

Chalk.—Spain's largest natural calcium carbonate-producing areas were located north of Tarragona. Three chalk producers, Reverte-Productos Minerales S.A., Clarianacal S.A., and Jose Andreu S.A., were in operation in the area during 1978. Reverte had capacity to produce about 200,000 tons per year of calcium carbonate products in its plant at Bellvey; products included surface-treated and micronized grades. Clarianacal, a member of the Omya-Plus-Staufer group, operated a 30,000-ton-per-year plant at Arbos. The third producer mined chalk at Bellvey and operated a plant at Montblanch. The Montblanch plant was rated at 50,000 tons per year of products.

Fluorspar.—During 1978 and 1979, Spain was an important producer of fluorspar. However, Fluoruros, S.A. (Bethlehem Steel Corp, 49% holding) had financial problems. A slump of fluorspar prices on international markets, competition, and reevaluation of pesetas against the dollar have made the problems more difficult. Because they were not paid, most of the suppliers of crude ore stopped deliveries, including Minas de Villabona, which had a large mine in operation but not flotation facilities, and Fluoruros Villabona. In addition to these two firms, MINERSA-Minerales y Productos Derivados, S.A., operated a mine at Osor-Gerona, Ribadesella-Asturia, and Beraja-Almeria. Flotation plants at Osor, Ribadesella, and Beraja had an aggregate acidspar capacity of close to 120,000 tons per year.

MINERAL FUELS

During 1978 and 1979, the Government of Spain continued formulation of the Spanish energy plan for a 10-year period, 1978-1987, against a background of increasing scarcity of fuels and constantly rising prices. The energy position of Spain was characterized by an excessive growth rate of energy demand relative to GDP growth rate, insufficient domestic exploration for fuels, heavy dependence on imports, and lack of conservation plans.

At present rates of consumption and without serious conservation, projections foresee a demand for 161 million tons of standard coal equivalent (SCE) in 1987 compared with 97 million in 1977. However, with conservation efforts, the plan predicts a demand of 145 million tons of SEC by 1987 without affecting economic growth. Investments in terms of 1977 pesetas should reach 630,000 million. The plan seeks to reduce oil's contribution to total energy use from 66% in 1978 to 59% in 1987. The nuclear energy program was also scaled down. Only three instead of seven plants will be completed, in view of lower projected demand for electricity. Nevertheless, the share of nuclear power in the total supply of energy in Spain will reach 15% by 1987.

Coal.—During 1978 and 1979, efforts continued to increase domestic production of coal. Lignite deposits at Meira and Puente de Garcia Rodriquez and anthracite mines in northwestern Spain were sites of increased activity. The new Government plan called for an output of about 36 million tons by 1987, or 19.7 million tons of SCE. To assure this supply, the plan calls for encouraging exploration, setting national prices, increasing mechanization in the coal industry, passing clear environmental laws, coordinating construction of thermal powerplants with coal production, assuring coking coal imports, and assisting national railways in purchasing additional rail cars for coal and in building coal-shipping terminals.

Natural Gas.—Domestic output of natural gas was small, and Spain depended heavily on imports to meet its demand. Discoveries of natural gas were announced in the Gulf of Cadiz and Sabiñánigo (Jaca), northern Spain. Preliminary reports indicated natural gas reserves between 20,000 and 40,000 million cubic meters at Sabiñánigo and 9,000 million cubic meters in the Gulf of Cadiz. For a more accurate assessment of the deposits, further drilling was planned.

Work on a natural gas pipeline from Algeria to Spain involved mapping, surveying, and examining possible routes. The consortium for pipeline construction, Segamo, consisted of the Algerian Sonatrach 50%, the Spanish Enagas 25%, and Gaz de France 25%. After crossing into Spain at an as yet undetermined point, the line is planned to join the French national gas network at Laq. Although the details of financing were not worked out, it appeared that Algeria's only contribution to the consortium would be natural gas while the other partners would supply finance and technology.

Petroleum.—Exploration continued offshore Valencia and in the delta of the Ebro River. Chevron found oil with its second well in the Montanazo stepout near its Casablanca offshore field.

Construction was completed of the coking-cracking unit of Chevron's petroleum refinery in La Coruña Province. Investment amounted to approximately $120 million. Installation of a cracking facility in the Enpetrol industrial complex at Puertollano has been announced. Investment reportedly should reach $285 million.

Combining the Spanish state interests in various oil companies was under consideration. The preliminary proposal called for a 100% State-owned company under Instituto Nacional de Industria (INI). The new company would be involved in all aspects of the oil industry from exploration to distribution. This plan was opposed by private interests in the companies concerned, and it was thought that it might conflict with EEC regulations on state monopolies.

Spain was almost completely dependent on imported crude oil to meet its demand in 1978. Ten petroleum refineries, with an installed annual capacity of about 59.6 million tons, were in operation.

Uranium.—Discovery was announced of about 1,200 tons of uranium oxide in ore in the province of Salamanca. In addition, discovery of uranium deposits between Villcastin and Riaza, in Segovia Province, was made public, and a Spanish-French group obtained a mining concession covering approximately 132,000 hectares in the area. Permission was granted for construction of a new uranium concentrator at Saelica el Chico, Province of Salamanca.

The Mineral Industry of Sudan

By E. Shekarchi[1]

The mining industry contributed only marginally to Sudan's gross national product of approximately $5.6 billion[2] in 1978-79. However, exploration was underway for both petroleum and minerals. Commercial quantities of chromite, iron ore, cement, gypsum, and salt were produced during 1978 and 1979. Intensive exploration by the Geological Society of Sudan continued on uranium, asbestos, copper, gold, and mica. With only 400 kilometers of paved roads, located mostly in the vicinity of Khartoum, the capital, the Sudan Railway Corporation (SRC) provided the best means of transporting goods and material over Sudan's expanse of sand. A major plan to modernize the Sudanese rail network was incorporated into the Government's Forth Railway Development Plan. During the first phase (1978-80), the European Economic Community was to provide about $11.2 million to help finance the cost of improvements and SCR was to seek an additional $8 million from other sources. Reconstruction work, replacing track and installing new signals, was initiated on the road linking Bahanousa and El Rahad. The 363-kilometer line passes through the semiarid savannah country and serves the Provinces of Darfur and Bahr el Ghazal and the western part of Kordofan Province.

With the noticeable exception of telecommunications, Sudan's infrastructure remained primitive and inadequate. Poor transportation continued to handicap overall economic efficiency and growth; power generation was inadequate for the existing demand and inhibited future growth, particularly in the industrial sector; and lack of water was a constraint to development in some areas.

From a relatively insignificant role in the economy, the industrial sector expanded rapidly in the early and mid-1970's. Since 1977, however, shortages of spare parts, raw materials, and electricity have reduced the growth rate. Output in 1978 and 1979 actually declined, and little improvement was expected in the early 1980's. As a whole, the industrial sector operated at only 30% of capacity, which increased unit costs considerably and threatened a number of firms with bankruptcy.

The cement industry was plagued by technical problems, poor planning, and power shortages, resulting in output well below the 1974 level. Cement shortages seriously affected the construction industry, because no cement was imported owing to lack of foreign exchange. The newly established import substitution industries, producing steel pipes and bars and dry cell batteries, proved particularly susceptible to foreign exchange shortages, and many operated at only 25% of capacity.

Reportedly a project for diamond exploration financed by the U.N. Revolving Fund at a cost of $1.5 million was to begin in 1980. The area being explored in the South-Western region of Darfur was suggested by the Geological Mineral Resources Department of Sudan, from the previous work by this organization.

1978 was the low point for the Sudanese economy. The interim agreement with the International Monetary Fund (IMF) in May 1979, followed by a long-term agreement, changed the Sudan's economic prospects noticeably. A number of policy changes coupled with pledges of new financing produced modest improvements in external accounts which would be accelerated in

1980. The IMF provided about $150 million on the interim agreement and another $150 million under a long-term agreement, while Saudi Arabia provided a $350 million balance of payments grant with the possibility of supplying additional funds later. Western donors pledged significant increases in their bilateral agreements, and the Government of Kuwait provided a commodity loan for the railroad. All of these events were expected to have a significant effect on Sudan's exports in the 1980's.

PRODUCTION AND TRADE

Chromite ore and concentrates, refined petroleum products of distillate fuel and residual fuel, were the main exports of Sudan during 1978 and 1979. In addition some manganese, gold, and mica were exported. The production of minerals in Sudan in 1978 and 1979 is given in table 1.

Sudan continued to evidence a balance of payment deficit, partly because of inadequate foreign assistance in supporting the country's ambitious development programs, and partly due an unfavorable debt structure and inflation. An interim agreement with the International Monetary Fund in 1978 and several internal policy changes improved the economic situation by the end of 1979. Fiscal and monetary restraint and clear import priorities were expected to stabilize the economy in the 1980's. Crude oil imports were primarily from Iraq, and petroleum products were imported from Kuwait. Most fertilizer material was imported under a long-term supply agreement with Kuwait Chemical Fertilizer Co.

Tables 2 and 3 show imports and exports of mineral commodities for Sudan during 1978.

Table 1.—Sudan: Production of mineral commodities

(Metric tons unless otherwise specified)

Commodity[1]	1976	1977	1978[p]	1979[e]
Cement, hydraulic ... thousand tons	130	137	171	175
Chromium: Chromite concentrate, gross weight	[r]21,873	17,273	18,000	18,000
Gold, mine output, metal content[e] ... troy ounces	300	300	300	300

COMMODITY REVIEW

METALS

Chromite.—The Government-owned Ingessana Hills Mine Corp. and the privately owned Blue-Nile Chromium Ltd. were the only producers of chromite during 1978 and 1979. The feasibility study on the Blue Nile chromite deposits, by Mitsubishi in partnership with Japan Metals and Chemical Co., which cost close to $1 million, was somewhat disappointing. Because the chromite deposits were mostly podiform and lacked consistent grade of higher than 48%, the company finally phased out its feasibility program at the end of 1979. However, the company's commitment to erect a ferrochrome plant at a cost of $50 million remained unchanged. No starting date for construction was given. Most of the chromite production was exported to Japan, under an agreement made a couple of years ago. Reportedly, about 9,000 tons of chromite produced by the Ingessan Hills Mining Co. was exported to Switzerland. A potential joint venture to mine 200,000 tons of chromite per year by Sudanese (51%) and Japanese companies (49%) remained uncertain by the end of 1979, owing to lack of proven reserves and lack of infrastructure.

Gold.—Two areas, Jubayt al-Ma'adin and Serkoit, both in the Northern Province of Sudan, were the center of gold mining activities during 1978 and 1979. Reportedly the areas of Gebeit an Um Nabari were also involved. Since gold mining in Sudan was primarily by local operators, families, or partnerships, using very primitive methods, no Government production figures were available, but it is estimated that because of high gold prices on the international market there were sharp production increases. It is of interest to note that prior to 1974 these gold mining areas were considered uneconomical but at the end of 1979 the Sudanese Government and the British firm, Robertson International, were discussing a joint gold mining venture.

Iron Ore.—Mapping and evaluation of the Fodikwan iron ore deposit, north of Port Sudan, and the Sufaya iron ore deposit, in the northern Red Sea Hills, continued during 1978 and 1979. Also, geological investigation progressed on a new discovery at Qarurah with estimated iron ore reserves of about 20 million tons and an average grade of 35% to 40% iron. All of these deposits were considered economical, since they were located within transportation distance of the Red Sea where loading facilities were adequate. The average grade of Sudan's iron ore at Sufaya and Fodikwan was given at 60% to 63% iron. A team of U.S.S.R. geologists working in the Karova area near the coast submitted their final report in 1979. An estimated 25 million tons of iron ore were found. The Government was discussing financing of iron ore mining and beneficiation in this area with the Arab Mining Co., and reportedly some preliminary agreements were reached. With completion of feasibility studies and development of an appropriate international market, Sudan could become a net exporter of iron ore by the mid-1980's. Negotiations continued during 1979 between the Government of Sudan and the Federal Republic of Germany to install a benefication plant in Kordofan Province for iron ore concentrate.

Manganese.—Manganese production remained small, because none of the 28 manganese occurrences was suitable for a large operation. Feasibility studies by the Geological Survey of Sudan to prove the extent of manganese mineralization and estimate reserves progressed in 1978 and 1979. No substantial finding was reported. The local producers resorted to hand cobbing of the ore in order to reach the acceptable grade of 48% for their production. Manganese deposits are found in the Red Sea Hills at Abu Samr, Tolik, Allaikaleib, and Sinkat. They appear as veinlets and pods, which makes the cost of large-scale mining prohibitive.

Uranium.—By the end of 1979, results of exploration activities by Azienda Generale Italiani S.p.A. (AGIP) and Wyoming Minerals Corp., a subsidiary of Westinghouse (U.S.A.), during 1978 and 1979 were not available. However, from fragmentary information given by the Government it was evident that Minex Corp. was successful in discovering an important deposit of uranium and other radioactive elements in Jebel Dumbeir and Jebel Ed Dair, near Rahdad in west-central Sudan. The company started formal discussions with the Government for an agreement to carry out further evaluation of the deposit with a view to future exploration.

NONMETALS

Asbestos.—The asbestos mining evaluation program of the company, shared by Johns-Manville of Canada, Gulf International Group of Kuwait, and the Government of Sudan, continued during 1978 and 1979. Drilling was concluded by the end of 1978, and the preliminary reserves estimate was about 20 million tons of ore with 2.7% asbestos fiber No 4. The mining would be underground, about 160 meters below surface, and a processing plant with 100,000 tons of fiber capacity per year would be installed at the mine site. Total expenditure for exploration, mill, and infrastructure was given at $120 million.

Cement.—Renovation of the Nile Cement Co.'s Rahak plant was completed during 1978 and it produced 65,000 tons in 1979. Even though the amount produced represented only 65% of the planned capacity, the company was expecting a better performance in 1980 by converting the transportation of material from the quarry to the plant over 60 kilometers of dirt road to transportation on the Nile River. This haulage diversion was expected not only to increase availability of material to the plant but also to be more economical.

Construction work on the $53 million Red Sea Cement plant at Derudeb continued during 1979, and production was slated to begin in 1980. The plant capacity was given at 500,000 tons, with feed material to be supplied from the Sayit gypsum deposit, which has proven reserves of 220 million tons. Expansion work on the Maspion Cement Corp's plant in the Northern Province at Atbara continued during 1979. It was anticipated that the plant capacity would be increased from 225,000 to 500,000 tons.

Fertilizer Materials.—The construction status of Sudan's first ammonia-urea complex, which was to start in 1979, remained unclear by yearend. Apparently, owing to price increases on the feedstock naphtha, both partners of the project, Sudan's Government (65%) and N-Ren International, had to restudy its economic implications. The plant was to have a capacity of 200 tons per day of ammonia and 300 tons per day of urea. Most of the end products were slated for use in the Gezira agricultural belt.

Mica.—About 1,000 tons of mica were produced in the vicinity of Shereik, where mica occurs in pegmatites as large sheets or more commonly as small scraps. In order to utilize the mica scrap as a commercial product, the Government was seeking financial assistance to install a mica processing plant, including grinding, sorting, and packaging facilities. By the end of 1979 there was no firm commitment on the plant construction. Pegmatites continued to yield the highest production recorded in the country. Apparently a new private company was organized to explore and exploit a new area around the Bayuda Desert region in 1981.

MINERAL FUELS

Petroleum.—Chevron Overseas Petroleum Inc., a subsidiary of Standard Oil of California, was the operator and sole mineral fuel concessionaire for vast areas of the remote central and southern part of the country. The company drilled its first dry well at Baraka, some 50 kilometers south of Muglad. In the second well, located north of Bentiu, at a depth of 14,400 feet some oil show was encountered but not of commercial quality. The third well, to the east of Muglad, was suspended to await the dry season, while the fourth, south of Bentiu, was in progress at the end of 1979. A feasibility study by Bechtel Corp. for a pipeline to connect these oil finds to Port Sudan, a distance of 1,500 kilometers, was undertaken; the Government indicated it is part of the economic study, in case commercial oil is discovered. Chevron was financing its exploration and was to participate with the Government in the profits from any discovery, after the cost had been recovered, to the extent of 25% or 30% depending on output. Exploration was also carried out along Sudan's Red Sea coast by a Texaco, Ball, and Collins group, with Chevron in charge of the actual operation. Of the three offshore wells drilled during 1978 and 1979, two tested noncommercial flows of gas and condensate, while the third was dry. At the end of 1979 concessions along the coast were relinquished.

The Port Sudan refinery, owned 50% by the Sudan Government and 50% by Royal Dutch-Shell and British Petroleum, produced at full capacity during both years. The fate of a second refinery, a joint venture between the Sudan Government and the Saudi Arabian firm Triad Naft, remained unsettled. By the end of 1979 Petroleum General Administration of Sudan was discussing the terms of financing and the capacity of the plant with Petromin of Saudi Arabia, but no agreement was in sight. Sudan imported close to 8 million tons of petroleum products from the Middle East countries, mostly from Iraq and Kuwait.

The only concession awarded during 1979 was to Burmah Oil Exploration and Eastern Petroleum Co., a joint venture, for exploration covering 1,600 square kilometers, in the Tokar Delta region of the Red Sea.

The Mineral Industry of Sweden

By Joseph B. Huvos[1]

In 1978-79 Sweden's economy grew at a lively pace thanks to an upswing in foreign demand and was followed in this trend by the mineral industry, whose principal products were iron ore, some nonferrous metals, and some fossil fuels.

In 1978, Sweden's gross national product (GNP) was about $102 billion,[2] [3] and the foreign trade balance showed a loss of $400 million. Unemployment was 2.1% at yearend.

Government participation (ownership) in the Swedish mineral industry was about 25% in the gas industry, 75% in iron and steel, and 50% in electric power.

The most important event in Sweden's mineral industry during the period was the formation of Swenskt Staal AB, a 50%-Government-owned steel company designed to improve the efficiency of the fragmented steel industry. One new tungsten mine was opened and two mines, a silver and a complex sulfide ore mine, were closed; there were plans for the closing of two iron ore mines. The capacity of one nonferrous metal mine was expanded, and construction of a modern dry process cement plant was completed.

Indices of Swedish mineral industry production in 1978 and 1979 are shown in the following tabulation (1968=100):

Industry sector	1978[r]	1979[p]
Iron ore mining	79	98
Nonmetallic mineral products	83	85
Metal industries	107	112
Mining, quarrying, manufacturing	122	130

[p]Preliminary. [r]Revised.

PRODUCTION

In 1978, production of the mineral industry was still at a low level, but in 1979 iron ore and metal production started to increase. Production of mineral commodities in 1976, 1977, 1978, and 1979 is shown in table 1.

Table 1.—Sweden: Production of mineral commodities

(Metric tons unless otherwise specified)

Commodity[1]	1976	1977	1978[p]	1979[e]

[e]Estimate. [p]Preliminary. [r]Revised. NA Not available.
[1]In addition to the commodities listed, cobalt, nickel (as nickel sulfate), and metallic titanium are also produced, but output is not reported and available information is inadequate to make reliable estimates of output levels.
[2]Reported figure.
[3]Production of sponge iron is as follows, in thousand tons: 1976—188; 1977—161; 1978—117; and 1979—NA.
[4]Includes clinker as follows, in thousand tons: 1976—111; 1977—43; 1978—15; and 1979—NA.
[5]Represents material for sale, not that produced.
[6]Includes strontium minerals, unspecified minerals, and fragments of ceramic materials.

TRADE

There was no change in the country's mineral trade pattern. Scandinavia and West European countries remained Sweden's main trading partners. Principal minerals industry export commodities were iron and steel, iron ore, and nonferrous metals. Sweden's total mineral trade in 1977 and 1978 is shown in tables 2 and 3.

Table 2.—Sweden: Exports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1977	1978	Principal destinations, 1978
METALS			
Aluminum:			
Bauxite and concentrate	4,133	5,717	Denmark 3,603; Norway 2,104.
Alumina	31	78	Denmark 47; Finland 22.
Metal including alloys:			
Scrap	3,813	2,213	West Germany 1,178; United Kingdom 511.
Unwrought	32,458	38,529	United States 12,061; West Germany 8,339.
Semimanufactures	49,799	57,465	Denmark 9,066; United Kingdom 8,875; Norway 5,628.
Arsenic oxides and acids value, thousands	$2,039	--	
Copper:			
Ore and concentrate	36,220	15,794	All to West Germany.
Metal including alloys:			
Scrap	718	350	West Germany 153; United Kingdom 93.
Unwrought	40,759	29,870	United Kingdom 14,180; Belgium-Luxembourg 5,204.
Semimanufactures	52,041	70,025	United States 12,604; Norway 10,926; West Germany 9,736.
Iron and steel:			
Ore and concentrate, except roasted pyrite thousand tons	18,903	22,259	Belgium-Luxembourg 6,254; West Germany 4,575.
Roasted pyrite do	327	355	United Kingdom 205.
Metal:			
Scrap do	75	79	Spain 29; Pakistan 19; Denmark 9.
Pig iron, including cast iron do	256	611	United States 137; Italy 134; China, mainland, 110.
Ferroalloys do	110	168	West Germany 50; Italy 29; Japan 16.
Steel, primary forms do	243	482	United States 90; United Kingdom 81; West Germany 78.
Semimanufactures:			
Bars, rods, angles, shapes, sections do	428	492	West Germany 135; United Kingdom 90.
Universals, plates, sheets do	684	601	West Germany 121; United Kingdom 88; Denmark 59.
Hoop and strip do	81	95	West Germany 15; Denmark 10; United Kingdom 6.
Rails and accessories do	21	44	Norway 20; Singapore 7; Italy 6.
Wire do	68	74	United States 12; West Germany 10; Finland 6.
Tubes, pipes, fittings do	14	14	Norway 3; Denmark 2; Finland 1; United Kingdom 1.
Castings and forgings, rough do	28	30	Norway 7; Denmark 4; West Germany 4.
Lead:			
Ore and concentrate	65,421	58,385	West Germany 45,516; Belgium-Luxembourg 7,030.
Oxides	88	161	NA.
Metal including alloys, all forms	49,140	54,746	West Germany 25,503; Netherlands 8,722.
Magnesium metal including alloys:			
Scrap	822	494	United States 243; Italy 129.
Unwrought and semimanufactures	3	14	Denmark 5; Norway 3.
Mercury 76-pound flasks	1,566	754	Netherlands 522; United Kingdom 145.
Molybdenum ore and concentrate	1,241	921	Netherlands 440; United Kingdom 251.
Nickel:			
Matte	358	798	All to United States.
Metal including alloys:			
Scrap	831	498	India 302.
Unwrought	2,549	1,720	Netherlands 1,241.
Semimanufactures	1,417	1,059	France 267; United Kingdom 132.

[1]Includes potassic material valued at $15,098 in 1977 and $16,225 in 1978.

COMMODITY REVIEW

METALS

Aluminum.—During 1978-79 primary and secondary metal production ran near capacity.

Gränges AB and Alcan Aluminium Ltd. of Canada concluded an agreement whereby Gränges acquired the 21% Alcan holding in Gränges Essem AB, a Gränges subsidiary, for $26 million. Gränges owned Sweden's only aluminum reduction plant, located at Kubikenborg, near Sundsvall, on the Baltic; capacity of the plant was 85,000 tons per year.

Arsenic.—Environmental considerations necessitated a reduction in Boliden's arsenic metal production to 75% of its capacity of 1,200 tons per year in 1979. Boliden still remained the world's largest producer. Arsenic trioxide production was 20,000 tons in 1968, but has recently fallen to 6,000 tons per year.

Copper, Lead, and Zinc.—Boliden announced a $22.7 million investment in its 55,000-ton-per-year lead smelter at Rönnskär. The largest portion of the investment would go towards a fluidized bed roaster and a top blown converter which were to increase capacity of the smelter by an additional 15,000 tons of lead per year.

Boliden also decided to spend $35 million on increasing the capacity of its Aitik copper mine from 8 million tons to 11.3 million tons of ore per year.

The processing plant was rebuilt in 1978 at Boliden AB's Laisvall mine, raising ore capacity to 1.5 million tons per year.

The concentrator of Boliden's Stekkenjok mine, located on the Norwegian border, was expanded, raising its capacity by 50%. Boliden's Hällefors silver mine and Grängsgruvan metal mine, in central Sweden, were closed.

In 1978, Luossavaara Kirunavaara AB (LKAB) test-mined its copper deposit at the Viscaria Mine near Kiruna. Drilling, geophysical measurements, and mapping were also performed. Prospecting for base metals was carried out by LKAB in the Arjeplog area, near Laisvall. Exploration work, completed in 1979, was also performed on a copper-cobalt deposit at Haakansboda, about 2 kilometers south of Straassa.

Boliden continued to account for most nonferrous metals mined and produced in Sweden and operated the country's only large nonferrous smelter at Rönnskär on the Gulf of Bothnia near Skelleftea. Vieille Montagne accounted for 30% of the country's zinc ore production; zinc concentrates were exported for processing at the company's Belgian plants.

Iron Ore.—In 1978, iron ore production slumped further to 18 million tons, although exports, aided by strikes at Canadian mines, and domestic consumption had picked up somewhat. Due to these circumstances iron ore stocks were reduced from 18 to 15 million tons. The f.o.b. price of iron ore was 66 to 69 kroner ($14.67 to $15.33 per ton), down by 14% from 1977, as the price was tied to the exchange rate of the U.S. dollar. In 1979 iron ore production increased by about one third because a continued improvement in foreign demand had decreased stocks.

In 1978, investments in the iron ore mining industry were $53 million compared with $118 million in 1977, because a few large projects, such as the extension of the Narvik harbor and the Svappavaara processing plants, were completed.

The Swedish Government proposed to the Parliament that it provide $200 million for LKAB's financial reconstruction, for losses, and as an employment subsidy.

The Svappavaara iron ore mine in Swedish Lappland was reopened in October 1978 by LKAB. The Svappavaara pelletizing plant had been processing Kirunavaara ore during the mine's shutdown. LKAB also planned to build a new pellet plant at Kiruna, at a cost of about $100 million.

An intensive core drilling program was undertaken in Kiruna to delineate and sample ores down to the 775-meter level. Deep drilling from the 795-meter level down to 1,000 meters and deeper was started.

Stora Kopparberg Bergslags AB reported that when Svenska Kugellager Fabriken AS shut down its blast furnance at Hofors, Gastriksland, in 1978, the market for Stora Kopparberg's Vintjärn concentrate was lost. The mine was closed and allowed to flood, ending iron ore mining at Stora.

Svenskt Staal AB has taken over Gränges Gruvor AB's Exportfält Mine and Stora Kopparberg's Riksbergsfält Mine in central Sweden. There were plans to concentrate all hoisting and processing at Exportfält in 1980; for the moment both mines are shut down and 100 persons have been dismissed.

At Straassa, in Örebro County, a new crushing plant was installed.

There were plans to close the Blötberg iron ore mine, in Ludvika County, after 78 years of operation.

At Stora's Falu Mine, production of pellets from roasted pyrite was discontinued.

Fagersta AB decided to close down the Smältermossan high-sulfur iron ore mine, in Falun County.

Iron ore ports in Sweden included LKAB'S Luleaa terminal for loading vessels up to 45,000 deadweight tons at a rate of 4,000 tons per hour from a 5-million-ton storage area, and Svenskt Staal's Oxelösund terminal for loading ships up to 75,000 deadweight tons at a rate of 3,000 tons per hour from a 1-million-ton storage area.

Iron and Steel.—On January 1, 1979, Svenskt Staal AB (SSAB) came into existence. The merger of the predecessor companies was necessary because of inability to compete with growing steel industries in Sweden's traditional foreign markets, and because of poor Volvo sales and consequent low domestic demand for steel. The new company was formed by the merger of the Government-owned Norrbottens Järnverk AB (NJA) and the steel plants, iron mines, and other related facilities of two large private companies: Gränges AB, which owned the Oxelösund steel mill near Nyköping, and Stora Kopparberg Bergslags AB, which owned the Domnarvets steel mill near Borlänge. SSAB is a joint venture of Government and private industry, with the Government owning 50% of its capital stock and the two private companies, Gränges and Stora Kapparberg, owning 25% each. It was understood that SSAB was not to compete unfairly with the country's remaining smaller, privately owned steel companies through the help of Government grants. Finally, in 1978, Fagersta AB decided to discontinue ore-based carbon steel production at its Fagersta plant; in the future only pig iron and scrap will be used at the plant.

High-carbon ferrochromium production in Sweden was in the hands of two wholly owned subsidiaries of U.S. companies: Airco Alloys AB, owned by Airco Inc., Montvale, N.Y., had a capacity of 117,000 tons of high-carbon ferrochromium (chromium content); and AB Ferrolegirengar, owned by Metallurg Inc., New York, had a capacity of 39,000 tons per year.

Following completion of a share transaction, the Swedish special steel producers, Fagersta AB and Sandvik AB, were to increase their collaboration; previous mutual rationalization agreements had already covered a wide range of their production. Kinnevik, a major Sandvik shareholder, now controls a 20% share of the equity of Fagersta, which represents a 40% share in voting rights.

Tungsten.—LKAB's Wigström tungsten mine, at Sandudden near Yxsjöberg, started operations. The ore is trucked to the company's concentrating plant at Yxsjöberg for processing. Test mining of tungsten ore started in 1979 at LKAB'S Norra Hörken Mine near Ludvika.

NONMETALS

Apatite.—In 1978, construction began on a processing plant designed to produce apatite concentrate from the nonmagnetic fraction of the pelletizing ore at Kiruna. The plant is ultimately to produce 200,000 tons of apatite concentrate per year.

Cement.—In 1978, cement shipments declined further to about 70% of present plant capacity. Construction of a new dry process cement plant was completed in 1979 at Slite, Gotland Island; the plant replaces four obsolete plants and leaves a total of three plants in opearation with a total capacity unchanged at about 3.5 million tons per year. During the period Sweden's cement industry was operated by Industri AB Euroc, owned by Cementa AB (95%); LKAB was a minority coowner of Cementa (5%) and also operated four limestone plants.

Industrial Minerals.—In 1978, dolomite pellets were prepared on an experimental basis at LKAB's Svappavaara Mine.

Höganas AB reported that clinker clay mining at the company's Bjuv Mine, near Helsingborg, ran at a reduced rate due to an accumulation of stocks.

Ytong AB continued production of quartz-sandstone at Kvantorp and marble at Glanshammar and Brannlyckan in Bergslagen Province.

MINERAL FUELS

In 1978-79 about one-fifth of Sweden's energy was supplied by domestic hydroelectric power and fuelwood. The remainder was from imported oil, coal, and enriched nuclear fuel. Supply and apparent consumption of fuels and power in 1978 are shown in table 4.

Table 4.— Sweden: Supply and apparent consumption of fuels and power for 1978

(Million tons of standard coal equivalent)

	Total energy	Coal and coke	Petroleum and refinery products	Black liquor fuelwood and waste	Hydroelectric power[1]	Nuclear power[2]
Production[3]	12.4	--	--	5.4	7.0	--
Imports	34.2	2.0	28.9	--	.5	2.8
Exports	4.2	.1	3.5	--	.6	--
Apparent consumption	42.4	1.9	25.4	5.4	6.9	2.8

[1]Includes foreign trade of all electric power.
[2]Thermal burnoff of imported uranium fuel.
[3]Includes only primary energy.

Source: Foreign Trade 1978. Monthly Bulletin. December 1978, p. 14.

Nuclear Power.—For the first time nuclear power had more supporters than opponents, as released in a 1978 survey on energy by the Swedish Institute for Public Opinion Polls. However, the controversy on nuclear power led to the fall of the conservative Fälldin Government, which had favored limited use of nuclear power.

Five nuclear powerplants were operating in the country with a total capacity of about 3,800 Megawatts electrical (MWe). Five additional nuclear powerplants, with a capacity of 4,340 MWe, were under construction.

Natural Gas.—If approved by the Danish and Swedish Parliaments, a project to bring Danish natural gas to Sweden will be started. A pipeline will be built to transport up to 200 million cubic meters of natural gas per year to south Sweden, by crossing the Öresund between Dragör south of Copenhagen and Klagshamn south of Malmö. Later on, the line should also transport Norwegian North Sea gas from the Federal Republic of Germany to Sweden.

Petroleum.— Government-controlled Svenska Petroleum AB's Oil Prospecting, Inc. (OPAB) concluded a long-term crude supply contract with Iraq, the first Swedish contract since the Iran crisis; initial deliveries of 400,000 tons in 1979 were to be increased each year as necessary. Sweden was also in the process of expanding its underground crude oil storage capacity by 9.6 million cubic meters. One new 1.2-million-cubic-meter storage emplacement at Göteborg was already filled. Other storage emplacements, to be completed soon, included an 800,000-cubic-meter facility at Nynashamn, another of 2.6 million cubic meters at Brofjorden, and a third of 1 million cubic meters at Göteborg.

In 1978 OPAB's record 30-well drilling program, all on Gotland Island, produced only one small oil find. Seismic work was carried out in 1979 on Gotland and offshore Angelholm, in the Kattegat, in southwest Skaane Province, and in the Baltic between southeastern Skaane Province and Bornholm Island. On Gotland, a low-cost exploratory drilling system was employed using 50-millimeter holes drilled with core drilling equipment mounted on a twin-axle trailer.

Because of the shallowness of the Danish Straits, supertankers cannot reach Swedish oil terminals along the Baltic coast, and these terminals have therefore no supertanker facilities. Only Göteborg can receive tankers as large as 350,000 tons; there are plans for expanding capacity there eventually to 500,000-ton tankers. The Swedish Government also had plans to use empty tankers for the storage of oil.

The companies OK and Texaco, joint owners of the Scarnraff refinery at Lysekill, southwest Sweden, started to expand its capacity during 1979 from the current 8.3 million tons per year to 10 million tons per year.

Sweden's four oil companies operated six oil refineries with a total capacity of about 21 million tons per year.

The Mineral Industry of Switzerland

By Roman V. Sondermayer[1]

During 1978-79, cement, lime, gypsum, salt, and sand and gravel were produced from domestic raw materials in Switzerland, and the industry processed imported crude oil, alumina, and iron and steel raw materials. Imported fuels supplied most of the energy of the country, and hydropower and fuelwood were the only domestic energy sources. About 2% of the gross national product (GNP) was credited to the mineral industry of Switzerland, and roughly 1% of the labor force was employed by the mineral industry, including processing. Except for some exploration for oil and gas, 1978-79 were uneventful years for the Swiss mineral industry.

PRODUCTION

The minerals industry was privately owned, and for the most part, was modern and efficient. The tabulation below shows principal companies in operation in Switzerland during 1978-79, and table 1 shows variations in production of minerals.

Commodity	Major companies-principal facilities (ownership)	Percent of domestic output
Aluminum	Schweizerische Aluminium A.G.-ALUSUISSE - plants at Steg and Chippis.	80
Cement	Cement Werk Wuerenlingen - plant at Siggenthal	36
Petroleum, refined	Raffinerie du Sud Ouest S.A. - refinery at Collombey (PB, ENI, Esso).	40
	Raffinerie de Cressier S.A. - refinery at Cressier (Shell, Gulf).	40
	Raffinerie Rheintal S.A. - refinery at Sennwald (ENI, Italy).	20
Steel, crude	Von Roll Ltd. - plants at Geralafingen and Bodio	75

[e]Estimate. [p]Preliminary. NA Not available.

[1]In addition to the commodities listed, a variety of crude construction materials (common clay, sand and gravel, and stone) is undoubtedly produced, but output is not reported and available general information is inadequate to make reliable estimates of output levels.

TRADE

Switzerland was a significant trader in minerals and related commodities, but such trade did not reflect accurately the activities of the country's mineral industry or the needs for minerals. Many of the transactions recorded were commercial in nature (imports for reexport only). The United States had a positive trade balance in minerals trade with Switzerland. Tables 2-3 show the trade of Switzerland in minerals.

COMMODITY REVIEW

METALS

Aluminum.—Three plants, with a total annual capacity of 88,000 tons, were in operation during 1978-79. Two of them, Chippis (30,000 tons per year) and Steg (48,000 tons per year) in Valais, were operated by Swiss Aluminium Ltd. The third one, at Martigny (10,000 tons per year), was operated by Usine d'Aluminium Martigny SA. All of them processed imported alumina.

Iron and Steel.—During 1978-79, the steel industry of Switzerland differed from most steel industries operating in Europe because of its modest size and narrow range of products it delivers. Reinforcing bars continued to be the major product of the industry, making the sector sensitive to variations of construction activities in the country and abroad. In addition, a number of rolling facilities produced semimanufactured steel products. Four companies, Monteforno Acciaierie e Laminatoi SA, Von Moos Stahl AG, Von Roll Ltd., and Ferrowohlen AG (with aggregate capacity of 700,000 tons per year), produced steel during the period.

NONMETALS

Cement.—Cement continued to be the most important nonmetal produced in Switzerland. Except for energy, all other materials required for production of cement were produced in the country. Reserves of raw materials are ample. During 1978-79, 14 plants were in operation with a total capacity of 6.6 million tons, but the industry operated at about 55% of capacity. Most installations were rotary dry kilns. Fuel oil was the chief fuel used, and about 1,500 persons were employed in the country's cement industry. The largest producer was Portland Cement Werk Wuerenlingen Siggenthal AG with its 1-million-ton-per-year plant at Siggenthal.

Other Nonmetals.—Output of other nonmetals was of domestic significance only. Table 1 shows details of production.

MINERAL FUELS

Imported primary energy carriers were the major sources of energy in Switzerland during 1978-79. Domestic output was limited to hydropower and noncommercial fuels. During past years, apparent energy consumption ranged between 23 and 25 million tons of standard coal equivalent (SCE).[2] Petroleum was, by far, the major energy source and accounted for about 79% of total consumption; hydropower, the only domestic commercial source, contributed about 13% of the total. Imported natural gas contributed 4%, coal, also imported, 1%, and nuclear power 3%.

Petroleum and Natural Gas.—There was no oil or natural gas production in Switzerland during 1978-79. Exploration, however, which started in 1974, continued in pre-Alpine and Jura regions. About 150 kilometers of seismic profiles were completed in the eastern cantons (Zurich, Aargau, Zug, Schwyz) for SA pour le Petrole Suisse, Zurich. The Jura Bernois Petrole SA completed 81 kilometers of geophysical profiles and about 120 meters of shallow holes in the same area. Results of two wells drilled for stocking imported natural gas led to an indication of possible natural gas and crude oil occurrences. One well on the Fribourg Sud concession was dry and was abandoned at 4,022 meters. BEAG and Bochumer Mineralöl GmbH (BOMIN) were the investors. At yearend, drilling was underway on one location near Treycovagnes, south of Yverdon. No details on depth or results were made public. The operator was Consortium de Jura Vaudois Petrole SA.

Three petroleum refineries, La Raffinerie du Sud-Ouest SA at Collombey, La Raffinerie de Cressier SA, and La Raffinerie Rheintal AG, produced about 4.6 million tons of petroleum refinery products, or about 34% of total demand.

In 1979, crude oil was imported, mostly from the United Arab Emirates 46%, Iran 16%, Nigeria 14%, Algeria 10%, Libya 8%, and Saudi Arabia 6%. East European countries 29%, France 22%, and Italy 16% were the major suppliers of petroleum products.

Uranium.—Nuclear powerplants and the need for nuclear power were closely examined by the Government and various groups of citizens during 1978. As a result, a Federal referendum was held in February 1979 in which voters decided to approve further development of nuclear power.

Three nuclear powerplants were operational in 1978-79, and four were in various stages of construction. If all are completed, installed capacity of nuclear powerplants in Switzerland should reach 4,500 megawatts electric.

[1]Physical scientist, Branch of Foreign Data.
[2]1 ton of SCE = 7,000,000 kilocalories.

The Mineral Industry of Taiwan

By E. Chin[1]

The gross national product (GNP) of Taiwan for 1979 was estimated at $30.1 billion[2] at current prices and at $13.8 billion at 1971 prices, compared with $24.7 billion and $12.8 billion, respectively, for 1978.[3] The average annual growth rate in GNP during the last two decades was 9% in absolute terms, while the growth in 1978 over the previous year was 7.8%. The net domestic product (NDP) in 1978 was $18.9 billion in current prices. By sectors the largest inputs to the NDP were manufacturing, 30.5%; agriculture, forestry, fishery, and livestock, 12.0%; Government services, 12.4%; commerce, 11.5%; real estate, 6.2%; transportation and communications, 6.3%; construction, 6.0%; and banking 5.6%. The mining sector accounted for only 0.9% in 1977, compared with 1.5% in 1970.

Owing to strong export demand for domestically produced goods, Taiwan's industrial production index grew by 25% in 1978. Manufacturing (the largest component of the index), construction, and public utilities were the major sectors showing vigorous growth. The indexes of industrial production for minerals-related components of the economy (1971=100) are given in the following table:

Sector	1976	1977	1978
Mining:			
Coal	80.8	73.8	72.0
Metal	263.7	255.0	319.7
Nonmetal	260.8	333.8	349.0
Salt evaporation	71.6	73.6	49.8
Crude petroleum and natural gas	170.6	176.0	171.0
Chemicals and petroleum refining:			
Acids and alkalis	101.8	109.1	122.1
Fertilizer	161.4	167.5	203.7
Petroleum refining	189.5	212.8	251.3
Petroleum products	406.6	503.8	638.5
Coke	89.9	90.1	93.9
Nonmetallic mineral products:			
Structural clay products	117.3	127.5	133.7
Cement	165.7	195.4	216.7
Cement products	88.2	78.0	78.8
Basic metals:			
Ferrous	147.9	172.5	285.6
Nonferrous	107.5	121.8	184.2
Metal products:			
Ferrous	139.3	169.0	220.0
Aluminum	143.9	168.1	215.9
Other	193.9	207.4	215.5
Overall industrial production: General index	187.9	209.9	262.3

Taiwan has small coal mines, small to medium-sized quarries, and medium to large industrial plants. Taiwan is deficient in minerals, except construction raw materials. Ranked by value, fuels (primarily coal with some crude petroleum and natural gas), dolomite, and limestone (including marble) were the leading mineral products mined in Taiwan. However, output of each of these minerals was not significant in terms of world market. Other economically important minerals that are mined locally include copper, gold, salt, sulfur, and talc. However, the value of Taiwan's processing activities of imported minerals and metals overshadows the value of indigenous extraction. In 1978, the mineral-processing sector outweighed the domestic mining sector 27 to 1 in output value compared with a 22-to-1 ratio in 1977. A breakdown by value of output for mineral-related sectors, in million Taiwan dollars, follows:

Sector	1976	1977	1978
Mining:			
Coal	4,388	4,043	4,072
Crude petroleum and natural gas	4,420	4,472	4,331
Metal	1,022	912	956
Nonmetal	1,208	1,469	1,653
Salt evaporation	261	265	179
Total	11,299	11,161	11,191
Manufacturing:			
Chemical products	99,151	116,375	129,295
Petroleum and coal products	55,546	66,280	77,416
Basic metals	23,324	28,137	51,970
Metal products	6,665	8,088	10,933
Nonmetallic mineral products	20,328	23,969	27,892
Total	205,014	242,849	297,506

On the basis of a monthly average, the number of persons employed by the mining and quarrying sector in 1978 was 45,585 compared with manufacturing, 1,247,092; transportation and communications, 286,778; construction, 188,699; and services, 144,817. The average monthly working days for employees in mining and quarrying was 22.3, lower than the other major industrial sectors, which ranged between 23.7 and 27.8 days. Employees of the electricity, gas, and water utilities had the highest average monthly earnings, $261, followed by mining and quarrying, $214; transportation and communications, $201; construction, $180; manufacturing, $178; and services, $119.

During the 1969-78 period, Taiwan's total supply of energy increased at an average annual rate of 11.0%. The largest growth during the decade was from the imports of coal (27.2%), crude oil (18.0%), and petroleum products (10.2%). In 1978, the island's total supply of energy was estimated at 29.2 million kiloliters expressed in oil equivalent. Production of domestic fuels accounted for 19% of the total and, by sector, was as follows in percent: Coal, 37%; natural gas, 35%; hydroelectric power, 24%; and crude oil, 4%. Imports provided 81% of the total energy supply and were distributed as follows in percent: Crude oil, 84%; petroleum products, 9%; coal, 4%; and nuclear, 3%. The configuration of demand for commercial energy was as follows in million kiloliters of oil equivalent: Hydroelectric power, 1.3; thermal electric, 7.6; coal and coal products, 2.4; petroleum products, 13.3; natural gas, 1.9; nuclear, 0.7; and exports, 1.9.

Taiwan's industrial consumption of energy increased by 16% in 1978. The estimated breakdown of consumption, expressed in electrical energy equivalent and detailed by the minerals-related industries, was as follows in million kilowatt-hours:

Sector	1976	1977	1978
Mining and quarrying	364	382	439
Basic industrial chemicals	1,236	1,222	1,404
Chemical fertilizers	472	520	359
Other chemical products	2,519	2,894	3,343
Cement	1,127	1,311	1,424
Iron and steel	1,726	1,966	2,442
Aluminum	334	517	831
Metal products	523	591	711
Other industries	10,057	10,998	12,648
Total	18,358	20,401	23,601

On September 6, 1979, the Government of Taiwan announced the extension of the limits of its territorial waters from 3 to 12 nautical miles. Additionally its economic zone would extend to a distance of 200 nautical miles and any conflicts on overlapping zones would be negotiated with the Governments respectively concerned to determine boundaries under the principles of international law.

In 1974, the Government announced the Ten Major Development Projects, designed to spur the domestic economy, to lay a foundation for future growth, and to bring Taiwan into the world ranking of industrial and modern countries. The projects, to be completed within 5 years, included six in the transportation sector, three in the heavy and chemical industries, and one in the energy sector. By the end of 1979, five projects were completed and substantial progress had been made on the other five. The North-South Freeway, connecting Keelung and Fengshan and with two sections linking Taoyuan and Hsiaokang International Airports, was completed on October 31, 1978. The total length of the freeway runs 373 kilometers, and cost of construction was NT$45 billion. The first of the 10 projects to be completed was the Kaohsiung Shipyard in June 1976. (The shipyard of the China Shipbuilding Corporation is also located in the Kaohsiung Coastal Industrial District, next to the integrated steel mill near the second harbor of Kaohsiung.) Kaohsiung Shipyard has an annual shipbuilding capacity of 1.5 million metric tons and a repair capacity of 2.5 million metric tons. Since its completion, two 445,000-ton tankers have been launched and delivered.

The first-stage construction of Taichung Harbor was completed and opened to traffic in October 1976 at a cost of NT$5.7 billion. Construction on the second stage is currently in progress. Also, first-stage construction of the integrated steel mill of the China Steel Corporation was completed at the end of 1977, and construction on the second stage is due to be completed in 1982. First-stage construction on the first of three nuclear powerplants was completed in November 1977 when the first generator (636,000-kilowatt capacity) began operation. Installation of the second generator was completed in 1979. With the exception of one downstream project, all components facilities of the petrochemical complex have been completed and put into operation.

Construction status on the remaining four projects were as follows: The $281 million Chiang Kai-shek International Airport at Taoyuan was opened in March 1979. Construction of the first-stage plan for Suao Harbor was scheduled for completion in June 1979. By August, the railway between Keelung and Kaohsiung was fully electrified at a cost of $603 million. Finally, the North-Link Railway was completed at the end of 1979, at a total investment of $140 million.

In 1977, the Government subsequently proposed 12 additional projects, almost all of which are a continuation of the 10 previous projects. These included further expansion of the railroad, highways, integrated steel mill, harbor, nuclear powerplants, and agricultural mechanization. However, the planned extension of the North-South Freeway designed to link Kaohsiung with Pingtung was suspended. Additionally, Government owned enterprises such as the Chinese Petroleum Corporation, Tang Eng Iron Works, and Taiwan Machinery Manufacturing Company were also to invest substantially in large-scale facilities to manufacture heavy industry products.[4]

In early 1979, formal diplomatic relations between the United States and Taiwan were severed. Communications were conducted through nongovernmental organizations: American Institute in Taiwan and the Coordinating Council for North American Affairs. Despite the change, the United States remained as Taiwan's largest export market and its primary supplier of technology and investment capital.

PRODUCTION

Coal was the most important mineral commodity mined in Taiwan. Output of bituminous coal, however, has decreased annually since 1967. Domestic crude petroleum production is negligible. The principal significance of indigenous oil was as a very small supplement to imported crude oil in the production of refinery products. Natural gas output likewise is of little consequence by world standards.

The overall value of production by the mining industry was estimated at $313 million and was distributed as follows, in million dollars: Coal, $113; crude petroleum and natural gas, $124; metals, $26; evaporated salt, $5; and miscellaneous nonmetallic mining and quarrying, $46. In comparison, the value-added output by secondary and tertiary industries related to minerals and metals was as follows in million dollars: Chemicals and chemical products, $3,587; petroleum and coal products, $2,147; nonmetallic mineral products, $774; and basic metals and metal products, $1,745.

In addition to coal, the only minerals domestically mined of significant quantity include salt, dolomite, limestone, marble, clays, and talc soapstone.[5] Amounts of metal ores are produced domestically, notably copper, iron, gold, and silver. In addition to byproduct sulfur, local production of other nonmetallic values includes gypsum, serpentine, asbestos, talc, feldspar, mica, and sands.

The bulk of Taiwan's industrial output of minerals-derived products is from imported materials. Domestic production of finished articles and semimanufactures is for export markets as well as internal consumption. Metal production includes ingot and manufactures of iron and steel, aluminum, copper, gold, and silver. In addition, there is significant output of derivative materials from nonmetallic mineral and petroleum refining, including mineral acids and alkalis, chemical fertilizers, chemicals and pharmaceuticals, organic solvents and fuels, refractory bricks, and cement. In 1978, the output value of the mineral-processing sector was estimated at $8.3 billion.

Total ____ do	79,961	92,753	109,387	106,531

[e]Estimate. [p]Preliminary. [r]Revised.
[1]In addition to the commodities listed, iron, lead, tin, and zinc may also be produced, but information is not available.
[2]Reported figure.
[3]From Chinkuashih only.
[4]Largely processed into natural gas liquids.
[5]Naphtha, solvent oil, and base oil.
[6]Includes liquefied petroleum gas and jet fuel.

TRADE

Taiwan's two-way trade in 1978 totaled $24.3 billion, up 36% from that in 1977. Total trade in 1979 was estimated at $30.6 billion. Exports increased from $9.3 billion in 1977 to $13.0 billion in 1978, and to $15.9 billion in 1979. Similarly, imports increased from $8.5 billion in 1977 to $11.3 billion in 1978 and to $14.7 billion in 1979. The largest import categories during 1978 were as follows in million dollars: Basic metals and metal products, $4,699 (includes iron and steel, $798, and nonferrous metals, $292); minerals, $5,858 (includes crude petroleum, $1,631); agricultural, forest, and food products, $1,506; chemical and pharmaceutical products, $1,341 (includes chemical compounds, $609, and chemical fertilizers, $48); textiles and related products, $834; and nonmetallic mineral products, $289 (includes refined petroleum products, $208).

Textiles, leather, wood, and related products constituted 34% of total exports, or $4,443 million, in 1978. Exports of basic metals and metal products totaled $3,885 million, the major share of which was electrical machinery and apparatus, $2,059 million. In this category, exports of iron and steel and nonferrous metals were, respectively, only $294,000 and $35,000, illustrating Taiwan's ability to export value-added manufactures. The other leading export categories included agricultural and food products, $978 million; nonmetallic mineral products, $494 million (included $261 million for refined petroleum products, $41 million for cement, and $60 million for glass and glass products); and chemical and pharmaceutical products, $282 million. Exports of minerals were small and were valued at only $4 million.

By value, imports from Japan accounted for 31% of Taiwan's total imports, followed by the United States, 22%; Kuwait, 7%; Saudi Arabia, 6%; and West Germany, 4%. Receipts from Malaysia and Singapore, Australia, and the United Kingdom were each around 2% to 3% of all imports. The remainder of the imports was contributed by a host of countries.

Taiwan's major export destinations were the United States, 40% by value of total shipments in 1978; Japan, 12%; Hong Kong, 7%; and West Germany, 5%. Receipts by Malaysia and Singapore, United Kingdom, Canada, Saudia Arabia, and Australia each ranged between 2% and 3% of the value of total shipments during the year.

Taiwan is dependent on imported raw materials to meet the demands of its export-oriented industries. Petroleum is the single largest import item. Moreover, the country's foreign trade is highly concentrated in two countries, Japan and the United States, which together represent about 50% by value of both imports and exports. To counterbalance currency revaluations, higher fuel costs, and other factors that would adversely affect the economy, Taiwan was attempting to diversify export markets and overseas supply sources. The Government abolished restrictions on many trade items in a move to reduce inflationary pressures on the economy due to higher import prices. During 1978, the Government moved toward easing trade restrictions; most liberalizations became effective on July 14, 1978. The item changes relating to the minerals industries were as follows:

Category	Number of commodities	Imports			Exports	
		Permissible	Controlled	Prohibited	Permissible	Controlled
1977:						
Minerals	465	457	8	--	267	198
Nonmetal mineral products	657	655	1	1	622	35
Chemicals	1,900	1,790	101	9	1,778	122
Basic metals	1,794	1,790	4	--	1,594	200
Metallic products	2,677	2,653	24	--	2,655	22
1978:						
Minerals	446	446	--	--	419	27
Nonmetal mineral products	676	674	1	1	642	34
Chemicals	2,178	2,077	92	9	2,088	90
Basic metals	1,551	1,545	--	--	1,359	192
Metallic products	3,078	3,045	--	--	3,052	26

Minerals-related goods to be admitted duty-free included unroasted pyrite; sulfur (other than sublimed, precipitated, or colloidal); natural calcium phosphate, aluminum-calcium phosphate, apatite, and phosphate chalk; potassic mineral or chemical fertilizers; and copper matte and native copper. Items with reduced tariffs included natural graphite (from a duty rate of 13% to 7.5% ad valorem); artificial and colloidal graphite (20% to 15%); natural cryolite (7% to 2.5%); stainless steel plate and sheet (16% to NT$9,000 per ton); and stainless steel forged rod (16% to NT$8,400 per ton). Moreover, the Executive Yuan lifted custom duties on pollution control equipment and measuring and testing instruments which the country was not able to produce locally.

Table 2.—Taiwan: Exports and reexports of mineral commodities[1]

(Metric tons unless otherwise specified)

Commodity	1977	1978	Principal destinations, 1978
METALS			
Aluminum:			
Oxide and hydroxide	3,964	2,380	NA.
Metal including alloys, all forms	3,741	8,271	Japan 2,779; Hong Kong 1,450; Saudi Arabia 234.
Copper:			
Copper sulfate	66	22	NA.
Metal including alloys:			
Scrap	3,261	5,518	Mainly to Japan.
Unwrought	536	428	NA.

COMMODITY REVIEW

METALS

Aluminum.—Taiwan Aluminum Corp. (Talco) is the country's sole producer of aluminum. Talco is 100% Government owned and was integrated from alumina production through the metal-semifabricating stage. In July 1977, a typhoon hit southern Taiwan, inflicting substantial damage to the industrial area of Kaohsiung. Smelter No. 1, with an annual capacity of 38,000 tons, was severely damaged by the typhoon.

Construction of Talco's unit No. 2 (annual capacity of 37,000 tons) was completed in 1976. However, full commissioning of the newly completed smelter was delayed until 1977. When Typhoon Thelma struck on July 25, the new smelter was only partially in operation. Because of storm damage, Talco operated at 40% of rated capacity in 1977, compared with 67% in 1978.

Alumina production was by Talco's caustic leach plant at Takao, also in the Kaohsiung area. Taiwan imports bauxite as the primary raw material for its aluminum industry. The traditional overseas suppliers of Talco were Seaba Co. of Alcan in Malaysia and Comalco in Australia.

The third-stage expansion project of Talco was completed in March 1978, costing about $73.7 million. The project included the expansion of the alumina plant and the addition of more rolling and processing facilities. Talco also planned to start the fourth expansion phase in December, whereby metal capacity would be increased to 90,000 tons per year.

The aluminum industry consumed 831.4 million kilowatt-hours of electricity in 1978 compared with 516.9 million in 1977. Talco supplies 30% of its energy requirement from its diesel-fed thermal generator and receives 70% of its energy from thermal and nuclear powerplants of Taiwan Power Co.

Copper.—Taiwan Metal Mining Corp. (TMMC), a Government owned company, controlled most of the copper industry in Taiwan. TMMC operates the only copper mine in Taiwan at Chinkuashih which produced about 1,000 tons (metal content) annually during the 1978-79 period. Copper concentrate is also imported to feed the smelter near the mine. Metal output capacity per year was 14,500 tons. TMMC/Lurgi Chemie was awarded contracts for plant construction of a 50,000-ton-per-year smelter at Taichung. Estimated cost of the project was $50 million with completion scheduled for June 1980.

Iron and Steel.—Taiwan's small magnetic placer operations are located along the northern coast between Tanshui and Wandi. Annual mine production is negligible compared with annual consumption, and most of Taiwan's requirements for iron ore and concentrate were met by large-tonnage imports from India and Australia to feed the Government owned integrated steel mill. Additionally, China Steel Corporation (CSC) reached an agreement to purchase 2.5 million tons of iron ore from South Africa for delivery over a 5-year period. The initial shipment of 500,000 tons, scheduled in July, will be transported by the Yi Li Shipping Company. The industry's demand for other ferrous metal requirements are met by imports of iron and steel scrap metal and by imports of old ships and vessels for scrapping. Power consumption by the iron and steel industry in 1978 was estimated at 2.4 billion kilowatt-hours.

CSC, a State enterprise, completed the first-stage construction of its integrated steelworks at Kaohsiung in late 1977. Presently CSC produces steel plate, rebar, wire rods, pig iron, and billet. Construction began on the second-stage facilities in May 1978 to increase the output capacity from 1.5 million tons of steel per year to 3.25 million tons. Upon completion of stage 2, CSC's products will include hot-rolled sheet, strips and sheets, cold-rolled sheet, and base plate. Second-stage construction was scheduled for completion in mid-1982, costing $1.4 billion, with financing provided equally by the Government and banking institutions. On October 6, 1979, CSC concluded a US$80 million loan agreement with a U.S. banking consortium headed by the Bank of America. The monies would provide about half of the investment required to finance the second-stage expansion (or the total cost of the first stage of the second-phase expansion project). A third-stage expansion was planned whereby annual capacity would reach 4.75 million tons, a target considerably below the original plans of 6 million tons per year. However, the final capacity will depend on market conditions.

As part of the Government's overall policy to establish and strengthen the economy, Taiwan Machinery Manufacturing Corp. (a State enterprise) had initiated five major projects (some of which were already underway), costing $238 million. The projects included a $24.7 million heavy machinery plant; a $30.8 million plant for producing large diesel engines, turbines, and other industrial equipment; a $1.8 million expansion of the tin electroplating plant; and a $158 million investment to develop heavy industrial equipment manufacturing capability. Intrinsic to the Government's scheme is to reduce expenditure on purchases of foreign industrial items which Taiwan is not presently capable of producing and to export eventually locally produced machinery to developing countries.

In August 1979, Tang Eng Iron Works Co. ratified a contract for the purchase of a US$60.9 million stainless steel plant from General Electric Co., Textron Inc., and Production Machinery Corp. The plant will have an annual capacity to produce 50,000 tons of stainless steel products. Financing for the purchase will be provided by a $47.3 million loan bearing an annual interest rate of 8% from the U.S. Export-Import Bank.

Other Metals.—Small quantities of gold were produced from vein deposits at the Chinkuashih mine. No placer deposits were presently being worked in Taiwan. In 1978, domestic production of gold was valued at NT$95 million, while the output of silver was valued at NT$15.6 million. Taiwan does not produce any primary zinc, lead, tin, or nickel, but consumes sizable tonnages of these metals annually. Industrial demand for these metals is met by imports primarily from Australia, Canada, Japan, Malaysia, and the United States.

NONMETALS

Cement.—There were 20 operating cement plants of 13 manufacturing companies in Taiwan with a total production capacity close to 12.3 million tons per year. Eighteen plants were in the west and two in the east. Most of the cement plants had their own limestone quarries, and only a few small plants purchased limestone raw materials from quarries operated by others. The east coast of the island was becoming the cement export center because of rich natural resources and Government directives aimed at accelerating the growth of eastern Taiwan. Also, the completion of the Suao-Hualien Railroad provides a direct link for cement plants to Hulien Harbor. Since 1975, exports of cement increased sharply, reaching 1.56 million tons in 1977, then falling to 1.14 million tons in 1978. The principal export destinations were Hong Kong, Singapore, and Saudi Arabia. Demand for cement, however, continued to increase owing to consumption resulting from construction in connection with Taiwan's Ten Major Construction Projects, construction starts of new Government projects, and an increase in export shipments. Total shipments in 1979 were estimated at around 11.5 million tons.

Taiwan Cement Corp. (TCC) was the largest producer on the island with four plants, one each at Kaohsiung, Chutung, Suao, and Hualien, and a combined annual capacity of 3.8 million tons. Asia Cement Corp., with a 2.5-million-ton plant at Tahu near Hsinchu, ranked next to TCC. The remaining cement capacity, 6.0 million tons, was distributed among 15 plants of 11 companies. The energy consumption by the cement industry was estimated at 1,424 million kilowatt-hours.

Construction of a new cement plant, with an annual capacity of 800,000 tons per year, was completed near yearend 1978. Hsin Hsin Cement Enterprise Corporation of Chayi is a newly established firm and is a joint undertaking of the Vocational Assistance Commission for Retired Servicemen and local businessmen. Asia Cement Company planned to invest $33.9 million in the construction of a second cement factory adjacent to its Hualien facility. When completed, the company's annual capacity will increase from 2.4 million to 3.4 million tons. New facilities and expansion to existing ones were expected to increase the country's annual capacity to more than 16 million tons by 1980.

On January 20, 1979, Chia Hsin Cement Corporation began construction of a 1-million-ton-per-year cement plant to be completed at the end of 1980. The new plant will feature U.S.-made equipment.

Fertilizer Materials.—In 1978, Taiwan produced 529,121 tons of ammonium sulfate, 533,583 tons of anhydrous ammonium, 253,774 tons of compound fertilizers, 174,754 tons of calcium superphosphate, 365,659 tons of urea, and 12,760 tons of nitrochalk. Taiwan has no potash resources and only small apatite resources. During 1978, Taiwan imported 314,950 tons of natural phosphates and 285,429 tons of chemical fertilizers to meet domestic demand for fertilizer materials. In 1978, energy consumption by the chemical fertilizer industry totaled 358.9 million kilowatt-hours of electricity. During 1978, Taiwan Fertilizer Company, a Government enterprise, exceeded its output target of 1.1 million tons of chemical fertilizers by 32,700 tons. However, sales during the year totaled 891,834 tons. The shortfall was credited to slackened demand in local markets.

Salt.—All salt production was by the Taiwan Salt Works, a Government enterprise. The saltfields are distributed along the southwestern coast, and crude salt was produced by solar evaporation. In 1978, salt production was about 155,000 tons below the 1976-77 level of output because of typhoon damage. Imports of salt were over a million tons. The largest consumer of salt was the soda-chlorine industry, which produced 121,364 tons of caustic soda, 325,665 tons of liquid soda, 71,820 tons of soda ash, and 25,796 tons of liquid chlorine.

Stone.—Dolomite deposits are extensive and widespread, particularly in eastern Taiwan. The most important dolomite quarries were situated along the Tachoshuichi stream north of Hualien, with lesser quarries operating near Hoping, Hojen, and Chungte. Total production of dolomite in 1978 was valued at US$3.6 million, compared with US$1.9 million in 1977. Most of the dolomite was used by ironworks, glass manufactures, and chemical plants.

Commercial limestone deposits occur in many parts of Taiwan, and large quarries were being worked, particularly in the southwest and east. Limestone reserves were estimated at more than 450 billion tons. Production in 1978 was valued at US$25.7 million compared with US$23.3 million in 1977. The cement industry continued to be one of the largest consumers of limestone. Considerable quantities were also used for sugar refining. Burned or cal cined limestone went into lime manufacture, and high-purity raw limestone was the chief raw material for making carbide cyanamide.

The crystalline limestone in the metamorphic terrain of eastern Taiwan is classified as commercial marble. The production of marble was valued at about US$13.2 million in 1978. Most marble consumption was by the cement and fertilizer industries. The percentage of the total output of marble used as a building stone was small but was increasing. The output of decorative marble in 1978 was 1.64 million cubic meters, compared with 1.62 million in 1977 and 1.24 million in 1976.

Other Nonmetals.—Sulfur production was mainly from the Kaohsiung refinery of Chinese Petroleum Corp. and from pyrite recovery from copper mining. Sulfur recovery during the year was about 10,000 tons. Taiwan produces small quantities of asbestos and gypsum from schistose rocks in the eastern part of the island. Production of other nonmetallic minerals included low-grade clay, gem stones, mica, glass sands, serpentine, and talc.

MINERAL FUELS[6]

Under the current economic plan, Government expenditures for major energy projects in 1978 were projected at $793 million. Included in the projects were construction of three nuclear powerplants (six reactors); five thermal power generators; three hydropower plants and one hydrorecycling (pump storage) powerplant; development and utilization of geothermal energy; and offshore exploration for oil and natural gas. Additionally, the Government announced a policy for large energy users to maintain at least a 60-day emergency stock of energy supplies to minimize the impact of supply fluctuation. Stockpile guidelines for large energy users were as follows: Users consuming more than 1,000 kiloliters of fuel per year were to maintain at least a 60-day stock of fuel; Chinese Petroleum Corp. shall maintain stocks of petroleum products sufficient to meet at least 90 days of domestic demand; Taiwan Power Co. was to maintain at least a 60-day emergency stock of coal for its thermal powerplants and an appropriate stock of uranium for its nuclear powerplants (and maintain contracts for at least a 5-year uranium supply); and natural gas distributors were to construct storage facilities for at least a half-month's supply.

Because most of Taiwan's energy is imported, the Government was planning the exemption of import duties on primary energy supplies. A preliminary proposal made by the Ministry of Economic Affairs to the Executive Yuan was referred to the Council for Economic Planning and Development for study and coordination among various Government agencies. If ratified, duty exemptions would apply to imports of coal, crude oil, liquid natural gas, and uranium.

Coal.—Coal, the most important mineral commodity mined in Taiwan, occurs mainly in northern Taiwan. The coalfields are geologically complicated, having abundant faults and folds. Generally, coal production has decreased annually since the 1960's.

By output volume, 92 mines produced less than 500 tons per month; 22 produced 500 to 1,000 tons per month; 54 produced 1,000 to 2,000 tons per month; 10 produced 3,000 to 5,000 tons per month; and 10 produced above 5,000 tons per month. Under the current economic plan, the target output for coal in 1978 was 3.1 million tons, a shortfall of 200,000 tons of actual output.

About 20% of the coal produced in Taiwan was classified as coking coal. Pioneer Chemical Corporation and Hsin-Chu Chemical Corporation operated the only byproduct coke plants in Taiwan; both also produced coal gas for municipal use. The principal domestic user industries were iron and steel works, carbide manufacturers, and the plastics industry.

Natural Gas.—The Government's target production of natural gas in 1978 was 2,145 million cubic meters. Actual output in 1978, however, was about 85% of the target. Production was largely from 20 wells in the Chinshui gasfield and from 29 producing wells in the Tienchenshan gasfield. Taiwan's reserve of natural gas was estimated at 29 billion cubic meters. While annual production is small by world standards, the reserves and output of natural gas were considered an important energy supplement sufficient to meet the current consumption level of natural gas. The Chinese Petroleum Corp. continued drilling for natural gas, but all wells were either dry or lacked sufficient gas reserves for commercial production.

Petroleum.—Domestic production of oil equals less than 2% of annual crude oil imports. During 1978, Taiwan imported 17,130,000 tons of crude oil, valued at $1,631 million, and 2,409,393 tons of refined petroleum products, valued at $208 million.

The Chinese Petroleum Corporation

(CPC), a Government owned enterprise, produces, imports, refines, and markets all petroleum, natural gas, and their products used in Taiwan. CPC owns seven 100,000-ton tankers and one 36,000-ton ship, which collectively are capable of handling 70% of the crude oil Taiwan imports. In addition, CPC maintains loading and storage facilities for the imported oil (the storage field contains six tanks capable of holding 450,000 tons of crude oil).

CPC has two refineries in operation at Kaohsiung; the first has a capacity of 334,500 barrels per day, and the second, which was put on-stream in 1977, a capacity of 100,000 barrels per day. Construction of a new refinery at Taoyuan, with a capacity of 100,000 barrels per day, was on schedule for completion. Additionally, CPC operates two petrochemical complexes: The larger one, at Kaohsiung, utilizes petroleum as its raw material, and the other, at Toufen in the north, uses natural gas. Kaohsiung has three naphtha crackers, one with a capacity of 54,000 tons of ethylene per year and two with annual capacities of 230,000 tons of ethylene.

Uranium.—The Atomic Energy Council and the China Phosphate Industries Corporation (a state-run enterprise) constructed a pilot plant for phosphoric acid uranium extraction. Overseas patent applications have been filed for this process, which was developed by the Atomic Energy Institute. The plant represents a significant step for domestic production of yellowcake for use in nuclear electric power generation in Taiwan.

The Mineral Industry of Tanzania

By David E. Morse[1]

The mineral industry of Tanzania continued to be a small contributor to the nation's primarily agrarian economy but was nonetheless an important source of foreign exchange in 1978-79. Tanzania's major mineral exports were diamond, salt, and gem-quality minerals. The Government-owned State Mining Corporation(SMC) controlled most of the nation's mining operations. In cooperation with geologic teams from foreign countries and the United Nations, the SMC was investigating deposits of iron, coal, gold, nickel, phosphate rock, and coastal sands that contained ilmenite, zircon, and rutile. Systematic geological mapping on a scale of 1:125,000 was continued by the staff of the Geology and Mines Division of the Ministry of Water Development, Energy, and Minerals. Service contracts were maintained for oil and natural gas exploration by foreign companies with the Tanzania Petroleum Development Corporation (TPDC).

An airborne geophysical survey that was intended to cover the entire country began in 1978. Preliminary reports from the survey indicated that several radiometric and gravitional anomalies had been located that warranted follow-up surface investigations, notably in southern Tanzania near the border with Mozambique.

Contributions provided by the United Nations Development Program and the Government of Ethiopia enabled Tanzania to begin building the East African Minerals Center at Dodoma near the Geology and Mines Division Headquarters. The center was being established to provide a variety of services to assist in mineral exploration and development studies for member governments. The original agreement for establishing the center was signed in 1975 by representatives from Botswana, Ethiopia, Kenya, Madagascar, Somalia, Tanzania, and Uganda.

Tanzania's third 5-year development plan (1977-81) projected an annual 6% increase in the gross domestic product (GDP). The plan emphasized self-sufficiency in food production and expansion of the nation's iron, steel, cement, fertilizer, textile, chemical, and energy sectors. The plan also called for increased import substitution which was to be accomplished by the processing of domestic raw materials into finished goods. Growth in the mining sector was targeted at 9.3% per year during the 5-year period. Total expenditures were projected at $3 billion[2] of which nearly half was expected to be raised from external loans and grants.

Tanzania's GDP grew by 5.5% (at constant 1966 prices) in 1978, but events during the year severely restricted the nation's economic performance in 1979. The 1978 spending boom, coupled with a costly conflict with Uganda, caused a drastic decline in Tanzania's foreign exchange reserves in 1979. World prices for the country's major agricultural exports also declined in the 1978-79 period, and prices for imported fuels and crude oil nearly doubled in 1979. Shortly after the conflict with Uganda began in October 1978, the Government commandeered a significant portion of the nation's heavy -duty trucks, which severely curtailed the movement of general supplies, spare parts, and petroleum products to many areas of the country and also to neighboring, landlocked Burundi and Rwanda. The lack of necessary supplies and the reduced flow of agrarian export items caused a decline in the performance of both the industrial and agriculture sectors in 1979. Strict Government actions to reduce imports and aid from European countries halted the drop in foreign exchange reserves late in 1979 but did not alleviate the country's underlying economic weaknesses.

PRODUCTION AND TRADE

Production statistics for most of Tanzania's mineral products were not available. As a result, the statistics that follow reflect a considerable use of estimates. Based on export data, diamond retained its position as Tanzania's most valuable mineral production in 1978 and 1979. Salt, gem stones, mica, and tin concentrate (cassiterite) were Tanzania's other important mineral export commodities in 1978 and 1979. The value of Tanzania's mineral exports was approximately $24 million for each of the two years and represented nearly 5% of the value of all exported goods. Tanzania produced gypsum, lime, cement, kaolin, bentonite, glass sand, and crude construction materials from indigenous deposits for domestic consumption. Imported materials were processed to manufacture fertilizer materials, steel products, farm implements, and metallic household utensils and fixtures.

The nation continued to rely on outside sources to supply a major share of its needs for iron and steel, aluminum, lead, zinc, fertilizers, and refractories. Cement was also imported in significant quantities. Imported crude oil and refined petroleum products were valued at nearly $140 million in 1978 and at $200 million in 1979; these imports represented approximately 10% of the value of all imported materials in 1978 and 18% of the total import value in 1979.

COMMODITY REVIEW

METALS

Iron and Steel.—The Government planned to develop an iron and steel industry near Mbeya in southwestern Tanzania that would utilize domestic iron ore from the Chunya deposits and coal from the Songwe-Kiwira coalfields. The National Development Corp. planned to invest $6.5 million to increase the capacity of the Tanga Steel Rolling Mills Ltd. plant from 25,000 tons per year to 90,000 tons per year. The Tanga rolling plant produced wire, rod, bars, angles, and flat steel products from imported rolling stock.

NONMETALS

Cement.—Tanzania's only cement plant, at Wazo Hill near Dar es Salaam, continued to operate at less than capacity in 1978 and 1979. A third kiln completed in 1979 expanded the facility's capacity to 600,000 tons per year. A new 1,600-ton-per-day cement plant at Tanga in northeast Tanzania was scheduled to be in production in 1980. Also, an 800-ton-per-day single-kiln cement plant was planned to be built at Mbeya in the southwest. Tanzania Saruji Corp. awarded a contract to F.L. Smidth of Denmark to supply the major components for the Mbeya plant. Tanzania's cement industry expansion was designed to minimize cement imports and reduce foreign exchange expenditure.

Diamond.—There was a significant and unexplained drop in diamond output in 1978, and production in 1979 continued at a relatively low level. Diamond production had previously been declining because of a decrease in the grade of the ore processed. Despite the decreased level of production, diamond retained its positon as the most important mineral commodity exported by Tanzania.

Mica.—Exports of sheet mica decreased by 1,000 kilograms in 1978 compared with those of 1977; but the average price per kilogram increased more than fourfold, from $2.51 per kilogram to $11.27 per kilogram. Small quantities of material of exceptional quality brought prices of over $700 per kilogram in 1978. Although complete information on mica exports from Tanzania in 1978 was not available, it was known that the United States imported over 212 kilograms of sheet mica with an average f.o.b. value of $73.86. The traditional mica mining district is located in the Uluguru Mountains south of Morogoro in east-central Tanzania.

Phosphate.—West German experts who conducted tests on phosphate deposits near Lake Mangara in the Arusha region reported that the material was suitable for the production of all types of phosphatic fertilizers. The Tanzania State Mining Corporation planned to exploit the deposits to supply the 60,000- ton-per-year Tanga fertilizer plant, which manufactured complex fertilizers from imported materials.

MINERAL FUELS

Coal.—Coal was mined in the Songwe-Kiwira district of southwestern Tanzania for use by local tea plantations. SMC planned to boost production to 30,000 tons per year in an attempt to substitute coal for wood and charcoal, owing to heavy deforestation in areas adjoining settlements.

The Songwe-Kiwira coal deposits have been the subject of an intensive study conducted for the SMC by investigators from Mainland China. Results of the study were expected to be reported in early 1980. Tanzania planned to utilize the coal for the production of pig iron and steel by the mid-1980's.

Natural Gas.—The Oil and Natural Gas Commission of India, working under a service contract for the State agency TPDC, drilled a single well on Songo Songo Island in 1978. Natural gas was reported, but flow-test data were not released. TPDC estimated natural gas reserves at 1.04 trillion cubic feet in the Songo Songo Island gas-field.

Petroleum.—No significant petroleum exploration activity was reported in Tanzania during 1978. In 1979, Agip Tanzania Ltd. retained its service contract with TPDC covering a 16,486- square-mile area both onshore and offshore along the east coast. Ocean Exploration Co. was the only other company holding exploration rights under a service contract with the TPDC.

Imports of crude petroleum for the Dar es Salaam petroleum refinery, operated by the Tanzania and Italian Petroleum Refining Co. Ltd., continued to be restrained owing to Tanzania's shortage of foreign exchange. The oil refinery operated well below its 17,000-barrel -per-day capacity in both 1978 and 1979. The oil refinery was closed for the month of September 1979 because of supply disruptions and the lack of foreign exchange. Tanzania secured commitments from Iraq for crude oil supplies for 1980 which covered nearly two-thirds of the nation's requirements. The remaining third of the country's crude oil needs was to be supplied from Abu Dhabi under a long-term commercial agreement.

The Mineral Industry of Thailand

By Gordon L. Kinney[1]

The year 1978 was one of vigorous growth for most sectors of the Thai economy. The mineral industry in particular had a good year, with the value of total mineral production more than 40% higher than in 1977. Moreover, the construction and manufacturing industries contributed significantly to the overall growth of the economy. Real growth of the gross national product (GNP) reached 8.7%, exceeding the Government's goal of 7.0% growth. The highly important agricultural sector recovered fully from the severe 1977 drought, despite major flooding in September and October of 1978. Paddy rice production during the 1978 crop year was expected to total about 16.5 million tons, or 1.5 million tons more than production for 1977.

In 1979, the agricultural and industrial sectors of Thailand's economy remained strong. Overall real economic growth was around 6%. The important rice harvest showed a small gain over 1978 and yielded an exportable surplus of 2.6 million tons. Other commercial crops, led by tapioca, did well during both 1978 and 1979.

The GNP for 1978 was reported at more than $21.7 billion,[2] reflecting a growth rate of more than 14% over the 1977 GNP, at current prices, and more than 8.7% in terms of constant 1972 prices. In 1979, the current-price GNP was estimated at over $25 billion, reflecting an increase of more than 16% over the 1978 current-price GNP.[3] Because of the continuing high rate of inflation, however, the 1979 current-price GNP represented an increase of only about 6% at constant 1972 prices. The official rate of inflation was recorded at 8.4% in 1978. In 1979, inflation was fed by large increases in the cost of energy imports, and the rate by yearend was estimated by various sources at between 10% and 20%.

The farming sector continued to employ about 70% of the labor force, but its relative importance in the Thai economy has declined since 1973, when farming accounted for 34% of the gross domestic product (GDP); in 1978, the farming sector's share of the GDP was a little over 27%. The mining and quarrying sector, however, has gained in relative importance. This sector's share of the GDP increased steadily from 1.3% in 1975 to 2.2% in 1978 and 1979. The increased importance of mining and quarrying was also reflected in the employment data which varied widely from month to month. Total mining industry figures (using December as the index month) showed that employment increased from 58,500 in 1977 to over 84,000 in 1978. Monthly employment figures through September 1979 were slightly ahead of those for the corresponding months in 1978. Tin and tin-tungsten operations were the dominant employers in Thailand's mining industry, and the country's relative dependence on tin operations for mining employment has increased steadily in recent years. The percentage of the mining work force that was employed by tin operations grew from 75% in 1974 to nearly 88% in December 1978.[4]

Developments in the tin sector combined to produce a 43% increase in the value of tin production in 1978 over that of the previous year. As in 1977, a major factor in the increased value of tin production was the continued increase in the world price of tin. In 1979, Thailand surpassed Bolivia as the world's second largest tin producer. Preliminary data showed that tin production through September 1979 was ahead of production for the corresponding period in 1978.

The long pricing impasse between the Government and Union Oil Co. was finally broken in September 1978 when the Government's Natural Gas Organization of Thailand (NGOT) and Union Oil signed a 20-year natural gas sales contract. The signing of this agreement removed the last obstacle for the development of large offshore natural gas deposits and the laying of a sea-floor pipeline to the Bangkok area. During 1979, contractors were chosen for the offshore platforms, and the pipeline construction contractor was expected to be chosen in January 1980. The first gas from these deposits was scheduled to begin flowing in October 1981.

At yearend, Texas-Pacific Co. and the Thai Government had still not signed a pricing agreement for Texas-Pacific's nearby gas discovery.

In December 1978, the Government created the National Petroleum Authority of Thailand (NPAT), which was established essentially as a vertically integrated Government oil company. NPAT was created to explore and develop petroleum resources, market products, control activities of the refineries, and transport crude oil and petroleum products. It was anticipated that NPAT would integrate the activities of all petroleum-related State agencies.[5]

PRODUCTION

The value of Thailand's total mineral production in 1978 was reported at $487 million, or 2.2% of GNP. This figure represented a record increase of 44% over the previous year's mineral production value and reflected both a larger output of mineral products and a higher world price of tin. Preliminary data for 1979 indicated that the value of total mineral production for that year was more than $600 million, reflecting another significant increase. Thai mineral production is strongly oriented toward the export market. Domestic demand was very low, and consumption of mineral products (excluding imports) totaled about $20 million, or just over 4% of the total value of mineral production.

As in the past, tin played the dominant role in Thailand's mining industry in 1978 and 1979. Tin-in-concentrate, valued at nearly $380 million, accounted for more than three-quarters of the total value of Thai mineral production in 1978. The 1979 production of tin was valued at over $500 million, or 83% of the total. Tin and tungsten led the industry in production value growth in 1978 with substantial gains, but nearly all the important mineral products showed increases in both tonnage and value for the year. The value of tungsten concentrate production for 1978 was approximately $57 million, and tungsten was the country's second ranking mineral by value.

TRADE

As a result of high world prices for tin and tungsten, Thailand exported minerals and metals worth over $440 million in 1978. Of this total, tin accounted for about $350 million. Exports of tin for the first 9 months of 1979 were valued at over $330 million. The other major exports were tungsten, gem stones, fluorite, antimony, and lead concentrate. A new lead concentrate processing facility that was brought into operation in 1979 contributed to a more than sevenfold increase in lead concentrate exports over exports for the previous year. Cement, formerly a major export item, was in short supply. Exports dropped to virtually nothing as cement became an imported item in 1978 and 1979. Overall, minerals ranked third as a major export group, following tapioca and rice exports in value.

The value of Thailand's total trade in 1978 came to $9.4 billion. Exports rose from $4.1 billion in 1978 to an estimated $5.2 billion in 1979. Imports, however, rose at an even faster rate, from $5.3 billion in 1978 to an estimated $7.5 billion in 1979. The trade deficit was projected at over $2 billion for 1979, or nearly twice the 1978 deficit, which had been held to a 10% increase over the 1977 deficit. Japan was again the main market for Thai exports, taking 20% of the total in 1978 and 22% of the total in the first half of 1979. The Netherlands, the United States, and Singapore followed Japan as major purchasers of Thai exports, taking 15%, 11%, and 8%, respectively, of the 1978 export total. These countries purchased approximately the same portions of Thailand's exports during the first 6 months of 1979.

Agricultural products were the major foreign exchange earners, accounting for over 50% of total exports in 1978 and 1979. In 1978, tapioca and rice exports were each valued at over $500 million and together accounted for more than 25% of total exports.[6] In addition, rubber, maize, and sugar together contributed another $800 million to the export market. Other agricultural exports generally showed small increases during 1978.

Thailand's major imports in 1978 were machinery, mineral fuels and lubricants, manufactured goods, and chemicals, in that order.[7] About 31% of total imports came from Japan; 14% came from the United States; and the Federal Republic of Germany and Saudi Arabia each supplied 6%. The value of mineral fuels accounted for over 21% of total imports in 1978 and nearly 22% of the total in the first 10 months of 1979.

COMMODITY REVIEW

METALS

Antimony.—The value of antimony production in 1978 decreased by about 16%, despite an increase in production volume. Production of antimony concentrate in the first 9 months of 1979 was well ahead of production for the corresponding period in 1978 and ranked Thailand about fifth in world output. Production of antimony metal in 1978 was less than one-fourth the 1977 total, but production reversed in 1979 and showed a substantial increase.

Most of Thailand's antimony is mined in small-scale manual operations that are highly sensitive to price fluctuations. When the price falls too low, the diggings are simply closed until prices recover. Because of recent unstable marketing conditions, mine owners have been reluctant to make large capital investments for modernization or to increase production capacities.

Most of Thailand's antimony was mined for the export market. Exports were valued at over $4 million in 1978 and at $4.2 million for the first 9 months of 1979.

Iron and Steel.—Iron ore production was of little significance to Thailand's mineral industry in 1978, despite a production increase of almost 40% over the previous year's output. In 1979, the upward trend in production continued. Thailand's production of iron and steel was all consumed locally in the Siam Iron and Steel Co. Ltd.'s small blast furnace (which had a capacity of less than 100,000 tons per year). Thailand consumes over 1 million tons per year of steel, most of which is imported. The small domestic smelters and rerolling mills, using imported scrap as raw material, primarily produce structural and reinforcing bars for the construction industry.

Thai industry and Government planners have long considered establishing an integrated steel industry, but economic conditions and the lack of raw materials have been continuing deterrents. However, the discovery and imminent development of natural gas deposits in the Gulf of Thailand have improved the prospect for establishment of such a steel industry. A detailed feasibility study, commissioned by the Government in November 1977, was completed and submitted to the Industry Ministry in early 1978. The study, undertaken by Austromineral-Austroplan of Austria, suggested that a 600,000-ton-per-year direct-reduction (D-R) plant based on natural gas would be a suitable first step in the development of an integrated steel industry. Thai scrap supplies are uncertain, but it is anticipated that the proposed D-R plant would ensure dependable supplies of sponge iron for electric-furnace steelmaking. Laem Chabang or Sattahip, both coastal sites, were suggested as possible locations.[8]

Tantalum.—Thailand was the world's largest producer of tantalum source materials in 1978 and 1979. Tantalum occurs with tin ore and is generally obtained in Thailand in one of the following ways: 1) from the processing of tin smelter slags, 2) from the processing of tin mine dumps for struverite, and 3) as a tantalite-columbite concentrate separated physically during the tin ore concentration cycle.

Slag from the Thaisarco tin smelter in Phuket is particularly rich, ranging from 11% to 14% Ta_2O_5 and from 7% to 9% Cb_2O_5.[9] All of the slag from this smelter was exported in 1978 and 1979. Several companies have applied separately for Government permission to build treatment plants at Phuket for the extraction of tantalum from tin slag.

Tin.—Tin continued to be Thailand's most valuable mineral commodity during 1978. Total production of 73%-tin concentrate from all mining methods was reported at over 41,000 tons, reflecting an increase of almost 25% over the previous year's production. The smelting of concentrate by the Thaisarco plant produced nearly 29,000 tons of metal, or more than 12% of world production. Total tin production was valued at about $378 million in 1978, representing an increase of almost 50% over output for 1977. The increased value of production was a result of the large increase in world tin prices. In addition to the officially reported production, an estimated 2,000 to 3,000 tons per year of tin concentrate, and possibly much more, may have been smuggled out of Thailand during 1977 and 1978 to avoid payment of Government royalties.

In the first quarter of 1979, tin production and export revenues increased. However, production in the second quarter declined to slightly below that of the corresponding period in 1978 and then dropped in the third quarter to well below the 1978 third-quarter level.

A breakdown of tin mining methods showed that gravel pumping still predominated but was losing ground to other techniques. Offshore dredging was expected to show a continuing gain in the percent contributed to total output during the next few years. Small suction boats employed by far the most miners during 1978, followed by onshore gravel pumping operations and dulang washers. The big commercial dredges employed relatively few workers, probably less than 4% of the tin mining labor force.

On February 8, 1978, the Ministry of Industry issued a new schedule that lowered the tin tax royalty rate. The revised sliding scale tax rate varies according to how much tin is produced by the company or lease-holder. The 4.4% business tax and the tax royalty combined will take a maximum of about 32.5% of the miner's smelter return on concentrates; under the old rate, imposed in July 1977, the combined tax share was about 37%. By lowering the tax, the Government hoped to reduce the lucrative smuggling of tin and help stimulate the growth of the industry.

In January 1978, the Thai cabinet approved a proposal for a large new offshore dredge. The Offshore Mining Organization (OMO) shortly thereafter awarded an $18 million contract to Mining and Transport Engineering B.V. Co. Ltd. of Amsterdam. It was anticipated that the new 0.45-cubic-meter-bucket (16-cubic-foot) ladder dredge will displace 4,000 tons and will be able to operate in 100 feet of water at the rate of 330,000 cubic meters of ore per month. Special equipment was expected to enable the dredge to operate in 2.5-meter bow waves or 1.5 meter waves on the beam. It was also anticipated that operations will be possible about 8 1/2 months of the year, which would be a considerable improvement over most other offshore dredging equipment. The OMO planned to operate the dredge directly, rather than through a contractor. The Government thereby hoped to increase its tin revenues considerably and also keep a tight control on offshore mining operations. Construction progressed satisfactorily during 1979, and delivery of the dredge was scheduled for the spring of 1980.

The OMO continued to sign contract-dredging agreements with dredge operators during 1978. The operators were required to meet criteria set by the Thai Government, and one of these criteria was that the operators be partially owned by Thai stockholders. By early 1979, several companies were operating a total of about nine dredges under OMO contracts. The main legal producers of tin concentrate from the offshore areas were Billiton Thailand Ltd.; Sethasap Mining Co. Ltd. (formerly Sethasap Karn Ree. Co.); Aokham Tin Co., Ltd. (formerly Aokham Tin Berhad Co. of Malaysia); Southern Kinta Associated Co. Ltd. (formerly Southern Kinta Consolidated Berhad Co. of Malaysia); and Tongkah Harbor Tin Co. Ltd.

Offshore mining was complicated by the presence of thousands of small suction-pump mining boats operating in the shallow offshore areas. The OMO reserved an area of about 4,000 hectares for these boats to exploit on condition that production be sold to the Government. The 4,000 hectares was quickly depleted of high-grade ore, and many of the boats resumed illegal operations in OMO territory. The small operators skim the richest pockets of ore and recover only about 30% of the tin present. The deposits that remain are uneconomic or just marginally profitable for the big contractors. In mid-1979, Southern Kinta Associated Ltd. halted offshore dredging operations near Takuapa because of poor production from its leased area. The area had been heavily poached by suction boat operators.

In mid-1978, the Government decreed that all illegal suction boat activities must cease by June 1979. The original deadline was not enforced, and a new deadline of May 31, 1980, was set. The suction boats will be difficult to curtail, and it was generally conceded that the use of force to stop their activity would be politically undesirable. Over 30,000 people were involved in illegal dredging operations, and their officially reported output in 1978 amounted to nearly one-third of the country's total.[10]

Planning continued on the Thailand present and Smelting Co. Ltd.'s new 3,600-ton-per-year tin smelter. The plant will be Thailand's second major facility for smelting tin. Original plans called for the plant to be located in Nakon Pathom near Bangkok in order to save costs of shipping ore concentrates from the North. In late 1979, however, it was reported that the planned plant's location had been changed to Phuket, far to the south.

Plans for a third tin smelter were delayed during the latter part of 1977 and the first half of 1978 for lack of financing. Subsequently, Thai Pioneer Enterprise Co. signed an agreement with Lurgi Chemie Huttentechnik GmbH of West Germany for construction of a plant near Pathum Thani about 30 kilometers north of Bangkok. The initial annual production of tin metal is expected to be 3,600 tons, rising to 5,200 tons over the ensuing 4 years. The plant was scheduled for completion in late 1980.[11]

Tungsten.—In August and September 1978, conflict centered around a newly discovered wolframite deposit being worked without Government sanction at Doi Ngon (Doi Tham Ngom Hill) in Phrae Province. An estimated 4,000 to 5,000 illegal miners had moved into the area, and the resulting disorder was similar to that which occurred at the rich Khao Soon Mine in the mid-1970's. Thai authorities were hesitant to remove the fortune seekers, but finally called in police in mid-September to restore order. The Thai Cabinet approved a proposal to control the illegal mining and protect the rights of concessionaires, and by early 1979, the situation was reported under control. In April 1979, a mining lease was granted to Doy Ngom Corp. (owned 40% by the Phrae District Government, 40% by local private interests, and 20% by the Thai central Government). The new company was working out marketing arrangements prior to the actual start of its mining operation.

Production at the Khao Soon Mine, which produced much of Thailand's tungsten in 1978, dwindled in 1979 to around 100 tons per month.[12]

Tungsten concentrate has been Thailand's second most valuable mineral commodity since 1972. In 1978, despite a substantial 44% increase in production over that of 1977, the value of Thailand's tungsten production increased only about 25% because of a general lowering of world tungsten prices. The country's tungsten production of almost 6,200 tons ranked Thailand as fifth in world output among the market economy countries. However, inefficient labor-intensive mining methods have tended to leave behind significant amounts of low-grade tungsten ores. As a result, many mines with substantial low-grade reserves were being closed as uneconomical to operate. This resulted in a significant drop in production and exports of tungsten ores during 1979.

There were 21 tungsten lode mines and 182 tin-tungsten placer mines in operation at yearend 1978. Over 700 people were employed in lode mining. About 6,300 additional workers were counted as mainly tin miners, but they also contributed a significant proportion of the tungsten mined from the combined tin-tungsten operations.

At yearend 1979, the Government was considering a proposal by Siam Tungsten to build the country's first ammonium paratungstate plant at Ayuttahya, near Bangkok. The plant was expected to cost $11 million and a capacity of 3,000 tons per year was projected.

Zinc and Lead.—In September 1978, New Jersey Zinc Co. announced the sale of its 55% interest in Thai Zinc Ltd. to Whashin Industrial Co. Ltd. of the Republic of Korea. Whashin was the proposed prime contractor for a planned 60,000-ton-per-year zinc refinery at the provincial capital of Tak. The Government's plan was to form a joint venture, with Thai interests holding 55%, and to limit foreign shares to a maximum of 45%. Thailand's participation was expected to include the Government (with a 20% share), the Sino-Thai Engineering and Construction Co. (10%), and another interest, possibly Industrial Finance Corp. of Thailand (25%). The foreign share was expected to be held by Whashin and a Belgian firm, Vielle Montaigne-Mechim, which was also expected to supply zinc-extraction expertise.

However, delays in arranging financing for the proposed refinery continued throughout 1979. The estimated cost of the plant had risen from $95 million to $120 million. At yearend 1979, Thai officials stated that the company must begin plant construction by April 5, 1980, or forfeit all development rights to the project.[13]

A small lead deposit was developed west of Bangkok. It was reported that Metallgesellschaft AG and Phoi and Sons Co. Ltd. constructed a small lead beneficiation plant at Srisawat in Muang District of Kanchanaburi Province. The plant was designed for 150 to 200 tons per day of concentrate with provision for doubling of output.[14] The plant was completed in late 1978. The value of lead concentrate production increased from $1.3 million in 1978 to $10.6 million in 1979. Almost all of this increase came from the new facility.

NONMETALS

Barite.—Thailand's barite mines had particularly good years in 1978 and 1979. Production in 1978 more than doubled over that of 1977 and was worth about $14 million. Barite was the third most valuable mineral produced in Thailand in 1978. Also in that year, about $5 million worth of barite was exported to foreign oil exploration industries. The production increase continued in 1979, with about the same amount of barite mined in the first 9 months as was mined in all of 1978. The Thai Board of Investment (BOI) had been studying the barite industry with regard to promoting and diversifying investment in domestic mineral industries. It was also interested in increasing the value of Thailand's mineral resources by encouraging as much domestic processing of materials as is possible. The BOI study recommended diversifying usage of domestic barite resources, particularly in nondrilling mud applications. It suggested the possibility of an integrated barium chemical plant for the production of lithopone and barium carbonate.

Cement.—The cement industry continued to operate at its design capacity during 1978 and 1979. Nonetheless, its annual production of over 5 million tons was not sufficient to satisfy demand, and Thailand was forced to import about $19 million worth of foreign cement in 1978. This was of particular concern to the Government because Thailand was a substantial exporter of cement until 1977.

In an effort to increase production, the BOI in August 1977 announced it would accept applications for new cement plants. By February 1978, the BOI had received 10 applications for construction of cement projects ranging in capacity from 800,000 tons per year to over 2 million tons per year. After evaluating the applications, the BOI awarded promotional tax and zoning privileges to four firms in May 1978 and to an additional new company later in the year. Planning for expansion were the Siam Cement Co. Ltd., which planned to increase capacity by over 1 million tons per year at its Thung Song plant in Nakhon Si Thammarat and also planned to increase capacity by the same amount at its Tha Luang plant in Saraburi; and the Siam City Cement Co. Ltd., which planned to increase the capacity of its Saraburi plant by 1.5 million tons per year. New projects were planned by the Mah Boonkrong Cement Co., which expected to produce 800,000 tons per year at a plant planned to be built near Korat; and the Thai Cement Industry Co., which was planning an 825,000-ton-per-year plant at

Saraburi. The later approval went to a Thailand-Republic of Korea joint venture expected to produce 1.6 million tons per year, of which 70% was expected to be exported.

Approval by the BOI only gives permission to build and does not mean that construction of a project is assured. Often the company fails to get financing, or conditions change, and the project founders. However, construction at Siam Cement Co.'s Thung Song site did begin in 1978 and progressed rapidly during 1979. Also, a contract was signed in 1978 for the Tha Luang plant, and construction began in early 1979.

Fluorite.—The fluorite industry employed about 2,800 people in 47 active mines at the end of 1978. The value of fluorite production continued a modest rise in 1978 for the second year, after experiencing rather sharp declines starting in 1974. The value and tonnage of exports, however, declined slightly from the 1977 level. Fluorite production in 1978 was valued at nearly $10 million, and fluorite fell from its position as the country's third most important mineral product to fourth most important in 1978. The 1979 production continued at about the same pace as in 1978.

The Japanese steel industry had been the major market for Thai fluorite until a slump in world steel production that began in 1974 and a reported drop in the quality of Thai fluorite caused a decline in exports. Despite the rebounding of steel production to almost prerecession levels, the Japanese steel industry had not resumed purchasing Thai fluorite at the former level. Efforts to find new markets were only partly successful. The Thai Commerce Ministry revealed that Romania had agreed to buy 6,500 tons of fluorite per year, but delivery and price details were not available.

The BOI completed a preliminary study of the domestic fluorite industry as part of its effort to promote and diversify investment in local mineral industries. The study suggested establishment of a fluorite briquet plant, a hydrofluoritic acid facility, and a synthetic cryolite plant. The study suggested that development of these plants would increase the overall value of domestic fluorite output, create new job opportunities, and increase foreign exchange earnings considerably.

Salt and Potash.—The Thai Government continued seeking ways to develop the huge rock salt deposits in the northeast, where reserves were estimated at around 4.8 billion tons. The basic project that is envisioned would consist of a 1- to 2-million-ton-per-year salt mine and 400,000- to 500,000-ton-per-year soda ash plant with downstream facilities. A detailed feasibility study was completed during 1978; it concluded that the technical aspects of the mine and plant were satisfactory. However, the viability of the project was contingent on competitive pricing and its projected profitability. The project would require a large expenditure for infrastructure development, particularly for rail and port facilities. Early in 1979, it was reported that the project was going ahead. In October 1979, it was further reported that the Thai Asahi Glass Co. was to set up a holding company to control Thailand's two-thirds equity share in the project. Total investment in the project was estimated at around $230 million. The other four Association of Southeast Asian Nations (ASEAN) nations, Malaysia, Singapore, Indonesia, and the Philippines, were expected to share a small part of the equity.[15]

Soda ash was the largest chemical import into Thailand, by volume, in 1978. Thus, development of the soda ash industry and its related chemical plants would be beneficial to the Thai economy because it would reduce the country's balance of trade deficit.

The Government was promoting the development of large potash reserves in the remote Khorat and Sakon Nakhon Basins in the northeast. A large market exists in the south and east Asian area for potassium for the fertilizer industry. While Thailand's reserves are the only large high-grade deposits in the area, a great deal of capital investment would be required for their development and production. Consequently, investors have had reservations about the project's economic viability. The only company to show an interest in these reserves was Amax Exploration Inc., which submitted a proposal to the Government late in 1979 for exploring and mining on the Khorat Plateau. Amax's target was an area located in the Wanoniwat District in Sakon Nakhon Province, where sylvite occurs in bodies up to 34 meters thick. The deposits are at depths as shallow as 90 meters.[16 17]

MINERAL FUELS

Lignite.—Production of lignite jumped by more than 45% over the previous year's production in 1978, then more than doubled in 1979. The source of this increase was the Mae Moh Mine in Lampang Province, which completed a major expansion in 1978. In Thailand, the primary use of lignite is for the generation of electric power at onsite thermal powerplants. At Mae Moh, the first 75,000-kilowatt turbogenerating unit was completed early in the year, and a second 75,000-kilowatt unit was scheduled to come online by yearend 1978. In addition, a third 75,000-kilowatt unit was scheduled for completion in 1981, and two 150,000-kilowatt units were planned for the mid-1980's. In November 1979, the Asian Development Bank management proposed an $82 million loan to cover part of the cost of installing the 150,000-kilowatt Mae Moh No. 4 generating unit. A continuing development program at the mine was planned to provide additional fuel as the later generating units are installed.

Production at the Krabi lignite mine in southern Thailand remained at about the 300,000-ton-per-year level. Reserves at the Krabi deposit are not large, however; and in order to assure continued production, site preparations for construction of new mining operations at nearby Klong Wai Lek and Klong Bang Mark were planned to begin at yearend 1978. Lignite from these new mines was expected to be available for the Krabi thermal power plant in 1980.

Natural Gas and Petroleum.–On September 28, 1978, Union Oil Co. of Thailand finally signed a contract with the Thai Government setting the conditions of sale for the natural gas discovered in Union's offshore contract area in the Gulf of Thailand. After months of tedious negotiations, agreement was reached on a price of $1.04 per thousand cubic feet. The contract stipulated a maximum wellhead delivery rate of 250 million cubic feet per day. Signing of the contract allowed Union to begin design and construction of production platforms and drilling of production wells. Responsibility for laying an undersea pipeline and construction of the gas processing plant and distribution system rested with the Thai Government. Fluor Corp. was hired as the major pipeline contractor. The 86-centimeter-diameter (34-inch) pipeline was planned to run about 425 kilometers from the field northward to landfall at Sattahip, southeast of Bangkok. After processing onshore, plans were for the gas to be moved 160 kilometers to the Bangkok area via a 71-centimeter-diameter (28-inch) pipeline. The estimated cost of the project was between $400 million and $700 million.

The Union Oil-Mitsui Oil Exploration Co. partnership (40% Mitsui) continued exploration drilling during 1979 and announced a gas discovery in exploration block 10 about 300 kilometers north-northeast of Songkhla. A confirmation well was being drilled 3 kilometers northeast. In June 1979, Union Oil was awarded the concessional rights for drilling in exploration block 23, northwest of its discoveries in blocks 12 and 13.

Pricing negotiations began late in 1978 between the Government and the Texas Pacific Thailand Inc. consortium (TexPac), but ended in deadlock in December 1978. TexPac was ready to begin development of its large gas discovery upon resolution of the price controversy. Its field is located about 135 kilometers southeast of the Union field and about 200 kilometers east-northeast of Songkhla. Negotiations were scheduled to resume near the end of 1979 on the pricing controversy. Virtually all other conditions on the gas sale have been mutually agreed upon.[18] Plans were to connect the TexPac field by pipeline to the pipeline that was planned for servicing the Union field. It was anticipated that gas from both fields would then be transported via the pipeline to Sattahip. Although the gas composition differed in the two fields, it was believed that no serious problems would result from mixing the gas. Development of this field was estimated at about $450 million, not including the $47 million already spent by TexPac for exploration. TexPac hit commercial gas flows in two more wells in the same area at yearend 1978.

Proved and probable gas reserves in the Gulf of Thailand were estimated at 6.6 trillion cubic feet by the Government, and TexPac owned rights to about two-thirds of the total. Deep exploration drilling in the Andaman Sea off western Thailand has been discontinued, with no commercial finds reported.

It was announced that subsidiaries of Royal Dutch/Shell Group and Exxon Corp. signed 8-year onshore oil exploration agreements with the Government early in 1979. Shell Exploration B. V. received drilling rights to a 72,000-square-kilometer area of the Chao Phraya River Basin, roughly between Sukhothai (17°01'N, 99°49'E) and Ang Thong (14°35'N, 100°27'E). Esso Exploration Inc. planned to explore a 52,000-square-kilometer concession around Nokhon Ratchasima, (14°58'N, 102°07'E), and this exploration was expected to be the first comprehensive oil exploration in either of these areas.

The Government announced the establishment of the National Petroleum Authority of Thailand (NPAT). NPAT was set up as a state enterprise and was intended to include all functions concerned with the petroleum and natural gas sector. Its responsibilities included the surveying, production, transportation, and distribution of petroleum and related products.

At yearend 1979, the Thai Cabinet approved the expansion of the Thai Oil Refinery Co. (TORC) from 65,000 barrels per day to 120,000 barrels per day. The cost of the expansion was estimated at $300 million. The Government, through the NPAT, planned to acquire a 49% share of TORC; the private TORC group was slated to own 49%, and the Bureau of Crown property was to hold the remaining 2%. The other two major refineries were also considering expanding throughput capacities.

Domestic oil production was economically insignificant at less than 300 barrels per day. The country's three large refineries operated entirely on imported crude oil, mostly from the Persian Gulf countries. When the gas pipelines become operational, in late 1981 or 1982, it was expected that there will be an increase in domestic petroleum production of several thousand barrels per day, in the form of light-end gas condensates. The main anticipated benefit, however, was that energy from domestic natural gas production was expected to replace about 30% of the current crude oil imports.

The Mineral Industry of Tunisia

By E. Shekarchi[1]

Phosphate rock and crude oil exports, valued at \$232 and \$430 million respectively, accounted for more than 50% of total exports of Tunisia during the year 1978 and increased somewhat in 1979. Production and export of other mineral commodities such as fluorite, barite, iron ore, lead-zinc, and silver remained at the level of 1977. Phosphate rock production increased 2.7% compared with 1977 output, whereas the production of super and triple superphosphate increased about 6% during the same period. Cement production reached a new high of 882,000 tons in 1978, and with the construction of the fifth cement plant in 1979, Tunisia was planning to satisfy most of the domestic consumption demand by the mid-eighties.

The Tunisian economy rebounded vigorously with overall growth of 8.4% in 1978 and 6.2% in 1979. Despite these performances, major goals set for 1978 by the Fifth Plan (1977-81) were not attained, leading to a review of priorities. Nevertheless, the forward momentum of the Tunisian economy in both years produced a creditable increase in per-capita gross national product (GNP), for example; \$987 in 1978 compared with \$825 in 1977.

Several major projects were implemented or under study in 1978 and 1979 and merit a brief description because of their impact on development and the economy in general. Implementation of the Miskar offshore gas project, which was estimated to cost about \$500 million, was postponed until 1980 because of the need for further cost analysis of gas distribution and shipments of the gas by pipe to overseas markets. Another major energy project was to raise the capacity of Tunisia's only petroleum refinery, at Bizerte, from under 1.5 million tons to 4 million tons annually. Rapid production increases in phosphate were programed, with a goal of 7 million tons of phosphate rock annually by the early eighties. Preliminary studies of this project, expected to cost \$60 million, were to begin in early 1980. Another project to upgrade phosphate processing and to increase production of phosphoric acid and fertilizers at Gabes was underway during 1979. Railroad improvements and a new line from Gafsa to Gabes were planned to handle the expanded traffic of the phosphate industry.

PRODUCTION AND TRADE

The trade balance continued in deficit; imports of foodstuffs, agricultural and industrial equipment, and finished goods were all up in 1978. Total imports, rising 17%, reached \$2.2 billion. Exports, composed of crude oil, 39%, consumer goods, 24%, foodstuffs, 16%, and miscellaneous, 21% reached \$1.2 billion. The annual deficit was covered by long- and medium-term credits, foreign investment, and a grant aid of \$17 million. Production and trade information is presented in tables 1, 2, and 3.

COMMODITY REVIEW

METALS

Iron and Steel.—Production of iron ore from Djebel, Djerissa, Douaria, and Tamera decreased in 1978 and 1979, owing to exhaustion of the ore bodies. Djerissa mine was the only iron ore deposit for which reserves, about 4 million tons were given. Iron ore production was geared primarily to internal demand; no export programs were planned and investment in iron ore mining was cut from $0.7 million in 1977 to $0.3 million in 1978, with $0.25 million for 1979.

Expansion of Tunisia's only steel mill, El Fouladh, was the only major project foreseen under the current fifth development plan to meet the fast-growing demand, particularly for reinforcing beams, in a booming construction industry. W.S. Atkins and partners, a British firm, conducted a feasibility study and a market projection in Tunisia to determine whether the present plant at Menzel Bourguiba should be expanded or a new plant should be built elsewhere. It was recommended that the present facilities be expanded by 250,000 tons in the first stage and by an additional 180,000 tons in a second stage. Atkins' study indicated that domestic demand for reinforcing bars and medium and light sections will exceed 450,000 tons by 1995. In

1979, El Fouladh officials examined some small size steel manufacturing facilities in Europe, but no concrete decision was made.

Lead and Zinc.—In 1978 and 1979 lead and zinc ore was beneficiated at the mine site. Lead concentrates declined both years owing to exhaustion of the mine. Some of these concentrates were shipped overseas, while the rest were smelted at Megrime. Most of the zinc concentrates were exported. The Société Tunisianne d'Expansion Minére (SOTEMI), the Government-owned mining company, was the only lead-zinc producer in 1978 and 1979. Lead concentrates declined in both years owing to exhaustion of the mine and limited capacity of the beneficiation plant. The efforts of the Geological Survey and the Mines Bureau to locate new deposits have been negative, even though private company geologists have shown interest in developing new findings of lead-zinc mineralization.

Other minerals.—Limited amounts of silver and mercury were produced as byproducts from lead and zinc ores. Some arsenic was produced from the Tabett ben Ksouri deposits, for domestic consumption and limited exports.

NONMETALS

Cement.—Efficiency in cement production to meet domestic demand remained a national priority. In 1978 Tunisia produced about 882,000 tons of cement, which was increased to 1.4 million tons in 1979. The output goal of 1.5 million tons by 1981 remained unchanged. After 1981, Tunisia planned to become an exporter of cement to neighboring countries and perhaps to the Persian Gulf Emirates. To this end the Government allocated $700 million to build new facilities for production of cement. Work on the western cement plant near the Algerian border was completed during 1979, and trial runs were slated for the early 1980's. Construction work on the asbestos cement products plant was completed within the year 1979. This facility with an annual production capacity of 26,000 meters of pipe, primarily for irrigation and sanitation purposes, was to go into full production in 1980. The plant was financed by a group of private, mostly domestic, investors called Ciment-Aminate. A company was formed by the Government called Société Les Ciments Tunisians to administer a cement plant, which was to be built near Jebel Oust with an annual capacity of 1 million tons of cement and 200,000 tons of lime. An international call for bids on the construction of the plant was to be issued by 1980. According to the feasibility study performed by La Forge Conseils et Etudes of Paris, the plant will commence production in 1984 and would cost close to $200 million.

Fertilizer Materials.—Phosphate rock production by the state-controlled Cie. des Phosphates de Gafsa (CPG) rose to 3.7 million tons of concentrate in 1978 and slightly more than that for 1979. The phosphate deposits extend from the Algerian frontier 160 kilometers east into Tunisia. The most important producing mines in this belt were concentrated in the Gafsa basin. Seven underground mines and one open cast mine were operated during 1978 and 1979. Total capacity for rock production in Tunisia by the end of 1979 was 5.6 million tons of ore and 4.6 million tons of concentrates per year. The extended plan of the CPG called for ore handling facilities to be expanded to 10 million tons and concentrator capacity to be increased to 7 million tons annually by 1981. To achieve this expansion in capacity and supply the feedstock, CPG was to increase mining capacity in Sehib and Kef es Schfair. By early 1980, the company expected Kef es Schfair to produce 2.5 million tons of phosphate ore per year, which would make it the largest mine in the basin. Mined material will be processed in the treatment center at Metlaoui, where a new washing plant was under construction in 1979. The Sehib mine was to be the second largest mine in the basin, with an expanded 2-million-ton annual capacity, by the end of 1982. Until 1978 the mined ore from Sehib mine was treated in M'dilla washing plant; however, after 1979 a new treatment plant in the vicinity of Sehib mine was to handle all the ore mined there. The production capacity of the M'dilla mine itself was to be increased to 1.6 million tons by 1981. All other producing mine capacities in 1977 were to be increased in order to reach the goal of 10 million tons of ore set for 1981.

For years about 74% of Tunisian phosphate production consisted of 66% to 68% BPL, and a metallurgical-grade ore came from Kaiaa Khasha. However, owing to generally declining ore grades in the Gafsa Basin, CPG planned an investment in new benefication facilities to upgrade the old treatment plant and increase capacity to handle lower grade ores. The need for ore beneficiated by washing rather than by air-separation units was increasing; therefore, the company installed four new washing plants—at Sehib, M'dilla, Moulares, and Metlaoui—which were to be operating by the end of 1980.

Western Europe and Latin America remained the most important export markets, importing Tunisian phosphate rock at a steady level. In contrast to the situation on export markets, domestic deliveries continued to increase and in 1978 reached 1.8 million tons. Tunisia was one of the first of the North African phosphate rock producers to invest in chemical treatment facilities to process its own output. Domestic deliveries to the chemical plants within the country exceeded export sales, accounting for well over half of Tunisia's total sales. By the end of 1979, a new phosphoric acid and diammonium phosphate complex became operational and further increased domestic consumption of rock phosphate over exports. Since this last chemical plant was funded mostly by the Kuwait Fund for Arab Development, it was to be known as Arabe des Engmis Phosphates et Azotes. Also, Industries Chimiques Maghrebines (ICM) was planning to add a third phosphoric acid unit to the existing complex at Gabes in 1980, which would again boost domestic sales of phosphate rock.

Other Nonmetals.—Starting in 1977, most of the fluorspar production of Tunisia was consumed domestically as feedstock for the Industries Chemiques de Fluor's aluminum fluoride plant. During 1978 and 1979 the plant used close to 30,000 tons of fluorite mined at Zriba mine, located 45 kilometers southeast of Tunis. Barite associated with fluorspar also was mined at Zriba; however, owing to the lack of an international or domestic market, it was accumulated in the waste ponds and saved for possible future use at home or abroad. Marine salt production from Sfax, Sousse, and Magrine declined during both 1978 and 1979, because of curtailed demand by the local industry.

MINERAL FUELS

The Government-owned Public Utility Office launched an onshore gas distribution system designed to take natural gas from the Miskar gas field and/or the Algerian-Italian pipeline and distribute it to major industrial consumers along the Bizerte to Gabes coastline, approximately 550 kilometers. Total cost of the project was given at $190 million, and completion was to be by the end of 1981. Engineering studies were carried on during 1978, and a call for bids to supply pipe and related pumps was issued during 1979.

Enterprise Tunisienne des Activities Petroliers (ETAP), the Tunisian state oil company, planned to issue a tender in 1980 for supply and installation of a petroleum products pipeline between Bizerte and La Goulette, about 70 kilometers. The pipeline would convey petroleum products from the refinery in Bizerte to Tunis and its international airport. Also, ETAP, in partnership with Société Tunisienne des Industries de Raffinage (STIR), intended to construct a lubricant reprocessing plant at Bizerte. Plant construction, estimated at $13 million, was to begin in early 1980, with a slated production date of late 1981 or early 1982. Total annual capacity was to be 10,000 tons, and most of the products were to be consumed locally.

A major project of the fifth plan was expansion of Tunisia's only petroleum refinery, at Bizerte. Plans called for an increase of capacity from 1.2 million tons per year to 4 million tons annually. During 1978 execution of this plan was delayed, but detailed engineering work was finished in 1979 and it was indicated that initial expansion work would be started in early 1980. Fuel for the Bizerte refinery was imported primarily from Iraq and Saudi Arabia, while Tunisian crude petroleum was exported, as it was found pricewise economically advantageous. During 1978 and 1979, Bizerte refinery produced at full capacity.

The Mineral Industry of Turkey

By Candice Stevens[1] and W. Thomas Cocke[2]

Despite substantial mineral resources, the mineral industry was a minor contributor to Turkey's gross national product (GNP) of $51 billion[3] in 1978 and an estimated $55 billion in 1979. Mineral development lagged owing to insufficient exploration, a shortage of capital, and managerial problems. The Government instituted measures to stabilize the economy and provide the basis for economic growth with the mineral sector playing a key role. Increased foreign aid, a new 5-year plan (1979-83), and revised mining and investment codes were to provide the impetus for the Government's industrialization program.

Increased expenditures for oil imports caused successive balance of payments deficits and raised Turkey's foreign debt to over $13 billion in 1978 and higher in 1979. An economic crisis was precipitated by 60% inflation, 25% unemployment, and large production declines owing to the foreign exchange shortage. In 1978, the International Monetary Fund (IMF) approved a $450 million standby loan dependent on the implementation of certain austerity measures which included monetary devaluation, moderation of annual growth rate of GNP to 5%, reduction of deficit spending, reduction of inflation rate, and reduction of foreign trade deficits. A consortium of 18 nations and international organizations was to provide an additional $900 million in emergency relief to help solve the balance of payments problems. The Government in turn introduced provisions for the devaluation of the lira, a reduction in Government spending, increases in prices and interest rates, limitations on credit, and the expansion of investment and export incentives. In August 1979, $2.2 billion of foreign debt was restructured as a prerequisite for a number of financial packages designed to relieve Turkey's hard-pressed economy. In 1979, the IMF cleared the way for massive financial assistance, totaling more than $1.5 billion from official and private sources.

The Fourth 5-Year Development Plan (1979-83) proposed a total investment of $60 billion, of which $4 billion was allocated to the mining sector and $18 billion to the industrial sector. Its goals were an annual growth rate of 8%, an annual increase in export value of 18%, and an increase in industry's share of the GNP from 29% to 32%. In the minerals sector, the emphasis was on increased exports of processed minerals and a decrease in the export of ores and concentrates. The planned annual growth rates for mineral products were 16.5% for iron and steel, 15.3% for fertilizer and petrochemicals, 12.4% for petroleum products, and 11.9% for cement. Increases in processing capacity were also designated for chromite, copper, lead-zinc, and boron. Special attention was to be given to the expansion of lignite production to provide fuel for processing industries and reduce dependence on foreign energy supplies.

In October 1978, the Government passed a new mining law (No. 2172) which authorized the expropriation of private mines deemed essential to the state. Compensation for each mine was to be assessed by an Appraisal Commission which would take into account the value of mineral stocks, installations, machinery and equipment, and land rental. Expropriated properties were to be placed under the direction of the State Economic Enterprises (SEE), industrial and commercial enterprises that produced approximately 15% of Turkey's GNP and employed 40% of the nonagricultural workers of the country. In November 1978, the Government nationalized private mines for lignite, iron ore, and boron which were being operated under 650 exploration and/or exploitation permits.

The Government was further revising the Foreign Investment Encouragement Law (No. 6224) in order to eliminate bureaucratic barriers to foreign investors. The law would allow foreign companies to hold a majority equity in Turkish ventures, and, in certain cases, would allow foreign companies to hold 100% equity in export-oriented operations. Guarantees for profit and capital repatriation and for the employment of foreign personnel were also included in the law.

Maden Tetkik ve Arama Enstitusu (MTA), the Mineral Research and Exploration Institute, was responsible for exploration and evaluation of the country's mineral resources. Surveys were being conducted of the eastern Provinces which contained substantial reserves of lignite at Elbistan, petroleum at Batman, and iron ore at Divrigi. The SEE agency responsible for the operation of most mines and wells in the public sector was Etibank Genel. Mudurlugu, which had under its jurisdiction more than 38 commodities including copper, chromite, bauxite, and aluminum. It was estimated that in 1978 the Government owned 80% of the country's metallic ore reserves and 40% of the nonmetallic ore reserves.

PRODUCTION AND TRADE

As shown in table 1, Turkey produced a variety of metals, nonmetals, and mineral fuels. Production was generally at low levels, about 60% capacity, owing to a lack of foreign exchange, inadequacy of demand, shortage of raw materials, and power cuts due to electricity shortages. Ferrous metal production, including iron and steel and chromite, was valued at $1.6 billion in 1978. Nonferrous metal production, including bauxite, copper, and lead-zinc, was valued at $660 million. The production of nonmetallic minerals, of which boron was the most significant, was valued at $80 million. Coal, petroleum, and other fuel production was valued at $600 million.

Turkey experienced balance-of-trade deficits of $2.3 billion in 1978 and in 1979 owing primarily to fuel imports, although the deficits were down nearly 50% from 1977. The Government instituted measures to promote industrial exports including tax incentives, streamlined export licensing procedures, and foreign exchange remittances to exporting companies. Mineral exports were 6% of total exports in 1978. Boron ($60 million), chromite ($35 million), and iron and steel ($20 million) were the principal mineral exports. Mineral exports were valued at about $135 million.

Turkey imported mostly raw materials and capital goods as inputs to domestic industry. Phosphate rock and iron and steel were the leading nonfuel mineral imports. Turkey imported approximately 80% of its crude and refined petroleum requirements.

COMMODITY REVIEW

METALS

Aluminum.—Etibank was the sole producer of bauxite in Turkey with an annual production capacity of 700,000 tons. Bauxite deposits were located principally in the Seydiseher District of Antalya Province, but bauxite was also mined in Western Anatolia on the Aegean coast near Mugla. The country's total bauxite reserves were estimated at 264 million tons assaying 42% Al_2O_3.

The Seydisehir Aluminum Complex operated at half capacity during 1978 owing to shortages of electricity and also of imported caustic soda. Designed and constructed by the Soviet Union, the plant had a production capacity of 460,000 tons per year of raw bauxite to produce a maximum of 200,000 tons per year of alumina and 60,000 tons per year of aluminum products. Negotiations were proceeding with the Soviet Union for doubling the plant's capacity by 1982.

The Milas Bauxite Works near Mugla had a production capacity of 150,000 tons per year of diaspore-type bauxite. The hardness of the ore made crushing difficult and limited sales.

Bazik Refractories Ltd. had a 3,000-ton-per-year-capacity refractory bauxite deposit to the northeast of Istanbul and a small high-alumina refractory brick plant nearby.

Antimony.—Ozdemir Antimuan Madenleri A.S. remained Turkey's largest producer of antimony from its Turhal mine in Tokat Province. Annual capacity was 40,000 tons of ore. The Turhal Works included a facility to produce 63% antimony concentrates. Reserves at Tokat were estimated at 400,000 tons of 14% antimony ore.

Etibank contracted Tectomin (Italy) to construct a 2,600-ton-per-year-capacity antimony plant at Balikesir. Reserves in the area were established at 305,000 tons of ore averaging 5% to 6% antimony. Etibank also converted the Halikoy mercury smelter into a 500-ton-per-year antimony smelter in response to decrease in world demand for mercury.

MTA continued its evaluation of antimony deposits in the Balikesir and Aydin regions. Turkey's total reserves were estimated at 2.4 million tons.

Chromite.—Turkey was ranked as the world's fourth largest producer of chromite. Chromite deposits occurred in 40 of the country's 67 Provinces, but generally in two east-west belts. Reserves in the major producing areas of Guleman, Mugla, and Eskisehir totaled 5 million tons of high-grade metallurgical ore averaging 48% Cr_2O_3. Etibank's Eastern Chromite Works in the Guleman area had an annual capacity of 250,000 to 300,000 tons of ore, which was processed to 48% Cr_2O_3 concentrates. The Uckopru Chromite Works near Mugla had a capacity of 80,000 tons per year of lumpy ore and 20,000 tons per year of concentrates. Problems at the Kefdag concentrator were solved, and production continued satisfactorily.

About two-thirds of Etibank's production was delivered to the state's two ferrochrome plants. The Elazig Ferrochromium Works, located near Mardin, reached full production of 50,000 tons per year of high-carbon ferrochrome in 1978. Capacity was to be doubled by the addition of two electric furnaces. The Antalya Ferrochromium Works produced 10,000 tons per year of low-carbon ferrochrome, 90% of which was exported. Production at the Antalya plant changed from ferrochrome in 1978 to ferrosilicon.

The largest private chromite producer was Egemetal Madencilik AS, which had 150,000 tons per year capacity. The company, which is associated with Metallgesellschaft (Federal Republic of Germany), is not only a chromite producer, but also acts as a clearinghouse for the small Turkish chromite producers. Turk Maadin Sirketi, a subsidiary of Metallurg Inc. (U.S.), had a production capacity of 150,000 tons per year of concentrates from its mines at Kavak near Eskisehir and Goeck in Mugla Province. Other private producers were Sitki Koeman, Fethiye Maden, and Bilgin Maden Ltd., each with 60,000 tons per year capacity.

Copper.—Turkey's two copper producers were Etibank and Karadeniz Bakir Isletmeleri (KBI), owned 49% by Etibank. Production was centered in three major districts: Murgul, Ergani, and Kure. Reserves were estimated at 250 million tons of ore grading 1% to 4% copper.

The Murgul District was estimated to contain reserves of 150 million tons of copper-pyrite ore. Etibank's Murgul Copper Works had a mine production capacity of 1 million tons of ore per year. The mill and smelter production capacity is 40,000 tons per year of 18% copper concentrates and 10,000 tons per year of blister copper. The project to increase blister copper production by 10,500 tons was almost complete. KBI's two open pit mines in the Murgul District, Cakmakkaya and Damar, had a combined production capacity of 3.7 million tons of ore per year. KBI planned to increase production at its Cakmakkaya concentrator to 180,000 tons per year of 17% copper concentrates from the present capacity of 20,000 tons per year.

The Ergani District was estimated to contain reserves of 20 million tons of copper-pyrite ore. Etibank's mine-mill-smelter complex at Ergani had an annual production capacity of 1 million tons of ore, 70,000 tons of 14% copper concentrates, and 25,000 tons of blister copper. Pyrite concentrates were produced as a byproduct.

The Kure District near the Black Sea coast had reserves of 20 million tons of copper-pyrite ore. Both Etibank and KBI operated mines in the area. Etibank's Kure Cuprous Pyrite Works mined the Asikoy open pit mine at the rate of 1 million tons of ore per year. KBI mined the Bakibaba underground mine at a parallel rate at its Black Sea Copper Works. KBI's new smelter at Samsun had an annual capacity of 40,000 tons of blister copper and 365,000 tons of sulfuric acid. It never attained designed output, and to carry the continuing burden of its financial losses, it was nationalized. Etibank and KBI planned a joint venture to construct a concentrator and smelter complex in Kure with an annual capacity of 120,000 tons of blister copper by 1981.

Etibank's objective in the copper industry was to reach blister copper production capacity of 60,000 tons per year by 1982 and 125,000 tons per year by 1985. Investment planned in existing and new projects was aimed at these targets. The Integrated Copper Project at Kure was expected to add 35,000 tons per year. Development of the Rize-Cayeli deposit, where reserves of 30 million tons were delineated, began in 1979. Production of 65,000 tons per year of blister copper was to begin in 1985.

Iron Ore.—The state-owned Turkish Iron and Steel Works produced approximately half of total iron ore production, and the Government share of iron ore output was expected to increase as steps were taken to nationalize several of the smaller iron producers. The demand for iron ore was expected to increase to 18 million tons per year by 1982. The country's reserves were estimated at 870 million tons with an overall average iron content of 52%.

The largest supplier of directly chargeable iron ore for the steel industry was the Divrigi mine, located in Sivas-Malatya Province. Reserves at Divrigi were estimated at 300 million tons averaging 52% to 58% iron. Turkish Iron and Steel Works planned to expand production capacity from 2.5 million tons per year in 1978 to 5.2 million tons per year in 1980. The Divrigi Concentration and Pelletizing Plant had an annual capacity of 1.4 million tons of 67% iron pellets and 2 million tons of sintering concentrates containing 64% iron.

The Government planned to conduct feasibility studies for exploiting the Hasancelebi iron deposit, located southwest of Divrigi. Reserves were estimated at 300 million tons of low-grade magnetite ore ranging from 28% to 48% iron. It was expected that the Hasancelebi deposits would begin producing in 1984 at the rate of 1.5 million tons per year, increasing to 3 million tons by 1985.

Iron and Steel.—The Government nationalized the import of iron and steel products, which averaged 2 million tons per year. Plans were made for the expansion of production capacity and the construction of new steel mills. Iron and steel production was far below that programmed for 1979, and the Government offered premiums of 1% for meeting individual production goals. Lack of sufficient production of electricity was a major factor.

Turkish Iron and Steel Works produced about 60% of the total steel production at its two plants at Karabuk and Iskenderun. The Karabuk plant, located 175 kilometers north of Ankara on the Black Sea coast, had a production capacity of 600,000 tons per year. The Iskenderun plant, located in southern Turkey near the Syrian border, had an annual production capacity of 1 million tons. The Iskenderun facility was built with technical assistance from the Soviet Union and began production in 1976. Tremendous problems existed at the facility which required Turkish Army troops to maintain peaceful operation. The workforce ballooned to twice that designed, but production stood at less than 25% of capacity by 1980. Shortages of coking coal also complicated progress toward reaching designed production capacity, which was to be doubled by 1982.

Eregli Demir ve Celik Fabrikalari A.S. (ERDEMIR) operated the private steel mill at Eregli on the Black Sea coast. The Eregli facility used iron ore from Divrigi and coal from the Zonguldak coal district. In 1978, a loan was received from the International Bank for Reconstruction and Development to expand capacity from 800,000 tons per year to 1.6 million tons per year.

Izmir Metalurji Fabrikasi T.A.S. (METAS) was conducting feasibility studies for the construction of a direct reduction steel complex at Izmir. METAS produced reinforcing rods and bars from scrap metal. The proposed facility would use coal fuel to produce an initial 400,000 tons per year of steel.

Lead-Zinc.—Etibank accounted for about 40% of lead-zinc production. Four private producers accounted for the remainder of output. Turkey's total reserves were estimated at 5 million tons of lead-zinc ore.

Etibank's Keban Lead and Zinc Works milled a capacity of 40,000 tons per year of ore averaging 6.4% zinc and 4.5% lead. Lead and zinc concentates were produced in a small flotation plant at Keban, located west of Elazig.

Cinko-Kursun Metal Sanayii AS (CINKUR), owned 47% by Etibank, mined lead-zinc ore in Zamanti. Reserves in the area were estimated at 3.5 million tons of high-grade ore. CINKUR's smelter at Kayseri, which came onstream in 1977, operated at 25% capacity in 1978. The plant was designed to process 238,000 tons per year of mixed ore and to produce 40,000 tons of zinc, 6,000 tons of lead, and 120,000 ounces of silver.

The three other producers were Rasih ve Ihsan at Akdagmadeni, Selim Budin Ltd. at Kalekoy, and Karamanci Sirketin in the Zamanti Valley.

Manganese.—Manganese ore in Turkey was mined principally for metallurgical applications, with only minor amounts of nonmetallurgical grade. Unimin Madencilik Sanayi ve Ticaret A.S. had a production capacity of 3,000 tons per year of battery-grade ore. Production was kept low as the pyrolusite ore had to be hand-sorted.

Installation of a magnetic separation unit to boost capacity to 7,500 tons per year was being considered.

Tungsten.—The major tungsten mineralization, occurring in skarns near the contact zones of acid intrusives, was found at Uludag near Bursa, but many similar contacts occur elsewhere and were being explored. Ore reserves at Uludag were reportedly over 16 million tons grading 0.5% WO_3.

Etibank and Metallgesellschaft (Federal Republic of Germany) constructed a concentrator at Uludag for extraction of tungsten by the dry cycle system. Production, long delayed due to technical difficulties and fire, began in the last quarter of 1978. Around 400 to 500 tons per day of ore were processed yielding 45% to 50% purity in concentrated ore. Mine production was advancing toward 1,000 tons per day in 1979 with the implementation of a ring-blasting technique replacing the costly longwall method previously used. Full production was to begin in 1980 at the design rate of 1,750 tons per day. All production was to be exported, and small shipments of tungsten were made to Japan and West Germany.

NONMETALS

Asbestos.—Asbestos production in Turkey was confined mainly to the amphibole varieties; however, Amyant Sanayi A.S., a subsidiary of Unimin, had a deposit of tremolite. Production capacity was 30,000 to 40,000 tons per year, but owing to low demand for tremolite asbestos, production from the mine and plant near Eskisehir was confined to about 3,000 tons per year.

Other producers of asbestos included Bilfer Maden Ltd. Sirketi (5,000 tons per year), Ozgur Atermit Sanayi ve Ticaret A.S. (150 tons per year), and Sark Amyant Isletmesi (1,300 tons per year).

Barite.—The production of barite increased owing to the opening of new processing facilities. Deposits of barite are known in nine scattered localities in Turkey and contain reserves estimated at 33 million tons. The important producing regions were Mus, Alanya, and Konya.

Bastas Barytes Industry and Trading Co. Inc. has deposits with production capacity of 150,000 tons per year at Alanya and Sarikaraagac. A grinding plant with 120,000 tons per year capacity was opened in Antalya in February.

Until 1978, Barit Maden Turk A.S. was the largest single producer of barite in Turkey. Approximately 50,000 tons per year were mined from the deposits near Maras. Barit Maden expanded capacity at its processing plant in Adana to 70,000 tons per year in 1978.

Etibank produced small quantities of barite. Etibank was constructing a grinding plant at Beysehir to comply with the current export regulations which permitted only ground barite to be exported.

Polbar Baryte Industries A.S. had a production capacity of 40,000 tons per year from its mines near Alanya. Construction of a 50,000-ton-per-year grinding plant was underway. Production capacity at the mines was to be increased in line with the grinding capacity.

Baser Maden Sanyii ve Ticaret A.S. operated a 60,000-ton-per-year barite mine at Sarkikaraagac. An extension to the grinding plant was underway to increase capacity to 80,000 tons per year.

Kimya Tesisleri Sanayi ve Ticaret A.S. (Kimtes) shut down its grinding plants at Yarimca and Kocaeli in 1978 to expand and totally reorganize operations. In July 1979, the company resumed production with a total capacity of 100,000 tons per year. Kimtes operated mines at Silifke (20,000 tons per year) and Kutahya (10,000 tons per year).

A new intergrated mine and grinding plant was being brought onstream by Emas Industrial Minerals A.S. at Mus. Only limited production was possible at the 60,000-ton-per-year-capacity plant in 1979 owing to a delay in electrical power connection. Full production was to begin in 1980.

Other barite producers were Dolsan Dolga Maddeleri Sanayii Kollektif Sirketi (35,000 to 40,000 tons per year), Durmus Yasar ve Ogullar (12,000 tons per year), Egemetal Madencilik (10,000 tons per year), and Kale Madenicilik (1,000 tons per year).

Boron.—After the United States, Turkey was the world's most important source of boron as it accounted for almost one-third of total world production. Etibank accounted for about 60% of the country's boron production in 1978. Under the Government's nationalization decrees, Etibank took over all mines except the Emet mine in 1979. Turkey, with 500 million tons of boron minerals assaying 25% B_2O_3, possessed more than half of the world's known reserves. Almost all production was exported, in either crude or processed form, from the port of Bandirma on the Sea of Marmara.

Boron was mined in three major districts in northwest Turkey: Kirka, Bigadic, and Emet. Etibank mined 750,000 tons per year of tincal at Kirka in Eskisehir Province. About 100,000 tons per year of colemanite and ulexite was mined at Bigadic in Bilakesir Province. Total capacity at Emet in Kutahya Province was 60,000 tons per year of colemanite.

The Emet Colemanite Works upgraded colemanite from Hisarcik and Espiye to produce 500,000 tons per year of concentrates averaging 40% to 47% B_2O_3. The Etibank facility at Kirka upgraded tincal to produce 400,000 tons per year of 35% B_2O_3 concentrates. A refinery was under construction at Eskisehir to process tincal concentrate into sodium borate compounds. Design capacity of the $63 million plant was to be 180,000 tons per year of borax pentahydrate, 17,000 tons per year of refined anhydrous borax, and 6,000 tons per year of refined decahydrate borax. A 150,000-ton-per-year colemanite plant was also under construction in the Balekesir region. Expansion of the Bandirma Borax and Acid Works on the Sea of Marmara was planned to increase capacity of boric acid from 35,000 to 135,000 tons per year, sodium borate from 20,000 to 40,000 tons per year, and refined decahydrate borax from 55,000 to 70,000 tons per year.

There were five other producers of colemanite. The Mortas-Bortas Group had mines at Bigadic, Emet, and Mustafa Kamal Pasa. Rosih ve Ihsan A.S., a subsidiary of Pechiney Ugine Kuhlmann (France), and Suyakei Pazarlama Ticaret A.S. had mines near Bigadic. The other two producers were Yakal Borasit Ltd. and Kemal A.S. Total capacity of these producers was 40,000 to 50,000 tons per year.

Cement.—Total capacity was 17 million tons per year concentrated in 34 factories in 25 different Provinces. The state-owned Turkiye Cimento Sanayii A.S. operated 15 cement plants with a total annual capacity of 1.5 million tons per year in 1978. Orders were placed for the erection of seven new plants averaging 1,750 tons per day. Two finish cement mills were to be supplied for each plant. The largest private producer was the Sabanci Group, which accounted for 25% of total annual production. Polysius reported the startup of a 3,000-ton-per-day plant at Taslium in 1978. Canakkale Cimento Sanayii T.A.S. of Istanbul increased production capacity to 5,000 tons per day in 1979. Expansions to facilities in both the public and private sectors were to increase cement production capacity to 20 million tons per year by 1980.

Emery.—About 80% of the world's production of emery of fine grain quality was produced in Turkey. Most material was produced and exported in the raw form to France, the United Kingdom, the Netherlands, and the Federal Republic of Germany for use mainly in abrasives. Etibank had a production capacity of 30,000 tons per year from the area of Milas in Western Anatolia. There was only one major producer of emery, apart from Etibank, Lutfullah E. Kitapei Mineral Co. Ltd., which had a production capacity of 70,000 tons per year from several small mines in the vicinity of Mugla.

Fertilizer Materials.—Turkey had an annual production capacity of 3.9 million tons of phosphate fertilizer and 3.6 million tons of nitrogen fertilizers in 1978 with planned expansions to reach 10 million tons total capacity to satisfy domestic requirements. Only about one-third capacity was reached, however, and Turkey remained dependent on fertilizer imports. The primary reason the fertilizer plants did not operate at full capacity was the lack of effective cooperation in the procurement of phosphate rock, ammonia, sulfuric acid, pyrite, and phosphoric acid required to produce fertilizer.

The state-owned Azot Sanayii T.A.S. planned the construction of a fertilizer complex at Mersin, located in southern Turkey. Annual production was to consist of 630,000 tons of sulfuric acid, 215,000 tons of phosphoric acid, 544,000 tons of ammonia, 330,000 tons of urea, and 420,000 tons of diammonium phosphate.

A fertilizer and industrial chemicals complex was completed in 1978 at Karatas near Adana.

Negotiations between Istanbul Gubre Sanayii and Toyo Engineering (Japan) took place in 1978 for the construction of a nitrogen fertilizer complex at Kirikkale in central Anatolia. The International Bank of Reconstruction and Development was to provide most of the financing for the $130 million project. Construction of the plant, to produce 1,000 tons per day of ammonia and 1,750 tons per day of urea, began in 1979.

Etibank had a sulfuric acid plant at Bandirma with annual capacity of 120,000 tons (H_2SO_4 content) and was increasing sulfuric acid capacity at its copper plant at Ergani in 1979. The Black Sea Copper Works was also a large byproduct producer of sulfuric acid, with an annual capacity of 365,000 tons from pyrite concentrates.

Phosphates.—Etibank continued development of the Mazidag phosphate deposits located in southeast Turkey near Mardin. Turkey planned to increase capacity at Mazidag from 250,000 tons per year to 1 million tons per year by 1982. Processing and storage facilities were under construction at Karatas. Reserves at Mazidag were estimated at 410 million tons of phosphate ore assaying 10% to 21% P_2O_5.

Magnesite.—Magnesite was produced at three major mining districts: Eskisehir, Kutahya, and Konya. The state accounted for about 25% of production and was considering the nationalization of private magnesite operations. Total reserves were estimated at 65 million tons with an average content of 46% Mg0.

There were four important producers of magnesite in Turkey: Kutahya Manyezit Isletmeleri A.S. (Kumas), Manyezit A.S., Sumerbank, and Continental Madencilik Sanayi ve Ticaret A.S. (Comag). Kumas is the largest dead-burned magnesite producer. Its mines at three deposits had an annual capacity of 250,000 tons. The Kutahya Magnesite Works, a joint venture of Etibank and Kumas, had an annual capacity of 70,000 tons per year of sintered magnesite and was to produce 55,000 tons per year of refractory bricks by 1981. The other state-operated facility, Konya Magnesite Works, was to increase production from 50,000 tons per year to 100,000 tons per year of refractory bricks. Sumerbank was the only major producer outside the Kutahya-Eskisehir region. The rest of the dead-burned production comes from Manyezit A.S. with an annual capacity of 60,000 tons.

Comag manufactured only caustic-calcined magnesia. Two areas were mined with total capacity of 30,000 tons per year. Plants were located at Tavsanli and Kumbet.

Perlite.—Interest in mining known perlite deposits scattered all over the country was gaining ground owing to the rise in world demand. There were two mines at Camaovasi near Izmir with total annual capacity of 180,000 to 200,000 tons.

Etibank had developed an integrated perlite mine together with a processing plant at Camaovasi, Izmir, to manufacture 137,000 tons per year of processed perlite and 50,000 cubic meters per year of expanded perlite. Zihni International Trade and Marketing owns the other mine in the Izmir area with an annual capacity of 50,000 tons. Plans called for setting up a grinding plant with a capacity of 75,000-100,000 tons per year.

Palbalk Ticaret Ltd. produced about 70,000 cubic meters of expanded perlite per year. Izmir Perlite Mining and Industry Ltd., Anadolu Per-Mer Madencilik Sanayi ve Ticaret Ltd. Sti, and Durum Urum each have an annual capacity of less than 10,000 tons.

Pyrophyllite.—Turkey became a commercial producer of pyrophyllite in 1976. Industrie Mineralleri ve Taslari Sanayii Ltd. produced 3,000 tons per year and planned to substantially increase production. Reserves were estimated at 6 million tons.

MINERAL FUELS

Coal.—Absolute dependence on lignite for home heating and thermal power stations caused Government nationalization of all lignite mines. Abundant lignite sources existed, but the air pollution problems caused by high ash and volatile content limit the use of lignite on a large scale. About 70% of Turkey's coal requirements were met by domestic production. Turkey planned a long-term expansion program to increase the mining of hard coal and to triple lignite production for use in thermal powerplants.

Hard coal was mined in the Zonguldak District by Eregli Coal Mines. Annual production was 4.8 million tons and was to increase to 5.8 million tons per year. Reserves were estimated at 1.3 billion tons. Turkiye Komur Isletmeleri (TKI) operated the major mines of Kandili, Kozlu, Uzulmez, and Gelik.

The major part of lignite production came from Tunebilek, Seyitomer, Soma, and Beypazari districts. TKI operated production capacity of 4 million tons. Reserves were estimated at 250 million tons. State-owned Western Lignites Co. mined approximately 2 million tons of lignite annually at Seyitomer. Reserves were estimated at 230 million tons. Both public and private companies operated at Soma. Krolin Madencilik, the largest private lignite company, had an annual capacity of 1.5 million tons. Reserves were estimated at 100 million tons.

Over 3 billion tons of lignite were estimated in the Afsin-Elbistan area. Output was expected to reach 20 million tons per year by 1980. Development of the Elbistan coal open pit began with the stripping of 4,200,000 cubic meters of oveburden. Production was expected to begin in 1981.

Work was continuing without interruption in order to commence operations at the recently nationalized Pekeric lignite deposits in Erzurum's Pasinler District. Deposits contained approximately 7.5 million tons of lignite. Production was to begin by 1980. The Alicevrek lignite fields were also turned over to the Erzurum Eastern Lignite Establishment.

Petroleum.—Domestic production supplied about 20% of the country's petroleum requirements. There were no significant discoveries of oil despite extensive land and offshore seismic exploration by the state-owned Turkiye Petrolleri Anonim Ortakliki (TPAO) and N.V. Turkse Shell (Shell), the largest producers. It was felt that known oil reserves were sufficient only for another 15 years' production and that it was unlikely that new fields would be located, at least onshore. Total reserves were estimated at 350 million barrels.

TPAO initiated a $3 million program to test enhanced recovery methods for Bati Raman oilfield near Batman. Production from Bati Raman was expected to exceed 10,000 barrels per day by 1980. TPAO planned to open 40 new production wells by 1980 which were to increase production from 25,000 barrels per day to about 30,000 to 32,000 barrels per day. Shell was producing about 32,000 barrels per day. The other two producers, Mobil Exploration Mediterreanean Inc. and Ersan Petrol Sanayii, were producing at the 7,000-to-8,000-barrel-per-day level.

Turkey's crude oil consumption rose to 350,000 to 360,000 barrels per day in 1979.

Refining.—Negotiations were in progress for the nationalization of the Anandolu Tasfiyehanesi A.S. (ATAS) refinery at Mersin, which would put all petroleum refinery operations under TPAO. The 90,000-barrel-per-day refinery is a joint venture of Mobil Oil Co. (51%), Royal Dutch Shell (27%), British Petroleum (15%), and Marmara Refining (7%). This action was initiated following 40% capacity operations in 1978 and resulting product shortages owing to the shortage of foreign exchange for imported crude oil.

TPAO's refineries at Batman and Izmir operated at rated capacity. A catalytic cracker was added at the Izmir refinery, which was undergoing expansion to 200,000 barrels per day by 1981. The refinery at Izmir, operated by Istanbul Petrol Refineries A.S., a TPAO subsidiary, was to increase production capacity to 250,000 barrels per day by 1980.

TPAO signed an agreement with Romania for the construction of a 100,000-barrel-per-day refinery at Kirikkale in Central Anatolia to be completed in 1980. Naphtha from the refinery was to supply the 1,000-ton-per-day ammonia and 1,750-ton-per-day urea fertilizer plants at Kirikkale.

Uranium.—Although Turkey did not mine uranium, the 1978 program budgeted $80,000 mining investment by Turkey's atomic energy agency. Extensive ground and airborne surveys continued in the Manisa-Afyon region. A deposit of 2,700 tons of ore was delineated at Koprubasi, Manisa, and a pilot plant was established. Production was to start upon completion of Turkey's first nuclear powerplant, scheduled for 1984. Surveys were also conducted over the Thrace and Beypazari basins near Ankara where uranium potential was suspected.

It was reported by the Woods Hole Oceanographic Institute and the Institute of Palaentology at Hamburg University that the world's largest known uranium deposits were discovered in deep water in the Turkish part of the Black Sea. Approximately 6.7 million tons of uranium oxide were suspected to be contained in the deposits covering 100,000 square miles at depths from 3,500 to 7,000 feet. Deposits were fine grained and nonconsolidated, and while mining was technically possible, it was more costly than land mining.

The Mineral Industry of the U.S.S.R.[1]

By V.V. Strishkov[2]

The U.S.S.R., with complete nationalization and low-wage labor, is the world's second largest producer of industrial products. It is the leading world producer of iron ore, manganese ore, platinum-group metals, petroleum, steel, potassium salts, asbestos, and cement. It occupies second place, following the United States, in world output of aluminum, lead, natural gas, coal and phosphate rock; it ranks second, after Canada, in the production of nickel and follows South Africa in gold and chromium ore output. Production targets are determined in principle by the 1976-80 national plan for economic development. The U.S.S.R.'s mineral industry has been a major factor in the country's development. The country has large reserves and resources of many minerals and because of its export position is a significant factor in the mineral economy of the world.

For many years Soviet industrialization was directed towards the expansion of heavy industry, which in turn necessitated the expansion of mineral and metal output. Although successful in achieving production targets, Soviet technology has not developed in parallel with that of the expanding economies in the West.

In 1978, industrial output increased 4.8% (4.5% planned) to a value of 587 billion rubles. National income rose 2.5% (2.4% planned) to 417 billion rubles. Heavy industry (group A) output rose 5% (4.7% planned), and consumer goods (group B) production rose 4% (4.7% planned). Investment rose to 129 billion rubles, or 5% (3.5% planned).

In 1979, industrial production rose only 3.4% (5.7% planned), national income increased by 2% (4.3% planned), and the Soviet Union has confirmed that its economy has suffered its worst year since the Second World War. Heavy industry grew 3.5% (5.8% planned), and consumer goods production rose 3.3% (4.6% planned). Industrial labor productivity grew only 2.4% (4.7% planned).

The U.S.S.R. Ministry of Ferrous Metallurgy failed to fulfill targets for the production of steel, pig iron, finished rolled products, and iron ore. The poor performance of the ferrous metallurgy industries resulted mainly from delays in plant modernization, labor shortages, and transportation problems. The U.S.S.R. has insufficient capacity to produce certain steel products, and it has been forced to rely more on imports after failing to produce the desired quality of pipe and sections for its various industrial projects. Ferrous metallurgy has not solved the problem of improving the quality of products and extending and optimizing quality grades. The balance in the development of ferrous metallurgy works is not being maintained; for instance, at Cherepovets a powerful rolling mill was built before the blast furnace and oxygen-converter shop, and thus metal had to be brought from Zhdanov and other distant places.

Chemical and petrochemical output in a number of key sectors has failed to achieve planned goals for the fourth successive year. In 1979, the chemical and petrochemical industry registered a 3% increase compared with the 1978 level. This was below the 6% increase in 1978 and 7% increase in 1977 and certainly falls behind the 10.5% compound annual growth envisaged in the 1976-80 plan. Fertilizer production fell by 3.6%. The industry is unlikely to achieve the 1980's originally planned target of 143 million tons. Fertilizer deliveries to consumers of 76 million tons in 1979 fell behind the planned target of 85.6 million tons.

The slow development of advanced methods of mining, concentration, roasting, smelting, and metal rolling has resulted in a great deficiency of nonferrous and rare metals. Copper, lead, nickel, cobalt, and tin are mainly extracted by pyrometallurgical routes, and almost all the furnaces are of outdated design. The installation of outdated furnaces in new shop plants continued in 1979.

Because of the use of ordinary refractories in furnace linings, productivity is affected. Their reliability is very low, and idle time is great. The refractory industry does not produce the large bricks necessary for suspended roofs of reverberatory furnaces and the tuyere zones of converters, nor does it produce the more durable heat-resistant brick.

On the whole, the Soviet mineral industry is lagging. Despite the fact the U.S.S.R. is the world's leading producer of steel, pig iron, mineral fertilizers, and cement, the mineral industry has failed to deliver to the economy its requirement of iron, steel, rolled metal, cement, mineral fertilizers, and other products. The shortage of metals and cement is holding back the development of allied industries, especially machine building and construction. This stems from the fact that the performance of the Soviet industry is measured by units of gross weighed output rather than units efficiently consumed in the economy.

Expansion of the mineral industry continues to be achieved mainly through increased labor and capital rather than advancing technology. It is estimated that two to three times more investment and labor in real terms are required in the U.S.S.R. than in the principal countries of the West to achieve a given increase in mineral output.

The U.S.S.R.'s reported mineral commodity consumption per capita approaches that of Western Europe, although there is still a significant difference in the living standards. One reason for the apparent difference is that the growth is measured in terms of energy and minerals produced, not in terms of energy and metals usefully consumed. In addition, fuel and mineral shortages often bring with them substandard commodities which are marketed as standard items.

Mineral Industry Labor.—Practically all sectors of the mineral industry maintained a greater number of production personnel than called for by plan targets. The Soviet economy employed 111 million industrial workers, 51% women. The Soviet ferrous and nonferrous industries employed over 3 million workers,[3] and the coal industry employed 2.2 million.[4] The oil, gas, and petrochemical industries employed 2.6 million, including over 250,000 in the development of oilfields and gasfields.[5] The crude oil extraction industry employed about 740,000 persons.[6] There were about 155,000 graduate mining engineers in the Soviet economy in 1979. Mining engineers are trained at 38 Soviet institutes. The workweek in the U.S.S.R. is 41 hours for standard workers and 36 or 30 hours for underground miners. Soviet statistical agencies do not publish data on the actual earnings of mineral industry workers. The average official monthly earnings of all Soviet workers and employees in 1979 were 164 rubles,[7] compared with 160 rubles in 1978, an increase of 3%. In 1979, the monthly minimum wage was 70 rubles. Wage increases for some 12 million workers and employees in the nonproductive sectors of the Soviet economy went into effect in 1979. Although the increases range up to 30%, they affect primarily the lower paid workers and employees who are on or near the minimum wage scale of 70 rubles a month.

Labor turnover remains a serious problem, particularly in the north and northeast. Turnover of personnel in individual mineral industry operations ranged from 25% to 80% per year. This was caused mainly by the lag in building houses and in providing public and medical services, and by low material incentives. The output quota-bonus principle, once condemned as an exploitation of the worker, has become an important feature of the mining industry. Soviet labor legislation requires that workers achieve a minimum output within a given period. This minimum is the work norm and is established for virtually every phase of employment. Following the significant increase in output quotas, there has been a substantial increase in the proportion of workers not meeting the increased quotas established during the last 4 years.

Government Policies and Programs.—A Decree of the CPSU Central Committee and the U.S.S.R. Council of Ministers "On Improving Planning, Increasing Impact of Management on Production Efficiency and Quality," adopted July 12, 1979, provides priority for the following major economic programs: saving fuel and metal, building the Baykal-Amur Railway, reducing manual labor and comprehensive mechanization of manual and auxiliary operations, the program of increasing the production of new consumer goods, and new methods of evaluating production.

Until now the basic evaluation index has been gross production, but according to the new Decree, results are to be evaluated by the index of net production. Soviet planners believe that the net output index will remove the incentive to use the more expensive raw materials and semifinished goods, thus increasing the cost of an enterprise's gross output.

The new system, if it can really be called such, is based on the old idea that enterprises should be given fairly detailed targets and then be required to meet them. Fifteen years ago, the belief that such a system of rigid centralized planning was ineffective prompted the economic reform of 1965. That reform failed, however. Now there has been a definite return to the traditional system of planning.

Much attention is now being paid to economic "integration" and industrial "cooperation" within the Comecon[8] group of countries, and this tends to make East Europe, Mongolia, Cuba, and Vietnam more dependent upon the Soviet mineral industry. The East European countries are uniformly interested in the widening of economic contacts with the Western countries. The 33rd Session of Comecon, held in Moscow in June 1979, adopted special programs for long-term cooperation until 1990 in energy, fuel, raw materials, the agricultural food industry, and machine building.

On the average, for each of the two successive 5-year plan periods during 1981-90, the value of Comecon joint investments made directly by members is to be more than four times the level planned for the 1976-80 period. The largest element will be directed towards the development of the Soviet Union's energy and raw material sectors. The long-term Comecon joint investment projects (Target Programs) planned for the 1981-90 period, involving five major economic sectors, will require 65 to 85 billion transferable rubles. As during the current 5-year plan period, a very large part of the Comecon joint investment will be spent for the development of the Soviet fuel, energy, and raw material sectors.

The Plan for Multilateral Integration Measures for the Comecon (1976-80), includes, among other Soviet projects, the joint construction and financing of the Kiyembay asbestos complex (first stage completed), the development of the Orenburg Gasfield and the gas pipeline from Orenburg to the Soviet western border (completed), the 750-kilovolt transmission line from Vinnitsa to the Hungarian border (completed), and new facilities for iron ore mining, ferroalloys production, and petroleum refining elsewhere in the U.S.S.R. (under construction). Reportedly, the total investment in joint projects involves about 9 billion transferable rubles by participating Comecon countries with provisions for repayment to be made in raw material produced (asbestos, iron ore, ferroalloys, natural gas, petroleum, and electric power).

One of the new forms of economic cooperation is "compensation" or "buy-back" agreements which provide for the creation in the U.S.S.R. of large industrial enterprises with the investment of foreign credits. Because of the limited availability of good-quality mineral industry machinery and equipment, the U.S.S.R. is showing increasing interest in "joint" or "compensation" development ventures and in the exchange of scientific and technical services with foreign countries and Western firms. While the law prohibits any direct foreign capital investment, foreign investors are invited to develop deposits and to construct plants in the U.S.S.R., and repayment is promised in the form of commodities produced. The joint ventures should help the Soviets to introduce new technology.

According to Soviet sources, the value of buy-back agreements and contracts is estimated at several billion rubles for many projects in the chemical, petrochemical, petroleum, gas, and coal industries as well as in ferrous and nonferrous metallurgy. Some of the arrangements with the West have also involved Comecon joint investment projects. This category includes the agreement with Austrian, French, Italian, and West German firms for delivery of large-diameter steel pipes, fittings, equipment, and materials for developing the gasfields and building gas pipelines. Deliveries of natural gas will pay for the credits.

This type of transaction fits well with the Soviet planning system. The foreign trade organizations do not have to worry about the lack of hard currency, and the Soviets do not need to search for markets in order to earn the much-needed hard currencies.

Reportedly, the chemical industries of the Federal Republic of Germany, the United Kingdom, and France are beginning to experience some economic dislocations caused by buy-back deliveries, and fears of more pronounced effects in the near future have stimulated objections by trade unions and chemical plant owners.

Economic cooperation between the U.S.S.R. and the developing countries concentrates mostly on the establishment and expansion of energy and raw material production. Ties between Morocco and the U.S.S.R. received another boost with the signing in July 1979, of a 5-year agreement for development of phosphates and the possible development of oil shale. Reportedly, Nigeria and the U.S.S.R. have signed an agreement for the construction of an integrated steelworks at Ajaokute worth some £960 million, and Guyana may purchase machinery and equipment made in the U.S.S.R. using Soviet credits. The U.S.S.R. has not assisted directly in the development of mineral deposits in developing countries.

Mineral Industry Technology.—The mechanization of labor-intensive manual work in the Soviet economy is proceeding very slowly. In the past several years, the number of manual workers has increased substantially, and, in many enterprises, their proportion has become significant. According to Problems of Economics,[9] there were about 45 million manual workers in the Soviet economy in 1974. The work performed manually without machines is indicated by the following figures: 55.7% at coal mines, 60% at longwalls, 57% in development, and 100% on repair of workings. At nonferrous mines and plants in Kazakhstan, manual labor comprises 54% and planned production goals are met by increasing manual labor levels. More than 50% of the heavy and labor-intensive operations at ferrous-metallurgical enterprises have to be done manually. Over 67% of the workers in blast furnace production perform manual operations. The situation is somewhat better in steel-smelting production, where 55.8% of the workers perform manual labor.[10]

The equipment currently used in mining is not large by Western standards. Excavators with scoop capacities of 4 to 8 cubic meters are needed in combination with trucks of 110- to 180-ton capacity. The use of one 500-horsepower bulldozer to replace four of the T-100s now in use makes it possible to release 12 persons at once.[11] The main trouble, however, is that the machine builders have been failing to manufacture new equipment for many years. Over the past 10 years, only one-third of the equipment ordered for nonferrous metallurgy has been supplied.[12] Equipment used in Soviet mineral industry is standardized and of types made earlier in Western Europe and the United States. The production of mining equipment has grown substantially, but the technical standards and the quality are poor.

At a number of concentrating plants, the recovery of metals is low. Still unsolved is the problem of gold and zinc recovery from the copper pyrite ores in the Urals. At many polymetallic ore deposits, the constituent elements, especially rare metals, are being inadequately recovered. A major reason for the poor recovery is ore dilution. Tonnage extracted rather than grade or quality is the criterion, and this leads to the extraction of large tonnages regardless of the grade. Research and planning agencies appear not to cooperate adequately wtih the industries. New ideas are abundant, but their testing and application are delayed by the absence of a research testing base, insufficient coordination, and duplication of effort on the part of the research institutes.

The Soviet economy is going through one of its worst periods since the end of World War II, and a rapid increase in productivity is needed. The planned average annual increase of productivity for the period 1976-80 was 6.1%, but the actual official increases have been 3.3% in 1976, 4.0% in 1977, 3.6% in 1978, and only 2.4% in 1979. The 1980 plan calls for an increase of 3.8%, much too high a figure as there can be little hope of increased labor productivity. Moreover, the yearly average labor productivity growth has been decreasing.

Transfer of Technology.—Scientific and technological cooperation with developed Western countries holds an important place in the system of foreign economic relations of the U.S.S.R. Recently, these programs have become longer term and larger in scale. Western technology is a key factor that can favorably influence Soviet economic performance. The transfer of technology and licensed manufacture of products is largely one-sided, with the U.S.S.R. usually on the receiving end.

The rate of growth in Soviet trade with the West will slow substantially in the next few years. In the 1973-78 period, Western companies completed more than 60 compensation agreements. In the next 5-year period (1981-85), Soviet planners expect that only 15 new compensation projects will be completed. According to Soviet sources, projects for the chemical industry will receive less attention in the future. Demand for Western technology by the U.S.S.R. is unlikely to diminish, and the gap between Eastern and Western technology will continue.

In the past decade, the Soviet Union has made a major effort to catch up with Western technology. Imports of Western technology and equipment have not given a sharp boost to Soviet productivity, and inefficient use of material resources, especially metals and energy, continued in 1978-79.

A Soviet-Japanese conference on the development of natural resources in Siberia ended in Moscow on September 27, 1979. It examined several projects already underway, including the production of coking coal in Southern Yakutia, exploration of natural gas fields in Yakutia, and exploration for oil and gas off Sakhalin. It is expected that Japan will extend an additional yen loan, equivalent to $40 million, for the U.S.S.R. to import a coal-dressing plant from Japan for Southern Yakutia. Both sides confirmed their interest and promised to continue discussion on the building of an integrated steelworks on the Soviet Far East coast, the construction of a copper smelter in Udokan, and asbestos development in Molodezhnaya.

The Soviet Union and France have signed agreements on economic, industrial, and technical cooperation for 1980-90 and on economic cooperation for 1980-85. However, there are growing indicators that Italy is postponing negotiations with the Soviet Union for a new $1,000 million 3-year Italian credit.

The Federal Republic of Germany was the largest Western exporter of equipment and machinery to the U.S.S.R. in 1978-79. Its involvement includes deliveries of trucks for the construction of the Baykal-Amur Main Railway, the Kama automobile works, the Oskol metallurgical complex, and a number of large chemical complexes. Daimler Benz has received Soviet orders worth DM15 million for 150- to 320-horsepower trucks. Krupp of Essen is to build an electrosmelting plant at the Soviet iron and steel complex in Staryy Oskol near Kursk, which is to start operating in 1982. Under the contract, signed in Moscow in March 1979, four electric furnaces are to be installed, mainly for the production of high-grade steel (1.45 million tons annually). The contract is worth about DM350 million to Krupp, and the total cost of the electric steel plant is estimated at DM600 million. The project is largely being undertaken by Krupp and four other German companies. Within the framework of an agreement worth DM50 million, the Schiess AG group will supply a mill capable of working pieces weighing up to 800 tons. A contract was signed in April between Metallurgimport of the U.S.S.R. and Creusot-Loire of France for the delivery of equipment for the manufacture of 170,000 tons of seamless pressed pipes a year. Under a contract worth F1,000 million, France and the Federal Republic of Germany are to supply the Soviet Union with equipment.

Over 90% of the natural gas supplied by the U.S.S.R. to Western Europe is exported under compensation agreements signed between 1968 and 1974. Discussions with German energy companies on the construction of a 4,300-kilometer natural gas pipeline from West Siberia to Europe at a cost of $11,600 million continued in 1979. It could be in operation by 1986 with a 40,000- to 50,000-million-cubic-meter-per-year capacity.

The Soviet Union depends on Western, in particular U.S., oil and gas technology. Reportedly, the U.S. Department of Commerce has approved 75 applications for the export of petroleum equipment to the U.S.S.R. The value of equipment and machinery to be delivered is understood to be about $280 million. Dresser Industries has sold a $144 million plant to manufacture oil drilling bits. The Soviet Mashinoimport has awarded a $15 million contract to International Enterprise Inc. of Oklahoma City for 10 combination drilling rigs. The Soviet Union has placed F140 million worth of contracts with Dutch firms for chemical products used to maximize Soviet oil and natural gas production.

Reportedly, Japan, the United States, and Soviet Union have agreed on a plan to construct the Yakutia-Olga (near Nakhodka, Soviet Far East) gas pipeline to transport natural gas to Japan and the United States. It is designed to supply the United States and Japan with 1 billion cubic meters of natural gas each, with the gas liquefied at Olga. Both countries are expected to supply equal amounts of bank loans for the procurement of steel pipes, excavators, liquefaction plant, and other necessary equipment. The estimated cost of the project is $4 billion. At the Nerunga coal deposit in Southern Yakutia, U.S. and Japanese heavy earthmoving equipment is being used. Komatsu Ltd. has supplied 30 HD-1200 dump trucks (120-ton capacity each), worth about $22 million to be used in cold areas of the Soviet Union.

Davy International has signed a £50 million contract with Tekhmashimport for the engineering and supply of a 75,000-ton-per-year alpha-olefins plant to be built at Nizhnekamsk in the Tatar A.S.S.R.

Monsanto has agreed with Société pour l'Equipment des Industries Chimiques of France to supply technology for production of orthonitrophenol in Navoi in the south-central region of the U.S.S.R. In November 1979, the Brussels-based chemical subsidiary of Exxon (Esso Chem Impex) signed two technical agreements with the Soviet Ministry of Oil Refining and Petrochemicals and the Ministry of the Oil Industry, respectively. These call for technical cooperation in developing the use of Esso Chem Impex chemicals in the Soviet Industry.

The Swedish company Asea has received an order worth SKr150 million for the construction of a special type of plant for the Staryy Oskol steelworks near Kursk. Delivery of equipment is to be completed by 1982. Large high-pressure slurry pumps made by Holtius B.V. of Holland will be delivered to the U.S.S.R. The 1,600-kilowatt pumps, which will be used on an iron ore concentrate pipeline, have a capacity of 520 cubic meters per hour. The Auran enterprise of Finland was to export 38 mine loaders, valued at Fmk18.6 million, in 1980 and a further 16 in 1981.

The largest compensation deal so far arranged was with Occidental Petroleum in 1973-74. The agreement provided for the delivery of equipment for nitrogen fertilizer plants and for building pipelines to transport liquid ammonia to the coast. In return, products from these plants, for a value of $20 billion, are to be shipped to the United States over a period of 20 years. The U.S. equipment is being installed in the Soviet Union's largest chemical complexes in Togliatti, Novgorod, Dneprodzerzhinsk, and elsewhere. Some 400,000 tons of liquid ammonia were exported to the United States in 1978. It was planned to export about 1 million tons in 1979. Reportedly, on December 14, 1979, Occidental signed two new contracts with Soviet foreign trade organizations. One calls for the delivery of 450,000 tons of Soviet ammonia in 1980, in addition to the 250,000 tons already contracted for that year, while the second involves the purchase of 1 million tons each of potash and urea from the U.S.S.R.

President Carter has imposed an import quota of 1 million tons of ammonia for 1980. Imports were previously scheduled to rise to 1.2 to 1.4 million tons in 1980, having reached 0.9 million tons at a value of $100 million in 1979. U.S. sales of superphosphoric acid to the U.S.S.R. totaled $97 million in 1979 and were expected to reach $400 million in 1980. President Carter has ordered an embargo on shipments of phosphates to the U.S.S.R. for an indefinite period.

In 1979, France supplied the Stirka production association in Rozdol, Lvov Oblast' with plant to produce nitro-ammophosphates. U.S. drilling rigs were delivered to the Baykal-Amur Railway for driving the Severomayskiy tunnel.

The Soviet Union is to assist in the construction of a 3-million-ton steel plant at Vishakapatnam in India at a cost of 1.4 billion. This is the third Soviet-aided steel plant in India. The U.S.S.R. and India are to cooperate in developing processes for selective flotation of copper and lead, in investigating low-grade ores, on coal development in India, and in the application of computer modeling technology.

The U.S.S.R. has agreed to deliver the necesary equipment to complete the construction of the second stage of the Esfahan steel complex in Iran. This will increase the plant's annual capacity to 1.9 million tons of steel. Reportedly, Nigeria and the U.S.S.R.'s Tyazhpromeksport have signed a contract for the construction of a 1.3-million-tons-per-year steelworks at Ajaokuta worth some f900 million. The Soviet Union is to assist in the construction of the La Maste steelworks in Algeria; the financing will be provided within the terms of the 1976 Soviet-Algerian credit agreement.

Turkey and the U.S.S.R. are reported to have agreed in principle for the Soviets to construct and equip a nuclear powerplant in Turkey. The Soviet Union is planning to construct one 120,000-barrel-per-day refinery in Vietnam. The U.S.S.R. is engaged in a joint project with a Finnish steel company to sell small steelworks to developing countries. The Soviet Union, together with some Finnish firms, has submitted a tender to build four thermal powerplants in Iraq.

The Plan for 1980.—The state plan for 1980 was ratified by the Supreme Soviet on November 30, 1979. The original target for 1980, set as part of the 1976-80 plan, had been reduced. A significant cutback in industrial growth targets, in a bleak economic projection, confirmed that the economy will fall far short of meeting the targets of the current 5-year plan. Overall industrial output in 1980 will grow by only 4.5%, which is well below the plan target of 5.7% for 1979 and the average annual rate of 6.5% projected in the 10th 5-year plan. Heavy industry, or category A production, was to grow by 4.5%, compared with 5.8% projected in 1979. Light industry, category B, production was also to grow by 4.5% compared with 5.4% for 1979. Achievement of these targets would mean a total rise in industrial production over the 1976-80 period of 25.7%, far short of the original target of 36%.

The 1980 targets for all fuels except natural gas were scaled down from those set in 1976. Oil output in West Siberia, the main producing region, is to rise from 5 million barrels per day in 1979 to 7 million by the end of 1980. The increase in 1980 was to be achieved by increased drilling of new wells in West Siberia. To accomplish this, 23% more drilling equipment would have to be produced in 1980. It was planned to put into operation the 1,000-kilometer section of the Surgut-Polotsk oil pipeline in 1980. It was also planned to commission new facilities at the Baku XXII Congress CPSU, Kirishinsk (Leningrad Oblast'), and Kuybyshev primary refineries.

The brightest spot in the energy picture is natural gas. The 505-kilometer section of the second string of the Urengoy-Chelyabinsk pipeline and the 608 kilometer section of the Petrovsk-Yelets pipeline were to be commissioned in 1980. For lignite, the main increase was to be from open pit operations in Kazakhstan and Siberia. Increased coal production was to be from the Kuznetsk, Karaganda, Ekibastuz, and Kansk-Achinsk Basins.

For steel it was planned to commission additional facilities at the Mikhaylovsk (Kursk region), Novokrivorozhsk, and Central (Krivoy Rog) iron ore mining and concentration complexes.

Soviet priorities for the 1980's will continue to be the vital oil, gas, and machine-building industries. Oil and gas production are so important (as energy and hard currency sources) that adjustments will be made elsewhere to ensure fulfillment of the planned targets. There will be continued exports of petroleum and natural gas and imports of steel pipe, pipelining, and petroleum and natural gas extraction equipment.

Table 1 compares the revised goals for 1980 with those originally set.

Table 1.—U.S.S.R.: Soviet industrial planned production, 1980

(Million tons)

Commodity	Originally planned (low range)	Revised goals
Iron ore, usable	276	NA
Pig iron	NA	115
Steel, raw	169	157
Coal, raw (bituminous, anthracite, and lignite)	800	745
Crude oil (including condensate)	620	606
Natural gas, billion cubic meters	400	435
Mineral fertilizers (Soviet standard)	143	115
Power, electric (billion kilowatt hours)	1,340	1,295
Cement	143	NA

NA Not available.

Exploration.—Over 5,000 deposits of various minerals were being exploited in 1978-79. Extensive prospecting and exploration for practically all commodities was carried out on a large scale. There were over 500,000 employees in the geological and prospecting organizations in 1979, including over 120,000 graduate specialists with university and technical education. The Ministry of Geology had 36 research institutes and 2 design establishments with a total staff of over 40,000 persons. A total of over 4 billion rubles was allocated for geological exploration in 1979. Over 2 billion rubles was for oil and gas and some 200 million rubles for coal. Every year geologists of Ministry of Geology alone complete more than 20 million meters of core well drilling, over 3 million meters of petroleum and gas wells, and about 300,000 meters of various underground mining excavations. The geologists have at their disposal more than 10,000 drilling rigs. In the 20-year period, the total expenditure on prospecting increased four times.[13]

The main purpose of recent Soviet mineral exploration has been to improve the regional distribution of resources for the production of major metals, all fuels, and many nonmetallic minerals. However, during the past 15 years no increment in tin reserves has been achieved even in the Soviet Far East. Poor results were also reported in the growth of reserves of bauxite, lead, zinc, mercury, tungsten, molybdenum, antimony, and nickel (Kola Peninsula).

In recent years, the effectiveness of prospecting and exploration has been reduced resulting in the reduction of the number of deposits transferred for mining. Effectiveness has been especially low at Rudnyy Altay, Dzhungariya, Karatau, and Balkhash. The raw material base is especially poor at the Achisay, Balkhash, Tekeli, Belogorsk, and Kargayly polymetallic complexes, and all gold mining enterprises of Kazakhstan.[14]

There are shortages of bauxite, copper (Urals), nickel (Kola Peninsula), mercury (Ukraine), and lead (Rudnyy Altay and Kazakhstan). While there have been problems in improving the distribution of reserves, production has been increased from existing deposits. Good results were obtained in increasing the quantity and quality (by 50%) of copper-nickel reserves in the Norilsk area, where over 20 teams of geologists were employed in 1979.

Over 2,500 geological and geophysical teams are permanently employed in oil and gas exploration, and about 2,200 exploration wells are completed each year, using some 2,500 drilling rigs. In 1979, the target for oil and gas exploratory drilling by the Ministry of Geology was not met. The speed of drilling remained essentially at the 1976 level (387 meters per rig-month). In 1979, Western Siberia continued to be the main target for Soviet oil and gas exploration, but the speed of drilling was low. The main causes of low performance of drilling operations in West Siberia are the complex transport system for delivery of the basic materials, pipes, and tools, organizational deficiencies, and the severe climatic conditions, which influence the duration of all forms of operations.[15]

Soviet geologists are not well equipped with geophysical instrumentaton, particularly with automated data acquisition and processing equipment. The main method of contouring deposits remains the mechanical method—drilling wells and drifting mine workings.[16] Expenditure on geophysical surveying of oil and gas accounted for 25% of the total exploration cost for these commodities. The total drilling of exploratory and development wells in the oil and gas industry by all ministries amounted to some 15 million meters in 1979. The U.S.S.R. is purchasing large quantities of oil equipment from Western suppliers as exploration of its "vast" oil and gas reserves continues. Offshore prospecting needs specialized geological and geophysical ships and floating drilling rigs, but production of these is proceeding slowly. The first Soviet-made floating rig, *Baku*, is being used for exploratory drilling at great depth in the Caspian Sea. Three wells have been drilled since it has been in operation. Three floating semisubmersible drilling rigs (*Samur*, *Araks*, and *Mamedali Aliyev*), built by Rauma-Repola of Finland, were delivered to Baku in November 1979.

The 1979 plan called for the completion of detailed exploration of the Podol'skoye copper deposit in the Urals, and the Karabinskoye tungsten and Shalkiya lead-zinc deposits in Kazakhstan. Great attention was attached to the completion of exploration of the following iron ore deposits: Severogoro-Blagodatskoye in the Urals, Belanovskoye in Kremenchug region of the Ukraine, and Aleshinskoye in Kazakhstan. Completion of surveying of the Udokan (East Siberia) and Aktogaysk (Kazakhstan) copper deposits and the Kholodnenskoye lead and zinc deposit in East Siberia was planned for 1980. There are almost 25,000 prospectors at work in the area of the Baykal-Amur Railway. It was planned in 1979 to increase the value of prospecting work by 12.5% and to achieve a 20.2% increase in the capital investment in oil and gas drilling.

Prospecting was intensified on copper in the Urals, at the Udokan deposit in Chita Oblast', and in Central and Southern Kazakhstan; prospecting on lead and zinc was conducted in the Rudnyy Altay region on areas adjacent to the Leninogorsk and Zyryanovsk complexes and at the Uchkulachsk deposit in Uzbek S.S.R. Tin prospecting was increased in the Khabarovsk Kray, in the Yakut A.S.S.R., in the Badzhal region of the Khabarovsk Kray, in the Pamirs, and in other promising regions. Prospecting was also undertaken on the northern side of the Talnakh ore deposit at Norilsk. Reportedly, at Gomel' Oblast' near Zhitkovitsy in Belorussia, deposits of lignite have been discovered. The reserves will be mined by surface methods and used in thermal powerplants in Belorussia.

A highly promising oilfield has been discovered on the continental shelf off the northeastern coast of Sakhalin at a depth of 3,400 meters below the bed of the Okhotsk Sea. Oil and natural gas exploration has been going on through the joint efforts of Japan and the Soviet Union in this area. The Soviet Union has asked Japan to provide undersea tunnel drilling technology so that tapping of crude oil may continue even when the sea is frozen over. Several wildcat wells were drilled in 1979. Under the 1975 Japan-Soviet agreement, Japan will receive half of the oil produced from the Sakhalin shelf. Agreement between the U.S.S.R. and Japanese firms has been reached on extending joint exploration of oil and natural gas off Sakhalin by 2 years to the end of 1982. The new agreement calls for the Japanese side to provide additional funds of $70 million.

Exploration for oil and natural gas in the Anadyr area (Soviet Far East) is expected to increase sharply during the 1981-85 plan period. Also, according to an agreement, the U.S.S.R. will help Turkey in oil exploration and drilling.

Mineral Reserves.—According to the Soviet classification, the reserves of all mineral raw materials, including gas, oil, and coal, are classified under two correlated systems, as follows:

a. For the purpose of the managed mineral economies of the U.S.S.R., the reserves are divided into two groups, "economic" and "uneconomic." The balance sheet of mineral reserves suitable for exploitation includes only the first of these groups.

b. Depending on reliability of the estimates, the reserves are classified in four categories, A,B,C_1, and C_2 (D_1 and D_2, the still lower reliabilities, are permitted for oil and gas).

The appropriate specifications for each one of the four categories are as follows:

A—The reserves in place are known in detail. The ore body (field) boundaries are outlined by preliminary mining or by exploratory boreholes (wells); the depositional environment, the proportions of different industrial grade of the ore (oil or gas), and the hydrogeologic conditions of the exploitations are ascertained; quality and technological properties of the ore (oil or gas) are ascertained in detail, assuring the reliability of the projected beneficiation (processing) and production operations.

B—The reserves in place are explored. The ore bodies (fields) are outlined by mining or by exploratory boreholes (wells); the depositional environment is known; types and industrial grades of the ore (oil or gas) are ascertained, but without details of their distribution; quality and technological properties of the ore (oil or gas) are known sufficiently well to assure the correct choice of the system for its benefication (processing); general conditions of the exploitation and the hydrogeologic environment, as a whole, are known in a fair detail.

C_1—The reserves in place are estimated by a sparse grid of exploratory boreholes (wells) or mining. This category includes also the reserves adjoining the boundaries of the A and B categories of the ore (oil and gas) and the reserves of the very difficult deposits in which the distribution of the mineral values cannot be ascertained even by a dense exploratory grid; quality, types, industrial grades, and technology of the beneficiation (processing) are ascertained tentatively, by means of analyses and of laboratory tests and by analogy with known deposits (fields) of the same type; general conditions of the exploration and a general hydrogeological environment of the deposit (field) are known tentatively.

C_2—The reserves in place adjoining the explored reserves of A plus B plus C_1 categories and reserves indicated by geologic and geophysical evidence confirmed by boreholes (wells) and mining.

Planning and construction of mining enterprises and the appropriate capital investment are authorized on the basis of economic reserves in place, certified as the sum of the $A+B+C_1$ categories of reserves, in the prescribed ratios. The reserves in place of the $A+B+C_1$ categories are called "explored reserves." Reserves in the C_2 categories are also taken into account in project planning for mining enterprises, to provide a general perspective of the development, but they do not constitute a justification for project planning.

It is planned to increase explored reserves in place during the 1978-80 3-year period by the following quantities: more than 1,000 million tons of iron ore, 25 million tons of manganese ore, more than 4 billion cubic meters of natural gas, 11 billion tons of coal and lignite, 106 million tons of phosphorus pentoxide, 75% of the 5-year target for oil, 68% for copper, 90% for zinc, 57% for tin, and 100% for tungsten, mercury, and other nonferrous metals.[17]

The lag in the ore base is due to the decrease in the volume of survey and exploration work in the seventh (1961-65) and eighth (1966-70) 5-year plans.[18] According to Socialist Industry,[19] the 1979-80 target for exploration of additional reserves of natural gas, copper, zinc, iron ore, and apatite has been met.

A summary of reported Soviet reserves in place in categories $A+B+C_1$ is given in table 2.

Table 2.—U.S.S.R.: Reported Soviet mineral reserves in place in the $A+B+C_1$ categories

(Thousand metric tons unless otherwise noted)

Commodity	$A+B+C_1$
METALS	
Iron ore, 38% iron	60,200,000
Manganese ore, 23% to 26% Mn	250,000
NONMETALS	
Cement	27,720,000
Phosphate rock:	
Apatite, 16% P_2O_5	2,750,000
Sedimentary rock, 13% P_2O_5	2,700,000
Potash, K_2O content	3,800,000
MINERAL FUELS	
Coal: Bituminous and anthracite	230,000,000
Lignite and brown coal	190,000,000
Gas, natural (million cubic meters)	29,000,000
Peat	39,000,000
Oil shale	163,200,000
Petroleum	12,900,000

Construction.—The U.S.S.R. continues to experience difficulties completing mineral industry projects on schedule because of shortages of material, equipment, and labor, and organizational problems. Construction of new projects has remained slow and expensive with the work taking two to three times as long as specified by the State Construction Committee. The 10- to 15-year period required to develop a mine with a capacity of 1 to 2 million tons per year contributed to disparities between the capacities of mines, mills, and metallurgical plants. According to the plan, the renovation time of coal mines with an annual capacity of up to 3 million tons of raw coal is 5 to 9 years. In fact, it takes almost three times as long. For example, the renovation of the Taybinskaya mine in the Kuznetsk Basin should have been completed in 1975, producing 2.4 million tons of raw coal per year. However, the completion of renovation has been postponed to 1981. By this time, the lower seam of coal at this mine will be mined out completely. Thereby, attainment of the planned capacity of renovated mine is ruled out.[20]

The number of uncompleted projects in the construction industry has risen considerably in the last 10 years. In 1965, only 1.7% of the total planned construction projects were not completed, but in 1975 the figure had risen to 40.8%. The total volume of unfinished construction at the beginning of 1979 reached 85% of the annual level of capital investment instead of the 65% average according to established standards. An All-Union U.S.S.R. Ministry of Construction for the Soviet Far East and the Baykal Area was established in November 1979. Several large industrial complexes mining coal and ore, smelting metal, and processing timber are to be located there.

Additional new and renovated production facilities are given in table 3.

Table 3.—U.S.S.R.—Capacity of new and renovated production facilities

(Million ton unless otherwise noted)

Commodity	1976	1977	1978		1979	
			Planned	Completed	Planned	Completed

PRODUCTION

A Soviet decree dated April 28, 1956, classifies as state secrets all data on production capacity, information on reserves, and production plans of nonferrous, precious, and rare metal enterprises and data on fulfillment of these plans. Since Soviet mineral statistics are not published in most cases, much of the data in the production tables is estimated. The country also no longer publishes trade information on many mineral commodities.

Reportedly, 70 elements were recovered in the U.S.S.R. In 1979, one-third of the total crude steel and 20% of nonferrous metals were produced from scrap. The maximum depth of underground coal production reached 1,150 meters in 1979, while the average depth was 430 meters. Many new plants and mines, which were put into operation in the 1971-75 period, produced at only 50% to 60% of their design capacity.[21] During the 1977-80 period, the Asian part of the country (east of the Urals) was to provide an increase of 100% of oil, natural gas, and aluminum, over 90% of raw coal and lignite, and about 80% of copper.

In 1979, the Russian Soviet Federated Socialist Republic (R.S.F.S.R.) continued to rank first among the 15 Soviet Republics in mineral production and produced about 80% of the gold and silver, practically 100% of the platinum-group metals, 90% of the petroleum, over 50% of the natural gas, more than half the coal and steel, and about two-thirds of the electric power. The Ukraine occupied first place in output of coking coal, manganese, and iron ore, and second place in natural gas. This Republic continued to provide about one-third of the total Soviet coal output, over 50% of iron ore, about 50% of pig iron, 39% of steel and rolled metal, and nearly 50% of metallurgical and electric engineering products. The Republic also produces a considerable share of the country's output of titanium, mercury, sulfur, and graphite. Kazakhstan occupied third place in Soviet mineral production and was leader both in reserves and in production of lead, zinc, copper, chromium, and cadmium. There was also considerable production of alumina, titanium, and magnesium.

Although about 400 different minerals are mined and processed in the U.S.S.R., insufficient attention is paid to the comprehensive use of mineral resources. At the Zyryan lead and zinc complex, for example, only 8 out of 16 main components of the ore are extracted; the remainder go to waste. Generally, only the main metals in a given ore type are extracted, and most of the byproducts (zinc, cobalt, silver, barium, etc.) are discarded. Losses of byproducts amount to more than half of the total value of the ores. Losses of associated gas accounts for 20,000 million cubic meters per year, and loss of sulfur from petroleum is 10,000 tons per year.[22] Most of the beneficiation plants at the Kazakh nonferrous metals industry process polymetallic ores, containing pyrite, but only one recovers a pyrite concentrate. The others lose some 1.6 million tons in tailings annually. They contain some 775,000 tons of sulfur, 670,000 tons of iron, about 4,400 tons of lead, over 13,500 tons of zinc, 6,000 tons of copper, and much gold and silver.[23]

The chemical, ferrous, and nonferrous metals industries did not fulfill their 4-year production plans. There were production shortfalls for zinc, sulfuric acid, and copper concentrates.[24] The Krivorozhstal' metallurgical complex in the Ukraine, one of the largest enterprises in the ferrous industry, has had difficulties for a long time, and the performance of the Zhdanov Il'ich metallurgical works is poor.

The coal industry operates under great strain. Many mines, especially at the Donetsk Basin, have not met planned targets. There were shortages of supports and coal-cutting machinery. The railway has failed to supply enough cars for shipping coal.[25]

Many projects have operated over a long period with lower capacities than originally planned. For example, in January 1979, only 6 of Kazakhstan's 23 nonferrous industry complexes attained designed capacity. Inadequate use is being made of capacity for ore mining at the Karagayly and Vostochnyy Kazakhstan copper and chemical complexes, for mining and processing ore and producing blister copper and refined copper at the Dzhezkazgan complex, for the output of lead and sulfuric acid at the Ust'-Kamenogorsk lead and zinc complex, and for producing alumina at the Pavlodar aluminum plant.[26]

The demand for metallurgical raw materials is not being satisfied. As a result, the production of pig iron, steel, and rolled metal is impeded. The Dnepr, Kachkanar, Lebedinskiy, Mikhalylovskiy and other iron ore complexes did not meet their production quotas in 1979.[27] Many Soviet rolling mills are kept idle because of a steel shortage.[28] The problem of delivering ferrous scrap to metallurgical plants has not been solved. Each year more than 100 million rubles is spent for this purpose. Crosshauls of metal scrap continued in 1979. Most machine-building and metallurgical plants deliver completely unprocessed scrap, often representing a mixture of ferrous and nonferrous metals, owing to lack of the needed equipment.[29] Soviet price of nonferrous metals scrap in rubles per ton was as follows:[30] Copper, 500; brass, 450; bronze, 600; tin, 5,000; nickel, 2,000; lead, 300; aluminum, 350; and zinc, 150. The average production cost of coke was 41.76 rubles per ton in 1977.

Long-term selective mining of the richer and more easily beneficiated ores at a number of the mines in the Maritime region has resulted in shortages of raw materials at a number of operations. The remaining deposits are now relatively poor-grade ores. Under these conditions, the profitability continually decreases, and a number of operations are operating at a loss.[31]

The quality of Soviet metal is low. The U.S.S.R. expends 50% more metal than is used in the United States per unit of product. Every year, large sums are appropriated for new construction to increase the production of metal, but the same effect could be achieved at a lower cost by improving metal quality. Of 3.2 million tons per year of rail production, only one-third undergoes special thermal treatment. The system of planning which is oriented towards quantitative indices, is the chief obstacle to the introduction of new materials, solutions, and design.[32] Drilling bits, drilling pipes, and drilling rigs produced by the industry are of poor quality.[33]

Over the past 12 years, the average quality of Kizel and Karaganda coals has fallen by 600 kilocalories per kilogram (Kcal/kg), that of Kuznetsk coals by 900 Kcal/kg, and that of Donetsk coals by 1,200 Kcal/kg to 4,060 Kcal/kg in 1979. As a result, additional deliveries of 36 million tons of coal have been required by thermal powerplants, and transportaton has required about 600,000 railroad cars.[34]

About 100 million tons of coal and lignite a year are railed from Siberia to beyond the Urals. The volume of shipments is increasing. The transportation problem will, therefore, become still more acute, and yet the Moscow electric powerplants are receiving coal and lignite containing more than 40% foreign matter. These plants were designed to operate with standard coal and lignite, but not with the 50% ash content now being received. Equipment is wearing out quickly, causing the discrepancy between the planned and actual generation of electricity. Corrosion is a further problem in Soviet industry and, for example, causes 60% of the freight trucks to go into premature retirement.

Poor management of the Soviet metal economy results in large losses of usable equipment, spare parts, pipe, and other capital stock being deliberately expended as scrap in order to meet high plan targets for industrial scrap delivery, and in corrosion and deformation of excess stocks and supplies due to inadequate storage and handling.[35] Although 50 million tons of ferrous scrap metal was procured in 1979, it was insufficient to meet the collection plan, which is currently unfulfilled and whose implementation is labor intensive. The responsible recycling agency, Soyuzvtorchermet, incurs many losses and problems. The greatest losses are in the widely scattered rural areas. Another problem is the poor sorting of industrial scrap into metallic and nonmetallic and ferrous and nonferrous components.[36]

[7]Not distributed by type and therefore not suitable for conversion to volumetric units. Data include all energy products and some nonenergy products as well as refinery fuel and exclude petrochemical feedstocks, paraffin, petroleum coke, white spirit, unspecified minor nonenergy products, and refinery losses.

[8]1976-78 data are from United Nations. World Energy Supplies 1973-78, New York. Ser. J, No. 22, 1979, p. 148.

MINERAL TRANSPORTATION

Over 90% of 1979 mineral production was shipped by rail. The average transportation distances of selected mineral commodities shipped by rail and pipeline in 1978 follow, in kilometers: coal, 725; crude oil (by pipeline), 600; petroleum products (by pipeline), 585; iron ore, 795; coke, 830; ferrous metal, 1,410; and mineral fertilizers, 985.

The decree of the Central Committee CPSU and the U.S.S.R. Council of Ministers on "Measures to Develop Rail Transportation in 1976-80" named fuel as being the first among the high priority types of railway freight. Timely fuel delivery is viewed as a most important state task. Actually, rail transport has not been meeting targets with respect to raw coal and lignite and petroleum haulage, especially in the eastern coal regions of Siberia and Kazakhstan.

Rail transport, once a Soviet "succcess story," is increasingly acting as a spoiler of all other branches of the economy. Investment in the vast railroad network has been neglected in the recent past. The result is that the system is now undercapitalized and overloaded. Performance indicators, such as the average speed, turnaround times, and freight car utilization factors, have been deteriorating steadily. Railroad cars are hoarded by regional authorities with the result that shipments are delayed.

One of the country's biggest construction projects is the Baykal-Amur Railway (BAM), but with its completion the bottleneck in Western Siberia and westwards to the Urals, where there is only one line, will remain.

The U.S.S.R. has the sixth largest merchant fleet in the world and the largest number of general cargo vessels. It continues to expand, mainly to reduce the Soviet dependence on Western ships for the carrying of bulk cargoes. Fleet performance was expected to increase by more than 22% during the 1976-80 period. A net increase of 3.4 million deadweight tons in fleet capacity is planned for the same period after allowing for the retirement of 1.6 million deadweight tons.

The second section of the Vostochnyy (Nakhodka) terminal for oceangoing container ships was to be commissioned at the end of 1980. Like the first section, this will be fitted out with Japanese equipment. By the mid-1980's Vostochnyy will be the largest port of the Pacific Coast.

TRADE

The Soviet Union trades with 131 countries, and for 111 the trade is based on interstate agreements. The trade continues to be oriented towards imports of large quantities of Western industrial machinery and technology (including complete industrial plants) and substantial grain purchases. The Soviets rely heavily on both foreign Government-backed and commercial credits to finance the increasing foreign currency deficit. Exports of minerals help pay for these imports.

In the Soviet minerals economy, international trade is given high priority. Since the value and volume of trade are both outlined in the national plans, foreign trade reflects national goals and priorities. There is, therefore, an implied commitment to export to achieve a desired trade balance, and this can result in sales below world prices. Domestic consumer demand is a less important motivation than exports. Almost all exports could easily be consumed domestically.

Exports in 1979 increased 6.7 billion rubles to 42.4 billion rubles, while imports increased 3.4 billion rubles to 37.9 billion rubles. The centrally planned economy countries of the CMEA nations account for 52% of the Soviet foreign trade turnover in 1979 compared with 56% in 1978. The Soviet trade with developed countries grew by 31%, increasing from 20 billion rubles in 1978 to 26 billion rubles in 1979. Most active here are the Federal Republic of Germany, the United States, France, Japan, and Finland. Soviet trade with developing countries amounted to 11%, reaching a total of 9.5 billion rubles in 1979.

Fuels, mineral raw materials, and metals play the largest role in Soviet exports, representing over half of total official exports during 1979. Fossil fuels have been the top export category since 1974. Commodities falling within this classification include crude oil and petroleum products, natural gas, coal, and coke.

Large-scale and long-term cooperation increasingly accounts for the rapid growth in Soviet trade with Western countries, which more than quadrupled in the 1970-78 period, showing a rise of 15 billion rubles. The U.S.S.R.'s main exports to Western Europe are crude oil, petroleum products, and natural gas. Western Europe has been an importer of Soviet natural gas since 1968, when a branch of the Brotherhood Trunkline, which feeds Eastern Europe, reached Austria. Exports contracts have since been signed with Federal Republic of Germany, France, Italy, and Finland, guaranteeing shipments of natural gas over a 20-year period. Natural gas exports will soon become the Soviet Union's second main trade commodity (after petroleum). More than half of the hard currency earnings come from oil and gas sales. Shipments to France were scheduled to begin in February 1980 under a 4-billion-cubic-meter annual contract.

Soviet foreign trade continues to be oriented towards imports of needed machinery and equipment, including complete industrial plants. Also important are the substantial grain imports. In 1979, the volume of total official Soviet trade with leading Western developed countries, in billion rubles, was as follows: Federal Republic of Germany, 4.2: United States, 2.8; France, 2.6; Japan, 2.6; Finland, 2.6; Italy, 2.2: United Kingdom, 1.9; Netherlands, 1.1; Austria, 0.8; and Sweden, 0.8.

The Soviet Union adopts an unpredictable gold sales policy, presumably geared towards the international price. Estimated sales of Soviet gold decreased from 1978 to 1979. Despite the reduction, however, the value of gold sales in 1979 was about the same as in 1978. The absence of Soviet supplies of platinum-group metals over the past 2 years cannot be regarded as permanent, and export of platinum-group metals must return to normal levels in the future.

Exports of chromium have fallen, and the U.S.S.R. is withholding high-grade chromium supplies. Reportedly, the Rochester Gas and Electric Co. of the United States is to import $45 million worth of enriched uranium from the U.S.S.R. The import involves 94,600 pounds of enriched uranium to be imported over a 5-year period ending in 1984.

The U.S.S.R. provides nearly 100% of the Comecon countries' imports of crude oil, natural gas, pig iron, and electric power, about two-thirds of their petroleum products, rolled ferrous metals, and phosphorous fertilizers, about 60% of their coal and manganese ore, and up to 90% of their iron ore. Of the six East European members of Comecon, only Romania and Hungary do more business with the West than the U.S.S.R. Soviet exports of fuel and power to its Comecon partners in 1981-85 are to be 20% higher than under the 1976-80 plan. Most of this increase will probably consist of natural gas. For oil, iron ore, and other raw materials, the East Europeans pay the Soviets less than world market prices, and they pay in rubles. The Soviet Union's exports permit a controlling influence over the economies of its Comecon satellites. In Eastern Europe, this control rests largely on the fuels and energy trade. Romania is the only country producing moderate quantities of oil; all others are heavily dependent upon liquid fuel imports. The U.S.S.R. has a controlling influence over the metallurgical industries of the Comecon nations through exports of coke and ferrous and nonferrous metals. Soviet mineral import dependence is shown in table 5.

From a net exporter of steel and rolled products the Soviet Union became a net importer in 1978, and total steel imports are second only to grain in value.

The Soviet Union now buys two-thirds of all the large-diameter steel pipe manufactured in the Federal Republic of Germany, and it will import large quantities of Japanese pipe in the future. The Soviets planned to import some 0.7 million tons of Japanese large-diameter pipe in 1980.

COMMODITY REVIEW

METALS

Aluminum.—The Soviet Union, second only to the United States in aluminum production, operated 14 primary reduction plans, with a total probable annual capacity of 2 million tons in January 1980. Production of alumina and aluminum fell short of the planned increase[37] because planned goals were not reached at the Krasnoyarsk, Regar, and several other plants, and output did not start at the new potline at the Tadzhik plant.

During the 1966-75 period, the output of aluminum grew by 220%. Under the present 5-year plan, output in 1980 was scheduled to be 20% to 30% above the 1975 level; the regions east of the Urals are to account for the entire increase. To achieve the goals, it is planned to put into operation several potlines at the Tadzhik and Sayansk plants and to complete construction of the Krasnoyarsk plant in Siberia. It is also planned to accelerate construction of additional alumina facilities at the Bogoslovsk and Uralsk plants in the Urals and at the Kirovabad plant in Azerbaydzhan. The Nilolayev alumina plant, with an annual capacity of 1 million tons, was to be completed by 1980. Due to slow construction and delays in the delivery of equipment, construction of the first half of the Regar plant in Tadzhikistan and the first potline at the Sayansk plant was deferred until 1980.

Aluminum is produced more for export than for domestic consumption, and the U.S.S.R. has exported approximately 500,000 tons in each of the past 6 years. Primary and secondary aluminum is exported to European countries, Japan, and the United States. Exports were expected to increase to about 600,000 tons in 1980.

The domestic wholesale price of different grades of aluminum is indicated by the following figures from Finansy S.S.R. (July 1978): A995 grade, 2,250 rubles per ton; A95, 1,050 rubles per ton; A85, 710 rubles per ton; A0, 630 rubles per ton.

Construction continued at the Krasnoyarsk, Regar (Tadzhik), and Sayansk primary aluminum plants. At Krasnoyarsk, the second largest aluminum plant in the country, one potline (No. 14) was completed in July 1978. Construction of the enterprise is nearing completion. The No. 2 potline at the Regar plant was commissioned in October 1978 and No. 3 in November 1979. It was planned to put into operation two potlines (Nos. 3 and 4) at this plant in 1979. Output of metal at the Regar plant has increased by almost one-third. Renovation of potlines at the Bratsk plant started in 1978. The first potline at this plant was commissioned in 1966 and the last one (No. 18) in 1976.

The first potline of the Irkutsk aluminum plant was brought onstream in 1962, and the last one (No. 8) was put into operation in 1971. The total probable capacity is 240,000 tons per year, and probable 1979 output was 200,000 tons. It is planned to increase capacity of this plant by 20% to 25% during the 1981-85 period. The plant produces aluminum wire and ingots. About one-third of production is exported. The plant's raw material comes from the Urals.

Reportedly, two contracts worth $4.3 million have been concluded between the Soviet Union and the Italian-based company Coe e Clerici, Genoa. The contracts provide for the supply of primary aluminum by the U.S.S.R. in exchange for aluminum foil from the Italian company.

Table 8.—U.S.S.R. estimated capacity and production of primary aluminum plants

(Thousand metric tons)

Plant	Operations began	Probable annual capacity Jan. 1, 1979	Probable output 1978
Bogoslovsk	1945	140	120
Bratsk	1966	540	450
Dneprovsk	1933	70	60

Krasnoyarsk	1964	390	275
Nadvoitsa	1954	35	25
Novokuznetsk	1943	160	135
Regar (Tadzkhik)	1975	60	35
Sumgait	1955	70	60
Uralsk	1939	135	120
Volkhov	1932	20	15
Volgograd	1959	125	90
Total		2,085	1,660

Although the Soviet Union is a large producer of low-grade bauxite, supplies are insufficient and it is developing alumina production from nepheline and alunite. The alumina is produced in the U.S.S.R. only at the Volkhov aluminum plant and at the Pikalevo complex in Leningrad Oblast' from the nepheline concentrates of the apatite complex in the Kola Peninsula and the Achinsk alumina plant from nepheline rock in Siberia. In 1978, over 79% of primary production was derived from bauxite, 18% from nepheline, and less than 3% from alunite.

Construction of reduction plants has outstripped the construction and expansion of alumina facilities. The Urals possess deposits of high-quality bauxite, and Soviet alumina production is concentrated at the Ural and Bogoslovsk aluminum plants. Alumina production in the Urals is being expanded by the new Bogoslovsk-2 alumina shop.

Production of alumina in Kazakhstan increased by 98% during the 1967-76 10-year period. It was planned to increase production of alumina in 1978 by 1.3% over the 1977 level and at the Uralsk aluminum plant, in particular, by 30,000 tons per year in 1978. In practice, additional facilities, with an annual capacity of 10,000 tons, were put into operation only at the Uralsk plant in June 1979. Because of poor recovery of alumina from nepheline rock at the Achinsk plant, it is planned to construct a nepheline concentration plant at this complex in the 1981-85 period. Construction of the Pikalevo No. 2 alumina-from-nepheline plant is also forseen for the 1981-85 period.

The Achinsk alumina-from-nepheline plant achieved only about two-thirds of its designed capacity of the first stage (two lines). The second stage (three lines), which was under construction, was scheduled for completion in 1980.

The Kirovabad alumina-from-alunite plant in Azerbaydzhan started production in 1965 but has not reached its planned output. A massive capital investment was allocated to this plant for the 1976-80 period. New facilities for alumina-from-bauxite were commissioned at this plant in October 1978 and capacity of the plant increased by 50%.

Pechiney Ugine Kuhlmann is currently building an alumina plant at Nikolayev near Odessa on the Black Sea, following an agreement concluded in July 1976. The first stage of the plant was to be operating in 1980, and full production of 1 millon tons was planned for 1981. The alumina will be transported from this site some 6,000 kilometers to the Sayansk plant in Siberia. Reportedly, the plant is being built under a barter agreement, and Pechiney is to receive 500,000 tons of aluminum from the Soviet Union. According to Socialist Industry,[38] 6,000 workers were employed on construction in 1979. The first stage of the Dneprobugskiy bauxite port was put into operation in November 1979. The new port will handle bauxite for the Nikolayev plant.

Major reserves of presently minable bauxite are situated in the Turgay in Kazakhstan, on the eastern slopes of the Urals, and in the Tikhvin area of Leningrad Oblast'. About 75% of the reserves are in the Asian part of the U.S.S.R. Bauxite is the main source of alumina in the U.S.S.R., although the grade is frequently low and transportation often presents a problem. Large quantities of high-grade bauxite and alumina have been imported from Guinea, Greece, Yugoslavia, Hungary, India, and other countries. The U.S.S.R. buys around 30% of Greek bauxite exports. In 1978, the Soviet Union delivered 147,000 tons of aluminum in return for 394,000 tons of Hungarian alumina. The difference between exports of metal and imports of alumina is the sum Hungary paid to the Soviet Union for the smelting of its own alumina.

The Turgay bauxite open pits in Kazakhstan, the main supplier of raw material for the Pavlodar alumina plant, doubled ore production over the period 1968-76. The Verkhne Ashutsk open pit of the Northern mine of the Turgay mine administration was put into operation in October 1978.

Development of the Belinsk mine at Turgay did not start until 1979, although completion had been planned for 1980. Although ten ESh 15/90 draglines and more than 50 BelAz trucks were in operation at Turgay in 1979, overburden removal was behind schedule. Shortage of housing, 33% turnover of workers, and low labor productivity resulted in poor performance of the Turgay group of open pits.[39] There are from 8% to 20% alumina losses during the processing of bauxite. The reserves of the Vezhayu-Vorykvin bauxite deposit in Komi A.S.S.R. and the Vislovsk deposit in Belgorod Oblast' were confirmed in 1978.

The U.S.S.R. operated 15 secondary aluminum units with a total estimated annual capacity of 190,000 tons in 1978.

The U.S.S.R. has given financial and technical assistance for projects in Egypt, Guinea, India, Turkey, and Yugoslavia in exchange for bauxite and alumina. Reportedly, Jamaica has agreed to supply 250,000 tons per year of alumina to the Soviet Union under a long-term contract from 1984 onwards. Until then, the latter has agreed to purchase a minimum of 50,000 tons per year of alumina, starting in 1980. A feasibility report on the erection of an alumina plant, with a capacity of 60,000 tons per year, is to be submitted to the Indian Government.

Discussion on construction of an alumina plant in Greece by the U.S.S.R., with an annual capacity of 400,000 tons, continued in 1979. The anticipated yearly production would be imported by the Soviet Union as payment, and some may go to Bulgaria and Poland.

The Soviet Union has helped Guinea to develop a bauxite mine. It has also agreed to carry out feasibility studies on a proposed 600,000-ton-per-year alumina plant for Guyana's State-owned Bidco.

Antimony.—The Kadamzhay complex in the Kirgiz S.S.R. is the principal antimony center, where integrated facilities produce most of the country's refined products. Output at this complex was to increase by 50% in the 1976-80 plan period.

Construction of the new Aznob mine and mill unit (Dzhidzhikrutskiy complex) in Tadzhikistan continued slowly in 1978-79. Completion of the first stage was scheduled for 1975 but was rescheduled for 1980. Deposits of antimony also occur in Kazakhstan and Sarylakh and Tazhdolinsk in Siberia. Production of antimony at the Ust'-Kamenogorsk lead-zinc complex increased slightly in 1979. Detailed exploration of the Novoye antimony-mercury deposit in Kirgiziya continued in 1979. The wholesale price of antimony in the U.S.S.R. is 2,350 rubles per ton for SU0 and 1,850 rubles per ton for SU2.

Arsenic.—Arsenic ores contain 0.2% to 0.5% As_2O_3. Small arsenic deposits are located in Tadzhikistan, but all output in 1978-79 was obtained as a byproduct from the smelting or roasting of metallic ores. The only plant in the U.S.S.R. to recover arsenic from sulfur has been installed at the Mednogorsk copper and sulfur complex in Orenburg Oblast'.

Beryllium.—The Soviet Union continues to be one of the world's largest producers and consumers of beryl, beryllium alloys, and metal. Beryllium is found in variable quantities in most of the pegmatites all over the U.S.S.R. There are numerous deposits mainly in Kola Peninsula, Kazakhstan, Urals, Altay, Transbaykal, Soviet Far East, and Western Ukraine. Domestic reserves are more than adequate. Production is being expanded. It is planned to recover beryllium from the Dzhidinsk tungsten and molybdenum ores in Buryat A.S.S.R.

Bismuth.—Bismuth is recovered as a byproduct of lead and zinc smelting in Kazakhstan and other areas in the Soviet Union, from dust and crude metal at the Balkhash, Kirovograd, and Mednogorsk copper complexes, and from tungsten and molybdenum ores. Two copper bismuth deposits (Taryzkan and Kantarkhana) are under exploitation in Tadzhikistan. The Ustarassy mine in the Chatkal Mountains is the only enterprise to mine bismuth ore. Its concentrates are shipped to the Chimkent lead plant in Kazakhstan for processing.

Renovation and enlargement of bismuth production facilities at the Dalpolimetall lead complex in the Primorsk Kray began in 1979. In 1980, the complex is to begin receiving bismuth-bearing ore.

Cadmium.—Cadmium is produced at various lead and zinc smelters and at some copper complexes as a byproduct. Kazakhstan continues to be the national leader both in reserves and production, and the Leninogorsk polymetallic complex there is one of the largest producers. Average overall Soviet cadmium recovery was about 50%.[41]

Chromium.—The U.S.S.R. continued to be the world's second producer and exporter of chromite in 1978-79. About 75% of exports were destined for market-economy countries. Approximately 70% of the output was consumed or stocked in the Soviet

Union. Based on 1978 data, Soviet consumption of chromite was distributed as follows: Metal production 45%, refractories 35%, chemical and other products 20%.

Chromium ores are situated at Kazakhstan and in the Ural Mountains. The Donskoye operation at Khrom-Tau in Western Kazakhstan, which produces 95% of the Soviet output, is the only supplier of high-quality ore. Deposits in the Ural Mountains have a low chromium oxide content (20% to 40%), as well as a low Cr_2O_3:FeO ratio. These are mostly used in the chemical and refractories industries. It was planned during the 1976-80 period to put into operation new facilities for production of 2.55 million tons per year of crude ore. Development of the open pit at the "40-years of Kazakh S.S.R." mine was nearing completion. For transportation of overburden, M-120 Unit Rig dump-trucks (109-ton capacity) are used.

Currently, the south Kempirsay chromite deposits are being mined by the Ob'yedinennyy mine (Millionnyy, Gigant, and Geofizicheskiy open pits), the 20th Anniversary of the Kazakh S.S.R. mine (Yuzhnyy open pit), and the 40th Anniversary of the Kazakh S.S.R. mine (open pit of the same name and the Molodezhnaya underground mine, which is under development). Beside these large deposits, the small, shallow Spornoye, No. 16, No. 28, No. 29A, and Geofizicheskoye V deposits are currently being mined or are under development for surface mining. For the mining of deep parts of the "Millionnoye," "Almaz-Zhemchuzhina," "Pervomayskoye," and No. 21 deposits, the Tsentral'naya underground mine will be developed. Mines for the extraction of chromite ore from a maximum depth of 1,200 meters are under development at the Donskoye mining and concentration complex in Aktyubinsk Oblast'.

Marketable ores include those with a chromium oxide content of at least 45%, a maximum silica content of 10%, and a maximum lump size of 300 millimeters. Ore preparation at the Donskoye mining and concentration complex consists of crushing, grading, and handpicking. Rich and lean ores are blended. From 1974 through 1978 (first stage of the plant began operation in 1974), 1,556,000 tons of feed material with a chromium oxide content of 42.8% was processed, and 973,000 tons of concentrate with a chromium oxide content of 50% to 56% was obtained. Designed capacity of the gravimetric concentrator is 1 million tons per year of feed.

During the 1975-77 period, the concentrator's marketable output increased by 110%, reaching 435,000 tons, with an average chromium oxide content of 49.8% in 1978. It was planned in 1978 to put into operation additional annual capacities of 700,000 tons of crude ore, to accelerate development of the Molodezhnaya underground mine, and to attain the planned output of the concentration plant, by producing 575,000 tons of concentrate (30% over the 1977 level) with an average chromium oxide content of 50.8%. These targets were not met, however. Output of marketable chromite from the Saranov underground operation in the Urals is estimated at about 5% of the total Soviet production.

Cobalt.—Cobalt reserves are chiefly in nickel-cobalt ores and in cobalt ores of the Khovu-Aksinsk deposit in the Tuva Autonomous Republic. Production continues to be concentrated at Norilsk in East Siberia; at Monchegorsk and Pechenga on the Kola Peninsula; in the Urals at the Yuzhuralnikel, Ufaley, and Rezhsk plants; and at some copper plants. Recovery of cobalt remains low, especially from the copper pyrite ores of Bashkiria. The planned production cost of cobalt in concentrate at the Pechenganikel complex was 6,780 rubles per ton.

Cobalt production rose by 16% between 1970 and 1975, and probably increased by a similar amount during the 1976-80 period. The planned increase of cobalt production at the Norilsk complex by 5.8% was not met in 1979. Since the beginning of 1976, capacity of the Tuva cobalt complex almost doubled as a result of renovation. During the 1975-78 period, production of cobalt at the Norilsk complex increased by 35%.

Large quantities of Cuban nickel-cobalt concentrates have been shipped to the Soviet Union.

Copper.—There are 13 smelters, with a total probable annual capacity (January 1978) of 1.1 million tons, and 13 refineries in operation in the U.S.S.R. The secondary blister copper is produced by the Kirovgrad smelter in the Urals, by the Moscow smelting and electrolytic plant, and by several small units of secondary nonferrous plants. The wholesale prices of copper-ingot are CBIA, 890 rubles per ton; CH1 and CH2, 860 rubles per ton. Exports of copper increased from 123,000 tons in 1970 to 205,618 tons in 1975. Estimated exports in 1980 are 250,000 tons.

Under the 10th 5-year plan, output of copper in 1980 was scheduled to be 20% to 30% over the 1975 level. The plan provided for 80% of production to come from the Asian part of the U.S.S.R. by 1980. The

1976-80 plan called for a 25% increase in refined copper production in Kazakhstan. The planned targets for copper production in this Republic were not met in the 1976-79 period. Soviet planned output of copper in 1979 was not attained.[42] Some evidence indicated that the 1980 copper production in the Soviet Union would amount to about 1 million tons. Over the period 1976-80, the increment would be about 14%. Production is estimated at a probable 1.1 million tons in 1985 and 1.3 million tons in 1990.

Reverberatory smelting continues to be the main process, and the change over to natural gas fueling has improved conditions for workers and made it possible to improve copper extraction. At the Almalyk complex in Uzbekistan and Sredneuralsk plant in the Urals, the use of oxygen in the reverberatory furnaces made it possible to improve the melting of the charge by 20% to 25%. Plans are to replace reverberatory smelting of blister by the oxygen-flash process at the Krasnouralsk plant in the Urals.

The country operates 40 concentrators with a total probable annual capacity of about 5 million tons of concentrates. Production of concentrates in 1979 has been estimated at 4 million tons with an average copper content of about 20% (from 12% to 36%). Sixty-five underground mines and open pits produced an estimated 125 million tons of ore in 1979. Approximately 80% of all ore was mined by open pit methods. Up to 10% of primary copper is produced as a byproduct.

The main copper ore regions are located in Central and Eastern Kazakhstan, the eastern slope of the Ural Mountains, Uzbekistan, the Transcaucasus, Eastern Siberia, and Norilsk. Among other regions containing copper deposits of lesser importance are the Northern Caucasus, Western Siberia, and the Kola Peninsula.

Kazakhstan contained about half of the total copper reserves in 1979 and is the main producer. There are 48 known copper deposits in the Republic, of which 19 (containing two-thirds of the Republic's copper reserves) were under exploitation in 1979. Important copper deposits are located in four main areas: Dzhezkazgan, Kounrad, Boshchekul, and the Altay. The 1976-80 5-year plan called for a 25% increase in refined copper production in Kazakhstan. During the past decade copper ore mining increased by 30% but planned targets for production were underfulfilled in 1976-79.[43] The Irtysh copper smelter has been under construction for 12 years and only 25% has been completed.[44] At the pilot plant of this complex, a Kivset process for treating copper-zinc sulfide concentrates was tested.

During the 1976-78 period, output of blister copper at the Dzhezkazgan complex in Kazakhstan increased by 17% and that of refined copper by 20%. There are three underground mines and one open pit in operation. Development of the Annensk mine at this complex continued in 1979. At the Balkhash complex, the largest copper producer in the U.S.S.R., the assembly of a nonferrous metal rolling mill was completed in January 1978. Construction of a new copper smelter at the Irtysh complex in Kazakhstan, which started in 1968, continued in 1978-79.

The Kounrad and Sayak mines are the main suppliers to the Balkhash complex in Kazakhstan. Four open pits (Sayak-I, Sayak-II, Sayak-III and Tastau) were in operation at Sayak. Expansion of the Sayak open pit at the Balkhash complex continued. The Sayak No. 4 open pit was put into operation in August 1979. Construction of the Zhezkentskiy complex, Nikolayevsk concentration plant and development of the Nikolayevskiy open pit in Kazakhstan continued in 1979. Exploration of the Koksayskoye copper deposits in Kazakhstan has been completed. Exploration in the Republic continues, but shortages of drilling rigs and trucks have limited operations.

The Ural region occupies second place as a copper producer. The deposits are mostly copper pyrites and contain zinc, gold, silver, and other metals. There are over 100 individual pyrite deposits in the Urals. Copper ore is surface-mined at Uchalinskiy, Mezhozerskiy, Sibayskiy, and Gayskiy and deep-mined at Degtyarsk, Karabash, Gayskiy, Imeni III International, and Levikhinskiy. With the development of the Gayskiy, Uchalinskiy, and Ob'edinennyy open pits of the Uchalinskiy complex and the decline of the Degtyarsk, Krasnouralsk, and Karabash underground mines, the proportion of open pit ore has increased from 39% in 1958 to 75% in 1979. This trend is expected to continue. The Krasnoural'sk, Kirovograd, and Karabash copper smelters in the northern Urals have experienced major shortages of concentrates, and one-third of their feed has been transported from Central Asia, the Altay region, the Caucasus, and other regions. It is planned to increase production of ore at the Gayskiy complex by development of a 1,200- to 1,600-meter-deep mine.

Uzbekistan holds third place; the copper-porphyry occurrences near Almalyk and

Kalmakyr are of great industrial significance. The Almalyk complex is one of the largest copper-producing centers in the U.S.S.R., and it is planned to invest 29 million rubles to double ore production in the future by development of the newly discovered and explored Dal'neye and other deposits. It is also planned to replace the reverberatory furnace at the Almalyk complex with a second oxygen-flash smelting furnace by 1984. It is expected to increase output of copper at this complex by 40%.

The Zangezur copper-molybdenum complexes and the Alaverdy metallurgical plant in Armenia showed a poor performance in 1979. The planned production goals were not met, and copper recoveries were much below design expectations. A new level, No. 950, was added to the open pit of the Zangezur copper and molybdenum complex. The copper concentrates from Kadzharan, Agarak, Madneuli, and Urup mining and concentrating complexes are shipped to the Alaverdy complex.

During the 1976-80 period, extraction of ore at the Bashkirskiy copper and sulfur complex in the Urals was to be increased by 37% and processing of ore by 30%. Assembly of shovels began at the Uchaly mining and beneficiation complex in Bashkiria, where the third open pit, the Molodezhnyy, is being developed for the production of copper and zinc. The first shafts for underground mining are also being sunk.

During the 1975-78 period, output of refined copper at the Norilsk complex increased by 7.2%. It was planned to increase production of refined copper by 3.2% in 1979. The country's deepest shaft, at the Taymyr copper-nickel deposit of this complex, has been sunk to the planned depth of 1,415 meters. A parallel ventilation shaft is now being sunk. Construction of the Norilsk No. 2 copper and nickel smelters with Finnish technical assistance continued in 1979. Flash smelting plants for copper and nickel from Outokumpu Oy, Finland, have already been delivered. The smelters' capacity will be 650,000 tons per year of copper concentrate (200,000 tons copper) and 550,000 tons per year of nickel concentrate (100,000 tons nickel). Completion of the first stages was scheduled for 1980. The first stage of the Nadezhda complex to produce copper-nickel concentrates (Norilsk No. 2 copper and nickel smelter), which has been under construction for 8 years, was commissioned in October 1979.

The first stage of the anode plant at the Severonikel complex in the Kola Peninsula was completed in 1978. A blister copper smelter is under construction at the Solnechnyy complex in Khabarovsk Kray. It is to be commissioned at the beginning of the 1981-85 5-year plan. Byproduct copper concentrates are produced from the polymetallic ores of 14 deposits in Tadzhikistan.

Copper reserves of the country in 1979 averaged 1.1% Cu. The reserves are chiefly in low-grade cupriferous sandstones and porphyries but also include high-grade pyritic-polymetallic ores, copper-nickel ores, and smaller quantities of copper-molybdenum and miscellaneous ore types. The gross reserves of the Udokan copper deposit in Eastern Siberia, which has not yet been exploited, amount to over 700 million tons averaging 1.15% copper (20% oxides, 80% sulfides). It is planned to develop this deposit in 1981-90. The Soviet Union has been negotiating from time to time with British, French, and Japanese companies to develop the Udokan deposit "jointly". Reportedly, the Soviet Union asked Japanese firms for loans, technology, and equipment to develop the deposit at the last meeting of the Japan-Soviet economic committee in March.

Practically all of the Soviet copper reserves are in Asia, east of the Urals watershed and south of the Great Caucasus. Exploration for additional reserves is continuing on a large scale. With the exception of the partially depleted copper districts of the eastern Urals, the sources of copper are at considerable distances from the densely populated and highly industrialised European part of the country. This situation is partly responsible for the slow rate of development.

Gold.—Since the early 1930's, few data on Soviet activities in precious metals exploration, production, trade, and stockpiles have been published officially. Available information, however, indicates that in 1979 the U.S.S.R. was probably second among world producers. Over two-thirds came from the Soviet Far East and East Siberia (mainly from placers at Kolyma, Aldan, Dzhugdzhur, Indigarka, Yana, and Chukotka); most of the balance came from gold and polymetallic ores in the Urals, Kazakhstan, Armenia, Uzbekistan, and West Siberia. Substantial quantities are produced as byproduct at nonferrous operations.

Soviet gold production has maintained a steady growth rate. Prompted by the higher international prices, the U.S.S.R. plans to increase production and has been importing large-scale equipment from West Europe, the United States, South Africa, and Japan. Based on ore reserves, geological and mining conditions in the country's largest gold-producing regions, and fragmentary, indirect reporting, production was estimated at

8.2 million troy ounces for 1980.

Soviet gold holdings are secret. Current production does not automatically reach the world market for gold. Soviet sales are conditioned by both economic and political considerations. Throughout the 1970's, the U.S.S.R. has managed its gold sales to the West carefully, and it is likely that this policy will continue. In the past, gold sales have been used occasionally to finance emergency grain imports. With the price of gold soaring to new heights in the world market, it is conceivable that the Soviet Union may use gold revenues to pay for the import of Western equipment to finance hard-currency trading deficits. At the beginning of 1979, the Soviet net hard-currency debt was estimated at over $11 billion.

Dealers estimated Soviet gold sales in 1979 at some 200 tons, about half of the 1978 figure. The Soviet gold enters the markets mainly in Zurich, Frankfurt, and London. Soviet gold and platinum-group metal sales strategy will be critical in shaping world prices of the 1980's. Official gold sales are declining as prices increase.

Although Soviet sources report reserves sufficient for 12 to 15 years at present rate of production, extensive prospecting continues. Several big mines are suffering from lack of reserves, and new mines have been opened in the northeastern parts of the Soviet Far East and the Yakut A.S.S.R. In view of the importance of gold, an intensive search is in progress in the Asian part of the country.

Magadan Oblast' is the main producing center with 35 placer mines, 23 dredges, over 500 sand-washing rigs, and about 1,500 bulldozers. Although the Soviets built the world's most northerly Bilibino nuclear powerplant specifically for the mineral industry, the mines are still primarily dependent for power on diesel generators, and this frequently causes lost gold production. Construction of the Dukat complex in the Omsukchansk County of this Oblast' was begun 11 years ago. More than 12 million rubles have been spent on construction, but due to lack of personnel and shortages of supplies the construction quota for 1979 was not met. Construction of the Karamken mining and concentration complex in Khasinsk County was completed in March 1978. This is the first enterprise in Magadan Oblast', that will extract gold and silver from ore. Completion of this complex was behind schedule for many years.

Development of the Muruntau deposit in Uzbekistan, which was discovered in 1960, continued in 1979. The Muruntau open pit was over 100 meters deep in 1979, and the overburden-ore ratio was 35:1. Special attention was paid in 1979 to improving technology of gold recovery at the Ararat plant in Armenia, which is fed by ores from the Zod deposit. In Yakutia, the second largest gold-producing region, the Lenzoloto Trust was the leading gold-dredging enterprise. The deepest shaft (890 meters) in the Soviet gold-mining industry was under development at the Bestube mine in Tselinograd Oblast' in Kazakhstan.

The Soviet Government has issued its first gold coin of 100 rubles. Soviet production of Olympic gold coins will be limited to 130,000 pieces. The face value sales of the coins outside the U.S.S.R. are expected to reach $150 million according to Soviet sources.

Iron Ore.—In 1979, 71 underground mines and 64 open pits, with a total estimated capacity of 297 million tons of usable iron ore, produced less of direct-shipping ores plus concentrates compared with the 1978 level. There were 92 iron ore concentrators, of which 29 had sinter facilities and 7 had pelletising facilities in operation (Sokolov-Sarbaysk, Kachkanar, Lebedinsk, Kremenchug, and 3 in Krivoy Rog) with a total annual capacity of 37 million tons.

Production of usable ore is scheduled to reach 276 million tons (crude ore 560 million tons) in 1980, compared with 233 million tons in 1975, an increase of about 19%. Output of iron pellets was planned to increase from 27 million tons in 1975 to 62 million tons in 1980. To achieve the planned targets, the following capacity increases were to be accomplished during the 1976-80 period: For usable iron ore, 115 million tons; and for sinter and pelletised concentrate, 22.5 million tons. It was planned to increase capacities at the Lebedin, Mikhaylov, Stoylev (Kursk Magnetic Anomaly-KMA), Dneprov, Northern, Central (Ukraine), Kachkanar (Urals), Kovdor, and Olenogor (Polar region) mining and concentration complexes and to achieve the rated capacities at the Kazsk, Sheregesh, Sokolov, and Bakal underground mines.

Although a large exporter of iron ore, the U.S.S.R. has continuous problems supplying its own plants, both quantitatively and qualitatively. The principal importers of Soviet iron ore are Poland, Czechoslovakia, Romania, Hungary, the German Democratic Republic, and Bulgaria, which represent about 90% of the total Soviet exports.

The iron content in crude iron ore decreased from 50% in 1950 to 44.5% in 1960, 37.3% in 1970, and 35.1% (planned) in 1980. As a result, the ratio of ores subject to beneficiation increased from 37% in 1950 to 86.6% in 1978.

Open pit mining is used in about 74% of the total volume of usable iron ore. In 1978, there were 13 pits, 150 meters deep and more, including 7 pits over 200 meters deep (250 to 265 meters at the Sokolovskiy and Sarbayskiy pits). The main underground mining regions are the Krivoy Rog Basin in Ukraine (60%), Gornaya Shoriya in Western Siberia (16.7%), and the Tagilo-Kuvshinskiy region in the Urals (16.4%).

The total iron ore reserves in place in the $A+B+C_1+C_2$ categories are 111 billion tons (as of January 1, 1976), averaging 34.8% iron. These were distributed as follows: Ukraine 31%; European Centre 24.4%; Urals 15.7%; Kazakhstan 15.0%; Siberia 7.4%; Northwest 3.0%; Soviet Far East 2.5%; and others, 1%. Total national reserves in categories $A+B+C_1$ were estimated at 60 billion tons of ore averaging 38% iron. This figure included 10 billion tons of ore, averaging over 55% iron, which does not require dressing, and 34 billion tons of easily dressed iron ore.

The Ukraine produced over 50% of Soviet iron ore, and the Krivoy Rog Basin produced about 89% of Ukraine's total in 1979. The Kursk region was the second largest producer, followed by the Urals, Kazakhstan, Siberia, and the Kola Peninsula. There were 23 underground mines (10 mining administrations), 9 large, and several small open pits in operation in Krivoy Rog in 1979.

During the 1976-78 period, the following capacities were commissioned at the Dneprovskiy complex (Kremenchug) in Poltava Oblast', Ukraine: 12.5 million tons per year of crude ore, 4.0 million tons per year of concentrate, and 6 million tons per year of pellets. In 1979, facilities for output of 3 million tons of crude ore and 14 million tons of concentrate went onstream. The design capacity of this complex is 34 million tons of crude ore, and 14 million tons of concentrate. At the Severnyy mining and concentration complex in Krivoy Rog, installation of equipment began in another two concentration sections with a total capacity of 1.5 million tons of iron ore concentrate a year. They were to be put into operation by the beginning of 1980, increasing annual capacity to 19 million tons of concentrate.

Some 40 million tons of crude iron ore was produced in the Kursk region in 1979. It was planned to reach 47 million tons by 1980. There were four iron ore producing enterprises in this region in 1979: The KMAruda complex, the first stages of the Lebedin and Mikhaylov complexes, and the Stoylensk open pit. Development of the Yakovlevsk underground mine, which began in 1974, is proceeding slowly, and the sinking of the second shaft (700 meters deep) started in 1979. The Lebedin complex did not meet production targets for any year of the 1976-79 period.

There are shortages of iron ore in the Urals, and over 10 million tons of ore are shipped annually to the Urals from KMA and other regions of the country. Iron ore production in Kazakhstan accounted for 9% of the total, mainly from the Sokolov-Sarbay complex, with an annual capacity of about 30 million tons of crude ore (13 million tons of concentrate and pellets). Facilities for mining of 1 million tons of crude ore and production of 0.4 million tons of concentrate were put into operation at the Kovdorslyuda (Kovdor mica) complex in Murmansk Oblast' in August 1979.

According to an October 1973 agreement, Finnish companies are building the Kostamush iron ore complex in Soviet Karelia about 30 kilometers from the Finnish border. This project will be built in three stages and will have an annual capacity of 8.9 million tons of pellets (24 million tons of crude ore). Construction of the first stage for the production of about 3 million tons of pellets per year began in 1977 and will continue until 1982. Finland will buy up to 1.2 million tons of pellets per year during the 1983-90 period. The deposit contains an estimated 1,200 to 1,500 million tons of ore with an average iron content of 31%. Construction will take from 8 to 10 years. When the first stage is completed, production will be 3.0 million tons of pellets annually from 3.3 million tons of concentrate (8 million tons of crude ore).

Iron and Steel.—While the Soviet Union is the largest steel producer in the world, it may also waste more steel than any other country. According to the various published accounts in the Soviet press, the Soviet industry in 1979 used only 73% of the rolled steel which it consumed, with the remaining 27% being wasted. There is also considerable wastage in the production of steel. Additional use of continuous casting processes could save 1 million tons of steel each year. A careful and exhaustive study of Soviet publications shows that only about 45% of the total crude steel production is efficiently used in the Soviet economy; 55% is remelted or lost.

The 10th 5-year plan called upon the steel industries to increase output quantitatively and qualitatively. Production of crude steel was to increase from 141 million tons in 1976 to between 160 and 170 million tons in 1980. Production of finished rolled steel was to increase from 99 million tons to between 115 and 120 million tons. It appeared unlikely that these quantitative and qualitative goals would be achieved, and that production of steel and finished rolled steel would probably be below 160 million tons and 115 million tons respectively.

Of 126 projects under construction and due to come onstream in 1978, only 93 were actually completed. Construction lagged and still is lagging at a number of important projects, including Lebedin, the Northern and Southern iron ore mining and concentration complexes, the equipping of electrosteel shops at the Donetsk and Uzbek metallurgical plants, and the ferromanganese smelting furnace at the Nikopal plant.[45] The construction of the No. 6 blast furnace (3,200 cubic meters, 2.2 million tons per year of pig iron) at Lipetsk was completed in November 1978.

The cost of increasing crude steel output is considerable. Estimates in Soviet publications range from some 600 million rubles to 1 billion rubles per 1 million tons of increased output. At these prices, boosting raw steel output to the 10th 5-year plan levels would consume most, if not all, of the industry's capital investment funds, which should be some 16 billion rubles over the 5 years.

In 1979, 36 enterprises, operating 138 blast furnaces, did not meet planned production quotas of 114.3 million tons of pig iron. The average blast furnace capacity increased from 1,135 cubic meters in 1971 to 1,258 cubic meters in 1979. About two-thirds of all blast furnaces use oxygen for enrichment, over 83% of the pig iron was produced by partial use of natural gas, and 75% was produced by use of oxygen. It was planned to produce 115 million metric tons of pig iron in 1980.

Renovation of the third blast furnace of the Novolipetsk metallurgical complex was completed in August and No. 1 of the Chelyabinsk complex in October 1979. As a result of an inadequate supply of raw materials, there are production shortcomings at the blast furnaces of the Chelyabinsk complex.[46] The majority of the blast furnaces at the Ukrainian metallurgical plants are operating below their capacities.

Enlargement of the converter shop at Nizhniy Tagil was completed on December 31, 1978; the shop's annual production capacity has been increased by 0.6 million tons. The 120-ton converters have been replaced by new ones of 160-ton capacity. Renovation of the first converter shop of the West Siberian metallurgical works was completed in December 1978. The converter's capacity has increased 0.5 million tons annually. The second oxygen-producing plant, with a capacity of 30,000 cubic meters of oxygen per hour, was commissioned in May 1978.

Construction of the first section of the first stage of the oxygen converter shop (two units, each 350-ton capacity, with the construction cost of 180.4 million rubles) at the Cherepovets plant was not completed in 1979. The total designed capacity of all stages is 5 million tons of steel per year. Construction of a big oxygen converter shop at the Dzerzhinsk works in the Ukraine began in 1978. The first section of the complex was to be commissioned in 1980. It was planned to complete construction of No. 4 oxygen converter at Nizhniy Tagil complex in 1979. Because of the shortage of pig iron, open-hearth furnaces at some plants were underutilized.[47]

The second electric furnace, with an annual capacity of 250,000 tons of steel, at the Uzbek steelworks and the 100-ton electric unit at the Donetsk metallurgical plant were commissioned in 1978. Construction of the steel electric smelting shop at the Orsk-Khalilovo and West Siberian complexes began in 1978.

In 1979, crude steel production from 76 metallurgical works was below the planned quota of 156 million tons. The 1980 plan called for production of 157 million tons of crude steel. There were 42 oxygen converters (including 9 with a capacity of 250 to 300 tons) in operation in January 1980. Construction of the first continuous casting machine began in 1979. It will run 1 million tons of steel into billets ready for rolling. These will go to the large rolling mill, which has already been built. About 10,000 workers were engaged on construction at the Cherepovets complex in 1979.[48] Construction of a big oxygen converter shop at the Dzerzhinsk works in the Ukraine continued in 1979; the first stage was to be commissioned in 1980. Completion of the construction of the No. 4 oxygen converter at Nizhniy Tagil, in the Urals, was rescheduled for 1980. Renovation of No. 1 open hearth furnace at the Amurstal plant in Khabarovsk region started in May.

Development in the electric steelmaking

sector continued. At the Azvostal' works in Zhdanov, a new electric smelting complex with two furnaces each of 250,000 tons capacity was built. This is the second section of the works. The Orsk-Khalilovo works began construction of an electric steel plant, and the first two 250,000-ton furnaces and a continuous casting machine were due to be in operation in 1980. Foundations have also been laid for an electric steel shop at the Kuznetsk works, where four furnaces are to produce 1 million tons per year of steel. A third electrical steel furnace of the same capacity is under construction at the Uzbek metallurgical complex in Bekabad.

Soviet finished rolled steel products output in 1979 was below the planned quota of 109 million tons. It was planned to produce over 109 million tons in 1980.

A rolling mill, with a capacity of 3 million tons per year of cold-rolled steel, is under construction at the Lipetsk metallurgical complex. The first stage of this mill, with a capacity of 1 million tons per year of steel sheet for the automobile industry, was rescheduled for 1980, owing to difficulties in obtaining materials. A rolling mill at the Moscow pipe works was put into operation in April 1979; this is the second mill supplied to this plant by a French firm. Completion of a rolling mill at the iron and steel complex in Beloretsk in the Urals was rescheduled for 1980. At the Zhdanov Il'ych metallurgical works in Donetsk Oblast' construction of a rolling mill, with a capacity of 2.5 million tons per year of sheet for gas trunklines, began in March 1979. At the Bekabad Lenin metallurgical complex in Uzbekistan, the building of a rolling mill began in October 1979. It will form part of an electric steel production complex being built there, where three of the five planned furnaces are in operation.

Renovation plans have been announced for Magnitogorsk. It is planned to replace the 10 existing blast furnaces by larger units, to build an oxygen converter shop, to go over to continuous steel casting, and mechanise all operations. Expansion and renovation of the West Siberian works were underway in 1979. All open hearth furnaces are being modernized and transferred to gas firing using gas from Tumen'.

The Oskol electrometallurgical complex, which will process ore from the Kursk Magnetic Anomaly, has become one of the major construction sites of the current 5-year plan period. This is the first enterprise in the country designed for the production of steel by direct iron reduction. It is being constructed by German firms; in December 1977, Soviet Metallurgimport awarded to Korf Stahl AG and Lurgi Chemie and Huettentechnik a DM500 million contract for four Midrex direct reduction units. A DM 185 million order for a pelletizing plant, with an annual capacity of 2.5 million tons, was awarded to Salzgitter.

In terms of tonnage, the Soviet Union was the largest world producer of steel pipe. The modernization of the 400-millimeter pipe-rolling mill was completed at the Rustavi metallurgical works in Georgia in May 1978. Several pipe manufacturers (Nikopol, Dneprovsk, Il'ich) and engineering works have been publicly criticised for delays in their deliveries to oil and gas industry enterprises. The gas industry has consumed about 4 million tons of steel pipe (including over 3 million tons of 530- to 1,420-millimeter pipe). Construction of facilities for pipe production continued at the Vyksa metallurgical plant in Gor'kiy Oblast'. Pipe developments in the U.S.S.R. include the construction of a new 15,700-ton-per-year pipe mill at the Azerbaydzhan plant and the 320,000-ton-per-year mill at the Severskiy plant in Sverdlovsk Oblast'. A ferroalloys furnace, with an annual capacity of 33,000 tons of ferrochromium, at the Chelyabinsk electrometallurgical complex was put into operation in November 1978. Installation of new equipment, with an annual capacity of 50,000 tons, at the Yermak ferroalloys plant in Kazakhstan began in June 1978. At the Yermak ferroalloys plant in Pavlodar Oblast' in Kazakhstan, the sixth and last electric furnace, with an annual capacity of 50,000 tons, started production in February 1979. This completes the construction of a complex with a production capacity of 300,000 tons per year.

During the 1976-80 period, it was planned to organize the production of 300 new, efficient hot-rolled shapes of steel, 250 cold-rolled shapes, and 20 high-precision shapes. The share of oxygen-converter steel in the total volume of smelting in 1980 was to increase to 34%, and production of steel by electroreduction was to increase to 19.5%. More than half of the capital investment for the development of ferrous metallurgy in the 10th 5-year plan period was assigned to the renovation and reequipment of existing units.

A £128.5 million agreement between the Soviet Union and Pakistan, which will provide more Soviet credits for a Karachi steel plant, was signed in July 1978. The initial designed annual capacity of the plant will be 1 million tons. The first blast furnace is to go into operation in the mid-1980's.

Lead and Zinc.—The Soviet lead and zinc industry is probably the second largest in the world. Estimated primary production in 1980 was 530,000 tons of lead and 775,000 tons of zinc. Reportedly, under the 1979-80 2-year contract, Cyprus Anvil Mining was to supply about 15,000 tons each of lead and zinc concentrates. The wholesale price of lead in the U.S.S.R. is from 530 to 675 rubles per ton.

During the 1966-77 period, output of zinc increased by 80%, but neither lead nor zinc output quotas were reached in 1979 nor in previous years, owing to the slow construction of new facilities and low metal recoveries.[49] Over 10% of the total lead and zinc production was recovered as a byproduct in 1979.

Over two-thirds of ore reserves are located in Kazakhstan, chiefly in the Altay region and in the district of Kara-Tau. There are also large reserves of zinc in the Urals. Exploration of the Uchkulach lead and zinc deposit in Uzbekistan, Chekmar' in Kazakhstan, and Kholodninskoye in Buryat A.S.S.R. continued in 1979. An exploration shaft was being sunk at the Achisay polymetallic complex in Kazakhstan.

Kazakhstan continues to be the leading lead and zinc producer, followed by the Urals, Uzbekistan, Siberia, North Caucasus, and the Ukraine. Production of zinc in Kazakhstan increased by 80% and that of lead by 32% during the 1967-76 period. It was planned to increase production of zinc in Kazakhstan by 8.8% in 1978 and that of lead by 3.1%. The planned quotas for lead and zinc production in Kazakhstan for the 1976-79 period were not met.[50] The planned increase in zinc and lead output for 1978-79 was based on increased production at the Leninogorsk, Zyryanov, and Tekeli complexes, as well as on the completion of the first stage of the Kargayly complex.

The Achisay complex in Kazakhstan, with its three main groups of mines, produced about 70,000 tons of lead, an unspecified quantity of silver, and an unknown quantity of barite in 1978. The Achisay ore contains from 1.5% to 2.0% lead, 13% to 15% barite, and 0.5 ounce of silver per ton.

In other mine and plant developments, the first stage of the Kargayly lead-zinc concentrator in Kazakhstan was completed in June 1978. It will supply raw material to the Chimkent lead plant and other plants. A lead section of the Solnechnyy tin concentrator in the Soviet Far East was commissioned in August 1978. In accordance with the plan for complex utilization of raw materials, a metallurgical plant is under construction at Solnechnyy. The complex is to be put into operation at the beginning of the 1981-85 5-year plan period, and its shops will extract blister lead and copper. Designing of the Ozernoye polymetallic mining and concentration complex in Buryat A.S.S.R. was completed in August 1978. A new shaft-smelting furnace was commissioned at the Chimkent lead plant in Kazakhstan in 1979. Because of ore shortages, production of concentrate at the Leninogorsk polymetallic complex decreased by 50% during the 1970-79 period.[51]

The future development of the ore base of the Altay region in East Kazakhstan is a serious concern to Soviet officials: The output of polymetallic ores has increased fourfold in the past 10 years, but grades have dropped by 40%. A 20% increase in the output of mined ore was reported at the Zyryanovsk complex with a 25% drop in lead-zinc content.

It is expected that the startup of the Nikolayevsk open pit will somewhat improve the situation, but that overall ore shortages will hold back lead and zinc production during the 11th 5-year plan period of 1981-85.[52] In order to compensate for the lack of incoming ore, the Ust'Kamenogorsk lead-zinc complex has begun to process large quantities of metallurgical wastes. Dust and slags from the Pyshminsk and Irtysh copper smelting plants, cakes and clinker from the Ust'Kamenogorsk zinc shop, and slags from old dumps have been treated in the smelting furnaces.[53]

In the Urals, the second largest zinc-producing region, the problem of zinc and gold recovery from the copper-pyrite ores remains unsolved. Slow development of the mines in the Urals has resulted in shortages at the concentrators. There are also shortages of lead-zinc reserves at the Sadonsk deposit in North Caucasus. This is the main supplier to the Elektrotsink zinc plant in Ordzhonikidze.

Magnesium.—Five magnesium plants, with an estimated combined annual capacity of 80,000 tons, were in operation in 1978-79. Production and consumption of rolled metal in the U.S.S.R. is small. Reportedly, over the years of the 9th 5-year plan (1971-75), the output of magnesium and its alloys increased 20%. According to the 1976-80 plan, output of magnesium and its alloys was to increase by 24% to 74,000 tons, compared with an estimated 60,000 tons in 1975.

Manganese.—The Soviet manganese industry remains the largest in the world. About 80% of the total 1979 production came from the Nikopol' Basin in the Ukraine, and the rest from the Chiatura Basin in Georgia. Some 300,000 tons of crude ore were produced in Kazakhstan. During the 1976-80 period, new facilities for production of 6.4 million tons of crude ore were to be put into operation. Estimated production of marketable ore in 1980 was placed at 10 million tons. During the 1976-80 period, the greatest increase in manganese ore output was to be from open pit mining in the Ukraine.

About 20% of manganese exports were shipped to Western countries and some 80% to Comecon countries.

At yearend 1969, reserves of manganese ore in categories $A+B+C_1+C_2$ were estimated at 2.5 billion tons, with an average manganese content of 23% to 26.4%. This included 1,020 million tons in the Nikopol' Basin. Reserves of high-grade ore are located in the Chiatura Basin. Detailed exploration of the Ushkatyn III manganese deposit in Kazakhstan and preliminary examination of the Porozhin manganese deposit in Krasnoyarsk Kray continued in 1979.

The principal Soviet manganese basin, the Nikopol' in the Ukraine, has reserves many times greater than the Chiatura, but the ore (average grade 26.4% manganese) is little more than 2 meters thick and lies under some 80 meters of overburden. Two concerns, the Ordzhonikidze and Marganets, operate in the Nikopol' basin. There were 19 underground mines, 10 open pits, and 9 concentrators in operation in 1979. More than 75% of the ore mined there is from open pit operations. Of the concentrated ore, about 48% had a manganese content of over 45%; the balance contained 34%. The first stage of the new No. 9-10 mine at the Marganets mining concentration complex was put into operation in May 1978; development of the second stage of this mine continued in 1979. The first section of the No. 2 Grushevsk concentrator, with an annual capacity of 740,000 tons of concentrate, was commissioned in July 1978. Construction of the Tavricheskiy manganese complex in Zaporozhye Oblast' began in October 1979. Development of an underground mine at this complex, with an annual capacity of 2 million tons of crude ore, began in July 1979.

The Chiatura manganese basin in Georgia, the richest in the U.S.S.R., produced about 2.5 million tons of concentrates in 1979 from 24 underground mines and open pits and 8 concentrators. Over 80% was extracted from underground mines. Of the total beneficiated ore, 66% of the concentrate contained 48.7% manganese and the rest 25.6% manganese. New mining facilities, with an annual capacity of 350,000 tons of crude ore, began operation at the Chiatura basin in January 1978. The third section of the Akhali Itkhvisi mine in this basin, with an annual capacity of 130,000 tons of crude ore, was put into operation in October 1978. Development of two small mines continued in 1979. They were to be commissioned in 1980.

Small amounts of manganese ore were produced at the Dzezhdy and Atasuy mines in Kazakhstan. The Dzezhdy manganese ore-dressing plant, which was put into operation in May 1965, processed low-grade ore for the Nikopol' (Ukraine) and Yermak (Kazakhstan) ferroalloys plants. Kazakhstan's manganese ore is sulfur-free and does not contain other impurities. The small Zhaksykotyr manganese open pit became operational in 1978. Development of the Tsentral'naya mine of the Dzhedy Ore Administration continued.

Mercury.—In 1978-79, the U.S.S.R. was the world's largest producer of mercury and was apparently self-sufficient. There are numerous deposits mainly in Central Asia, the Soviet Far East, and the Ukraine. The Khaydarkan complex in the south of Kirgiziya, the largest Soviet mercury operation, had four mines and a recovery plant in operation in 1979. At this complex, mercury is mined by both underground and open pit methods. Sinking of the 850-meter Tsentralnaya shaft of the Ulug-Too mine at this complex continued in 1979. A new shaft at the Chanvay mine of the Khaydarkan complex was under development in 1978-79. It is planned to develop the Novoye mercury-antimony deposit at the Khaydarkan complex. The renovation of metallurgical facilities at the Khaydarkan complex continued in 1979 and was scheduled for completion in 1980.

The Nikitovskiy complex in the Ukraine, where over 70% of ore is mined by underground and about 30% by open pit methods, is the second major producer of mercury. Two underground mines (2-bis Novaya and Novozavodskaya) and the Polukupol Novyy open pit were in operation here in 1978-79. The small Zakarpatskiy mercury complex processes ores from the Borkutnoye, Shayanskoye, and other small deposits in Zakarpatskaya Oblast', West Ukraine.

Mercury output in Magadan Oblast' was higher in 1979 than in 1978. Construction of the new Dzidzikrutskiy (Aznob) mercury-antimony complex in Tadzhik S.S.R. continued during the year. Completion of the first stage of this complex had been rescheduled for 1980 from 1976. The development of small deposits is planned in North Caucasus, at Chukotka in Magadan Oblast', and in other regions of the U.S.S.R. Exploration for new deposits in Kirgizia, the Soviet Far East, and other regions of the country continued in 1979.

Molybdenum.—About 50% of the production is based on copper-molybdenum ores from Armenia, Kazakhstan, Sorskoye, and Siberia; over 30% is from the tungsten-molybdenum ores of Tyrny-Auz (Kabardin A.S.S.R. in the North Caucasus) and Dzhida (Buryat A.S.S.R.). The remainder arises from molybdenite ore mined in Uzbekistan and Siberia. There are more than 100 known deposits of molybdenum, mainly in the Urals, but most are too small to be economically mined.

The deposits now in exploitation are in eight geographical areas. Armenia occupies first place, but concentrates are shipped out of the Republic for further treatment. The Zangezur copper-molybdenum complex (the former Kadzharan and Kafan complexes) supplied over 25% of Soviet molybdenum in 1979. Open pit mining and high metal content in the ores have made Kadzharan molybdenum concentrate among the cheapest in the U.S.S.R. However, there are shortages of ore reserves at the Kafan and Agarak mining and concentration complexes. A drying shop for molybdenum concentrate at the Zangezur complex was put into operation in August 1979. It is planned to install a molybdenum converter at the Alverdy metallurgical complex in Armenia.

The Sorsk molybdenum complex in Krasnoyarsk Kray in Eastern Siberia became one of the leading individual molybdenum enterprises of the U.S.S.R. in 1978. Renovation of the 29-year-old Sorsk complex, which began in 1973, continued in 1978-79. The slow increase of the production capacities of this complex has been mentioned in several Soviet published sources. The molybdenum concentrators of the Balkhash metallurgical complex in Kazakhstan and Dzhida tungsten and molybdenum complex in Buryat A.S.S.R. increased output of molybdenum concentrate in 1978. The Chorukhdayron deposit in Tadzhikistan has been almost completely depleted. Currently the Yuzhno-Yangikan copper molybdenum and the Yubileynyy tungsten deposits, both discovered in the 1960's are being mined.

The Tyrny-Auz tungsten-molybdenum complex, which operates the Molibden underground mine and the Mukulanskiy open pit, was undergoing enlargement in 1979. Output of ore at the Mukulanskiy open pit increased. The Chorukhdayransk concentrator processes copper-molybdenum ores from the Chorukhdayransk and South-Yashransk deposits in Tadzhistan. Output of rolled molybdenum in Uzbekistan increased in 1979. Construction of the Zhireken molybdenum complex in Chita Oblast', the completion of which was originally planned for 1975, lagged behind schedule in 1979.

The first stage of the Erdenet copper-molybdenum mining and concentration complex in Mongolia was completed in 1979. Exploration in the 1960's outlined large ore reserves grading 1% copper and 0.02% molybdenum. The concentrates from this complex are shipped to the U.S.S.R.

Nickel.—In 1978-79, Soviet nickel output was second to Canada. During the 1966-75 period, output of nickel increased by 94%. There is a plan to increase metal production by 20% to 30% in 1980 compared with that of 1975. Production was estimated at a probable 155,000 tons in 1980. About half of known reserves consists of low-grade silicate ores. Over 50% of the total reserves is in cupriferous pentlandites, containing commercially recoverable copper, cobalt, platinum-group metals, and some minor metals. Sulfide ores are mined at Norilsk in Krasnoyarsk Kray (East Siberia) and in the Pechenga-Monchegorsk area in the Kola Peninsula. Oxide ores are produced in the Aktyubinsk area of Southern Urals, the Ufaley area of the Central Urals, and the Ukraine. The centers of production, in order of importance, continued to be Norilsk, Urals, and the Kola Peninsula. Of the seven smelters in operation, Norilsk is the most important; Ufaley, Rezh, and Khalilovo smelters in the Urals are a close second; Monchegorsk and Pechenga smelters are third; and the Pobuzhsk ferronickel plant in the Ukraine is fourth. About 20,000 tons of nickel cobalt concentrate from Cuba is smelted in the U.S.S.R. In the future, the Soviet Union will be an important nickel exporter based on both Soviet and Cuban concentrates.

The Norilsk complex in East Siberia is

producing copper, nickel, cobalt, platinum-group metals, gold, silver selenium, and other rare metals. During the 3-year period prior to 1979, production of refined nickel increased by 10.9% compared with a 20% planned target. It is planned to construct the first stages of the No. 2 concentrator and Nadezhda smelter by the end of 1980 and to develop additional mining facilities. The new facilities are to increase capacities for production of nickel by 80%, copper by 70%, and cobalt by 160%. Prospecting is being carried out north of Norilsk.

One open pit (Medvezhiy Ruchey) and one underground mine (Zapolyarnyy) operate the Norilsk I deposit. Two underground mines (Mayak and Komsomol'skiy) operate Talnakh deposit. Four stages of the Oktyabr' underground mine are in operation and a fifth stage is under development. The Oktyabr' mine, the larget underground mine in the nonferrous sector, was to produce about 50% of the total ores at Norilsk in 1980. Sinking of the 1,428-meter ventilation shaft at the Taymyrskiy mine was continued in 1979. The first stage of the Taymyrskiy mine is due to be commissioned at the end of 1981. Prospecting is being carried out north of Norilsk by 30 exploration teams, comprising 270 persons.[54]

During the 1976-77 period, two electric furnaces went into operation after renovation at Norilsk. The capacities increased by 11% to 17%. The third and fourth furnaces at this complex were to be renovated in the 1978-79 years. Construction of the 1,000-million-ruble Nadezhda metallurgical complex at Norilsk, a major project of the 10th 5-year plan (1976-80), continued with the technical assistance of Finnish companies. The capacity is to be 550,000 tons per year of nickel concentrate (100,000 tons of nickel). The autoclaves to be used here are the first in the Soviet Union's nonferrous metallurgy. The first section was put into operation in October. When the Nadezhda complex attains full capacity, it is expected that output of nickel will be doubled. The new facility will be fed by a 32-kilometer slurry line from Talnakh.

The ores at the Severonikel complex at Monchegorsk are mined by both open pit and underground methods. The Zhdanov complex is the largest in this area. Four small underground mines (Kaula, Kotselvaara, Kammikivi, and Northern) and two small open pits (Kaula and Kammikivi) were in operation at the Pechenganikel complex. The port of Murmansk continued handling Norilsk ore for the Severonikel complex. During the 7 to 8 months of the navigation season, some 200,000 tons were shipped; this figure is to be increased in the future. Oxide ore is mined at Promezhutochnoye, Novo-Burenov, Oktyabr', and other deposits. The Scherbakov oxide-ore open pit at the Kempersay region in the Aktyubinsk area of the south Urals in Kazakhstan was put into operation in January 1979.

The U.S.S.R. is financing a $600 million expansion of Cuban nickel production, with output of 20,000 tons per year scheduled for 1985. It was planned to expand production of the Nicaro plant from 18,000 to 22,500 tons per year by 1980, to expand production of nickel at the Moa plant from 18,000 to 24,000 tons per year by 1980, and to construct two 30,000-ton-per-year nickel cobalt oxide plants within 8 kilometers of the Moa plant. The first new plant (Punta Gorda) is scheduled for completion by 1983-84, and the target for the second is 1985-86.

Platinum.—The Soviet Union remains the largest producer and exporter of platinum-group metals, supplying 20% to 25% of international exports of platinum and more than 50% of world consumption of palladium and rhodium. The U.S.S.R. is steadily expanding its output of platinum-group metals. Ore reserves are adequate to maintain production and increased exports for many years. In 1975, it was planned to increase production of platinum-group metals at Norilsk by 60% over 1970 levels. The 5-year plan called for Norilsk output to rise by about 80% in 1980 over that of 1975. But slow construction of the Nadezhda plant has limited Soviet primary production increases to an annual rate of 4% to 5%. Production of platinum and platinum group metals may reach 3.3 million ounces in 1980.

Production of platinum and platinum-group metals comes principally from the Norilsk copper and nickel complex in Krasnoyarksk Kray, the Severonikel and Pechenganikel complexes ("Nikel" association) on the Kola Peninsula, and several small placer deposits in the Urals. Virtually all platinum-group metals were produced as byproducts with over 75% coming from Norilsk. The first section of the Nadezhda plant at the Norilsk complex was put into operation in October. The high priority given to the Norilsk development suggests a determination to proceed with increased production despite high cost imposed by the harsh northern climate. Expansion is expected to accelerate in a few years, with completion of the Oktyabr' underground mine and the No. 2 concentrator, and the attainment of capacity of the first stage of the Nadezhda smelter. The mine, under development since 1969, was scheduled for completion in six stages by 1980; the first four were in operation, and development of stages 5 and 6 was in progress in 1979.

The first of five platinum coins in the 1980 Moscow Olympic series, a 150-ruble piece, was distributed in the United States and Western Europe in November 1978. The coin contains 15.55 grams of almost pure platinum and sells at a suggested retail price of $390. Reportedly, production of the coins is limited to a total of 40,000 with an additional 10,000 reserved for distribution in the U.S.S.R. and other centrally planned economy countries. During the first 9 months of 1978, the United States imported from the Soviet Union platinum-group metals at a value of $25.1 million, including palladium worth $18.6 million, rhodium worth $4 million, and platinum worth $2.5 million.

Silver.—Almost all silver is produced as a byproduct from nonferrous operations although 14 gold treatment plants also produced silver in 1978-79. The Norilsk complex in Krasnoyarsk Kray and some copper-nickel enterprises in the Kola Peninsula are also producing silver. Production continued to be centered in the Urals, Kazakhstan, the Soviet Far East, East Siberia, and Armenia. The recovery of silver at benefication plants in the Urals ranges from 15% to 50% from complex ores containing 6 to 15 grams per ton of silver. The silver content in Soviet lead concentrates fluctuates from 680 to 860 grams per ton.

The ash of burned Soviet film contains almost 0.2% grams of silver per kilogram. The Riga secondary precious metals plant increased production of secondary silver again in 1979, having done so several times in the 1970-79 period. The Moscow plant for secondary production of precious metals is the main producer of secondary silver. The L'vov Electron Production Association collected 227 kilograms of secondary silver in 1979.

Tin.—Although the Soviet tin production policy is based on self-sufficiency at any price, output continues to be inadequate and about 20% of requirements had to be imported in 1979. The Soviet Far East, Yakutia, and Transbaykal were the main tin producers. The estimated output of tin may reach 35,000 tons by 1980. Most new production will come from existing or currently developing mines in the Soviet Far East and Central Asia. In 1979, over 25% of total output was from placers, of which the Soviet Northeast accounted for 75%.

There are shortages of explored tin reserves at many enterprises. The average content in ores ranges from 0.6% to 1% Sn. Intensive exploration programs have been carried out, and new small deposits have been reported. The reserves of the Uchkoshon deposit were confirmed in 1978.

The Maritime Kray is the largest producer, and the Khrustal'nyy complex, which operates both lode and placer deposits, is the largest enterprise there. This complex operated the Khrustal'nyy, Ege-Khaya, Imeni Lazo, Kholodnyy, and Alyakavityy mines in 1979. The Ternistyy and Arsen'evskaya mines of this complex, which were scheduled for completion in 1975, were under development in 1979 and had been rescheduled for completion by 1980. The ore grade is 0.18% to 0.91% Sn at the Arsen'evskaya mine and 0.87% at the Valkumey mine in Magadan Oblast'.

The Khingan complex at Birobidzhan, Jewish Autonomous Oblast', Khabarovsk Kray, the largest tin-producing enterprise in the U.S.S.R., was to produce 12% more tin concentrate in 1979 following renovation of the concentrator. Development of the Berezovyy mine at this complex continued. The Solnechnyy complex operated the Solnechnyy, Molodezhnyy, and Pereval'nyy mines. Expansion of the Solnechnyy complex at Khaborovsk Kray, Sherlovgor in the Transbaykal area, and the Deputatskiy complex in the Yakut A.S.S.R. continued in 1979. The Tagobikul, Kumarkh, Mushiston, and Kaznor deposits of Tadzhikistan are producing small quantities of tin. Ores from both the Svetlyy and Tultin mines are processed at the Iultin complex in Magadan Oblast'.

Three known tin refineries were operating in the U.S.S.R. in 1978-79: Novosibirsk, Ryazan', and Podol'sk (near Moscow). Concentrates from Siberia and the Soviet Far East are shipped to the Novosibirsk plant, which is the principal supplier of tin in the U.S.S.R. It was planned to increase output of metal at the Sherlova Gora, Ege-Khaya, Leningrad, Sinancha, and other smelters. Construction of a tin-processing unit at the Rustavi secondary nonferrous metals plant in Georgia continued in 1979. Reportedly, the Soviet built volatilization plant at Palca near Potosi in Bolivia was completed in 1978. The project for a similar facility at Machacamarca is at the feasibility study stage. Each of these complexes will handle some 400 tons of ore daily, producing 2,400 tons of tin annually.

Titanium.—Production of titanium was programed to be raised 40% in the 1976-80 period. Estimated output for 1980 was 41,000 tons. Soviet reserves of ore are averaging 10% to 20% TiO_2. The industry continued to be based mainly on Ukrainian and Siberian ilmentite and rutile.

The Soviet Union, which was supplying about 35,000 tons per year of titanium sponge to the world market, curtailed shipments in 1979. As a result, prices jumped from under $10 per kilogram to about $40. Reportedly, the U.S.S.R. imported 44,000 tons of titanium ores (ilmenite, rutile, and zircon) from Australia in 1979.

The most important sources of ilmenite are placer deposits on two right-bank tributaries of the Dnieper River in the Ukraine. Major producers continue to be the Samotkanskoye zirconium-titanium alluvial deposit and the Volchanskoye titanium deposit in Dnepropetrovsk Oblast'; the Irshanskoye, Streminogorskoye, and Zelenogorskoye titanium deposits in Zhitomirskaya Oblast'; and the Tarasovskoye deposit in Kiyevskaya Oblast'.

Two complexes, the Irshanskiy using dredges and the Verkhnednepprovskiy, operate these deposits and are the main raw material suppliers for the Soviet titanium industry. Four stages of the Irshansk concentrator were in operation in 1979.

The output of titanium sponge in Kazakhstan was increased by 125% in the 1966-76 period and by 41% over the years of the ninth 5-year plan (1971-75). Output of titanium sponge at this complex was planned to be raised by 7.7% in 1978 over the 1977 level, but later adjusted to 5.6%.

Tungsten.—North Caucasus, Kazakhstan, Uzbekistan, Transbaykal, and the Soviet Far East continued to be the principal producers. Production of tungsten was insufficient to satisfy growing domestic needs, and about one-third of the concentrate requirements were imported. The following deposits were under exploitation in 1979: Tyrny-Aug (North Caucasus), Dzhida (Buryat A.S.S.R.), Chorukh-Dayron, Lyangar, Yubileynoye, and Ingechka (Central Asia), Akchataus, Karaobin, and Verkhne-Kayraktin (Kazakhstan), Iultin (Magadan Oblast'), Vostok and Lermontov (Maritime Territory), and Kul'gutin in Altay region. Most of the deposits in the U.S.S.R. are low grade. Production is estimated at 8,900 tons in 1980. The large deposit in the North Caucasus, the Tyrny-Auz deposit, contains both molybdenum and tungsten. The largest deposits in Kazakhstan are the Verkhne-Kayraktin tungsten and Akchatau molybdenum-tungsten deposits. There are considerable reserves of tungsten at the Ingechke deposit in Uzbekistan and the Jidda deposit in Siberia.

The main producer of tungsten concentrates is the Tyrny-Auz tungsten and molybdenum complex, where both underground and surface methods are used. The Nal'chik plant, based on Tyrny-Auz concentrates, continued operations with the expected increase in tungsten metal output. The Iultin complex is the only tungsten mining enterprise in Magadan Oblast', and extensive improvements are being carried out here. The Chorukh-Dayronsk deposit in Tadzhikistan is almost completely depleted and has been replaced by the Yubileyonye deposit, which was put into operation recently. The exploration of the Bogutin deposit in South Kazakhstan and the Maykhura deposit in Tadzhikistan was completed.

The second stage of the Martime Kray complex was under construction and scheduled for completion in 1982. Originally the richest tungsten ores were mined by surface methods, but an underground mine is now under development.

Vanadium.—The Soviet Union, with large vanadium resources, is becoming an important producer and exporter. The principal sources in 1978-79 continued to be vanadium-rich slag, a co-product with iron from the titaniferous magnetites of the Kachkanar open pits in the Urals. The Nizhniy Tagil metallurgical complex and the Chusovskoy metallurgical plant in the Urals are the enterprises that produce raw material for the production of vanadium and its alloys. Nizhniy Tagil, where the vanadium slag is produced from 130-ton oxygen converters, is the only modern enterprise. The vanadium content of the pig iron at Chusoyoy is 0.54%, and that at Nizhniy Tagil is 0.45%. After devanadisation of the pig iron, the average V_2O_5 content of the slag at Chusovoy is 17.2% and that at Nizhniy Tagil is 21.2%.

The enlargement of facilities at the Kachkanar complex, from 33 million tons of crude ore to 40 million tons, and the processing of vanadium at the Nizhniy Tagil metallurgical complex has made it possible to increase the output of vanadium products considerably. It is planned to develop the Kachkanar No. 2 and to increase production of vanadium in the future. It is also planned to construct special units at some alumina plants for the recovery of vanadium pentoxide as a byproduct from bauxite and other raw materials.

Minor Metals.—The Soviet Union possesses commercial deposits of all the rare metals that have assumed importance in modern rocketry, aircraft, and nuclear energy. However, extraction of many of them remains low. The main deposits are in Kazakhstan, Kola Peninsula, Uzbekistan, Armenia, Urals, Ukraine, Norilsk, Transbaykal, and the Soviet Far East. Known resources of rare metals were sufficient to satisfy the needs of the 1976-80 5-year plan, but prospecting still lagged behind the potential of the main producing regions of the Soviet Union.

The primary sources of rhenium are molybdenite from copper-molybdenum deposits of Armenia, Kazakhstan, and East Siberia. Byproduct rhenium is recovered at the Balkhash and Dzezkazgan complexes in Kazakhstan, at the Kadzharan copper-molybdenum complex in Armenia, at the hard-alloy plant in Uzbekistan, and at some other plants.

The selenium content in the copper-molybdenum ores of Armenia ranges from 3.6 to 10.5 grams per ton and that of tellurium from 1.5 to 6.2 grams per ton. Copper concentrates of Armenia contain 46 to 110 grams per ton selenium and 18 to 62 grams per ton tellurium. There are 110 grams of selenium and 40 grams of tellurium in the charge of the Alaverdy metallurgical complex in Armenia. Extraction of both metals increased there in 1979.

Production of gallium increased at the Chimkent lead plant in Kazakhstan in 1979. Byproduct gallium is recovered from raw materials used to produce aluminum at Volkhov (Leningrad Oblast') and Pavlodar (Kazakhstan) aluminum plants and at the Tikhvin (Leningrad Oblast') alumina plant. The main centers of indium and thallium extraction continued to be the Ust'Kamenogorsk lead and zinc complex (Kazakhstan) and the Chelyabinsk zinc plant. The Ust'-Kamenogorsk titanium and magnesium complex in Kazakhstan began recovering scandium.

During the 1965-75 decade, the production of rhenium began at the Balkhash and Dzhezkazgan complexes and the Chimkent lead plant in Kazakhstan, as well as gallium at the Pavlodar aluminum plant, and vanadium and scandium at the Ust'-Kamenogorsk titanium and magnesium complex. At the Chimkent lead plant, facilities for production of thallium, cadmium, tellurium, germanium, and other minor metals from slag have been put into operation.

Zircon alluvial deposits exploited in 1978-79 included the Samotkan deposit in Dneprovsk Oblast' in the Ukraine. The Verkhnedneprovskiy complex, brought into operation in 1969, increased output of zircon concentrate in 1979. The Mekhanobr Institute in Leningrad has developed technology for recovery of baddeleyite (ZrO_2) from magnetite iron ore of the Kovdor deposit at the Kola Peninsula.

The Soviets claim the world's largest deposits of columbium and tantalum within the limits of the Lovozero massif in the Kola Peninsula. There were two underground mines, the Karnasurt and Umbozero, in operation at Lovozero in 1979. Smaller columbium-tantalum-bearing deposits are found in the Urals, Ukraine, Caucasus, and Transbaykal. The Soviet ilmenite concentrates contain at the average 0.12% Cb_2O_5 and 0.008% Ta_2O_5.

NONMETALS

The Soviet Union produces a wide variety of nonmetallic minerals. However, the resource position varies from an adequacy for many nonmetallic minerals to an apparent shortage of others such as barite, fluorspar, mica, and talc.

Bentonite.—Armenia, Tadzhikistan, and Kazakhstan remained the three principal centers of bentonite production. The Isfara plant in Tadzhikistan, which supplies ground clay for oil well drilling, was renovated, and output is expected to increase more than twofold. New bentonite deposits were found in the Ishdevan mountains in Armenia, and new facilities for production of 130,000 tons of bentonite clay at the Izhdevan complex were put into operation in 1978. Construction of the Barsa-Gelmez clay works in Turkmenistan continued in 1979.

Asbestos.—For the fifth consecutive year, the Soviet Union has maintained its lead over Canada as the largest world producer of asbestos. Over 62% of the total production came from the Uralasbest complex, about 26% from Dzhetygara in Kazakhstan, 10.5% from Tuvaasbest complex in Tuva A.S.S.R., and 1.2% from Kiembay complex in Orenburg Oblast'.

During the 1971-77 period, new facilities with an annual capacity of 1 million tons of asbestos were put into operation. In addition, as a result of renovation, capacity increased by 204,000 tons. Because of the asbestos export expansion in recent years, there was a domestic deficit of about 100,000 tons in 1979. Estimated output for 1980 was 2.6 million tons.

Development in the asbestos industry has been concentrated in the Urals, Kazakhstan, Tuva A.S.S.R., and Orenburg Oblast'. Total output of the seven grades of asbestos at the Uralsasbest complex was estimated at 1.54 million tons. Three open pits at this complex produced 41 million tons of crude ore and dumped 103 million tons of overburden in 1979. It was estimated that mining of crude ore and overburden would be increased from 144 million tons in 1979 to about 150 million tons in 1980, but production of marketable asbestos was expected to remain unchanged at about 1.5 million tons because of reduced grades.

In Kazakhstan, a large complex has been developed for the Dzhetygara deposit in Kustanay Oblast', the second largest in the Soviet Union. The first mill (annual capacity 200,000 tons) was commissioned in 1965. During the 1971-75 period this mill was renovated, and production increased from 259,000 tons in 1970 to an estimated 350,000 tons in 1979. The Dzetygara No. 2 mill (annual capacity 400,000 tons) was completed in 1975 and produced an estimated 290,000 tons in 1979. Total output at the Dzhetygara complex was to fall from 645,000 tons in 1978 to an estimated 640,000 tons in 1980.

The first mill of the Tuvaasbest complex (commissioned in 1964) produced over 60,000 tons in 1979. A second mill was commissioned in April 1976, and estimated production was 200,000 tons in 1979. Total output at this complex was to be increased from an estimated 250,000 tons in 1978 to a planned 265,000 tons in 1980.

Construction of the Kiembay asbestos complex in Orenburg Oblast' (Southern Urals) was started in 1968 and continued in 1979. Seven Comecon members are assisting with this project. It calls for a total contribution of 106.2 million transferable rubles from the six East European member countries. The total cost of the project is 300 million rubles.

The design capacity of the Kiembay project is 500,000 tons per year of grade III through VI from 24 million tons of ore. The first 250,000-ton stage was completed in November 1979, and some 30,000 tons were produced. The output will be shared among the Comecon members in proportion to their contribution. Equipment was supplied by Bulgaria, Hungary, the German Democratic Republic, Poland, and Romania; Czechoslovakia shipped machinery for ore transport. From 1980, some 170,000 tons of asbestos will be supplied annually to the participating countries for 12 years, and afterwards they will be able to extend the agreement for another 10 years.

Prospecting of the Moladezhnoye asbestos deposit in North Buryatia was completed in 1979. Reportedly, it contains about 18 million tons of asbestos and will be mined by surface methods. The original design was completed in 1974, and construction will be started when the western section of the Baykal-Amur railway is built. Exploration of the Sayan asbestos deposit on the border of Krasnoyarsk Kray and Tuva A.S.S.R. in East Siberia was completed, and reserves are estimated at 7 million tons of asbestos. The Lenin complex, with an annual capacity of 200,000 tons, is to be built there. The asbestos lies at a comparatively shallow depth and will be mined by the open pit method. An experimental pit was set up at this complex in 1979. When the complex is put into operation, it will reduce the U.S.S.R.'s asbestos shortage.

Barite.—Barite is mined by both open pit and underground methods at many operations; crude output is concentrated by flotation. About 50% of the country's barite consumption in 1979 was produced domestically; the balance was imported mainly from North Korea, Yugoslavia, and Bulgaria. The main centers of production continue to be Georgia, West Siberia, and Kazakhstan. Construction of a 45,000-ton-per-year complex in Khaishi in Svanetia, Georgia, and the development of the underground mine at the Zharemsk polymetallic complex in Kazakhstan continued in 1979. Production of barite was estimated at 525,000 tons in 1980.

Diamonds.—The U.S.S.R. continues to make progress in expanding its diamond industry, which is centered in Yakutia, where about 20 deposits have been discovered. Production of diamonds was estimated at a probable 11 million carats in 1980. Next to fossil fuels and precious metal exports, diamonds account for a large share of the Soviet Union's overall foreign currency earnings.

Production in Yakut A.S.S.R. started at a small plant in 1957. In January 1979, the industry consisted of the Mirnyy open pit with five concentrators, the Aykhal open pit and concentrator, the Udachnaya placer mine and concentrator, and the Irelyakh placer mine with two dredges. Small quantities of gem and industrial stones are produced from the Vishera River Region in Perm Oblast' (western Urals) where four dredges and two seperation plants were operated at two deposits in 1979. The enlargement of the Udachnyy complex was completed, and the second stage of the concentrator was put into operation in August 1978. A fleet of about 40 75-ton Bel AZ 549 dump trucks are in use at the Udachnaya open pit for ore and overburden. This pit is the second mining enterprise (after the Mirnyy open pit) in the country where these trucks are used. The town of Udachnyy is being built at the diamond deposit at the edge of the Polar Circle.

The principal task of Yakutia's special geological expedition in 1979 was to discover new diamond deposits for which more funds were allocated. The amount of drilling was to be increased from the 1978 total of 110,000 meters to 150,000 meters in 1979. Work was to be concentrated on the most promising areas in the central and northern part of the Yakut A.S.S.R.

Output is about 80% industrial stones and 20% gems. Gem stones are cut at Leningrad, Sverdlovsk, and Smolensk. Sales of cut stones are rising steadily, and substantial increases are expected by 1980. The U.S.S.R. has arranged to market part of its diamond output in Antwerp through a newly formed Soviet-Belgian company in which the Soviet export organization, Almazyuvelirexport, has the controlling interest.

A substantial but unknown quantity of synthetic diamond was produced in 1979 by plants in Kiyev, Yerevan, Moscow, Tashkent, and Poltava.

Nitrogen.—Ammonia production was to benefit from imported technology. Some 26 large ammonia plants were planned to be commissioned in 1976-80, representing 11.4 million tons of the 13.5 million in planned additional capacity. The results achieved by 1979, however, did not appear to justify the goals set in 1976. During the 1976-80 period, equipment for 26 ammonia plants, each with a capacity of 450,000 tons, was to be supplied by Western companies. All these plants will be constructed with the assistance of Toyo and Mitsui Engineering (18 plants), Chemico (4 plants), and Cruesot-Loire (4 plants). Of 14 ammonia plants scheduled for completion in 1978, only one plant, in Togliatti, was commissioned on December 31, 1978. Eight were completed in 1979: Berezniki No. 2, Gorlovka No. 2, Kemerovo No. 2, Cherepovets, Dneprodzerzhinsk, Cherkassy, Odessa No. 2, and Togliatti No. 3. Additional facilities at Sumgait were commissioned, bringing the total capacity to 1.2 million tons per year. Two ammonia plants near Odessa (Odessa Nos. 1 and 2) have been built on a compensation basis under an agreement with Occidental. They will supply urea to the United States in exchange for superphosphate acid.

Phosphate.—The main producing centers continued to be the Apatite Association on the Kola Peninsula and phosphorite deposits at Karatau in Kazakhstan. The Chilisay phosphorite basin in Aktyubinsk Oblast', Kazakhstan, which is under development, will be the third main center of phosphorite production. Deposits of phosphorites also occur in Upper Kama in the Urals, Egor'evsk and Lopatino in Moscow Oblast', Kingisepp in Leningrad Oblast', and some other regions, but the grade is rather low. Generally they produce phosphorite flour with about 19% P_2O_5. The apatite concentrate provided over 80% of all raw materials for the production of phosphate fertilizers. Production in 1980 was estimated at 46 million tons of apatite ore (17 million tons of concentrate) and 19 million tons of sedimentary rock. Over a number of years, the Soviet Union has been progressively reducing its exports of apatite concentrate to Western Europe.

The Khibiny apatite-nepheline deposits are the largest single phosphate source. Mined ore averaging 16.3% is upgraded to 39.4% P_2O_5. The Apatite complex produced an estimated 16.3 million tons of concentrate (44.7 million tons of ore) in 1979 from the following mines: Kirovskiy, Yukspor-skiy, Rasvumchorskiy, and Tsentral'nyy. The concentration is by flotation in two plants. Plant No. 2, with an annual capacity of 11.5 million tons of concentrate (30 million tons of ore), is under enlargement. New facilities, with a yearly capacity of 4 million tons of ore and 1.3 million tons of concentrate, were commissioned at the Apatite complex in 1978. Exploration of the Partomchor apatite-nephiline deposit in the Khibiny Mountains was completed in 1978. It is planned to produce 17 million tons of apatite concentrate (46 million tons of ore) in 1980. By 1990, production of concentrate is to reach 22 million tons from 60 million tons of ore.

A new apatite deposit at Mount Koashva was assigned to the Apatite Association in 1973. The Koashva (Vostochnyy) open pit, with an annual capacity of 7 million tons of ore, was under development in 1979. The first stage of this open pit was rescheduled for completion in 1980 and will be linked to Kirovsk by rail. Detailed exploration of the Nyorpakhsk apatite deposit was completed in 1979, and development was to start in 1980. It will be the sixth mine of the Kola Apatite Association.

At the Kovdor iron ore complex of the Kola Peninsula an apatite concentrate plant with a first-stage capacity of 880,000 tons was commissioned in 1975; the second stage was under construction in 1979. It processes tailings from the iron ore concentration complex. Construction of flotation plant No. 3 at the Apatite Association began in 1979, and the first stage, with an annual capacity of 3 million tons of apatite concentrate, is to be completed by 1985. Preliminary surveys of the Seligdar apatite deposit in South Yakutia were completed in 1979.

There are 45 commercial deposits at the Karatau phosphate basin in Kazakhstan. The five largest contain more than half of the total reserves of Karatau. Seven open pits at the Aksau and Zhantas deposits and the Molodezhnyy underground mine at the Chulaktau deposit produced an estimated total of about 10 million tons in 1979. Surface mining of the Aksay deposit terminated, and sinking of the shaft began in 1978. Development of the Tyesay deposit for surface mining continued in 1979. Approximately 1 billion rubles was to be spent on increasing Karatau's production during the 1976-80 period. It was planned to increase capacity from existing and new mines by about 20 million tons per year of phosphate ore and 13 million tons per year of concentrate by the end of 1980. Three new mines (Kokdzhan, Tyesay, and Koksu) were to start production, and the Zhantas mine was to be enlarged. The second stage of the Novo-Dzhambulskiy phosphate plant was commissioned in 1979. It was planned to produce 9.6 million tons of concentrate and 4.1 million tons of phosphate flour at Karatau in 1980. During 1977-80, the following mines were to be commissioned: Kok-Dzon (annual capacity 4.75 million tons of ore), Tyesay (capacity 2 million tons), Kok-Su, Ur-Bas, Geres, Kis-Tas, and other small mines with a total capacity of 20 million tons of ore and 13 million tons of marketable products.

Development of the Chilisay open pit in Aktyubinsk Oblast', Kazakhstan, began in 1978. It was planned to mine 5.9 million tons of ore and to produce 1.77 million tons of phosphorite flour from this deposit in 1980. Construction of the Chilisay complex continued in 1979. The Voskresensk complex in Moscow Oblast' produced over 2 million tons of phosphate flour in 1979. Production of ground phosphate rock at the Verkhnekansk phosphorite area reached about 0.6 million tons in 1979 and was to reach 0.7 million tons in 1980.

The phosphate reserves in place at the Karatau basin in categories $A+B+C_1$ were estimated in 1978 at about 1.5 billion tons and 500 million tons in category C_2 (overall average grade 21% to 26% P_2O_5). The reserves in place of the Chilisay phosphorite basin were estimated at over 1 billion tons in categories $A+B+C_1$ and about 800 million tons in category C_2.

An agreement on development of a new phosphate mine and auxiliary facilities at Meskala, Morocco, has been reached between Morocco and the U.S.S.R. The contract calls for the Soviets to provide about $2,000 million for development of the mine and construction of a railway linking it to a new harbor to be built on the Atlantic coast. The Soviets will build and equip the mine, which is scheduled to come into production in the mid-1980's at a capacity of 2 million tons per year and to increase to 10 million tons per year by the early 1990's. The capital investment is to be repaid by shipment of phosphate rock, triple-superphosphate, and phosphoric acid to the U.S.S.R. Reportedly, Jordan has asked the Soviet Union to aid the development of a phosphate deposit at Aqaba in return for repayment in long-term supplies of phosphate rock.

Potassium.—The Soviet Union is one of the world's leading countries in potassium ore reserves, production, and exorts of potash salts. Under the 1976-80 plan, output of potash was to increase 35% from 19.1 million tons (41.6% K_2O) in 1975 to 26 million tons in 1980. It was planned to complete construction of Soligorsk No. 4, Berezniki No. 4, and Novosolikamsk No. 1 by 1980. It was also planned to enlarge Solikamsk No. 1 and Soligorsk No. 3 by 0.2 million tons per year each and No. 3 Berezniki by 0.14 million tons per year during the 1977-80 period.

The total output of the potassium mines in the U.S.S.R. exceeded 60 million tons of ore in 1979. The estimated level of potash output for 1980 was 18.5 million tons (41.6% K_2O). The U.S.S.R.'s major market for potash remains the centrally planned economy countries of East Europe.

Gross potash reserves are reported at 22.9 billion tons of 16% to 40% K_2O content (3.8 billion tons of K_2O). About two-thirds of the reserves are located at the Upper-Kama basin in the North Urals. Reserves are principally carnallite and sylvite with a 13% to 20% K_2O equivalent. The second largest reserve region (4.6 billion tons) is Starobinsk (Soligorsk) in Belorussia, which contains sylvite (16% to 20% K_2O). The third important basis, Livov Oblast' (2.9 billion tons), is in the West Ukraine. The reserves of potassium ores in the Karlyuksk deposit in Turkmen S.S.R. were reported in 1975 at 2 billion tons, and those of the Tuva-Gutansk deposit were reported at 400 million tons. The first discovery of potassium salt in the Western U.S.S.R. was recently made at Ladushkin in Kaliningrad Oblast'.

There are four potash-producing centers: Solikamsk-Berezniki on the western side of the Central Urals, Soligorsk in Belorussia, and Stebnikov and Kalush in the Western Ukraine. The following complexes, with a total annual capacity of 21.38 million tons (41.6% K_2O), were in operation in 1978: Berezniki Nos. 1, 2, and 3, Solikamsk Nos. 1 and 2, Soligorsk Nos. 1, 2, and 3, and the first stages of the Novostebnikov and Kalush complexes. In 1979, three complexes were under construction: the second stage of the Soligorsk No. 4 in Belorussia, Berenzniki No. 4, and Novosolikamsk in the Urals.

Five potash-producing complexes, with a total annual capacity of 12.6 million tons, were in operation at the Uralkaliy (Urals potash) concern in 1979. It was planned to produce 14.3 million tons at this concern in 1980. Construction of the Berezniki No. 4 complex in this area began in 1973 and that of the Novosolikamsk complex in 1975. The total designed capacity of both complexes is 14 million tons per year (capacity of each is 7 million) of potassium chloride.

Belorussia produced about 50% of the total Soviet output of potassium fertilizers in 1979. There are three potassium complexes in operation with a total annual capacity of 6.5 million tons of fertilizers. The designed capacity of the Soligorsk complex is 16.6 million tons of ore (four shafts) and 5.5 million tons of potassium fertilizers. The first stage, with an annual capacity of 1.7 million tons of fertilizers (4 million tons per year of ore), of the Soligorsk No. 4 complex was completed in 1979. It was expected that the second stage (capacity 1. 8 million tons per year) of the complex would be completed in 1980. Three of Belorussia's complexes produced about 27 million tons of potassium ores and about 9 million tons of concentrate in 1979.

Fluorspar.—Despite the Soviet Union's effort to achieve self-sufficiency, it remained a net importer of fluorspar, mainly from Mongolia, Mainland China, and Thailand. Soviet consumption of fluorspar in 1979 was over 1 million tons. The iron and steel industry consumed more than 85% of the total, and consumption is increasing by 8,000 to 10,000 tons each year. Estimated levels of fluorspar output for 1980 was 550,000 tons.

The Maritime Territory (Yaroslavsk deposit), Transbaykal (Kalunguysk, Abagatuysk, Usuglinsk), Uzbekistan, and Kazakhstan were the main production areas in 1978-79. Small quantities of fluorspar are also produced in Tadzhikistan and other regions of the country. The mined ore contained from 20% to 45% CaF_2. The Central concentrator in Uzbekistan, which is treating ores with 24.3% to 26.5% CaF_2 content, produced a 95% CaF_2 concentrate with recovery of about 85%. The mine in Maritime Territory is treating ores with an average of 40.5% CaF_2 content with about 75% recovery in a 92% CaF_2 concentrate. During the 1976-80 period, it was planned to increase recovery and quality of calcium fluoride at the Yaroslavsk, Kalunguysk, and Takobsk complexes, and the Kyakhtinsk mine. Exploration of the Suppatash, Kengutan, and Shabres small deposits continued in 1979.

Mica.—The domestic supply of mica was augmented by large imports, despite the increasing use of substitutes. Strategic-grade mica continues to be imported from India to meet special industrial demands. Estimated output for 1980 was 47,000 tons.

Almost three-quarters of all muscovite mica production continued to come from the Mamsko-Chuyskiy region of Irkutsk Oblast'. Over 1,500 veins have been discovered in this area, and 9 small underground mines were in operation in 1978-79. The Irkutsk and Petrozavodsk mica factories are the largest in the U.S.S.R. Mica is also mined in Murmansk Oblast' on the Kola Peninsula, Kareliya, and Yakutiya.

The Kovdorslyuda (Kovdor mica) complex in Murmansk Oblast' operates the Yena, Pikolatva, and Kovdor underground mines and vermiculite open pit. Mining of vermiculite began here in 1960, and the capacity of the concentrator is 56,000 tons per year of concentrate. The Karelslyuda (Karel mica) complex in Karelia operates the Plotina, Malinovaya Varakka, and Tedino underground mines. Two 400-meter-deep exploratory shafts were sunk at the Malinovaya Varakka mine in 1979. It is planned to develop the Slyudyanoy Bor deposit in Karelia in the future.

Salt.—The Soviet Union is one of the world's leading countries for salt reserves, production, and exports. It was planned to increase salt production from 12.4 million tons in 1970 to 14 million tons in 1975, and to 20 million tons in 1980. However, the estimated production level for 1980 was revised to 15 million tons. Salt development is concentrated in the Donets Basin (40% of output), the Urals, East Siberia, Armenia, and West Ukraine. The increase in production came mainly from the Iletsk mine in Orenburg Oblast' and the Avansk mine in Armenia. Development of a new mine, with an annual capacity of 2 million tons, at Artemovsk in the Donets Basin continued in 1979. The Nizhniy Baskunchak salt complex, with capacity of 700,000 to 900,000 tons per year, was also under construction. The construction of the Verkhnekamsk salt complex in Perm Oblast and the renovation of the Iletsk mine continued in 1979. Construction of the Mozyr' salt complex in Belorussia (capacity 360,000 tons per year), which began in 1974, based on rock salt deposits which lie at a depth of up to 700 meters, continued in 1979.

The survey of the rock salt deposit near Gusev in Kaliningrad Oblast' was completed in 1976. Gross salt reserves in place were reported at 1,597 million tons including 88 million in category A, 266 million in category B, and 1,243 million in category C_1. The salt reserves in place in category C_2 are reported at 4,182 million tons. It is planned to develop new mines at this deposit with a capacity of 600,000 tons per year. The Kuuli-Sol complex in Turkmeniya, one of the country's larget suppliers of table salt, has shipped almost 800,000 tons of salt, part of which has been exported to Norway, Denmark, and Yugoslavia. The reserves of the lake, which extends for 10 kilometers along the eastern shores of the Caspian Sea, are very large. The complex's capacity has been increased, and it was planned to raise its output to 400,000 tons per year by the end of 1980. Rock salt is also produced in Tadzhikistan.

Sulfur.—The U.S.S.R. has large reserves of sulfur, but grades are low and costs high. The principal producers of native sulfur continue to be Rozdol (West Ukraine), Gaurdak in Turkmen S.S.R., Yavorov in West Ukraine, and the Volga group of the Kuybushev sulfur complex, which together produced the bulk of the country's requirements. The dressing mills of all four complexes are treating ore with a sulfur content from 8% to 40% and produce a flotation concentrate with a 70% to 85% sulfur content. Production doubled during the past decade as a result of growth both in the elemental sulfur and as byproduct output. Frasch and the Orenburg sour-gas sulfur projects have become important in the last few years, and it is expected that these sources will account for most future growth in the Soviet sulfur industry. The U.S.S.R. is currently ranked fourth in the world in terms of brimstone production. Estimated level of total sulfur output for 1980 was 11.0 million tons.

The native sulfur sources are concentrated in four regions: the Carpathians, Central Asia, Central Volga, and the Soviet Far East. Production is concentrated at the Carpathian sulfur basin, where the Rozdol' and Yavorov sulfur plants are currently in operation together with open pits, beneficiation plants, sulfur melting plants, and Frasch process production. The increase in the native sulfur production will depend on full-capacity operation of the Yavorov sulfur plant and the expansion of the Gaurdak and Yavorov Frasch installations.

About 30% of the total Soviet output of native sulfur is produced by the Frasch process at the Yavorov and Gaurdak plants, where production began in 1969. The deep-lying reserves at the Yazovsk, Nemirovsk, Tlumach, Sororsk, Zhidachevsk, Gumenetsk, Syreysk-Kamenodol'sk, Gaurdak, and other sites are the most suitable for the production of sulfur by the Frasch process. About 1 million tons of sulfur was recovered from Orenburg sour gas in 1978. The Soviet Mashinoimport foreign trade organization has issued invitations to bid for a 6-billion-cubic-meter-per-year high-sulfur gas processing complex which will include a 2-million-ton-per-year elemental sulfur plant. The complex is to be built near Astrakhan at a cost of some $1 billion. Reportedly, construction of the first stage of the Yavorov sulfur ore mining and processing complex in West Ukraine was completed in August 1978. Over 1 million tons of sulfur was recovered from sour gas in 1979.

There were three 100,000-ton-per-year installations using the Frasch process at the Gaurdak complex in operation in 1979. During the 1976-80 period, production of sulfur at Gaurdak was to increase by 50%

through the commissioning of a new open pit and expansion of Frasch production. The second stage of the Frasch plant at Gaurdak was put into operation in October 1979.

Production of sulfuric acid increased from 22.4 million tons in 1978 to an estimated 23 million tons in 1979. Sulfuric acid production began at the Voskresensk (near Moscow) mineral fertilizer complex in June 1979 with an annual capacity of 0.5 million tons. Construction of a second sulfuric acid plant began in 1979 with the same capacity; it is to be ready in 1981. A third of similar size is to be delivered within the next few years. Poland is building these plants and is also supplying the complex with the necessary raw sulfur. Over 40% of the total Soviet sulfuric acid production came from Polish plants in 1978-79, and by the end of 1980 this figure was to rise to 45%.

Talc.—Only the Onotsk deposit in Irkutsk Oblast', with an annual capacity of 45,000 tons, produced high-grade iron-free material. Despite large reserves and the development of new mines, imports of talc from North Korea and Bulgaria continued in 1978 and 1979. Estimated level of talc output for 1980 was 500,000 tons.

The Kirgiteysk deposit in Krasnoyarsk Kray was the major producer of lower quality talc. The Miass and Shabrovsk deposits in the Urals ranked second in output. Some talc is mined from the Tetri-Mindorskoye and Kvachevskoye deposits in South Osetinsk, Georgia. The raw material at the Onotsk deposit is shipped for processing to the Miass talc mill in the Urals. The Medvedevskoy talc deposit in Chelyabinsk Oblast' was under development in 1979.

MINERAL FUELS

Compared with 1975 output, the 1980 production of oil was to rise by 30%, natural gas by 55%, coal by 15%, hydroelectric power by 48%, and nuclear power by 333%.

The share of petroleum and natural gas in the total Soviet primary energy consumption increased from 65% in 1978 to 66% in 1979, while that of coal declined from 31% to 29%. Total consumption of all types of primary energy in the U.S.S.R. was expected to be equivalent to about 1,685 million tons of standard coal in 1980.

Soviet long-range forecasting placed the demand for raw coal and lignite at over 800 million tons in 1980 and 1 billion tons by 2000.

The primary energy balance of the U.S.S.R. for 1978 and 1979 is shown in table 9.

Table 9.—USSR: Total primary energy balance for 1978 and 1979

(Million tons of standard fuel equivalent)

	Production	Imports	Exports	Apparent consumption
1978:				
Total primary energy	1,814	34	314	1,535
Coal (lignite, anthracite, bitumous and coke)	498	12	32	478
Crude oil and petroleum products	813	12	240	585
Natural and associated gas	426	10	40	396
Peat	15	--	--	15
Oil shale	12	--	--	12
Hydropower	19	--	2	18
Nuclear power	6	--	--	6
Fuelwood	25	--	--	25
1979:				
Total primary energy	1.883	30	319	1,594
Coal (lignite, anthracite, bituminous and coke)	484	12	32	464
Crude oil and petroleum products	840	12	240	612
Natural and associated gas	484	6	45	445
Peat	9	--	--	9
Oil shale	12	--	--	12
Hydropower	23	--	2	21
Nuclear power	7	--	--	7
Fuelwood	24	--	--	24

Coal.—In 1979, the Soviet Union produced an estimated 719 million tons (planned 753 million) of run-of-mine coal as follows: bituminous coal, 473 million tons; anthracite, 79 million tons; and lignite, 167 million tons. Estimated according to Western practice, this was equivalent to 413 million tons of "clean coal," placing the U.S.S.R. second among the world's coal producers. Over 33% of the total output was surface-mined.

Production of raw coal and lignite in 1978-79 was from Donets, 31%; Kuznetsk, 19%; Karaganda, 7%; Moscow, 4%; Kansk-Achinsk, 4%; Pechora, 4%; and other areas, 31%. There were about 800 underground mines with an average annual capacity of some 600,000 tons of raw coal, and 70 open pits with an average annual output of 3.4 million tons of run-of-mine coal and lignite.

The annual capacity of coal and lignite mines increased by 26 million tons (raw coal and lignite) in 1978 and by 19 million tons in 1979. In 1980, the reduced planned production of raw coal and lignite was to reach 745 million tons, but actual output (based on the 1979 result) comprised about 730 million tons.

Preparation of coal for the market does not play a great role in the industry and is normally restricted to coking coals and coal for export. The shortage of coal preparation facilities forced Soviet planners to place greater emphasis on improvement in quantity as an expedient.

Practically all Soviet coal requires upgrading, but of the 724 million tons produced in 1978, only an estimated 297 million tons was treated to produce an estimated 157 million tons of clean coal. In 1979, only an estimated 345 million tons was treated to produce an estimated 182 million tons of clean coal. Some 66 preparation plants are treating coking coal, 38 plants are processing anthracite, and 50 preparation plants are treating coal and lignite for powerplants.

The official average ash content of coal shipped to consumers in 1979 was about 20.3%. The average calorific value of coal from the Karaganda, Kuznetsk, and Donets basins fell by 600, 900, and 1,200 kilocalories, respectively, during the last decade. Up to 40 million tons of substandard-quality coals and lignite are delivered to thermal powerplants annually, or about 20% of the total requirements of these plants.[55]

Total Soviet economically minable coal and lignite reserves in place in categories $A+B+C_1$ in January 1975 were 420,000 million tons, including 87,000 million tons of coking coal and 190,000 million tons of lignite. Over 70% of the total coal and lignite reserves are located in the eastern (Asian) part of the U.S.S.R.

Natural Gas.—In 1980, the output of natural gas was to reach 435 billion cubic meters. According to Soviet data, gas reserves in place in the $A+B+C_1$ categories as of January 1978 were 29,000 billion cubic meters, 15% of which were in the European part of the U.S.S.R., 72% in Siberia and the Soviet Far East, and 13% in Central Asia and Kazakhstan.

Petroleum.—The Soviet Union is rich in oil. However, despite the new discoveries, the rate of growth in reserves is lagging behind the rate of growth in extraction. According to Soviet sources, crude oil reserves in place in the $A+B+C_1$ categories as of January 1979 were 12.9 billion tons. A 30% to 40% recovery of crude oil in place was claimed in 1979.

For the sixth year, the U.S.S.R. remained the world's largest oil producer. The country continues to expand its exports of crude oil and petroleum products even though the quantities available for internal consumption have been inadequate. The Soviet Union became a net exporter of crude oil in 1951 and of petroleum products in 1954 and has gradually stengthened its position since that time. The U.S.S.R. exported about 30% of its production in 1979.

In 1979, over 500 (including 36 large) oil and gas condensate fields were in operation, with a total of about 77,000 wells. Most of the increased production was derived from the West Siberian fields. There were about 150 oilfields in Western Siberia in January 1980, including 50 fields "ready for operation." The Samotlor oil field in Tyumen' Oblast', the largest oil field in the U.S.S.R., accounted for the production of some 145 million tons of crude in 1979. Over 2,000 production wells were in operation at this field in 1979. The Fedorov field was the second largest in West Siberia in 1979.

Crude oil extraction (including condensate) is planned to be increased to 606 million tons in 1980, almost in line with the lower range of the present 5-year plan. Investment in oil has increased from 3,802 million rubles in 1975 to 4,450 million in 1977, 6,000 million in 1979, and probably about 7,000 million in 1980. The output of crude and gas condensate will rise less rapidly beyond 1980, and will reach about 675 million tons in 1985. The main increase will be from the fields in West Siberia. In 1985 crude oil output has been estimated on the basis of projections from earlier years, as modified by information in the long-range plan. The Volga-Urals area will continue to decline in relative importance, whereas Tyumen' Oblast' in West Siberia will make the most notable gains.

The anticipated date of peaking of the Samotlor fields, the largest in the U.S.S.R., is 1979-86 and that of the Fedorovsk field is 1983-90. There is no reason, therefore, why the growth in petroleum production will not continue into the 1980's. The U.S.S.R. will continue importing a high level of petroleum equipment and technology. With current Soviet technology and partially with equipment from the West, oil output in the U.S.S.R. could peak between 1986 and 1989.

Contrary to continuing reports that the U.S.S.R. would no longer increase its oil deliveries to its Comecon partners, some countries reported slight increases in deliveries in 1979. Soviet exports of petroleum to the East European Comecon countries are still increasing at present, more or less in line with existing trade agreements, but in the future the increase will probably be smaller. The Soviets have an explicit policy to limit oil exports to the Comecon countries of East Europe and assist them in expanding their domestic coal and nuclear energy production.

Based on signed trade agreements and the latest Soviet forecasts, oil exports (crude oil and products) from the U.S.S.R. were expected to increase from 130 million tons in 1975, 149 million in 1976, and an estimated 155 million in 1979 to 160 million tons in 1980. Soviet petroleum exports to market-economy countries were 53 million tons in 1975, 65 million in 1976, and an estimated 65 million in 1979; the probable figure for 1980 was 66 million tons.

Oil has long been a major export earner for the U.S.S.R., and it is intended to become more important. In recent years there has been a growing emphasis on Soviet coal and natural gas production, making more petroleum available for export. In terms of value, the exports of petroleum rose from 25% of total Soviet official exports in 1975 to 28% in 1976 and also 28% in 1978. (The trend runs counter to any forecast that the U.S.S.R. might become a major importer of petroleum after 1980.) Despite rising Soviet domestic consumption of oil, deliveries to centrally planned economy countries should increase according to obligations entered into, and deliveries to the West should stay at the same level or increase only slightly. The Soviet preference, however, is to sell to the West more refined products, as compared to crude.

The Mineral Industry of the United Arab Emirates

By Candice Stevens[1]

The petroleum industry of the United Arab Emirates contributed over 65% of the gross domestic product (GDP) of $13.9 billion[2] in 1978 and an estimated $16 billion in 1979. Increasing petroleum revenues have accounted for the 90% growth in the GDP of the seven former Trucial Coast sheikdoms since 1972. In 1978, the emirates agreed upon the need for an overall development plan and established a Federal Planning Authority to outline national objectives of economic and social development. Emphasis was placed on diversifying sources of income, using capital-intensive projects owing to the scarcity of labor, developing education and training systems to meet manpower requirements, and encouraging individual initiative in the private sector. The federal budget of the United Arab Emirates was $2.8 billion in 1978 and $2.6 billion in 1979, most of which was contributed by Abu Dhabi. Since 1974, the Abu Dhabi Fund for Arab Economic Development has disbursed loans and grants of more than $1 billion per year to foreign countries.

General aspects of exploration and development of oil and minerals in the United Arab Emirates are under the direction of the Ministry of Petroleum and Mineral Resources. Although united politically, the oil-producing emirates of Abu Dhabi, Dubai, and Sharjah exercised independent control over their petroleum policies. Abu Dhabi maintained a 60% share in major oil operations and required 51% interest in all ventures to exploit natural gas. In 1978, Abu Dhabi issued Law No. 8 for the conservation of hydrocarbon resources, which required measures for prevention of damage to oil-bearing structures, detailed studies for oil exploration and production programs, and official permission to flare natural gas. In 1979, Abu Dhabi promulgated new commercial regulations that required foreign firms to do business through local branches and permitted trade licenses only to companies wholly owned by Abu Dhabi nationals. Dubai nationalized its oil and gas industries in 1975 but retained foreign shareholders under management contracts. Sharjah acquired 25% interest in domestic oil operations and opted for a 60% share in any new vetures. Foreign oil companies were engaged in exploration in the various emirates under diverse types of production-sharing agreements.

Abu Dhabi and Dubai initiated infrastructure construction for their new industrial centers. Fluor Corp. (United States) was contracted for overall planning and construction management for the city of Ruweis in Abu Dhabi. Projects included an oil refinery, a natural gas liquids (NGL) plant, a petrochemical complex, a fertilizer plant, and an iron and steel complex. Infrastructure for Ruweis, which was to require 10 to 12 years for completion, comprised a port with three major shipping terminals, a residential community, and airport modernization. The new industrial city of Jebel Ali in Dubai was to include an aluminum smelter, an NGL facility, a steel plant, a fertilizer plant, and a petroleum refinery.

An expansion in port handling capacity was a major priority of the United Arab Emirates. The Abu Dhabi Petroleum Ports Operating Co. was established in 1978 with Lamnalco Ltd. (United Kingdom) as manager. The company was to manage the Jebel Dhanna port, supervise construction of a new deepwater port at Ruweis and an oil terminal on Zirku Island, and oversee feasibility studies for a drydock project. In Dubai, the worlds largest drydock was under construction by Costain-Taylor Woodrow (United Kingdom) and was scheduled to be operational in 1980. The new deepwater port at Jebel Ali, managed by SeaLand Services Inc. (United States), was partially commissioned in 1979. Sharjah's intermodal transportation port system came onstream in 1978 with the commissioning of the specialized container facility at Khor Fakkan. A new deepwater port in Ras al-Khaimah was to be completed in 1980.

PRODUCTION AND TRADE

Petroleum production decreased in 1978 owing to the imposition of production ceilings by Abu Dhabi, which accounted for about 80% of the oil production of the United Arab Emirates. New fields under development in Abu Dhabi were expected to raise production capacity to more than 2 million barrels per day by 1981. Petroleum reserves in Abu Dhabi, Dubai, and Sharjah were estimated at 40 billion barrels. Abu Dhabi produced refined petroleum products and NGL; new facilities coming onstream in Abu Dhabi and Dubai were to greatly increase output of both commodties. The emirates of Abu Dhabi, Dubai, Sharjah, and Ras al-Khaimah produced cement and new plants were under construction. Mineral production in the United Arab Emirates is given in table 1.

The United Arab Emirates evidenced a balance-of-trade surplus of $4.6 billion in 1978 and $6 billion in 1979. Exports of oil and gas, valued at $8.7 billion in 1978 and $11.5 billion in 1979, accounted for 90% of export value. In 1978, the United Arab Emirates exported 381,000 barrels per day of crude oil to the United States amounting to 6% of U.S. petroleum imports. The import bill of the United Arab Emirates increased from $560 million in 1972 to more than $5 billion in both 1978 and 1979. Japan was the United Arab Emirates' most important trading partner, taking 30% of petroleum exports and supplying about 20% of total imports. Imports from the United States were valued at $540 million in 1978 and $575 million in 1979.

Table 1.—United Arab Emirates[1]: Production of mineral commodities

Emirate, commodity,[2] and unit of measure	1976	1977	1978[p]	1979[e]
ABU DHABI

COMMODITY REVIEW

METALS

Aluminum.—Arrangements for financing the United Arab Emirates' first aluminum smelter were nearing completion. In 1979, the Dubai Aluminum Co. (DUBAL) received a $230 million Eurocurrency loan arranged by a consortium of international banks. In addition, the British Export Credits Guarantee Department allocated $320 million in support of British Smelter Constructions, the main contractor on the smelter located in Jebel Ali, Dubai. Production was to begin in early 1980. The smelter was owned 80% by the Dubai Government, 7.5% by Southwire Aluminum Co. (United States), 7.5% by Nissho-Iwai Co. Ltd. (Japan), and 5% by local interests. Annual production capacity was to be 135,000 tons of billets rising to 180,000 tons of billets by the mid-1980's. Fuel was to be supplied by the Dubai Natural Gas Co. (DUGAS) plant under construction in Jebel Ali. The DUBAL smelter's power station, with an installed generating capacity of 515 megawatts, would be the largest industrial gas turbine powerplant outside North America. An agreement was reached with Alcoa of Australia for the supply of 200,000 tons of alumina per year for 10-year period.

In August 1978, Gulf Extrusions Ltd. brought into production Dubai's first aluminum extrusion plant in Jebel Ali. The $10 million plant produced 3,000 tons per year of various aluminum shapes. Billets were obtained from Aluminum Bahrain Ltd. (ALBA) in 1978 and were to be supplied in the future by the DUBAL smelter. An aluminum cable plant, with a nominal capacity of 1,500 tons per year, was also under construction.

Iron and Steel.—In October 1978, the Abu Dhabi Executive Council approved the establishment of a major iron and steel complex in the new industrial city of Ruweis. A $200,000 contract for a feasibility study of the project was awarded to Eisenbau A.G. (Federal Republic of Germany). The plant was to have an annual production capacity of 400,000 tons of steel and was to use locally produced natural gas. It was reported that Abu Dhabi and India were studying a possible joint venture to finance the project. In 1978, Abu Dhabi imported approximately 160,000 tons of steel.

NONMETALS

Asbestos.—An asbestos plant was inaugurated in June 1979 in Umm al-Qaiwain. The $22 million plant had an annual production capacity of 40,000 tons of asbestos pipes, sheets, and plates. A study was being conducted on expanding the plant's capacity to 120,000 tons per year of asbestos products for export.

Cement.—Cement production increased to 1.3 million tons in 1978 from 700,000 tons in 1977 as the new Dubai National Cement Co. plant came onstream. Constructed by Costain Civil Engineering (United Kingdom) at a cost of $65 million, full production capacity of the plant was 500,000 tons per year. The Gulf Cement Co. was to construct a 1-million-ton-per-year cement plant in Ras al-Khaimah. Ishikawajima-Harima Heavy Industries Co. Ltd. (IHI) (Japan) was contracted for construction of the $68 million plant which was to begin production in 1982. Fujairah Cement Industries contracted Voest-Alpine A.G. (Austria) for the construction of 520,000-ton-per-year cement plant to be onstream in 1982. Production capacity of the United Arab Emirates' four operating cement plants was as follows:

Location	Operator	Capacity (tons per year)
Al Ain, Abu Dhabi	Union Cement Co.	200,000
Ras al-Khaimah	do	500,000
Sharjah	Sharjah Cement Co.	270,000
Dubai	Dubai National Cement Co.	500,000

Fertilizer Materials—A nitrogen fertilizer plant came onstream in Sharjah in 1978. The $5 million facility had a production capacity of 10,000 tons per year of fertilizer which were to increase to 36,000 tons per year by 1979.

The Abu Dhabi National Oil Co. (ADNOC) appointed Creusot-Loire (France) as project manager for the nitrogen fertilizer complex to be constructed in Ruweis. Daily production capacity was to be 2,000 tons of ammonia and 1,500 tons of urea. Natural gas from Abu Dhabi's onshore oilfields was to be used as feedstock. ADNOC also entered into two joint ventures for the construction of nitrogenous fertilizer plants in Pakistan and Tunisia. Pak Arab Fertilizers Ltd., owned 48% by ADNOC and 52% by West Pakistan Industrial Development Corporation, was to construct a 1,000-ton-per-day plant in Multan, Pakistan. The Arab Co. for Phosphatic and Nitrogenous Fertilizers, owned 40% by ADNOC, was to construct a 1,000-ton-per-day plant in Tunisia.

MINERAL FUELS

Natural Gas.—The Das Island natural gas plant, commissioned in October 1977, operated at half capacity in 1978 owing to technical difficulties and a decline in gas output from Abu Dhabi's offshore oilfields. The plant, which was expected to reach full capacity by 1980, was designed to process 550 million cubic feet per day of gas and to produce 15 million barrels of liquefied natural gas (LNG), 5.6 million barrels of liquefied petroleum gas (LPG), 1.5 million barrels of light distillate, and 1.6 million barrels of pelletized sulfur per year. Abu Dhabi Gas Liquefaction Co. Ltd. (ADGLIC) was owned 51% by ADNOC, 22.1% by Mitsui and Co., 16.3% by British Petroleum Co. Ltd. (BP), 8.2% by Compagnie Française des Petroles (CFP), and 2.4% by Bridgestone Liquefied Gas Co.

In 1978, ADGLIC awarded Stone and Webster (United Kingdom) a contract to recover and transport associated gas from the offshore Lower and Upper Zakum Fields to compensate for any shortfall in gas available from Umm Shaif Field. The gas-handling system was to recover 300 million cubic feet per day of gas for transmission to the existing platform at Umm Shaif Field and then to the Das Island LNG facility. It was due for completion in 1980. Also in offshore Abu Dhabi, the Abu Dhabi Marine Areas Operating Co. (ADMA-OPCO) reported a major gas discovery west of the Umm Shaif Field. The test well yielded 80 million cubic feet per day of gas from a depth of 15,200 feet. A deep gas exploration well was also to be drilled near Zakum Field in 1980.

Abu Dhabi Gas Industries Ltd. (GASCO) was established in 1978 to gather and process associated gas from Abu Dhabi's onshore oilfields. GASCO was owned 68% by ADNOC, 15% by Shell, 15% by CFP, and 2% by the Portuguese Participations and Exploration Corp. (PARTEX). The joint venture planned to process associated gas from the Bab, Bu Hasa, Asab, and Sahil Fields and produce 185,000 barrels per day of

NGL. Fluor Corp. (United States) was contracted to design and supervise the construction of gas-gathering facilities. Bechtel Inc. (United States) was contracted for the design and construction of the fractionation plant at Ruweis. Saipem (Japan) was to construct an NGL export terminal and tanker loading facilities at Ruweis. The project, estimated to cost $1.6 billion, was to come onstream in 1981.

The natural gas processing plant under construction by DUGAS in Jebel Ali, Dubai, was scheduled to begin export operations in January 1980. DUGAS is a joint venture of the Dubai Government and Scimitar Oils Ltd. of Canada (formerly Sunningdale Oils. Ltd.). The facility was to process 125 million cubic feet per day of associated gas from offshore Fateh and Southwest Fateh Fields and produce 20,000 barrels per day of NGL. Oceanic Contractors Inc., a subsidiary of J. Ray McDermott (United States), was contracted for the design and construction of the processing facility. The gas-gathering system included two offshore compression platforms, 105 kilometers of subsea pipeline, and an export terminal at Ruweis. C. Itoh of Japan contracted to purchase nearly 60% of output for 15-year period.

A gas well drilled offshore Umm al-Qaiwain by Zapata Exploration Co. was abandoned as dry at 18,700 feet. An agreement previously concluded with DUGAS for development and sale of the gas was canceled in 1978. The DUGAS agreement was dependent on studies confirming that gas reserves were sufficient to meet minimum delivery needs. The Umm al-Qaiwain Oil Group planned to continue drilling in the offshore area in the hope of eventually exporting gas to Dubai for use in the Jebel Ali aluminum smelter.

Petroleum.—*Abu Dhabi.*—In 1978, the Government-owned ADNOC increased its decisionmaking role in the two major oil companies, Abu Dhabi Petroleum Co. (ADPC) and the Abu Dhabi Marine Areas. Ltd. (ADMA). Under a participation agreement reached in 1974, ADNOC held a 60% interest in both groups. New companies established in 1978 would be managed by a nine-member board comprising three members from ADNOC in addition to representatives of the other shareholders. The companies were to be registered locally and to undertake an active program to employ and train local personnel. ADPC was replaced by the Abu Dhabi Company for Onshore Oil Operations (ADCO) and ADMA was replaced by the Abu Dhabi Marine Areas Operating Co. (ADMA-OPCO). Shares in ADCO were held 60% by ADNOC, 9.5% by BP, 9.5% by CFP, 9.5% by Shell, 4.75% by Exxon, 4.75% by Mobil, and 2% by PARTEX. Shares in ADMA-OPCO were held 60% by ADNOC, 14.67% by BP, 13.33% by CFP, and 12% by the Japan Oil Developmet Co. (JODCO).

ADCO worked under a production ceiling of 850,000 barrels per day in 1978 and 1979 and this was to be lowered even further to 740,000 barrels per day in 1980. Production capacity of the onshore Bab, Bu Hasa, Asab, and Sahil Fields was rated at 1.3 million barrels per day. The new Shah Field, located south of Asab Field, was brought onstream in 1979 with an initial production capacity of 50,000 barrels per day. The two major offshore fields operated by ADMA-OPCO were limited to an average output of 500,000 barrels per day in 1978 and 1979 and this was to remain unchanged in 1980. Water injection programs were completed in the Zakum and Umm Shaif Fields and each maintained a production rate of 250,000 barrels per day.

The balance of Abu Dhabi's oil production came from smaller offshore fields. Amerada Hess Corp. operated the Abu Al Bu Koosh Field and brought the Arzanah Field onstream in mid-1979 at an initial production rate of 22,000 barrels per day. The Mubarraz Field, operated by the Japanese consortium Abu Dhabi Oil Co. Ltd. (ADOC), produced about 18,000 barrels per day of oil. In 1978, ADOC was awarded additional offshore acreage totaling 1,580 square kilometers. In 1979, Qatar and Abu Dhabi made a joint decision to shut down the El Bundug Field owing to reservoir pressure maintenance problems.

Two new companies were formed in 1978 to develop two offshore fields. The Zakum Developmet Co, owned 88% by ADNOC and 12% by JODCO, was to exploit the Upper Zakum Field at an initial rate of 500,000 barrels per day. CFP was appointed overall manager of the project and was to develop technology to enhance recovery from the low-pressure field. Recoverable reserves were estimated at 16 billion barrels. Foster Wheeler Corp. (United States) won a contract for overall construction supervision services for an export terminal to be built on Zirku Island. R. J. Brown and Associates (Switzerland) was to engineer and construct

500 kilometers of subsea pipeline. Total cost of the project was estimated at $500 million. The Umm al-Dalkh Development Co. was created as a joint venture between ADNOC (88%) and JODCO (12%) to exploit the Umm al-Dalkh Field. Umm al-Dalkh was expected to produce 50,000 barrels per day of oil by 1981 with production exported from the Zirku Island terminal.

Deliveries of Bab crude to the Umm al-Nar Island petroleum refinery averaged 13,000 barrels per day. A lube oil blending plant was inaugurated on Umm al-Nar Island in 1979 to produce 100,000 barrels per year of lubricants for the local market. The United Arab Emirates imported more than 75% of its requirements for refined products. A $650 million refinery was scheduled to begin production in Ruweis in 1981. Snam Progetti (Italy) was overall construction manager for the project. Projected capacity was 120,000 barrels per day.

Ajman.—Forma Exploration Co. (United States) and Londo and Scottish Marine Oil Co. Ltd. (United Kingdom) were awarded a 35-year concession in Ajman's offshore. The company contracted to spend a minimum of $10 million on exploration work in its 300-square-kilometer tract.

Dubai.—The Dubai Petroleum Co. (DPC) continued its water injection program to increase the production capacity of the Fateh and Southwest Fateh Fields to 460,000 barrels per day. DPC began production from the offshore Rashid Field in June 1979 at the rate of 2,000 barrels per day of condensate. DPC expected to begin production from the Falah Field in 1980 at an initial rate of 15,000 barrels per day of oil.

Ras al-Khaimah.—In 1978, Ras al-Khaimah amended its tax laws in an attempt to increase oil exploration activities. Gulf Oil Co. and Amoco were awarded a 1,630-square-kilometer onshore concession. Offshore, feasibility studies were in progress on the development of two oil discoveries which could lead to the production of 70,000 barrels per day of oil by 1983. Kellogg Inc. (United States) was conducting engineering studies for the construction of petroleum refinery in Khor Kuwait. The project was a joint venture between Ras al-Khaimah Oil Co. (RKOC) (51%) and the Kuwait National Petroleum Co. (49%). The refinery, was to process Kuwaiti crude oil and produce 120,000 barrels per day of petroleum products for both domestic use and export.

Sharjah.—In 1978, Crescent Petroleum Co. settled its dispute with the Sharjah Government over tax and royalty rates on production from the offshore Mubarek Field. The tax rate was raised from 55% to 65.65% in 1978 and to 77% in January 1979. Royalty rates were increased from 12.5% to 14.5%. The agreement was made retroactive on July 1, 1977, and Crescent Petroleum Co. was to pay the Sharjah Government approximately $13 million in back payments. In 1978, exploration concessions were awarded to Amoco Sharjah Oil Co. and a joint venture of Forman Exploration Co. and London and Scottish Marine Oil Co. Ltd.

Umm al-Qaiwain.—The Umm al-Qaiwain Oil Group, with Zapata Exploration Co. as operator, abandoned two oil and gas discoveries as uncommercial in 1978. The group planned to continue its exploration activities in the 1,200-square-kilometer offshore concession area.

The Mineral Industry of the United Kingdom

By William F. Keyes[1]

A sustained rise in consumer expenditures was largely responsible for the rapid expansion of the British economy in 1978, but slower growth and higher inflation undermined the economy in 1979. Industrial production grew at 3% to 4% in real terms during both years, but after discounting the steady increase in crude petroleum production, this growth was reduced to 2.1%. The gross national product (GNP), in terms of 1978 prices, increased to £141 billion[2] (about $275 billion) in 1978, reflecting an increase of 13.8%, over the previous year's GNP. This increase, however, was equivalent to 3.0% in constant terms. The GNP in 1979 was estimated at £160 billion.

The minerals and metals economy of the United Kingdom ranked among the dozen largest in the world. The country is particularly well provided with fuels, both onshore, in the form of coal, and offshore, in the form of oil and gas. Nevertheless, the industry's performance was disappointing during the 1978-79 period, except for that of the petroleum sector. The nationalized coal mines and steel plants suffered large operating losses. The country's major potash mine still had not reached full-capacity production after 6 years. Two tin mines that constituted half the tin industry were closed, although plans were afoot to reopen them. Needed aluminum expansion remained in doubt because of high electricity costs. In addition, the North Sea oilfields were approaching full output more slowly than was originally planned.

The Mining Association of the United Kingdom expressed hope that the Government would soon respond to the recommendations of the Stevens Report, completed in 1974, which urged changes in planning control of mining operations. Another stimulus to mining which the association called for was reinstatement of Regional Development Grants, which had been withdrawn in 1976. For the first time under the Mineral Exploration and Grants Act of 1972, the Department of Industry did, however, grant aid for minerals exploration in the amount of £1.6 million in the year ending March 1978. Forty-four companies applied for aid in 1978, requesting a total of £2.5 million, and awards amounted to about £1 million in the year that ended March 1979.

PRODUCTION

The index of mining and quarrying production increased notably during the period, from 187.7 in 1977 to 232.5 in 1978 and to 294.2 in 1979 (1975=100). The increases were largely due to the continued growth in oil production from the North Sea, which was reflected in the extraordinarily high and increasing index of "other mining and quarrying;" this index went up from 638.6 in 1977 to 895.0 in 1978 and 1,241.0 in 1979. Movement of the index of metal manufactures was mixed; the ferrous metals index increased from 99.8 in 1977 to 102.7 in 1979, and the nonferrous metals index declined from 108.5 to 104.4 in the same period. The coal production index declined from 90.1 to 89.4. The total index for all industries during this period increased from 106.0 to 112.7.

Production of minerals in the United Kingdom in 1978 and 1979 is reported in table 1.

[e]Estimate. [p]Preliminary. [r]Revised. NA Not available.
[1]Reported figure.
[2]Includes wheels, centers, tires, axles, and semimanufactures for immediate sale.
[3]From imported bullion, including Pb content of alloys produced.
[4]From scrap materials. Series revised to comprise all secondary output including Pb content of secondary antimonial lead and to exclude output from domestic ores.
[5]Excludes plasters.
[6]Consists of brick, retorts, molds, and other refractory products made from clays, silica, silicious materials, magnesite, alumina, and chrome materials.
[7]Gas made at gasworks plus purchased coke oven refinery gas.

TRADE

Total imports of the United Kingdom in 1978 were valued at £36.6 billion, and were estimated at £40 billion in 1979. Basic materials, including ores and concentrates, accounted for £3.4 billion in imports in 1978; another £4.8 billion in imports were fuels, largely petroleum products. Total exports amounted to £35.4 billion in 1978, including £1.0 billion in exports of basic materials and £2.4 billion in fuels exports. In 1979, the total value of exports was estimated at £39 billion.

Trade with the United States in mineral-related products in 1977 was heavily in favor of the United Kingdom. The approximately $393 million worth of U.S. exports to the United Kingdom was equal to only about a quarter of U.S. minerals-related imports from the United Kingdom, which were valued at $1.43 billion. U.S. exports were chiefly nonferrous metals, coal and coke, and lubricants. Major U.S. minerals imports from the United Kingdom were petroleum products, iron and steel, semifabricated products, and reexports of diamonds and radioactive materials.

The minerals trade of the United Kingdom in 1977 and 1978 is given in tables 2 and 3.

Lead:			
Ore and concentrate	5,558	6,860	Belgium-Luxembourg 5,669.
Oxides	8,988	6,950	Ireland 2,319; Egypt 701; Federal Republic of Germany 667.
Metal including alloys:			
Scrap	6,874	16,615	Federal Republic of Germany 4,805; Italy 4,592; Ireland 3,001.
Unwrought	126,080	122,126	Federal Republic of Germany 24,932; Netherlands 17,947.
Semimanufactures	3,111	2,292	NA.
Magnesium metal including alloys:			
Scrap	56	330	NA.
Unwrought	714	1,009	United States 314; France 235; Canada 219.
Semimanufactures	388	814	Belgium-Luxembourg 170; India 128.
Manganese:			
Ore and concentrate	6,767	7,169	Italy 1,920; Federal Republic of Germany 1,630; Republic of South Africa 1,597.
Oxides	1,048	1,011	NA.
Mercury 76-pound flasks	1,334	1,479	NA.
Molybdenum metal including alloys, all forms	144	147	France 52.
Nickel:			
Matte, speiss, similar materials	445	265	Sweden 119.
Metal including alloys:			
Scrap	6,575	3,423	Japan 937; Sweden 626; Federal Republic of Germany 621.
Unwrought	26,323	20,412	Federal Republic of Germany 5,290; Belgium-Luxembourg 4,090.
Semimanufactures	10,492	10,070	France 1,886; Federal Republic of Germany 1,194; Sweden 974.
Platinum-group metals and silver:			
Ores and concentrates value, thousands	$830	$2,480	Brazil $1,283; Republic of South Africa $984.
Waste and sweepings do	$9,768	$7,035	Spain $3,178; Federal Republic of Germany $1,846; France $813.
Metals including alloys:			
Platinum-group thousand troy ounces	1,157	1,286	United States 321; Japan 225; Federal Republic of Germany 192.
Silver:			
Refined do	53,531	15,207	France 3,665; Sweden 2,025; Italy 1,704.
Other do	675	675	NA.
Tin:			
Ore and concentrate	180	3,608	Belgium-Luxembourg 1,095; Spain 915; Federal Republic of Germany 617.
Oxides	504	8,746	United States 2,349; Canada 834; Netherlands 809.
Metal including alloys:			
Scrap	212	153	NA.
Unwrought	8,734	8,500	U.S.S.R. 4,239; Netherlands 1,135.
Semimanufactures	1,008	350	Norway 69; Sweden 58.
Titanium oxides	9,852	12,763	Hungary 1,474; Poland 1,301; Japan 1,112.

See footnotes at end of table.

Table 2.—United Kingdom: Exports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1977	1978	Principal destinations, 1978
METALS —Continued			
Tungsten:			
Ore and concentrate	366	135	Federal Republic of Germany 50; Netherlands 50.
Metal including alloys, all forms	455	358	Federal Republic of Germany 112; Netherlands 102.
Uranium and thorium metals including alloys, all forms kilograms	7,000	7,000	NA.
Zinc:			
Ore and concentrate	9,795	9,443	Italy 4,075; Belgium-Luxembourg 2,895; France 2,461.
Oxide and peroxide	10,610	11,585	Netherlands 1,862; Cuba 1,324; Belgium-Luxembourg 1,146.
Metal including alloys:			
Scrap	3,856	6,018	Federal Republic of Germany 3,890; France 786.
Unwrought	23,769	21,162	Netherlands 4,020; Ireland 3,713; Greece 2,548.
Semimanufactures	3,322	2,198	Sri Lanka 166; Federal Republic of Germany 100.
Other:			
Ores and concentrates:			
Of molybdenum, tantalum, titanium, vanadium, zirconium	4,893	7,690	France 3,206; Federal Republic of Germany 1,022; Netherlands 702.
Of base metals, n.e.s value, thousands	$13	--	
Ash and residue containing nonferrous metals	60,541	49,042	Federal Republic of Germany 20,992; Canada 8,094; Belgium-Luxembourg 7,625.
Oxides, hydroxides, peroxides of metals	238,274	NA	
Metals including alloys, all forms:			
Metalloids, n.e.s	1,487	4,787	China, mainland, 1,629; Malaysia 968; Australia 751; Netherlands 685.
Alkali, alkaline-earth, rare-earth metals	207	238	NA.
Pyrophoric alloys	320	3,829	Federal Republic of Germany 972; Ireland 799; Saudi Arabia 221.
Base metals including alloys, all forms, n.e.s	7,055	6,469	United States 2,350; Federal Republic of Germany 554; France 464.
NONMETALS			
Abrasives, natural, n.e.s.:			
Pumice, emery, natural corundum, etc	2,954	2,763	NA.
Dust and powder of precious and semiprecious stones value, thousands	$2,743	$2,890	Ireland $483; Belgium-Luxembourg $393; Japan $366.
Grinding and polishing wheels and stones	8,800	7,826	Sweden 849; Federal Republic of Germany 696; Poland 674.
Asbestos, crude and waste	705	522	NA.
Barite and witherite	3,904	3,424	NA.
Boric oxide and acid	963	1,280	Netherlands 650.
Cement thousand tons	1,700	1,879	Nigeria 671; United States 373; Togo 273.
Chalk	58,525	60,455	Sweden 10,792; Australia 7,448; Nigeria 6,210.
Clays and clay products (including all refractory brick):			
Crude thousand tons	2,730	2,767	Federal Republic of Germany 434; Italy 427; Finland 335.
Products:			
Refractory (including nonclay brick) do	256	217	Italy 28; Sweden 19; Brazil 10.
Nonrefractory do	157	198	Ireland 38; Netherlands 37.
Cryolite and chiolite	1	15	NA.
Diamond, all grades value, millions	$1,135	$1,310	Switzerland $652; Belgium-Luxembourg $355.
Diatomite and other infusorial earth	1,085	859	NA.
Feldspar and fluorspar	26,220	9,925	Norway 3,109; Federal Republic of Germany 867.
Fertilizer materials:			
Crude:			
Nitrogenous	180	123	NA.
Phosphatic	72	35	NA.
Potassic	--	10	NA.
Other	2,824	3,454	NA.
Manufactured:			
Nitrogenous thousand tons	255	136	Netherlands 35; Belgium-Luxembourg 30.
Phosphatic	49,228	58,184	Ireland 38,479; Bangladesh 14,400.
Potassic	35,068	63,274	Netherlands 31,866; Norway 19,012.
Other, including mixed	539,994	520,530	Ireland 234,396; Turkey 75,599; Federal Republic of Germany 73,025.
Graphite, natural	2,544	2,648	United States 1,703.
Gypsum and plasters	14,767	12,401	Ireland 3,100.

See footnotes at end of table.

Table 2.—United Kingdom: Exports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1977	1978	Principal destinations, 1978
NONMETALS —Continued			
Lime	47,098	40,547	Nigeria 13,786; Venezuela 9,275.
Magnesite	50,260	52,736	Poland 14,759; Federal Republic of Germany 6,671; Venezuela 4,974.
Mica:			
Crude, including splittings and waste	3,589	3,349	Federal Republic of Germany 682.
Worked, including agglomerated splittings	65	244	India 31; United States 10.
Pigments, mineral:			
Natural, crude	6,403	NA	
Iron oxides, processed	9,059	11,721	United States 1,895; Italy 753; Canada 684; France 546.
Precious and semiprecious stones, except diamond:			
Natural value, thousands	$21,751	$18,100	Switzerland $8,967; France $3,702.
Manufactured do	$245	$121	Switzerland $11.
Salt thousand tons	468	405	Sweden 138; Nigeria 74; Ireland 59.
Sodium and potassium compounds, n.e.s.:			
Caustic soda	313,788	50,925	Nigeria 7,495; China, mainland, 5,948; Ireland 4,568.
Caustic potash and sodic and potassic peroxides	895	285	NA.
Stone, sand and gravel:			
Dimension stone:			
Crude and partly worked	12,208	10,411	France 2,970.
Worked	5,349	4,015	Federal Republic of Germany 589.
Dolomite, chiefly refractory grade	3,704	12,079	NA.
Gravel and crushed rock thousand tons	5,177	5,835	Belgium-Luxembourg 2,126; Netherlands 1,812; France 1,427.
Limestone, except dimension	14,288	356,267	Belgium-Luxembourg 130,475.
Quartz and quartzite	1,332	12,876	NA.
Sand, excluding metal bearing	67,875	78,123	Ireland 34,748; Sweden 15,594.
Strontium minerals: Celestite	3,800	NA	
Sulfur:			
Elemental:			
Other than colloidal	1,387	1,422	NA.
Colloidal	211	123	NA.
Sulfur dioxide	110	26,061	Ireland 5,229; United States 4,073.
Sulfuric acid	54,449	159,741	Portugal 55,845; Spain 35,962; Ireland 31,629.
Talc, steatite, soapstone, pyrophyllite	4,348	3,978	Ireland 1,568.
Other:			
Crude	890,824	501,489	Belgium-Luxembourg 144,197; Norway 128,104; Sweden 104,295.
Slag, dross, and similar waste, not metal bearing:			
From iron and steel manufacture	100,803	126,826	Federal Republic of Germany 111,034.
Slag and ash, n.e.s	4,635	4,674	Sweden 1,490.
Oxides and hydroxides of magnesium, strontium, barium	7,647	570	Federal Republic of Germany 154; Netherlands 112.
Halogens, other than chlorine	2,660	1,958	France 583; Ireland 401; Italy 354.
Building materials of asphalt, asbestos, and fiber cement, and unfired nonmetals, n.e.s	147,388	94,345	Nigeria 17,125; Ireland 16,392.
MINERAL FUELS AND RELATED MATERIALS			
Asphalt and bitumen, natural	5,837	4,294	NA.
Carbon black	36,384	35,235	Ireland 6,209; Nigeria 3,595; Federal Republic of Germany 3,511.
Coal and briquets:			
Anthracite and bituminous coal thousand tons	1,941	2,266	France 950; Federal Republic of Germany 494.
Briquets of anthracite and bituminous coal do	157	146	Norway 137.
Lignite and lignite briquets	--	98	NA.
Coke and semicoke thousand tons	679	3,932	NA.
Hydrogen and rare gases	4,083	7,588	Ireland 4,020; Norway 1,632.
Peat, including peat briquets and litter	3,954	2,841	NA.
Petroleum:			
Crude and partly refined:			
Crude thousand 42-gallon barrels	106,756	168,668	Federal Republic of Germany 34,922; United States 30,091.
Partly refined do	1,497	NA	

See footnotes at end of table.

Table 2.—United Kingdom: Exports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1977	1978	Principal destinations, 1978
MINERAL FUELS AND RELATED MATERIALS —Continued			
Petroleum —Continued			
Refinery products:			
Gasoline, including natural thousand 42-gallon barrels	17,434	18,453	Ireland 5,002; Sweden 2,415; Denmark 1,958.
Kerosine and jet fuel do	4,852	6,301	Ireland 3,027; Denmark 884.
Distillate fuel oil do	35,600	37,260	Denmark 9,716; Netherlands 7,859; Sweden 5,514.
Residual fuel oil do	37,321	25,776	Ireland 7,149; Sweden 6,853.
Lubricants do	5,050	8,601	France 2,219; Netherlands 1,898.
Other:			
Liquefied petroleum gas do	5,695	8,661	Portugal 2,009; Spain 1,775; Ireland 1,235.
Mineral jelly and wax do	254	356	Nigeria 81; Federal Republic of Germany 64.
Nonlubricating oils, n.e.s do	556	NA	
Bitumen and other residues and bituminous mixtures, n.e.s do	909	929	Ireland 627; Nigeria 30; Dubai 19.
Pitch, pitch coke, petroleum coke do	1,963	2,658	NA.
Total do	109,634	108,995	
Mineral tar and other coal-, petroleum-, or gas-derived crude chemicals	125,520	490,034	Netherlands 291,312; Norway 58,335.

NA Not available.
[1]Value only reported at $1,604,000.

Table 3.—United Kingdom: Imports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1977	1978	Principal sources, 1978
METALS			
Aluminum:			
Bauxite and concentrate thousand tons	345	321	Ghana 229; Greece 43.
Oxide and hydroxide do	703	699	Jamaica 511; Surinam 99.
Metal including alloys:			
Scrap do	6	5	Federal Republic of Germany 1; Netherlands 1.
Unwrought do	203	191	Norway 128; Iceland 20.
Semimanufactures do	135	164	Federal Republic of Germany 27; France 21; Belgium-Luxembourg 20.
Arsenic trioxide, pentoxide, acids value, thousands	$582	NA	
Beryllium metal including alloys, all forms	12	10	United States 6.
Bismuth metal including alloys, all forms	394	NA	
Cadmium metal including alloys, all forms	1,298	NA	
Chromium:			
Chromite thousand tons	198	138	Republic of South Africa 110.
Oxide and hydroxide	578	1,033	Federal Republic of Germany 367; Netherlands 269.
Cobalt:			
Oxide and hydroxide	1,096	1,141	Canada 980.
Metal including alloys, all forms	1,100	NA	
Columbium and tantalum: Tantalum metal including alloys, all forms	115	106	United States 77.
Copper:			
Ore and concentrate	1,112	548	Czechoslovakia 495.
Matte[1]	--	1,448	Federal Republic of Germany 1,425.
Metal including alloys:			
Scrap	12,365	9,592	Ireland 1,958; Federal Republic of Germany 1,434; United States 1,040.
Unwrought	443,972	405,000	Zambia 76,972; Chile 74,450; Canada 71,998.
Semimanufactures	43,059	67,067	Federal Republic of Germany 16,469; France 12,308; Sweden 6,755.
Gold bullion:			
Refined thousand troy ounces	20,630	16,342	NA.
Unrefined do	216	92	NA.
Other do	11	--	
Iron and steel:			
Ore and concentrate, except roasted pyrite thousand tons	15,539	15,453	Brazil 3,573; Canada 3,124; Australia 1,723; Republic of South Africa 1,573.

See footnotes at end of table.

Table 3.—United Kingdom: Imports of mineral commodities —Continued

Commodity	1977	1978	Principal sources, 1978
METALS —Continued			
Iron and steel —Continued			
Roasted pyrite thousand tons	212	227	Sweden 181.
Metal:			
Scrap do	100	458	All from Federal Republic of Germany.
Pig iron, cast iron, sponge, powder, shot do	180	169	Norway 35; Federal Republic of Germany 34; Brazil 21.
Ferroalloys:			
Ferromanganese do	86	84	France 13.
Other do	226	95	Norway 66.
Steel, primary forms do	912	803	Netherlands 132; Federal Republic of Germany 119.
Semimanufactures:			
Bars, rods, angles, shapes, sections:			
Wire rods do	167	131	France 28; Federal Republic of Germany 27; Netherlands 19.
Other bars and rods do	278	345	Sweden 90; Norway 41; Italy 40; Spain 36.
Angles, shapes, sections do	207	230	Belgium-Luxembourg 48; Republic of South Africa 31.
Universals, plates, sheets:			
Heavy and medium plates and sheets, uncoated do	567	NA	
Light plates and sheets, uncoated do	834	NA	
Tinned plates and sheets do	109	112	Netherlands 60; Norway 15; United States 14.
Other coated plates and sheets do	200	NA	
Unspecified do	--	1,698	Federal Republic of Germany 365; Netherlands 221; Belgium-Luxembourg 214.
Hoop and strip do	87	91	Federal Republic of Germany 38; Belgium-Luxembourg 12.
Rails and accessories do	1	25	France 22.
Wire do	35	47	Belgium-Luxembourg 18; Federal Republic of Germany 8.
Tubes, pipes, fittings do	363	267	Federal Republic of Germany 59; Netherlands 58.
Casting and forgings, rough do	20	20	France 8; Federal Republic of Germany 4; Portugal 3.
Total do	2,868	2,966	
Lead:			
Ore and concentrate do	45	43	Canada 10; Honduras 10; Australia 8.
Oxides	147	371	NA.
Metal including alloys:			
Scrap	7,450	2,618	Ireland 1,160; United States 446.
Unwrought thousand tons	185	199	Australia 144; Canada 39.
Semimanufactures	1,610	1,834	Ireland 912; Netherlands 269.
Magnesium metal including alloys:			
Scrap	733	389	NA.
Unwrought	5,172	5,283	Norway 2,595; Netherlands 1,417; Canada 1,231.
Semimanufactures	222	440	Norway 187.
Manganese:			
Ore and concentrate thousand tons	328	261	Republic of South Africa 121; Brazil 53; Ghana 37.
Oxides	4,764	5,955	Ireland 2,911; Greece 1,560.
Metal	3,900	NA	
Mercury 76-pound flasks	8,789	12,270	Spain 3,858; Netherlands 3,626.
Molybdenum:			
Ore and concentrate	9,820	NA	
Metal including alloys, all forms	162	220	Australia 95; Federal Republic of Germany 51.
Nickel:			
Matte, speiss, similar materials	61,608	31,693	Canada 27,414.
Metal including alloys:			
Scrap	3,488	2,854	United States 611; Netherlands 541; France 454.
Unwrought	21,621	16,807	Canada 8,459; Norway 2,183; Australia 1,908.
Semimanufactures	2,930	3,199	Federal Republic of Germany 1,160; United States 1,002.
Platinum-group metals and silver:			
Ores and concentrates value, thousands	$35,356	$42,828	NA.
Waste and sweepings do	$22,936	$24,272	NA.
Metals including alloys:			
Platinum-group thousand troy ounces	354	386	Republic of South Africa 193; U.S.S.R. 32; United States 32.

COMMODITY REVIEW

METALS

Aluminum.—Prospects of an expanding aluminum market in the 1980's caused the three major British producers to consider expansion. The major obstacles were considered to be the high cost of electricity and the reluctance of the British Government to authorize subsidized lower rates.

Anglesey Aluminium Ltd., at Holyhead, Wales, a joint subsidiary of Kaiser Aluminum Co. of the United States (66.7%) and Rio Tinto Zinc Ltd. (33.3%), had sought to double its capacity of 100,000 tons per year at a cost of £150 million. However, the Central Electricity Generating Board (CEGB), a Government entity, refused to negotiate a contract for new supplies at a rate as advantageous as in the original contract, which was tied to the costs of nuclear generation, and Anglesey abandoned its plans early in 1979. It was reported that the CEGB had lost over £200 million under the original contract.

The British Aluminium Co. Ltd. (BA), also abandoned plans to expand its 100,000-ton-per-year smelter at Invergordon, Scotland, because cheap electricity was not available. BA concentrated on expanding its small plants at Lochaber, Fort William (at a cost of £20 million), and at Kinlochleven, also in Scotland. The Lochaber plant was scheduled to be expanded from its capacity of 28,000 tons to 37,000 tons per year by late 1981 at a cost of about £35 million. It was anticipated that the expansion would also permit a reduction in the work force from 518 to 337 persons.

BA reverted to its original U.K.-owned status when Reynolds Metal Co. of the

United States sold its interests in both BA and Reynolds Tube Investments Aluminum Ltd. (RTIA) in September 1978 for an estimated $86 million. Reynolds had owned 45.9% of BA directly and 2.45% through RTIA. Reynolds declared that it intended to use the proceeds for investment in the U.S. industry; it had held the interest in BA since 1959. After the sale, 58% of BA belonged to Tube Investments Ltd., the former partner of Reynolds, and the remaining shares went to over 100 institutions, mostly in the United Kingdom, none of which held more than 5%.

The third large U.K. aluminum producer, Alcan (U.K.) Ltd.'s 120,000-ton-per-year smelter at Lynemouth, Northumberland (owned 100% by Alcan Canada), produced its own electricity from coal bought from a neighboring coal mine at favorable rates. Alcan's plans for expansion of this smelter depended on continuation of this cheap coal.

The Aluminum Co. of America (Alcoa) opened a new aluminum rolling mill complex at Swansea, Wales, on July 21, 1978. Built at a cost of £40 million, with a capacity of 50,000 to 60,000 tons per year, the mill represented the largest single investment by Alcoa in Europe. It was designed specifically for the production of rigid container sheet for beverage cans.

The London Metal Exchange on August 22, 1978, announced the establishment of an aluminum futures contract, and trading started on October 2, 1978. The action was viewed as a move away from the producer price, which has been set mainly by large North American producers.

Copper.—Commonwealth Smelting Ltd. decided to build a £5 million processing plant to process the copper dross that arises from its zinc smelting operations at Avonmouth. The company planned to use leaching and electrolysis to recover the copper, and plans to treat the remaining lead sludge in a rotary furnace to produce bullion. The plant was scheduled to be completed by the mid-1980's.

BICC Metals Ltd. was constructing a new refinery at Prescot, near Liverpool, to replace its older plants. A shaft furnace, a reverberating furnace, and a tankhouse with a capacity of 55,000 tons per year, were planned to be integrated with a continuous casting and rolling unit installed in 1976. Completion was expected in 1979.

Elkington Copper Refiners Ltd., at Walsall, near Birmingham, was hit with a wildcat strike that reduced production in midyear. Elkington, a subsidiary of Brandeis Goldschmidt of London, had been refining only secondary copper for at least 2 years. Its production capacity was about 25,000 tons per year of cathodes.

Iron and Steel.—In March 1978, the Secretary of State for Industry issued a White Paper entitled "British Steel Corporation: The Road to Viability," which addressed the very difficult problem of the enormous and continuing financial losses of the British Steel Corp. (BSC). In the financial year ending that March, BSC's losses were £433 million, which was somewhat smaller than had been expected, but still equivalent to about £25 per ton for each of the 17.4 million tons produced. In relation to employment, the loss was £2,250 for each of BSC's 197,100 employees. All six divisions of BSC lost money, but the largest, the Welsh division, (5 million tons per year), also lost the largest amount, £173 million. In the following fiscal year BSC's loss was equivalent to about £300 million, and a loss of £330 million was projected for the year to March 1980.

The White Paper in effect abandoned the 10-year strategy to which BSC had been committed since 1973. Emphasis was to be placed on efficiency and product quality, rather than expansion of capacity, but there was to be no formal blueprint. According to the White Paper, however, the two major projects at Redcar, in North Yorkshire, and Ravenscraig, near Motherwell, Scotland, which were too far along for termination to be considered, would be completed. Also, a doubling of stainless steel capacity to 400,000 tons of ingot and 200,000 tons of flat-rolled stainless steel was completed in July 1978, chiefly at the Tinsley Park and Shepcote Lane plants in Sheffield. Construction of electric arc furnaces at the Selton plant near Stoke-on-Trent and at Hunterston and Ravenscraig in Scotland was deferred indefinitely. Also deferred indefinitely were two major planned expansions at Port Talbot, Wales, where £385 million had been slated for raising capacity from 3 million tons to 6 million tons per year, and at Teesside, where construction of a £250 million plate mill had been scheduled with a capacity of 1 million tons per year. The two direct-reduction plants being built at Hunterston, Scotland, were to be mothballed when completed in 1979. Five large steelmaking plants were concurrently closed; they were Clyde Iron, near Glasgow; Hartlepool (Teesside); East Moors, at Cardiff; Ebbw Vale, in Wales; and Shelton, at Stoke-on-Trent. These closings reduced BSC's employment rolls by about 17,000 workers, to a total of 189,000, including

164,500 workers actively engaged in iron and steelmaking. Furthermore, 5,000 more jobs were scheduled to be abolished later in 1979. BSC's capacity was reduced to about 22 million tons per year, but was expected to increase by about 5.5 million tons when Ravenscraig and Redcar come onstream. (This increase could be diminished, however, by any additional negotiated closures of Beswick plants.) It was expected that actual production would be only about 17 million tons in the 1978-79 financial year, the lowest since nationalization of the industry in 1967.

As 1979 progressed, it became apparent that the long-term demand for steel in the United Kingdom would probably settle at around 15 million tons per year, or about half the amount projected by optimistic predictions of only a few years before. Closures were therefore planned to cut capacity to this figure, and it was expected that employment would be further reduced by over 50,000, to a total of 100,000 steelmaking employees. The new facilities completed in the 1972-78 period were all built to take advantage of the economies of scale, and this meant that additional smaller plants would have to be closed. Consett Works in County Duram and the Hallside Works in Scotland were both scheduled to be closed, resulting in the loss of 4,000 and 600 jobs, respectively. A number of rolling mills around Britain were scheduled to be shut down, as were parts of the Scunthorpe works and the Lincolnshire works. But the hardest hit area was expected to be South Wales, where a choice was anticipated between closing either Port Talbot or Llanwern, or a partial closure of each, to scale down production in the area from 5 million tons per year to 3 million tons per year.

In a booklet sent to all members of Parliament, the BSC in April 1978 outlined its needs for continued Government assistance. These needs included financing for new plants required to merely maintain BSC's position in the market and financing to cover expected losses for the next few years. An annual investment program for the BSC, originally set at £2 billion, was scaled down to £1 billion earlier in 1978, but was then further limited to a replacement-only level of £350 to £450 million a year. BSC included 14 major projects in the program, of which Redcar, South Teesside, and Ravenscraig were the longest. These 14 projects would account for the £1 billion available under the program for capital investment up to 1980, and about 38 smaller schemes would call for additional £110 million.

The House of Commons Select Committee on Nationalized Industries produced a report that made numerous suggestions for improving the operations of the BSC, suggesting in particular improvement in relations between the Government and the BSC. The suggestions were chiefly procedural or administrative in nature, and the committee received a cool response from the Government in the form of another White Paper. The Government's White Paper suggested that any such reforms would be of only marginal value.

Tin.—Because of two mine closures, production of tin in Cornwall in 1978 and 1979 was 30% to 40% less than the 1977 total of 3,851 tons. The industry directly employed about 1,000 workers.

In April 1978, the Mount Wellington mine was shut down by the operator, Cornwall Tin and Mining Ltd., a conglomerate of U.S., Canadian, and Swiss interests. The mine's output tonnage and product grade had both been substantially below expectations, and severe water inflow problems had been encountered at the mine. The closure, which cost 320 jobs, came only 18 months after the start of operations. In the last full year of operation, the mine produced 420 tons of tin in concentrates from 144,500 tons of ore, compared with a nominal annual capacity of 200,000 tons of ore. A few weeks after the Mount Wellington mine closed, the neighboring Wheal Jane mine of Consolidated Gold Fields Ltd. was forced to close because of increased pumping costs that resulted from the closing of the Mount Wellington mine. The closing of the Wheal Jane mine, however, also followed long-term unsatisfactory mining results. If this shutdown became permanent, it would cost another 418 jobs. The Government, however, temporarily assumed the cost of pumping the two closed mines to keep them from flooding. The Wheal Jane mine produced about 750 tons of tin in concentrates in 1977, compared with about 1,000 tons in the previous year. In December 1978, the London consultants Mackay & Schnellman issued a report of an examination of the Wheal Jane mine on behalf of a prospective purchaser. Measured ore reserves were given as 192,470 tons grading 0.86% tin, 4.87% zinc, and 0.26% copper; and indicated reserves were put at 509,068 tons grading 0.89% tin, 6.03% zinc, and 0.3% copper. In addition, the mine's inferred reserves were estimated at 2.725 million tons.

In mid-1979, the Rio Tinto Zinc Corp.

(RTZ) announced that it would reopen the Wheal Jane and Mount Wellington mines as a unit, without a Government subsidy, through its subsidiary, Carnon Consolidated Tin Mines Ltd. (95% owned by RTZ). RTZ estimated that the cost of restoring production by January 1981 would be about £8.5 million (about $20 million), including the cost of purchasing the assets of the former owners. Under RTZ's plan, concentrates from the operation would be smelted by RTZ's Capper Pass smelter at North Ferriby, Yorkshire, which normally handles about 11,000 tons per year of low-grade tin concentrates, including material from Bolivia and Cornwall. The Mount Wellington concentrator at Bissoe was taken over by Billiton (UK) Ltd. to be used chiefly for processing material from old tailings dumps.

The two remaining major tin mining companies at the end of 1978 reported relatively good results for the financial years that ended in March of 1978 and 1979, due to the increased price of tin. Geevor Tin Mines Ltd., operator of the 60-year old Pendeen mine at Pendeen, was due to complete its subincline extension in 1978-79 and was planning a major expansion of its mill. In the financial year that ended in March 1979, the mine treated 119,088 tons of ore, producing 1,052 tons of 65% tin concentrate. Ore reserves as of March 31, 1979, were 379,320 tons grading 1.2% tin oxide, with a recoverable metal content of about 3,000 tons. St. Piran Ltd., at South Crofty and at its smaller Wheal Pendarves mine, both near Camborne, produced a total of 1,548 tons of tin in concentrate in the financial year to March 1979. Ore reserves were reported to have increased somewhat above the 1977 total for both mines, which at that time included 317,834 tons of measured reserves, 676,765 tons of indicated reserves, and 1.25 million tons of inferred reserves. About £1.88 million was being spent at the South Crofty mine to sink a subincline from the 380 fathom level to the 400-fathom level by 1981, in order to develop additional ore.

Marine Mining (Cornwall) Ltd. received a license from the Crown Commissioners to dredge for tin in two areas along the northwest coast of Cornwall over a period of 21 years. The main zones of interest were a 36-square-kilometer area off St. Agnes and a 23-square-kilometer area in St. Ives Bay.

Tungsten.—Initial exploration by Amax Exploration (U.K.) Ltd. on the Hemerdon Ball tungsten deposit near Hemerdon, east of Plymouth, indicated there was about 20 million tons of ore to depths of 330 feet below the surface. This led to a contract to test-drill some 5,000 meters to depths of 600 feet. Late in 1978, it was announced that results were sufficiently favorable for Amax to start a 3-year feasibility study involving exploratory drilling, bulk sampling, and financial marketing studies. A pilot plant may also be built. The survey was being done in conjunction with the owner of the property, Hemerdon Mining and Smelting Ltd., of Bermuda, and it was estimated that the survey would cost Amax about £1.5 million. By agreement, the work, if completed, would earn Amax a 50% interest in the mine. In mid-1979, Amax announced that its estimate of the Hemerdon Ball ore reserves had been increased to about 45 million tons of ore grading 0.17% tungsten trioxide and 0.025% tin and extending to 200 meters below the surface. A pilot plant to process 120 tons of ore per day was scheduled to be commissioned in March 1980. If the pilot plant is successful, plans called for a full-scale plant to treat 2,500 tons of ore per day; the full-scale plant would be started in 1983 and completed in 1985. Amax and Hemerdon also entered into an agreement to conduct exploration on adjoining property owned by English China Clays Ltd. Hemerdon officials, however, were involved in a dispute in Ontario, Canada, over company finances.

The small tungsten production of the United Kingdom in 1978 and 1979 came chiefly from the Carrock Fell mine, near Penrith, Cumbria. The 50% share of Carrock Fell held by Amalgamated Industrials Ltd. was sold in 1978 to NCC Minerals Ltd., a subsidiary of National Carbonising Ltd.

NONMETALS

Barite.—Dresser Minerals International Inc. acquired the 3-year exploration rights on 2,500 acres of Forestry Commission land near Pitlochry, Scotland. The zone targeted for exploration, near Loch Tummel, was 7 kilometers long, up to 50 meters thick, and extended 100 meters below the surface. It contains barium, zinc, and lead mineralization.

There were two major sources of barite in the United Kingdom in 1979. These were Athole G. Allen Ltd., which operated the

Closehouse mine near Lunedale in the North Riding of Yorkshire, and Horace Taylor (Minerals) Ltd., which worked a mine at Silverband, northeast of Appleby in Cumbria. The capacity of the Closehouse mine was 16,000 tons per per year of concentrate, and the Silverband mine was producing 12,000 to 15,000 tons of concentrates per year. Additional smaller producers were Laporte Industries Ltd., at its Glebe fluorspar mine near Eyam, Derbyshire; and Bleaklow Mining Co. Ltd., near Bakewell, Derbyshire. Another producer in the future may be Force Crag Mines (U.K.) Ltd., a prospective lead-zinc producer, in the Lake District of Cumbria.

Bentonite.—A prospective leading producer of bentonite was developing reserves and completing a plant to produce sodium-exchanged bentonite. Brett Bentonite Ltd., a subsidiary of Robert Brett & Sons Ltd., was granted permission to exploit a deposit at Baulking, Oxfordshire, in October 1976. Production was expected to start in the spring of 1979.

The two major bentonite producers in 1978-79 were Laporte Industries Ltd., with mines near Redhill, south of London, and Bath (underground) and Maidstone in Kent; and Berk Ltd., a subsidiary of the Steetley Co. Ltd., which operated a mine at Woburn, Bedfordshire, and a plant at Middlesbrough that processed chiefly imported clays. Permission was granted to Steetley to extend mining to a new site near Woburn.

Fluorspar.—The £2.5 million fluorspar processing plant that was being built for Swiss Aluminum Mining (U.K.) Ltd. (SAMUK) at the Broadwood Quarry, Frosterley, County Durham, was finished 4 months ahead of schedule and was opened officially in November 1978. The plant was expected to produce 50,000 to 100,000 tons of products, the grade of which will depend on the feed. It was expected that the feed would include dump ores and high-grade ore. SAMUK operates five small mines in the vicinity and, in addition to their output was also planning to treat waste dumps of nearby abandoned lead mines. SAMUK was also reported ready to shut down the old Rookhope plant, which it purchased from ICI Ltd. in 1977, in order to concentrate its efforts on the much larger plant at the Broadwood Quarry.

In order to supply its Ryder Point flotation plant near Matlock, Derbyshire, Dresser Minerals International Inc. applied for permission to mine fluorspar near Youlgreave, in the same vicinity, in the Peak District National Park. After Dresser agreed to post a bond covering future restoration of the land, permission was granted by the park board. It was estimated that when the mine and mill are at full capacity, output would be about 100,000 tons per year of acid-grade fluorspar, of which it was expected a sizable portion would be exported.

Gypsum.—The United Kingdom's largest gypsum producer, British Gypsum Ltd., dominated the domestic market, producing all but a very small part of the total production. The company had mines near Kirkby Thore, Cumbria; Sherburn-in-Elmet, east of Leeds; Fauld, northwest of Burton-on-Trent; East Leake (which was the main producing area) and Newark, in Nottinghamshire; and Robertsbridge, in East Sussex. Most deposits are worked underground, and most pass into anhydrite at relatively shallow depths.

Potash.—The mine at Boulby, Cleveland, incorporated as the Cleveland Potash Co. Ltd., required some £16 million of additional financing in the financial year to June 1978. This brought total financing for the mine presumably to about £121 million, including operating costs of £40 million since startup in 1973 and 1974; and there were reports of further requirements of £18 million. Production had still not reached the planned goal of 1 million tons of product (or 600,000 tons of K_2O). At yearend 1978, production was in the neighborhood of only 30,000 tons of product per month, but improvement was evident during 1979. The same problems that had plagued the mine since startup continued, in spite of a switch from conventional room-and-pillar mining to continuous mining with two Jeffrey Heliminers. These problems were the uneven and undulating nature of the seam, gas pockets, poor roof conditions, a higher insoluble content than was forecast, and high working temperatures. Charter Consolidated Ltd., the operator, defended itself from criticism that the 15 preliminary boreholes it had sunk were inadequate by asserting that the conditions could not have been discovered even with twice that number of boreholes.

In October 1979, Imperial Chemical Industries Ltd. (ICI) withdrew from its 50% participation in Cleveland Potash, leaving Charter Consolidated and the Anglo-American Corp. Ltd. as sole owners. A review of operations late in 1979 led to a statement by Charter Consolidated early in 1980 that it had decided to continue operations indefinitely, with no further review.

MINERAL FUELS

Coal.—Early in 1979, the National Coal Board (NCB) and the National Union of

Mineworkers (NUM) agreed on an incentive bonus scheme to improve productivity. Under local option, miners could earn upwards of £23.50 per week above their basic pay, raising total pay in some cases close to £135 per week, a figure unions had demanded in earlier negotiating rounds that had led to a 10% increase in base pay in February. Productivity, in terms of output per worker shift, thereafter increased only marginally. However, 4-year decline in output per worker shift was reversed, and in 1978 this output increased by an estimated 3.2%; counting only workers at the coal face, the increase was 12.1% by one reckoning. Overall output per worker shift in U.K. deep coal mines in 1978 was 2.2 tons (or 434 tons per year for about 200 shifts).

Production in 1978 was believed to have been about 1 million tons higher than it would have been without the incentives. This improvement came, however, at a time when the BSC, operating in a slack market, was forced to cut its coal purchases back by 3.5 million tons, to a total of 8.2 million tons for the year and total coking coal sales for the year fell to 14.5 million tons from their normal range of 17 to 18 million. The Central Electricity Generating Board, the nation's largest coal customer, however, agreed to increase purchases from 68 million in 1977 to 73 million in 1978, but presumably was forced to stockpile much of the increase. In addition, the coal industry was facing stiffer competition from the rapidly expanding hydrocarbon producers in the North Sea and from producers of low-priced natural gas in particular.

The NCB showed a profit of £74.7 million in the 1977-78 financial year, but the figure was deceiving. The underground mines suffered a loss of £13.4 million, while the opencast mines, which were all operated for the NCB by private contractors, showed a profit of £88.1 million. Nevertheless, opencast mining in the United Kingdom accounts for only about 11% of the total coal mined, which is a smaller proportion than that of any other major coal-producing country. In 1979, there were about 223 underground mines and 57 surface coal mines in operation, producing about 119 million tons of coal annually, of which about 105 million tons came from underground.

The NCB's underground mine results in South Wales were again disastrous; the 37 mines of this group (out of 238 coal mines nationwide) lost £31.8 million, leading to renewed suggestions that the area be abandoned. Abandonment of these mines was considered unlikely, however, because of the unemployment it would cause, but a tripartite committee including members from the Government, the NCB, and the NUM was looking into the problem.

For the 1978-79 financial year, a loss on nationwide underground mining was expected in the range of £50 to £100 million, even after Government grants of £124 million. It was believed that future prospective losses could only be avoided by price increases (which would make coal less competitive with oil and gas), the selective closing of pits (in 1979, four or five were already earmarked for closing), increased productivity (which might be further improved through the incentive scheme) or additional Government subsidies.

Surface mining of coal was expected to be increased by 50% under the 1974 Plan for Coal, from an annual level of 10 million tons in the early 1970's to 15 million in the early 1980's. By the middle of 1979, surface coal output had reached the rate of 13.5 million tons, and it appeared the goal would be reached. The 1978 updated Plan for Coal, "Coal for the Future," noted various problems in surface mining, including its volatile production record, which was due to the relative ease of expanding, and especially cutting back, production; the distrust with which surface mining is viewed by underground miners, who consider it a threat to their livelihood; and its conflict with environmental considerations in heavily populated areas. The Plan for Coal assumed that 20 million tons annually would be the maximum possible surface production in the United Kingdom by the year 2000, given all these constraints.

About 25 major contractors were on the NCB's list of approved strip miners. Most of these were active at some 60 sites, with operations ranging in size from 40,000 to several million tons of production per year. The largest site was at Butterwell, in Northumberland, and was operated by Taylor Woodrow Ltd. Others among the largest contractors were Costain Mining Ltd., Derek Crouch Ltd., Murphy Bros. Ltd., Shand Mining Ltd., and Shepherd Hill Ltd. Strip mines were generally between 100 and 200 feet deep. The deepest mine was the Westfield site in Fife, Scotland, which is over 600 feet deep. The average stripping ratio (the amount of waste removed to coal removed) in the U.K.'s opencast mines was 16 to 1.

Following the revelation in 1977 that coal had been found in drilling for oil in the

North Sea, the NCB announced early in 1979 that it had located extensive reserves 2 miles offshore in the estuary of the River Dee, in North Wales. It may be possible to work these reserves through tunnels from the Point of Ayr colliery nearby. In Scotland, work started on a £37 million project to mine a total of 50 million tons of recoverable reserves under Musselburgh Bay, near Edinburgh, by tunnelling 2.5 miles north from the Monktonhall coal mine. This project, the largest coal project ever undertaken in Scotland, was scheduled to be operable in 1986 and was expected to provide employment for 500 persons.

A third major project, the Park New mine, was well underway at yearend. Potentially, its production would rank only behind that of the Selby (10 million tons per year) and Vale of Belvoir (7 million tons per year) projects. These three projects were major components in the ongoing Plan for Coal, initiated in 1974, which provided for investments of about £500 million annually for new coal facilities. The Park New mine, located north of Stafford, between the villages of Hopton and Salt, was planned to be developed by the NCB to produce over 2 million tons of coal annually by 1987 or 1988 from up to 10 workable seams. Interest in the project was high because productivity, an important consideration in the United Kingdom, was expected to be three times the national average of 2.2 tons per worker shift.

Full output at Selby was expected by 1987 or 1988. A contract for the surface plant at nearby Wistow was let. It was reported that underground recovery at Selby would amount to only about 20% of the coal in place there because of the danger of flooding of the low-lying surface, which is below sea level at high tide. A first loan from the European Commission, amounting to £65 million, was approved to cover the Selby project's capital expenditures up to March 31, 1980.

Planning continued on the North East Leicestershire project in the Vale of Belvoir, which was expected to include three mines, near Hose, Saltby, and Asfordby, that would yield 7 million tons annually by the mid or late 1980's.

The Betwys anthracite mine near Ammanford, north of Swansea in Wales, was opened on schedule in mid-1979, with a capacity of 500,000 tons of anthracite produced per year. The Welsh anthracite field, which stretches northwest from Glyn-Neath for 25 miles, is the only source of anthracite in the United Kingdom. Its production had declined in the previous 5 years from about 3 million tons per year to 2 million tons per year because of declining productivity and increasing costs. The Betwys colliery was expected to slow or reverse this trend because it was projected that productivity there would be 5 tons per worker shift, compared with the national average of 2.2 tons per worker shift and the South Wales coalfield average of 1.3 tons per worker shift. Of the coal mined in the Welsh anthracite field, half was mined from the surface, and half was mined underground.

Natural Gas.—Gas Gathering Pipelines (North Sea) Ltd., the company formed in 1977 to study the viability of gas-gathering pipeline systems in the Northern Basin of the North Sea, submitted its final report in March 1978. It concluded that information available at that time indicated no immediate need for a new gas trunk pipeline to shore and that gas should accordingly be accommodated in the existing trunk lines from the Brent and Frigg fields. However, the report admitted uncertainty with regard to these conclusions and recommended a continued review.

The Morecambe gasfield in the Irish Sea, northwest of Liverpool, was planned to be developed by the British Gas Corp. (BGC) by the mid-1980's. The field was discovered in 1974 by the BGC, the State gas monopoly, and after further successful drilling in 1978, was estimated to contain 2 trillion to 3 trillion cubic feet of gas.

An estimated 25% of the supplies purchased by the BGC was associated gas from the country's northern oilfields. According to the BGC, average prices to consumers were expected to rise above those for more easily accessible southern gas; the wellhead price for northern gas paid by the BGC was 10 pence per therm (about 100 cubic feet), compared with 1.9 pence per therm for southern gas. It was claimed that future development of more marginal fields, such as South Indefatigable and Sole Pit, would require prices near the 10-pence level.

At the end of 1979, the BGC announced price increases of 20% for domestic consumers and 10% for industrial and commercial users, to be phased in beginning April 1 and October 1. This attempt to bring gas prices more in line with the cost of other fuels was a controversial move, since the BGC's pre-tax profits in the 1979 fiscal year were £361 million on £3.0 billion in sales, and since profits could in a few years exceed

£1 billion.

Petroleum.—Crude oil production, largely from North Sea offshore fields, reached only about 380 million barrels in 1978, as opposed to forecasts early in the year that it would be in the range of 450 million to 500 million barrels. In 1979, production reached 560 million barrels. Labor disputes, bad weather in the North Sea, accidents, Government policy decisions, and technical difficulties all played a part in the failure to reach expected levels. Later in the year, a consensus of a feeling of lesser urgency seemed to be developing, according to which the United Kingdom would perhaps be better off if production were permitted to reach, by the mid-1980's, only a level somewhat above self-sufficiency (2 million barrels per day, or 100 million tons per year). A lighter production level at a 3-million-barrel-per-day level would permit substantial exports and foreign exchange earnings but deplete unrenewable resources at a slower rate. At yearend, however, no change in the country's depletion policy had been announced.

In October 1978, revised estimates of the impact of North Sea oil and gas on the gross national product (GNP) and balance of payments were issued by the U.K. Treasury. Assuming a peak production of 125 million tons per year (2.5 million barrels per day) in 1985, the annual benefit of oil and gas output to the GNP would rise to £6.6 billion in 1985, versus earlier estimates of £5.9 billion. The benefit to the balance of payments in the same year was revised upwards from £7.9 billion to £8.5 billion.

By the closing date in November 1978, 55 applications, reportedly involving about 100 companies, had been received by the British Government for the 40 oil exploration blocks on offer in the Sixth Round of Licensing. This was the smallest number of blocks ever offered; it compared with 71 blocks in the Fifth Round in 1977 and several hundred in each of the previous rounds. Most of the acreage offered was in the southwestern approaches (southwest of Cornwall) and north of the Shetland Islands. Six additional blocks were awarded noncompetitively to the British National Oil Corp. (BNOC), the State-owned oil company. By spring 1979, conditional awards were made on 42 of the 46 blocks, involving 59 companies.

The conditions attached to the licensing by the Government, which were described as an attempt to strengthen British control over offshore resources, gave rise to some fears that the industry's desire to bid might be adversely affected. Exxon in fact did not bid, and Shell's bid was limited. Under the license conditions, the BNOC would receive at least 51% of the equity, as in the Fifth Round, but in addition, bidders would be allowed to offer the BNOC the right to purchase more than 51%. Also, companies must offer to carry the BNOC free in the exploration stage, and the exploration and production phases would be awarded separately, so that they might or might not be awarded to the same company. Again, as in the Fifth Round, licenses would be valid for two periods totaling 7 years, with one-third of the licensed area retained for an additional 30 years.

Two moves by the Government tended toward a further strengthening of its control over the industry. In April 1978, the BNOC was given the right of first refusal on all pre-Fifth Round oil license transfers. Then, in August, the Government proposed to Parliament that the Petroleum Revenue Tax (PRT) be changed. (This tax is in addition to royalties and the corporate income tax.) The proposal was to (1) raise the PRT from 45% to 60% as of December 31; (2) reduce the "uplift," or additional tax credit, for capital expenditures to commence or increase production, from 75% (which amounts to a 175% total tax credit on approved expenditures) to 35% (or a 135% total credit); and (3) cut the oil allowance, which is free of the PRT, from 1 million tons per year to 500,000 tons per year, with the maximum allowance for any one field to be cut from 10 million tons per year to 5 million tons per year.

The advent of the Conservative Government in 1979 resulted in several changes in Government policy toward the petroleum industry. It had been the Government's intent to sell off all or part of the assets of the BNOC, but the plan was later abandoned for political reasons. The BNOC was later asked to raise about £400 million through the issuance of bonds or shares, both to broaden its ownership base and to help reduce the national budget deficit. Plans to sell the British Petroleum Company Ltd. (BP), which represented 5% of the Government's 51% holding in the BNOC, were set later in the year, but there were no plans for further sales.

Four more fields came into production in the North Sea during 1978. These were Thistle, with 530 million barrels of recoverable reserves, operated by the BNOC, in February; Dunlin, 592 million barrels, by

Shell Transport and Trading Co. Ltd., U.K., in August; Heather, 148 million barrels, by Union Oil Co., in October; and Ninian, 1,000 million barrels, by Standard Oil Co., in December. This brought the total number of operating fields to 12, until late in 1979. Then, the South Cormorant field in the East Shetland Basin, operated by Shell, went onstream at 30,000 barrels per day on December 11, 1979. Ultimately this field was expected to produce 60,000 barrels per day.

Four oil groups sought permission late in 1979 to develop new offshore oilfields. Plans were for the Hutton field, with reserves of 250 million barrels, to be developed by Continental Oil Co., BP, the BNOC, and five other companies. The Thistle field group (composed of Burmah Oil Co. Ltd. and others) was expected to ask for a new field in block 211-18. Marathon Oil Co., along with the BNOC and others, planned to develop a major extension of the Brae field that would make possible an anticipated production of 100,000 barrels per day by 1983. Also, Mobil Corp. was seeking permission to extend the Beryl field with a second platform.

The £813 million Sullom Voe terminal in the Shetland Islands was opened in November 1978. It was expected to eventually be the largest oil terminal in Europe, with a throughput of 1.4 million barrels per day from the Ninian field and the Brent system. Expansion of Sullom Voe, by adding storage and loading facilities and a fifth jetty, could ultimately raise its capacity to 2 million barrels per day, at a final total cost of £1.2 billion.

The median line between the United Kingdom and Norway was extended northward to 63°53' 40.03N, by mutual agreement, through strict application of the equidistance principle.

The refinery planned by Occidental Petroleum Co. on Canvey Island in the Thames estuary, which had been expected to cost over £200 million, was cancelled because of what the company described as "an unexpected escalation of construction costs." The refinery had been criticized on the grounds that it would add unnecesary capacity (120,000 barrels per day) at a time when U.K. and European refineries were operating well below capacity. Another planned refinery, Cromarty Petroleum Ltd.'s 200,000-barrel-per-day plant at Nigg Point, on Cromarty Firth in Scotland, was also abandoned.

Uranium.—Two areas in the United Kingdom were under examination for uranium deposits. In County Tyrone, Northern Ireland, Sabina Industries Ltd. of Canada and E & B Exploration Ltd. provided 50% each toward an initial $165,000 program of stream and water samples and analysis on the Fintone block. The European Economic Community provided a grant of £350,000 to Minatome, a subsidiary of the French companies PUK and Total-CFP, to undertake prospecting for uranium in Cornwall and southern Scotland. Charter Consolidated Ltd. was also participating in the venture. Speaking against uranium development, however, were the Orkney Islanders, who mounted a protest against possible uranium mining around Stromnes and Yesnaby on the island's west coast.

The Mineral Industry of Venezuela

By Doris M. Hyde[1]

In 1978 and 1979, petroleum accounted for 63% and 65%, respectively, of total Government revenue earnings as compared with 71% in 1977. Revenue contributions from other segments of the mineral industry were modest. Import expenditures on industrial expansion in steel, aluminum, and hydropower continued and contributed to a 1978 adverse balance of trade estimated at $1.5 billion, as opposed to about $289 million in 1977.[2] Although imports declined by $400 million in 1979, it was the upward price spiral of petroleum exports that accounted for an estimated $4 billion positive trade balance.

In real terms, the gross domestic product (GDP) grew by 4.9% in 1978 and by 4% in 1979. The mineral export sector, primarily the petroleum industry, accounted for 9.2% of the real GDP in 1978 and 9.6% in 1979.

Despite the $613.9 million spent in 1977, the $1.0 billion in 1978, and the $1.5 billion spent by the petroleum industry in 1979, light- and medium-gravity crude oil productive capacity has continued to decline. New discoveries of light oil in the Maracaibo region have slightly increased reserves, and offshore drilling in 1979 showed promise of additional light oil and natural gas reserves. As crude oil prices continue to increase and market conditions warrant, marginal fields containing as much as 7 billion barrels of recoverable reserves may be brought back onstream.

Expansions underway in the steel industry are expected to be completed by 1980. Final planning for the steel complex in the State of Zulia, near Maracaibo, made slow progress in 1978 and 1979, partially attributed to a hesitancy on the part of the Government to commit itself to large capital investments in the face of a number of uncertainties.

Government Policies and Programs.—Ministry of Energy and Mines Resolution 148 of March 21, 1978, detailed implementation procedures for changes in the mining law established by the February 1977 issuance of Presidential Decree No. 2039. These new regulations detail the procedures and requirements the applicant must follow to obtain prospecting licenses and, subsequently, exploration and mining concessions. Financial and technical competence must be documented by applicants. Development plans are also required, which may offer special advantages, such as worker training and maximum use of Venezuelan technical services and equipment.

It was anticipated that the new regulations will permit an exhaustive evaluation of Venezuela's mineral resources. The Government also expected them to eliminate the former practice of some concession holders of retaining their concessions with no incentive for timely development.

In June 1978, the Venezuelan Income Tax Court upheld a 1976 claim by the Comptroller General against American Petrofina of Venezuela for outstanding assessments due under the Comptroller's interpretation of legislation enacted in December 1970 and implemented in March 1971. In October 1979 the Venezuelan Supreme Court refused to hear Petrofina's appeal. The controversy stemmed from a general understanding on the part of the foreign oil companies that the higher level of reference prices used as a basis for tax levies would be effective for the year 1971. The Comptroller ruled that the legislation was retroactive and, therefore, also applied to 1970. The additional assessment claim of $23,225 against Petrofina may be significant as a precedent in that there remain a number of outstanding tax levy claims against the Guarantee Fund deposits of the former oil company concessionaires and participants amounting to over $465 million. In 1979 about $380 million remained in the Guarantee Fund.

Other actions also affected the oil company ex-concessionaires. In March 1978, the Government published in the Offical Gazette, 38 separate but similarly worded resolutions issued by the Ministry of Energy and Mines which set forth the amounts to be deducted from each company's Guarantee Fund deposit for the renovation of assets nationalized in December 1975. The total sum deducted for renovation amounted to about $134 million.

In July 1978, the Venezuela Supreme Court ruled that Occidental Petroleum Co. was entitled to pursue in the courts its suit for compensation for the nationalization of its assets in Venezuela, a claim which had been delayed pending investigation of various allegations. Although the Attorney General is obligated to answer Occidental's suit, originally filed in May 1977, no time limit was specified for the response.

PRODUCTION

Venezuela's mineral industry in 1978 continued to be dominated by petroleum and iron ore. In 1979 aluminum surpassed iron ore in contributions to the economy; the increased production was from Venezuela's second aluminum smelter, Industria Venezuelana de Aluminio (Venalum), which came onstream in 1978.

Increased operating costs and a slightly lower average price defeated iron ore production gains in 1979 as the industry continued to suffer from poor world market conditions. In 1979 net profit to the industry was about one-half of that reported for 1977 and 6% less than for 1978, in spite of the production increase of over 2.6 million tons in 1979 over that of each of the two preceding years.

World events in 1979 escalated the demand and price for crude oil, and Venezuela increased production to an average of 2.35 million barrels per day. Production in 1978 averaged 2.165 million barrels per day. Late in 1979 the Government announced a crude oil production cut of 150,000 barrels per day for 1980. The per barrel production cost in relation to total investment for 1978 increased 71% over that of 1977, partly because of the deeper drilling required in new exploration for light crude, completion of preparations for costly offshore drilling, the implementation of additional secondary recovery, and improvements to refining facilities. The per barrel cost for 1979 increased 37% over that for 1978.

Other sectors of the mineral industry registered mixed performances during 1978 and 1979.

TRADE

Exports of crude oil and refined petroleum products accounted for 95% of the total value of exports in 1978 and 1979. In 1979, aluminum displaced iron ore as the second major mineral export when aluminum exports were valued at $156 million and iron ore at $142 million.

Export sales of petroleum during 1979 soared to $13.7 billion, a 57% increase over the $8.7 billion for 1978. This amount was primarily due to the 44% increase in the overall average price of petroleum and petroleum products that occurred during 1979 rather than to increased volumes. By the end of 1979, petroleum prices had increased an average of 85% more than those of December 31, 1978. Additional price increases were scheduled to become effective January 1, 1980.

New petroleum marketing agreements

between Petróleos de Venezuela, S.A. (PDVSA) and foreign companies were agreed to in principle in 1979 and were expected to be formalized early in 1980. These agreements will limit sales through multinational companies to 50% of total petroleum exports. In 1979 these sales equaled about 65% of petroleum exports. The remainder of petroleum exports will be through increased Government-to-Government contracts and PDVSA direct sales to users.

In 1978 the United States imported 48% of Venezuela's iron ore exports and small quantities were sold to new markets in the German Democratic Republic, Romania, and Colombia. In 1979, the U.S. share of iron ore exports dropped to 36%, while sales to Europe increased to 59%. Sales to the German Democratic Republic in 1979 increased 160% over those of 1978, and sales to the United Kingdom and France increased 74% and 36%, respectively, over 1978 figures.

COMMODITY REVIEW

METALS

Aluminum.—The first 70,000-ton-per-year stage of Venezuela's second aluminum smelter came onstream in mid-1978 and marked an important step in the expansion of the mineral industries. At the end of 1979, 420 of the total 720 pot cells were in operation and plant completion was projected for 1980. However, it was also reported that this Ciudad Guayana plant of Industria Venezolana de Aluminio (Venalum) encountered production problems which could delay achievement of the full 280,000-ton-per-year capacity until 1981. These problems resulted in a disappointing 14,500 tons of aluminum output for 1978, but Venalum estimated 1979 production at 121,500 tons, with 220,000 tons targeted for 1980. In 1979 Venalum was considering the possibility of adding a fifth 70,000-ton-capacity potline.

The Aluminio del Caroni, S.A. (Alcasa) smelter at Ciudad Guayana operated below its 120,000-ton-per-year capacity during 1978 and 1979. Financial problems experienced by Alcasa during those years have been attributed to an aggregation of factors including labor problems, poor management, poor maintenance, expansion cost overruns, and an unfavorable sales contract.

Since the new alumina plant of Interamericana de Alúmina, C.A. (Interalumina) is not scheduled for production until 1982, Venezuela signed an agreement with Suriname in July 1978, which provided for alumina purchases of 25,000 tons per year until the new facility is operational. Also in July, another agreement was signed with Suriname which provided for Venezuela to purchase bauxite for use in the new alumina plant. The agreement provided for an adjustment of quantities after Venezuela's Los Pijiguaos deposits are under production. Suriname agreed to make its bauxite mining technology available to Venezuela, and provision was made for the formation of a joint Venezuela-Suriname commission to be appointed to study all aspects of a possible integration of the aluminum industry of the two countries.

Venezuela may obtain additional bauxite resources as Cia. Vale do Rio Doce (CVRD) announced plans to sell 5% of its share of equity in Brazil's Trombetas bauxite project to Corporación Venezolana de Guayana (CVG), which holds an 85% interest in Interalumina.

In 1979 a new State company, CVG Bauxita Venezolana, C.A. (Bauxiven), was established to mine and market the bauxite deposits at Los Pijiguaos in the State of Bolívar. It was reported that the Swiss firm Aluminio Suizo, S.A. (Alusuisse), which has an interest in Interalumina, will assist CVG in developing the estimated 500 million tons of reserves. Another 40 million tons of bauxite deposits were reported as having been discovered in the eastern region of the State of Guayana.

Gold.—About 80% of 1978 gold production came from operations of the Sindicato de Patrones Mineros, 1% came from independent miners, and 19% from other concessionaires. In 1979 the Sindicate accounted for over 92% of production while independent miners and the other concessionnaires produced about 6% and 2%, respectively. The continuing rise in world market gold prices softened the impact of a 1978 production decline and encouraged increased 1979 production.

Iron Ore.—The mines of Cerro Bolívar yielded 69% of total Venezuelan iron ore production during 1978, while the El Pao mines contributed 27% and the San Isidro deposits almost 4%. In 1979, Cerro Bolívar produced 51% of total production, El Pao yielded 27%, the now-producing Altamira deposit 16%, and San Isidro accounted for 6%. About 600,000 tons of ore were consumed domestically in 1978 and 700,000 tons in 1979.

Net industry earnings from iron ore in 1978 were estimated at \$12.7 million, a substantial decline from 1977 earnings of \$24.2 million. Although there was some improvement in the volume of export sales over those of 1977, the 1978 decrease in net earnings reflected continued poor world market supply-demand conditions. During 1979 sales again increased but net earnings were estimated at \$11.9 million, mainly as a result of increased costs.

In 1978 CVG Ferrominera Orinoco, C.A., announced the investment of over \$58 million for the expansion of crushing, drying, and screening facilities, and the completion of a railway between Ferrominera installations and the Siderúrgica del Orinoco (SIDOR) steel complex in the State of Guayana. Increased demand from the expansion of SIDOR's pelletizing and steelmaking plants and the prospects of a second integrated steel complex in the Maracaibo region accounted for Ferrominera's decision to upgrade its installations.

In November 1978, SIDOR's two-strand 6.6-million-ton-per-year iron ore pelletization plant was brought onstream. The plant, part of SIDOR's \$3,500 million expansion program, was reported to be the largest of its kind in the world.

Venezuela's estimated proven iron ore reserves grading over 55% iron total 1,748 million tons; reserves under 55% iron total 575 million tons. Deposits of ferruginous quartzite containing 35% to 45% iron are estimated at about 8 to 10 billion tons.

Iron and Steel.—In 1978 Ferrominera allocated \$35 million to remodel the direct-reduction high iron briquet (HIB) plant at Puerto Ordaz which had closed in 1977 due to operational problems. The plant entered its startup phase in 1979. It was reported that the production will go to the export market.

Fior de Venezuela, S.A., a privately held company, brought its concentrated iron ore briquette plant onstream in 1978. The plant uses a fluidized direct-reduction process developed by Exxon Corp. to produce iron briquettes of about 92% concentration. The product was designed to be used in electric furnaces but may have other uses in steel manufacturing. Annual production was expected to reach 280,000 tons in 1980 and 300,000 tons in 1981.

During 1979 SIDOR brought three Midrex direct-reduction modules onstream. A three-module, direct-reduction plant using the Hyl process developed by the Mexican company Hojalata y Lámina S.A. (HYLSA), was scheduled to come onstream in late 1979 or early 1980. When fully operational these plants, and the one-module Midrex and Hyl plants commissioned in 1977, will provide an annual sponge iron capacity of almost 4 million tons.

Shortages of skilled labor, high operating costs, and technical difficulties have worsened SIDOR's financial status and it has continued to operate at a loss since 1977. The steel complex employed about 15,000 workers in 1978 and was expected to reach 20,000 by 1980. Worker training programs were emphasized and an assistance agreement was signed with Empresa Nacional Siderúrgica de España, S.A. (ENDESSA), of Spain to allow SIDOR's employees to be trained in Spanish steelworks. Another agreement with Nippon Steel Corp. will provide SIDOR with technical assistance for the operation of newly installed steelmaking equipment. SIDOR anticipated that capacity steel output would be achievable by 1984.

Development of the new steelmaking complex planned for the Maracaibo region in the State of Zulia progressed slowly as international bidders for a 49% equity partnership were evaluated. The cautious approach to a firm commitment to proceed with the Zulia steel complex was variously attributed to some uncertainty over financial priorities, the previous commitment to SIDOR's ongoing expansion and modernization, and to the problems experienced by SIDOR with skilled labor shortages and poor productivity, which could forewarn of similar problems at the Zulia complex. At the end of 1979 the project was still under active consideration and study.

In late 1979, Siderúrgica Venezolana, S.A. (Sivensa), Venezuela's largest private steel company, announced its intention to acquire Siderúrgica del Turbio (Sidetur), the second largest private steel company.

NONMETALS

Cement.—In 1978 a strong domestic demand and a desire to stockpile against possible future shortages led the Government to contract with the Colombian Government for the importation of cement at the rate of 425,000 tons per month. Total imports of Colombian cement were expected to reach at least 3.8 million tons during 1978 and 1979.

Construction of new plants and plant expansions during 1978 and 1979 were expected to increase national output to about 8.1 million tons per year.

Diamond.—The total value of diamond production during 1978 was about $46 million, registering a substantial gain over that of 1977 because of the greater proportion of gem quality stones produced. In 1979 the total value declined to about $42 million owing to the increased proportion of Bort grade diamonds. In 1979 Venezuela began to expell illegal foreign diamond prospectors.

The majority of production comes from the alluvial gravels in the Paragua and Caroní Rivers. It has been theorized that the diamonds originated in conglomerates of the Mesozoic Roraima series. The Roraima has been considered the same as the Kaieteur Series in the diamondiferous region of Guyana. Kimberlite minerals have been identified in recent sedimentary deposits in the western part of the State of Bolivar and additional exploratory work is underway.

MINERAL FUELS

Coal.—The State of Tachira coal deposits provided 58% of total production in 1978, while 41% came from the Naricual mines in the State of Anzoátegui and 1% from other areas. Coal production from the State of Zulia has continued to undergo evaluation studies. A drastic 98% reduction in output from the mines of C.A. Minas de Carbón de Naricual during 1979 resulted in total coal production decreasing substantially from that of 1978, despite a 20% increase in production from the C.A. Minas de Carbón de Lobatera operation in the State of Tachira. In 1978, lower output from the Naricual mines was also largely responsible for the sizable overall production decline from the 1977 level.

In October 1978, the Government established a new company, Carbones del Zulia, C.A. (Carbozulia), to exploit the Guasare coal deposits in the State of Zulia. The ownership of the new company is shared by Corporación de Desarrolla del Estado de Zulia (Corpozulia) (60%), and Fondo de Inversiones de Venezuela (40%). Carbozulia was capitalized at $39.7 million. Prequalification of contractors for mine design and railroad transport projects was to begin in 1979. Early in 1978 open pit operations for coal analyses were begun on Seam IV near Paso del Diablo. Open pit mining of the 12-foot-thick Seam IV down to a depth of 200 meters should yield 70 million tons of coal with total recoverable reserves estimated at 120 million tons. Projections of total coal reserves in the Guasare belt were greater than 1,500 million tons. During 1979 progress continued on drilling, road building, and coal analyses.

Petroleum and Natural Gas.—In 1978 Petróleos de Venezuela S.A. (PDVSA) completed its internal reorganization. Final consolidation of subsidiaries has resulted in four major operating companies, as shown below:

New operating company	Companies consolidated
Corpoven, S.A	Bariven, S.A. (Barinas field).
	Boscoven, S.A.
	Corp. Venezolana de Petróleo.
	Deltaven, S.A.
	Llanoven, S.A.
	Palmaven, S.A.
Lagoven, S.A	Amoven, S.A.
	Lagoven, S.A.
	Roqueven, S.A. (eastern fields).
Maraven, S.A	Maraven, S.A.
	Roqueven, S.A. (western fields).
	Taloven, S.A. (western fields).
	Vistaven, S.A. (western fields).
Meneven, S.A	Bariven, S.A. (El Chaure refinery).
	Guariven, S.A.
	Meneven, S.A.
	Roqueven, S.A. (San Roque refinery).
	Taloven, S.A. (eastern fields).
	Vistaven, S.A. (eastern fields).

In its effort to revitalize Venezuela's petroleum industry and reverse the decline in light oil production, PDVSA invested over $1.1 billion for production, exploration, refining, and marketing operations in 1978. In 1979 investment spending was increased to about $1.5 billion, and a $2.9 billion program was announced for 1980. PDVSA net earnings for 1978 declined about 20% from those in 1977 to $1.45 billion. The profit decline was attributed to increased costs, depressed world demand, and the increased export of lower priced heavy crude and refined products. Net earnings in 1979 almost doubled, reaching $2.8 billion. The profit gain reflected increases in production, export sales, and prices.

The 1978 year-end estimate of crude oil reserves increased to almost 18.2 billion barrels, and natural gas reserves increased to 42.1 trillion cubic feet. In 1979, the estimate of crude oil reserves increased to over 18.7 billion barrels, and in 1980 is expected to reach 19.4 billion barrels. Natural gas reserves at the end of 1979 were estimated at 44 trillion cubic feet.

The deep Cretaceous drilling in Lake Maracaibo during 1978 and 1979 added light-gravity oil to proved reserves, and younger sediments also contributed significant new reserves. The huge heavy oil deposits of the Orinoco basin will provide additional reserves; the oil-in-place has been conservatively estimated at 700 billion barrels, with some estimates as high as 3 trillion barrels. Recovery factors vary between 5% and 30%, which would conservatively result in some 35 billion barrels of recoverable oil.

Secondary recovery accounts for about one-half of Venezuela's current production. Steam-injection programs have been very successful and constitute a major part of planned secondary recovery projects.

Exploration efforts were underway in several areas: the Maracaibo basin, the Perija area of Zulia, the Gulf of Vela, Gulf of Triste, the Tuy-Cariaco belt near Margarita Island, the Norte-Paria area approaching Trinidad, and the Orinoco River delta.

Lagoven began drilling about 50 miles off the Orinoco River delta in 1978. After three dry holes the company moved north to the Gulf of Paria. In 1979 gas was found at 12,000 feet in a well drilled about 25 miles north of the peninsula. It was estimated that the field may contain 10 trillion cubic feet of natural gas. Further drilling was planned to delineate the size and structure of the field and determine its relationship, if any, to a field in Trinidad. When the company concludes this and other activities in the Gulf of Paria, it plans to return to the Orinoco Delta.

After three dry holes, Corpoven drilled successfully in the Gulf of Vela and anticipated that the area will eventually add significant oil reserves. Corpoven's discovery, located north of the town of Coro, may be related to the old onshore Cumerebo field. The well tested over 2,000 barrels per day of 31° API oil.

After three unsuccessful tests during 1978 and 1979 in the Gulf of Triste, in 1979 Maraven drilled a well between the islands of Margarita and La Tortuga which tested at 1,000 barrels per day of 30° API oil. This discovery was significant in that it established the existence of petroleum in the virtually unexplored Tuy-Cariaco basin. Maraven planned further drilling in this area before returning to the Gulf of Triste.

The Maracaibo basin has been considered the probable southern half of an oil rich area which extends northward into the Gulf of Venezuela. A border dispute with Colombia has, to date, effectively prohibited exploration in the northern area.

Investigations of improved recovery techniques for the heavy metals-rich oil along the Orinoco River continued during 1978 despite some debate as to practicality and priority. World developments in the petroleum sector during 1979 modified the Government's policy towards the Orinoco deposits from one of holding the reserves for future development to one of using the reserves to benefit present economic priorities as well as accomodate increased world demand. To help conserve the light- and medium-grade crude oils, more heavy oil production capability will be developed and sold.

In 1979 PDVSA announced it would invest $2.3 billion over the next 10 years to develop the Orinoco petroleum resources. It was thought that as much as 1 million barrels per day of oil could be produced from this area by the end of this century. Current recovery techniques involving both steam injection and cold production have not been sufficiently tested to provide meaningful comparisons.

Venezuela has a refining capacity of 1.445 million barrels per calendar day, which represents the largest of the Organization of Petroleum Exporting Countries (OPEC) member countries. Refinery outputs were structured to yield about 60% heavy fuel, but market demands have altered and Venezuela is now upgrading the Amuay and

El Palito refineries to include a greater range and quantity of lighter products and to accomodate the input of a wider range of crude oil gravities. The Amuay modifications will cost in excess of $650 million and are scheduled for completion in 1982. The $300 million expansion program for the El Palito refinery will be completed in 1981.

The Mineral Industry of Yugoslavia

By Roman V. Sondermayer[1]

During 1978 and 1979, low mineral and metal prices high cost of equipment and supplies, transportation difficulties, labor problems, Government regulations, and lack of capital hampered the activities of the Yugoslav mineral industry, but the sector remained among the most active segments of the economy. Yougoslavia was among the leading mine and smelter producers of nonferrous metals in Europe. The major minerals mined, with production expressed in approximate ranges of percentage of recent world output, were as follows: magnesite 5% to 6%, lead 4% to 5%, bauxite and antimony 3% to 4%, copper and zinc 1% to 2%. Production of other minerals was only of domestic significance. Lignite was again the principal fuel produced in the country. As in the past, imports of liquid fuels and bituminous coal were essential to meet the energy demand of the country. In addition, Yugoslavia became an importer of natural gas in 1978.

During 1978 and 1979, the mineral industry contributed about 10% to the gross social product (GSP), and its share in the industrial labor force ranged between 5% and 6% of the total. Inflation (13% to 20%), unemployment (about 14%), and foreign trade deficit afflicted the country's economy.

During 1978, the major events in the minerals industry included completion of alumina plants near Zvornik, Bosna i Hercegovina (BiH), near Obrovac, Hrvatska (Croatia); construction of an aluminum smelter near Mostar, BiH; completion of a plant for recovery of magnetite at Majdanpek, Srbija (Serbia); completion of construction of a new blast furnace at Zenica (BiH); beginning of construction of a new lead refinery at Zvecan, Serbia; and completion of gas pipelines bringing natural gas from the U.S.S.R. into Yugoslavia. During 1979, major accomplishments of the country's mineral industry were as follows: expansion of Sibenik aluminum plant; construction of aluminum smelter near Mostar; development of an opencast copper mine at Veliki Krivelj, Serbia; discovery of new chromite reserves near Radusa, Macedonia, and start of development of a nickel mine and beginning of construction of a nickel smelter at Glogovac, Serbia; construction of another nickel mine and smelter at Rzanovo, near Kavadarci, Macedonia; and completion of construction of a pipeline between the island of Krk on the Adriatic and inland refineries in Yugoslavia, Hungary, and Czechoslovakia.

PRODUCTION

The size of mining and mineral processing enterprises in Yugoslavia range from large integrated operations with modern technology, mostly in production of metals and petroleum, to small, rather primitive operations, mostly in production of nonmetals.

The mineral industry was State-owned. However, investment of foreign capital in Yugoslavia's industry, including the mineral industry, was permitted provided that Yugoslavia retained ownership of the deposit and a controlling interest in the venture, and that management of the venture be in accordance with Yugoslav laws concerning workers' self-management. The tabulation below lists the major enterprises, with principal facilities, operating in Yugoslavia during 1978 and 1979.

Structure of industry

Commodity	Major companies—principal facilities (all State-owned)
Aluminum	Boris Kidric Tvornica Lakih Metala - smelter at Sibenik, Croatia.
Antimony	RTB Zajaca - smelter at Zajaca; mines at Kopaonik Mountain, Serbia.
Bauxite	Energoinvest - mines at Vlasenica, Bosnia.
Coal, brown	Titov Rudnici (Uglja) - mines at Kreka Banovici Breza, Kakanj, Bosnia.
Copper, metal	RTB Bor-mines at Bor and Majdanpek; smelter at Bor, Serbia.
Lead, smelter	RMK Trepca - mine at Stari Trg; smelter at Zvecan, Serbia.
Lignite	REK Kolubara - mines at Kolubara and Tamnava, Serbia.
Petroleum	INA Naftaplin - oilfields at Benicanci and Struzec; refineries at Rijeka and Sisak.
Steel, crude	RMK Zenica - integrated iron works at Zenica, Bosnia.
Zinc, mine	RMK Trepca - mine at Stari Trg.
Zinc, smelter	Zletovo, Topilnica za Cink i Olovo - Imperial smelter at Titov Veles, Macedonia.

[1]In addition to the commodities listed, germanium, bentonite, kaolin, common clay, and diatomite are also produced, and tellurium may be recovered as a copper refinery byproduct, but available information is inadequate to make reliable estimates of output levels.

[2]Reported figure.

[3]Apparently included with ferrosilicon.

[4]Excludes refinery gas (12,639 million cubic feet in 1976, 15,351 million cubic feet in 1977, and an unreported quantity in 1978 and 1979), as well as other materials produced by and used in the refineries as fuel.

TRADE

During 1978, latest year for which, complete data are available, Yugoslavia was a net importer of minerals, with fuels causing most of the deficit. Imports of minerals, valued at 43.3 billion dinars[2] ($2.5 billion), accounted for 26% of total imports. Fuels, mostly crude oil and bituminous coal, were 51% of mineral imports. Exports of minerals, valued at 14.4 billion dinars ($800 million), were about 16% of total exports. Exports of nonferrous metals accounted for 37% of mineral exports. Tables 2 and 3 show details on foreign trade of Yugoslavia in 1978.

Iron and steel:			
Ore and concentrate	--	16,290	East Germany 16,290.
Roasted pyrite	27,674	33,833	Hungary 30,393.
Metal:			
Scrap	42,399	79,288	Italy 69,857; Switzerland 6,272.
Pig iron, ferroalloys, similar materials	181,614	179,381	United States 87,494; Italy 27,446; Austria 25,307.
Steel, primary forms	10,071	16,551	Hungary 15,608.
Semimanufactures:			
Bars, rods, angles, shapes, sections	35,106	87,130	U.S.S.R. 32,342; West Germany 6,148; Poland 5,379.
Universals, plates, sheets	14,003	28,565	West Germany 16,488; Poland 4,650; Austria 3,923.
Hoop and strip	4,549	3,430	Poland 1,861; Italy 839.
Rails and accessories	33,857	27,875	Romania 24,929.
Wire	701	520	Hungary 199; East Germany 162.
Tubes, pipes, fittings	136,128	183,506	China, mainland, 37,149; U.S.S.R. 37,041.
Castings and forgings, rough	8,454	7,593	Poland 3,028; East Germany 1,799.
Lead:			
Ore and concentrate	5,430	39,893	Poland 33,774; U.S.S.R. 4,170; Czechoslovakia 1,949.
Oxides	14	2	U.S.S.R. 1.
Metal including alloys:			
Unwrought	51,540	47,923	U.S.S.R. 27,719; Czechoslovakia 6,479; Austria 6,228.
Semimanufactures	2,239	1,601	France 466; Italy 458; West Germany 376.
Manganese ore and concentrate	3,070	--	
Mercury 76-pound flasks	1,400	--	
Nickel metal including alloys, all forms	302	309	Switzerland 151; West Germany 73; Italy 48.
Platinum-group metals including alloys, all forms: Palladium troy ounces	75,168	66,745	Netherlands 33,887; West Germany 28,550.
Selenium, elemental kilograms	36,000	--	
Silicon	20,419	27,825	U.S.S.R. 9,306; United States 7,443; Romania 2,628.
Silver metal including alloys, all forms thousand troy ounces	2,805	2,182	United States 1,307; Czechoslovakia 412.
Tin metal including alloys, all forms	135	65	West Germany 49; Switzerland 11.
Titanium oxide	13,355	13,453	East Germany 12,839; United States 578.
Zinc:			
Ore and concentrate	NA	2,271	U.S.S.R. 2,271.
Oxide	936	1,270	Romania 880; Hungary 360.
Metal including alloys:			
Blue powder	5,180	--	
Unwrought	41,968	45,241	U.S.S.R. 20,513; Czechoslovakia 17,049.
Semimanufactures	2,942	9,253	Czechoslovakia 4,566; U.S.S.R. 3,479.

See footnotes at end of table.

Table 2.—Yugoslavia: Exports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1977	1978	Principal destinations, 1978
METALS —Continued			
Other:			
Ash and residue of nonferrous metals	22	28,991	Bulgaria 16,248; Italy 10,147.
Oxides, hydroxides, peroxides of metals, n.e.s.	102	87	Sweden 85.
NONMETALS			
Abrasives, natural: Grinding and polishing wheels and stones	2,749	2,773	Romania 1,309; Poland 710.
Asbestos	2,159	1,902	Albania 1,369; West Germany 280; Romania 110.
Barite and witherite	25,309	16,495	Hungary 16,445.
Cement	410,116	326,079	Nigeria 111,010; Tunisia 83,770.
Chalk	6	15	Hungary 15.
Clays and clay products (including all refractory brick):			
Crude:			
Bentonite	38	136	Guinea 136.
Fire clay	5,734	9,975	Italy 8,391.
Kaolin	10,638	9,812	Italy 5,637; Greece 4,171.
Products:			
Refractory (including nonclay brick)	61,777	61,923	Romania 29,275; West Germany 9,786; Poland 5,413.
Nonrefractory	4,812	7,153	Venezuela 4,786; Austria 949.
Feldspar	8,932	7,904	Hungary 4,753; Greece 1,923; Czechoslovakia 1,209.
Fertilizer materials, manufactured:			
Nitrogenous	35,042	72,819	Turkey 50,425; West Germany 14,910.
Phosphatic	159,937	160,263	Hungary 104,901; U.S.S.R. 24,940; Nigeria 19,992.
Other, including mixed	156,245	184,090	Turkey 61,453; Italy 49,334; Hungary 19,948.
Gypsum and plasters	14,354	288	U.S.S.R. 259.
Lime	6,231	27,534	Hungary 16,264; Kuwait 11,193.
Magnesite	r29,113	31,348	West Germany 20,184; Italy 4,125.
Pyrite, gross weight	214,214	93,421	Romania 74,664; West Germany 18,757.
Salt and brine	50	54	Hungary 50.
Sodium and potassium compounds, n.e.s	3,024	1,274	France 300; Romania 275; West Germany 212.
Stone, sand and gravel:			
Dimension stone:			
Crude and partly worked	59,715	49,745	Italy 29,115; Czechoslovakia 14,181.
Worked	8,172	6,252	West Germany 4,147; Austria 1,304.
Dolomite, chiefly refractory grade	90	1	West Germany 1.
Gravel and crushed rock	178,915	57,238	Gabon 51,180.
Limestone (except dimension)	4,071	10	West Germany 10.
Quartz and quartzite	8,141	9,767	West Germany 9,467; Greece 300.
Sand, excluding metal bearing	1,570	2,376	Greece 1,584; Albania 755.
Sulfur:			
Elemental other than colloidal	NA	266	Romania 244.
Sulfuric acid	r1,737	1,192	Albania 1,154.
Other:			
Crude:			
Calcite	242	2,149	Greece 1,797.
Unspecified	1,130	257	Greece 254.
Slag, dross, and similar waste, not metal bearing	1,779	1,615	Austria 1,554.
MINERAL FUELS AND RELATED MATERIALS			
Carbon black	21	55	West Germany 55.
Coal and briquets:			
Anthracite and bituminous coal	NA	940	Romania 940.
Lignite and lignite briquets	217,375	434,929	Austria 216,761; Italy 185,043.
Hydrogen, helium, rare gases kilograms	378,301	633,265	Austria 492,280; Italy 108,785.
Peat, including peat briquets and litter	26	25	Italy 25.
Petroleum:			
Crude	(1)	(1)	All to Czechoslovakia.
Partly refined thousand 42-gallon barrels	(1)	NA	
Refinery products:			
Gasoline do	2,652	3,536	Netherlands 1,777; Switzerland 1,717.
Kerosine and jet fuel do	186	395	United Kingdom 101.
Distillate fuel oil do	3,088	2,380	Italy 1,380; Switzerland 836.
Residual fuel oil do	1,758	306	Italy 280.
Lubricants do	14	336	Italy 315.
Other:			
Liquefied petroleum gas do	NA	174	Italy 174.
White spirits do	r34	33	Austria 33.
Mineral jelly and wax do	39	39	Italy 16; West Germany 8.
Petroleum coke do	55	40	West Germany 39.
Total do	r7,826	7,239	
Mineral tar and other coal-, petroleum-, or gas-derived crude chemicals	7,950	20,293	Italy 10,225; United States 4,907; France 2,651.

rRevised. NA Not available.

[1]Less than 1/2 unit.

Table 3.—Yugoslavia: Imports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1977	1978	Principal sources, 1978
METALS			
Aluminum:			
Bauxite and concentrate ___ thousand tons__	51	44	Greece 17; Guinea 11; Australia 9.
Oxide and hydroxide	1,347	30,162	Guinea 29,000.
Metal including alloys:			
Unwrought	43,699	41,590	U.S.S.R. 35,714; Hungary 4,200.
Semimanufactures	13,921	9,538	U.S.S.R. 4,798; West Germany 1,561.
Antimony:			
Ore and concentrate	2,209	2,789	Turkey 800; Australia 604; Morocco 504.
Metal including alloys, all forms	170	145	China, mainland, 145.
Arsenic:			
Trioxide, pentoxide, acids	50	NA	
Metal including alloys, all forms	r21	36	U.S.S.R. 25.
Beryllium metal including alloys, all forms kilograms__	323	167	Denmark 104; West Germany 63.
Bismuth metal including alloys, all forms	31	18	China, mainland, 13.
Cadmium metal including alloys, all forms	7	NA	
Chromium:			
Chromite	r225,471	219,069	Albania 126,971; U.S.S.R. 74,840.
Oxide and hydroxide	740	619	United Kingdom 450.
Metal including alloys, all forms	17	NA	
Cobalt:			
Oxide and hydroxide	35	32	Netherlands 10; Belgium-Luxembourg 8.
Metal including alloys, all forms	71	NA	
Columbium and tantalum: Tantalum metal including alloys, all forms ________ kilograms__	574	859	West Germany 705.
Copper:			
Ore and concentrate	20,137	23,994	Mexico 13,825; Peru 10,168.
Copper sulfate	1,537	1,553	U.S.S.R. 1,536.
Metal including alloys:			
Scrap	10	(1)	
Unwrought	27,186	39,791	Zambia 25,117; Peru 11,727.
Semimanufactures	r6,670	8,469	Hungary 3,425; U.S.S.R. 1,540; Belgium-Luxembourg 1,293.
Iron and steel:			
Ore and concentrate	515,443	547,006	India 247,168; U.S.S.R. 185,352.
Metal:			
Scrap	409,022	402,594	U.S.S.R. 367,104; Bulgaria 31,866.
Pig iron, including cast iron	17,757	71,612	East Germany 34,880; U.S.S.R. 21,190.
Sponge iron, powder, shot	2,031	2,626	Sweden 2,235.
Ferroalloys:			
Ferromanganese	799	815	West Germany 473; Switzerland 140; Belgium-Luxembourg 126.
Other	7,789	6,584	West Germany 2,163; France 1,470.
Steel, primary forms:			
Blooms, billets, slabs, sheets, bars	621,869	581,773	Czechoslovakia 191,961; Romania 133,849; U.S.S.R. 133,118.
Coils for recoiling	360,085	435,191	Czechoslovakia 117,196; U.S.S.R. 79,076; Bulgaria 72,177.
Semimanufactures:			
Bars, rods, angles, shapes, sections	r185,948	278,601	Hungary 80,503; Romania 33,282; Poland 29,804; Czechoslovakia 18,694.
Universals, plates, sheets	479,226	441,289	Czechoslovakia 111,562; West Germany 82,849; Austria 54,235.
Hoop and strip	102,729	90,270	West Germany 28,927; Poland 18,266; Czechoslovakia 13,322.
Rails and accessories	7,478	7,482	West Germany 5,847; U.S.S.R. 712; Austria 668.
Wire	r57,015	30,145	West Germany 7,623; Austria 4,310; Romania 1,935.
Tubes, pipes, fittings	144,010	88,054	East Germany 17,456; West Germany 10,011; France 9,530.
Castings and forgings, rough	1,258	2,198	Czechoslovakia 624; West Germany 478; France 375; Italy 288.
Lead:			
Ore and concentrate	22	5,623	Greece 4,123; China, mainland, 1,500.
Oxides	2,765	3,084	Bulgaria 1,511; West Germany 698.
Metal including alloys:			
Scrap	2,187	NA	
Unwrought	5,321	8,192	Bulgaria 7,010.
Semimanufactures	51	104	West Germany 104.
Magnesium metal including alloys, all forms	1,430	976	Norway 342; U.S.S.R. 316.
Manganese:			
Ore and concentrate	r126,860	96,346	Gabon 42,242; Switzerland 26,240; U.S.S.R. 16,870.
Oxides	2,606	794	France 320; Belgium-Luxembourg 149; West Germany 122.
Metal	437	NA	
Mercury ______________ 76-pound flasks__	58	230	China, mainland, 203.

See footnotes at end of table.

Table 3.—Yugoslavia: Imports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1977	1978	Principal sources, 1978
METALS —Continued			
Molybdenum metal including alloys, all forms	12	18	Austria 10; West Germany 6.
Nickel metal including alloys:			
Scrap	135	10	Switzerland 10.
Matte, speiss, similar materials	193	108	Netherlands 108.
Unwrought	234	238	Hungary 99; West Germany 51; Sweden 40.
Semimanufactures	597	430	West Germany 320.
Platinum-group metals including alloys, all forms:			
Platinum troy ounces	1,929	71,375	West Germany 64,655.
Palladium do	79,766	NA	
Rhodium do	129	NA	
Other do	r932	NA	
Silver metal including alloys thousand troy ounces	7,779	1,475	Austria 547; West Germany 389; Poland 286.
Tellurium, elemental kilograms	505	NA	
Tin:			
Oxides	17	13	West Germany 12.
Metal including alloys:			
Unwrought	1,960	1,833	China, mainland, 1,779.
Semimanufactures	25	36	West Germany 21; Italy 15.
Titanium:			
Ore and concentrate	47,305	45,980	Australia 45,482.
Oxides	2,853	2,578	France 1,126; West Germany 967.
Metal including alloys, all forms	43	NA	
Tungsten metal including alloys, all forms	18	23	China, mainland, 7; Austria 5; Netherlands 3.
Zinc:			
Ore and concentrate	33,641	33,465	Peru 16,510; North Korea 13,954.
Oxides	676	227	West Germany 223.
Metal including alloys:			
Unwrought	14,127	4,794	Zambia 2,203; Poland 1,979.
Semimanufactures	85	74	Italy 39; France 20; East Germany 14.
Zirconium metal including alloys, all forms	3	NA	
Other:			
Ores and concentrates:			
Of vanadium, tantalum, zirconium	1,691	2,117	Australia 961; Hungary 750; West Germany 403.
Ash and residue containing nonferrous metals	872	1,614	Switzerland 1,183.
Oxides, hydroxides, peroxides of metals, n.e.s.	988	1,222	West Germany 890; U.S.S.R. 100.
Metals including alloys, all forms:			
Metalloids	r74	NA	
Alkali, alkaline earth, rare-earth metals	342	230	France 210.
Pyrophoric alloys	(1)	33	Poland 30.
Base metals including alloys, all forms, n.e.s	3	615	Netherlands 101; West Germany 73; United Kingdom 73.
NONMETALS			
Abrasives, natural, n.e.s.:			
Pumice, emery, natural corundum, etc	303	505	Denmark 184; Hungary 154; Italy 84.
Grinding and polishing wheels and stones	1,233	793	Austria 322; Italy 141; Poland 108.
Asbestos	57,032	47,797	U.S.S.R. 27,037; Canada 11,944.
Barite and witherite	1,110	1,206	West Germany 1,030.
Boron materials:			
Crude natural borates	24,930	28,736	United States 20,856; Turkey 7,500.
Oxides and acids	731	372	U.S.S.R. 337.
Bromine	15	12	West Germany 6; Austria 5.
Cement:			
Portland thousand tons	r601	552	U.S.S.R. 208; Hungary 161; Czechoslovakia 95; Bulgaria 75.
Other do	97	89	Bulgaria 55; Italy 23; Austria 11.
Chalk	r3,184	2,383	France 1,594; Austria 606.
Clays and clay products (including all refractory brick):			
Crude clays, n.e.s.:			
Bentonite	759	16	Italy 12; Austria 3.
Fire clay	25,803	35,610	Czechoslovakia 32,884.
Fuller's earth, Dinas earth, chamotte	4,086	5,442	Poland 4,230; Czechoslovakia 888.
Kaolin	67,062	73,464	Czechoslovakia 38,416; East Germany 11,052.
Other	2,903	8,660	Czechoslovakia 7,292; West Germany 499; Poland 302.
Products:			
Refractory (including nonclay brick)	50,980	40,928	West Germany 10,420; France 7,654; United States 6,479.
Nonrefractory	37,272	27,487	Italy 8,098; Czechoslovakia 8,054; Romania 4,354.
Cryolite and chiolite	1,127	120	Denmark 120.
Diamond:			
Gem, not set or strung carats	80,000	100,000	West Germany 45,000; United Kingdom 25,000.
Industrial do	736,645	35,000	Switzerland 20,000; United Kingdom 10,000.
Powder do	408,330	130,000	Switzerland 65,000; United States 25,000; United Kingdom 20,000.

See footnotes at end of table.

Table 3.—Yugoslavia: Imports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1977	1978	Principal sources, 1978
NONMETALS —Continued			
Diatomite and other infusorial earth	87	152	Austria 94; Sweden 20; Switzerland 14; Denmark 10.
Feldspar	1,189	1,001	France 998.
Fertilizer materials:			
Crude, phosphatic thousand tons	1,066	903	Togo 470; Morocco 169.
Manufactured:			
Nitrogenous	126,139	210,581	U.S.S.R. 98,604; Hungary 39,382; Czechoslovakia 39,000; Bulgaria 23,846.
Phosphatic	44,220	47,089	Tunisia 45,856.
Potassic	378,732	443,173	East Germany 223,707; U.S.S.R. 195,161.
Other, including mixed	28,855	97,361	Poland 52,748; Romania 24,210; United States 17,470.
Ammonia	82,930	65,908	Hungary 43,902; U.S.S.R. 13,675.
Fluorspar	6,861	3,140	East Germany 1,421; France 1,099.
Graphite, natural	1,806	1,812	Austria 690; Czechoslovakia 418; East Germany 350.
Iodine	41	28	Japan 21.
Magnesite	r21,582	27,671	Greece 12,413; Turkey 11,826.
Mica:			
Crude, including splittings and waste	523	716	India 400; Norway 216.
Worked, including agglomerated splittings	133	144	Austria 56; Czechoslovakia 35.
Pigments, mineral:			
Natural, crude	70	NA	
Iron oxides, processed	2,096	4,506	Hungary 1,630; West Germany 966; Czechoslovakia 660.
Precious and semiprecious stones, except diamond:			
Natural kilograms	21	61	West Germany 59.
Manufactured do	491	483	Austria 313.
Pyrite, gross weight	72,625	19,126	U.S.S.R. 19,094.
Quartz, piezoelectric kilograms	400	NA	
Salt and brine	158,055	149,216	Romania 103,969.
Sodium and potassium compounds, n.e.s.:			
Caustic soda	128,552	206,639	France 69,695; Italy 53,262; Romania 25,392; Poland 22,160.
Caustic potash and sodic and potassic peroxides	197	120	Romania 86; Czechoslovakia 33.
Stone, sand and gravel:			
Dimension stone:			
Crude and partly worked:			
Calcareous	9,620	193	Mainly from Italy.
Slate	170	374	France 300.
Other	2,281	1,503	Italy 918; Sweden 460.
Worked	60	197	Italy 187.
Dolomite, chiefly refractory grade	1,457	947	Austria 782; Italy 103.
Gravel and crushed rock	113,921	168,902	Hungary 168,090.
Limestone (except dimension)	47,616	63,391	Hungary 59,805.
Quartz and quartzite	12,069	18,323	West Germany 7,647; Greece 9,404.
Sand, excluding metal bearing	r116,449	98,159	Italy 32,222; East Germany 23,201; Hungary 20,500.
Sulfur:			
Elemental, all forms	1,852	1,763	Italy 1,442.
Sulfur dioxide	547	300	Italy 300.
Sulfuric acid	102,074	84,857	Hungary 67,212; West Germany 9,984.
Talc, steatite, soapstone, pyrophyllite	3,261	5,127	West Germany 2,534; Italy 781; France 727.
Other nonmetals, n.e.s.:			
Crude	13,331	14,127	Hungary 11,485.
Slag, dross, and similar waste, not metal bearing	r240,305	389,622	Italy 290,940; Romania 98,195.
Oxides and hydroxides of magnesium, strontium, barium	4,291	1,622	Norway 1,109.
MINERAL FUELS AND RELATED MATERIALS			
Asphalt and bitumen, natural	7,268	6,610	Romania 5,906.
Carbon black and gas carbon	11,600	16,971	Italy 12,235; West Germany 2,739.
Coal and briquets:			
Anthracite and bituminous coal thousand tons	2,604	1,674	U.S.S.R. 1,112; Czechoslovakia 342; United States 82.
Briquets of anthracite and bituminous coal do	6	1,379	U.S.S.R. 883; Czechoslovakia 283.
Lignite and lignite briquets	224,527	161,413	East Germany 114,787; U.S.S.R. 46,131.
Coke and semicoke thousand tons	175	97	Poland 66; Italy 12.
Hydrogen, helium, rare gases kilograms	25,322	143,557	Italy 132,926.

COMMODITY REVIEW

METALS

Aluminum.—Completion of one alumina plant, construction of one aluminum smelter, and expansion of another one were the principal events of the aluminum industry of Yugoslavia during 1978 and 1979.

During 1978, a 600,000-ton-per-year alumina plant, using U.S.S.R. technology, started production at Birac, near Zvornik, BiH; designed capacity should be reached in 1980. Energoinvest of Sarajevo, BiH, was the investor. Total investments by the State-owned Energoinvest were reported at 6.7 billion dinars (about $330 million) of which the U.S.S.R. provided $130 million, mostly used for purchasing equipment made in the U.S.S.R. For a period of 10 years all alumina from Birac will be shipped to the U.S.S.R. as repayment of the credit. The contract between Energoinvest and the U.S.S.R. for credit and technical assistance, signed in 1972, was the first direct loan granted by the Government of the U.S.S.R. to a Yugoslav enterprise. Bauxite for the new plant will be trucked from Energoinvest's bauxite mines some 60 kilometers away. The Birac plant has its own plant for power and steam production, providing about 40% of the total. Fuel was initially residual fuel oil, but it will be replaced with natural gas. In 1979 the gas pipeline connecting gas fields in Vojvodina, Serbia, and in Hungary and the U.S.S.R. with consumers in Zvornik and other parts of Yugoslavia went onstream.

Energoinvest of Sarajevo was the largest producer in Yugoslavia of bauxite and alumina. During 1978 and 1979 Energoinvest continued construction on a 92,000-ton-per-year aluminum electrolytic plant at Bacevici near Mostar, BiH, due for completion in 1980; expansion of the Sibenik aluminum plant, operated by the Tvornica Lakih Metala Boris Kidric enterprises, to a capacity of 100,000 tons per year also continued. In addition, a secondary aluminum plant with a capacity of 15,000 tons per year was completed nearby, at Lozovac, in 1978.

Copper.—During 1978 and 1979, the copper industry continued to expand mining facilities and metal processing installations. Rudarsko Topionicki Bazen Bor (RTB Bor), Bor, Serbia, was the only smelter producer of copper in Yugoslavia. A new opencast mine developed on ore body "X", which started trial production during 1977, began regular production in April 1978, at a rate scheduled to reach 250,000 tons of ore per year. The new ore body will extend the life of the surface operations at Bor for another 6 years.

Expansion of the electrolytic plant at Bor continued; when completed in 1980 capacity will be 180,000 tons of copper per year. A 100-ton-per-day oxygen plant was commissioned at Bor in the fall of 1978; use of oxygen was expected to increase smelting capacity by 23,000 tons per year without additional smelting facilities. Plans were also completed for construction of a new plant to produce sulfuric acid from pyrite in the ore and from the smelter gases. Steam for electric power generation will also be recovered.

At Majdanpek (part of the RTB Bor) a plant to recover 120,000 tons of magnetite from the tailing started production in 1978. A factory for production of 15,000 tons of copper pipes, ranging in diameter from 6 millimeters to 76 millimeters, was commissioned by Bor at the village of Debeli Lug and went onstream, also in 1978. Initial production was exported principally to England and France.

During 1978 and 1979 at Veliki Krivelj, in the general area of Bor and Majdanpek, eastern Serbia, RTB Bor started development of a new opencast mine and mill, to cost half a billion dollars. About 20 million tons of overburden was to be removed before ore production started. After a large exploration program, the ore body was estimated at 250 million tons containing about 0.42% copper. Plans called for annual production of 25,000 tons of copper in concentrates, 240,000 tons of pyrite concentrates, 50,000 tons of magnetite concentrates, 250 tons of molybdenum concentrates, and undisclosed quantities of gold, silver, and selenium.

To finance the purchase of mining and metallugical equipment for Bor and Veliki Krivelj, the Bank of Japan granted a 7-year, $10 million credit to Yugoslavia; there was no commitment for repayment in commodities.

The copper mine and mill at Bucim, Macedonia, started production in 1979. Three ore bodies, Cukar, Vrsnik, and Bucim, are present; the tabulation below shows annual planned output and length of production for each of these:

Product	Unit	Cukar (3 yr)	Vrsnik (4 yr)	Bucim (13 yr)
Ore	million tons	3.7	5.4	7.2
Concentrates	tons	200,322	113,750	107,712
Copper content	tons	21,027	23,983	21,669
Gold	kilograms	463	695	950
Silver	kilograms	846	1,802	2,400
Iron concentrates	tons	--	--	108,000
Planned date for last production	--	1982	1986	1999

Chromite.—New reserves of chromite were discovered near Radusa, an old and exhausted chromite mine in Macedonia. Reportedly over 1 million tons of chromite were located. Grade of ore and date of startup of production were not made public. It should be noted that at Radusa mine site a chromite upgrading plant was in operation processing imported ores. Consequently new reserves will need only capital for development of a mine.

Gold.—In 1978, Jugohrom, a producer of ferroalloys at Jegunovce, Macedonia, announced a discovery of gold in the vicinity of the town of Krusevo, Macedonia. During 1979, exploration was underway in the area, but at yearend results were not made public.

In large gravel deposits near Bela Crkva, Vojvodina, Serbia, minor quantities of gold were found. Because the deposits are large, Geozavod of Belgrade was asked to determine whether profitable production of gold would be possible.

Gold was produced in Yugoslavia as a byproduct of copper production at Bor and of lead-zinc production at Trepca.

Iron Ore.—Exploration for and production of iron ore was limited to iron ore provinces in Bosnia, BiH, and western Macedonia during 1978 and 1979.

The Radovan Iron Ore Mine, in Bosnia, BiH, was preparing to open new mines at the locality of Tovarnica, near Jablanica, and Razevica in the general area of the town of Gornij Vakuf, both in Bosnia; when these become fully operational, the Radovan complex should produce 500,000 tons of iron ore per year.

In 1978, discovery of a new iron ore deposit was announced near the village of Tevanovici in the iron ore province of Ljubija, in Bosnia, BiH. Preliminary results indicated 2 million tons of iron ore with an average content of iron of 50%. During 1979, exploration continued on the Tevanovici deposit. Results confirmed preliminary results.

In 1978, production of magnetite started in a 120,000-ton-per-year magnetite plant at Majdanpek, Serbia, operated by RTB Bor. Magnetite is a byproduct of copper mining at Bor and Majdanpek. RTB Bor was planning to build a plant for processing iron cinders left after production of sulfuric acid. Reportedly Bor should have facilities to deliver about 800,000 tons of iron cinder and magnetite annually to Smederevo Iron & Steel works by 1985, if financing is assured.

A new mine to produce 2 million tons of iron ore per year, later to be expanded to 4 million tons, was to be built at Omarska, Bosni, BiH, where large reserves of ore containing 48% iron have been proven.

Yugoslavia was a net importer of iron ore in 1978, latest year for which data were available, but domestic production supplied almost 88% of the country's demand; the largest domestic iron mines were operated by RMK Zenica at Vares and Ljubija, BiH.

Principal suppliers of foreign iron ore were India and the U.S.S.R.

Iron and Steel.—Production of steel in Yugoslavia reached an alltime high of 3.5 million tons, but imports of semimanufactured products were still required. Expansion of RMK Zenica in Bosnia, the leading producer, continued during 1978 and 1979. The fourth blast furnace, which increased pig iron output by 700,000 tons per year, went onstream in November 1978. A 750,000-ton-per-year coking plant will start production in 1980, completing the second stage of expansion, and Zenica then should produce 2.3 million tons of steel per year.

In the Boris Kidric plant near Niksic, Montenegro, a new 400,000-ton-per-year blooming mill, imported from Czechoslovakia, started production during 1978. A 126,000-ton-per-year cold-rolling strip mill started production at Ramici, near Banja Luka, BiH; 13-centimeter strip can be rolled to thicknesses between 0.15 and 4 millimeters.

During 1978 and 1979, RMK Zenica was the largest integrated steel plant in the country. The enterprise employed about 37,000 persons and shared 37% in the total output of steel in Yugoslavia.

Lead and Zinc.—During 1978, a new mine, operated by Veliki Madjan, started production at Tisovik near Osecina, Serbia, at a rate of about 1,500 tons of lead in ore per year. Because of the high lead content of the ore (30% to 45% Pb), it was shipped to the smelter at Trepca without concentration. Proven reserves were reported to be enough for 10 years of operation. Employment was about 50 persons. Furthermore, Energoinvest decided to develop the Veovaca mine and a flotation plant based on a lead and zinc deposit on Zvijezda Mountain, near the Vares iron ore mine about 50 kilometers northwest of Sarajevo, BiH. An annual output of 400,000 tons of ore was planned, and annual production should reach 9,000 tons of lead concentrates, 10,000 tons of zinc concentrates, 65,000 tons of barites, and 25 tons of silver. Energoinvest planned to invest about 253 million dinars ($14 million). During 1978 and 1979, several mines and mills had expansion underway; Trepca's program, which was implemeted during the 2-year period, was the most important. The annual capacity of Trepca mine was to increase from 650,000 tons to 1 million tons of ore, output of lead concentrates from 40,000 tons to 65,000 tons, and production of zinc concentrates from 35,000 tons to 56,000 tons. In addition, Trepca's output of bismuth should reach 70 tons and that of cadmium 100 tons. A new ventilation shaft was completed, preparation of levels 10 and 11 was underway, planning for startup of production in the opencast mine at Zijaca was underway, and construction of a 1.5-million-ton-per-year mill at Tunnel 1 continued. In addition, work started on a new 170,000-ton-per-year lead refinery. To abate pollution, the new lead refinery will have a chimney 320 meters high.

The Trepca combine of Kosovska Mitrovica, Serbia, commenced expansion at the Kopaonik lead and zinc mill at Leposavic, located northwest of Kosovska Mitrovica, Serbia. A new circuit for annual recovery of 65,000 tons of pyrite will be added, and crude ore mill capacity was to be increased from the present 420,000 tons to about 500,000 tons of ore per day by the end of 1980.

At the Kisnica and Novo Brdo Mines, located near Pristina, Serbia, reconstruction included a new aerial tramway, deepening of the shaft at Badovac and a ventilation shaft in Ajvalija, and modernization of the opencast mine. The completion data has not been announced.

During 1979, about 21 mines and 14 flotation plants were operational. Two lead smelters (Trepca-Zvecan and Mezica) and one lead refinery (Trepca-Zvecan) produced lead. In addition, one Imperial smelting plant (Titov Veles) produced lead and zinc, and two zinc electrolytic plants (Sabac and Kosovska Mitrovica) produced zinc.

RMK Trepca was the largest lead-zinc producer in the country. Among other facilities, Trepca operated the largest lead and zinc mine, Stari Trg, the largest lead smelter and refinery, Trepca-Zvecan, and the zinc electrolytic plant at Kosovska Mitrovica.

Nickel.—During 1978 and 1979, development continued on Feni's mine and ferronickel plant at Rzanovo near Kavadarci, Macedonia, and at Glogovac in Kosovo and Metohija, Serbia, development started on a mine and ferronickel smelter with an annual capacity of 12,000 tons of nickel in ferronickel. The Rzanovo facility consists of a mine and nickel plant which incorporates a concentrator and a ferronickel smelter. At the underground mine, the cut-and-fill mining method was adopted, and the first ore was mined during 1979. In addition, the 25-mile-long conveyor belt, the longest in Europe, connecting the mine and plant was near completion at yearend 1979. The conveyor consists of nine continuous section; the longest (more than 12 miles) follows the rugged mountain terrain and passes through a tunnel. The belt, 24 inches wide, is steel-reinforced Goodyear Flexsteel belt. It was designed to operate at temperatures ranging between 0°F and 108°F. It is expected that the conveyor will move about 20 million tons of ore during 10 years of operation. The long conveyor belt system was chosen because its construction cost was lower then the cost of a comparable truck and rail system. At the Rzanovo plant the construction of the concentrator, made of a dry magnetic separator and wet magnetic seperator, was delayed because of late deliveries of equipment during 1979. According to the plan, the dry magnetic separation will produce 1.176 million tons of FeNi concentrate and 1.086 million tons of magnetic ore. Supposedly wet magnetic separation will be used to separate the magnetic portion of the concentrates. At design rates the concentrator should produce 1.720 million tons of nickel concentrates and 0.543 million tons of iron concentrates. The concentrating process produces a fine powder which must be pelletized before being fed to the furnace. The nickel concentrate is easily pelletized only by adding water due to its high talc content.

At the nearby smelter the pellets are then fed to electric furnaces. The recovered nickel accumulates in the metal bath as ferronickel. To meet specifications it has to be desulfurized. The desulfurizing process is divided into two steps. The first step is carbonizing by adding coke to the metal and increasing the carbon content in order to remove oxygen and provide the reducing conditions for desulfurization. The second step is desulfurization by blowing in calcium carbide with nitrogen to remove sulfur as slag. The desulfurized ferronickel is charged into an oxygen blown furnace where excess carbon and silicon will be eliminated and enough iron oxidized so that the content of nickel will increase to 25%. The plant will be completed in 1981, and overall recovery of nickel is expected to be 78%.

At Glogvac, after 15 years of delays and unsuccessful attempts to start development of a mine and a ferronickel plant, all preliminaries, like planning and financing, were completed and actual work on mine development started in 1979. The operating enterprise was named Feronikl and was organized by Rudarsko-Energetski Kombinat Kosoyo, one of the largest energy-producing organizations in the country. Financing and equipment deliveries were arranged through contracts with the U.S.S.R., Poland, The Federal Republic of Germany, Japan, Denmark, Norway, and the United States. However, most of the financing has been arranged by a syndicate of Japanese and European investors, represented by Daiwa Security Co., which agreed to provide a total of $120 million to Yugoslavia's Jugobanka for the nickel project and expansion of a coal mine. The loan is for 10 years at interest which is 7/8% higher than the interest paid on 6-month deposits in London. The mine and smelter should have an annual capacity of 12,000 tons of ferronickel when completed in 1983 or 1984. Because of its early stage of development, technical details of the Glogovac operation were lacking at yearend 1979.

Tungsten.—Recent low-keyed exploration for tungsten ore in Serbia had determined several regions where tungsten ore was found. Five, Blagojev Kamen, in the vicinity of Bosiljgrad, the region of Bresnica and Bistrica, Stara Planina, and areas on Kopaonik Mountain, all in Serbia, were the most promising. The State of Serbia decided to firm up tungsten reserves by 1980 at a cost of 21 million dinars.

Demand for tungsten has been met by imports since production in Yugoslavia ceased in 1964.

Other Metals.—Yugoslavia also produced bismuth, chromite, germanium, manganese, platinum, palladium, selenium, and silver during 1978 and 1979. Bismuth was a byproduct of lead and zinc output at Trepca, Serbia, and at Titov Veles in Macedonia; cadmium was produced as byproduct at Trepca's plant at Kosovska Mitrovica in Serbia, and at Titov Veles in Macedonia. The Bor complex in Serbia yielded germanium, platinum, and selenium as a byproduct of copper. Manganese was produced in Bosnia. Trepca was the main source of silver, a byproduct of lead and zinc processing.

NONMETALS

Asbestos.—At the Korlace asbestos mine near Raska, Serbia, plans were made for building a new asbestos separation plant with a capacity to process 200,000 tons of ore per year by 1980.

Yugoslavia remained a modest producer of asbestos (slightly over 300,000 tons of ore yielding about 10,000 tons of fiber). Three mines were in operation during 1978 and 1979. Two were in Serbia, and one was in BiH. The Bosna-Asbest Mine, near Bosanski Petrovac in BiH, was the largest producer of asbestos ore and fiber in Yugoslavia and accounted for 44% of ore output and 57% of fiber production of the country. Yugoslavia remained a net importer of asbestos, and imports supplied about 86% of the country's demand in 1978. The U.S.S.R. was by far the major supplier.

Barite.—At Licko Cerje, near Gracac, Croatia, a new 70,000-ton-per-year barite plant started trial production in December 1978. Most of the barite-producing enterprises in Yugoslavia are modest, and the Government of the State of Croatia, with three producing mines, remained the largest producer of barite in the country.

Cement.—Although domestic output was at an alltime high in 1978 and 1979, cement shortages delayed some construction in the country.

During 1978 a new 600,000-ton-per-year cement plant started production in Kakanj, BiH. The plant was designed for rapid expansion, but no decision to expand has yet been made. Expansion of the Popovac plant, Serbia, to 1 million tons continued. In addition, a decision was made to increase annual capacity of the cement plant in Kosjeric, Serbia, by 650,000 tons by 1980. Construction of a 600,000-ton-per-year cement plant in Nasice was delayed, and completion was expected in 1980.

In spite of cement shortages, a 200,000-ton-per-year cement plant at Gorazde, operated by the Azot Chemical Combine, lost 13 million dinars during 1977. During 1978 a special commission was studying problems at Gorazde; at yearend no report were made public on the future of the plant, but closing was mentioned as a possibility. Apparently no reports on the status of the Gorazde cement plant were released during 1979.

During 1979, 21 cement plants were in operation: the largest was a 1,750,000-ton-per-year cement plant at Beocin, Yojvodina, Serbia, operated by Beocinska Fabrika Cementa.

Gypsum.—The Japra gypsum mine at Bosanski Novi, which was a unit of the Beocinska Fabrika Cementa cement factory, was to expand its facilities from 200,000 to 500,000 tons of crude gypsum per year, equivalent to about 60,000 tons of final product. This plan was mostly based on 11 million tons of new gypsum reserves recently confirmed between Bosanski Novi and Svodna. In addition to gypsum, dolomite output was planned to reach 700,000 tons per year based on 2 billion tons of reserves at Blatna, BiH.

Four enterprises produced burnt gypsum in Yugoslavia during 1978 and 1979. Two of them, located in BiH, accounted for slightly over half of the country's output.

Lime.—During 1978 and 1979, construction continued on a lime plant at Drnis, Croatia. Announced capacity was 100,000 tons of lime per year.

Yugoslavia was self-sufficient in lime and has extremely high reserves of limestone. The industry was scattered throughout the country, and producing facilities ranged from primitive to modern. Large quantities of lime were also produced by homeowners in villages, but production was not reported.

Magnesite.—After authorities at Bar, Montenegro, a port on the Adriatic, granted conditional permission for construction of an installation for production of sinter magnesite from seawater and dolomite in 1977, debate continued on the environmental impact of the factory on tourist areas along the Adriatic Sea. However, during 1978 Magnohrom of Kraljevo and representatives of Polish enterprises signed an agreement to finance construction of a 100,000-ton-per-year plant, to start in 1982. About 40% of the output will be used to repay the Polish credits.

At the Vencacki Rudnici i Industrija Mermera Mines, at Arandjelovac, Serbia, expansion should double present output of marble slabs by 1980.

At Svileuva, Serbia, discovery of a new marble deposit was announced, and a decision by local inhabitants was made to start a quarry.

Salt.—The Bajo Sekulic marine salt plant in Ulcini, Montenegro, completed construction of a salt refinery with a capacity of 240 tons per day. Equipment was purchased in Italy. The refinery started operation in 1979 after trial output in 1978, but an earthquake severely damaged the plant in 1979.

Silicon.—Near Bosiljgrad, Serbia, reserves of 40 million tons of quartz sand were established, and an opencast mine started production at a rate of 100 tons per day. All production was sold to Electrobosna, Jajce, BiH, one of the major producers of ferroalloys in the country.

Near Pula, Croatia, the Mikrosil mining

enterprise took over the operation and debts of the former Istarski Rudnici Nemetala enterprise and started production of very fine quartz sand. An output of 60,000 tons was planned for 1979, and reserves were reportedly high.

Stone.—The Pomoravlje construction enterprise of Svetozarevo, Serbia, and the Vencac mining enterprise of Arandjelovac, Serbia, agreed to jointly develop deposits of onyx near Lozovik, a village near Svetozareva, Serbia. Estimates by local experts set onyx reserves at over 700,000 cubic meters. During 1979, about 12 million dinars was invested in facilities to produce about 1,000 cubic meters of onyx per year.

In 1978, the Opalska Breca mining enterprises of Kumanovo, Macedonia, received a credit of 32 million dinars to develop a travertine quarry and build a plant for cutting travertine into blocks and slabs. The plans call for a quarry output of 3,500 cubic meters of travertine block and a plant capacity of 2,000 cubic meters of slabs.

Marble.—After several years of exploration in the general area of Kicevo, Macedonia, marble was identified in two localities, Cer and Kamni Most. Reserves at Cer were set at 680,000 cubic meters of marble, which should yield about 102,000 cubic meters of marble blocks; at Kamni Most, reserves were reported at 250,000 cubic meters that could yield about 28,000 cubic meters of marble blocks. At Cer, an opencast mine went onstream during 1978, and a new marble-cutting facility was soon to have an annual capacity of 5,000 cubic meters of marble blocks and 60,000 square meters of marble slabs.

New equipment was installed in the marble-cutting facilities at the Kosmaj mine near Mladenovac, to increase annual output of marble slabs from 55,000 square to 70,000.

MINERAL FUELS

During 1978 and 1979, domestic low-rank coals remained the principal source of energy, and Yugoslavia was dependent on import of high-rank coals and crude oil.

Coal.—Although financial difficulties persisted, production of coal, mostly lignite and brown coal, was among the most active sectors of the mineral industry of Yugoslavia. An alltime high output of coal in the country reflecting a decision to revert to domestic coal as a major fuel for generating electric power in the future.

In Serbia, the largest coal-producing State in Yugoslavia, new coal development was focused on Kolubara and Kosovo. During 1978, in the Kolubara basin, approximately 60 kilometers southwest of Belgrade, Kolubara Rudarsko Energetsko Industrijski Kombinat continued development of the Tamnava low-grade lignite (1,800 kilocalories per kilogram) opencast mine, and 1979 production started. Output of 18 million to 20 million tons of lignite per year is to be reached sometime between 1980 and 1985. Most of the production will be used by several powerplants situated and to be built near Obrenovac.

In the Kosovo lignite basin, near Pristina, Serbia, Rudarsko Energetsko Hemijski Kombinat Kosovo continued work on construction of two power generating units, capacity 339 megawatts each, situated near Obilic. Work was started on expanding Belacevac mining field to increase production from 5.5 million tons to 10 million tons to meet increased demand in nearby powerplants.

At the Kostolac lignite basin, development of the 2.5-million-ton-per-year Cirkovac opencast mine is nearing completion. When completed in 1980, the mine should produce 2.5 million tons of lignite.

Coke.—The coking plant at Bakar started production in the spring of 1978; capacity was reported at 850,000 tons of coke per year from imported coal, but the plant design allows for a second battery of coke ovens of the same capacity. The Sisak iron and steel works will consume the entire output. Excess gas will be delivered to the thermal powerplant at Urinj.

Petroleum and Natural Gas.—In 1978, annual crude oil production went over the 4-million-ton mark for the first time, although only about 30% of refinery throughput was met by domestic output, and imports from Iran, Iraq, and the U.S.S.R. were essential to meet demand.

In 1978, upon completion of the natural gas pipeline system in western Yugoslavia, natural gas from the U.S.S.R. started to arrive, mostly at facilities in Slovenia and Croatia.

Industrija Nafte-INA, headquartered in Zagreb, Croatia, and Naftagas, headquartered in Novi Sad, Serbia, remained the only producers of oil and natural gas in the country. At the end of 1979, six petroleum refineries, three operated by INA (Rijeka, Sisak, and Lendava), two by Naftagas (Novi Sad and Pancevo), and one by Energonvest (Bosanski Brod), had a total installed capacity of 23 million tons.

Exploration, Development, and Pro-

duction.—INA drilled about two-thirds of the approximately 400,000 meters of holes drilled in Yugoslavia during 1978 and 1979. Exploration was conducted onshore in the Pannonian Basin and offshore along the Adriatic coast.

During 1978 and 1979, the Pannonian Basin remained the principal area of exploration for oil and gas and the only oil- and gas-producing province in the country. INA's major discovery was the Molve gasfield, near the town of Koprivnica, Croatia, containing gas reserves equal to all previously known reserves in Croatia (20 billion cubic meters). The Adriatic coast of Yugoslavia remained the only promising sedimentary basin with possibilities for oil and gas from offshore fields in the same basin. INA's major exploration effort was onshore and offshore on the Adriatic coastline. One discovery of natural gas was announced on an offshore well 50 kilometers west of the town of Pula, Istria, and two wells, one on Brac Island and the other in the Gulf of Trieste, were drilling below 5,000 meters.

Naftagas, during 1978 and 1979, continued exploration in Serbia proper and in Vojvodina, the only oil- and gas-production area in Serbia. Several discoveries of natural gas were announced, but details about the size of the new field were lacking.

Production of oil and gas in Yugoslavia came from deposits in the Pannonian Basin. Naftagas commissioned the Coka field in Banat; it should peak at 100,000 tons of crude per year. Benicanci in Croatia remained the largest oilfield in the country; it was operated by Naftaplin, a division of INA.

Refining.—During 1978 and 1979, construction continued on a refinery near Skopje (2 million tons of crude oil per year), Macedonia, which is designed to process heavy crude from Iran. The U.S.S.R. is providing equipment and technology.

Transportation.—The natural gas pipeline system in western Yugoslavia was completed during 1978. The system is about 340 miles long and supplies 26 towns in Slovenia and Croatia with gas from the U.S.S.R. and from local fields. In addition to distribution lines, the project includes 340 miles of 16- to 20-inch transmission lines and will have a total capacity of 2.5 million cubic meters of natural gas per day.

In eastern Yugoslavia, construction continued on another gas pipeline passing through Vojvodina and in Serbia branching to Bosnia. The gas was to be used for heating in Sarajevo and supplying the Zvornik alumina plant. Financial problems delays construction.

During 1978, construction continued on the pipeline system which should bring Middle East crude oil to refineries in Yugoslavia, Hungary, and Czechoslovakia, and in 1979 the system was completed. The starting point of the 34-million-ton-per-year crude oil pipeline is on the island of Krk near Omisalj, where a deep-sea port, with berths for two 350,000-deadweight-ton tankers, was operational. Cost of the project reached about $510 million, an increase of about 35% over figures published in 1969.

Uranium.—During both years, 1978 and 1979, construction, by Westinghouse, of the first Yugoslav nuclear powerplant, Krsko (615 megawatts electrical), continued near the town of Krsko in Slovenia. Reportedly the new completion date should be sometime in 1980. Work on development of the Zirovski Vrh mine and the yellow cake plant at Rudnik Urana Zirovski Vrh, at Skofija Loka, Slovenia, also continued.

The Mineral Industry of Zaire

By Miller W. Ellis[1]

The mineral industry of Zaire continued to provide 60% of the country's foreign exchange and to maintain its position as the world's leading producer of cobalt and industrial diamond. High transport costs, lack of fuels, and low prices for copper, all contributed to diminished production of Zaire's minerals (except for cobalt) during 1978, but higher copper and cobalt prices the following year improved the economic position of the State-owned La Général des Carriéres et des Mines du Zaire (Gécamines) in the Shaba Region, and contributed to increased production by the entire mineral sector.

Construction of additional production and township capacity at Kolwezi, Gécamines largest and westmost center of operations, was interrupted by armed invaders early in the morning of Saturday, May 13, 1978. The shutdown of mine and plant operations ordered by the invaders proceeded in a sequential manner for the next 6 days. French and Belgian paratroops regained control of the area and, by May 23, the remaining expatriates were evacuated, most to Europe, a few to Lubumbashi. Electricity supply was restored and operations resumed at mining, concentrating, and refining plants by Zairian staff with limited supervision by expatriate staff commuting by air from Lubumbashi. Despite the imposition of a dusk-to-dawn curfew and shortages of automobiles, light trucks, and acid; near-normal ore and metal production had been achieved by about June 14. Resumption of most construction projects was delayed for months, and construction of the Inga-Shaba powerline was not fully restored until October 1979. Short-term European employees of contractors appeared to have borne the brunt of both casualties and looting, and the resultant dearth of skilled and experienced staff extended throughout 1979. Hundreds of European and African casualties resulted from this second armed invasion in little more than a year, and the subsequent exodus of expatriates caused a shortage of skilled and experienced technical staff that was not completely relieved by yearend 1979.

Gécamines P-2 expansion plan was interrupted and its priorities directed at completing the Dikuluwe-Mashamba (DIMA) concentrator. The country's external debt was rescheduled and its finances monitored by officials of the International Monetary Fund (IMF). Zaire's unit of currency the Zaire (Z) was quoted at Z0.82=US$1.00 in January 1978 but was devaluated in May 1978 and again in January and August 1979. It was quoted at Z2.046=US$1.00 in September 1979. The Bank of Zaire (BOZ) has continued to allow Gécamines to retain 45% of its foreign exchange earnings.

PRODUCTION AND TRADE

Production of most of Zaire's mineral commodities declined through 1978 except for Gécamines byproducts cobalt and silver, which showed substantial increases over 1977 levels. World copper price increases in late 1978 and early 1979 enhanced the country's credit and financial status and improved the delivery time of fuel and consumable stores to Gécamines and the mining industry in general and resulted in a generally higher mineral production rate in 1979. Details of mineral production for both years are shown in table 1.

The Société de Développement et Miniére

du Zaire (Sodimiza) continued to ship copper sulfide concentrates through Zambia, Southern Rhodesia, and Botswana, for dispatch to Japan from the South African port of East London. Part of Gécamines copper metal was also shipped from East London, but most of its copper went by rail-river barge-rail Voie Nationale to the sea port of Matadi in the Zaire River mouth. The alternative route by rail to Kalemie on Lake Tanganika, lake steamer to Kigoma, and Tanzania railroad to the congested port of Dar es Salaam was little used as was the Zambian Tazara route, also to Dar es Salaam. Internal strife in Angola restricted international traffic on the Benguela Railroad, and the Rhodesia-Beira railroad remained closed at the Mozambique border. Most of Zaire's cobalt and minerals of high unit value were shipped by airfreight.

COMMODITY REVIEW

METALS

Copper, Cobalt, Zinc, and Associated Metals (Shaba Region).—Gécamines production of zinc, and cadmium metals declined in 1978 and increased slightly in 1979, but selective mining of high-cobalt ore was reportedly responsible for cobalt output increasing in 1978-79. World prices of copper, tin, and zinc also declined in early 1978 but increased slowly during the latter part of the year. A substantial increase was reported in early 1979 and by mid-year Gécamines and Zaire's financial position was substantially improved.

Gécamines and Zaire's foreign exchange earnings were increased by the enhanced prices for cobalt metal following the invasion of May 1978. The following table lists producer and spot prices per pound of cobalt metal in U.S. dollars.

Dates	Producer price	Spot price
December 21, 1977	$6.40	
February 24, 1978	6.85	
May 24, 1978	8.50	
July 20, 1978	12.50	
September 14, 1978	18.00	
October 27, 1978	20.00	$39.00
November 10, 1978	20.00	49.00
February 1, 1979	25.00	39.00
May 23, 1979	25.00	42.00
July 27, 1979	25.00	30.00
August 24, 1979	25.00	29.00

Gécamines copper metal production dropped nearly 60,000 tons because of the inability to move copper concentrates from Kolwezi to Shituru and to Lubumbashi for more than a month in May and June; and of the lack of sulfuric acid after furnaces at Shituru collapsed while imports from Zambia were temporarily cut off. Exports of Gécamines copper continued by the rail-river barge-rail route to Matadi and by the longer southern route to the port of East London in the Republic of South Africa. Much of the cobalt was packed in drums and shipped by air.

Part of Gécamines shortfall in copper production was balanced by increased amounts of copper in the concentrates exported by way of East London to Japan by Sodimiza. In 1978 the Musoshi concentrator handled a larger proportion of higher grade ore from Sodimiza's Kinsinda mine than of the chalcopyritic ore from the Musoshi mine. The tonnage of ore milled decreased but both the amount and copper content of the concentrate increased during 1978-79. Sodimiza continued to operate at a loss because of transport costs on the long rail route to the port of East London in the Republic of South Africa. Returning rail cars carried coal, coke, maize, and other foodstuffs vital for the Shaba Region's mining industry. Sodimiza's operations were 40 to 100 kilometers southeast of Lubumbashi and Gécamines eastern center of operations and were not directly affected by the May 1978 invasion, but Sodimiza's staff was reduced from 3,769 to 3,071 Africans and from 138 to 94 expatriates, mostly Japanese employees of Nippon Mining Co., in 1978.

The Société Minière de Tenke-Fungurume (SMTF) was reorganized in mid-1979. The U.S. firm Amoco Minerals Co., Standard Oil Co. (Indiana), sold its 28% interest to Bureau de Recherches Géologiques et Minières (BRGM) who became majority owner at 34.4%. Chartered Consolidated Ltd., with 28%, relinquished management of SMTF to the French BRGM, and the manager of Leon Tempelsman and Sons, Inc. of New York became chairman. The SMTF concession had reported reserves of 55 million tons of ore containing 5.7% copper and 0.45% cobalt. Approximately $280 million of an estimated capital cost of $600 million had been spent in developing the property formerly owned by Gécamines, when work was halted because of lack of fuel and supplies following the closure of the Benguela Railroad in August 1975. The cost of care and maintenance since January 1, 1976, was estimated at $400,000 per month. It was reported that new mining equipment and ore trucks were sold locally during 1979.

Gécamines zinc, cadmium, and most of its silver production came from the Kipushi mine and concentrator which produced both copper and zinc sulfide concentrates. The copper sulfide concentrates were smelted at Lubumbashi to produce blister copper ingots and zinc and cadmium-rich flue dusts. Both the zinc concentrates and the flue dusts were shipped to the Metalkat factory on the Musonoi River north of Kolwezi. The zinc sulfide concentrate was roasted and sulfuric acid made from the exhaust fumes while zinc metal ingots were produced from the residues. Both zinc and cadmium were extracted from the flue dusts and silver was recovered from both zinc and copper refinery tank house sludges either in Zaire or in Belgium where much of Gécamines blister copper was refined.

Gold.—Most of Zaire's gold continued to come from mines operated by the State agency, Office des Mines d'Or de Kilo-Moto, near the Ugandan and Sudanese borders in the Haute-Zaire Region of northeastern Zaire. Smaller amounts were byproducts of Gécamines copper industry, recovered by treatment of refinery tankhouse slimes in Belgium, and from alluvial-eluvial operations in many of Sominki's tin and tungsten mines. The following table shows the declared sources of Zaire's gold output since 1974 in troy ounces.

	1974	1975	1976	1977	1978	1979[e]
Kilo-Moto	11,724	79,830	66,809	59,479	58,032	55,700
Sominki	17,426	17,201	19,548	16,525	14,114	15,000
Gécamines	4,662	4,983	4,180	3,601	3,633	4,000
Miscellaneous	979	976	556	813	298	300
Totals	134,791	102,990	91,093	80,418	76,077	75,000

[e]Estimate.

Kilo-Moto reported reserves containing approximately 40,000 and 360,000 troy ounces of recoverable gold in vein deposits near Kilo and Moto, respectively. The company was also exploring the D7 Kanga orebody with a potential of 1.28 million troy ounces of gold near Kilo, and a sulfide orebody with a potential of an additional 210,000 troy ounces of gold in the Moto area. Sominki estimated reserves of 640,000 troy ounces at its newly discovered Twangiza deposit in Kivu Region. Since 1976 when the Government outlawed mining of alluvial gold, illicit placer mining has continued in both Haute-Zaire and Kivu Regions. Much of this contraband gold is reportedly marketed in Goma and Bakuvu or smuggled to Bujumbura in Burundi or to Uganda or Sudan.

Manganese.—There has been no production of manganese ore reported by Société Minière de Kisenge (SMK) since the invasion of March 1977 and occupation of the company headquarters at Kisenge, about 200 kilometers west of Kolwezi. The only mineral cargo carried on the abortive Benguela Railroad reopening trip in April 1979 was reportedly manganese ore from SMK's 500,000 ton stockpile. Meanwhile, Japanese, West German, and Spanish firms have examined SMK's installation, and have considered various proposals for upgrading the ore, producing manganese metal, or manufacturing dry cell batteries. SMK reported that 54 railway carloads of ore had arrived in Lobito Bay during November and December 1979.

Tin, Tungsten, and Byproduct Columbium-Tantalum.—The northeastern part of Shaba Region and east-central part of Kivu Region were the sources for Zaire's output of several resistant minerals recoverable by relatively simple methods of gravity concentration. The 50% State-owned Société Zairetain managed by the Belgian company Geomines was one of two major producers of these commodities. Zairetain produced refined tin, columbite-tantalite, and tantaliferous slag or scoria at its smelter near Manono. Severe floods on the Lualaba River in March of 1979 cut both rail and road traffic between Manono and Lubumbashi preventing the delivery of heavy equipment, food, fuel, and other supplies to Zairetain, and export of its minerals for nearly 6 months. A study of the feasibility of mining the hard unweathered pegmatite of the Manono deposit and extracting tin and lithium minerals therefrom was to be completed in 1980.

The Société Minière et Industrielle de Kivu (SOMINKI) was the largest mining company in the Kivu Region, with a staff of nearly 18,000, including about 100 expatriates. The 28% State-owned company operated a number of mines in the central and eastern parts of the Kivu Region producing tin ore (cassiterite), tungsten ore (wolframite), columbite-tantalite, gold, and monazite. Diminished production during 1978-79 was chiefly due to shortages of motor fuel and spare parts aggravated by the isolated position of many of the deposits. SOMINKI was exploring a deposit of pyrochlore (a columbium-thorium-rare-earth mineral). The Krupp Co. reported encouraging results from preliminary pilot plant tests in the Federal Republic of Germany. They proposed spending $2 million for testing at another pilot plant to be built in Zaire, and constructing a full scale plant by about 1984 if the results so warrant.

NONMETALS

Cement.—The Belgian firm, Société d'Etudes et de Gestion de Cimenteries (EGECIM), was the parent of three of Zaire's cement companies. Gécamines agreed to purchase 40% of EGECIM's Cimenteries du Shaba (CIMSHABA) in 1976, and in 1978 completed payment from its foreign exchange earnings. CIMSHABA produced 42,670 tons of portland cement, 20,478 tons of rough cast cement, and a little lime in 1978, most of which was sold to Gécamines with lesser amounts to Sodimiza and to Constructeur Inga-Shaba (CIS), the local subsidiary of the American Morrison-Knudsen Co. At the beginning of 1979 CIMSHABA's cement was sold at the Government-controlled price of Z3.50 per 50-kilogram bag, but a subsequent devaluation of the local currency made this the equivalent of $2.28, far below cost. Another Gécamines subsidiary, Calcaire, Chaux, Ciments of Kakontwe, near Likasi, produced 387,904 tons of limestone, 7,224 tons of metallurgical cement, and 94,669 tons of lime, all sold to Gécamines. A third oven to increase lime production was finished in 1979. Ciments-Laçs, another subsidiary of EGECIM, operated a small cement plant near Kalemie on Lake Tanganyika at reduced capacity in 1978 and ceased operations because of flooding in early 1979.

EGECIM owned 51% of Zaire's largest cement manufacturer, Société des Ciments du Zaire (CIZA). The Zairian Government owned 15%, two Zaireian development banks held 12.5%, and private interests 21.5%. CIZA's plant at Lukala had a capacity of 630,000 tons, but produced only 231,381 tons of cement in 1978 and less than that in 1979. Most of the production was consumed in or near Kinshasa, but 22,000 tons were exported to the Congo (Brazzaville) and the Central African Republic. The Cimenterie Nationale's (CINAT) 300,000-ton-capacity plant near Kimpese sold most of the 163,517 tons of cement produced in 1978 to customers in the Kinshasa vicinity.

Diamond.—The Zairian-owned Société Minière de Bakwanga (MIBA) continued to be the largest producer of low-grade industrial diamond in the world, accounting for approximately 30% of world production in 1978. Operations at the Mbuji Mayi pits were handling increasing amounts of hard unweathered kimberlite with attendent higher recovery costs. Even at the low price of $3 to $4 per carat for Zairian industrials, diamonds continued to be the country's fourth largest earner of foreign exchange after copper, cobalt, and coffee. The value of 1978-79 production was about $150 million, and it was estimated that illicit mining and smuggling involved 30% to 50% of the declared Zairian production. Most of the smuggled diamonds were sold through Bujumbura in Burundi, and Brazzaville in the Republic of the Congo. Total production for 1979 was estimated at 14.2 million carats worth $250 million including smuggled diamonds.

In May 1978 the Zairian Government (GOZ) returned 20% of MIBA's equity to its former owners, the Société Généràl de Belgigue and the Oppenheimer group, and allowed the company access to 20% of its foreign exchange earnings. In return, a purchasing service for spare parts and supplies was reactivated with a loan to MIBA worth $2.45 million in hard currency at 6% interest with a 5-year grace period. The GOZ also agreed to partially finance MIBA's security, school, and hospital services and freeze diamond export tax at 12.5% of gross receipts for 4 years.

MINERAL FUELS

Coal.—The Societe des Charbonnages de la Luena, north of Kolwezi, and the Makala coal mine near Kalemie on Lake Tanganyika were Zaire's only domestic sources of low-grade coal. Production from Makala was used for the production of cement at the nearby Ciment-Laçs plant, and that from Luena was extracted by Gécamines for use in its metallurgical and cement plants. Coal and coke were imported from South Africa, Southern Rhodesia, and possibly from Zambia.

Petroleum.—Production of crude petroleum from Zaire's offshore fields decreased slightly in 1978 and increased again in 1979. A desalinization plant to process Zaire's heavy, salty, crude and to blend it with high-grade imported crude to make a suitable feedstock for Zaire's Moanda refinery was completed.

[1]Physical scientist, Branch of Foreign Data.

The Mineral Industry of Zambia

By Miller W. Ellis[1]

The mineral industry of the Republic of Zambia continued to provide some 90% of the country's foreign exchange credit, and Zambia maintained its position as the world's fifth largest copper producer through 1978 and 1979. With the increased production from a new cobalt facility at Chambishi in 1979 it became the world's second largest cobalt producer, after neighboring Zaire. Transport delays through the Tanzanian port of Dar es Salaam continued to be an expensive item in the cost of producing and delivering copper metal, but were substantially offset by the increased world price of copper during 1978 and 1979.

Zambia's 1978 copper exports were valued at $760.3[2] million and accounted for 27% of the gross domestic product (GDP) estimated at $2,819.5 million, up 10% from the GDP for 1977. Both major copper producing companies reported a return to profitable operation during the latter half of 1978, and Roan Consolidated Mines Ltd. (RCM) declared a dividend for the first time in 5 years for the fiscal year ended June 30, 1979. The overall profit by both companies through 1979 was estimated at more than $600 million, but the tax benefit to the Government of the Republic of Zambia (GRZ) was negligible because the tax system allowed losses to be carried forward from bad years and applied against profits in good years.

In mid-1979 RCM followed the precedent set by Nchanga Consolidated Copper Mines Ltd. (NCCM) in 1978 and agreed to convert at least $50 million of indebtedness to the GRZ into 7.4 million RCM shares to be held by the Government owner-agency Zambia Industrial and Mining Corp. Ltd.(ZIMCO). This effectively diminished the minority share holding (mostly AMAX Inc.) from 49% to 40% and increased GRZ's share from 51% to 60%.

Zambia's use of Kenya's Mombasa port was halted when Tanzania closed its Kenya border in February 1977. Subsequently Zambia depended almost entirely on Tanzania's increasingly congested port of Dar es Salaam for both imports and mineral exports. The lack of vehicle capacity and other deficiencies on both the Tanzania Zambia Railway (Tazara) and the older TanZam Road Service contributed to a transport fiasco involving large tonnages of imported commodities awaiting handling at the port and at their destination, and a total of 100,000 tons of copper metal stranded at the port, along the transport route, or stockpiled at the mines. Payment for most of Zambia's copper could be made as soon as it was certified as loaded aboard ship, so that efficient handling and smooth transit would have allowed both Zambia and Tanzania larger and faster profits. Some of the delay was due to natural causes such as track washouts causing derailments in both Tanzania and Zambia, but there was some question as to whether inadequate maintenance of equipment and roadbed had contributed to these accidents.

Early in October 1978 the Zambian President announced the reopening of the southern route through Southern Rhodesia (Zimbabwe) to South African ports in order to expedite the arrival of food and fertilizer in Zambia, and speed the sale of its copper. South Africa also loaned Zambia four locomotives to assist in the distribution of fertilizer. Heavy rains in April and May of 1979 washed out some 100 kilometers of track in Tanzania. Road traffic through Botswana to South Africa was halted when the pontoon across the Zambezi River at

Kazungula was damaged in April 1979. Repeated attempts to export copper and import fertilizer by way of Mozambique's ports of Nacala and Beira met with scant success. These routes reportedly handled 7,200 tons each during the dry month of July, but the road hauls from Lusaka to Salima railhead in Malawi for Nacala port, and to Moatize coal mine and railhead in Mozambique for Beira port, could not maintain this rate for an extended period. During most of the year 10,000 tons per month was handled by TanZam Road Services trucks to Dar es Salaam, 20,000 tons per month was hauled by Tazara, and a similar quantity went by the southern rail route to South African ports. Traffic over the southern route increased by 50% in October 1979 when the multispan bridge over the Chambishi River in northeastern Zambia was destroyed. TanZam trucks travelling an alternate route continued hauling copper to Dar es Salaam where a backlog of 32,000 tons of copper helped maintain copper export shipments through the yearend.

PRODUCTION AND TRADE

Production of copper in Zambia increased slightly in 1978 but decreased during 1979. The London Metal Exchange (LME) price per ton of copper rose from $1,467 in December 1978 to $2,010 in March 1979 and thereafter fluctuated between $1,620 and $2,050 until the yearend. Prices of other mineral commodities also rose during the 2 year period, but none so much as cobalt, which was in short supply and subject to a 70% quota on sales even before the May 13, 1978, invasion of Zaire's Kolwezi metallurgical center. Panic buying and a short-lived "gray market" pushed cobalt spot prices to more than twice the producer price. The following tabulation compares, in U.S. dollars per pound, the producer price changes agreed on between Zambian and Zairian officials and the prevailing spot prices for this period.

Date	Producer price	Spot price
Dec. 21, 1977	$6.40	NA
Feb. 24, 1978	6.85	NA
May 24, 1978	8.50	NA
July 20, 1978	12.50	NA
Sept. 14, 1978	18.00	$35.00

Despite the more favorable prices in 1979 Zambia's mineral production slumped except for cobalt. The continuing and ubiquitous shortages of spare parts, supplies, and skilled staff to effect repairs promptly and carry out preventive maintenance on schedule produced epidemics of partial and temporary shutdowns. As a result, fewer tons of lower grade ore were mined from which reduced amounts of substandard concentrates were milled, and less metal was smelted thoughout the mining industry. Production of zinc by the Broken Hill Division of NCCM was up slightly in 1978, while lead production declined. Prices of both metals reached near record levels in the first half of 1979. Zambia's reported mineral production for 1978 and estimated production for 1979 appear in table 1.

The dollar value of Zambia's 1974-78 trade is shown in the following tabulation:

	1974	1975	1976	1977	1978
Total exports(A)	1,406.6	809.8	1,054.0	898.1	818.4
Copper exports(B)	1,303.1	733.5	965.4	818.7	760.3
Total imports(C)	985.0	1,137.7	800.5	828.5	745.1
A-C balance	+421.6	-327.5	+253.5	+69.6	+73.2

Source: International Financial Statistics. v. 33, No. 3, March 1980, p. 426.

The balances do not indicate an accumulation of foreign exchange because of repayments, servicing of loans, and other disbursments.

Zambia's mineral exports are shown in table 2, copper exports and destinations in table 3, and imports of mineral-related commodities in table 4.

COMMODITY REVIEW

METALS

Copper and Byproduct Cobalt.— Zambia's two major mining companies milled nearly 31 million tons of ore containing almost 753,000 tons of copper. Nearly 7 million tons of ore contained 122,171 tons of copper and 8,691 tons of cobalt. Production of copper improved marginally in 1978 but declined sharply in 1979 as did most other metals except cobalt. RCM treated over 14.5 million tons of ore with copper and cobalt contents of 304,812 tons and 3,336 tons respectively. Details of ore milled during calendar 1978 and of RCM ore reserves as published in RCM's annual report for the year ended June 30, 1979 are shown in table 5.

Table 5.—Zambia: RCM copper production and ore reserves

Mine	Ore mined and treated: Gross weight (thousand metric tons)	Ore mined and treated: Copper (percent)	Ore mined and treated: Copper content (metric tons)	Ore reserves: Gross weight (thousand metric tons)	Ore reserves: Copper (percent)	Ore reserves: Cobalt (percent)

OP Open pit. UG Underground.
[1]Mining in both the Kalengwa and Chambishi open pits was halted in the rainy season of late 1978. Stockpiled ore was used to supplement underground ore feeding at Chambishi and as total feed at Kalengwa.

RCM production of finished copper decreased as concentrate stocks were depleted, and as the demand for cathode copper supplanted that for wirebar, some reverberatory furnaces became available for toll smelting. Wirebar production ceased in January 1979, and by June all RCM's smelting requirements were being met by the Mufulira electric furnace and Luanshya's No. 1 reverberatory furnace. One tankhouse line at the Ndola Copper Refinery was shut down in March 1979 and the other was used for toll refining of NCCM copper, while all RCM'S cathode copper was produced at the Mufulira refinery. A 1,000-ton dry concentrate storage bin and two electrostatic precipitators were installed at the Mufulira electric furnace to recover cupriferous dust from the exhaust gases. The Government Mining Engineer and the Chief Inspector of Mines granted permission for lower cost caving methods to be resumed in certain parts of the Mufulira mine, and large-diameter blast hole stoping was also introduced in some areas. The installation of 8.5-cubic-meter Fagergren flotation cells in place of smaller units improved operating results at both Mufulira and Luanshya. An evaporative cooling system was installed to replace the waste heat boilers at Luanshya's No. 1 reverberatory furnace in April 1979. Extensions to Luanshya's Buluba concentrator increased its ore handling capacity to cope with increased ore production, as more of Baluba's underground development was completed.

Equipping of the 1,000-meter Chibuluma West shaft was completed, and the winders and headframe were erected by yearend 1979. Underground development of the Chambishi orebody was completed to the 500-meter level of its 1,000-meter shaft in order to replace the shortfall in ore production caused by the shutdown of open pit mining in late 1978. Mining at the Kalengwa open pit was also halted late in 1978, but the small Kalengwa concentrator continued to treat ore stockpiled during previous years. Extensions to the relatively new roast-leach-electrowin plant at the Chambishi mine were completed early in 1979 and provided facilities for the production of 2,400 tons of degassed electrolytic cobalt metal per year as well as 21,000 tons of leach cathode copper. Feedstock consisted of about 80,000 tons of high-cobalt concentrate from the Chibuluma concentrator, containing 7.15% copper and 2.28% cobalt, and nearly 40,000 tons of similar concentrate from the Baluba concentrator containing 6.88% copper and 3.90% cobalt.

During the 1978 calendar year, NCCM's ore included nearly 4.9 million tons of Rokana ore containing almost 75,000 tons of copper and 5,355 tons of cobalt. Table 6 shows details of production for 1978 and ore reserves as published in the annual report for the year ended March 31, 1979. The Rokana cobalt plant ceased to produce metal from RCM's cobalt hydroxide in January 1979 when Chambishi's new cobalt plant was commissioned. Substantial quantities of gypsum resulting from the use of lime to neutralize spent acid was discarded, but 500 to 1,000 tons per month was sold and railed to Chilanga Cement Ltd. and nearly 1,500 tons per month was used as flux for smelting the high-grade, high-sulfur concentrates produced in early 1978. This practice was halted when the concentrate grade decreased in 1979. Development work was continued in connection with shaft deepening at the Mindola, the Central, and the South Orebody sections of the Nkana mine, with the objective of increased production of cobaltiferous ore in 1980.

Table 6.—Zambia: NCCM copper production and ore reserves

OP Open pit. UG Underground.

In July 1978, the presence of cobaltiferous ores near Nchanga was disclosed, and plans for mining them were later announced by NCCM's Managing Director. The evaluation of cobalt mineralization was accelerated in the Nchanga Mining Area, and the following blocks were sampled by diamond drilling for metallurgical testing and mining:

Mine location	Quantity thousand metric tons	Cobalt (percent)	Cobalt (metric tons)
Open pit: Upper orebody	20,800	0.44	91,520
Open pit: Intermediate orebody	3,000	.38	11,400
Underground: Lower orebody (1,820-1,970 feet)	2,100	.40	8,400
Underground: Upper orebody, (1,750-2,270 feet)	3,400	.54	18,860
Totals and averages	29,300	.44	129,680

The copper grades of the cobaltiferous areas sampled in the open pit were not disclosed, but for the underground mine they were 3.70% and 2.13% respectively for lower and upper orebody blocks. Sulfide ores from Nchanga underground mine were to be treated in a section of the Konkola mill, and the high-cobalt concentrate was to be sent to the Rokana cobalt plant, which was to be enlarged and modified for expanded future production. The Nchanga open pit also supplied oxidized ore in the latter part of 1979, but mining was expected to progress into sulfide ores in the pit by 1983. A section of the Chingola concentrator was to be modified, and a new 2,000-ton-per-year roast-leach-electrowin plant was to be completed at Rokana. NCCM negotiated a loan of nearly $30 million from its British customers against cobalt supply contracts for the next 3 years.

Operations at Mimbula I and Chingola C open pits were scheduled to halt in 1978, but additional good-grade ore was found and mined during the rainy season late in 1978 when a slide had stopped the mining of richer ore in the western end of the Nchanga open pit. Higher grade ore from the Fitula pit also compensated for the shortfall of Nchanga ore. The massive new Muntimpa tailings disposal system over basement rocks footwall to the ore horizon was commissioned early in 1978, but in October inspection revealed failure of the natural rubber lining the 24-inch tailings pipelines. The damage was blamed on organic compounds in the tailings, and extensive sections of the line were replaced with pipe containing a nitrile rubber lining. Deliveries of both acid and lime were behind schedule, and a shortage of lubricants forced the shutdown of earthmoving equipment at the Nchanga open pit. Overburden stripping fell behind target and was blamed for the lower grade of ore delivered to the mills. The tailings leach plant was intermittently shut down for lack of lime.

A 57,000-cubic-meter-per-hour air compressor was ordered for installation in an extension to the main Nchanga compressor building. At the Konkola mine, pilot development for the 1,940-meter-level pump chamber was completed and the quantity of water pumped from the mine decreased from 403,000 to 391,000 cubic meters per day. The presence of cobalt in Konkola ore was announced in April 1979.

NCCM's Nampundwe mine southwest of Lusaka was shut down much of 1979 because of civil disturbances. Underground development work during 1978 yielded some 16,000 tons of diluted ore, and the mill produced 2,515 tons of concentrate containing 3.6% copper and 39.4% sulfur, or 991 tons of sulfur equivalent. Virtually none of the concentrate was charged into the Rokana smelter for acid production, and at yearend some 21,000 tons of concentrate remained in stockpiles at the mine, at railhead, and at Rokana.

In January 1979 the Managing Director of Geomines, the Romanian company, joint owners with the GRZ of the Mokambo copper mine, announced the possible reopening of the mine depending on the favorable results of an economic feasibility study to be completed during the year. The Mokambo deposit, about 12 kilometers northeast of Mufulira mine, was discovered and drilled on behalf of Mufulira but was relinquished in the early 1970's. The Romanian company took over the property and, after additional drilling, put down a shaft and developed the property to the point of production. It was flooded by torrential rains in 1976 and was not reopened since because of the unfavorable state of the copper market.

Lead, Zinc, and Byproduct Cadmium.—NCCM's Broken Hill Division reported mining 256,000 tons of ore during 1978 including the concentrator feed of 192,000 tons containing 8.53% and 27.04% of lead and zinc respectively, or 16,378 tons of contained lead and 51,917 tons of contained zinc. Selective flotation produced 15,367 tons of lead concentrate with 49.3% lead and 12.3% zinc, and 40,976 tons of zinc concentrate containing 1.1% lead and 56.8% zinc. Mechanical and process control failures and erratic coke supplies limited the operation of the Waelz Kilns, the sinter furnace, and the Imperial Smelting Furnace.

Exploration for additional ore continued in the vicinity of the known orebodies and some ferruginous mineralization containing 3.06% lead and 14.98% zinc over a drilled length of 51.3 meters was found at a depth of 50 meters north of the No. 1 orebed. The recalculation of December 31, 1978, indicated reserves of 2.143 million tons of ore containing 11.0% lead and 23.0% zinc.

Other.—Italy's Government-controlled energy company Agip SpA, which has explored known and prospected for new uranium prospects in Zambia for the past 8 years, announced that it expected to establish by 1980 whether any of its uranium deposits are economically workable. It was reported to be sinking exploratory shafts at prospects in the North Western Province during 1979.

NONMETALS

Cement.—Chilanga Cement continued to produce cement from three coal-fired rotary kilns south of Lusaka. A minor but significant proportion of the production was exported by truck to Mpulungu at the south end of Lake Tanganyika and by lake steamer to Bujumbura in Burundi, and to destinations in Tanzania.

Fertilizer Materials.—Since February 1971 Nitrogen Chemicals Co. Ltd. has produced ammonium nitrate for both fertilizer and explosives from a 68,000- ton-per-year (23,800 tons of nitrogen equivalent per year) plant upstream from the Kafue River damsite.

Gem Stones (Amethyst and Emerald).—The production of amethyst from mines located near the foot of the Zambezi scarp northwest of Lake Kariba has continued to decline. Rough amethyst continued to be upgraded for export by wet cobbing at the Lusaka factory where faceted stones and jewelry were also prepared for domestic sale.

Emerald mining was resumed in early 1978 by the Government Mining Development Corporation (Mindeco) which, as 70% shareholder in a new partnership, agreed to mine and deliver supplies of rough emerald to Jardine Matheson, which was to cut and polish the emeralds and train Zambian lapidaries in its Hong Kong headquarters for a 15% interest. Consultancy services in both security and mining were to be provided by Anglo American Corporation as the other 15% shareholder. Marketing of both the rough and cut stones was to be handled by the Zambian Metal Marketing Company (MEMACO). Zambia's emerald deposits, south of Kalulushi and northwest of Luanshya, have long been the target for illicit mining and smuggling operations.

MINERAL FUELS

In July 1979 the GRZ announced price increases for oil products except diesel fuel. The equivalent price for regular gasoline became $3.07 per gallon, and premium gasoline increased to $3.36 per gallon as a result of recent OPEC prices hikes.

Production of bituminous coal from the Maamba colliery reached more than 1 million tons during 1978, but the lack of spare parts, faulty ropeware, and problems with the washing plant became chronic drags on throughput during 1979. The company received a $6 million loan from the African Development Bank for expansion and improvements in 1979 but found difficulty in securing import licenses.

The Mineral Industry of Other Central African Countries

By Janice L. W. Jolly [1]

CONTENTS

CAMEROON

Owing to an upsurge in export earnings, Cameroon made substantial economic progress in 1978 and 1979. With a real growth estimated at 6%, the gross domestic product (GDP) for 1979 surpassed $5 billion.[2] Crude petroleum production was providing a new potential in 1978 and 1979 for achieving national self-sufficiency. Among other benefits, crude petroleum exports were helping to offset the escalating costs of refined petroleum imports and to reduce the 14% to 17% annual rate of inflation. Over the 4 years prior to 1978, Cameroon's petroleum imports increased by 12.1% in volume annually, while the import cost increased by 24.5% annually to about $105 million.

Total export earnings for 1978 were $805 million,[3] to which crude petroleum contributed $25.3 million and crude aluminum product exports contributed $25.9 million. Petroleum exports had increased to about $240 million in 1979 and were in third place after coffee and cacao. Total imports for 1978 were valued at nearly $1 billion. The volume of petroleum imports decreased in 1979 to 552,000 tons, compared with 622,000 tons in 1978. The European Economic Community (EEC) countries purchased over 75% of total Cameroonian exports and provided most of the Nation's imports. The United States purchased $12.4 million in petroleum exports from Cameroon in 1978. Domestic consumption of aluminum metal from imported Guinean alumina continued to grow; thus exports of this metal to France (valued at $2 million in 1978) and Japan continued to fall. Production and exports of cassiterite by the Société de Fibre et de Mecanique (SOFIMEC) continued to decrease. Gold production increased in response to the Department of Geology and Mines program for purchasing gold from small workers.

Cement was being produced from two plants, one serving southern Cameroon at Bonaberi near Douala, and one serving northern Cameroon at Fiquil. In 1979, Cimenteries du Cameroun (CIMENCAM), whose principal shareholders were Société Nationale d' Investissement du Cameroon (SNI) and Finsider International, received $30 million in loans from the European Investment Bank, Caisse Centrale de Cooperation Economique (France) and the Banque de Developement des Etats de l'Afrique Centrale (BDEAC) for increasing clinker and cement production. Both plants were to be expanded. Capacity at the Bonaberi clinker crushing works was to be increased from 480,000 tons per year to 870,000 tons per year, and capacity at the Figuil cement works was to be increased from 70,000 tons per year to 100,000 tons per year. Domestic demand for cement will exceed current cement production by early 1980. The new Figuil plant was to come onstream in 1982 and the Bonaberi plant in 1983.[4] Cement clinker imports increased in 1979 to 391,763 tons, compared with 329,660 tons in 1978. Cement was also produced from locally produced limestone. The price of cement in Douala was $105 per ton in early 1979 and $141 per ton in Yaounde, compared with 1978 prices of $83 per ton and $121 per ton, respectively.[5]

Crude petroleum production began in late November 1977 from the Kole offshore field in the Rio del Rey permit area, and by October 1978 from the Betika Marine and Ekoundou-Sud Marine fields; all permits were owned 51% by Elf-Serepca and 49% by the Shell Oil Company affiliate Pecten Cameroun. Elf-Serepca was a joint venture with the French Société Nationale Elf Aquitaine and the Cameroonian Government. In conjunction with becoming an oil producer, Cameroon was also constructing a petroleum refinery. The National Refining Company of Cameroon (SONORA) was to spend $255 million to build the 15-million-barrel-per-year refinery, which was expected to be completed in 1981. SONORA was composed of 66% Cameroonian Government, 10% Total Afrique, 8% Mobil International Petroleum Corporation, 8% Elf Aquitaine, and 8% Pecten Victoria Company. In addition to the refinery, a deepwater port facility with access to the refinery and a petrochemical facility were planned.

Although it was still too early to estimate the commercial potential, new petroleum reserves were being added to the announcement in 1979 by Mobil Exploration Equatorial Africa Inc. that good quality light crude oil (42°API) and natural gas had been discovered offshore in the Sanaga Sud A-1 zone. Mobil was operator (54%) in the permit shared by Compagnie Francaise des Pétroles-Total of France (18%), Ocelot Industries Ltd. of Canada (16%), and Damson Petroleum Company of the United States (12%). Elf Serepca also announced two finds, both in the Rio del Rey permit. Wells Tanda-1 and Japane-1 showed oil and gas between 1,000 and 1,800 meters.

In December 1978, the Government of Cameroon passed two new petroleum laws governing exploration and production agreements and fees and taxes. A tax of 57.5% was set for production revenues, and the new production agreements were to allocate the Government a minimum of 40% of the production. The final percentage was to be a function of the size and cost of development of the producing field. All past agreements were to be renegotiated under the terms of the new laws.

In September 1978, the Société Camerounaise de Depots Petroliers (SCDP) was formed in compliance with a Government decree that each oil marketing company be required to maintain petroleum product reserves equal to 20% of the amount sold in the previous year. SCDP which was to manage and own all petroleum product storage and transportation operations, was composed as follows: 51% Cameroonian Government, 10% Mobil, 10% Total, 10% Shell, 8% British Petroleum (B.P.), 6% Azienda Generale Italiana Petroli (AGIP), and 5% Texaco Petroleum Company. SCDP was to increase petroleum storage capacity from the current 102,600 cubic meters to 250,000 cubic meters by July 1, 1981.

Planning for the development of Cameroon's mineral resources was well underway, and the Government was indicating an interest in attracting foreign investors to participate. Recent United Nations studies had indicated potential deposits of lead-zinc, rutile, barite, uranium, kyanite, copper, diamond, chromite, and cobalt, in addition to known undeveloped deposits of iron ore and bauxite. Diamonds were discovered in the alluvial deposits of tributaries to the Dja River, phosphatic and uraniferous formations between Lomie and Yakàdouma, and uranium at Lolodorf. Prospecting for uranium also continued at Kitongo Cliff and Teno Valley. A close-spaced scintillometer survey was to be followed by drilling. Iron ore deposits near Mbalam, Menongo, and Nkout in southeastern Cameroon were estimated to contain over 1 billion tons of 45.8% iron as hematite in a belt some 50 kilometers wide. Iron ore reserves at Kribi were confirmed by the French Bureau de Recherches Géologiques et Minières (BRGM) at 120 million tons, and the ore had responded well to preliminary metallurgical testing. Confirmed bauxite reserves in northern Cameroon at Minim-Martap, southwest of Ngoundere, and also near Dschang were estimated at 1 billion tons of 43% alumina. Their development has been hampered by their remote location and lack of adequate transportation. Société des Etudes des Bauxite Du Cameroun, a Government joint venture with a number of international aluminum companies, was formed in 1970 to conduct feasibility studies on these deposits, which may not be developed in the near future because of the high expenditures required, estimated at over $1 billion. The United Nations Development Programme (UNDP) was continuing its airborne magnetic survey of the country. The BRGM was increasing its efforts in southwestern Cameroon. The mineral exploration effort was being jointly financed by France and the European Development Fund.

With an installed capacity of about 314 megawatts, Cameroon was the second largest producer of hydroelectric power in formerly French sub-Sahara Africa. It will become the largest producer in the region upon completion of the Edea Dam complex, which currently generates 95% of the total electricity. Major projects under construction were the Song Loulou Dam at Edea and the Lagdo Dam at Njock, which will add another 300 to 400 megawatts to meet growing needs of the aluminum and petroleum industries. About 70% of all electricity generated is consumed by the Edea aluminum smelter, which has a capacity of 55,000 tons of aluminum per year. With completion of the new dams, the smelter capacity will be increased to 80,000 tons per year.

Table 1.—Other countries of Central Africa: Production of mineral commodities

[e]Estimate. [p]Preliminary. NA Not available.
[1]In addition to the countries listed, Equatorial Guinea and São Tomé and Principe, covered textually in this chapter, presumably produce modest quantities of a variety of crude construction materials (clays, stone, and sand and gravel), and may produce minor amounts of other mineral commodities (most notably gypsum, lime, and salt), but output is not reported quantitatively and available information is inadequate to make reliable estimates of output levels.
[2]In addition to the commodities listed, modest quantities of unlisted varieties of crude construction materials (clays, stone, and sand and gravel) presumably are produced, but output is not reported quantitatively and available information is inadequate to make reliable estimates of output levels.
[3]Reported figure.

CHAD

Except for minor production of natron, salt, clays, and local building materials in 1978 and 1979, there was no mineral production of significance in Chad. The long-smoldering civil war was escalating and spreading, despite several truces signed in early 1979. Chad's hope of becoming an oil producer was delayed as a result. Because of Chad's distance from the sea, and owing to the absence of any railroads, the costs of petroleum exploration and development have been high. Transportation has always been a principal impediment to economic progress in Chad. The United Nations Development Programme (UNDP) was to rebuild 470 kilometers of roads in the Sahel region of Chad, spending about $20 million.[6] The most promising area for road improvement was that which paralleled the planned crude petroleum line from the Sedigi oilfield to Ndjamena.

Plans for construction of the minirefinery (topping plant), the 350-kilometer crude petroleum pipeline, and the Ndjamena residual fuel powerplant were delayed indefinitely because of the escalation in the civil war in early 1979. About $65 million was estimated as necessary to complete these projects with funds obtained from the International Development Association (IDA), the Arab Bank for Economic Development in Africa (ABEDA), and the Central Fund for Economic Cooperation (CFEC). The refinery was to process 3,000 barrels per day and to be fed by wells in the Sedigi field. The Société D'Etudes et D'Exploitation de la Raffinierie du Tchad (Seerat) had been scheduled to begin construction of the refinery in early 1979. Seerat was owned 51% by the Chadian Government, 18.375% by Shell Oil Company, 12.25% by Exxon Corp., 12.25% by Chevron Oil Company, and 6.125% by Continental Oil Company (Conoco). Conoco was operator for the Sedigi Oilfield exploration and production, and Shell was to operate the pipeline and refinery. In early 1978, Standard Oil of California was operator for a group including Shell (50%), Conoco (12.5%), and Exxon (12.5%) that discovered oil near the town of Moundou in southeastern Chad. The well, Manga-ra No. 1, flowed at rates up to 1,875 barrels per day of 36° to 38° API, paraffin-based oil.[7] Reserves were estimated at 365 million barrels.

With United Nations assistance, the Government of Chad was doing detailed mineral exploration in the Mayo Kebbi Region of southwestern Chad. A rather poor gold deposit and some interesting nickel and uranium anomalies were discovered. Secondary yellow uranium minerals were observed in veins 0.5 to 1.0 meter wide, containing from 0.1% to 9% uranium. The uranium veins occur in granite at Lere and were thought to present a promising target for future exploration. Some interesting mineralized areas, including tungsten, tin, and uranium, known to occur in the Tibesti Mountains, but these have been unavailable for some time owing to the rebel offensive that captured that region in July 1977. The brines and evaporates of the Lake Chad Basin were the subject of a recent paper in Geochimica et Cosmochimica Acta.[8]

CENTRAL AFRICAN REPUBLIC

In 1978 and 1979, the mineral industry of the Central African Republic, which consisted primarily of diamond and gold production, was laboring under conditions of a stagnant economy that had resulted from 14 years of neglect. At yearend 1979, 3 months after the coup that changed the government as well as the country's name (renamed from the Central African Empire), the economy was still far from recovering. The new Government inherited huge external debts, a disorganized administration, and a weak economy. Four major weaknesses needed to be addressed: the deplorable conditions of river, road, and air transport; inadequate state and foreign investment; bad management of public enterprises; and a neglected agriculture and mining base. Industrial equipment was worn out, and new capital was not yet entering the country despite favorable tax legislation for foreign investment. By late 1979, a major reconstruction effort had been drafted under the guidance and cooperation of France and the International Monetary Fund (IMF).

France was to lend some $6 million[9] to start the economic reforms. In a new balanced budget drawn up in collaboration with the IMF, the number of civil service personnel was to be reduced by about 6,000 and salaries were to be frozen, abusive tax and customs levies were to be abolished, debt settlement plans for past nationalizations were to be drafted, and state-run companies were to take on private partners. Under the reforms, fuel distribution was to be split up into several companies, because the state-dominated (60%) company Centra-Hydro had proven in 6 years of operation that it could not carry out the task on its own. A shortage of petroleum dominated the country's economic troubles. Funds were also allocated for a new public-private transportation company for the Oubangui and Congo Rivers, the counry's main means of transport to the Atlantic Ocean, via barge to Brazzaville and rail to Pointe Noire in the Republic of the Congo. Lesser quantities of imports come overland from Douala, Cameroon. The main road crossing the western part of the country was to be repaired, and the airport was to be improved.

The investment code of the Central African Republic provided liberal tax, tariff, and other benefits for foreign investors, but some nationalizations have occurred. Total foreign investment in 1978 was valued at about $130 million, of which French interests made up $80 million, Portuguese interests $14 million, and U.S. and Belgian investments $7 million each. United States, Israeli, and Belgian diamond interests accounted for 14% of foreign investment. The U.S. company Diamond Distributors International (DDI) has invested $6 million in a buying office and cutting factory. Operating from New York, DDI was operating a diamond cutting industry through a Government mixed enterprise. This partnership, the Comptoir National du Diamont, was allocated 5% of raw diamond production and was the exclusive processor of gem-quality diamonds in the country.

Total exports for the Central African Republic were valued at $78 million compared with $89 million for 1977 and $62 million for 1976. Total imports (c.i.f.) were valued at $57 million compared with $70 million in 1977 and $48.3 million in 1976.[10] The volume of imports declined in 1978 because of both transportation difficulties and deteriorating terms of trade. Imports were largely petroleum and industrial and consumer goods. The Central African Republic's leading trading partner was France with 43% of total imports and 53% of non-Union Douaniére et Economique d' Afrique Central (UDEAC) imports. The Federal Republic of Germany, Japan, Belgium, and the United States were also primary suppliers. Among countries importing diamonds, Belgium was first with $16.4 million in uncut diamonds and $1 million in cut diamonds. The United States was second ($5.2 million in uncut diamonds), and Israel was third ($2.8 million). Lesser amounts went to France (1,018 carats), the Netherlands (10,106 carats), and Great Britain (2,632 carats) in 1978. The Central African Republic obtained petroleum products from Gabon under arrangements that included a loan-grant agreement with Iraq and shipments by the Congolese State-owned Centra-Congo company. Petroleum imports have been irregular since the nationalization of foreign company interests in 1974. Owing to payment difficulties with the Congo and the slowdown in river transport, imports have come increasingly overland by Cameroon. As a result, prices for imported goods escalated. The decline in export value for 1978 was due primarily to reduced prices for agricultural products. Lower revenue from basic commodities was offset somewhat by increased world diamond prices, which drove the average price per carat for diamonds from $79 in 1977 to $135 in 1978.

Diamond production was valued at $45.6 million for 1979, $39.7 million for 1978, and $23.4 million for 1977. The increase in value was due entirely to an increase in market prices, and was not a reflection of increased production. To the contrary, since 1968, when 609,360 carats were produced, there has been a steady decline to less than half that amount by 1978. Industrial diamond production represented approximately 20% of the value received for 1979. Of the total 1979 production, 4,299 carats, valued at $2.8 million, were cut locally. Cut diamonds exported in 1978 were valued at $1.8 million, compared with $660,000 for 1977. Gold production in 1979 was valued at $5.4 million, a considerable increase over the $500,000 earned for 1978. A small amount of uranium was produced in both 1978 (0.75 tons U_3O_8) and 1979 (1.25 tons U_3O_8). [11] The ore was shipped to France for processing at a pilot plant. Commercial exploitation had not yet begun.

Development of the Bakouma uranium deposits continued with small shipments of ore being sent to France for preliminary testing. The Société de l'Uranium Centrafricain (URCA) was formed in 1975 as a joint venture with the Central African Empire Government (33.3%), Swiss Aluminium Ltd. (Alusuisse) (33.3%), Compagnie Francaise des Mines d'Uranium (16.7%), and the French Atomic Energy Commission (16.7%), and had exclusive uranium mining rights in the Central African Republic. Cost of developing the mine was estimated at $400 million, including an open pit mine and processing facilities. In April 1979, France contributed an initial $1.7 million for the first stage of site construction. Uranium reserves were estimated at 17,000 tons U_3O_8 in phosphate-bearing ore. Samples tested by Alusuisse averaged 0.3% uranium in the phosphate ore. Nearby lignite deposits were to be utilized to provide electric power for the project.[12]

PEOPLE'S REPUBLIC OF THE CONGO

Petroleum continued to be a major contributor ($185 million)[13] to the Congo's gross domestic product (GDP), estimated at $895 million for 1978.[14] Maufacturing, including cement production, accounted for about 10% of the GDP. The petroleum refinery was still inoperable. Some natural gas was produced and copper, lead, zinc, and some gold were mined, but potash production was never resumed after serious flooding closed the mine in 1977. Hopes for improvement in the mineral sector were raised by the start-up of the Soviet-built lead concentrator at Mfuati in 1979, and by encouraging resuls from increased petroleum exploration. At the end of 1978, proved oil reserves stood at about 746 million barrels, compared with 465 million barrels at the end of 1977. Petroleum revenues were also increasing as prices rose and production from new fields started. A new constitution and government were voted in during July 1979, following which, in a major message to the nation, the new Chief of State earmarked the mining industry as an area in which the Government would specifically encourage private investment. The financial situation of most state enterprises had deteriorated over the past few years owing to overemployment, inadequate management, and declining productivity.

A serious development problem continued to be the lack of adequate transportation. High priority was being given to transportation projects necessary for the mining sector and to strengthening the Congo's role as an inland transportation corridor for the Central African Republic, Chad, and Gabon. The Agence Transcongolaise des Communications (ATC), a state enterprise that manages rail and river transport, was to receive considerable foreign aid for transportation improvement. In 1973, the World Bank had approved a credit of $6.5 million for the expansion of the Congo-Ocean railway. Feasibility studies for improvement of the railway were done by Tecsul International of Canada, and tenders for the construction of a new route between Holle and Dolisie were awarded in 1978 to a French, German, and Italian consortium, and to Pandrol Ltd. of the United Kingdom for materials supply. Track was also renewed between Holle and Loubomo and between Holle and Fourastie, and the marshaling yards at Point Noire and Brazzaville were to be updated. Financing was to come from Canada, France, the African Development Bank, Saudi Arabia, and Kuwait.

Petroleum and reexported diamonds

formed greater than 85% of the Congolese exports for both 1978 and 1979. Total Congolese exports for 1978 were valued at $235.4 million, and total imports (c.i.f.) at $261 million. Petroleum exports were valued at $347.4 million for 1979, a 58% increase compared with 1978 petroleum exports valued at $220 million. Diamond exports were valued at $5.5 million for 1977,[15] but were not a product of local mining.

Production levels at Emeraude, the largest offshore field, had decreased steadily from the peak production of 1974, and the field was expected to be depleted in the mid-1980's. Production began in 1977 at Loango (owned 35% by Elf-Congo and 65% by Azienda Generale Italiani Petroli Spa (AGIP)), and reached a level of about 20,000 barrels per day in 1978. Production at this field was expected to peak in 1980 and fall steadily thereafter as these resources also became depleted. Likouala, a new field located about 50 kilometers from Pointe Noire with recoverable reserves of about 72 million barrels, should reach full production of about 10.5 million barrels per year in 1981 and was to begin production at the rate of 4,200 barrels per day in 1980. With renewed Government encouragement, petroleum exploration activities increased. The outlook was also favorable that the Government-owned oil refinery at Pointe Noire would soon be operating. Negotiations were in progress with a French company for overhauling and operating the refinery. The State-owned company Hydro-Congo had the monopoly for distribution of petroleum products in the Congo.

Elf Aquitaine confimed the presence of exploitable petroleum by exploratory drilling in Sendji Marine-2 on the Pointe-Noire deepwater permit (Elf Congo 65%, operator; AGIP Recherches Congo, 35%). A second discovery was also made on a neighboring structure (Yanga) at Senji Nord Marine I, where petroleum was encountered at several depths, but the production potential was still to be determined. Congolese Superior Oil (operator, 25%), Canadian Superior Oil (25%), and Cities Service Congo Petroleum (50%) were awarded an offshore exploration permit for Marine-1 in 1979. Late in 1979, three U.S. companies also signed an offshore exploration agreement, leasing 40,000 hectares from Hydro-Congo. Under the terms of the agreement, the cost of exploration was to be reimbursed by production sharing. Accordingly, Hydro-Congo will get 50% of the production, Coastal Corp. (Houston) 22.5%, Agri Petco International Inc. (Oklahoma) 12.5%, and Ladd Petroleum Corp., 15%.

Production of lead concentrates from a lead-zinc-copper deposit at Mfuai started in 1979 and was expected to reach 30,000 tons of lead concentrates per year. Five years of reserves had been outlined. A nearby larger deposit was expected to support a production capacity of about 70,000 tons of concentrates per year over a 25-year period. Other sizable lead-zinc deposits have been discovered close to the Gabonese border. Société Minère de M'Passa's output of copper concentrates was unchanged in 1978 at 800 tons of contained metal, which was full capacity of the plant. Production of zinc at M'Passa fell to 4,800 tons of contained metal in 1978. No figures were available for Congolese gold production, which came mostly from the joint Soviet-Congo operation Société Nationale des Mines de Sounda-Kakamoeka (SONAMIS). About 6,430 troy ounces were believed to have been produced from the Magonise deposits, and about 570 troy ounces from other sources.

EQUATORIAL GUINEA

After a successful coup in August 1979, a new government was formed in Equatorial Guinea. In desperate need of economic assistance for revitalizing a country after years of political repression and economic neglect, the new Government moved to develop closer ties with several Western nations. Spain in particular was supplying $23 million for food, medicine, and technical aid. Equatorial Guinea was to have a new currency pegged to the Spanish peseta, and financial dealings were linked to Spain through the creation of the Banco Español de Guinea Ecuatorial y de España. Several aid agreements were also signed with France for economic, technical, and scientific assistance. France was expected to provide funds for work on the port of Molabo ($2 million), prospecting for minerals ($500,000), and the fishing industry. The Government was expected to prepare a new hydrocarbons law. In the meantime Spain's Hispanoil and the Equatorial Guinea Government formed a joint venture, Empresa Guineo Española de Petróleos (GEPSA), to explore for and produce hydrocarbons. No exploration work had been done since 1969, when Continental Oil Company withdrew after a border dispute between Equatorial Guinea and Gabon.

SAO TOME E PRINCIPE

Since proclamation of independence in 1979, the Democratic Republic of São Tomé e Principe has received aid from a number of international institutions and countries, including the U.S.S.R., Mainland China, Cuba, North Korea, the German Democratic Republic, Sweden, the Netherlands, France, and Portugal. Most of the aid has been in the form of technical assistance for public works, health, defense, and miscellaneous equipment. Portuguese cooperation also included highway and port construction and improvements to the air transport system. In 1978 and 1979, Portugal was the principal supplier and customer of São Tomé, purchasing mainly coffee and copra. In addition to agricultural assistance, the French have also done a study to set up a brickworks. A major shift in political stance in 1978 and 1979 led to greater emphasis being placed on consumer food production to reduce the massive imports of food, which had increased since independence. The most significant diplomatic move in 1978 was towards a closer relationship with Angola. In 1979, São Tomé joined Angola, Mozambique, Guinea Bissau, and Cape Verde at the first summit meeting of these former Portuguese colonies to decide on coordination of development policies.

Hidrocarbo, owned by Premier Consolidated through Ball and Collins (Oil and Gas) Ltd., remained the only exploration permit holder on the islands. Petroleum exploration contracts were renegotiated in early 1978.

The Mineral Industry of Other East African Countries

By David E. Morse[1]

CONTENTS

BURUNDI

Burundi, a small central African republic located between Tanzania and Zaire, remained essentially a nation of small family farms in 1978-79 with approximately 95% of the population engaged in subsistance agriculture. Coffee and tea continued as the nation's major export commodities. Mineral exports, small tonnages of cassiterite, wolframite and bastnäsite, accounted for an estimated 3% of total exports in 1978 and 2% in 1979, or $2 million[2] in both years. Burundi's major mineral imports in 1978-79 were cement, iron and steel, and refined petroleum products.

Abnormal weather conditions, a drop in world coffee prices in 1978, and the conflict in neighboring Tanzania and Uganda in late 1978 and early 1979 combined to restrict economic growth in Burundi during 1978-79. The gross domestic product (GDP) posted a gain of 6.7% in real terms for 1978 and an estimated 2.5% for 1979 which was significantly less than the 13.7% recorded in 1977, a time of high world coffee prices. The manufacturing and construction sectors were hard hit in 1979 by the conflict between Burundi's eastern neighbors because of transport disruptions which made building materials and manufacturing inputs almost unobtainable.

Fuel supplies fell drastically in 1979. In May, France, Belgium, and the Federal Republic of Germany helped set up an airlift to supply Burundi with fuels and vital supplies. The Mombassa (Kenya) to Bujumbura airlift was terminated in June as transport service through Uganda and Tanzania slowly returned to a more normal state.

In early 1979, the Burundi Ministry of Geology and Mines report entitled "Memorandum on the Development of Nickeliferous Laterite Deposits of Burundi" was released. The report included metallurgical studies, a peat energy study, an economic prefeasibility study and proposals for constructing a mining and smelting facility, and transport infrastructure including a rail link to the Dar es Salaam-Kigoma railroad at Uvinza, Tanzania. Burundi nickel reserves were reported at 300 million tons of ore with a nearly 2% nickel content and smaller values of copper, cobalt, and platinum. The United Nations (U.N.) Development Program funded a research project to study Burundi's extensive peat deposits near Akanyara.

The peat deposits were to be developed to provide an indigenous energy supply and to feed a domestic, peat-derived chemical complex. No major agreements to develop either the nickel laterite or peat deposits were announced in 1978 or 1979 although small-scale exploitation of four peat bogs by the newly formed Peat Office commenced in 1979.

Tungsten, mine output, metal content	110	110	110	55

[e]Estimate. [p]Preliminary. [r]Revised. NA Not available.
[1]In addition to the commodities listed, modest quantities of unlisted varieties of crude construction materials (clays, stone, and sand and gravel) presumably are produced, but output is not reported quantitatively and available information is inadequate to make reliable estimates of output levels.
[2]Limited quantities of other pegmatite minerals may also be produced, but output is not reported.
[3]Reported figure.
[4]Data represent sales; actual production is not reported.
[5]Actual production was zero; sales from stockpiles totaled 493,528 tons.

DJIBOUTI

The Republic of Djibouti lies on the west side of the Bab-el-Mandeb, which connects the Red Sea and the Gulf of Aden. Formerly the French Territory of Afars and Issas, Djibouti received its independence in June 1977. The economy of the country was based on the commercial and maritime activity of the port of Djibouti and the operation of Chemen de Fer Franco-Ethiopian (CFE) which connects the port with Addis Ababa, Ethiopia. The country continued to be plagued by chronic unemployment and a severe balance of trade deficit in both 1978 and 1979. Subsidies from France and aid from Saudi Arabia and other Arab states helped to sustain the economy.

Djibouti had no significant mineral production although small, unreported quantities of crude construction materials undoubtedly were produced for local use. The potential for production of salt, gypsum, limestone, cement, and perlite exists but the small population (250,000) and distance from substantial markets for these low unit value commodities has deterred investment. The Bureau de Recherches Géologiques et Minières of France (BRGM) has explored the possibility of utilizing geothermal resources in the area of Lake Asal.

ETHIOPIA

The mineral industry of Ethiopia continued to be a minor contributor to the nation's economy in 1978-79. Evaporite deposits were worked for the production of gypsum and salt. Gold and platinum were recovered from alluvial workings. Stone and sand and gravel were mined throughout the country for local consumption. Ethiopia had two cement plants, a 14,000-barrel-per-day oil refinery that was being expanded with the assistance of the U.S.S.R. and several salt-producing facilities on the shores of the Red Sea.

The U.N. classified Ethiopia as one of the world's 10 least developed countries with a per capita income of approximately $100.[3] Ethiopia had a small modern sector and a subsistance agriculture sector that provided the livelyhood for 85% of the population and contributed approximately 65% to the gross domestic product (GDP). Agriculture produce provided 90% of the country's export earnings while 75% of industry was engaged in the processing of farm products.

During 1978-79, Ethiopia experienced a sharp economic deterioration. A breakdown of transportation and communications due mainly to internal strife, together with a loss of workers to the armed services adversely affected both agriculture and industry. Food purchases, added to the heavy expenditures for military equipment, placed a severe strain on the nation's balance of payments resulting in a steady decline of international reserves and an increase in foreign borrowing.

In October 1978, the Government launched a development campaign, the "Green Zemecha," which emphasised the reconstruction and restructuring of the economy. Short-term goals were the elimination of illiteracy and unemployment; long-term goals were to diversify the economy with agriculture and light industry aimed at import substitution. The development campaign had little or no effect on the country's economy performance in 1979 owing to a stagnation in export earnings and a sharp increase in the cost of imported fuels.

LESOTHO

The Kingdom of Lesotho is a small, very mountainous, land-locked nation of 1.22 million people, and is completely surrounded by the Republic of South Africa. The mining industry consisted of the production of diamond and crushed stone in 1978-79. Remittances from about 100,000 Lesotho nationals working in mines in the Republic of South Africa constituted over 40% of the country's gross national product (GNP) and were nearly equal to the gross domestic product.

Lesotho's only significant mineral export was diamond in 1978-79. Other important exports were wool and live animals. The Kingdom's main trading partner was the Republic of South Africa.

Diamond was produced by licensed diggers on a small scale and at the Letseng-la-Terai diamond mine, the nation's only real mining operation, by De Beers Lesotho Mining Corp. (Pty) Ltd. Production in 1978, the mine's first full year of operation, was over 67,000 carats. The Letseng operation employed approximately 800 people of which 680 were locals and 120 were expatriates. The Letseng Mine is one of the lowest grade diamond operations worked by De Beers with the average grade of only 3.46 carats per 100 tons treated. The mine was only economically viable because of the occasional large, high-quality gemstones recovered.

MALAWI

Malawi is a landlocked nation of southeastern Africa with virtually no natural resources other than a fertile soil and adequate rainfall. The mining industry in Malawi was essentially confined to the production of industrial minerals, the majority of which were consumed by the domestic market. The main product mined was marble for use in the manufacture of cement and lime. Agate was produced for export.

Small and/or low-quality deposits of a wide variety of minerals were known including asbestos, chromite, corundum, iron ore, kyanite, magnesite, nickel laterite, uranium minerals, and zircon, but were not economically viable for development in 1978-79. The Ngana Coalfield in the north near the Tanzania border, reportedly containing 14 million tons of reserves, was considered by the Government as an excellent prospect for development. Other areas considered for possible mineral development were the Kapirikamodzi vermiculite ore bodies and the Kangankunde Hill monzanite-strontianite deposits.

MAURITIUS

Mineral production on Mauritius Island contributed an estimated $5 million to the island economy in 1978-79. Minerals produced included stone (basalt), salt, and lime. The production and export of sugar was the island's most important economic activity followed by a growing tourist industry. Mauritius needs for fuels, cement, iron and steel products, and a significant volume of food had to be imported in both 1978 and 1979.

REPUBLIC OF THE COMOROS

The Republic of the Comoros, a volcanic archipelago in the Mozambique Channel between Africa and northwestern Madagascar, had negligible mineral production in 1978-79. Small amounts of unrecorded stone and sand and gravel undoubtedly were produced. No significant exploitable mineral deposits had as yet been discovered by yearend 1979.

The most significant event in the Comoros in 1978 or 1979 was a forced change of government in May 1978. In early 1979 the new Government successfully normalized relations with France, the Republic's former colonial power, which had suspended all financial aid when the Comoros made a unilateral declaration of independence in 1975. France and the Comoros reached an economic, financial, and monetary agreement, and a cultural and military agreement in 1979. France was to defend the islands if attacked and the Comoros were to export perfume ingredients (ylang-ylang, jasmine, and geranium) to France.

REUNION

The economy of Reunion, an island in the Indian Ocean approximately 640 kilometers east of Madagascar, continued to be dependent on the agriculture sector, primarily sugar, in 1978-79. Reported mineral activity was limited to the operation of a 200,000-ton-per-year cement clinker grinding facility although the production of crude construction materials undoubtedly took place. The island hosted about 495,000 persons and was an overseas territory of France which financed the islands major development projects that consisted mainly of infrastructure improvements. BRGM continued a program of geologic mapping and ground water surveys in 1978-79.

RWANDA

Mineral production in Rwanda in 1978-79 was, for the most part, slightly less than it had been in 1977, but exports of mineral products continued to account for approximately 20% to 25% of the nation's foreign exchange earnings. Cassiterite concentrate (tin) continued to be Rwanda's most important mineral product and second most important export commodity after coffee. Tungsten minerals, columbo-tantalite concentrates, beryl, and alluvial gold were the country's other significant mineral output.

Most of Rwanda's mineral industry was controlled by Société Minière du Rwanda (Somirwa), which was managed and owned 51% by Compagnie Géologique et Minière des Ingenieurs et Industriels Belges (Géomines) and 49% owned by the Rwandan Government. Somirwa's mineral products were marketed by Socitété Gèneral des Mines in Belgium. In March 1978, Somirwa began construction of a smelting plant at Kilgali which was to produce tin metal and tantaliferous slag from Rwandan cassiterite ores.

Rwanda's chief route for exports and imports through Uganda to the Kenyan port of Mombassa was severed late in 1978 owing to the conflict between Uganda and Tanzania. Although the route was opened and critical supplies began arriving in June 1979, the transportation dislocation required the use of high-cost air transport. Significant portions of Rwanda's exports of coffee, tea, and cassiterite, and all of its wolframite were transported by air. There was an acute shortage of motor fuels, lamp kerosine, and some food items in the first half of 1979 but a more normal supply by yearend.

In 1979, the United Nations Development Program (UNDP) completed a geochemical and radiometric survey which covered a significant area of the country. Airborn radiometric and magnetic survey of selected areas have also been carried out. Geochemical anomalies of tin, tungsten, zinc, and uranium were found which merited further investigations. The UNDP was to assist with the followup investigations and BRGM of France was working in a 2,100-square-kilometer area in the north-central part of Rwanda.

SEYCHELLES

Tourism and agriculture were the more important sectors of the economy of the Seychelles Islands in both 1978 and 1979. The approximately 100 islands, located north of Madagascar in the Indian Ocean, 1,000 kilometers from the east coast of Africa, host a population of 62,000 on 40 granite and 60 coralline islands which average less than 4 square kilometers in area. The only product mined in the Seychelles was guano which was valued at $271,000[4] in 1978 and $279,000 in 1979. The other reported mineral activity was offshore petroleum exploration by a group comprised of Burma Oil Seychelles, Ltd. (40%). Amoco Seychelles Petroleum Ltd., (20%) Hematite Petroleum Seychelles, Ltd., (20%), and Norcen International (20%).

SOMALIA

The mineral industry of the Somalia Democratic Republic continued to be a minor contributor to the nation's economy in 1978-79. Official figures for Somali mineral production and trade were not available for either 1978 or 1979, which required considerable use of estimates in table 1. Mineral production was limited to industrial and construction materials, solar evaporated marine salt, meerschaum (sepiolite), and small quantities of cassiterite (tin concentrate).

In early 1979, production at the 10,000-barrel-per-day Mogadiscio oil refinery was initiated. The Iraqi Fund for Foreign Development financed the project and crude oil was supplied by the Iraqi National Oil Co. A 100,000-ton-per-year cement plant was scheduled to come online at Berbera in 1978 but information concerning the plant's status was lacking and it was not known if the facility was operational by yearend 1979.

Somalia's fragile economy was severely strained in 1978-79 by an influx of approximately 1 million refugees from neighboring Ethiopia. The Somali Government's request for aid from the U.N. to feed and provide a minimum of shelter and other basic amenities for the refugees was met with a U.N. commitment of 159,000 tons of food and over $40 million[5] in nonfood aid.

SWAZILAND

Mineral production in Swaziland continued to be one of the country's major sources of income in 1978-79; however, mining's contribution to total export values has declined from 40% in the early 1970's to approximately 15%. Asbestos was the most important mineral commodity in terms of revenue followed by iron ore and coal. Alluvial tin and gold were produced on a small scale and unrecorded amounts of clays and sand were utilized by the domestic construction industry. Stone output increased considerably owing to increased road construction and improvements and building of a railroad link (90 kilometers) between Phuzumoya and the South African railway system at Labumisa.

Shipments of iron ore from the Ngwenya Mine continued in 1978-79 although mining operations were terminated in 1977. Exports of 1,266,000 tons in 1978 and 957,000 tons in 1979 were significantly less than planned due to rail problems at the port of Maputo, Mozambique. Utilization of the nation's large, low-grade iron ore resources continued to be studied by the Government including the possibility of producing sponge iron domestically.

Exports of asbestos fiber from the Havelock Mine were approximately 38,000 tons in both 1978 and 1979, and were valued at $19.5 million in 1978 and an estimated $20.2 million in 1979. The mine was owned by Turner and Newall Ltd. of the United Kingdom (60%) and by the Swaziland Government (40%). Significant efforts were made in 1978-79 to reduce dust levels in and about the 120-ton-per-day asbestos fiber plant.

Production of anthracite by Swaziland Collieries Ltd. at Mpaka increased in both 1978 and 1979. Coal was used by the Swaziland railway and by local industrial and agricultural consumers; small tonnages were exported to Mozambique. The Government continued to encourage greater domestic use of coal.

Coal exploration was continued by Shell Coal Swaziland (Pty.) Ltd. and by the Geological Survey and Mines Department of Swaziland. Shell completed an exploratory shaft and underground workings on the Mpulme anthracite deposits.

A 3-year, geochemical stream sampling and analysis of stream sediments program, funded by the Canadian International Development Agency, was completed in 1978. Preliminary results of the sampling program indicated that 10 areas have good potential for base metal mineralization. A more detailed study of these areas was to commence in mid-1980.

UGANDA

The mining industry as well as most sectors of the Ugandan economy had suffered a period of neglect, mismanagement and significant decline from March 1972 to April 1979. The country experienced a crisis period from October 1978 through yearend 1979. Ugandan exiles aided by troops from neighboring Tanzania invaded the country in late 1978 and succeeded in ousting the former ruler in April 1979. The economy remained in a chaotic state of flux throughout 1979. The new Government called for monetary, technical, medical, and military assistance to restore the nation to a solid economic footing.

The state of the nation's mining industry was uncertain as no official information had been available for a number of years. The Kilembe copper mine had been the nation's most important mineral venture. Beryl, cassiterite, wolframite, and bismuth had been mined on a small scale. Phosphate rock and crude construction materials were also mined and quarried for domestic use. Salt was produced by solar evaporation of lake and well brines.

Uganda has significant mineral potential. Approximately 2 million tons of cobaltiferous pyrite has been stockpiled at Kilembe.

The Mineral Industry of Other West African Countries

By Phyllis Lyday[1]

CONTENTS

BENIN[2]

Mining did not contribute significantly to the economy of Benin, a small country on the coast of West Africa, during 1978-79. During these years, Benin continued to be rated by the United Nations as one of the 25 least developed countries in the world; its gross domestic product was under $200[3] per person per year. Salt from seawater, sand and gravel, bricks, and imported clinker for cement were the only minerals which contributed to the economy. Minerals were not expected to play an important role in the commercial sector of Benin's economy during the next decade.

Joint projects included infrastructure development to create a coordinated road and rail system between Niger and Benin that was begun in 1960 as "Operation Hirondelle." In 1976, an agreement for the construction of a rail link from Niamey, Niger, to Parakou was signed. At Parakou, the rail line would join the existing line to the port at Cotonou. Construction of the rail line was expected to take 6 years, and the cost was estimated at $287 million in 1979. During late 1979, the Federal Republic of Germany granted Benin a loan of $12 million for reconstruction of the port at Porto Novo. Benin and Nigeria were discussing a joint adventure in crude salt exploitation.

Exploration included proven deposits of asbestos in a zone between the ninth and tenth parallels by the Bureau de Recherches Geoligiques et Minieres (BRGM). Phosphate deposits from the Tapoa deposits of Niger, which extend into the Mekrou sector of Benin, were explored but were not considered to be commercially viable at the time of the exploration. An increase in the price of gold stimulated renewed interest in the Perma alluvial gold deposits. These deposits contain from 0.5 to 2.5 grams of gold per cubic meter.

During 1978, expansion of the 200,000-ton-per-year clinker grinding plant of Societe Nationale des Ciments (SONACI) to 400,000 tons per year was inaugurated. Cement production was marketed internationally by the Societe Benionoise de Materiaux de Construction. A second cement clinker project was planned for Onigbolo in eastern Benin, near Pobe, by Societes des Ciments d' Onigbolo (SCO). This project would use local raw materials and was expected to have a capacity of 500,000 tons per year. Approximately 100,000 tons per year was expected to be used locally, and the rest was planned to be exported. SCO was owned by the Government (49%), Niger (41%), and Denmark's F.L. Smidth & Co. A/S (10%). Construction was to be undertaken by F. L. Smidth, with a planned completion date of 1982. Henry Pooley Alkins (United Kingdom) was selected to monitor the construction. Arrangements were made for SCO to be financed by Denmark and Belgium-Luxembourg ($50 million) and by Nigeria and Benin ($20 million). The Arab Bank for Economic Development in Africa (BADEA) also contributed $8 million to the Onigbolo project.

The Seme oilfield, discovered in 1968 by Union Oil Co. (United States), was located 15 kilometers offshore. Reserves estimated at 22 million barrels were planned to be developed by Saga Petroleum (Norway) and Kvaerner Industrier A/S (Norway). Under the operating agreement, the Government retained ownership of the crude. The cost of the project, estimated at $98 million, was to be financed by Norwegian loans (90%) and the Benin Government (10%). Production was expected to begin in 1981, peaking at 15,000 barrels per day, which was expected to be exported. Benin's 3-year plan (1978-81) included $215 million for a refinery, but, in light of the fact that Benin consumes only 100,000 tons of petroleum products per year, this project may not be of primary importance.

CAPE VERDE

The Republic of Cape Verde consists of 16 islands of volcanic origin, 9 of which are inhabited by approximately 300,000 people. The islands are located in the central Atlantic Ocean, some 620 kilometers west of Senegal on the west coast of the African continent. The country gained independence in 1975 and was still in the process of establishing institutions and infrastructure during 1978 and 1979.

Cape Verde had an estimated gross national product of $179 per person during 1978. The Government's budget for the 1978 fiscal year included expenditures of $63.5 million against revenues of $55.8 million. Foreign assistance continued to provide the basis for the continued economic well-being of Cape Verde during 1978 and 1979. The United States continued to be a major donor, followed by France, the Federal Republic of Germany, the European Economic Community, the United Kingdom, and Portugal. Major U.S. aid projects to Cape Verde outside the agricultural sector were water desalination and electrical generation plants for the island of Sal and the city of Mindelo on the island of Sao Vicente.

Mineral production in the form of salt accounted for 6% of the export revenues. Production was from two solar drying pan facilities on Sal Island. Pozolana (a volcanic rock used in cement production) production from the island of Santo Antao was suspended during 1978 and 1979. Other mineral deposits in Cape Verde include gypsum on the Mao Island and lime on Boa Vista Island.

THE GAMBIA

The Gambia consists of 11,300 square kilometers of land ranging from 11 to 32 kilometers wide and extending 320 kilometers along the Gambia River into the interior of West Africa. The population in 1978 was approximately 538,000 people and income was $292[4] per person per year.

Banjul, the capital, is located in a natural harbour on the mouth of the Gambia River. Future development in Senegal could lead to mineral related traffic on the river, which was navigable for 240 kilometers. A $6 million hydroelectric powerplant was planned to be built at the mouth of the river near Koter and was expected to be operational by 1981. The African Development Bank granted a loan for the project. The Berreto Dam, which was begun in 1977, was expected to be completed by June 1980.

During 1978-79, Chevron Overseas Petroleum Co. (United States) and the French company, Compagnie Francaise des Petroles (CFP), obtained a 2,500-square-kilometer offshore area that included all of the Gambia's offshore waters up to a distance of 48 kilometers from the coast. Chevron's share in this holding was 75%, and CFP's share was 25%. Chevron-CFP completed seismic studies, and a well drilled by the Norwegian ship Pelcrin to 3,000 meters in water 700 meters deep was dry. The overall investment at yearend 1979 was reported to be $8 million.

GUINEA

During 1978 and 1979, Guinea, a crescent-shaped country in the west African "bulge," was on its way to becoming a major economic force in Africa. Bauxite and alumina accounted for about 23% of the country's 1978 gross domestic product of $1,209 million[5] and 95% of the total 1978 export revenue. A policy change had been initiated to encourage investment by foreign firms; the aim of this change was to secure foreign markets, capital, and technology. Foreign investment was a primary factor in the expansion of the mineral sector. Guinea owned all the mining facilities for which it contracted loans, and repayment of the loans was from mine production. All mining projects included the training of Guinea technicians.

Revenue from bauxite continued to increase, and a mineral export tax that was first levied in 1974, based on the price of aluminum ingots and the alumina content of exported bauxite, continued to be collected. Export revenues came from the major bauxite deposits of Boke-Sangaredi, Kindia, and Fria. Guinea maintained its position as the third largest producer of bauxite in the world during 1978 and 1979. Guinea's mining industry was founded on bauxite, but additional resources of iron ore, diamonds, and uranium were expected to continue to provide increased national income in the future.

Plans for expansion of the mineral industry continued during 1978, and by yearend 1979, the Government had announced that the Ayekoye alumina project had been given priority over all other mining projects. The Konkoure Dam and a proposed aluminum smelter at Fria were planned to become integrated projects. The Government asked all companies interested in the bauxite or alumina industries in Guinea to buy a portion of the 1-million-ton-per-year output of Ayekoye. The success of the bauxite industry resulted in plans for two additional bauxite projects at Dabola and Tougue. Planned and present production for various bauxite corporations in Guinea are given below:

Company	Production (million metric tons per year)		Date	Deposit	Reserves (million metric tons)	Content	
	Present	Planned				Al_2O_3	SiO_2
Societe d'Enonomic Mixte Friguia (Friguia)	2.2	4.4	1983	Frai-Kimbo	[1]650	45-48	2-3

A cooperative agreement was signed between the United States and Guinea during 1978; the two countries agreed to cooperatively prospect for bauxite and study the technical and economic data relative to bauxite extraction.

Expansion plans continued in the mineral industry. Depspite the recessed iron ore market, plans continued for a large iron ore mine along the Liberian border near Mount Nimba. Diamond concessions were awarded to a European company and a U.S. company for the mining and processing of diamonds. The signing of joint venture agreements by the two companies indicated that diamond mining, which stopped in 1975, would resume in the near future. Exploration continued for uranium and offshore oil, under contracts signed in 1977.

Other infrastructure developments related to the mineral industry included the building of a hydroelectric dam on the Kankoure River to furnish electricity for the exploitation of the Ayekoye bauxite deposit. The mine, factory, and hydroelectric dams were expected to cost over $1 billion. A planned trans-Guinean railway project, which would require 1,148 kilometers of track, would allow the exploitation of iron ore in the Simadou range and bauxite at Tongue and Dabola. A feasibility study on the railroad was conducted by the Japanese firm of Nippon Koei Co. Ltd.

The most important mining project in Guinea during 1978 was the Mount Nimba iron ore project. The orebody consisted of two high-grade deposits, the Pierre-Richard and the Sempete. Due to a negligible stripping ratio (less than 0.5 overburden to ore), exploration by the Mifergui-Nimbu Co. (MIFERGUI) was concentrated in the southwest section of the Pierre-Richard deposit. This deposit contained estimated reserves of 600 million tons of 65% iron ore.[6] Exploitation was expected to be concentrated at the most homogeneous southeastern section for the first 10 years of production. The primary crusher was planned to be located between the two deposits, and treatment was expected to be confined to crushing, milling to 6 millimeters, classification, and desliming, to produce a 0.15-millimeter sinter feed. Screening was planned to be by the wet process. The Guinea Government had a 50% interest in the project. The balance was shared among the governments of Liberia, Nigeria, Libya, and Algeria, together with the following foreign firms: Nichimen Co. Ltd. (Japan); Usinor Exploration S.A. and Somer (France); National Institute of Industry, Sierra Nemare, and Cofei, (Spain); Mineralimpex (Romania); and Energoprojekt (Yugoslavia). Kaiser Aluminum and Chemical Corp. (United States), which carried out the feasibility study in 1978, withdrew from the project. The Nimba project will be served by the existing Liberian American-Swedish Minerals Co. (LAMCO) railway for 10 years with the addition of a 17-kilometer spur under an agreement signed with the Liberian Government.

Except for the Nimba project, all other iron and bauxite projects depend on the building of a trans-Guinea railway. The annual capacity of the Mount Nimba mine was expected to increase from 15 million tons per year to some 25 million tons per year upon completion of this railway. The Mount Nimba project was expected to cost $800 million, with production estimated at about 15 million tons per year by the end of 1980 on a "take-or-pay" system. There were still unresolved problems with financing from the International Bank for Reconstruction and Development (IBRD), which distinguishes between plant and infrastructure loan rates.

Compagnie Generale des Matieres Nucleaires (COGEMA), a French Government nuclear energy company, began exploration in 1977 for uranium in Guinea. COGEMA signed a joint venture agreement in March 1978 with Power Reactor and Nuclear Fuel Development Corp. (PRNC), a Japanese Government-owned company, and the Guinea Government. In December 1978, an agreement was signed with GOGEMA, PRNC, Azienda Generale Italiani Petroli Nuclear (Italy), and the Government. Plans were to use aerial photogrammetry and ground-level techniques in the area north of latitude 11 degrees, 50 minutes, including northern Fouta Djallon in central Guinea. Initial exploration field work was being carried out from helicopters, almost entirely during the dry season (December to May). The project's cost for exploration was put at $5 million.

Bauxite in Guinea occurs in lateritic-type deposits. The total reserves were estimated at about 8,200 million tons, of which about half were proven.

The Compagnie des Bauxites de Guinee (CBG) was the largest bauxite producer in Guinea. The Boke deposit ore body consisted of 60% to 61% Al_2O_3 over a 2-square-kilometer area. About 8 million tons, or 67% of Guinea's bauxite production during 1978, came from this mine. Plans were formulated to improve the shipping port at Kansar and the infrastructure and housing facilities at the mine at Sangaredi. Plans were to finance these improvements through an international loan of $15 million that was obtained during 1978 and guaranteed by the Guinea Government. Kamsar was the world's largest bauxite shipping port.

The second largest mine in Guinea was the Friguia bauxite mine and alumina plant located at Fria near the junction of the Badi and Konkoure Rivers. Mining operations at Fria required the removal of overburden 2 years before mining was begun to allow the silica to leach. The ore, which consisted of 48% Al_2O_3, was converted to alumina onsite and shipped to smelters in Africa and Western Europe. Production during 1978 was around 600,000 tons of alumina, which was 85% of the mine's operating capacity.

Swiss Aluminium Ltd. (Alusuisse) studied the possibility of building an integrated aluminum complex at Ayekoye in the Boke-Gaoual region of northwestern Guinea. The Ayekoye bauxite deposit was estimated to contain 195 million tons of ore with an average content of 47% alumina and possible resources of 500 million tons of ore.[7] The initial producton capacity at Ayekoye was estimated at 1 million tons per year by a company named Societe Guinea-Arabe d'Alumine et d'Aluminium (ALUGUI). Partners providing capital for the Ayekoye project included Guinea, Egypt, Iraq, Kuwait, Saudi Arabia, and Libya. One-half of the $2.4 billion in capital was attributed to the Guinea Government in return for the land and mining rights. The area of consideration was in the northwest corner of Guinea, near the Boke deposit of CBG. The project was planned to involve a first phase, a 1.2-million-ton-per-year alumina-bauxite export operation at the port of Kamsar, followed by a second phase, a 150,000-ton-per-year aluminum smelter powered by the proposed Konkoure hydroelectric dam. The total cost of the infrastructure was expected to be $1.3 billion.

Guinea and Alusuisse formed the Societe Miniere de Participation Guinea-Alusuisse (SOMIGA), which was developing the Tougue bauxite deposits. The initial capacity of the mine planned at Tougue was estimated at 8 million tons per year,[8] and this output was expected to be exported.

The Guinea Government and Energoprojekt joined with Algeria and Nigeria to form the Societes des Bauxites de Dabola (SBD) in 1973. SBD reported reserves of 1 billion tons of bauxite in the Foute Djallon region.[9] The initial capacity of a planned mining project there was set at 5 million tons per year, which was designated for export. In 1978, Reynolds Metal Co. became a partner to manage mine operations and was prepared to take 200,000 tons of alumina and 1 million tons of bauxite per year from this project. SOMIGA and SBD were merged by the Guinea Government because of their similarity of their projects to form a joint Alusuisse-Energoprojekt committee to study the feasibility of an aluminum refinery.

A planned $12 million cement factory designed to produce 200,000 tons of bagged cement per year from imported clinker received aid from (BADEA). The plant was expected to begin operating in 1980, and all of its anticipated output was designated for domestic consumption.

No diamond production was reported during 1978 and 1979. A new company, Association pour la Recherche et l'Exploration de Dimants et D'Or (AREDOR), was founded by the Guinea Government with the help of British and Swiss investors. AREDOR was prospecting a 30,000-square-kilometer concession in the extreme southwestern part of the country. The operating firm was the International Diamond Corp. (IDC) of the United Kingdom. Two other groups were reported to be prospecting for diamonds, in an area in upper Guinea that covers almost one-third of the country. Reserves in this area were estimated at 300 million carats, two-thirds of which could possibly be industrial-grade diamonds. Reserves were centered within a triangle between Kissidougou, Keraouane, and Beyla.[10]

Petroleum exploration continued during 1978 in the 44,000-square-kilometer offshore concession areas. Societe des Guinee des Petroles (SOGUIP) contracted with a consortium of foreign firms specializing in offshore drilling. These firms included Buttes International (United States), Naftagas Kombinat Naftne Industrije (Yugoslavia), and Total S.A. (France). CFP dropped out of the project in 1977. One dry hole was drilled during 1977, and a second well was scheduled to be drilled during 1979, but no results of the second drilling were known by yearend 1979. A second petroleum prospecting agreement was signed during 1979 between Union Texas Petroleum (United States) and the Government which established Societe Guineene des Hydrocarbons. Conakry was seeking partners for onshore exploration during 1979.

GUINEA-BISSAU

Guinea-Bissau had no important mineral production during 1978 and 1979. The only mineral industry in operation was a brick and tile plant that produced 50 tons per day for domestic use. The country's import value for 1978 exceeded its export value by 78%, leaving a trade deficit of $908,000.[11] During 1979, it was estimated that export receipts covered no more than 8% of the cost of imports. During fiscal year 1979 (January to December), the Government budget totaled $43.36 million, with a deficit of $17.17 million. Guinea-Bissau's deficit has usually been offset by grants and loans from donor countries.

Bauxite found in the Boe region near Lugajol in the 1950's was investigated by the U.S.S.R. between 1975 and 1978. Reserves were estimated at 500 million tons of low-grade (47% Al_2O_3) ore.[12]

During 1978, the National Company for Oil and Mining Research and Exploration (PETROMINAS), a State-owned company, was in charge of a study of the integrated economic development of the southern part of the country as well as feasibility studies regarding the processing of petroleum. Italian Petroleum Enterprise-National Hydrocarbon Agency (AGIP-ENI) was exploring for oil during 1978.

IVORY COAST

No mineral production was reported in the Ivory Coast during 1978 and 1979. Mining industry activity during the period was characterized by exploration programs carried out principally by Societe pour le Developpement Miniere de la Cote d'Ivoire (SODEMI) and by Societe Nationale d' Operations Petrolieres (Petroci). SODEMI continued electromagnetic airborne prospecting for uranium and sulfur deposits. The regions where the most intensive studies were carried out for uranium were Odieune, Boundiali, Touba, Daloa, M'Bahiakro, and Kong. SODEMI's exploration of sulfur deposits by geochemical methods was actively pursued south of Touba. Also, SODEMI was considering a drilling program for uranium on the basis of geochemical prospecting at Kugbelo, Ira, Gouoplen, Godoufouma, and Silakoro. Other activities of SODEMI included projects in association or under agreement with private mining companies. These activites included a geophysical survey in the northern part of the Ivory Coast which was scheduled to be concluded at the end of 1979 and a similar survey in the southern part of the country which was planned to take place in 1980.

Petroci became interested during 1979 in the search for radioactive minerals. Its program consisted of spectrometric exploration at ground level, both in four-wheel-drive vehicles and on foot. By the end of 1979, no details of Petroci's findings were available.

With gold prices at an all time high, the gold deposits at Ity, 60 kilometers west of Main, became more economically viable. A consortium established to exploit this deposit continued its exploratory activity during 1979, and there was a strong possibility that the deposit would be mined in the 1980's.

Diamond mining was resumed in March 1979 by the Societe Franco-Ivoirienne Tortiya at the old workings of the Tortiya deposits and produced 48,000 carats by the end of 1979. Operations at the Tortiya deposits had ceased in 1975, after the successful operation of the Societe Anonyme de Recherches et d'Exploitations Minieres en Cote de Ivorie (SAREMECI) for almost 27 years. SAREMECI was forced to close between 1975 and 1979 because of the high cost of operation, whereas in 1979, the new company seemed to be more successful because of high diamond prices.

Petroleum production that was scheduled to begin during the summer of 1980 became a reality in the latter part of 1979 when the Esso-Shell-Petroci's offshore Belier oilfield tested flows ranging from 2,900 to 4,900 barrels per day. The oilfield was located 35 miles southwest of Abidjan, in water ranging from 300 to 2,400 feet deep. Also in this field, natural gas was tested at rates of from 1.25 to 2.1 million cubic feet per day. Previous discoveries made over the past 5 years, which were originally not considered to be commercially viable, seemed more economical in 1978-79. During 1979, the Ivory Coast imported 1.9 million metric tons of petroleum, mostly from Venezuela, Iraq, and Nigeria.

MALI

During 1978, the gross national product of Mali, at then-current prices, was estimated at $970 million.[13] Exports were valued at $96.6 million, compared with imports of $211.4 million. Twenty-five percent of Mali's foreign transactions were with other countries on the African continent. Transactions were limited by Mali's landlocked position in West Africa and the lack of infrastructure to the coast.

The investment climate for business remained favorable in Mali. Ordinance 26 of May 23, 1969, the Basic Code of Investments, was still in effect and offered certain incentives, mostly in the form of tax-free privileges for 5 to 10 years, to companies prepared to invest in areas of interest to the Government. Industries of interest included metallurgical industries and those involved in energy production. The Government required a 10% to 15% ownership interest for itself, and dealings were exclusively in the French language. Mali maintained a liberal system of payments and transfers in international transactions.

Construction continued on the Selinque Dam on the Sankarani River, a tributary of the Niger. The anticipated completion date of the project was August 1980, and its total cost was estimated at $142 million. The dam was designed to produce 66 million kilowatt hours of electricity for service to the area around Bamako.

The Senegal River Development Organization (OMVS), which included Mali, Mauritania, and Senegal, planned to build two dams to make the Senegal river navigable for over 930 kilometers. The cornerstone of the Diama Dam was laid in 1979, marking the completion of a project estimated to have cost $173 million. Construction of the Manantali Dam was planned to begin in 1980, and the total cost was estimated at $490 million. Abu Dhabi, Saudi Arabia, and Kuwait had pledged a total of $218 million to co-finance construction of the Mancintali Dam. Various other international agencies, including the European Development Fund and the African Development Bank, together with the Federal Republic of Germany, France, and Canada, have committed $225 million.

Other foreign investments and loans included a $6 million loan to Mali from the Central Treasury for Economic Cooperation (CTEC) to cover the Energy of Mali investment program and a $1.79 million CTEC loan to be used for the modernization of railroads and equipment. The project included the renewal of track and the rehabilitation of bridges to create an integrated line between Bamako in Mali and Dakar in Senegal.

The Federal Republic of Germany pledged $45.5 million to Mali for the period from 1979 to 1980. Projects planned to be included under this funding were development of the Sevare-Gao highway, exploitation of phosphate at Bourem, and studies of various mining and industrial projects.

The value of reported mineral production for 1978 and 1979, listed here respectively for each of the 2 years, included (cement, $5,000,000 and $2,500,000; gold, $169,000 and $272,700; salt, $135,000 and $135,000; limestone, $218,000 and $138,000; marble, $25,000 and $31,000; and granite, $135,000 and $33,000). Bauxite, diamond, iron, copper, nickel, manganese, thorium, platinum, petroleum, sulfur, bituminous coal, and uranium deposits of varying quality have been located, but the exploitation of these deposits was limited because of the lack of infrastructure, including power and transportation.[14] Investment in the minerals sector included financing by the Canadian Government for an airborne geophysical survey of the Liptako-Gourma area of Mali and Upper Volta under the Liptko-Gourma Authority which was supported by Mali, Upper Volta, Niger, and Togo.

A French-Malian agreement establishing a mining research syndicate was signed in December. Under the agreement, the Bureau de Recherches Geologiques et Minieres (BRGM) was to promote research and the exploitation of gold, copper, tin, diamonds, and other substances in Kenieba in southwestern Mali. BRGM also agreed to prospect for gold in the Kangaba and Bagoe regions (Bougouni-Sikasso). The first stage of the agreement left 70% of the funding to BRGM and 30% to the Malian Government. The cost of implementing this first stage was estimated at $718,000.

The U.S.S.R. was very active in mineral exploration and exploitation in Mali during 1978. In March, the U.S.S.R. and Mali signed a new trade agreement to replace a previous 17-year-old agreement. Three essentials of the agreement were as follows: Payments in convertible currency, freedom of merchandise exchange, and private sector participation in bilateral trade.

During 1978-79, traditional mining of gold continued on a small scale, but most of Mali's gold was mined by native women. Gold occurred in alluvial deposits in the Bale River and its tributaries at Ouassoulou, Faboulako, and Kalan (probable reserves of 4 tons).[15] Vein deposits, which required underground mining, occurred at the following locations: Kalana in southern Mali near the Guinean border (proven reserves of 30 tons);[16] Kodieran, which is 6 kilometers from Kalana (probable reserves of 7 tons);[17] and, in the Seventh Region, north of Kidal near the Algerian border. An alluvial deposit and a vein deposit were present near Kenieba in the First Region, on the border with Senegal.

The U.S.S.R. was assisting in starting gold mining operations in Kalana, near Sikasso, which were expected to produce about 400 kilograms in 1980. The ore averaged 35 grams of gold per ton, and proven reserves were estimated at 55 tons of contained gold metal.[18] In July 1979, the first stage of the Kalana I mine, which was owned by the Government and managed by the U.S.S.R., was almost complete. The total exploitation costs for the mine, up to year-end 1979, were $299 million. Its production capacity was estimated at 1,790 kilograms of gold and 49 kilograms of silver per year for 15 years.

Societe Nationale de Recherches et d'Exploitalion Minieres (SONAREM) and Soviet geologists had estimated proven reserves of 146 million tons of hematite ore containing 40% to 65% iron in the Bafing-Makana area, near the bank of the Faleme River opposite the Senegalese iron ore deposit.

Pechiney (France), Alusuisse (Switzerland), and mainland China were interested in bauxite deposits located in the southern and southwestern Mali (Balea and Sitaouma) near Keyes. The French National Service of Geology and Mining Prospecting (SGPM) and the private French company Societe Africaine de Recherches et d'Etudes Pour l'Aluminium, a branch of Pechiney-Ugine, carried out prospecting operations in the bauxite deposits. Probable reserves of 1,100 million tons of bauxite assayed at 45% Al_2O_3 with 3.4% silica were found.

The Federal Republic of Germany furnished Mali with a contribution of $165 million to finance a second cement plant in Kayes. Located 400 kilometers west of Bamako, the new dry-process cement plant was expected to be rated at 250,000 tons per year. The plant was scheduled to start operations by 1983.

A phosphate deposit 150 kilometers north of Gao, containing 25 million tons of 27% P_2O_5, was being mined by SONAREM during 1979. Production was estimated at 2,000 tons per year.

The Government had granted uranium concessions to three companies, two from France and one from Japan. Power Reactor and Nuclear Fuel Development Co. (PRNC), a Japanese firm, had expanded its original 1974 concession in the vicinity of Tessalit. The concession was in the region that borders Algeria and Niger. Also, sedimentary deposits north of Gao at Adrar Ti-N-Barakoye contained 0.48% U_3O_8.

The French company, Compagnie General des Matieres Nucleaires (COGEMA) had an initial concession near Mopti. COGEMA had discovered uranium deposits near Taoudeni in the Sixteenth Region and Kenieba (Kayes Region) near the Guinea border. COGEMA also had permits in Kenieba and Hombori-Douentza. BRGM had two uranium concessions; one was located along the Senegalese border and the other was along the Upper Volta and Niger front.

The largest U.S. directed investments in Mali were in the mineral fuel sector. Texaco Inc. had invested a total of $239 million in the Mauritania regions since 1970 and $1.1 million during 1978. Globe Oil Co.'s investments since 1973 totaled $269 million in the Menaka region. Mobil Oil Corp. invested $1.0 million in exploration during 1978.

A French company invested $52 million for a 5-year license in the Gao fault area. Elf-Aquitaine SA Societe Nouvelle (SNEA) became an operating partner with Murphy Oil Corp. in its Gao permit. This 50-50 partnership was expected to allow SNEA to expand its activites both in the Macina area and to the south. SNEA received exploration rights to 37,056 square miles in an Araouane permit and 33,899 square miles in a Macina permit. Investments of approximately $1 million were required. The Government's share was not known, although traditionally, the Malian Government has always sought to acquire large shares in prospecting oil companies.

NIGER

Uranium continued to be Niger's chief export, and Niger continued to be the world's fifth largest producer of uranium during 1978-79. The gross domestic product, at 1978 prices, was estimated at $681.3 million during 1978.[19] Uranium exports, in tons of metal equivalent, were valued at approximately 50% of the value of all exports. Anticipated growth was expected to increase the processed uranium at Niger's disposal and spur greater Niger participation in the world's uranium markets.

The economy of Niger continued to be handicapped because of the high cost of transporting goods which stemmed from Niger's landlocked position, poor roads, and absence of railroads. Construction, transportation, and related services accounted for over 30% of the 1978 gross national product. Niger's only mineral industries were a metal working firm, a chemical plant, a cement company, and two active uranium mines.

Societe des Mines de l'Air (SOMAIR) continued to mine uranium ore at its mine at Arlit. Reserves were estimated at 20,000 tons of uranium.[20] Increased production was attributed to the expansion of SOMAIR's capacity through the introduction of heap leaching and the doubling of design capacity throughout the solvent extraction section of the treatment plant.

During 1978, France bought 54% of Niger's exports, including 75% of its uranium output. Trade clients included the European Economic Community (EEC), Nigeria, the Arab countries, Pakistan, and countries of the West African Monetary Union. Foreign aid to Niger exceeded $173 million in 1978, and the bulk of it was given on a grant basis. Major aid donors were France, the United States, the Federal Republic of Germany, Canada and Saudi Arabia.

The Goverment's 3-year development plan was drawn to a close in December 1978. The first phase of the Kandadji Dam was completed, and six cities were electrified. Objectives were to develop known mining resources, continue research, and update mining and oil regulations. The Akouta mine began operation in 1978.

All uranium companies in Niger were asked to help finance the Tahoua-Arlit "Uranium Road." The Central Study Office for Overseas Equipment (BCEOM) was the supervisory construction contractor for this project. The Government viewed financial support of the road or similar development projects as a prerequisite for participation in uranium mining. The road was planned to connect Tahoua with Arlit through Agadez, and would be 656 kilometers long. Several hundred spanning construction projects were necessary because of poor drainage networks. Total costs were estimated at $200 million.

Production of a 70% concentrate of sodium uranate continued to be Niger's most important mineral commodity. Niger supplied 25% of COGEMA's production during 1978. Production from Niger in 1979 was expected to make up 30% of France's supply. Total known uranium reserves were estimated at 200,000 tons, and uranium production could reach 8,000 tons annually by the mid-1980's. The 60% increase in uranium prices between 1973 and 1977 provided a boost to Niger's economy.

Fluor Corp. and Drebs and Cie. had been contracted to undertake engineering-financial studies of the uranium reserves at the Imouraren deposit 100 kilometers south of Arlit. These reserves were estimated to contain 79,000 tons of uranium,[21] and this estimate ranked the Imouraren as the fifth largest deposit of uranium among those found in the market economy countries of the world. Partners in developing this deposit included ONAREM and Continental Oil Corp. (CONOCO) of the United States; ONAREM held a 30% share, and CONOCO'S share was 35%. COGEMA and CONOCO were both interested in acting as operators. Production was scheduled to begin in 1982, and the maximum production capacity was expected to be 3,000 tons of yellowcake per year.

A second mine, at Akouta, with a capacity of 2,000 tons per year, was located 10 kilometers south of Arlit. Production from 250 meters underground began in August 1978. The Japanese company, Overseas Uranium Resources Development (OURD), owned 25% of the mine, and the operator was Compagnie Mineire de l'Akouta (COMINAK). The other partners were ONAREM (31%), COGEMA (34%), and Spanish Nacional del Uranio (EUNSA) (10%). Reserves were estimated at 44,000 tons of uranium. The mine's production capacity was 1,500 tons of a 70% concentrate, with a maximum capacity of 2,000 tons anticipated in 1979. Jordisite, a molybdenum sulfide, was being processed from the Akouta mine's ore.

Societe Miniere de Tass planned to develop the Arni deposit within the COGEMA concession at Arlit. COGEMA and ONAREM were equal partners in this development. Reserves were estimated at 20,000 tons of uranium[23]. The processing capacity was planned at 2,000 tons of yellowcake per year.

Other uranium deposits planned for exploration included the Afasto-West deposit in the southwestern border of the Arlit concessions. This project was planned as an underground mine that would operate at 150 to 270 meters beneath the surface. Reserves were estimated at 30,000 tons of uranium.[24] Ownership was divided into thirds among ONAREM, COGEMA, and OURD. The Afasto-East (Techili) deposit northeast of Arlit was viewed as a possible replacement for the depleting SOMAIR mine. Reserves were estimated at 6,500 tons of uranium. Ownership included ONAREM (30%), COGEMA (30%), the Central Electric Generating Board (CEGB) (12%) of the United Kingdom, and Saarberg-Interplan Ges Fuer Rohstoff Energieing Techn MBH (12%) Federal Republic of Germany. Teguidda I-N Tessoum was a joint venture between International Resources S.A. (Japan) and ONAREM that aimed to develop reserves estimated at 15,000 tons of uranium[25]. Davey McKee Corp. (United

States) planned to construct the facilities. The Djado project included ONAREM (25%), COGEMA (25%), Urangesellschaft (25%) (Federal Republic of Germany), and Power Reactor and Nuclear Fuel Development Co. (PRNC) (25%) (Japan).

Cassiterite, an ore of tin, continued to be mined in the Air Mountains at small placer works. Societe Miniere de Niger was the operating company, and mines were located at Taroudji and Timia. Cassiterite reserves were estimated to be 250,000 tons.[26]

The National Cement Plant (SNC) continued to be plagued by management and financial problems, and the domestic product cost 40% more than imported cement. The Government expected to continue to be the only buyer of domestically produced cement until plant capacity could be doubled with the financial and technical assistance of mainland China.

Extensive phosphate reserves in the Parc "W" Game Reserve were being evaluated by ONAREM with international assistance. Some blocks were reported to exceed 100 million metric tons of phosphate. Exploration 150 kilometers southeast of Niamey indicated 500,000 tons of phosphate rock that could be readily concentrated to 34% P_2O_5. Phosphate rock deposits were also present in the Tahoua Region, but no reserve figures were available.

During 1978, Esso Exploration Inc. (United States) resumed active exploration of its Niger permits. Indications of gas and oil occurred in the second well drilled, which was located at Ti-n-Toumma in the Niger basin of Lake Chad. Esso planned a third well 50 kilometers to the northwest of Yogou and a fourth well near the Termet Massif in eastern Niger.

Other activity in petroleum concessions included the cancellation of the exploration permit of Bishop Oil and Refining Co., Inc., (United States) by the Supreme Military Council. The French company, Elf-Aquitaine SA Societe Nouvelle (SNEA), was awarded three exploration licenses covering 345,528 square kilometers.

The first stage of a combination coal mine and electricity generating plant being built by Société Nigerien du Charbon (SONICHAR) was nearing completion at yearend 1979. Plans were for the electricity to be used in nearby uranium mines and Niger's northern city of Agadez. The cost was expected to exceed $125 million.

SENEGAL

The gross domestic product (GDP) of Senegal was estimated at $1,949 million in 1978[27] and $2,357 million in 1979. The industry and mining sector accounted for approximately 20% of Senegal's GDP. The country's deficit in trade was reported to be $254 million for 1978 and $238 million for 1979. At yearend 1979, the debt service stood at 15% of the value of exports and at 19% of the value of tax receipts. The rate of real growth of the economy averaged 2.7% during 1973-79.

Phosphate, attapulgite, and refined petroleum were the main minerals produced in Senegal for export. During 1978, there was a decline in phosphate rock prices on the world market. During 1979, the production and prices of phosphate rock mined in Senegal remained steady. The value of exported aluminum and calcium phosphate rock during 1979 was $65 million. Refined petroleum products accounted for 40% of Senegal's export earnings during 1978-79. New mineral projects included the building of a cement plant, a petrochemical fertilizer plant, a phosphate tailings plant, and an oil refinery; studies of iron ore deposits; production of natural gas for electricity generation; and increased exploration for petroleum.

The Faleme iron ore deposit, in eastern of Senegal, was the main mining project being considered by the Government. Reserves included 290 million tons of magnetic ores suitable for production of pellets and 120 million tons of rich ore (60% to 65% Fe) suitable for the production of lumpy ores and sinter feed. Total Faleme reserves were 410 million tons of magnetic ore averaging 40% to 50% iron.[28]

Bureau de Recherches Geologiques et Minieres (BRGM) (France) studied the possibility of modernizing and reopening the marble works in the Kedougou Region after a major deposit of high-grade marble was found. The deposit contained proven reserves of 350,000 tons and was estimated to contain as much as an additional 1 million tons.[29] The company formed to exploit the deposit consisted of the Government, Senegalese private interests, and BRGM. The International Development Association (IDA) provided financing.

Compagnie Senegalaise des Phosphates

de Taiba (CSPT), the country's leading producer of calcium phosphate, continued to operate the N'Doumour Diop open pit mine in the Tivaouane Region. Proven reserves were estimated at 20 million tons, and probable reserves were estimated at 50 million tons.[30] BRGM provided technical assistance through ownership in the Phosvalor Co. The planned development of a major phosphate mine at Tobene was postponed in favor of plans for the gradual expansion of the Taiba Mine.

CSPT and Societe Industrialle d'Engrais au Senegal each had a 10% share in a new fertilizer company named Industries Chimiques du Senegal (ICS). ICS planned to process 400,000 tons of phosphate per year.

Societe Senegalaise des Phosphates de Thies (SSPT), operator of the Pallo Mine, is the only world producer of aluminum phosphate used for conversion to clinker and sold as a slow-release fertilizer. During 1978, the company was operating below its capacity of 650,000 tons due to adverse market conditions. France, which imported 116,000 tons per year, was the principal importer; domestic purchases were approximately 34,000 tons. The remainder was calcined to clinker at Thies and exported. Studies were being conducted to investigate ways to upgrade the ore and transform it into phosphoric acid.

The government planned to develop a 50-million-cubic-meter deposit of gas that was discovered in 1959-60 at Diam Niadeo near Rufisque. Plans were for the gas to be transported via pipeline to the Cap des Biches powerplant to produce electricity. Societe Sengalaise de Distribution D'Energie Electric was in charge of building and operating the infrastructure.

Coastal States Gas Corp. (United States) had initiated talks with the Senegalese Government regarding construction of an oil refinery with a projected capacity of 5 million tons per year, at a cost of $400 million. Senegal's domestic oil needs of 1 million tons per year were met by the Societe Africaine de Raffinage refinery (SAR) in M'Bao, near Dakar.

TOGO

The 1978 gross domestic product of Togo, in 1978 prices, was $765.5 million.[31] Phosphate exports accounted for 38% of the country's export receipts during 1978. Between 1972 and 1978, Togo's economy showed real growth estimated at 5% per year, and the consumer price index rose 1.4%. A 33% increase in production that was planned for 1980 was expected to expand Togo's export earnings significantly.

Togo maintained an open-door and nondiscriminatory trade and foreign investment policy that allowed 100% foreign ownership. The investment code provided for tax holidays, customs exonerations, and profit repatriations. Togo was a member of the Lome Convention and received preferential treatment on exports to the European Economic Commission (EEC). Togo and the United States signed a guarantee of private investment agreement in 1952 and a treaty of amity and economic relations in 1966. Togo was also a beneficiary of the U.S. Generalized System of Preference (GSP) for imports, and one-third or more of Togo's exports qualified for duty-free entry into the United States under the GSP.

Commerce and services continued to expand at a brisk pace in 1978 with the expansion of the port at Lome, the near completion of the north-south international road network, construction of a glass factory, and the opening of a petroleum refinery. Because of its developed road network, efficient port, airfield, communication facilities, fully convertible currency, and virtual lack of import or foreign exchange controls, Togo was an opportune place for mineral investment.

Most of Togo's commercial energy was supplied by the Akossombo Dam in Ghana. The completion of a thermal powerplant in 1979, built in conjunction with a new steel rolling mill, fulfilled some domestic energy requirements. Other infrastructure developments included a United Nations Development Program and World Bank feasibility study of the hydroelectric potential of the Mono River near the Benin border.

The Office Togolaise des Phosphate (OTP) continued to sell Togo's high-quality phosphate rock at top world prices. Yugoslavia became the largest consumer of Togolese phosphate rock in 1978, taking over 450,000 tons. Other deliveries, made to Malaysia, Japan, Lebanon, and Nigeria, totaled 82,000 tons. The largest regional market was Western Europe where exports totaled 1.82 million tons in 1978. Belgium-Luxembourg, France, and the Netherlands were the three largest consumers in the Western European market.

In January 1979, National Steel Co. (NSC) opened a 100% Government-owned steel rolling mill in the industrial zone surrounding Lome. The mill's producton capacity was 20,000 tons per year of steel rod for use in reinforced concrete. Construction of the $37 million mill began in 1977. In 1979, the mill operated on domestic scrap, but, beginning in 1980, the mill planned to operate on imported scrap.

Societe des Cement de l'Afrique de l'Ouest (CIMAO), the cement clinker plant located 80 kilometers northeast of Lome and jointly owned by Togo, Ghana, and the Ivory Coast, was scheduled for completion in January 1980. The plant was expected to have a capacity of 1.2 million tons per year. Plant costs were projected at $221 million, with associated infrastructure costs of $71 million. Part of the infrastructure included an 80-kilometer railroad link from the deposit at Tabligbo to the port at Lome. The complex was expected to utilize large quantities of locally produced power and fuel. Financing was provided through the World Bank, French Caisse Centrale, the European Investment Bank, the Arab Bank for Economic Development in Africa (BADEA), and the Canadian International Development Association (CIDA), among others.

In 1978, Compagnie Togalaise des Mines du Benin (CTMB), a 100% Government-owned company, operated the phosphate mine and beneficiation plant at Kpeme. High-grade concentrate that averaged 36% P_2O_5 was sold to the Government marketing agency. Stocks at yearend 1978 were down to 113,000 tons. Togo planned to add a fifth 750,000-ton-per-year beneficiaton stream to the Kpeme plant by 1980, which would raise the total capacity to 3.75 million tons per year. A sixth line was planned for a later stage. A European-Tunesian banking consortium lent approximately $21 million to the Government for the expansion, which was estimated to total $40 million.

The Societe Togalaise des Hydrocarbures (STH) managed Togo's Government-owned 1-million-ton-capacity oil refinery. The refinery opened in January 1978 and operated until August. In April 1979, the refinery reopened, and by yearend, a total of 340,000 tons of refined oil was imported from Nigeria and processed into 320,000 tons of refined products. During 1978-79, there was interest in both onshore and offshore oil exploration in Togo. Ocean Resources (United States) was reportedly drilling offshore at yearend 1979.

UPPER VOLTA

Upper Volta remained a stable and democratic country in the interior of West Africa with no mineral production but vast reserves of manganese. During 1978-79, the country had the lowest per capita income in West Africa. Upper Volta's gross domestic product (GDP) grew at an average yearly rate of 5.8% during the post-drought period of 1975-78. The GDP, at then-current prices, was $826.7 milion[32] in 1978 and was estimated at $969.8 million in 1979. Large-scale foreign aid was necessary for virtually all development.

The lack of an effective transportation system hampered the development of Upper Volta's economy. International aid was received for both road and rail projects, but it was likely to be some time before mineral extraction would become possible. The Niamey (Niger) to Dori (Upper Volta) road was financed by the African Development Bank (AFDB). AFDB also financed $6.7 million for the construction of a road from Dori to Djibo at yearend 1979. Construction had begun on the Mango-Upper Volta and the N'Gourma-Niamey truck roads were completed.

Other infrastructure development plans included a dam at Pama that was expected to include a 71-megawatt turbine for electricity generation. Surveyor Leniger Cheverete of Canada was in charge of the feasibility study. The project cost was estimated at $497 million, and construction was expected to begin in 1980.

The Bureau Voltaigue de la Geologie et des Mines (BUCOGMI) was instrumental in setting up the Societe Voltaique d'Intervention Miniere a Petite echell (SOVINPEC). SOVINPEC provided marketing services for small mine workings where normal operations would be uneconomical. Mining possibilites existed in nickel, manganese, diamonds, copper, bauxite, lead-zinc, phosphate, marble, limestone, and stibnite.

Upper Volta attempted to open the Poura gold mine 180 kilometers southwest of Ouagadougou. If opened, the mine would be operated by Societe de Recherche Miniere (SOREMI), which was owned by the Government (51%), Coframin (15%), and other shareholders. Feasibility studies indicated that the mine could have probable reserves of 2.15 million tons of gold ore containing 27.7 tons of gold. SOREMI indicated proven reserves of 15,000 kilograms of gold in Situ, plus 400 kilograms in the tailings from the original operation. It was estimated that 4 years of site preparation would be necessary before mining recommences.

Manganese deposits located in the northeast corner of the country contained 13.32 million tons of high-grade (51% Mn) manganese ore.[33] Exploitation of the deposit required the construction of a 360-kilometer rail spur from Ouagadougou, at a cost of $130 million. In addition to the spur, a satisfactory freight tariff for transporting the ore 1,150 kilometers to the new port at Abidjan, Ivory Coast, and infrastructure services would be required to mine the ore. In 1978, the international climate changed, and foreign investors were no longer interested in the Tamboa project because of high infrastructure expenses. A French subsidiary of Klockner-Ina of the Federal Republic of Germany was appointed to take over negotiations with foreign consortium members and financial backers. During 1979, Union Carbide (United States), which withdrew from participating in the project during 1977, showed renewed interest.

Other mineral-related projects included exploration of the 56-million-ton limestone deposit at Tin-H'Rassan by the Government with French assistance. In addition, a cement works at Ouagadougou was planned that was expected to have a capacity sufficient to meet domestic needs while also providing an excess for export to neighboring countries. Exploration of the marble and limestone deposits at Tiara started at yearend 1979. The Islamic Development Bank gave Upper Volta $97,000 to study the feasibility of a petroleum tank farm.

[e]Estimate. [p]Preliminary. [r]Revised. NA Not available.
[1]In addition to the countries listed, the Gambia and Upper Volta, which are covered in the text of this chapter, presumably produce modest quantities of a variety of crude construction materials (clays, stone, and sand and gravel) and may produce minor amounts of other mineral commodities (most notably gypsum, lime, and salt), but output is not reported quantitatively and available information is inadequate to make reliable estimates of output levels.
[2]In addition to the commodities listed, modest quantities of unlisted varieties of crude construction materials (clays, stone, and sand and gravel) presumably are produced, but output is not reported quantitatively and available information is inadequate to make reliable estimates of output levels.
[3]Reported figure.
[4]Products marketed under the trade names "Balifos" and "Phospal."

The Mineral Industry of the Islands of the Caribbean

By Doris M. Hyde[1]

CONTENTS

Limited geographically by size and geologically by origin, smaller countries and territories of the Caribbean are nonetheless engaging in efforts to encourage the initiation of mineral and mineral-related industries. Petroleum dominates the minerals sector, which otherwise consists principally of minor quantities of construction-oriented materials, usually for local consumption. The increased cost of petroleum has adversely affected most of the world, but these islands with their economies precariously balanced on the uncertainties of agriculture and tourism are especially vulnerable to petroleum's direct and indirect costs.

In 1975, the Government of Antigua acquired the financially troubled West Indies Oil Company refinery at St. Johns. The refinery ceased operations in 1976. In 1979, negotiations were underway to sell Ashland Oil Co. an interest in the small, 20,000-barrel-per-day refinery for $6.6 million. In 1977, Antigua granted petroleum exploration rights to the Antigua Mineral Exploration Company, which planned to drill in an undefined offshore area, possibly between Antigua and Barbuda. The company expected to spend about $200,000 per year through 1982. There have been no reports on its activity.

On Little Cayman Island, just south of Cuba, Cayman Energy Ltd. joined with Texas Eastern Corp. to conduct a feasibility study for a shore-based crude oil transshipment terminal. The terminal, with a capacity of more than 1 million barrels per day, would include storage and service facilities.

Santa Lucia's entry into the petroleum transshipment industry was scheduled for late 1979 when the terminal construction at the Hess Oil St. Lucia Ltd. petroleum complex will be completed. The time frame for refinery construction would be determined to some extent by the state of the market. The Government has no shares in the petroleum complex but benefits from taxes on throughtput and the employment of Santa Lucians.

In late 1979, the British Virgin Islands granted a petroleum exploration license to three Canadian firms—Noranda Mines, Ltd., Brenda Mines, Ltd., and Flin Flon Mines, Ltd. The license includes 462,000 acres on the Atlantic side of the islands. Geophysical surveys of the area were underway.

Table 1.—Islands of the Caribbean: Production of mineral commodities —Continued

Area, [1]commodity, and unit of measure	1976	1977	1978[p]	1979[e]
TRINIDAD AND TOBAGO —Continued				
Sulfur, byproduct of petroleum[10] thousand metric tons	55	30	54	55

[e]Estimate. [p]Preliminary. [r]Revised. NA Not available.
[1]In addition to the countries listed, Bermuda, Grenada, and St. Lucia presumably produced crude construction materials (clays, sand and gravel, and stone), but output is not reported and available information is inadequate to make reliable estimates of output levels.
[2]In addition to the commodities listed, other crude construction materials (lime, salt, and sand and gravel) may also be produced, but data on such production are not collected and available information is inadequate to make reliable estimates of output levels.
[3]In addition to the commodities listed, iron ore, manganese ore, and salt, all produced in significant quantities prior to the termination of publication of official statistics, presumably were produced during the period covered by this table, but available information is inadequate to make reliable estimates of output levels.
[4]Includes Ni content of nickel oxide and nickel fonte in addition to metallic nickel and ferronickel.
[5]Data represent exports; all production is presumed to be exported.
[6]Reported figure.
[7]Includes crushed volcanic rock, limestone, diorite, and quartzite used for building stone, aggregate, road construction, etc.
[8]Less than 1/2 unit.
[9]Revised to none.
[10]Limited quantities of sulfur as a byproduct of natural gas may also be produced.

BAHAMAS

New petroleum legislation was enacted during 1978, amending the Petroleum Act of 1971. Passage of the Petroleum Amendment Act of 1978 was followed by the publication of appropriate regulations in the Bahamas' Official Gazette, Supplement Part II, September 7, 1978. These extensive regulations detail the terms under which the Government will award permits, licenses, and leases for petroleum exploration and exploitation.

No applications for petroleum permits or licenses were initiated in 1978 or 1979 as companies awaited the issuance of official guidelines and the designation of specific areas to be open for exploration.

In 1978, the financial problems of the Grand Bahama Petroleum Co. (PETCO), a subsidiary of the U.S. based Carey Energy Corp., culminated in an unfavorable Bahamas Supreme Court decision on PETCO's outstanding trade credit debt dispute with the National Oil Co. of Libya. Unable to comply with the Court's order to pay the estimated $158 million owed to Libya, and with total debts thought to approach $500 million, PETCO was forced into liquidation proceedings. PETCO held a 65% interest in the Bahamas Oil Refining Co. (BORCO), and Standard Oil Co. of California owned the remaining 35% interest. Subsequently, as discussed below, the percent interest in BORCO was changed.

In May 1979, a U.S. firm, Charter Co., purchased Carey Energy Corp. and thus acquired ownership of PETCO and its interest in BORCO. After a series of negotiations with PETCO's creditors and ownership challenges through the Bahamian court liquidators by a Venezuelan company, Hideca Trading Corporation (which wished to purchase PETCO), Charter finally established ownership.

Part of Charter's negotiations to satisfy Standard Oil Co. of California for its outstanding $103 million loan to PETCO, involved transfering 15% of PETCO's interest in BORCO to Standard Oil, giving both companies a 50% interest in the refinery. The somewhat complicated relationships between Carey Energy and its subsidiaries and Charter's purchase of Carey Energy were covered by newspaper reports.[2]

In 1978, Burmah Oil Ltd. and the Government reached an agreement on the renegotiation of Burmah's management contract for the operation of the Grand Bahama Oil Transshipment Terminal. The new agreement guarantees the Government a minimum annual payment, starting in 1979, of $1.8 million plus an additional 1.8 cents per barrel on throughput in excess of 100 million barrels and 3 cents per barrel for amounts over 150 million barrels. Burmah also agreed to assume responsibility for all outstanding debts the Government incurred in constructing the terminal. Aside from its 1972-1992 management contract, Burmah has no holding in the terminal.

In January 1978, United States Steel

Corp. sold its 100% interest in the 520,000-ton-per-year capacity Bahama Cement Company to International Development Corp. S.A. of Luxembourg. Plant operation resumed shortly thereafter and cement again became an important mineral-related export.

BARBADOS

Even though Barbados produces crude oil and natural gas, it cannot provide for its growing domestic needs. In 1979, national gross commercial energy consumption was estimated at approximately 6,000 barrels per day, an amount conservatively predicted to double by 1985. In response to the economic strains posed by increasing prices for imported petroleum, in 1979 the Government announced the establishment of an Energy and Natural Resource Division within the Ministry of Trade and Industry. Increased exploration, improved operating procedures for existing wells, and an attempt to control the growth of petroleum energy demand, possibly through the use of alternative forms of energy, were options under consideration by the new agency to decelerate the prospect of increased oil imports.

In 1979, General Crude Oil Co., whose control of Barbados' oil exploration and exploitation operations have been the object of criticism for reduced production capability, sold its operations to Mobile Oil Barbados Ltd. Mobile also operates the small local refinery. In 1979 the Government allowed price increases for petroleum products to more realistically reflect crude oil import costs.

Proven petroleum reserves were estimated at 2 million barrels of oil and 2.5 billion cubic feet of natural gas. Preliminary evaluations of exploration work indicated that at least 10 onshore fields exist which are geologically similar to the now-producing Woodbourne field, and offshore prospects have also been encouraging. It was estimated that Barbados may have reserves of 15 million barrels of oil. A seismic survey was begun in late 1979. Based on the results of this survey, a more detailed survey and production study may be undertaken. The Government was reported to be interested in a joint partnership arrangement whereby contributions to its share of drilling costs would come out of royalties only if commercial quantities of oil were discovered.

Nonfuel mineral production was limited to construction-oriented materials, mostly for domestic consumption. The new cement plant, jointly owned by the Governments of Barbados and Guyana, was scheduled to become operational by the end of 1979. Barbados and the Government of Trinidad and Tobago have agreed to jointly establish a cement plant in Barbados. Trinidad and Tobago will provide fuel and financal assistance to the project.

CUBA

The mineral industries account for an estimated 7% of Cuba's total exports. On an international level, the only significant minerals are nickel and cobalt. Cuba has ranked fifth in world nickel production for the last 6 years. Expansion projects now underway or planned could eventually place Cuba as the second largest world producer of nickel.

Declining productivity and inefficient management have been the subjects of considerable internal criticism and were blamed for the Government's failing to meet some economic development objectives. Late in 1979, as Cuba entered the final year of its first 5-year plan (1976-1980), the Government promised legislation to strengthen efficient management practices and to provide material incentives to encourage productivity.

In recent years, Cuba's opportunities to expand trade and cooperation agreements have improved but hard currency for payments remains a problem. Cuba favors trade and industrial development compensation agreements in which at least partial payment can be made by domestic products.

Cuba remained unaffected by the continued depression in the world nickel industry during 1978. Nickel sales prices had been favorably established at $2.72 per pound of nickel through contracts with member countries of the Council for Mutual Economic Assistance (CMEA).[3] About two-thirds of Cuba's nickel production is exported to CMEA countries while the remainder is sold on the free world market. Cuba, with operating costs estimated at $1.20 to $1.90 per pound, was able to show some gain in hard currency.

Cuba's oil import costs have increased substantially. Oil imports from the Soviet Union in 1978 were placed at about 200,000 barrels per day at an estimated annual cost of $711 million, well above the $507 million value of 1977 oil imports. Fuel conservation and alternative energy sources are areas of immediate concern. Oil supplies are assured by the U.S.S.R. until 1985 at prices considerably less than those on the world market.

The construction of a nuclear power station near Cienfuegos appeared to be stalled. The first site choice was discarded when geological evidence proved the area unsuitable. A second site, not too distant from the first, was selected but evidently questions regarding plant safety standards, and possibly geological considerations, have arisen. At the end of 1979, the Government announced a 2-year delay in construction.

COMMODITY REVIEW

An economic and technical cooperation meeting of CMEA members was held early in 1978 during which it was generally agreed to intensify the development of Cuba's mineral industries, particularly copper, lead, zinc, and phosphate rock. Corroborating this interst in minerals industry diversification was Cuba's request for a loan from the Belgium Government, partly to be used in the construction of a nonferrous plant to produce lead, zinc, and pyrite concentrates. The nonferrous plant project included the participation of an unnamed Belgian company.

Metals.—*Iron and Steel.*—Negotations continued with French, Spanish, and Belgian concerns regarding participation in the construction of a 50,000-60,000 tons per year stainless steelworks in Oriente Province. A portion of the $500 million plant construction costs would be paid through shipments of stainless steel to the European firms. The expansion of the José Marti steelworks continued, and production capacity was expected to reach 450,000 tons per year by 1980 and 600,000 tons per year by 1985. There were reports that planners now envision a 2.6-million-ton-per-year capacity by 1990, although details were not made available.

Nickel.—The second phase of Cuba's nickel expansion program was underway in 1979. The new Punta Gorda smelter, east of the Moa smelter, was expected to be onstream in 1981. Another new plant, scheduled for completion in 1985, will be built at Las Camariocas. Czechoslovakian enterprises have contracted to supply a 24-megawatt thermal power station, a compressor station, pipeline system, and a cooling system for the Las Camariocas plant.

A study of the laterite nickel deposits near Moa and Nicaro has been completed. These deposits have been chosen to supply ore to the Camariocas complex. About half of the anticipated new nickel production is projected for CMEA trading partners, the remainder may be destined for Cuba's expanded trade on the world market. Cuba has entered into an agreement with a French firm to use nickel as partial payment for the construction of a paper mill.

Nonmetals.—*Cement.*—VEB Zementanlagembau Dessau was reported to be constructing a large, 1.6-million-ton-per-year cement plant at Cienfuegos. Upon completion of this plant, Cuba's cement capacity will exceed 4 million tons per year. Although cement production has not been sufficient to satisfy domestic needs, Cuba was reported to have made significant exports; some went to Jamaica in 1978 and to both Jamaica and Honduras in 1979. The premature export of cement may have been at least partially motivated by hard currency shortages.

Mineral Fuels.—*Petroleum and Natural Gas.*—Trade journals continued to estimate Cuba's oil production between 1,000 and 5,000 barrels per day, a range which may be interpreted as indicative of the paucity of factual information available. A recent publication on world energy supplies shows a steady decline in Cuban crude oil production and indicated volumes on the low side of most other estimates.[4] For 1978, production was estimated at slightly over 900 barrels per day. The lack of significant discoveries in 1979 would imply a continuing production decline.

Offshore exploration has not yet taken place, although it was discussed during the March 1978 economic and technical cooperation meeting held by CMEA members in Havana. It has been reported that Cuba may be interested in seeking foreign participation for petroleum exploration activities, particularly offshore. No negotiations have been made public.

In 1978, it was reported that a quadrilateral oil exchange had been arranged whereby U.S.S.R. oil supplies for Cuba would be diverted to Spain, while Venezuelan oil intended for Spain would be diverted to Cuba. Such an exchange would not only result in a reduction of freight charges but would increase the availability of tankers for other deliveries.

DOMINICAN REPUBLIC

Overall real economic growth continued a slow downward trend, from 6.4% in 1976 to 4.4% in 1977 and 2.3% in 1978. The real growth was estimated at 5.3% in 1979 in spite of the effects of two devastating storms. In 1978, the mining sector accounted for 4.4% of the gross domestic product.

In 1978, total exports were valued at $675.5 million. The three major minerals, bauxite ($23.4 million), nickel ($71.1 million), and gold and silver ($76.2 million), accounting for almost 25% of this amount. In 1979, the value of total exports increased to an estimated $775 million, mostly due to the performance of the mining sector which was not adversely affected by the hurricanes. The three major minerals, bauxite ($20.7 million), nickel ($128.5 million), and gold and silver ($145.3 million), accounted for 38% of total exports in 1979.

In 1978, petroleum and petroleum products accounted for 23% of the $859.2 million of total imports. In 1979, it was estimated that total imports reached $1,070 million, with petroleum responsible for 29% of this amount.

Foreign investors have shown some reluctance to make firm commitments in the

Dominican Republic. One reason is the confusion over certain technical aspects of the 1978 Foreign Investment Law. Under this law, existing foreign investments in certain controlled sectors do not have to divest, but all foreign investments are subject to the established reinvestment regulations. The law states that profits in excess of those currently allowable for repatriation (18% of foreign investment's registered capital per annum) may be reinvested. Confusion arose as to whether funds that are reinvested will increase the registered capital base upon which future profit repatriation is determined.

The promise of a new mining law also held uncertainties for foreign investors. A proposed mining law, drafted in 1977 was not submitted to the Dominican Republic's Congress in 1978. The Government set up another commission to revise the Mining Law of 1971. The revision was expected to be presented to Congress in early 1980 along with a recommendation to upgrade the status of the present General Directorate of Mining to that of a Ministry of Mining and Hydrocarbons. The mining program of the Government appeared to be firmly directed toward assuming a more positive role in minerals exploitation, including the use of service contracts and competitive bidding.

The continued escalation of gold and silver prices throughout 1978 and 1979 increased the gross earnings of Rosario Dominicana, S.A. Through taxes and a 46% ownership in the company, in 1978 the Government realized 76.2% of the profits from the mining operation. In response to congressional and public concerns that the Dominican Republic was indeed receiving adequate compensation from the mining operations, and in view of the widening trade deficit and increases in the market price of gold, in 1978 the Government initiated negotiations with Rosario to revise the 1976 contract.

In October 1979, the Government suddenly purchased for $70 million the 54% interest in Rosario Dominicana held by Rosario Resources Corp. and Simplot Industries, Inc. The loan for this purchase was obtained from four foreign banks at an undisclosed interest rate. Some reports have ventured that the Government was charged from 14% to 17.5% over 5 years. Rosario Resources gave its consent to manage the mining operation until the end of 1980.

At the end of 1978, Rosario's reserves of oxide ore were estimated at about 17.5 million tons grading 0.13 troy ounce of gold and 0.74 troy ounce of silver per ton. At the current rate of mining, these reserves would be exhausted in less than 5 years.

Exploration and development drilling of the large sulfide zone underlying the oxide ore body have not been completed, so the total potential sulfide reserves remain estimated at 21 million tons grading 0.11 troy ounce of gold and 0.84 troy ounce of silver per ton, with 1.40% zinc and 0.14% copper. Several types of sulfides are present in the ore body, and the determination of an acceptable metallurgical extraction process and more exact definitions of the deposit limits and geology are yet to be made.

Adjacent to Pueblo Viejo are the lower grade Monte Negro deposits where reserves have been estimated at about 15 million tons of oxide ore containing 0.12 troy ounce of gold and 0.45 troy ounce of silver per ton. Sulfide ore reserves at Monte Negro are estimated at 10 million tons containing 0.07 troy ounce of gold 0.39 troy ounce of silver, with minor amounts of zinc and copper.

In 1978, both the Dominican Republic's revenues and the financial status of Falconbridge Dominicana C. por A. suffered from the continuing depressed world market price for nickel and unfavorable producer and consumer inventories. In January 1978, Falconbridge closed a second electric melting furnace line, leaving only one of its three lines operational during the year. Concomitantly, the work force was reduced by one-fourth to about 1,550. By the end of 1978, inventories had been reduced, and the production lines were reactivated in 1979 when world nickel prices increased significantly.

In December 1977, the Aluminum Co. of America (Alcoa) and the Dominican Government agreed to a 6-month extention of an earlier agreement covering bauxite production levels, taxes, and royalty payments for the 1977 calendar year. In May 1978, a further extension was agreed upon, but in October another meeting ended inconclusively and no further discussions were held until late in 1979. Alcoa's Cabo Rojo bauxite operation is considered marginal and is the second smallest of similar operations in the world.

In July 1979, the Government agreed to a joint venture with a Spanish firm, Hullera Vasco-Leonesa S.A., for the exploration and exploitation of mineral deposits in a 4,000-hectare area in the central highlands along the Yujo River near the town of Jarabacoa.

Copper is the main exploration objective, although other minerals are also of interest. If gold or silver is found, the contract provides that terms will be renegotiated. Hullera received a renewable 15-year exploitation concession and will invest $6.5 million. For its share, the Dominican Republic contributed the property and mineral rights to the concession. Net profits of the venture are subject to a 40% income tax plus a sliding-scale tax ranging from 20% to 80% when dividends are greater than 20% of paid-in capital. Hullera will also contribute 5% of its annual net earnings to the town of Jarabacoa.

The Government has specified several mineral exploration projects for work—an evaluation of the Sierra de Bahoruco bauxite reserves in the southwestern part of the country, possibly in cooperation with Haiti, with the ultimate objective of constructing an alumina plant; an evaluation of the Mata Grande and Las Cañitas copper deposits; and an evaluation of the Monte Cristi and Hatillo iron deposits.

An agreement was signed with the United Nations for a minerals survey of the Cordillera Central. According to the agreement, the U.N. Revolving Fund would invest a minimun of $755,000 over a 6-year period. Later, the Government was concerned that some terms of the agreement could prove contrary to the country's best interest, and ratification was deferred pending renegotiation.

The four companies holding petroleum exploration and exploitation contracts were active during 1978 and 1979. Eastern Petroleum Dominicana, S.A., and Canadian Superior, Ltd., performed geophysical surveys on their concession in the Enriquillo Basin in the western region. Petrolera a Las Mercedes S.A., a private Venezuelan firm, concentrated its efforts on the area east of Santo Domingo. The consortium of Carboil Corp., Stalworth Oil and Gas, Inc., and Texas Crude Oil Corp., which has the concessions rights to the San Juan Basin located north of the Enriquillo Basin, accepted Weeks Petroleum Co. as a fourth partner. The Coporacíon Dominicana de Electricidad (CDE), which had purchased the rights to old wells in the Maleno field, sold the rights back to Las Mercedes. Las Mercedes performed surveys on the Cibao Valley holdings of Quisqueya Oil S.A.

[1]Less than 1/2 unit.

In August 1979, subsequent to public turmoil following a series of petroleum product price increases, it was reported that the Government would take over the 46% interest that Shell Petroleum Corp. holds in the Refinería Dominicana de Petróleo S.A. at Nagua.

HAITI

Bauxite remained Haiti's only significant mineral export, and there appeared to be little reason to anticipate any new developments in the immediate future. Bauxite exports from the Reynolds Haitian Mines netted the Government an estimated $9.8 million in taxes in 1978. In November 1978, a new cabinet-level Ministiere des Mines et Resources Energetiques was established.

In mid-1979, after reluctantly agreeing to price increases for petroleum products sold locally, the Government established Onacora-Petrole, a national office for the sale and refinery of petroleum products. Onacora operates within the dictates of the new Department of Mines and Energy and thus creates a mechanism by which Haiti can develop and promote its own energy potential. Onacora will be self-funded through profits.

Late in 1979, work was initiated on an economic feasibility study of the Maïssade lignite deposits. The project was part of a 1979 technical cooperation agreement between the Governments of Haiti and the Federal Republic of Germany. No developments were reported for the varous mineral exploration projects, notably copper, which have been underway for several years.

After evaluating data from three exploratory wells drilled in the Cul-de-Sac region and offshore in the Gulf of Gonâve in 1977, Crux International, Ltd., relinquished 590 square miles of its onshore and offshore petroleum concession in the Plaine du Nord area. No wells have been drilled in Haiti since that time. Hideca de Venezuela S.A. continued gravity surveys in the Plaine Centrale in 1978 and renewed its concession rights, but in mid-1979 Hideca apparently abandoned the project and the concession was assigned to a U.S. firm, Anschutz Corp. Anschutz will assume exploration costs and will drill at least two exploratory wells. Anschutz' concessions include a portion of east-central Haiti and the onshore and offshore areas of the southern peninsula west from about Les Cayes. No new seismic work was undertaken by Anschutz during 1979.

[2]Includes small quantities of pig iron, ferroalloys, and crude steel.
[3]Less than 1/2 unit.

JAMAICA

Throughout 1978 and 1979, Jamaica continued its efforts to solve major economic problems, which included a serious foreign exchange deficit, inflation, a high unemployment rate, a breakdown of private sector confidence, and continued emigration of skilled and managerial personnel. Preliminary data indicated that 1979 was the fifth consecutive year of negative economic growth.

In February 1978, the Government proposed that the bauxite companies make advance payments of the coming fiscal year's estimated bauxite levy by means of issuing promissory notes. The Government sold these notes to selected banks, partly for cash to improve reserves and partly as repayment of loans. The companies continued to remit monies due from the bauxite levy on a quarterly basis, but payments were made directly to the banks to redeem the notes.

Several actions were taken by the Government to encourage increased activity in the bauxite industry. The dual exchange rate had been instituted in April 1977 as an accompaniment to the first of several devaluations of the Jamaican dollar. The unfavorable rate had been applied exclusively to transactions of the bauxite-alumina companies and severely handicapped an industry already burdened by a high bauxite levy, a depressed world market, and increased operating costs in excess of productivity gains. In May 1978, however, responding to pressures from the bauxite industry and the International Monetary Fund, the dual exchange rate was unified.

Also in 1978, the Government reduced the bauxite levy from 8% to 7 1/2% of the averaged realized U.S. market price of aluminum ingots. The levy yielded the Government $193 million in revenues in 1978. The levy reduction, elimination of the dual exchange rate, and devaluations of the Jamaican dollar made the bauxite industry more competitive in world markets but the imposition of a 10% ad valorem stamp duty and increased labor costs reduced the beneficial impact.

Government negotiations with the bauxite producers during 1979 resulted in agreements providing for a further reduction of the bauxite levy based on a production incentive formula. The reduction was designed to maintain revenue income and restore mining and refining operations which have been producing at reduced levels since 1975. The agreements were reported as reducing the levy from 7 1/2% to 7% of the average realized ingot price of aluminum in the U.S. for production above a certain reference quantity. If the ingot price continues to rise, the percentage levy would be reduced. The agreement would be in force until 1983, by which time the levy rate could go as low as 5% or 6%. Other levy rates would be used for production over and above the operating companies' predetermined level in increments of 200,000 tons.

Total exports of bauxite and alumina during 1978 and 1979 did not change significantly from 1977 levels. All bauxite exports went to the U.S.; in 1978, four countries accounted for about 82% of Jamaica's 1978 alumina exports—the United States (28%), United Kingdom (26%), Norway (15%), and Canada (13%). Bauxite and alumina accounted for over 71% of the value of exports in 1978.

In 1978, Mexico withdrew from participation in Jalumex, the proposed Mexican-Jamaican aluminum smelter project planned for construction at Veracruz, Mexico, and from Javemex, the proposed joint Jamaica-Venezuela-Mexico alumina plant to be built at South Manchester, Jamaica. In the ensuing months, the Government secured an agreement from the U.S.S.R. to purchase 50,000 tons of alumina per year starting in 1980 and increasing to 250,000 tons per year in 1984. Agreements were also made for the sale of 150,000 tons of alumina per year each to Algeria and Iraq starting in 1984. An agreement to sell 150,000 tons per year of alumina to Hungary was cancelled since Hungary planned to resell the alumina on the world market.

These new contracts justified Jamaica's decision to proceed with plans for a 600,000 ton-per-year alumina plant at South Manchester. Financing the $500 million plant became an immediate consideration as construction would have to start in 1980 to ensure fullfillment of the 1984 alumina contracts. Plant designs have been prepared by Aluterv, the Hungarian engineering concern. Norway and Jamaica have held preliminary discussions regarding joint participation in the new alumina facility.

In September 1978, the Government of Jamaica, Alcan Jamaica, Ltd., and Aluminium Company of Canada, Ltd. (Alcan), announced they had reached agreement on the Government's acquiring a 7% participation in Alcan's integrated mining and refining operation. Jamaica's interest was vested in Jamaica Bauxite, Ltd., a state-owned company. The new joint venture, known as Jamalcan, became operational in November 1979 and is managed by Alcan and directed by a seven-member Board, on which Alcan has five members and the Government has two. The Government acquired all of Alcan's mineral lands at the lesser of book or market value. The new partnership will retain ownership of all land which contains the operational and support facilities of the mining and alumina operations. The Government granted a special 40-year mining lease to Jamalcan. Jamalcan will pay the Government a mining royalty of J$0.50 per dried long ton of bauxite until December 31, 1983.[5] The rated capacity of the facilities is 1,095,000 tons per year of alumina, and the Government's share would be 76,650 tons. A separate agreement provided that Jamaica's share of alumina can be bartered to Alcan for aluminum metal, which Alcan would then market on behalf of the Government.

The 1977 partnership agreement between Kaiser Bauxite Co. and the Government will become effective in February 1980 with the formation of the jointly-owned Kaiser Jamaica Bauxite Company. Kaiser will manage the new company.

In August 1978, the three neutral arbitrators appointed to rule on the disputed expropriation claim between Revere Copper and Brass, Inc., and Overseas Private Investment Corp. (OPIC) ruled unanimously that Jamaica's imposition of a high bauxite levy in 1974 was not confiscatory and that the levy itself did not justify recovery under the OPIC insurance contract. By a two-to-one majority the panel did find that the sum of Jamaican statements and actions amounted to a repudiation of the 1967 investment agreement between the Government and Revere and awarded Revere a settlement from OPIC of $1.1 million for this repudiation.

Revere's claim against OPIC was for $90 million, which included its $64 million investment insurance coverage, reimbursement of amounts paid on account of the bauxite levy and royalty payments imposed by the Jamaican Government, maintenance costs on the closed plant, all litigation expenses, and preaward interest. Revere refused to accept the $1.1 million and petitioned the U.S. District Court for the District of Columbia to correct or vacate that part of the arbitration award. The Court denied the petition and Revere appealed to the Circuit Court of Appeals in the District of Columbia. Arguments were presented in October 1979, but no decision had been reached by the end of the year. Should Revere accept the award, it must transfer its stock in Revere Jamaica Alumina, Ltd., to OPIC.

The Government negotiated the acquisition of the Caribbean Cement Co., Ltd., which operates a 400,000 tons per year plant at Kingston. Finalization of an agreement was expected in 1979. The Government's shares would be owned through the Jamaica National Investment Corp., the entity responsible for investing proceeds of the bauxite production levy. It was reported that some 4,000 shareholders who hold 8 million ordinary shares would be offered debentures in lieu of cash. Equipment to double capacity was available in storage near the plant and the Government expected to initiate expansion when financing becomes available.

Jamaica was also considering the construction of another cement plant to be undertaken jointly with Venezuela. The plant, with a proposed capacity of 600,000 tons per year, would supply cement for domestic use and for exports. In September 1978, Jamaica Gypsum Co. Ltd., a subsidiary of U.S. Gypsum Co., closed down its operations in the southwestern region of Bull Bay.

Funded by a $1.6 million grant from the Norwegian Government, 1978 geophysical exploration activity revealed that the Pedro Banks may offer a potential source of petroleum and natural gas. Invitations to bid for offshore exploration concessions were opened in 1979. Production-sharing franchise agreements were expected to be concluded by the end of December 1979. Legislation permitting petroleum exploration was enacted in 1979 and included production sharing, joint ventures, and service contract agreements with both state-owned and private foreign companies.

Onshore, two shallow exploratory wells drilled in 1978 were reported to have encountered shows of oil and gas. The newly formed state-owned company, Petrochemicals Jamaica Ltd., announced its intentions to initiate drilling in March 1980 at Windsor, St. Ann, near the resort area of Ocho Ríos. Two other areas, one near Montego Bay and one near Savanna La Mar in the southwest, will also be explored. The $14 million exploratory program will be financed by the Government funds, possibly with the assistance of loans from the Inter-American Development Bank.

MARTINIQUE AND GUADELOUPE

Guadeloupe's mineral industry is limited to construction-oriented materials, including a small, 180,000-ton-per-year-capacity cement plant at Pointe-á-Pitre. Martinique, with one small, 180,000-ton-per-year-capacity cement plant, was reported to have another plant coming onstream in 1978, but verification of this and data on plant capacity were not available.

The small refinery at Fort de France on Martinique imported crude oil from Venezuela and Saudi Arabia. The refinery products were used domestically and for export to Guadeloupe.

NETHERLANDS ANTILLES

The Shell Curacao N.V. refinery on Curaçao and the Exxon Lago refinery on Aruba continued to operate at a cost disadvantage in comparison with refineries located in the United States. The unprofitable operation of the refineries has had an adverse effect on the Netherlands Antilles through the loss of wages, increased unemployment, declining tax revenues, and increased balance-of-payments deficits.

Shell has indicated a willingness to accept one or more partners to share the burden of operating the refinery. Venezuela has held discussions with Shell regarding joint ownership. Both the Shell and Exxon refineries were designed to accomodate primarily Venezuela crude oil. An interest in the Shell refinery would give Venezuela an expansion of its export markets and also provide a new source of gasoline for its own increasing domestic use. The partnership would probably provide the refinery with a cost advantage on crude oil purchases. The Government of the Netherland Antilles was reported as a possible third partner in the venture.

The Government of Bonaire has been negotiating with Hess Oil of St. Croix, Virgin Islands, on the possibility of building a petroleum refinery next to the Bonaire Petroleum Corp. N.V. (BOPEC) oil transshipment terminal. No agreement was reached in 1979. The proposed $100 million refinery was expected to produce about 150,000 barrels per day.

In 1978, the Weeks Group, a consortium headed by Weeks Natural Resources, did not renew its petroleum exploration contract. The consortium conducted offshore seismic work in 1977.

TRINIDAD AND TOBAGO

Trinidad and Tobago continued the development of major energy-based industries supported to a large extent by the active petroleum sector. The Point Lisas industrial complex is the core of Government efforts to reduce economic dependence on oil and establish gas-fueled heavy industries. The increased industrial growth has stimulated employment opportunities.

In 1979, the Government announced that a new system of oil taxation will be introduced. The plan supposedly will abolish the tax reference price system currently used to calculate tax liability. The corporate tax rate of 45% will be applied instead of the petroleum profits tax rate of 50%. The refinery throughput tax will be replaced by the general corporation tax. A supplemental refinery tax is to be added which will be taken into account in computing the normal corporation tax liability.

COMMODITY REVIEW

Metals.—*Aluminum.*—The aluminum smelter project, which has been subject to some variation in capacity and ownership since originally conceived, appeared to be on the verge of receiving a positive decision to proceed. A feasibility and marketing study completed in 1978 viewed an aluminum smelter of between 135,000 and 180,000 tons per year as complementary to Trinidad and Tobago's industrial development program. In 1979, two U.S. companies, National Steel Co. and South Wire Aluminum Co., were chosen to be joint partners with the Government's National Energy Corp. in this $625 million project. A final decision for construction was expected in 1980. Sources for alumina input to the smelter remained undecided.

Iron and Steel.—The Iron and Steel Company of Trinidad and Tobago (ISCOTT) complex is scheduled for a mid-1980 startup. Armco, Inc., has agreed to provide iron ore and financial and technical assistance for the project. Armco has taken equity participation in the second Midrex direct reduction plant which will have the same 450,000-ton-per-year sponge iron capacity as the first plant. The first reduction plant is scheduled to come onstream in July 1980, and the second should be completed in 1982. At full production, some 200,000 tons per year of surplus sponge iron should be available for export.

Brazil has contracted to supply ISCOTT with 3 million tons of iron ore pellets over the next 10 years, an amount equal to about half of ISCOTT's pellet needs. The electric furnace steelmaking plant and rolling mill will produce about 750,000 tons per year of steel billets and rod, most of which is destined for the export market. Initial annual production is expected to be about 200,000 tons of billets and 70,000 tons of rod. The $300 million steel complex, when operating at full capacity, will employ some 1,000 workers. The Trinidad and Tobago Oil Co. (Trintoc) has agreed to construct a $5 million oxygen and nitrogen plant to service the ISCOTT complex.

Nonmetals.—*Cement.*—Construction projects at Point Lisas were somewhat hampered by the inability of the port facilities to accomodate the increased import of supplies and equipment. The construction industry has experienced a rapid growth due to industrial plant and infrastructural development projects as well as increased Government expenditures on nonindustrial projects.

In early 1978, the Government studied the advisability of constructing a new cement plant which would at first complement and then gradually replace the existing 270,000-ton-per-year facility of Trinidad Cement Ltd. Later in the year, it was announced that Voest-Alpine AG of Austria would construct a 950-ton-per-day plant scheduled to come onstream in 1981. The major portion of raw materials for cement manufacture are available locally. Limestone reserves are sufficient for 70 years at the current rate of extraction. In 1979, the Government reported that it would form a joint venture with Barbados to establish a cement plant in the latter country. Trinidad and Tobago will provide fuel and financial assistance to the project.

Fertilizer Materials.—The first of the Point Lisas industries, Trinidad Nitrogen (Tringen), came onstream in mid-1977. Tringen, a 400,000-ton-per-year anhydrous ammonia plant, is jointly owned by the Government and W. R. Grace Co. and expected to show a 1979 operation profit of $8.8 million. Fertilizers of Trinidad and Tobago (Fertrin), a $250 million joint venture of the Government (51%) and Amoco International Oil Co. (49%), should become operational in 1981. Fertrin will have a 2,300-ton-per-day capacity from two single-train, 1,150-ton-per-day ammonia plants.

Mineral Fuels.—*Natural Gas and Petroleum.*—The much-publicized LNG project, a joint venture between the Government (51%), Tenneco Trinidad LNG, Inc. (24.5%), and Peoples Overseas Inc. (24.5%), a subsidiary of Peoples Gas Corporation, came closer to final approval when information presented in a gas reserves study commissioned by the Government showed that proven, discounted probable, and discounted possible natural gas reserves as of January 1, 1978, equaled 12.04 trillion cubic feet. The Ministry of Petroleum and Mines believed that increased drilling activity, the leasing of new areas, and improved recovery techniques could reasonably be expected to increase total natural gas reserves to 21 trillion cubic feet. In addition, the reserves study discounted probable and possible reserves by 50% and 80%, respectively.

Estimates of the natural gas that domestic industries will consume over the next 40 years, to the year 2017, equaled 8.6 trillion cubic feet, leaving about 4 trillion cubic feet for allocation to a 500-million-cubic-foot-per-day LNG plant. Huffington, Inc., of Texas, has been intergrated into the LNG project as a technical adviser but not as an equity partner. Some reports indicated that Texas Gas Transmission Corp. might become involved in the project. In the event another 250 million cubic feet per day becomes available as anticipated, 50% of it would be offered to Texas Gas and the remainder would be made available to the other partners. King Wilkinson, Inc., was selected to prepare designs and cost estimates for the plant and marine facilities as part of phase 1 of the project. A preliminary gas pipeline system study was underway.

The flaring of associated gas amounted to about 160 million cubic feet per day in 1978, and the waste of this non-renewable resource has been a subject of much concern to the Government. Utilization in 1978 amounted to about 62% of production and this should increase to about 75% when the Government finishes construction of its own platform to collect and compress about 50 million cubic feet per day of associated gas from Amoco Trinidad Oil Co., Ltd.'s petroleum concession off the east coast. The Government continued to utilize Amoco's offshore platform facilities and transported the gas to shore through the existing state-owned pipeline.

Under Regulation 94 of the Petroleum Regulations, the Minister of Petroleum and Mines is entitled to receive, without compensation to the licensee, any quantity of natural gas produced in association with crude oil which is not required by the licensee for his operations or sale.

The Government has placed a high priority on finding new sources of crude oil and natural gas. Oil production has been steadily declining, which reduces the economic gains that could be realized from increased world prices.

In 1979, the Government awarded three offshore exploration concessions to the Trinidad and Tobago Oil Co., Ltd., and to Mobil Oil Comany. In addition to new oil production, the Government hoped that further gas reserves will be found for use in the major industrial programs. Exploitaion will be through the initiation of production-sharing contracts.

It was reported that construction of drilling and production platforms began in Trinidad in 1978, and their use represented a significant cost reduction for petroleum companies. There has been no onshore exploration for several years, but toward the end of 1978, Occidental Oil Co. was granted an option to explore and develop some 86,000 acres in the Nariva area. Occidental conducted seismic studies in 1979. Also in 1979, the Government entered into negotiations for the purchase of Premier Consolidated Oilfields Ltd., a small producer that has been reported as operating at a loss for several years.

In late 1978, following the receipt of formal complaints against the Texaco Trinidad Inc. (TEXTRIN) refinery by the Oilfield Workers Trade Union (OWTU), the Government took measures to investigate the allegations against the refinery. OWTU also demanded the nationalization of the refinery.

Government negotiations for securing participation in the TEXTRIN refinery were initiated in 1974. Some reports suggested that discussions have been stalemated due to TEXTRIN's failure to release financial data. Other reports suggested that the lapse in negotiations was due to world recession in the refinery sector which forestalled any sense of urgency on the Government's part in obtaining state participation. Public reaction to OWTU'S complaints could act as a catalyst for reviving these negotiations. The investigation of TEXTRIN's activities was not concluded by the end of 1979.

[5]Owing to a series of devaluations of the Jamaican dollar (J$), conversion to a U.S. dollar equivalent is impractical. In May 1978, the exchange rate averaged J$1.55=US$1.00; in December 1978, the exchange rate averaged J$1.70=US$1.00; and in May 1979, the exchange rate averaged J$1.78=US$1.00.

The Mineral Industry of Central American Countries

By Doris M. Hyde[1]

CONTENTS

BELIZE

The economy of Belize continued to be relatively unaffected by activity in the minerals sector. Mining production consisted of limestone, marl, and sand and gravel. All production was used for domestic construction projects.

By the end of 1979 the major oil companies had, temporarily at least, ceased active exploration efforts. Esso Ventures, Inc., after drilling three dry holes in southern Belize, planned to reappraise its activities. The Reef Exploration, Ltd., concession was acquired by Anschutz Oil Co. (81.25%), with minority interests held by Anglo Oil Co. and Carolina Oil Co. The Anschutz group drilled offshore in the Gulf of Honduras and in Belize Harbor. Echo Exploration has a concession along the Mexican border and Spartan Petroleum Corp. obtained seven exploration licenses covering 768,000 acres in northern Belize. Spartan's concessions included about 130,000 acres offshore, with the remainder along the southeastern rim of the Yucatán Peninsula. Placid Oil Co. took an interest in the Spartan acreage and became operator. Seismic exploration was underway in 1979. A Mexican company, Pan American Oil and Gas, S.A., was awarded two exploration concessions, one in southern Belize and one near the Mexican border.

To date, the theory that there exists a relationship between the prolific Reforma and Campeche fields of Mexico and geologically similar strata in Belize has not resulted in any oil discoveries.

[e]Estimate. [p]Preliminary. [r]Revised. NA Not available.
[1]Reported figure.
[2]Ni content of sinter.
[3]Exports.
[4]In addition to the commodities listed, Nicaragua produces a small but undetermined quantity of cadmium contained in zinc concentrates for export.
[5]Excludes 8,000 cubic meters per year.

COSTA RICA

External events during 1978-79 negatively influenced Costa Rica's economy. The civil conflict in Nicaragua resulted in a cutoff of traditional sources of raw materials as well as transportation links with other Central American countries which represent both buyer and seller for Costa Rican trade. Imports cutoff completely or on an interrupted basis included resins, gypsum for the cement industry, and paint pigments. Efforts to bypass the closed Nicaraguan border by using sea routes met with limited success.

Problems associated with a rising inflation rate and an increasing trade deficit were aggravated by the escalating cost of oil imports. In 1977 oil imports amounted to $93.8 million, or 9.4% of total imports; in 1978 the cost rose to $123.2 million, representing 10.4% of total imports; for 1979 oil imports costs were estimated at $190 million, about 14% of total imports.

No petroleum exploration rights are held in Costa Rica and the issuance of mineral exploration permits has been at a virtual standstill. New mining and petroleum legislation designed to encourage foreign investment and at the same time protect the national interest has been under contemplation for several years.

As Costa Rica's hydroelectric capacity is expanded, the demand for imported oil should lessen. The Government electric utility, Insituto Costarricense de Electricidad (ICE), expected its oil consumption to decrease after the late 1979 inauguration of the 157-megawatt first stage of the Arenal hydroelectric project. Looking ahead, ICE also estimated that oil imports for electricity generation will not be required after 1981. Financing has been obtained for the Corobici power project, a 174-megawatt facility, which will also use Lake Arenal to power the generating units. Corobici should be operational in 1983, at which time the country's total hydroelectric capacity will be 768 megawatts. Final design studies were underway for the future construction of the 760-megawatt Boruca hydroelectric project on the Río Grande de Térraba, upstream from Palmar Norte in southern Costa Rica.

A large portion of Boruca's output would supply a proposed 300,000-ton-per-year primary aluminum processing plant which Martin Marietta Aluminum Corp. is interested in building in Costa Rica. The feasibility of the aluminum smelter construction has been keyed to the availability of economical electric power from Boruca.

In mid-1979 Costarricense de Desarrollo S.A. (Codesa), the State development corporation, outlined plans for developing bauxite reserves in El General Valley. The continuing bauxite feasibility studies include refining and smelting facililties. The bauxite deposits under investigation incorporate and extend beyond the former Aluminum Co. of America (Alcoa) concession which was abandoned in 1976 as uneconomical due to the low grade of the ore (30% alumina content). Martin Marietta has not participated in Codesa's bauxite investigations.

United Hearne Resources completed its feasibility study for the Santa Clara gold property. The ore reserves estimate was increased to 6 million tons with a cutoff grade of 0.03 ounce of gold per ton and included about 3.6 million tons of minable ore grading 0.07 ounce of gold per ton. Tests were conducted using a cyanide leaching process and a 90% gold recovery was obtained.

Test cores taken from the Osa Peninsula in southern Costa Rica revealed gold mineralization. Of 25 test holes, 13 contained material grading up to 0.03 gram of gold per cubic meter and 5 holes were graded between 0.99 and 3.7 grams of gold per cubic meter. Metro International Corp. holds claims to about 740 acres on the peninsula. Barranca Corp. has an interest in the Metro properties, as well as a 30% interest in Hearne's Santa Clara gold mining operation.

Table 2.—Costa Rica: Exports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1975	1976	Principal destinations, 1976
METALS			
Aluminum metal including alloys, unwrought and semimanufactures	331	264	Nicaragua 82; El Salvador 68; Guatemala 57.

EL SALVADOR

In 1978 real economic growth in El Salvador amounted to 4.2%, a decrease from the 5.2% growth rate obtained during 1977. By mid-1979, a 4.5% growth rate was expected for that year, but an unexpected change of government leadership and continued political, civil, and economic instabilities made this estimate unreliable and less than a 2.0% rate appeared more likely at yearend.

The mineral industries contributed an insignificant amount to the gross domestic product in 1978. Gold and silver continued to represent the major mining activity with 1978 production valued at approximately $2.5 million. Other mining activity consisted primarily of construction-oriented material.

In July 1979, a new hydrocarbon law was submitted to the legislature. The law follows the service contract model. All petroleum resources were declared property of the State which may contract with private entities for exploration and exploitation. The risks and cost of exploration would be borne by the private company. In the event of a commercial discovery, a joint venture with the State would be formed for exploitation. No legislative action was taken during 1979 on the proposed hydrocarbon law. There have been no petroleum exploration permits issued in El Salvador.

El Salvador's oil import costs have risen steadily. In 1973 they represented 5.9% of export earnings; in 1978, the proportion had increased to 16%; and 1979 costs have been estimated at 19% of export earnings. The country consumes a high proportion of light petroleum products, such as diesel fuel, kerosine, and liquid petroleum gas. Conservation measures and price increases were expected to help hold the petroleum consumption increase to about 2% during 1979.

Hydroelectric and geothermal resources provided 304.2 megawatts of electric power capacity, more than enough for current use. An additional 186.8 megawatts are available from thermal plants which have been taken offline as representing surplus capacity. This action reduced petroleum consumption by 800,000 barrels per year. The thermal plants are maintained but only brought online during the dry season. Total potential geothermal capacity at Ahauchapán has been placed at 300 megawatts. Present installed capacity is 60 megawatts. Potential unused hydroelectric resources were estimated at 840 megawatts, but 500 megawatts of this must be considered as tentatively potential due to its geographic location along the Honduran border. Abundant power provides El Salvador the ability to expand industrially without undue concern for the growth of exports to pay for petroleum import costs.

Minas San Cristóbal S.A., opened its Los Encuentros Mine in 1979, processing the gold-silver ore at the San Cristóbal mill. The company also owns the El Divisadero Mine and holds an option on the Monte Mayor silver-gold mine located northeast of the Divisadero property.

Assessment activities continued on the Zancudo and Minita veins in the old El Dorado Mine, located in the Department of Canabus, which had ceased operation around 1950. Work has been carried out by Bruneau Mining Corp., a Canadian company.

In late 1979 it was reported that the Instituto Salvadoreno de Desarrollo Industrial (INSAFI) and the Comisión Nacional de Petróleo (CONAPE) have begun a $1.5 million geological survey to locate exploitable mineral deposits.

GUATEMALA

Guatemala's real economic growth continued to slow, falling from 8.3% in 1977 to 5.5% in 1978 and an estimated 4.5% in 1979. In 1978, the gross domestic product was about $5.8 billion in terms of 1976 dollars. The rate of inflation decreased from 12.6% in 1977 to about 8% in 1978. In 1979, the rate climbed to an estimated 11%, among the lowest in Latin America where inflation growth averaged about 27% for the region.

The cost of crude oil and its distillates added $167.7 million to the total value of imports during 1978, up 13% from that of 1977. The 1979 crude oil and distillates total import cost was about $219.3 million, a 31% cost increase over 1978 on what was estimated to be lower volumes. The projected cost for 1980 petroleum imports was $400 million. The value of petroleum exports in 1980 was estimated at $43 million. Guatemala produces about 13% of its oil requirements.

In 1978 the Government took further steps to encourage petroleum exploration. In January regulations were issued pertaining to the December 1975 revised petroleum law, a model contract was provided as a basis for negotiation, and six northern onshore areas were opened for bidding.

The regulations consisted of 201 articles that set forth definitions and obligations of both the Government and the contractor for the exploration and production of petroleum. The model contract was typical of such documents with most negotiable items left open. At the end of 1979 the Government raised the possibility that all existing oil and mining concession agreements might be renegotiated to increase the State's share of production.

The lateritic nickel mine and processing plant inaugurated in 1977 by Exploraciones y Explotaciones Mineras Izabal S.A. (Exmibal), owned by Inco. Ltd. (80%) and Hanna Mining Co. (20%), fared poorly in the wake of continued adverse nickel markets and shortages of fuel. The plant was closed down for 2 months starting in December 1978 and then again a few months later to allow rebuilding of slag separation facilities. By the end of 1979, Exmibal had increased its development activities.

Barite production should increase sharply when Cía. Minera del Caribe, S.A., and Fluidos de Centroamerica, S.A., bring their mining operations into production in 1980. They and the two other barite companies, Baritas de Guatemala and Tracmasa, will benefit from the increased oil exploration underway.

The shortage of cement continued during 1978 and demand was estimated at about 1,300 tons per day more than domestic production could supply. Legal importation could not cover the shortfall; a situation which worsened when El Salvador, due to its own increased domestic needs, banned export sales of cement to Guatemala. An import agreement was made with Honduras to supply about 7,000 tons of cement per month, some of which was believed to originate in Cuba. In November of 1978, the Government declared cement a matter of national emergency and stipulated that the El Progreso plant would have to sell 40% of its output to State firms at the fixed price of $1.50 per 110-pound bag. Cementos Novella, S.A., increased capacity at the San Miguel plant by 1,600 tons per day.

During 1978-79 the Government offered 8 areas for petroleum exploration. In 1978, bids were accepted for 3 of the 6 areas offered that year. One area went jointly to Texaco Oil Co. and Amoco Oil Co.; one to a consortium led by Getty Oil Co.; and one concession area was granted to Hispanica de Petroleos (Hispanoil) of Spain as operator, with Societe Nacional Elf Aquitaine and Petróleo Brasileiro S.A., as equal partners. Towards the end of 1979 the three untaken areas from the 1978 offering plus two additional areas were opened for bidding. The concessions are located in northern Guatemala where it is hoped that extensions of Mexico's productive southern zone will be found.

Texaco will invest about $20 million for exploration and the drilling of two wells to a depth of at least 12,000 feet. Getty's investment will exceed $19 million for exploration and drilling five wells to a depth of at least 9,000 feet. The Hispanoil group will invest over $12 million for exploration and drilling three wells to a depth of at least 9,000 feet.

Basic Resources International, S.A. (BRISA) purchased the Guatemalan subsidiary of Shenandoah Oil Co. and thus acquired a 100% ownership of the Rubelsanto Field. BRISA also obtained Shenandoah's 30% interest in the West Chinaja and Tortugas areas making their ownership now divided between BRISA, 30%, and BEA Petroleum Ltd., 70% (owned jointly by BRISA, 79%, and Elf Aquitaine, 21%).

In late 1979 BRISA completed the 230-kilometer pipeline from the Rubelsanto Field to Puerto Barrios on the Caribbean. Prior to this, oil was hauled by trucks.

Despite sporatic flurries of publicity, the promoters of a Guatemalan transcontinental oil pipeline project have yet to receive Government approval. The pipeline project has been under discussion for several years.

HONDURAS

In 1978-79 Honduras maintained its real economic growth rate, in terms of 1966 dollars, as one of the highest in Latin America. In 1978, the gross domestic product (GDP) increased 6.3% over that of 1977, and in 1979 it increased 6.7% over that of 1978. The rate of inflation was less than 6% in 1978; but by the end of 1979, after moderate increases for most of the year surged upward during the last quarter, the consumer price index was almost 19% higher than a year earlier. The Government officially estimated the rate of inflation for 1979 as 8.8%.

Honduras has remained dependent on imported oil and, although consumption has been a relatively low 12,000 barrels per day, successive price increases have diverted financial resources from development needs. In 1978 the fuel import cost was $76 million, almost 8% of the total value of imports, and by 1979 its cost had risen to $112 million, or about 11% of total imports. Energy conservation measures, including higher domestic prices, helped curb the growth of petroleum consumption in 1979 to 0.5% over that of 1978 when consumption was 2.5% greater than in 1977.

The El Mochito gold, silver, lead, and zinc mine of Rosario Resources Corp., was the principal mining operation during 1978-79. Increased reserves were obtained from downward and westward extensions of the San Juan orebody. Plant throughput increased to about 1,000 tons per day of ore in 1978 and was expected to be expanded to 2,300 tons per day by 1982. The San Juan sulphide orebody extensions were reported to average 3.8 ounces of silver per ton and contain 3.9% lead, 8.59% zinc, and 0.6% copper.

Canadian Javelin Ltd. planned to open the Moramulca gold-silver mine located in the Department of Choluteca. Mill capacity was expected to be 140 to 180 tons per day of ore.

A study was underway by Altos Hornos de Centro-America S.A. (AHCSA) to determine the feasibility of mining iron deposits near the capial city of Tegucigalpa as feed for a charcoal-fired blast furnace. AHCSA has been involved with a proposed $95 million steel plant at Agalteca. Steel production at the proposed plant was projected at 100,000 tons per year, half of which would be exported.

In 1978 a small iron and steel mill and foundry was the object of a proposed joint venture, Fundiciones Centroamericana, S.A., planned by the U.S. company, Obenchain Corp., and the Honduras Government's investment promotion agency, Corporación Nacional de Inversiones (CONADI). The $5.5 million plant complex would be established near San Pedro Sula and include iron ore reduction cupolas, electric steelmaking furnaces, iron and steel casting and forging, and related ore grinding and pelletization facilities. Ultimate annual capacity was expected to be 75,000 tons of iron and steel with initial output at about 25,000 tons per year.

Products from the Fundiciones project would include steel billets, rods, grinding balls, and forged and cast parts. Iron ore and limestone deposits are located about 10 miles from the projected plant site, although initially iron ore would be imported from Venezuela. As envisioned, the plant design would provide a pilot-scale proving ground for new technology in steelmaking as well as provide Honduras the obvious direct and indirect benefits derived from industrial development. Financing and additional partners were being sought.

In 1979, a new $80 million cement plant was under construction by Industria Cementera Hondureña, S.A., north of Tegucigalpa. Plant capacity was planned at about 360,000 tons per year. In 1979 Honduras purchased cement from Cuba, the first trade with that country in 17 years.

In 1978, 11 companies held onshore or offshore petroleum concessions. Two offshore wells were drilled in 1978 by Esso Standard Oil, S.A.; and Texaco Caribbean, Inc., was scheduled to drill at least one well in 1979. No discoveries were reported.

Table 8.—Honduras: Exports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1977	Principal destinations, 1977.
METALS		
Antimony ore and concentrate, gross weight	103	United Kingdom 42; Japan 35; Belgium-Luxembourg 25.
Iron and steel metal including alloys, all forms	1,571	Guatemala 893; Costa Rica 364.
Lead:		
Ore and concentrate, gross weight	35,244	All to United States.
Metal including alloys, all forms	19	All to Guatemala.
Silver:		
Ore and concentrate value, thousands	$11,574	Mainly to United States.
Metal including alloys, all forms thousand troy ounces	50	All to United States.
Zinc:		
Ore and concentrate, gross weight	52,716	United States 31,616; Japan 10,350.
Metal including alloys, all forms	63	West Germany 58.
Other: Ash and residue containing nonferrous metals	26	All to United States.
NONMETALS		
Cement	2,279	Belize 1,296; Guatemala 855.
Clays and clay products (including all refractory brick):		
Crude	22	Mainly to Nicaragua.
Products	74	Guatemala 41; Costa Rica 33.
Fertilizer materials, manufactured, phosphatic	7	All to Guatemala.
Lime, hydraulic	7	Mainly to Nicaragua.
Salt	117	All to Nicaragua.
Stone, dimension, crude and partly worked	20	Do.
Other: Building materials of asphalt, asbestos, and fiber cement, and unfired nonmetals, n.e.s	63	Spain 35; Nicaragua 24.
MINERAL FUELS AND RELATED MATERIALS		
Petroleum refinery products:		
Residual fuel oil thousand 42-gallon barrels	53	Mainly to Trinidad and Tobago.
Lubricants do	([1])	All to Guatemala.

Pigments, mineral, natural, crude do	60	All to Guatemala.
Precious and semiprecious stones, except diamond troy ounces	900	Switzerland 482; United States 354.
Salt	396	United States 384; Canada 12.
Sodium and potassium compounds, n.e.s.:		
Caustic soda	4,342	Nicaragua 3,502; United States 421.
Soda ash	9,648	Romania 7,156; Netherlands 1,407.
Caustic potash	9	United States 7; Colombia 2.
Stone, sand and gravel:		
Dimension stone, all forms	106	Guatemala 75; United States 26.
Other stone	19	All from Guatemala.
Sand, including ground quartz	77	United States 74.
Sulfur:		
Elemental, all forms	23	Mainly from Belgium-Luxembourg.
Sulfuric and sulfurous acids	380	Netherlands 115; United States 113.
Talc and steatite	148	United States 66; China, mainland, 40.
Other:		
Crude	98	West Germany 83; United States 15.
Building materials of asphalt, asbestos, and fiber cement, and unfired nonmetals, n.e.s	4,036	Costa Rica 3,115; Nicaragua 540.
MINERAL FUELS AND RELATED MATERIALS		
Coal and coke, including briquets	143	United States 81; Belgium-Luxembourg 60.
Hydrogen	70	United States 61; West Germany 9.
Petroleum:		
Crude and partly refined thousand 42-gallon barrels	3,158	Venezuela 1,923; Trinidad and Tobago 1,201.
Refinery products:		
Gasoline do	126	Trinidad and Tobago 64; Aruba 22; Nicaragua 22.
Kerosine and jet fuel do	50	Nicaragua 26; Panama 10; Trinidad and Tobago 10.
Distillate fuel oil do	387	Trinidad and Tobago 235; Aruba 78; Panama 44.
Residual fuel oil do	39	Aruba 20; Venezuela 19.
Lubricants do	61	United States 43; Jamaica 10.
Other:		
Liquefied petroleum gas do	40	Venezuela 39.
Mineral jelly and wax do	15	Japan 8; United States 3.
Unspecified do	93	Curaçao 63; Nicaragua 29.
Mineral tar and other coal-, petroleum-, or gas-derived crude chemicals	5,420	United States 4,089; Italy 1,079.

NICARAGUA

At the end of 1979 Nicaragua was attempting to resolve an economic crisis arising from about $600 million in service payments due on external debts totaling $1.5 billion. Available monetary reserves, although increasing, remained extremely low and precluded any immediate possibility of even partial payment. The Government was renegotiating the foreign loans to secure a realistic repayment schedule. Although economic vulnerability began several years earlier, problems were primarily caused by inadequate monitoring of loan use, and more recently by strikes, civil insurrection, and fighting which gained intensity during 1978 and finally culminated in the overthrow of the Government in July 1979.

In real terms, the gross domestic product declined by 5.5% in 1978 and by an estimated 25% in 1979. Steps toward restoring domestic and international confidence in Nicaragua's economic prospects were initiated in 1979 and the Government was proceeding with reconstruction planning.

A series of government actions in the latter half of 1979 included the nationalization of the mineral industries. In October it was announced that a national petroleum company, Empresa Nacional del Petróleo, would be established in the near future. The new company would operate under the jurisdiction of the Ministry of Foreign Commerce and assume the responsibility of purchasing all of the petroleum required by the local refinery operated by Esso Standard Oil, S.A., Ltd., which had been purchasing Venezuelan crude oil on a cash basis. As a Government entity, it was anticipated that the new company might be able to negotiate more favorable purchase terms which would ease the drain on available foreign exchange and defer the necessity of increasing the domestic price for refined products.

Pre- and post-revolutionary disruptions of normal economic activities resulted in reduced petroleum consumption. In 1977, Nicaragua imported about 5.4 million barrels of crude oil with a value of $77.9 million. In 1978, imports of crude declined to 3.9 million barrels valued at $57.8 million. It was estimated that in 1979 the volume did not exceed that of the preceeding year.

Through Decree No. 112 dated August 24, 1979, the Government established an institute of natural resources and environment, Instituto Nicaraguense de Recursos Naturales y del Ambiente (IRENA). The decree stated that Nicaragua's natural resources were the exclusive patrimony of the nation and that their management and exploitation was the State's exclusive jurisdiction. The State could delegate, when convenient, part of the country's natural resources to corporations and enterprises. IRENA's responsibilities, through its own actions or through its subsidiaries, include the planning, administration, control, and exploration of all natural resources.

A decree dated November 2, 1979, nationalized the Nicaraguan mining industry. Owners of mining companies were to be compensated at book value through bonds earning 6.5% with a 5-year amortization, which included 1 year of grace followed by four equal annual payments. The State reserved the right to claim indemnization for human damage, ecological deterioration, and fiscal evasions that may have resulted from the operations of the mining companies in Nicaragua. The decree also cancelled all rights granted by the previous Government for mineral exploration and exploitation.

The decree created a Nicaraguan Corp. for Mining Development (Codemina) to manage all mineral properties. Codemina will receive advice and coordination from IRENA. Shortly after the decree was issued the mining companies withdrew their foreign personnel from the country. Peru agreed to assist Nicaragua in developing its mining sector and appointed a technical mission for this purpose.

The principal companies affected by nationalization were Rosario Mining of Nicaragua, Inc., a subsidiary of Rosario Resources Corp., which recovered gold and silver from the Risco de Oro, Blag, La Luna, and Siuna mines; Neptune Mining Co., jointly owned by ASARCO, Inc. and Rosario Resources, which mined gold, silver, zinc, lead, and copper from the Vesubio mines at Bonanza; and the Empresa Minera de El Sententrion, majority owned by Noranda Mines, Ltd., which operated the Limón gold mine.

In February 1979, the Government contracted with a Japanese company to build a 35-megawatt geothermal energy plant on the flank of the volcano at Momotombo. This $57 million plant, scheduled for completion in 1981, was the first of three geothermal plants planned for Momotombo to provide a total of 105 megawatts of power at a total estimated cost of $117.5 million. It was anticipated that the project would be completed in 1983. A U.S. company, California Energy Corp., had supervised drilling operations and supposedly was to manage and develop the project.

Exploration activities by the several foreign petroleum companies who hold on- and offshore concessions came to a virtual standstill during 1978-79.

PANAMA

The gross domestic product (GDP) continued to benefit from the stimulus provided by the signing, ratification, and implementation of the Panama Canal Treaty. Real growth in the GDP registered 2.7% in 1978 and in 1979 was estimated at 4.5%, the highest rate since the early 1970's. Panama's rate of inflation was 4.2% in 1978 and about 7.5% in 1979, among the lowest in all Latin America.

The balance of trade deficit increased during 1978-79 as an expanding road system and growing air traffic added to oil import costs. Refined petroleum continued to be the country's biggest export earner. Petroleum refining accounted for about 25% of export earnings. The nonfuel minerals sector has had a negligible effect on the economy.

Development of the proposed $2 billion Cerro Colorado copper complex has been delayed because of questions regarding economic viability at the current market price for copper and assured adequate financing. In 1978 the Canadian Export Development Corp. announced its agreeement in principle to lend $1.1 billion for the project.

Towards the end of 1979 the Government announced that it would reduce its 80% equity in the project by as much as 20% or 30%. Texasgulf, Inc., appeared to be unwilling to increase its 20% equity in the venture. Texasgulf reported it would assist in finding other equity participation or, if convenient to Panama, would withdraw from participation in favor of a company willing to assume a 40% equity. The Government claimed that several companies had expressed interest in the project.

In 1978, Cobre Panama, S.A., a Japanese consortium composed of Mitsui Mining and Smelting Co. Ltd., Mitsubishi Metal Corp., and Dowa Mining Co. Ltd., began negotiations with the Government for development of the Petaquilla copper deposits. It was reported that reserves amount to about 300 million tons of ore averaging 0.7% copper. Costs for the project to produce copper concentrate were placed at about $250 million for a 20,000-ton-per-day ore mining facility. Negotiations were expected to continue for an extended period of time.

In 1978, Earth Resources International was reported to be operating manganese properties in a joint venture agreement with Merimax, S.A. The concession is located in the Distrito de Portobelo. In 1978 work was progressing on road construction and a docking area at Bahía de San Cristóbal. No further information has been made available.

Petroleum exploration has not yet resulted in any reported commercial discoveries. In 1978, Texaco Inc., through its subsidiaries Carib Exploration S.A., San Blas Exploration, S.A., Colon Exploration S.A., Balboa Exploration S.A., and Isthmus Exploration S.A., was awarded an additional 9,500 square miles of offshore concessions. In 1979 Texaco drilled unsuccessfully on the offshore concession held jointly with Amerada Hess Corp. Sossa Petroleum and Tacoma Resources were also unsuccessful in their joint drilling effort.

In April 1979, the Puerto Armuelles onshore terminal for the transshipment of Alaskan crude oil through the Panama Canal began operations. Petroterminal de Panama, S.A. (PTP) is jointly owned by the Panama economic development agency, Corporacion Financiera Nacional (25%), and a group headed by Northville Industries Corp. (60%), within which Telepsen Wallace of Houston, the construction contractor, and Chicago Bridge and Iron each hold a 7.5% interest.

The cost of the terminal was estimated at about $58 million, about $11 million more than the 1977 preconstruction estimate. The terminal, managed by Northville, can accommodate 550,000 to 600,000 barrels of oil per day. The terminal has three berths, three storage tanks, ballast and fresh water systems, and fire protection equipment. An access trestle to shore is connected to two of the jetties while the third birth is connected to shore by two 36-inch pipelines. The three berths can service tankers of 265,000 tons, 90,000 tons, and 60,000 tons, respectively, with 30,000 tons being the minimum size tanker for all three.

The Mineral Industry of Other Areas of the Far East and South Asia

By Staff, Branch of Foreign Data

CONTENTS

BANGLADESH[1]

The only economically important mineral currently produced in Bangladesh was natural gas. Bangladesh was not a world-ranked producer of any mineral commodity, but the possibility of producing and exporting commercial amounts of liquefied natural gas (LNG) was being examined. Proved reserves of natural gas were sufficient to supply most of the country's industrial and domestic heating and electric needs and still support an export-oriented LNG plant. Other mineral production was of virtually no significance to the economy, although there were a few prospects for nonmetallic mineral development.

Bangladesh continued to make economic progress during 1978 and into early 1979. Gross domestic product (GDP) at current prices rose from $6.6 billion in 1976-77[2] to $8.2 billion in 1977-78 and $9.3 billion in 1978-79.[3] In fiscal 1979, the economic conditions were favorable until a severe drought hit most of the country. It was reported that conditions were the worst in 40 years, and as of July 1979, substantial crop losses were predicted. The agricultural sector accounts for over 53% of the GDP and about 75% of all employment. The poor weather will cause economic problems in the form of slower growth, larger trade deficits, and a higher rate of inflation. The 1978-79 statistics showed that real GDP increased just 4%.

Population growth of about 2.8% per year continued to be a major problem for the country. The population was approaching

88 million by yearend 1979, and approximately 50% of the total had not reached their 18th birthday. Overall rural population density remained one of the highest in the world.

The Government's policy was to encourage new industry in the less developed and nonmetropolitan areas. Government incentives included liberal tax holidays, permission to bring in management teams and supervisors, and a "one stop" investment coordinating office to cut red tape. Since 1975, the country has moved slowly to resurrect previously nationalized private enterprise. Local businessmen have begun limited investment, and foreign capital has been trickling in. More than 100 industries have reportedly been denationalized and about 500 small shops and factories turned over to the private sector. Despite these changes, more than 80% of the industrial assets still remain under Government ownership. In addition to utilities, the Government has reserved basic jute, textile, and sugar processing and manufacturing as public industries. Specialized jute and textile operations, however, have been opened to the private sector.[4] In FY 1977-78, foreign investments worth $17 million were approved and actual money invested totaled $11.8 million. The primary areas of foreign investor interest included deep-sea fishing, shrimp culture, leather, garment making, food processing and pharmaceuticals. Foreign investment in Bangladesh has some disadvantages. The investor must cope with a poorly developed transportation and communications network, a limited domestic demand, an unskilled labor force, and an often stifling bureaucracy.

Power generation and distribution is wholly inadequate. Installed generating capacity is only 752 megawatts; total generation in FY 1978 was 1,912 million kilowatt-hours, 22 kilowatt-hours per capita. In comparison, Thailand used about 250 kilowatt-hours per capita and the United States 9,400 kilowatt-hours per capita. New generation facilities totaling 125 megawatts were planned. Distribution was being improved under a rural electrification plan.

The inflation rate, stimulated by shortages of crucial raw materials, by devaluations of the taka, and by a large increase in the money supply, rose to 15% during 1978-79. The cost of living indices also begin to rise rapidly during the fourth quarter of 1978-79 in response to high open market food grain prices and increase in the prices of certain subsidized products. The Dacca middle-class cost-of-living index rose over 14% between June 1978 and June 1979, and 9.7% alone in the last quarter of FY 1979.

Exports rose to $497 million in FY 1977-78 and then totaled $602 million in FY 1978-79. The sale of minerals was an insignificant part of the export market in 1978 and 1979. Jute, tea, and leather accounted for nearly all of the export value.[5]

Imports totaled $1,274 million during 1977-78 and increased to $1,572 million in 1978-79. The major import items were raw materials, industrial goods, and food grains. Because of the sharp increase in imports, the balance-of-trade deficit more than doubled from 1976-77 through 1978-79 and stood at nearly $1 billion at fiscal yearend.

COMMODITY REVIEW

Bangladesh's proved natural gas reserves were placed at over 250 billion cubic meters in 1979, greater than Asian producers like Afghanistan, Brunei, and India. Output, however, was very low compared with potential production. In an effort to increase production and decrease petroleum imports, several nations either signed agreements or were negotiating with Bangladesh in 1979 to help in the development of its gas reserves. The Asian Development Bank advanced an additional $25 million for the gas-based fertilizer plant under construction at Ashuganj. The United Kingdom was to provide funding to help boost output at the Titas Gasfield. The Titas Field is to supply the Ashuganj plant with feedstock. Output will reportedly be tripled as a result of the improvements.

Other plans call for construction of a 196-kilometer-long, 60-centimeter-diameter pipeline from the Bakhrabad gas discovery to the Chittagong area. Various industries would switch to natural gas from oil, or be established to use natural gas as their energy source and/or raw material. The World Bank, which was asked to finance the project, has questioned the initial cost and advised a smaller size pipeline be constructed. Earlier tentative plans for an export-oriented liquefied natural gas plant had been postponed because of the high cost and current lack of an assured market.

Bangladesh's first liquefied petroleum gas (LPG) plant was inaugurated in July 1978 at the Eastern Refinery, Ltd., in Patenga, Chittagong. The plant will produce about 6,000 tons per year of LPG from refinery waste gas which was formerly flared. The LPG will be used for domestic fuel in place of imported kerosine.[6]

The vigorous offshore oil exploration program has yielded no commercial oil discoveries and only one gas strike. Several of the foreign drilling companies which held production sharing contracts with the Government withdrew from further drilling during 1977 and 1978. No offshore drilling was reported during the first half of 1979.

Bangladesh imports all of its petroleum needs, mostly as crude oil and diesel fuel, but with supplemental amounts of other refined products as well. There were shortages of diesel fuel in March 1979 because of the changes in Iran, Bangladesh's major supplier in past years. Several other countries, however, helped to supply the shortfall and no severe problems were reported. The Government was making arrangements to import petroleum from a number of different suppliers in coming years.

Except for natural gas production, the mineral industry contributed virtually nothing to the overall economy in 1978 and 1979. Some mineral projects were, however, in the planning stage and while insignificant by world standards, could mean a great deal to the local economy.

Bangladesh's construction sector is a potentially large market for hard rock building stone and aggregate, perenially in short supply because of the river delta setting of most of the country. The Government proposed to develop the large Ranipukur granite gneiss deposit at Madhyapara in the northwest. The deposit is deeply buried beneath the surface. The Saudi Development Fund will reportedly provide the $32 million needed to construct the underground mine. The State-owned Bangladesh Mining Corp. will undertake the 1.7-million-ton-per-year project. The mine will provide direct employment for 600 men and indirectly another 1,800 workers. Construction of the project was to start in February 1979 and be operational by yearend 1981. However, building of the requisite infrastructure may double the cost and delay the starting time of the project.[7]

Another plan by the Government was the development of the cement industry. The plan envisioned a limestone mine and clinker production plant being set up at Jaipurhat in Bogra District. The deposit, containing about 100 million tons of cement-grade limestone, lies at a depth of more than 500 meters. The mine will be designed to supply 5,500 tons per day of limestone. Estimated cost of the limestone project will be over 100 million dollars. Bangladesh currently needs about 308,000 tons of limestone annually for cement factories and other uses. Of the total needs, 60,000 tons of limestone are produced by the existing Takerghat limestone mine and the balance is imported from India. The new mine will meet the country's current demand as well as that of the planned cement factory.

A large cement plant will be built at Jaipurhat and will ultimately produce 3,000 tons per day of clinker. The first stage construction will supply 1,000 tons per day of clinker to an existing plant at Chittagong that presently imports clinker, and 1,000 tons per day to a planned grinding plant at Khulna. The final stage will be to put in a clinker grinding section at Jaipurhat and bring the plant to the final 3,000 tons per day capacity. Cost of the cement project was estimated at $120 million. Foreign credit had not been secured for the project at yearend 1979.[8]

Bangladesh imports cement from countries such as North Korea and Indonesia since demand generally exceeds the local production capacity.

The Government was considering the establishment of a 500,000-ton-per-year direct-reduction-based steelworks. The plant would use imported ore but domestic natural gas as reductant and fuel.

The Bangladesh Atomic Energy Commission has been conducting geologic exploration for uranium in the hills of Sylhet and the placer sands off Chittagong. Reportedly, mineral deposits containing both thorium and uranium were confirmed in early 1978 after more than one year of work.

Construction continued during 1978 and 1979 on a large and increasingly expensive nitrogen fertilizer plant at Ashuganj. The plant is scheduled for completion in late 1980 and will significantly reduce Bangladesh's need to import nitrogenous fertilizer. Rapidly rising costs during the construction period, however, caused problems and the need for additional financing from the Asian Development Bank. The 1,600-ton-per-day-urea plant was originally estimated to cost $250 million but will probably exceed $430 million before it goes into production. Despite the increased cost, the project was considered to be economically and financially sound. The Government has emphasized that it has accorded the highest priority to the completion of the plant, which is needed to help the country achieve self-sufficiency in food production and increase agricultural production for export.

Table 1.—Other Areas of the Far East and South Asia: Production of mineral commodities

Area, commodity, and unit of measure	1976	1977	1978[p]	1979[e]
BANGLADESH[1]				
Cement, hydraulic[2] ---- metric tons	[r]157,000	307,600	341,000	[3]304,000
Clays: Kaolin ---- do	1,575	[2] [4]4,211	[2]6,524	6,350
Gas, natural, marketed[5] ---- million cubic feet	31,344	32,026	34,294	[3]42,975
Iron and steel:[2]

[e]Estimate. [p]Preliminary. [r]Revised. NA Not available.
[1]In addition to the commodities listed, other crude construction materials such as sand and gravel and other varieties of stone presumably are produced, but available general information is inadequate to make reliable estimates of output levels.
[2]Data are for years ending June 30 of that stated.
[3]Reported figure.
[4]May include other clays.
[5]Gross production is not reported; the quantity vented, flared, or reinjected is believed to be negligible.
[6]In addition to the commodities listed in the body and footnote 1, molybdenum production was initiated in October 1978, but output is not reported and no basis is available for reliable estimates of output levels.
[7]In addition to the commodities listed, iron ore was mined in the past and pig iron and crude steel were produced at industrial facilities, but the status of these industries under prevailing conditions is not sufficiently clear to allow formulation of reliable estimates of output levels. Similarly, data on output of crude construction materials are not available and no reliable basis for estimation is available.

[1]Data are for the fiscal year, which is the year begining July 1 of that stated.
[2]Figures include 338,192 metric tons valued at $14,360,780 in 1976-77 and 393,860 metric tons valued at $23,767,315 in 1977-78.

BRUNEI[9]

Brunei, a small country on the northwest coast of Kalimantan island (formerly called Borneo), was one of the world's largest exporters of liquefied natural gas (LNG). It was also an important South Asian exporter of crude oil in 1978 and 1979. Brunei's economy was almost totally dependent on oil and natural gas.

In both 1978 and 1979, as in the past few years, Brunei was one of the few nations in the world having a very significant budget surplus, estimated to be about $600 million in 1978,[10] resulting in a balance in the consolidated revenue fund of $2.8 billion for a nation of fewer than 200,000 population. The projected surplus by the end of 1979 was to reach about $3.4 billion.

Neither oil nor natural gas production in 1979 was expected to vary a great deal from the output levels in 1978. Natural gas sales in particular were virtually fixed by the capacity of the liquefaction plant at Lumut which has run at designed capacity since completion in mid-1976. The gross national product (GNP) for 1979 will be closely tied to the price obtained for exported crude oil and LNG. The Government reportedly earned about $960 million in 1978, and earnings were projected at around $1,022 million for 1979.[11] Government earnings were derived mainly from dividends, taxes, and royalties from the production of oil and natural gas. A small income also came from the sale of timber and natural rubber.

Recurring Government expenditures were approximately $385 million in 1978, approximately $420-$450 million was to be spent during 1979. By far the largest expense was for the upkeep and improvement of the Royal Brunei Military Regiment.

Spending for development projects was to take about $90 million during 1978, but owing to slow deliveries and optimistic building schedules, only $46 million was actually used on new Government construction projects.

On January 7, 1979, Brunei and the United Kingdom signed a treaty that will grant Brunei full political independence at the end of 1983. It replaced the treaties of 1959 and 1971 that gave the Sultanate self-government but allowed the United Kingdom responsibility over its external defense and foreign relations.

In order of value, the major exports from Brunei were crude oil, 62%; LNG, 32%; and refined petroleum products, 4%. The major imports were consumer goods, plant and capital equipment, raw materials, and food.

COMMODITY REVIEW

Petroleum and Natural Gas.—Crude oil production was from the Seria, Ampa SW, Fairley, and the Champion Oilfields. Output by the Champion Oilfield, discovered in 1970, rose significantly to more than offset the decline in production of the older fields. Brunei Shell Petroleum Co. (Brunei Shell) continued development drilling in offshore oilfields and stepped up exploration activities. Seven drilling rigs were reportedly active during 1978 and 1979 and the small new offshore Tali Oilfield was being developed for production.

Current output level was in the range from 210,000 to 225,000 barrels per day of crude oil. Natural gas production remains roughly constant at about 775 million cubic feet per day, the amount needed by the Lumut LNG plant to fill its contractual obligation with Japan. The plant supplies over 5 million tons per year via LNG tankers.

Exploration for new deposits will be conducted to maintain the current production level. The old Seria Oilfield, which has furnished over 900 million barrels of crude oil since 1928, was expected to begin to taper off in coming years.

CHRISTMAS ISLAND[12]

Phosphate rock and dust was the only mineral commodity produced commercially on the Island during 1978 and 1979. Christmas Island, located 2,600 kilometers northwest of Perth, Australia, and 300 kilometers south of Java, produced over 28 million tons of phosphate rock between the initiation of mining in 1900 and yearend 1979.

Mining was controlled by the British Phosphate Commission, which has shareholders from United Kingdom, Australia, and New Zealand. A strike by mine workers in 1979 brought exports to a stop in June. Although the problems were not completely resolved, work resumed by early July and exports for that month were 120,000 tons. An Australian government commission was appointed to report on the problems and the overall phosphate operation.

Australia and New Zealand are the main importers of the Island's phosphate rock. However, Malaysia began buying a Grade B rock in 1979. This Grade B material was of variable P_2O_5 content and was high in aluminum and iron. It was not suitable for normal superphosphate production but can be used satisfactorily for direct application in Malaysia under some agricultural conditions.

Table 4.—Christmas Island: Exports of phosphate rock, by destination

(Thousand metric tons)

Destination	1976	1977	1978
Australia	480	541	610
Indonesia	7	13	15
Malaysia	133	--	135
New Zealand	417	575	624
Singapore	--	133	4
Total	1,037	1,262	1,388

HONG KONG[13]

Hong Kong's gross domestic product (GDP) in 1978 was estimated at United States $12.0 billion in 1977.[14] In constant 1966 prices, the GDP increased 11% from $5.5 billion in 1977 to $6.1 billion in 1978. Services account for about 60.0% of the GDP, followed by manufacturing, 25.0%; agriculture, 1.0%; mining, 0.1%; and other, 13.9%.[15] The British Crown Colony relies almost wholly on foreign raw materials and resources to meet the needs of its population and the requirements of its industries and service-oriented businesses. Aside from tourism, light industries dominate the local economy, which is dependent on sales and shipments of export goods. Production of textiles and clothing, electronic articles, plastic products, watches and clocks, and other consumer articles account for about 73% of the Colony's total domestic export. Moreover, about 68% of the total industrial work force is employed in these sectors. The only heavy industries in Hong Kong are construction and ship building (small vessels) and repairing.

In the past, the principal minerals mined and produced in Hong Kong have included beryl, feldspar, graphite, iron ore, kaolin, quartz, cassiterite, and wolframite. In 1976, the Ma On Shan iron ore mine was closed and remained idle on a standby basis throughout 1977. By 1978, mine production in the Colony was limited to clays, feldspar, quartz, stone, and sand and gravel. Local production of ores and minerals is small and insignificant quite naturally by world standards.

Taiwan was the major market for the feldspar. Local light industries consumed all the quartz, more than half of the kaolin, and some of the feldspar.

Because of heavy demand for construction raw materials, contracts for two new quarries were issued in 1978. One began operations during the year, and the other was scheduled for startup early in 1979. In addition to the two Government quarries, there were seven contract quarries in operation during the year. The Government-owned quarry at Mount Butler was modernized and in full production during 1978. Modernization at the other Government quarry at Diamond Hill in Kowloon began in 1978. Total production of crushed rock aggregates by all quarries was 5.7 million cubic meters in 1979.

A large portion of the sand produced was from dredging deposits in Mirs Bay and lesser amounts from the production of crushed rock. During 1979, Government-owned sand depots sold 987,653 cubic meters of marine sand. The depot at Kowloon Bay was completed in 1978, and construction was started on a sand depot at Lai Chi Kok, which will be used for maintaining service for marine sands. The Government also began designing additional sand depots in Sha Tin and Tai Lam Chung to serve the New Territories.

Under the Mining Ordinance, the Crown has ownership and control of minerals. The land office is empowered to grant mining leases, and the Commissioner of Mines, to grant mining and prospecting licenses. At the end of 1979, there were two mining leases, five mining licenses, and two prospecting licenses valid for various areas in the Colony. The Mines Division of the Labour Department enforces legislation on mining, explosives, and safety regulations. In addition, it processes mining and prospecting applications; inspects mining and prospecting areas, stone quarries, blasting sites, and explosives storage; and issues blasting certificates.

China Light and Power of Hong Kong completed the negotiations for construction of a coal-fired powerplant to be sited in the New Territories. In exchange for electricity to service Guangzhou, China was to supply Hong Kong annually with steam coal. In addition, rail service between the Colony and Guangzhou was increased and electrification of the railway was initiated.

Hong Hong's trade in 1979 totaled $32,484 million. Total two-way trade in 1978 was $24,367 million, an increase of 25% over that of 1977, comprised as follows: $13,137 million for imports; $8,481 million for exports; and $2,749 million for reexports. Imports of raw materials comprised 42% of total imports in 1978 (includes $420 million for iron and steel); followed by consumer goods, 27%; foodstuffs, 14%; and capital goods, 13%. Imports of mineral fuels, lubricants, and related materials during the year were valued at $617 million. Receipts of fuel oil were supplied mainly by Singapore (75%), Bahrain (9%), and China and Iran (each 6%). Japan continued to be the Colony's major supplier of total shipments, accounting for 23% of all imports, followed by China, 17%, and the United States, 12%. Other sources included the Federal Republic of Germany, Israel, Taiwan, Switzerland, and the United Kingdom.

Domestic exports consisted almost entirely of manufactured goods; clothing; textiles and fabrics; watches and clocks; toys; radio receivers; metal manufactures, travel goods; and electronic components and parts, in that order by value. The principal export destinations were the United States, 37% of the total value of domestic exports in 1978; Federal Republic of Germany, 11%; and the United Kingdom, 10%. Shipments ranging between $100 million and $400 million were to Japan, Australia, Canada, Singapore, Netherlands, Switzerland, and Nigeria.

Reexports increased significantly by 34% over that in 1977 and were mainly to Japan, $475 million; Singapore, $290 million; Indonesia, $271 million; and the United States, $257 million. The main originating countries for reexported materials were China, Japan, and the United States.

Table 5.—Hong Kong: Exports and reexports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1977	1978	Principal destinations, 1978
METALS			
Aluminum:			
Bauxite and concentrate	8,223	4,500	Taiwan 3,900; Thailand 600.
Oxide and hydroxide	634	3,620	Mainly to Taiwan.
Metal including alloys, all forms	21,164	14,244	Japan 6,741; United States 1,725; Singapore 882.
Arsenic trioxide, pentoxide, acids	37	8	Mainly to Indonesia.
Beryllium metal including alloys, unwrought	--	3	All to United States.
Chromium oxide and hydroxide	70	63	Indonesia 47; China, mainland, 10.
Cobalt oxide and hydroxide	2	21	Belgium-Luxembourg 12; Thailand 4.
Copper:			
Oxide and hydroxide	3	3	Madagascar 2; Malaysia 1.
Metal including alloys, all forms	9,771	11,219	Mainly to Japan.
Gold metal, unworked or partly worked thousand troy ounces	14	84	Japan 55; Taiwan 27.
Iron and steel metal:			
Scrap thousand tons	227	286	Taiwan 178; Japan 56; Thailand 41.
Pig iron, steel ingot, similar material	165	100	Fiji 56; Indonesia 28.
Steel, primary forms	16,028	6,352	Philippines 5,155; Malaysia 852.
Semimanufactures	32,460	50,614	Indonesia 10,771; Macao 10,666; Malaysia 4,402.
Lead:			
Oxide	91	23	Indonesia 15; Singapore 7.
Metal including alloys, all forms	661	1,445	Mainly to Taiwan.
Magnesium metal including alloys, all forms	17	8	Mainly to United States.
Manganese oxide	18	60	Indonesia 50; Taiwan 10.
Nickel:			
Oxide and hydroxide	28	37	Taiwan 20; Republic of Korea 13.
Metal including alloys, all forms	512	1,292	Taiwan 398; Republic of Korea 390; North Korea 150.
Silver metal including alloys thousand troy ounces	646	429	Switzerland 246; United Kingdom 74; Taiwan 64.
Tin metal including alloys, all forms	690	1,013	Taiwan 433; Singapore 230; Philippines 73.
Titanium oxide	25,292	3,036	Indonesia 1,944; Taiwan 455; Pakistan 205.
Tungsten metal including alloys, all forms	1	3	Mainly to United Kingdom.
Zinc:			
Oxide	42	41	Indonesia 18; Macao 14.

Precious and semiprecious stones, including synthetic, except diamond value, thousands	$66,934	$77,601	Singapore $15,478; Australia $9,742; Thailand $9,391; Sri Lanka $7,979.
Salt	55,143	57,985	China: Mainland 27,593 and Taiwan 11,800; West Germany 5,118.
Sodium and potassium compounds, n.e.s	16,699	27,780	United States 10,597; China, mainland, 9,653; Romania 2,110.
Stone, sand and gravel:			
Dimension stone	5,947	4,525	Italy 2,129; China, mainland, 1,766; Philippines 168.
Gravel and crushed rock	293,577	276,685	Macao 221,948; China: Mainland 53,796 and Taiwan 389.
Limestone, except dimension	6,333	24,607	China: Mainland 23,353 and Taiwan 825; Vietnam 300.
Quartz and quartzite	2,973	4,021	China, mainland, 3,945; West Germany 26; Macao 25.
Sand, excluding metal bearing	788,134	991,358	China: Mainland 990,771 and Taiwan 250; Vietnam 100.
Sulfur:			
Elemental, all forms	2,309	1,624	Japan 1,165; West Germany 244; Singapore 150; Taiwan 42.

See footnotes at end of table.

Table 6.—Hong Kong: Imports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1977	1978	Principal sources, 1978
NONMETALS —Continued			
Sulfur —Continued			
Sulfuric acid	4,708	11,189	Japan 9,277; China: Mainland 99 and Taiwan 1,719.
Talc and related materials	7,207	7,684	China: Mainland 6,983 and Taiwan 120; United States 326; Pakistan 100.
Other:			
Crude	5,386	6,064	China, mainland, 5,850; Republic of South Africa 90; United Kingdom 56.
Mineral waste	7,455	1,605	China: Mainland 564 and Taiwan 556; Thailand 407.
Oxides, hydroxides, and peroxides of magnesium, strontium, barium	55	5	United States 3; Japan 1; United Kingdom 1.
Bromine, iodine, fluorine	5	1	Mainly from Japan.
Building materials of asphalt, asbestos, and fiber cement, and unfired nonmetals, n.e.s	20,259	20,363	United Kingdom 5,149; United States 4,180; Taiwan 2,779.
MINERAL FUELS AND RELATED MATERIALS			
Asphalt and bitumen, natural	193	1,129	Republic of Korea 525; United Kingdom 291; Taiwan 273.
Carbon black and gas carbon	749	1,244	Australia 491; Japan 444; United States 169; West Germany 64.
Coal, coke, and peat, including briquets	15,972	8,079	Japan 4,998; China: Mainland 2,182 and Taiwan 617.
Petroleum refinery products:			
Gasoline, including natural thousand 42-gallon barrels	1,228	1,527	Singapore 1,053; Republic of Korea 194; China, mainland, 159.
Kerosine, aviation and industrial, and white spirit do	6,648	6,425	Singapore 3,706; China: Mainland 1,906 and Taiwan 339.
Diesel and distillate fuel oil do	8,710	9,688	China, mainland, 6,090; Singapore 3,137; Kuwait 207.
Residual fuel oil do	24,896	26,067	Singapore 19,635; Bahrain 2,345; China, mainland, 1,671.
Lubricants do	49	16	China, mainland, 7; Singapore 2; United Kingdom 2; United States 2.
Other:			
Mineral jelly and wax do	86	109	China, mainland, 90; Japan 5; United States 4; United Kingdom 3.
Bitumen and other mixtures do	188	144	Singapore 132; Taiwan 5; Republic of Korea 4.
Liquefied petroleum gas do	1,057	1,146	Singapore 645; Republic of Korea 308; Japan 193.
Unspecified do	1	1	NA.
Mineral tar and other coal-, petroleum-, or gas-derived crude chemicals	297	186	United Kingdom 82; Netherlands 51; United States 33; Japan 20.

NA Not available.

KAMPUCHEA[16]

Intermittent armed conflict continued during the first part of 1978 along the Kampuchea-Vietnam border, then all-out warfare erupted at yearend. On January 7, 1979, Phnom Penh, and the Pol Pot Government, was overthrown by the Kampuchean National United Front for National Salvation, heavily aided by Vietnam forces. On January 10, 1979, the formation of the People's Republic of Kampuchea was announced.[17] The Government's preoccupation with political, military, and ideological concerns precluded any meaningful economic development in the country during this time. Mineral production was insignificant. Factual information on the situation in Kampuchea was unavailable due to the chaotic conditions within the country and along the border areas. Official economic data was not released, and it is doubtful whether comprehensive data were even collected. The population reverted to mostly subsistence agriculture during 1978 and 1979.

Hitherto, the overall value of the mineral sector was negligible, and local mining operations served only the needs of local immediate users. The country has never been considered an important world producer of any mineral commodity. A variety of minerals might be developed given halcyon times and a thorough exploration effort using modern geophysical and geochemical surveying techniques. The only minerals that have been produced on a significant level were phosphate rock, gems, salt, and nonmetallic construction materials for cement, brick, and tile manufacture.

Bauxite was known to occur in commercial quantities, but no development plans were made known. Deposits of antimony, copper, gold, iron, manganese, and tin minerals and coking coal reportedly have been identified.

No meaningful trade figures were available for 1978 or 1979. Exports of agriculture products probably totaled less than $1 million in value in 1978, while imports from Japan, Singapore, and Hong Kong were estimated at less than $2 million. Imports presumably from China and other countries probably consisted of pharmaceuticals, foodstuff, insecticides, fertilizer, steel manufactures, textile yarns, petroleum products, farm equipment, machinery, replacement and spare parts, and relief aid sent by governments and humanitarian agencies from around the world.

COMMODITY REVIEW

Bricks made from local clay minerals were produced at small plants in several of the Provinces during 1978. The Ao-3 kiln in Phnom Penh planned to produce 10,000,000 bricks,[18] the factory at Phum Prek Rieng doubled its 1977 production figures to 100,000 per month, and the factory in Tram Kak district claimed they could make 40,000 bricks "at a time."[19] There was also a local plant in operation in the Angkor Chey district, and a new 8-kiln factory in Chamkar Lev District began operations in May 1978. These small operations also provided roofing tiles and a variety of earthenware containers to immediate areas. Reportedly, some of these operations resumed production at the end of 1979.

An effort was being made to develop a small steel industry. During 1978, the Government was reportedly in the process of building a "steel mill" which would produce a quarter of the country's annual needs.[20] Also under construction was an ironworks of medium size as an industrial developmental project. Status of this project during 1979 was not known. The search for economic deposits of iron ore continued, and it was generally believed that sufficient reserves existed to support a modest steel industry. Crude iron foundries were operating at several locations. These were locally made, batch-fired, charcoal-fueled furnaces. Charges consisted of various types of steel or iron scrap, additives, and some locally produced iron ore. While production was only on the order of 1 or 2 tons per firing, the product was reported to be a good grade of malleable iron. Output from these smelters was used to turn out plowshares and other agricultural tools, pots, pans, pump parts, tools, metal fasteners, and replacement parts for a wide range of equipment.

Prime Minister Pol Pot, in his party anniversary speech on October 2, 1978, stated, "Our oil refinery is being repaired, and this repair work will be completed by the end of 1979. This refinery, when completed, will be able to refine 600,000 tons of crude oil a year."[21] Due to the change of government, however, no progress was made toward that completion. This small, old French refinery has not been maintained during the 8 years since it was damaged in military conflict. Total reconstruction by a large crew of foreign specialists would be necessary to bring the plant back into operation in light of deterioration as a result of tropic conditions.

Kampuchea produces no crude oil or natural gas nor was there any known exploration conducted either onshore or offshore. The country's modest petroleum needs were satisfied by imports of petroleum products.

Phosphate deposits in Battambang and Kampot Provinces were being exploited. The phosphate rock is simply ground to a fine powder and applied directly to cropland. No chemical processing or blending is attempted. The largest phosphate plant in the country was the Tuk Meas plant in Kampot Province, about 16 kilometers from the Vietnamese border. It was not known if the plant operated during 1979. The Monkol Borei phosphate fertilizer plant in Battambung Province, which opened in 1977, apparently operated satisfactorily during 1978. Reserves near the plant of 20% P_2O_5 ore were reportedly as high as 400,000 tons.[22]

Kampuchea produced salt for domestic consumption by evaporation of seawater. By mid-1979, it was reported that the salt pans of Kampot and Kompong Trach District were being brought back into production.

These beds could yield about 60,000 tons per year of salt.[23] Limestone was also mined near Chakrei Ting for use in a small local cement plant.

LAOS[24]

The People's Republic of Laos, a landlocked country of 3.2 million people, completed its third and fourth years of independence amid continuing troubles in its quest for national unity and consolidation of the national Government of the Pathet Lao. The Government had minimal success in effectively setting in motion its first 3-year plan, an interim plan to prepare the way for a full 5-year plan beginning in 1980 or 1981. The economy continued to be unstable and the national currency, the kip, fluctuated throughout 1978 and was revalued in 1979. Firm data or information were virtually unavailable on the economy of the country as a whole, much less on the mineral industry in particular.

Laos remained one of the poorest countries in the world with a gross national production currently around $260 million and a per capita income on the order of $90 per year.

The country is believed to be rich in natural resources, with a variety of minerals including tin, iron ore, salt, potash, gypsum, and coal. Moreover, there is a great potential for developing hydroelectric power, and 60% of the land is forested. Despite the potential, its resources remained practically untouched during the year and very little in the way of detailed geological surveying has been done for a country of its size.

Laos was not a major world producer of any mineral, and the small overall mineral output was of little importance to the economy of this agricultural country in 1978 and 1979. Between 500 and 1,000 tons of tin concentrate was produced annually before the nationalization of the French-owned Phontiou mine in 1977.

One critical factor affecting both the exploration and development of the mineral industry was the lack of an adequate transportation system. Any plans for large-scale exploitation of potash, iron ore, or salt deposits would be severely handicapped by the woefully few, poorly maintained roads and nonexisting rail system.

However, during 1978 and 1979 road construction and improvements were emphasized. Although a major problem continued to be the inadequate organization and management of manpower, a number of projects were reportedly completed. For instance, over 2,700 kilometers of new roads were built, and 240 bridges were constructed or repaired.

The Government's primary objective has been to achieve self-sufficiency in food production by 1980. However, the droughts of 1977 were followed by flooding in 1978, and a worsening political climate in 1979 fostered overzealous socialist programs. The people were highly resistant to being forced to join agricultural cooperatives and, in fact, large numbers fled to Thailand rather than comply.[25]

Phase 2 construction of the Nam Ngum hydroelectric project, north of Vientiane, was completed and commissioned in November 1978. The project was the largest man made structure in Laos, and after the capacity increase from 30 megawatts to 110 megawatts, was capable of generating more than five times as much electric power as Laos needed.[26] As a result, the sale of surplus electricity to Thailand increased from $2 million to over $7 million, the country's largest foreign exchange earner. Electric power output for domestic use increased to about 340 million kilowatt-hours, an increase of 16% over that of 1977. Twenty-one water pumping stations were reportedly installed serving agricultural state farms and nearby factories. The electric power grid was to be extended into the more remote communities, and it was expected that some previously inaccessible mineral deposits could then be developed.

COMMODITY REVIEW

Before the nationalization of the tin mines at Phontiou owned by Société d'Etudes et d'Exploration Minière de l'Indochine, tin was the major foreign exchange earner for Laos, bringing in several million dollars annually. The mines were wholly nonproductive for a time, but in 1978, were operating on a much reduced level. The low-grade ore (0.2%-0.5% Sn) was difficult to concentrate in spite of reported assistance by foreign technicians. Equipment maintenance, and obtaining spare parts were particularily difficult inasmuch as the machinery was of French, British, and U.S. manufacture. Laos officials expressed hope that, with Soviet assistance, production would reach 800 tons of tin concentrate during 1979.[27] Actual production was probably much less. Export of tin concentrate to Malaysia for smelting proved difficult owing to legal action from the former owners of the mine. The second tin mine, in the Boneng District, exported about 100 tons of concentrates to Malaysia for smelting in 1978. The total tin reserves were estimated to be far larger than the 65,000 tons already proved, but Laos had difficulty in obtaining foreign assistance in developing mines owing to the uncompensated nationalization at Phontiou.

The output of salt in the Vientiane area continued to be a locally important mineral product. The Industrial Department in Vientiane Province and Vientiane City built reservoirs for the local people and provided them with saltmaking equipment. At some sites, notably the Ban Keun area, water pumps were also installed to increase production. The salt was being obtained in part from ground water brines. Total production figures from these works were unavailable but were estimated to have been near 15,000 tons during 1978 and a similar amount during 1979, meeting local needs handily and providing a surplus for distribution to other Provinces.[28]

Efforts by the Government to obtain foreign assistance in developing the rich potash deposits along the Mekong River were unsuccessful. The extensive bed of sylvite, which continued southward into Thailand, averaged 3.5 meters thick and occurred at depths between 94 and 432 meters.

The largest identified mineral resource in Laos was iron ore, occurring in Xiangkhouang Province.[29] The two most favorable deposits were at Phou Nhouan and Pha Lek. In 1979, an agreement was signed with Vietnam for geological exploration of this resource which is known to contain several hundred million tons of high-grade magnetite and adjacent areas of limonite and hematite.

Gypsum occurrences were found in Savannakehet Province. An agreement was signed with Vietnam in April 1978 to cooperate in the construction of a mine for exploitation of gypsum. No information has been released as to the expected capacity of the mine. Presumably, much of the output will be exported to Vietnam.

There was no further exploration and activity during 1978 or 1979 on the reported oil discovery of a number of years ago between Thakhek and Pakse. Laos continued to import the small amounts of petroleum products needed from Thailand. In late 1979, a petroleum storage tank farm was completed with Soviet assistance at Dong Chong hamlet near Vientiane. The capacity of the eight tanks totaled 8,000 cubic meters (50,000 barrels). In addition, Vietnamese engineers completed a 900-cubic-meter (5,500-barrel) petroleum storage site in Laos during 1979.

Coal remained of minor importance to the Laotian mineral economy with only a few thousand tons being mined from the coalfields near Muang Vangviang. Coal was also known to occur in Saravane Province.

MONGOLIA[30]

Mongolia's sixth 5-year plan (1976-80) would transform the country into an industrial-agrarian-based economy. The plan called for closer integration of Mongolian and Soviet economies under the direction of the Mongolian-Soviet Intergovernmental Commission for Economic, Scientific, and Technological Cooperation. The plan stressed higher labor efficiency, increased industrial and agricultural output, and better product quality, and set a target of a 62.9% increase in gross industrial production over the 5-year period. Electrical generation was to reach 1,450 megawatt hours annually by 1980, and coal production, to reach 4.8 million tons. Output of bricks, timber, and other construction materials were to increase substantially to meet industrial development. As a basis for industrialization, much emphasis was to be placed on developing the mining industry, in particular coal, copper and molybdenum, fluorspar, and geological surveying for potential mineral deposits for commercial exploitation.

Mongolia continued to be dependent on foreign assistance. Harsh weather conditions in 1977-78 had compounded the country's economic development in the agricultural and animal husbandry sectors. Government revenue in 1978 was estimated at 3,600 million tugriks compared with Government expenditure of 3,650 million tugriks. Mongolia exports mainly raw materials and foods but imports value-added goods, such as machinery and plant equipment, manufactured consumer products, and petroleum. Eighty percent of Mongolia's external trade is with the U.S.S.R. and in 1977, the total two-way trade was estimated at 676 million rubles. Trade in 1978 was estimated to be 700 million rubles with Soviet exports to Mongolia comprising about 90% of the total. The principal source of outside financial assistance was the U.S.S.R. and the Council for Mutual Economic Assistance (CMEA).[31]

Most of the capital investment in 1978-79 for industrial expansion was largely for the copper and molybdenum development at Erdenet in Bulgan Province. This mining complex was also to be a large city combine with housing, schools, shops, and other industries such as carpeting manufacture. In 1978, it was estimated that there was a population of 32,000 with a work force of 14,000 Mongolians and Soviets engaged in construction. Also, under Soviet tutelage, training was in progress for 2,600 workers, engineers, and technicians for the mine. In August 1978, it was claimed that 6 million cubic meters of overburden had been moved and that 3 million tons of ore had been excavated. Opening of the combine, originally set for 1979, was announced as October 7, 1978. The 220-kilovolt powerline from Gusinoozersk in the U.S.S.R. to the industrial combine had been completed in 1976, and the power station's first generator was put on load utilizing coal from Gusinoozersk. Construction of a water pipeline from the Selange River was completed, measuring 80 centimeters in diameter and running 64 kilometers with a capacity to deliver 1,000 cubic meters of water an hour. Passenger train service was opened, linking Erdenet with Darhan and Ulan Bator in June 1977, and construction of a 265-meter bridge was completed across the Selange River providing railway access to Ulan Bator and timber from the Selange sawmill.

Fluorspar is produced by the Berhin fluorite mine. Reconstruction of the mine was well underway and, reportedly, construction of a similar enterprise began during the year near the area. Construction of the fluorite mine at Boro Ondor in southeastern Mongolia, described as the country's largest fluorite mine, had begun in 1977 with Soviet assistance. By the end of the current economic plan, export of fluorspar was expected to reach 2.1 times the current level.

Coal mining continued to be one of Mongolia's foremost mineral industries. About 75% of the country's coal output came from open pit mines with the bulk of the production from Nalayha, Sharyn Gol, land Chuluum. Development and construction purportedly begin in 1978 in a large open pit coal mine at Baga Nuur, located about 110 kilometers southeast of Ulan bator. A rail link with the Trans-Mongolian Railway was completed in 1978, and a high-voltage transmission line from Ulan Bator to Baga Muur was near completion. Development of this mine, scheduled for 1980, was to be one of the largest coal mining enterprises in the State, producing 2 million tons of coal a year. The output of lignite from this mine was to be the main supplier for 15 to 20 years for a 1,000-megawatt thermal power station, slated to be the country's main electricity producer. The new city combine was to be built along the bank of Hulen River, containing housing initially for 20,000 people.

Prospects for other mineral developments in Mongolia included the Tavantolgoy coking coal deposit in the Tsogttsetsiy district of South Gobi Province; the Borondor copper-molybdenum deposit in South Gobi Province; and the Tsagaansuvraga copper-molybdenum deposit in East Gobi Province. Unlike Erdenet, the latter would include metallurgical works as well as a concentrator if development was undertaken. These projects were expected to be carried out under assistance from CMEA.

Table 7.—Mongolia: Apparent imports of mineral commodities[1]

(Metric tons unless otherwise specified)

Commodity	1977	1978	Principal sources, 1978
METALS			
Aluminum metal including alloys, semimanufactures	--	[2]1	All from Switzerland.
Iron and steel metal:			
Pig iron	1,400	1,400	All from U.S.S.R.
Rolled semimanufactures	14,100	30,200	Do.
Pipes and tubes	1,900	5,800	Mainly from U.S.S.R.
NONMETALS			
Cement thousand tons	100	67	U.S.S.R. 60.
Clay products, refractory	[3]3,329	[2]2,315	All from U.S.S.R.
Fertilizer materials, manufactured:			
Nitrogenous, N content	17,600	25,800	U.S.S.R. 15,484.
Phosphatic, P_2O_5 content	7,700	18,900	Mainly from U.S.S.R.
Salt	[2]2,902	[4]4,262	All from U.S.S.R.
Sodium compounds, n.e.s.:			
Caustic soda	700	100	NA.
Soda ash	1,000	--	
Sulfuric acid	200	1,200	All from U.S.S.R.
MINERAL FUELS AND RELATED MATERIALS			
Coal: Anthracite and bituminous	[2]800	[2]100	Do.
Petroleum:			
Crude thousand 42-gallon barrels	37	42	Do.
Refinery products do	3,280	3,290	Mainly from U.S.S.R.
Mineral tar and other coal-, petroleum-, or gas-derived crude chemicals	[2]1,003	[2]1,008	All from U.S.S.R.

NA Not available.
[1]Owing to the lack of official trade data published by Mongolia, this table should not be taken as a complete presentation of Mongolia's mineral imports, with regard to either commodities or quantities. Unless otherwise specified, data are compiled from the Statistical Yearbook of Members of the Council for Mutual Economic Assistance, Moscow.
[2]United Nations. World Trade Annual, Walker and Co., New York.

NEPAL[32]

Nepal occupies the south slope of the Himalayan Mountains and forms a buffer state along part of the China-India border. Although the country has a considerable potential for mineral development, it has virtually no important mineral production. The mining industry accounted for approximately 0.01% of the gross domestic product (GDP) in 1978 and the manufacturing sector accounted for an additional 3.1%. Agriculture accounts for nearly two-thirds of the GDP and directly employs over 89% of the workforce. The farming throughout most of the country is on a local, household level with small amounts of surplus foodgrains exported.

The economic growth rate was nearly stagnant over the last two years. GDP in constant FY 1977[33] prices was $1,445 million in FY 1976,[34] $1,470 million in FY 1977-78 and estimated at $1,531 million in FY 1978-79. Per capita GDP in FY 1976-77 was $110 and rose only to $112 by the end of FY 1978-79.

Total exports were $91 million in 1978-79, a small decline over that of 1976-77. Imports, however, increased significantly from $167 million in 1976-77 to $242 million in 1978-79.

Two of the country's main problems were high population density on arable land, and a population increase of 2.5% per year that tends to offset the gains the country makes in economic and industrial development. Another important limiting factor is lack of basic infrastructure. There is no railroad network and the road network is at best primitive. The Government has been working steadily on expanding and upgrading roads and a considerable mileage of motorable roads have been completed in recent years. Opening of hitherto inaccessible areas to motor vehicles will help facilitate mineral exploration efforts.

Despite the scarcity of major mining operations, there has been some small-scale exploitation of several minerals during historic times. Most of the ancient Nepalese weapons were made from magnetite ore mined in Ramechap District and smelted locally. Primitive copper mines have been worked in several areas east of Kathmandu. A few are still operating, including one at Wapsa Khani in old Okhaldhunga District. Each operation is totally manual and can produce about 1,000 kilograms per year of copper metal for local fabrication into domestic utensils. Limestone, slate, dimension stone, and brick clays have all been locally exploited in recent times.

The Mineral Exploration Development Board (Nepal) and a United Nations Development Program team had conducted three field seasons of basic mineral surveying in central Nepal. The two main objectives of the jointly funded project were (1) to determine the mineral potential of a selected representative area, and (2) to strengthen the capability of the government geologists in exploration and analytical techniques. Regional geochemical mapping was undertaken and revealed a large number of anomalies. Almost all of the ancient basemetal workings were reflected in geochemical data. The reconnaissance data in fact revealed the presence of several previously unknown old workings.

Preliminary findings of the survey indicate that it is probable that economically attractive sulfide deposits exist in the area. Copper, lead, and zinc were the main metals indicated and the possibility of silver as a coproduct or byproduct also exists.

A considerable amount of detailed and expensive drilling will be necessary to locate and evaluate specific ore bodies. The ultimate controlling economic factor may well be the distance of a deposit from a motorable road and the cost of bringing roads, electric power, and housing into rugged sites.

COMMODITY REVIEW

Cement continued to be the most important mineral-based industry in Nepal. The 50,000-ton-per-year Himal cement plant was not able to operate at its designed capacity during 1978 and 1979. Problems with maintenance, spare parts, and raw material all combined to cut production at a time when demand far exceeded design capacity. Accordingly, shortages of cement caused delays in several construction projects and resulted in the import of large amounts of expensive foreign cement. Even with imports, cement was still in short supply at yearend 1979.

The Asian Development Bank provided a $40 million loan in late 1976 for the construction of a new cement plant at Hetuada south of Kathmandu. Progress has been slow since the loan was made. Construction apparently got underway during 1978 on infrastructure and site preparation for the plant. An Indian firm was reportedly chosen as the engineering contractor. The 260,000-ton-per-year plant was scheduled for completion in late 1981. A 13-kilometer aerial tramway will transport the raw material from the Bhaise limestone deposit to the plant.

In September 1978, Nepal and India completed a preliminary agreement on the establishment of a 1,500-ton-per-day export-oriented cement plant in Udaypur in southeast Nepal. India will have a 49% equity in the facility. In April 1979, the two countries began a joint survey to determine the route of a 50-kilometer railroad spur to the plant from the end of an Indian railroad line at Jaynagar (26°35'N, 86°09'E) in Bihar. The railroad will bring in coal and carry the cement out of Nepal.

In February 1979, Chinese representatives turned over Bhaktapur Brick and Tile Factory Ltd. to the Nepal Government. The plant, built at a cost of $3.3 million with Chinese assistance, has a capacity to produce 20 million bricks per year (approximately 50,000 tons).

After detailed study of the Kharidhunga magnesite deposit, the Nepalese Department of Mines and Geology has reached an agreement with Orissa Industries Ltd. of India to establish a magnesite mining operation at the site. The Nepal Government will take a 50% interest in the new company. Production from the mine will supply a 50,000-ton-per-year dead burnt magnesite plant to be set up at Lamusangu, which will provide raw materials for a planned basic refractories plant at Birganj.

The average minable thickness of the orebody is 55 meters and is near enough to the surface to be mined by open pit methods. Proved reserves of high-grade ore are about 12 million tons; total reserves were estimated at 180 million tons.[35]

After several years of delay, the Nepal Metal Company began the ground work for exploiting the small high-grade zinc and lead deposit in Ganesh Himal area of Rasuwa district. Shares of stock in the company were being offered and personnel was being hired at yearend 1979. The underground mine will be designed to produce 400 tons per day of ore averaging over 12% combined metal content. A small mill will produce concentrate for export to India. This will be the first modern metal mine in Nepal and is scheduled to begin operating in 1984.

SINGAPORE[36]

During the past decade, Singapore's gross domestic product (GDP) grew at an average annual rate of 9.6% in terms of constant 1968 prices. GDP reached $4.9 billion[37] in 1979, compared to $4.4 billion in 1978, and $3.8 billion in 1977. Singapore is a stellar performer in the Far East. In addition to being an entrepôt, the Republic's economy is buoyed with diverse industrial activities including petroleum, light manufacturing, ship building and repairing, and tourism.

Singapore is the third largest petroleum refining center in the world. Output by this sector alone was estimated to be valued at $4.4 billion in 1979 compared with $3.3 billion in 1978. The industry was expected to expand further with commitments by Mitsubishi Inc., Mobil Oil Co., Phillips Petroleum Co., and Sumitomo Co. for new petrochemical and associated projects, planned and in progress. Singapore is also Southeast Asia's oil exploration support center. Demand for oil rig construction for world exploration activities was reflected by a growth of about 15% in 1979 in Singapore's equipment industry.

In terms of activity, Singapore is considered the fourth largest port in the world (after Rotterdam, it is also the second largest non-U.S. oil refining center). The Republic is the major port in the area for transshipments of goods. In 1979, imports and exports were valued at $17.4 billion and $14.1 billion, respectively, compared with $13.0 billion and $10.1 billion in 1978. Trade with Japan, Malaysia, and the U.S. collectively accounted for 39% of Singapore's total trade in 1979 and 40% in 1978.

After the petroleum industry, manufacture by the electronics sector is the largest single producer by value. Output was valued at $1.8 billion in 1979 and at $1.4 billion in 1978. The value of iron and steel output in 1979 was $118 million; nonferrous metals, $30 million; cement, $93 million; and nonmetallics, $55 million.

Because of the inflow of foreign capital for new projects, the net manufacturing investment commitments in Singapore for 1978 totaled $353.5 million. Because of the Sumitomo petrochemical complex and associated downstream projects, along with other investments in high-value equipment and machinery, manufacturing commitments in 1979 were around $489 million.

The financial sector continued to expand in 1979 with bank deposits increasing by 16% and loans increasing by 28%. Paralleling the progress in industry, trade, and tourism, Singapore was becoming a major international financial center through the development of its Asian dollar, gold, and secondary money market. The Republic's foreign reserves position improved from $3.39 billion at yearend 1977, to $3.97 billion in 1978, reaching $5.22 billion at yearend 1979. Inflation during 1979 was 4% resulting directly from higher petroleum prices, which reflected the higher costs for energy, wages, imported consumer products, and transport rates.

PRODUCTION

Singapore's mineral economy is basically a pattern of processing foreign raw materials (and/or intermediate materials) and domestic scrap into finished products. More than 1 million tons per year of cement was produced to sustain continued high levels of construction, but the principal raw material was actually imported clinker. Output of cement and concrete products by 7 establishments employing 1,919 workers was valued at $136 million in 1979. The roughly 200,000 tons of ingot steel produced annually in recent years was from scrap; actually, Singapore also imported much larger tonnages of steel products and semimanufactures, some of which was converted to downstream products. The country's value added for cement in 1979 was $22 million; concrete products, $16 million; iron and steel, $56 million; nonferrous metals, $7 million; and nonmetallic minerals, $25 million.

In 1979, Singapore's petroleum industry, employing 3,149 workers, produced about $4.37 billion worth of petroleum products by processing $3.92 billion worth of crude oil, thereby earning $450 million in value added.[38] In 1978, corresponding output was $3.30 billion, input was $2.96 billion, and value added was $340 million. Residual fuel oil ranked first in production tonnage, followed by distillate fuel oil, gasoline, jet fuel, kerosine, and lubricants, in that order. The refining industry recovered somewhat from the loss of the Vietnamese market and Japanese reluctance to buy refined oil. Refining capacity utilization was about 84% in 1979. The country's mineral production statistics are shown in table 1.

TRADE

Singapore's total foreign trade in 1979 was valued at $31.5 billion (imports, $17.4 billion and exports, $14.1 billion), compared with imports of $13.0 billion and exports of $10.1 billion in 1978. In terms of total trade, Singapore's major trade partners were Malaysia ($4.46 billion), the United States ($4.43 billion), Japan ($4.32 billion), Hong Kong ($1.33 billion), West Germany ($1.12 billion), Thailand ($1.09 billion), and United Kingdom ($1.05 billion). Significantly, trade with China has increased annually, and in 1976 was valued at $343 million; 1977, at $371 million; 1978, at $412 million; and 1979, at $574 million.

In terms of commodity classification, Singapore's most important mineral-related imports in 1979 were crude petroleum, $3,778 million; petroleum products, $616 million; and steel plates, sheets, bars, and shapes, $345 million. Other major import classes in 1979 included office machinery ($1,336 million), industrial machinery and other equipment ($1,246 million), and textiles ($506 million). Comparable export categories were petroleum products ($3,319 million), machinery of all types ($1,679 million), crude rubber ($1,319 million), and telecommunications apparatus ($783 million).

The entrepôt nature of Singapore is exemplified by petroleum. In 1979, the Republic imported 28.2 million tons of crude petroleum, 0.3 million tons of diesel fuel, and 3.5 million tons of kerosine and other fuels. Conversely, exports in 1979 included 1.6 million tons of motor fuel; aviation fuel, 2.2 million tons; naphtha, 2.2 million tons; diesel fuel, 4.1 million tons; kerosine, 10.4 million tons; and lubricating oil, 0.5 million tons. In addition to sales of refined products, there was appreciable monies earned from bunkering.

COMMODITY REVIEW

Metals.—*Iron and Steel.*—The steel ingots, produced locally from scrap, amount to about 200,000 tons annually. The ingots, along with imported sheets and bars, are then made mainly into rolled semimanufactures. There were 14 small iron and steel establishments in 1979, employing 1,454 workers. Only two steel producers were of any consequence, namely the National Iron and Steel Mills Ltd. (NISM) and the Malaysia Iron and Steel Mills Ltd. NISM's plant at Jurong has electric furnaces, merchant bar mills, and a wire rodmill which together turn out more than 200,000 tons of steel products annually. NISM and Japan's Mitsui Co. have a small joint venture called Eastern Wire Manufacturing Co. Malaysia Mills' facilities are considerably smaller than those of NISM.

Tin.—This small island nation has no mine tin production. However, it plays a key role as a leading clearinghouse for Southeast Asia's tin smuggling syndicates.[39] The average wholesale price for tin per picul has risen annually since 1975. Unit price in 1977 was $652; 1978, $768; and 1979, $889. As reported by official (Government) sources, imports of tin-in-concentrates rose from 706 tons in 1976 and 2,290 tons in 1977, to 4,432 tons in 1978. The country's largest tin buyer is Kin Hok. Two new tin smelters have been recently built in Singapore, both in the Jurong industrial estate and owned by Kimetal Pty. Ltd. and Watson Mineral Enterprises. According to company executives, these smelters together can handle 5,000 tons per year as reflected by a 5,242-metric-ton gap between imported and exported tin metal in 1978. Accordingly, the two smelters were assumed to have been working at full capacity.

Before the construction and commissioning of the smelters, official imports of concentrates in 1976 (about 72% tin grade) were 982 tons, compared with exports of 5,498 tons. At the time, tin was worth well over $10,000 per ton. During 1978, more than 15,000 tons of tin concentrates and refined tin were exported, showing heavy traffic in both concentrates and metal. Singapore exported 6,112 tons of tin-in-concentrates in 1978. Customs officials have been unable to stop the steady stream of concentrates brought in by illegal operators, poachers, and intermediaries. Tin from Burma, Indonesia, Laos, Malaysia, and Thailand is transported across the Johore causeway by small boats, trucks, and private cars. About 10 small operations handle the influx. Exported concentrates have gone mainly to smelters in Spain, the Soviet Union, Brazil, and to a lesser extent to Mexico, Portugal, Republic of Korea, and Taiwan.

Nonmetals.—*Cement.*—Singapore had seven cement grinding and mixing establishments in 1979, employing 571 workers and realizing $21.7 million worth of value added from an output of $93.5 million and an input of $71.8 million. Virtually all production of cement was from grinding operations relying on imports of clinker. Singapore's imports of such clinker during 1979 was mostly from Japan and some from the Republic of Korea and Taiwan. Output of finished cement is closely tied to the amounts of clinker imported. Singapore's imports of finished cement have always been considerably less than 100,000 tons annually. Construction activities have averaged about $0.25 billion yearly during 1973-79, which represented about 6% of the GNP. One of the recent large construction projects was the international airport at Changi and its connecting expressway to the downtown district.

Three relatively old cement plants are Asia Cement (Malaysia) Ltd.'s 420,000-ton-per-year plant at Jurong; Singapore Cement Manufacturing Co. Ltd.'s 320,000-ton plant; and Pan Malaysia Cement Works Ltd.'s 260,000-ton plant at Jurong. Ssangyong Cement Pte. Ltd. of the Republic of Korea, purchased a $32 million, 600,000-ton clinker grinding system from the Fuller Co. for a joint venture in Singapore.[40] This "pollution-free" plant, with a 4,000-horsepower finish grinding mill and in-plant dust collector, started operations in 1978 and was running smoothly. Ssangyong's partners included the Development Bank of Singapore and the Afro-Asian Shipping Co. Pte. Ltd., both headquartered in Singapore.

Mineral Fuels.—*Petroleum.*—After Singapore had expanded oil refining capacity to nearly a 1-million-barrel-per-day throughput in early 1977, it became the world's No. 3 refining complex after Rotterdam and Houston. Shell Eastern Petroleum Ltd. (Shell) had expanded its refinery on Pulau Bukom Island to 550,000-barrels-per-day, making this operation the world's second largest single refinery after another of Shell's refineries at Rotterdam. At yearend 1978, Shell was operating close to capacity, whereas other Singapore refineries worked at around 60%. Esso Singapore Pvt. Ltd. (Esso) has a 230,000-barrel-per-day refinery at Pulau Ayer Chaway; Mobil Oil Singapore Pte. Ltd., a 180,000-barrel-per-day refinery in the Jurong Industrial Estate; and Singapore Petroleum Co. and B.P. Refinery Singapore Pte. Ltd., smaller refineries.

Singapore's refining companies redesigned facilities during 1977-78 in order to handle a greater variety of crudes and to produce more lighter products and distillates like automotive diesel oil and kerosine. Also, Singapore refineries had been designed for the high-sulfur crudes of the Middle East, and some redesigning took place in this regard also.

The Singapore Petroleum Co. installed a 15,000-barrel-per-day hydrocracking unit and started to expand its 70,000-barrel refinery by 100,000 barrels additional at a cost of $185 million. Mobil Oil announced a plan to add a S$200 million visbreaker and associated facilities allowing Mobil to produce higher value products such as kerosine and naphtha. The visbreaker will have a refinering capacity of 50,000 barrels per day of residual fuel oil. Royal Dutch Shell was adding a $144 million hydrocracking unit at its big refinery. Another dimension to Singapore's downstream oil activities was the expected construction of a large petrochemical complex on Pulau Ayer Merbau by a joint venture headed by Sumitomo Chemical Corp. of Japan and the Government of Singapore scheduled to come onstream in 1982-83. Initial proposals for the $1 billion complex include capacity to produce 100,000 tons of polyprophylene, 50,000 tons of polyethylene, and 100,000 tons of ethylene oxide. Other proposed projects included a Mitsubishi-Shell venture for downstream ethylene glycol and ethylene oxide plants, and Phillips Petroleum interest in a high-density polyethylene plant.

Many international oil companies working in Southeast Asia have established headquarters in this 200-square-mile small country. In fact, Singapore has been an oil logistics center in the Pacific for some time, with various kinds of seafaring oil exploration and development barges and equipment being built, assembled, and serviced here. Thus, increased oil exploration in China, Indonesia, Philippines, and other areas during 1978-79 directly affected Singapore's economy.

Table 8.—Singapore: Exports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1977	1978	Principal destinations, 1978
METALS			
Aluminum:			
Oxide and hydroxide	2,795	1,425	All to Malaysia.
Metal including alloys:			
Scrap	3,921	4,228	Japan 3,317; Pakistan 434; Taiwan 420.
Unwrought and semimanufactures	2,256	7,245	Malaysia 1,938; Taiwan 1,460; Philippines 931; North Korea 750.
Chromium oxide and hydroxide	40	66	Malaysia 62.
Cobalt oxide and hydroxide	([1])	3	North Korea 1; Malaysia 1.
Copper:			
Copper sulfate	274	385	Malaysia 317; Japan 30; Thailand 25.
Metal including alloys:			
Scrap	7,531	9,896	India 5,604; Japan 1,518; Republic of Korea 1,284.
Unwrought and semimanufactures	2,293	4,055	Malaysia 2,917; Bangladesh 454.
Iron and steel metal:			
Scrap	6,858	3,745	Malaysia 1,775; Japan 1,151.
Pig iron, ferroalloys, similar materials	4,032	6,143	Malaysia 5,975.
Steel, primary forms	6,579	7,982	Malaysia 6,097.
Semimanufactures:			
Bars, rods, angles, shapes, sections	74,429	122,021	Malaysia 38,421; Hong Kong 28,801.
Universals, plates, sheets	71,809	97,222	Malaysia 63,053.
Hoop and strip	2,214	3,230	Malaysia 3,009.
Rails and accessories	1,643	2,193	Malaysia 1,963.
Wire	2,934	6,807	Malaysia 4,160.
Tubes, pipes, fittings	216,801	259,660	India 192,427; Brunei 14,639; Malaysia 7,160.
Castings	871	438	United Kingdom 196; Brunei 99.
Total	370,701	491,571	
Lead:			
Ore and concentrate	25	34	India 33.
Oxides	37	244	Malaysia 229.
Metal including alloys:			
Scrap	1,699	2,642	Malaysia 1,205; Taiwan 1,199.
Unwrought and semimanufactures	922	632	Malaysia 336; Japan 114.
Manganese:			
Ore and concentrate	12,949	18,501	Thailand 2,365; Malaysia 2,277; Taiwan 2,227; India 2,131.
Oxides	352	596	All to Malaysia.
Mercury 76-pound flasks	56	36	Malaysia 28.
Nickel metal including alloys:			
Scrap	403	409	Japan 328.
Unwrought and semimanufactures	127	159	North Korea 101; Malaysia 57.
Platinum-group metals and silver:			
Waste and sweepings kilograms	8,578	6,126	Japan 3,283; Hong Kong 1,341; United States 1,008.
Metals including alloys:			
Platinum-group troy ounces	418	161	Malaysia 96; United States 64.
Silver do	19,740	73,561	Japan 58,419; Malaysia 7,909; Brunei 1,897.
Tin:			
Ore and concentrate	10,440	8,271	Spain 2,441; U.S.S.R. 2,350; Brazil 1,173.
Metal including alloys:			
Scrap	56	94	Taiwan 40; Malaysia 28; United Kingdom 26.
Unwrought and semimanufactures	3,477	7,876	United States 5,192; Taiwan 472.
Titanium:			
Ore and concentrate kilograms	49	--	
Oxides	281	536	Malaysia 420; Japan 64.
Tungsten:			
Ore and concentrate	131	440	North Korea 293; West Germany 121.

NONMETALS			
Abrasives, natural, n.e.s.:			
Pumice, emery, natural corundum, etc	39	30	Malaysia 25.
Grinding and polishing wheels and stones	143	340	Malaysia 223; Burma 74.
Asbestos	5,203	5,901	Malaysia 5,707.
Clays and clay products (including all refractory brick):			
Crude:			
Kaolin	893	1,539	Malaysia 1,163.
Other	15,760	21,716	Philippines 6,536; Brunei 4,381; Malaysia 3,888.
Products:			
Refractory (including nonclay brick)	571	619	Malaysia 527.
Nonrefractory	5,641	10,151	Malaysia 7,779; Brunei 1,337.
Diamond:			
Gem, not set or strung value, thousands	$2,090	$3,846	Hong Kong $1,358; Japan $1,217; Saudi Arabia $601.
Industrial do	$34	$12	Malaysia $6; United Kingdom $4.
Feldspar and fluorspar	5,806	4,008	All to Malaysia.
Fertilizer materials:			
Crude:			
Nitrogenous	1	185	Do.
Phosphatic	22,550	13,019	Malaysia 12,914.
Manufactured:			
Nitrogenous	22,134	50,606	Bangladesh 34,925; Malaysia 13,806.
Phosphatic	3,794	76,065	Bangladesh 45,423; Burma 25,900.
Potassic	196,433	203,616	Malaysia 99,776; Bangladesh 67,405.
Other, including mixed	68,946	97,006	Malaysia 96,053.
Ammonia	349	259	Malaysia 226.
Graphite, natural	7	20	Malaysia 19.
Gypsum and plasters	682	881	Malaysia 723; Taiwan 111.
Lime	3,575	3,811	Papua New Guinea 1,893; Malaysia 745.
Magnesite	114	50	All to Malaysia.
Mica, all forms	80	15	Thailand 12.
Pigments, mineral:			
Natural, crude	29	1	All to Brunei.
Iron oxides, processed	104	339	Malaysia 266.
Precious and semiprecious stones, including synthetic, except diamond value, thousands	$8,601	$19,604	Hong Kong $17,928; Malaysia $518.
Salt	18,146	17,029	Malaysia 12,583.
Sodium and potassium compounds, n.e.s	13,566	12,235	Malaysia 8,543; Philippines 2,576.
Stone, sand and gravel:			
Dimension stone	407	1,162	Malaysia 641.
Dolomite, chiefly refractory grade	11	--	
Gravel and crushed rock	9,040	4,529	Malaysia 2,127; Brunei 1,519.
Limestone	450	681	Malaysia 506; Brunei 175.
Quartz and quartzite	14	(2)	NA.
Sand, excluding metal bearing	1,582	1,640	Brunei 827; United Arab Emirates 351; Australia 200.
Sulfur:			
Elemental:			
Other than colloidal	13,371	14,137	Mainly to Malaysia.
Colloidal	2,075	4,905	Thailand 1,560; Malaysia 1,435; Burma 1,325.
Sulfur dioxide	1	1	All to Malaysia.
Sulfuric acid	2,140	1,458	Sri Lanka 895; Malaysia 411.
Talc, steatite, soapstone, pyrophyllite	1,658	735	Malaysia 638.
Other:			
Crude	42,920	52,937	Malaysia 49,466.
Slag, dross, and similar waste, not metal bearing	634	1,355	Malaysia 1,178.
Oxides and hydroxides of magnesium, strontium, barium	1	12	All to Malaysia.
Bromine, iodine, fluorine value	$5,901	$4,997	Malaysia $3,396; Thailand $1,376.
MINERAL FUELS AND RELATED MATERIALS			
Asphalt and bitumen, natural	1,527	1,007	Mainly to Malaysia.
Carbon black	678	418	Malaysia 391.
Coal, all grades, including briquets	774	298	Malaysia 110; Philippines 99.
Coke	5,003	7,002	Malaysia 5,612; Burma 1,001.
Hydrogen, helium, rare gases value, thousands	$281	$457	Brunei $130; Taiwan $91; Malaysia $81.
Petroleum:			
Crude and partly refined thousand 42-gallon barrels	1,388	665	All to Japan.
Refinery products:			
Gasoline:			
Aviation do	584	467	Australia 143; Papua New Guinea 79; Thailand 50.
Motor do	6,253	8,330	Malaysia 1,394; Australia 1,343; Thailand 928.
Kerosine and jet fuel do	14,927	19,651	United States 4,595; Hong Kong 3,544; India 2,662.
Distillate fuel oil do	24,661	26,884	Thailand 5,009; Australia 3,733; Malaysia 3,472.

SRI LANKA[41]

Sri Lanka was one of the world's major suppliers of gem stones (excluding diamond) and ranked sixth in world production of natural graphite during 1978 and 1979. Titanium minerals, industrial clays, and limestone were also produced but were important to the local economy and not significant on the world market.

The search for petroleum failed to discover any commercial deposits despite extensive surveys and several exploratory wells drilled onshore and offshore. Under a Norwegian Government grant, a review is underway of all geophysical data to determine the advisability of further exploration.

The mineral industry accounts for about 2% of the gross domestic product (GDP), and around 6% of total exports.

The new United National Party Government, elected overwhelmingly in the July 1977 elections, launched a comprehensive program to reform the economy and accelerate economic growth during 1978. Various policy changes started the process of freeing the economy from excessive controls and shifting Government spending from consumer subsidies to capital investment. The changes included unification and devaluation of the dual exchange rate, relaxation of import and most price controls, changes in the food subsidy program, and elimination of some Government monopolies to allow more private sector competition. The 1979 budget introduced tax reform to promote savings and capital investment.

As a result of the Government's efforts, the gross national product (GNP) rose 8.2% in 1978 in real terms, to rupees 36 billion,[42] the highest economic growth rate since 1968 and more than twice the average annual growth during the past decade.[43] The output of the industrial sector was slightly higher, expanding 11% in real terms in 1978.

As a result of the import liberalization program, raw materials and spare parts became readily available, and overall capacity utilization rose from 61% in 1977 to 70% in 1978. Major areas of growth were in basic metals, textiles, nonmetallic minerals, paper, and chemicals.

Good weather contributed to record rice crops in 1977 and 1978, aiding the economy in the important agricultural sector.

Concomitant with the favorable economic factors were the problems of inflation and unemployment. The Central Bank estimated the average rate of inflation in 1978 was between 15% and 16%, lower than the 16% to 20% estimated for 1977. Based on published indices, wages of private sector workers kept pace with inflation in 1978; workers' salaries in the public sector, however, showed a drop in real wages.

Unemployment continued to be a major problem in the economy, but the 20% level of the mid-1970's was apparently being reduced during 1978 and 1979 by the new or accelerated Government programs. The Central Bank estimated that unemployment was down to 900,000 in 1978, or 16% of the labor force of about 5.6 million. In order to create jobs as quickly as possible, the new Government began concentrating on three major development projects: (1) acceleration of the Mahaweli River irrigation system, (2) the establishment of a free trade zone north of Colombo, and (3) urban renewal of the greater Colombo area. The Mahaweli project is a series of dams, canals, and hydroelectric stations to more than double the amount of irrigated land in the country and greatly increase hydroelectric capacity. Work had been progressing slowly under the former plan and the project will now be implemented more quickly, in part by increased foreign aid commitments.

Economic progress in 1979 was not as dramatic as in 1978 because the industries were operating closer to installed capacity, and scarcities of skilled labor, construction materials, and other inputs began to appear. With continued good weather resulting in increased crop yields, Sri Lanka was predicted to sustain a real growth rate of around 5% to 6% through yearend 1979. By the end of September, the Colombo consumer price index was up 12% over the December 1978 level, while the corresponding increase in the Central Bank index was 20%. Price increases for foreign oil forced the Government-owned Ceylon Petroleum Corp. to raise consumer fuel prices in mid-1979. Some formerly subsidized products doubled or trebled in price, reinforcing inflationary pressures.[44]

PRODUCTION AND TRADE

Mineral production generally increased during 1978. A large increase in rutile and zircon production resulted from the completion and opening of the rebuilt mineral sands production facility at Pulmoddai.

Exports of gems, graphite, titanium minerals, and zircon increased in 1978. Exports of the titanium minerals in 1979 will be dependent more on market conditions than production capability.

The major mineral import was crude oil to supply the needs of the country's refinery. Crude oil or natural gas was not produced domestically. The cost of the imported oil reached rupees 2.2 billion in 1978 and will reflect world price changes in 1979. A small amount of the lighter petroleum products was also imported.

COMMODITY REVIEW

Gem minerals accounted for about three-fourths of the total value of mining output. However, the rapid rise in the value of exports, up 100% in the mid-1970's, slowed considerably in 1978. With the Government's elimination of the special foreign exchange bonuses for gem exporters in November 1977, a significant portion of gem production was believed to be smuggled out of the country and not reflected in official trade figures. The total value of gem production reported in 1978 was estimated at over rupees 526 million. This was a large rupee increase over the 1977 figure. Data for 1979 were not available.

Sapphire, ruby, cat's-eye, and alexandrite were the main stones produced. Clear deep blue sapphire accounted for the most value followed by star sapphire and cat's-eye. Japan, Hong Kong, Switzerland, and the United States were the major importers of the Sri Lankan stones. Most of the stones are cut and polished for jewelry but a small amount also are used in precision instruments and in the watch industry.

The twenty-year-old ban on diamond imports was removed in 1977 and the country's first diamond lapidary opened during 1978 at Seeduwa, 25 kilometers outside of Colombo. The privately owned shop, equipped with sophisticated grinding and polishing instruments, will import rough diamonds from Belgium and export finished gems. European experts staff the facility and are training Sri Lankans in cutting and polishing. The plant will employ about 150 workers.

The Government has reportedly invited local and foreign firms to examine areas to be flooded by the dams constructed during the implementation of the Mahaweli development project to mine out any gem discoveries prior to the flooding. Some of the areas to be inundated are believed to contain rich deposits of gem stones.

The second most valuable mineral-derived product in 1978 was cement. Production increased significantly in response to higher demand from the construction industry but was still well below the present 710,000-ton-per-year design capacity of the country's three plants. The favorable production trend continued during 1979.

Production of titanium minerals and zircon from the rich Pulmoddai mineral sands deposit showed a large increase with the commissioning of the Ceylon Mineral Sands Corp.'s (CMSC) new rutile-zircon plant in early 1978. The plant began trial production in December 1977 and was expected to reach optimum production by the middle of 1978 following the normal shake-down period. The ilmenite section of the plant was not operated in late 1977 and early 1978 because of a 20,000-ton stockpile of unsold ilmenite. CMSC officials were scheduled to negotiate future sales contracts in Japan.

Under a second phase expansion targeted for 1985, ilmenite capacity will be raised to 130,000 tons per year from 230,000 tons per year of raw sand.

The Sri Lankan Government was interested in increasing export earnings from Pulmoddai by further processing ilmenite. Possibilities include a plant producing titania slag and byproduct pig iron or a titanium dioxide plant. Tenders for a titanium dioxide plant have been invited.

Currently the capacity of the CMSC facility is 85,000 tons of ilmenite, 12,000 tons of rutile, and 5,000 tons of zircon per year. About 300 tons per year of crude monazite concentrate also was recovered as a byproduct and stockpiled. Reserves at the Pulmoddai deposit were put at 3.2 million tons of sands grading over 30% heavy minerals.

Both the value and quantity of graphite produced in 1978 increased substantially, but graphite dropped from second to third place in value of mineral exports because of the increase in titanium mineral exports.

Exports to the United States totaled over 2,000 metric tons, valued at more than \$1.1 million. This represented an increase both in tonnage and value of 30% and 184%, respectively, compared with 1977 shipments.[45]

A countrywide search for radioactive minerals was undertaken by the Sri Lankan Geological Survey in 1979 under an International Atomic Energy Agency program. It entailed stream sediment sampling and investigation of other heavy mineral deposits, mainly the beach sands of coastal areas.[46]

In 1979 the Asian Development Bank

approved an additional loan to finance continuing construction of the 147,000-ton-per-year (N) urea plant at Sapugaskanda. The cost of the project has escalated to at least $171 million. Completion was set for early 1980.

The Government was actively encouraging foreign participation in its oil exploration program. About 5,000 kilometers of geophysical survey lines have been completed and a Norwegian consortium was to assist the state oil company in an offshore search. The initial work will be a detailed analysis of the offshore geology to determine if drilling is warranted. Ten shallow water and two deep water exploration blocks were available for production sharing contracts.

Expansion of the Ceylon Petroleum Corp.'s refinery at Sapugaskanda was scheduled for completion by early 1979 and was designed to increase production of light distillates, particularly naphtha, which will be the feedstock to the fertilizer plant. The company planned an additional expansion costing $80-$100 million in the form of a sophisticated hydrocracking complex, and tenders were solicited from contractors in several countries. In September 1979, however, the Government reportedly rejected all of the tenders received.

Sri Lanka continued to be dependent on imported oil for its fuel needs. During 1978 Saudi Arabia supplied 65% of the crude imports and Iran the remainder. In 1979 the sources of supply were more diversified and reportedly included Oman, Iraq, Libya, and China in addition to the 1978 suppliers. Exports of surplus naphtha and bunker oil brought a return of over $17 million in 1978.

Table 11.—Sri Lanka: Imports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1977	1978
NONMETALS —Continued		
Other:		
Crude	2,502	5,563
Oxides and hydroxides of magnesium, strontium, barium	6	9
Building materials of asphalt, asbestos, and fiber cement, and unfired nonmetals, n.e.s	7	24
MINERAL FUELS AND RELATED MATERIALS		
Asphalt and bitumen, natural	27	2
Carbon black and gas carbon	1,715	1,898
Coal, all types, including briquets	150	484
Coke and semicoke	629	12,391
Hydrogen, helium, rare gases	7	42
Petroleum:		
Crude and partly refined thousand 42-gallon barrels	11,245	11,142
Refinery products:		
Gasoline do	28	33
Kerosine and jet fuel do	310	118
Distillate fuel oil do	269	201
Lubricants do	10	41
Other do	186	438
Total do	803	831
Mineral tar and other coal-, petroleum-, or gas-derived crude chemicals	294	124

NA Not available.
[1]Official trade statistics of Sri Lanka report substantial imports of several classes of gold, but the corresponding values reported suggest that 1) the material is not pure gold, 2) the quantitative unit is incorrectly reported, and/or 3) the values are substantially in error.
[2]Less than 1/2 unit.

VIETNAM[47]

During 1978-79 Vietnam produced a modest amount of at least a dozen minerals, including antimony, iron ore, clays, zinc, copper, hydraulic cement, building stone, salt, coal, phosphate rock, tin, and chromite. The last four were produced in sufficient amounts that a surplus was available for export. In addition, deposits of bauxite, graphite, lead, manganese, silver, and titanium were known to occur within the country. The mining sector generally accounts for about 5% of gross national product. In the overall picture though, Vietnam was not a major world producer of any mineral commodity. Data on mineral production are seldom specific, often conflicting or ambiguous and frequently stated in terms of percent increase over an unstated or unknown base period. Mineral data was particularly scarce during 1979 because the Vietnamese press was largely preoccupied with the reporting of political and military events.

Vietnam's economy, particularly the agricultural sector, was adversely affected by three successive years of droughts, floods, typhoon, insect pests, and unseasonal temperatures.

The economy was further hurt in July 1978 when the Chinese withdrew all of their advisors and technical experts from projects they were helping to develop with the Vietnamese. Some large coal mine projects in particular were set back as a result.

The year 1979 began with Vietnam being involved in military activity in Kampuchea and then in February the Chinese crossed the northern border in an attack on Vietnam.[48] During the short campaign, Chinese troops penetrated up to 40 kilometers inside Vietnam. The attack reportedly destroyed over 1 million square meters of housing space, bridges, factories, and railroad lines and damaged some important mines. These included the rock phosphate and iron ore mines near Lao Cai, and tin, copper, and chromite mines in the Lang Son and Cao Bang areas.

Economic plans were further disrupted by the diversion of enormous amounts of manpower and resources from industry and agriculture to the military effort. Shortages of fuel and trucks caused transportation problems and affected movement of goods intended for the export market.

On the industrial scene, the 1978 output grew by 7% compared with a target of 21%. As a result, the 1979 target was reduced to a more feasible 12%. It was doubtful, however, if this was achieved, in light of the difficulties already mentioned. In addition, the exodus of tens of thousands of refugees, many of them skilled ethnic Chinese, affected production in the coal mines and hence the generation of electric power and the overall industrial output.

The Government had planned to construct 4 million square meters of housing during 1978 but only about 1.5 million square meters were actually completed. The 1979 plan was cut back to 1 million square meters, but because of a large amount of defense-related construction after the border conflict, it was doubtful that even that reduced target was achieved.

The 1980 state plan, adopted at the Sixth Socialist Republic of Vietnam National Assembly, called for a 4.7% increase in total industrial output value over that of 1979, and an 11% increase in total agricultural output in the same period. Other goals in the 1980 plan included an increase of 14% in coal and cast iron, 30% in cement, and 32% in both phosphate and nitrogenous fertilizer.

The state plan called for total capital investments to be increased by 2.2% over that of 1979. Much of the new construction will be directed toward improving the agricultural sector. In addition, emphasis will be placed on increasing the output and capacity of electric power, cement, and fertilizer, all of which will indirectly benefit the agricultural output.

Despite their many problems, the Vietnamese did manage to engage in foreign trade with both Council for Mutual Economic Assistance and market economy nations in 1978 and 1979. The total value of merchandise exports reportedly amounted to about $482 million in 1978 and was planned to increase by 31% in 1979. Limited data for the first quarter of 1979, however, indicated a considerable decline in both volume and value of exports over the same period in 1978. Exports to Japan, the major market economy trade partner, showed a 32% drop during that period. Vietnam's chief export was high-quality coal. Approximately 900,000 tons were shipped in 1977 and 460,000 tons in 1978, mostly to Japan. Vietnam has been also a substantial exporter of phosphate rock. However, the quantities shipped and the current destinations are not available.

Merchandise imports during 1978 totaled about $1.16 billion and were estimated to increase to $1.20 billion in 1979.[49] Approximately one-third of the 1978 total was for food grain imports and most of the remainder was for fuels and raw materials.

COMMODITY REVIEW

Vietnam produces a modest amount of steel from domestically mined raw materials. Iron ore was mined at the Trai Cau mine in Bac Thai Province and smelted at the Thai Nguyen steelworks. The new Luu Xa rolling mill, using billets from Thai Nguyen, probably began operating during 1977. In 1978 the plant forged its own rollers, the first ever made in Vietnam. In addition, the older Gia Sang rolling mill underwent a complete overhauling and expansion during August and September of 1978. Planned capacity of the refurbished mill was to be 50,000 tons of rolled steel per year. The rolling mills comprised one of the few major industries that reportedly met their quotas in 1978 and 1979. In addition to domestic production, Vietnam has a three-year agreement with Japan to buy 200,000 tons per year of rolled steel products through 1980.

The most important development in the iron and steel sector during 1978 and 1979 was the abandonment of the planned construction of an integrated steel complex at the Thai Nguyen steel plant. The French firm Creusot Loire had completed a feasibility study and was ready to send the first shipment of equipment for the project, which would have expanded and modernized the primitive steelmaking facilities at Thai Nguyen. In the agreement the Vietnamese were to provide the necessary infrastructure, which involved site preparation at the plant, finding suitable ore deposits, building a railroad to transport ore to the plant, and building roads and bridges capable of handling the bulky and heavy equipment that would be transshipped from the port of Haiphong to the site. When Creusot Loire was ready to begin deliveries in mid-1978, Hanoi reported that their part of the work had not been started. Reportedly, Creusot Loire withdrew from the project, highlighting the country's infrastructure weakness, its managerial problems, and its inability to absorb large quantities of technological aid.[50]

Expansion of the steel production capacity continued to warrant priority on the Government's industrial development plan. The Thai Nguyen modernization will probably be revived as soon as the overall conditions are favorable enough to allow construction of the required support facilities.

The Vietnamese continued with their enterprising plans to increase cement production despite problems in other economic sectors. The Ha Tien and Haiphong plants were the only rotary-kiln cement mills operating during 1978 and 1979. Three large foreign engineered plants were under construction during the period.

The 1.2-million-ton-per-year plant at Binh Son in Thanh Hoa Province was being built with Soviet aid. The tube for the rotary kiln was nearly assembled by late autumn of 1979. The plant could be ready for production by late 1980 or early 1981 if no problems arise. The construction activity employs 14,000 workers.

The Hoang Thach plant in Hai Hung province is under construction with Danish and Japanese aid. The dry process, computer controlled plant will have a designed capacity of 3,100 tons per day. Installation of the kiln was completed in August 1979. Support equipment was at the mid-stage of assembly at that time.

The third major project was a French-aided, 1.0-million-ton-per-year expansion of the Kien Luong plant at Ha Tien in the southwest corner of Vietnam. The plant is scheduled for completion in 1980.

Of more immediate benefit to the economy was the construction of small vertical kiln plants with capacities ranging from 5,000 to 20,000 tons per year. The state plan called for completion of 26 such plants during 1977 and 1978. Plants which were reported to have begun operating by late 1979 were located in Uong Tu, Quang Ninh Province; Thai Nguyen, Bac Thai Province; Dong Vinh, Thanh Hoa Province; Long Tho, Binh Tri Thien Province; Da Nang, Quang Nam-Da Nang Province; Dieu Tri, Nghia Binh Province; Hon Khoi, Phu Khanh Province; and Ho Chih Minh City. Status of the other planned plants was not reported in the press. These small plants were inexpensive to build and use local raw materials to supply cement for the local building industry. Collectively output by the small plants will help relieve the current cement shortage until the big rotary kiln plants come onstream with their more uniform and higher quality product.

The Government has placed a priority on the expansion and modernization of the fertilizer industry in order to support increased agricultural output and maintain phosphate exports. Vietnam has large deposits of phosphate ores, with major production coming from the Lao Cai mine near the northwest border. Vietnamese sources indicated that present exploitation of the apatite deposits was not being done in an efficient manner and that large amounts of usable ore were being wasted during mining of the high-grade ores. Little or no beneficiation was done on the ores.[51]

Most of the domestic mine production goes to small plants that grind the ore for direct application. Some of these plants have roasting facilities to increase the solubility of the phosphate before grinding. In addition, there are a few plants producing a modest amount of single superphosphate fertilizer. A published account of 271,000 tons of fertilizer produced in the first half of 1978 may refer to gross weight of superphosphate for that period.[52]

Toward the goal of increasing fertilizer production, the Government commissioned seven new fertilizer factories (phosphate grinding plants) between January and October 1978. At least three of these had grinding capacities of 40,000 tons per year each, and were located in Ninh Binh, Hai Hung, and Nghe Tinh. Overall, the mining and grinding capacity of the fertilizer sector progressed as planned during 1978 but serious transportation problems limited the production increases to very modest levels.

Plans called for the production of 1.3 million tons per year of phosphate fertilizer (grade not specified) by 1980. This was to be accomplished by expansion of the Lao Cai mine to a production of 1.5 to 3.0 million tons per year of ore grading 32% to 34% P_2O_5 content. This would leave a surplus for a significant increase in the amount of exports.

The Government's expansion plans were disrupted by the occupation of the Lao Cai mine. Vietnamese press reports and photos released after the withdrawal claimed that the mining equipment had been systematically destroyed. In addition, the Lao Cai and Pha Ta powerplants were also reportedly destroyed.

The 1979 fertilizer production was certainly affected by these events and the 1980 output could be affected as well. The mining equipment will be difficult and expensive to repair or replace; Vietnam does not manufacture large shovels or earthmoving equipment and will therefore be dependent on the U.S.S.R. or other foreign countries for replacements. The long-term production loss will depend on how much equipment was actually destroyed, how much could be salvaged, and how quickly replacements are obtained.

Vietnam had planned to produce 10 million tons of washed coal during 1980. Events during 1978-79 have probably set that goal back at least one year and possibly two.

The Vietnamese claimed that work on new mines continued without serious difficulties, however, two months after the Chinese departure, Vietnam signed a coal mining cooperation accord with the U.S.S.R. No details were released.

On the natural scene, heavy rain caused at least one major mine to be inundated in 1978. Pumping of the lower levels continued well into 1979.

Another serious hindrance to increased coal production was the failure of the Government to plan for a balanced and rational system of moving the coal once it was mined, to maintain the new mining and transportation equipment, and to train sufficient technicians, miners, and mechanics to sustain the level of necessary work.

In late 1978, before the hostilities, labor was recruited on an emergency basis to try to increase or at least maintain the production and in particular the movement of the coal. Production apparently did increase during the last two months of 1978 but not enough to achieve the 1978 goal of 7.0 million tons of washed coal. The Government admitted to an 800,000-ton shortfall in 1978. There was little improvement during 1979 although a number of mines of widely varying capacity were nearing completion or producing some coal from development drifts or shaft construction. The Government's 1980 revised industrial plan called for a 14% increase in coal production over the 1979 output.

During 1978 Hanoi granted service contracts to three foreign exploration groups: Bow Valley Industries Ltd., a Canadian consortium; AGIP, the exploration subsidiary of Italy's ENI; and the West German company Deminex Deutsche Erdol Versergungsgessellschaft MBH. Negotiations to finalize an earlier protocol signed by Elf Aquitaine of France apparently were not successful.

Table 12.—Vietnam: Apparent imports of mineral commodities[1]

(Metric tons unless otherwise specified)

Commodity	1977	1978	Principal sources, 1978
METALS			
Aluminum metal including alloys:			
Unwrought	798	999	All from Japan.
Semimanufactures	2,121	1,511	Japan 843; Hungary 491.
Copper metal including alloys:			
Unwrought	1,696	--	
Semimanufactures	440	218	Japan 217.
Iron and steel metal:			
Pig iron	--	16,300	All from Japan.
Ferroalloys	700	900	All from U.S.S.R.[2]
Semimanufactures:			
Bars, rods, angles, shapes, sections	159,418	162,674	Japan 90,610; U.S.S.R. 60,000.[2]
Plates and sheets	89,830	106,140	Japan 100,931; Hungary 2,514.
Hoop and strip	2,662	2,122	Japan 2,109.
Rails and accessories	525	4	All from Japan.
Wire	17,002	15,157	Japan 13,721; Sweden 750; Netherlands 630.
Tubes, pipes, fittings	11,100	12,038	Japan 6,908; U.S.S.R. 3,500;[2] France 654.
Castings and forgings	--	1,457	France 1,240.
Lead metal including alloys:			
Unwrought	--	1	All from Japan.
Semimanufactures	--	51	Japan 50.
Manganese oxides	800	501	All from Japan.
Molybdenum metal including alloys, all forms	1	--	
Nickel metal including alloys, semimanufactures	4	--	
Silver metal, unworked or partly worked value, thousands	$26	$25	Do.
Tin metal including alloys, semimanufactures	--	2	All from France.
Titanium oxides	310	100	All from Japan.
Tungsten metal including alloys, all forms	--	1	Do.
Zinc:			
Oxide and peroxide	250	--	
Metal including alloys:			
Unwrought	1,890	--	
Semimanufactures	--	67	Japan 66.
Other:			
Ores and concentrates	--	200	All from Japan.
Oxides, hydroxides, peroxides	53	94	Do.
Metalloids	--	54	Japan 30; France 24.

Clays and clay products:			
Crude	--	9	All from France.
Products:			
Refractory	7,628	503	Japan 414; Hungary 63.
Nonrefractory	486	74	Singapore 40; Italy 34.
Diatomite and other infusorial earth	--	60	All from Japan.
Feldspar and fluorspar	650	302	Do.
Fertilizer materials:			
Manufactured:			
Nitrogenous	162,312	175,729	Japan 86,059; U.S.S.R. 77,670; Indonesia 10,000.
Potassic	21,600	15,984	All from U.S.S.R.
Other, including mixed	1	31	Singapore 25.
Ammonia	206	4	All from Denmark.
Gypsum and plasters	NA	4,100	All from Thailand.
Mica, worked	9	5	All from Japan.
Pigments, mineral: Iron oxides, processed	210	1	Do.
Sodium and potassium compounds, n.e.s.:			
Caustic soda	5,100	7,395	U.S.S.R. 5,300[2]; West Germany 2,095.
Caustic potash	--	30	All from Japan.
Soda ash	4,300	5,000	All from U.S.S.R.[2]
Stone, sand and gravel:			
Quartz and quartzite	--	2	All from Japan.
Sand, not metal bearing	1,165	243	All from Sweden.
Other	--	106	Sweden 105.
Sulfur, elemental, colloidal	--	110	Japan 100.
Talc	300	430	All from Japan.
Other: Oxides and hydroxides of magnesium, strontium, barium	452	--	
MINERAL FUELS AND RELATED MATERIALS			
Carbon black	700	1,253	Japan 1,150.
Coke and semicoke	20,706	27,870	All from Japan.
Petroleum:			
Crude oil and unspecified refinery products do	4,000	4,100	All from U.S.S.R.[2]
Refinery products:			
Gasoline thousand 42-gallon barrels	467	751	Italy 735.
Kerosine do	NA	44	All from Italy.
Distillate fuel oil do	--	753	Singapore 624; Italy 128.
Residual fuel oil do	2,651	1,492	All from Singapore.
Lubricants do	383	313	Italy 290.
Other:			
Mineral jelly and wax do	4	3	Japan 2.
Bitumen and other residues do	5	58	Singapore 57.
Bituminous mixtures do	87	--	
Mineral tar and other coal-, petroleum-, or gas-derived crude chemicals	3,715	4,712	All from Japan.

NA Not available.
[1]Owing to the lack of official trade data published by Vietnam, this table should not be taken as a complete presentation of Vietnam's mineral imports, with regard to either commodities or quantities. These data have been compiled from various sources which include United Nations information and data published by the trading partners.
[2]Estimated on the bases of reported ruble value.

Early in 1979 the first offshore drilling since 1975 was started by Bow Valley and resulted in two dry holes. By the end of the year it was reported that Deminex had completed two holes, both dry, and was drilling a third, and AGIP had abandoned one hole and was drilling a second.

During 1978, the Vietnamese Government again claimed hydrocarbon discoveries while drilling onshore in the Red River delta. The first hydrocarbon shows were reported in 1975. Drilling is being done with Soviet assistance and equipment. Bottom-hole temperatures as high as 200°C complicate the drilling effort. No specific claim was made that the discoveries were commercial.[53]

The Mineral Industry of Other Countries of the Near East

By Peter J. Clarke[1]

CONTENTS

BAHRAIN

The petroleum industry continued to be the most important mineral activity in Bahrain during 1978-79. Revenues generated by the petroleum sector increased from $378 million[2] in 1977 to an estimated $419 million in 1978 and approximately $522.5 million in 1979, despite decreasing production over the 2 year period. There were two oilfields that produced revenues for Bahrain; the Awali oilfield, the nation's only onshore producer, and the Abu Sa'fah oilfield, located in the Persian Gulf, north of Bahrain. The Awali oilfield has been decreasing output from a high of 27,973,000 barrels in 1970 to 19,000,000 barrels in 1979. Bahrain shared the revenues from the Abu Sa'fah oilfield with Saudi Arabia, as settlement of an ownership dispute. For the first time, in 1978, revenues from the Abu Sa'fah oilfield represented over 50% of the total receipts from the petroleum sector.

The years 1978-79 saw the gradual takeover of the Bahrain Petroleum Co. (Bapco), formerly a subsidiary of the California-Texas Petroleum Co. (Caltex), by the Government-owned Bahrain National Oil Co. (Banoco). By yearend 1978, Banoco owned 60% of Bapco, and Caltex the remaining 40%. The Government-owned company controlled exploration concessions, managed domestic marketing of petroleum products, and controlled natural gas production and marketing. On December 15, 1979, the Bahrain Government completed full takeover of the Bapco operations. Bapco will continue to own and operate the 250,000-barrel-per-day oil refinery located near Sitrah, as well as handle foreign marketing of petroleum products.

The Sitrah oil refinery processed all of Bahrain's crude oil output as well as over 70 million barrels of crude and blended stocks supplied from Saudi Arabia by underwater pipeline. For both 1978 and 1979, the refinery operated at or near its 250,000-barrel-per-day capacity, processing 247,000 barrels per day in 1978 and 251,250 barrels per day in 1979. The value of refinery exports were estimated at $1.2 billion in 1978 and $1.3 billion in 1979.[3] These export values were not to be confused with Government revenues, but were a combination of Bahrainian oil and reexported Saudi Arabian oil processed in Bahrain. The Government of Bahrain was following a formal policy to decrease domestic oil production by approximately 6% annually in an attempt to conserve the proven resources (estimated at 300 million barrels) until the end of the century.

The outlook for natural gas was more encouraging. Estimated reserves of 9 trillion cubic feet[4] of nonassociated gas were expected to last 70 years at 1979 production levels. The gas was derived from the Permian Khuff Formation, which underlies the oil-producing Triassic Bahrain Formation in the Awali oilfield. Production of natural gas rose from 131,150 million cubic feet in 1978 to 140,000 million cubic feet in 1979. During 1978, the gas was used to maintain pressure in the Awali oilfield, fuel the 300-megawatt powerplant at the Aluminum Bahrain Ltd.'s (Alba) smelter, fuel the Jupir powerplant-desalinization complex, and fuel the Sitrah refinery in its low-sulfur fuel oil complex and powerstation. The remainder (30%) was flared.

In March 1978, Banoco signed a $72 million contract with the Japan Gasoline Co. (JGC) to build a natural gas liquids (NGL) plant to utilize the flared natural gas. In April 1979, the Bahrain National Gas Co. (Banagas) was formed as a joint venture between Banoco (75%), Caltex (12.5%), and the Arab Petroleum Investments Corp. (Apicorp) (12.5%), to operate and manage the plant. On December 17, 1979, the plant was inaugurated 2 months ahead of schedule. The plant will utilize about 100 million cubic feet per day of associated gas for the production of 280,000 tons per year of NGL, 80,000 tons of propane, 75,000 tons of butane, and 125,000 tons of naphtha (natural gasoline), all of which was to be marketed by Caltex. Some of the residue gas was destined to become the base of a new petrochemical venture between Bahrain and Kuwait.

With supplies of oil running short within the next 20 years, the aluminum industry became the focal point of Bahrains attempt to diversify its economic base. For 4 consecutive years, the Alba smelter operated above its 120,000-ton-per-year design capacity. Export values of aluminum were $116.7 million in 1978 and $103.1 million in 1979.[5] The decrease in quantity and value of exported aluminum was due to a drastic reduction in Japanese aluminum imports in attempts to stabilize the yen on world markets.[6] All raw materials for the Alba smelter were imported except fuel. Australia was the sole supplier of alumina (235,000 tons per year),[7] coke and pitch were imported from the United States, and cryolite was imported from Japan. In 1979, plans were approved to expand the capacity of Alba by 45,000 tons per year, bringing the total capacity up to 165,000 tons per year. In addition, John Brown Engineers of Clydebank (United Kingdom) were awarded a $70 million contract for a new powerstation at the Alba plant. By 1980, Saudi Arabia was expected to acquire 20% ownership of the Alba plant, reducing the Bahrain Government's holdings to 57.9%, while leaving Kaiser Aluminum Bahrain's (United States) 17% and Breton Investments 5.1% shares unaffected.

The major imported minerals in Bahrain included cement from Japan (40,000 tons per year), stone and gravel from Dubai, and semimanufactured metals and nonmetals from Japan. The Government and the Saudi Cement Co. signed an agreement with Ishikawajima-Harima Heavy Industries Co. Ltd. of Japan to build a 6,000-ton-per-day cement plant near Ain Dar in the Eastern Province of Saudi Arabia. The plant was scheduled for completion in 1980 and was to supply approximately 500,000 tons per year of cement to Bahrain.

Plans were made in 1978-79 to further diversify Bahrain's economy. A joint venture was initiated between Bahrain and Kuwait to build a petrochemical plant to produce ammonia and methanol from Bahrain's abundant supplies of natural gas. The Bahrain-Kuwait Petrochemical Industries Co. was owned equally by the Kuwaiti Petrochemical Industries Co. (PIC) and Banoco. Production was to begin in late 1982. With completion of the modernization program of Mina Sulman Port, and the Arab Shipbuilding and Repair Yard (ASRY) scheduled for 1980, the reexporting industry in Bahrain was expected to grow. In addition, an $800 million multilane causeway, financed by Saudi Arabia, linking Jasra in Bahrain to Khobar in Saudi Arabia was planned to further increase Bahrain's flow of goods and also bring Bahrain closer into the Saudi defense sphere.

[e]Estimate. [p]Preliminary. NA Not available.
[1]In addition to the commodities listed, a variety of other crude construction materials (common clays, stone, and sand and gravel) presumably is produced, but output is not reported quantitatively and available information is inadequate to make reliable estimates of output levels.
[2]Reported figure.
[3]Production reported as 150,000 cubic meters.
[4]Includes gas reinjected into reservoirs, if any.

JORDAN

The mineral industry in Jordan continued to be the base of economic expansion during 1978-79. Mining and the mineral industry contributed approximately 12% to Jordan's \$1.8[8] billion gross domestic product (GDP) in 1978 and over 20% to the \$2.2 billion 1979 GDP. Fertilizer raw materials, namely phosphates, were the leading exchange earners, grossing \$70 million in 1978 and \$90.5 million in 1979. Petroleum products were the second leading industry, with the refinery's net sales increasing from \$65 million in 1978 to \$70 million in 1979. Petroleum products were followed by cement, with a revenue increase from \$40 million in 1978 to an estimated \$45 million in 1979. Salt was the fourth leading mineral with revenues of approximately \$300,000 for both years.

Despite the substantial (22%) growth in GDP from 1978 to 1979, Jordan continued to experience a growing trade deficit that amounted to \$361 million in 1979. However, over 50% of Jordan's imports were for capital goods, which should help to reduce the imbalance. The deficit was more than made up for by receipts from tourism, official transfer payments from other Arab countries, and remittances from Jordanians working abroad, leaving a general balance of payments surplus of \$17.3 million. The 1976-80 5-year plan aimed to reduce the trade deficit and keep an average GDP growth of around 12% per year, while increasing reliance on domestic revenues.

Phosphate production continued to be Jordan's major mineral industry. Output increased from 1.8 million tons in 1977 to 2.3 million tons in 1978 and 2.56 million tons in 1979. Phosphate exports reached a record 2.1 million tons in 1978 and an estimated 2.3 million tons in 1979. Earnings were down over previous years (\$70 million in 1978) because of depressed world prices for phosphate rock. Prices slowly returned to their pre-1978 level, and 1979 earnings rebounded to nearly \$90 million.[9] Phosphate mined in Jordan was exported to Western Europe (18%, mostly to Turkey and Italy), Eastern Europe (30%, to Romania and Poland), Asia (50% mainly to India, Japan, and the Philippines), and Africa (2%).

There were two mines producing phosphate in Jordan, both operated by the Jordan Phosphate Mines Co., and another was scheduled to go into operation in 1980. The phosphate beds are usually found in two or three horizons that range between 35 and 65 meters in total thickness. Deposits occur fairly close to the surface in most places and consequently, open pit mining methods were used. The Ruseifa mine, located 15 kilometers north of Amman produced phosphate at about 800,000 tons per year for both 1978-79. The El Hasa mine, 200 kilometers north of Aqaba, extended its output from 1.5 million tons per year in 1978 to 1.7 million tons per year in 1979. In 1978, a \$10 million walking dragline was purchased from Ransomes and Rapier (United Kingdom) for use at El Hasa. The equipment, which was to be commissioned in 1980, used a 35-cubic-meter bucket and could dig to a depth of 50 meters.

Plans were announced to open a mine at Wadi al Abuith, 20 kilometers north of El Hasa. Production was scheduled to begin in 1980 at about 1 million tons per year. Also, phosphate reserves at Shidayah, 130 kilometers north of Aqaba, were being considered for development, possibly for 1980. The general trend was to exploit the more southerly reserves, which are more abundant and closer to the port of Aqaba, and to decrease production in the north in a manner consistent with its smaller reserves. Jordan's total phosphate reserves were estimated at 2.5 billion tons.

Programs were underway in 1978-79 to expand the capacity of transportation, storage, and loading facilities for the phosphate industry. The third stage of the phosphate handling facilities at the port of Aqaba became operational in September 1979. The facility included a railway discharge station, a lorry discharge station, intermediate storage facilities, and shiploading facilities for an annual capacity of up to 5 million tons of phosphate.

One of Jordan's major industrial projects for 1978-79 was the construction of the \$325 million fertilizer complex at Aqaba. The plant was due to start production in 1981, with an annual output of 650,000 tons of sulfuric acid, 365,000 tons of phosphoric acid, and 700,000 tons of monoammonium and diammonium phosphate. A contract to supervise design, construction, training, raw materials purchases, and operational tests for the fertilizer complex was awarded to Spie-Batignolles S.A. (France) and Badger Co. (United States). Shareholders in the Jordan Fertilizer Industries Co. (JFI) were the Jordanian Government (26%), Jordan Phosphate Mines Co. (25%), public shareholders in Jordan (17.4%), Arab Mining Co. (10%), Arab Petroleum Investments Corp. (10%), International Finance Corp. (5%), Islamic Development Bank (4.1%), and Caisse Jordanienne de Retroites (2.5%). Fertilizer purchase agreements were reached in May 1979 with Czechoslovakia in exchange for heavy machinery, sugar, cars, and textiles.

The Dead Sea potash project, the largest single industrial scheme in Jordan was under development in 1979 by the Arab Potash Co. (APC). Potash production was to start in late 1981 at about 1.2 million tons per year and increase to 1.5 million tons per year by 1989. Located on a 150-square-kilometer area in the southern basin of the Dead Sea, the plant was to process 1.2 million tons of crystalline carnallite, a potassium mineral, obtained from solar evaporation of Dead Sea brines. The Austrian firm, Voest Alpine, was awarded a $107 million contract by APC to construct the potash processing refinery. APC also awarded several other contracts: $122 million to George Wimpey and Co. (United Kingdom) for construction of dikes and evaporation ponds, $25 million to Jacobs Engineering (United States) for operation and supervision of the project and technical training of personnel; and R.A. Hanson Co. for design and construction of the carnallite harvesting machines.

APC was owned by the Jordan Government (51%), Arab Mining Co. (25%), Islamic Development Bank (7%), and by other Arab countries. Funds for the project were provided by shareholders, in addition to loans from the Libyan Arab Foreign Bank ($50 million), the Kuwait Fund for Arab Economic Development ($35 million), the International Bank for Reconstruction and Development ($35 million), the U.S. Agency for International Development ($33 million), and the Organization of Petroleum Exporting Countries (OPEC) Special Fund ($7 million).

Marketing of potash was contracted to Enterprise Miniere et Chimique (France) for Western Europe and Africa (280,000 tons per year), Mitsubishi (Japan) for Asia (600,000 tons per year), and Woodward and Dickerson (United States) for North and South America (400,000 tons per year).

Arrangements were made in 1978 to produce magnesium and bromine in association with the Dead Sea project. Ruthner Co. (Austria) was to construct a 50,000-ton-per-year refractory magnesia plant at an estimated cost of $60 million. Great Lakes Chemical Co. (United States) was to acquire a 25% share and provide technical assistance for the construction of a 30,000-ton-per-year bromine plant, also estimated to cost around $60 million.

Jordan's cement production was to increase from 634,000 tons per year to 2.6 million tons per year through the expansion of the Jordan Cement Co. plant at Fuheis and the construction of a new plant at Rashadiyah. Cement production during 1978 (564,000 tons) and 1979 (634,000 tons) was still below the 2.2-million-ton-per-year demand. Two production lines were to be added to the plant at Fuheis, to bring capacity of 3,000 tons per day by 1980. The Government concluded a contract with Kaiser Engineers (United States) for the construction of a $100 million cement plant at Rashadiyah in South Jordan. The plant was to produce 100 million tons per year of portland cement, mainly for export.

Two companies were producing steel in Jordan in 1978 and 1979. The Jordan Iron and Steel Industry Co., Ltd., produced steel bars and billets at its plant at Zarqa, while the Jordan Pipes Manufacturing Co., Ltd., produced galvanized pipes at its plant also located in Zarqa. Total iron and steel production in Jordan between the two companies was around 100,000 tons for both 1978 and 1979. The feed material for both plants was pig iron and ferroalloys imported from South Africa and the U.S.S.R., and scrap iron from Syria and Kuwait.

The Zarqa petroleum refinery produced 11.2 million barrels of petroleum products in 1978 and over 12 million barrels in 1979. Crude oil was imported from Saudi Arabia by way of the Trans-Arabian Pipeline (TAPline). The Romanian firm, Industrialexport, was supervising the expansion of the refinery's capacity to 60,000 barrels per day, almost double the 1979 operating volume, at a cost of about $190 million. New facilities at the refinery were to include a 43,000-barrel-per-day distillation unit, a 7,000-barrel-per-day gasoline reforming unit, and asphalt and isomax units.

In 1978, the consortium operated by Filon Exploration Corp., relinquished its petroleum exploration concessions which covered an 8,000-square-kilometer area on the east bank of the Jordan River. The Jordanian

Natural Resources Authority contracted a nationwide aerial survey to locate possible petroleum reserves. Two U.S. firms, Phoenex Corp. and Geoterrex, were undertaking the survey, which was to be completed in 1 year.

The Jordan Government was also examining the possibility of developing its large reserves of oil shale. Bilateral negotiations with the U.S.S.R. were completed in September 1979 for the study of the economic advantages to developing the oil shale deposits.

Table 2.—Jordan: Exports and reexports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1977	1978	Principal destinations, 1978

LEBANON

The mineral sector was a minor contributor to Lebanon's economy during 1978-79. The principal mineral commodities and their approximate earnings for 1978-79 (respectively) were: refined petroleum products ($198 million[10] and $300 million), iron and steel semimanufactures ($100 million and $110 million), and cement ($70 million and $77 million). Lebanon also produced small amounts of gypsum, limestone, and salt.

Civil disturbances during 1978-79 created further problems for the nation's economy. Lebanon's trade deficit continued to worsen, from $1 billion in 1978, to $1.6 billion[11] in 1979, and the inflation rate remained above 30% for both years. Increased remittances from Lebanese workers abroad and reconstruction loans from other Arab countries helped to partially offset the balance of payments deficit. The Lebanese Board for Reconstruction and Development estimated that $7.2 billion was necessary to repair war damage in Lebanon. As of December 1979, Lebanon had received nearly $800 million in loans and grants over the past 5 years, mostly from Saudi Arabia, Kuwait, United Arab Emirates, and Qatar.

Lebanon's two refineries operated below capacity during 1978-79, owing mostly to civil disturbances. The Mediterranean Refining Co., (MEDRECO) refinery in Zahrani, just south of Sidon, operated at about 80% to 85% of its capacity of 17,000 barrels per day during 1978-79. MEDRECO was owned jointly by the Caltex (50%) and Mobil Oil Co. (50%). The Tripoli refinery operated at around 65% to 75% of its 35,000-barrel-per-day capacity during 1978-79. Operations at Tripoli were suspended for several weeks in late 1979 because storage tanks were full of refined petroleum products, and exports had been interrupted by closure of the Beirut-Tripoli road.

All of Lebanon's refinery feedstock for 1978-79 was imported from Saudi Arabia, by way of TAPline. In 1978, oil feedstock for the two refineries cost Lebanon $160 million. By 1979, the oil import bill had reached $287 million. Crude oil prices jumped from an average $13.00 per barrel in 1978 to around $18.50 per barrel in 1979.

On October 25, 1979, TAPline notified the Lebanon Ministry of Industry and Petroleum that it would discontinue supplies of Saudi crude from the ARAMCO oilfields to the Tripoli refinery as of January 1, 1980. The Saudi Government felt that Tripoli should draw feedstock from Iraq, its original source. The Iraq National Oil Co. (INOC) pipeline to the Banias terminal was reopened in February 1979, but no agreement was reached between Iraq and Lebanon for supplying the Tripoli refinery. On March 1, 1979, TAPline agreed to extend deliveries of crude to Tripoli only into the first quarter of 1980. TAPline was to supply 3 million barrels of oil to Tripoli before April 1, 1980.

Lebanon's cement production declined slightly from 1978 to 1979, but price increases generated greater revenues in the industry as a whole. Three cement plants were operating in Lebanon, all located in Chekka. All three plants were owned by private interests in Lebanon, and all three used limestone and gypsum quarried in Lebanon, just south of Tripoli for cement production. Production satisfied most of Lebanon's domestic requirements and also provided a substantial export market. Approximately 30% of cement production, valued at $25 million, was exported both years. In 1978, the Société des Ciments Libanais plant capacity was expanded from 1.2 million tons per year to 1.8 million tons per year by the addition of a 1,500-ton-per-day rotary kiln. The plant operated by Cimenterie Nationale S.A.L. was expanded from 500,000 tons per year to 1 million tons per year, and expansion was planned for the third plant, operated by Societe Libanais des Ciments, from 50,000 tons per year to 160,000 tons per year by 1980.

Production of iron and steel remained about the same throughout 1978-79. Approximately 20% of iron and steel produced in Lebanon was exported. Steel exports were valued at around $18 million per year. Consolidated Steel Lebanon S.A.L., located in Byblos-Amchit, north of Beirut, operated a bar, section, and rolling mill, with an annual capacity of 240,000 tons of rolled steel. The Lebanon Steel Mill Co. operated a steel furnace and bar mill with a capacity of 100,000 tons per year, and Societe Nationale des Tubes S.A.L. operated a tube and pipe mill in Dekwaneh, near Beirut.

Lebanon had reserves of low-grade iron ore in the north, and phosphate deposits in the south, which remained unexploited.

OMAN

Important developments in the minerals sector occurred during 1978-79 in Oman. New oil discoveries seemed likely to reverse the trend of declining production, while major steps were taken in the development of copper deposits, natural gas, the steel industry, and cement manufacturing.

Petroleum production continued to be the base of Oman's economy, constituting nearly 90% of Government revenues and 60% of the gross national product (GNP). Crude oil accounted for 95% of Oman's total exports, and contributed to the overall balance of payments surplus of $133.7 million[12] in 1978 and $328.2 million in 1979. The Government budget moved from a $100 million deficit in 1978, made up mostly by loans and grants from Saudi Arabia and the United Arab Emirates, to a $202 million budgetary surplus in 1979. Future revenues were to be derived from further petroleum development, utilization of natural gas reserves, development of northern copper deposits, a growing cement and steel industry, and possibly gypsum, limestone, and marble quarrying.

Since 1976, when oil production averaged 366,000 barrels per day, oil production in Oman has declined steadily. Production dropped from 340,000 barrels per day in 1977 to 314,000 barrels per day in 1978 and 295,000 barrels per day in 1979. Almost all Omani crude was exported, Japan (63.6%), United States (13.2%), Western Europe (18.4), Brazil (1.2%), and other (3.6%). Japan's share increased from 57% in 1978 to 64% in 1979, while the U.S. share declined slightly from 15% to 13%. Although not an OPEC country, Oman has generally followed the pricing policies of that organization. The official selling price of Omani crude throughout 1978 was a modest $13 per barrel. By December of 1979, that price had risen to $28 per barrel. Petroleum Development (Oman) Ltd., the only petroleum producer, was owned 60% by the Government, 34% by Shell, 4% by Compagnie Française des Petroles (CFP), and 2% by Participations and Explorations Corps. (Partex) (Portugal).

New discoveries of oil in 1978-79 showed promise for reversing the decline in production. While early oilfields were located in the northern Fahud area, exploration further south near Amal and Marmul turned up large quantities of medium- and heavy-grade crude. Soon after PDO announced plans in 1978 to ship the heavy crude out of a southern coastal terminal, other finds of higher quality 30° gravity oil were made nearby, allowing onfield blending. The mix was sufficiently light to be shipped north and join the Qarn Alam northern pipeline export system. The finds continued into 1979, when light crude was discovered in Jalmud, northeast of Marmul, and heavy crude in Runib, nearby. Again, mixing allowed more convenient transport north.

The southern reserves led to plans for a pipeline running from these Dhofar oilfields to Qarn Alam, where it would link to the main pipeline running to the Mina-al-Fahal terminal. Output of the pipeline, with all oilfields linked, was to total 100,000 barrels per day. Total project cost was estimated at $500 million.

In the Butabul region, near the Saudi Arabian border, the Essences et Lubrifiants de France (ELF) (48%), Sumitoro Metal Mining Co. Ltd. (SUMITOMO) (32%), and Wintershall A.G. (20%) consortium also struck oil. Flows of 12,000 barrels per day of

45° gravity crude from Sahmah, and an estimated 20,000 to 30,000 barrels per day of 41° to 45° gravity crude from Ramlat were predicted. These were to flow through a 10-inch, 100-kilometer pipeline into the main Marmul-Qarn Alam line. Oil was to begin flowing in late 1980.

In October 1979, the Oman Government awarded a contract to Shell Internationale Petroleum Maatschappij N.V. of the Netherlands for the construction of Oman's projected 50,000-barrel-per-day oil refinery. Originally planned for a capacity of 25,000 barrels per day, the project was upgraded and expected to meet Oman's domestic requirements and provide a surplus for export. Oman previously imported petroleum products from Bahrain and the United Arab Emirates at the rate of 3.5 million barrels per year.

Natural gas also began a major role in Oman's economy during 1978-79. In November 1978, Oman's NGL project, located near Muscat, was inaugurated. The $87 million project was built by Snam Progetti, and will utilize gas carried from the Yibal gasfield by a 20-inch, 325-kilometer pipeline. Initial flow through the pipeline was 60 million cubic feet per day.

Yibal gas was also used to fuel the 225-megawatt powerplant-desalinization complex at al-Ghubra. Oman planned to extend the pipeline along the Batinah coast to Sohar, to be used in the $120 million copper smelting project of the Oman Mining Co. Also planned was a NGL fractionator to be located onfield at Yibal. The fractionator was to produce liquid petroleum gas (LPG) for domestic use. Lean residue gas was to be fed into the al-Ghubra pipeline, while condensate above propane was to be fed into the crude oilstream, effectively upgrading heavy crude from elsewhere. Reserves in the Yibal gasfield were estimated at over 5 trillion cubic feet.

Quintana Overseas International (60%) and Gulf (40%) reported a substantial gas find in the Shams gasfield in northern Oman. Reserves were estimated at 350 billion cubic feet. Output was expected to be about 50 million cubic feet per day, and tentative plans were made to pipe the gas to Dubai for use in the United Arab Emirates' aluminum smelter complex (Dubal).

Aside from gas and petroleum, the major mineral activity in Oman was the Sohar copper mining and smelter complex, located 200 kilometers northeast of Muscat. The project was a joint venture of the Oman Government (75%), Marshall Oman Exploration Co. (12.5%), and Prospection Ltd. of Canada (12.5%), which together formed the Oman Mining Co. Golder Moffit and Associates (United Kingdom) was contracted for mining operations; Kilborne Engineering (Canada) for ore concentration and smelting facilities; Moneco Overseas (United Kingdom) for power transmission and desalinization; and Cansult (Canada) for workers' housing.

Of nearly 60 copper occurrences, the largest were in the northern Oman mountains, 40 kilometers west of Sohar, at Laseil, Aarja, and Bayda. These occurrences contained, respectively, 8, 3, and 1 million tons of 2.1% copper ore, mostly in sulfides. The three deposits were to feed 3,000 tons per day of ore to the concentrating plant, which was to feed 270 tons per day of copper concentrate (25% to 28% Cu) to the smelter and refining plant. The project was to start production in 1982 with an annual output of 20,000 tons of 99.8% copper. Power for the mine was to be supplied by a new 30-megawatt turbine powerstation, fueled by gas from the Muscat pipeline. The mines expected lifetime was 15 to 20 years. The project was partly financed by a $100 million loan from Saudi Arabia. Total copper reserves in Oman were estimated at 20 million tons.

In 1978, the Government contracted Dastur Engineering (India) to conduct a feasibility study for a steel mill to be located in the Rusayl industrial zone. Initial stages were to involve only a rerolling mill, but production from local ores was also considered. Production was to be around 100,000 tons per year of steel reinforcing bars. The project cost was estimated at $40 million.

Cement was to be produced by the Oman Cement Co., owned jointly by the Oman Government (60%) and the Kuwait Cement Co. (40%), in a plant located in the Barka industrial zone. Plant capacity was to be 1 million tons per year. Production was scheduled to begin in 1980. Asbestos cement was being produced in small quantities by Amiantit-Oman, owned by Amiantit of Switzerland and Bahwan Co. The plant was located in the Rusayl industrial zone.

The Petroleum and Mineral Resources Ministry announced in December 1979 the discovery of a significant gypsum deposit in south Oman. The deposit was capable of supporting a 2,000-ton-per-year mining operation. Other recognized mineral deposits in Oman included asbestos (8 to 10 million tons); chromite (5 to 10 million tons); coal (10 million tons); and zinc, gold, iron, manganese, and phosphate. Asbestos and manganese were to be the subject of further studies. Oman's high-quality marble was already utilized at four plants and there were eight aggregate quarries. Significant deposits of limestone were also under study, possibly for use in the cement industry.

QATAR

The petroleum industry continued to be the base of Qatar's economy, accounting for 99% of total export earnings, over 90% of Government earnings, and approximately 55% of the GNP, estimated at $4.5 billion[13] in 1978 and $4.9 billion in 1979. The other mineral commodities and their values for 1978-79 (respectively) were nitrogenous fertilizers ($65 million and $128 million), iron and steel ($27 million and $131 million), limestone ($21 million both years), and cement ($13 million and $17 million).[14]

Qatar's economy settled somewhat during 1978-79 when the growth rate dropped to around 11%. This was in contrast to the rapid expansion that took place between the years 1974 and 1977 as a result of rising oil prices. Cutbacks in government spending were responsible for the moderation of the growth rate and also reducing inflation to near 9% in 1979, from a high of 50% in 1975. The balance of trade surplus increased from $1.2 billion in 1978, to an estimated $2 billion in 1979,[15] owing mostly to oil price increases and the rapid growth of Qatar's steel industry.

Qatar continued its emphasis on diversification of its light and heavy industry, using its reserves of oil and gas as feedstock and fuel. Over $1.8 billion was allocated for industrial projects and construction loans in the 1979-80 budget. Projects included expansion of cement and fertilizer production capacity, completion of a petrochemicals complex, and utilization of the huge reserves of natural gas in the production of NGL and liquified natural gas (LNG). The post oil economy will no doubt be dominated by these gas reserves, conservatively estimated at 100 trillion cubic feet. The Government was moving cautiously on development plans, hoping to use the gas only when oil supplies become scarce.

Qatar's crude petroleum production in 1979 increased 5% over 1978 levels. Production averaged 506,000 barrels per day in 1979, as opposed to 485,000 barrels per day in 1978. The percentage of this output produced from the onshore Dukhan oilfield declined 2.9% from 1978 to 1979, and comprised 45% of the total output for 1979. Oil from the Bul Hanine, Maydam Mahzam, and Idd el-Shargi offshore oilfields registered a 12% increase in output from 246,000 barrels per day in 1978 to 276,000 barrels per day in 1979. Qatar also shares the small Bunduq oilfield, located in the Persian Gulf between Qatar and the United Arab Emirates, with Abu Dhabi on a 50-50 basis. The oilfield produced about 6,000 barrels per day in 1978, but was shut down in 1979 due to pressure maintenance problems. Both Governments told the main concessionaire, United Petroleum Development (Japan), that a secondary recovery program must be instituted before production can be resumed.

Petroleum production in Qatar was regulated by the Qatar Petroleum Producing Authority (QPPA), and marketing was controlled by the Qatar General Petroleum Corp. (QGPC); both of which were government organizations. Companies operating onshore were British Petroleum (BP), CFP, Shell, Mobil, Exxon, and Partex (Portugal). The former offshore concessionaires were Shell and Ente Nazionale Idrocarburi (ENI). These companies purchased over 55% of Qatar's crude oil under 5-year agreements signed in 1976. In 1978, oil prices averaged $13.19 for 40° API Dukhan (onshore) and $13.00 for 36° API Marine (offshore). By yearend 1979, that price had reached $23.19 for Dukhan and $23.00 for Marine. Qatar exported 98% of its crude oil in 1978-79.

Qatar operated a small refinery in the Umm Said industrial zone, with a capacity of 4 million barrels per year of refined petroleum products. With the refinery operating near capacity in 1979, Qatar imported nearly 20% of its domestic fuel requirements. The Ministry of Industry and Agriculture planned to construct a 150,000-barrel-per-day export refinery in Umm Said, as part of the plan to diversify Qatar's industry. The cost of the project was estimated at $408 million.

The Government undertook several steps to utilize its substantial production of natural gas, which averaged 590 million cubic feet per day in 1978 and 548 million cubic feet per day in 1979. Associated gas from the onshore Dukhan gasfield was used for local power generation, and the remainder was transported by pipeline to the Umm Said industrial zone for use in Government owned power generation-water desalinization plants, the Qatar Fertilizer Co. (QAFCO), and the Qatar Petrochemical Co. (QAPCO). Offshore associated gas was flared in 1978. Qatar had previously used Dukhan associated gas in the production of LPG for export in 1976-77, but the plant at Umm Said was destroyed by fire. Two new NGL plants were under construction in 1978-79. NGL-1, due onstream in 1980, will process Dukhan gas in the production of 1,200 tons per day of natural gasoline, similar to the original NGL plant. NGL-2 will utilize associated gas from the offshore fields. All three fields completed offshore gas processing plants, and expected to make available 250 million cubic feet per day of associated gas for use in NGL-2. A 290-kilometer pipeline was under construction to transport gas from the offshore fields to Umm Said. From NGL-2's 360-million-cubic-feet-per day input capacity, it was to produce 1,100 tons per day of propane, 900 tons per day of butane, and 900 tons per day of natural gasoline. The plant was due onstream in 1982. As of December 1979, Mitsubishi Heavy Industries Co. and Idemitsu Co. (Japan) were the only firm customers, the former requesting 100,000 tons per year of natural gasoline, and the latter requesting 100,000 tons per year of natural gasoline and 200,000 tons per year of liquified petroleum gas.

Feasibility studies were undertaken in 1978, by the Qatar Gas Co., a joint venture of the QGPC (70%) and Shell (30%), for the development of the Northwest Dome (NWD) nonassociated gasfield. Discovered by Shell in 1972, the NWD was one of the largest gasfields in the world. Located in the Permian Khuff Formation, the source of much of the gas in the Middle East, this 2,000-square-kilometer offshore area was estimated to contain between 100 and 200 trillion cubic feet of natural gas. Qatar was reluctant to make any development plans, insisting that gas was severely underpriced on the world market. Since its discovery, only 5 producing wells had been drilled into the structure by December 1979. Possible long-term plans for NWD gas were the production of LNG and NGL, mainly for export as a replacement for dwindling oil supplies.

QAPCO began construction of its petrochemical complex in Umm Said. It was a joint venture of the Government (84%) and Charbonnages de France (CDF) Chimie (14%). The plant was to utilize tail gases from the production of NGL, and possibly NWD gas to produce 280,000 tons per year of ethylene, 140,000 tons per year of low-density polyethylene, and 46,000 tons per year of sulfur. A $200 million contract was awarded to Technip (France) for the ethylene unit; Coppee-Rust (Belgium) received an $800 million contract for the polyethylene unit; Turbotechnica, a subsidiary of ENI (Italy) received a $30 million contract for construction of a 50 megawatt powerplant; and JGC was awarded a $79 million contract for ancillary facilities, including seawater intakes, a feed gas supply system, pipelines, and storage tanks. The entire system was expected to begin production in 1982.

QAFCO produced 201,000 tons of ammonia and 256,000 tons of urea in 1978. Through the addition of a second fertilizer plant, output was increased to 222,000 tons of ammonia and 337,000 tons of urea in 1979, all of which was exported. QAFCO was located in Umm Said, and was owned by the Government (70%), Norsk Hydro A.S. (Norway) (25%), Davy Powergas Corp. Ltd. (3%), and Hambros Bank Ltd. (United Kingdom) (3%). Norsk Hydro was managing contractor and also marketed products on behalf of the company. The total design capacity of both plants was 675,000 tons per year of ammonia and 730,000 tons per year of urea.

The Qatar Steel Co. (QASCO) began production in 1978, when output totaled over 85,000 tons. In 1979, that output had almost quadrupled to over 350,000 tons. The steelworks located near the capital, Doha, included a direct reduction plant, two arc furnaces, two four-strand, continuous-billet casters, and a rolling mill. The total design capacity was 400,000 tons per year of raw steel and 330,000 tons per year of rolled steel. Feedstock for the plant was 600,000 tons per year of pellets from Sweden and Brazil and scrap from the United States. Nearly 75% of the mill's output was exported to Iraq, Saudi Arabia, Kuwait, and the United Arab Emirates. The planned expansion of capacity by 200,000 tons per year was delayed, pending the formation of the Persian Gulf Steel Development Association, to oversee the steel production boom in the Middle East. QASCO was owned 70% by the Government, 20% by Kobe Steel, and 10% by Tokyo Boeki (Japan).

Cement production from the Qatar National Cement Co., the nations only cement plant, was around 210,000 tons of portland cement in 1978 and 237,000 tons in 1979; about 55% of the domestic requirement. The plant's annual production capacity was to be expanded from 300,000 to 580,000 tons, which was expected to meet Qatar's requirements into the 1980's. A lime calcination unit was being installed at the cement plant by Newell Dunford Engineering Ltd. (United Kingdom).

SYRIA

Syria's mineral sector contributed an average 15% to the 1978-79 GDP, estimated at \$6.8 billion[16] and \$7.4 billion (respectively). The major mineral commodities were petroleum and phosphate rock, which together comprised over 65% of total exports. Rapid growth following the 1973 war brought on high inflation and a widening trade deficit. Strong measures to alleviate these problems in 1977-78 succeeded in their aim, but only at the cost of a drastic reduction in GDP for 1978. Several projects in the 1976-80 5-year plan had to be cancelled. Over \$1.8 billion in Arab economic aid and increased revenues from oil turned the country around in 1979. Reopening of the Iraq-Syria oil pipeline, closed in 1976 after a dispute over petroleum transit fees, helped industry get back above pre-1978 levels. Balance of payments performance also turned around to a net increase in reserves, more than offsetting the \$100 million deficit in 1978. Syria encouraged foreign investment in the mineral industry, mainly on a production-sharing basis, and since 1977, four foreign oil companies have joined the renewed exploration efforts, three of them from the United States.

Syria's petroleum production in 1979 averaged 190,000 barrels per day, a slight increase over the 1978 level of 171,000 barrels per day, which was the lowest output in 4 years. Oil exports for both years remained around 132,000 barrels per day, 90% of which was destined for Western Europe. Five oilfields were being exploited (Rumeilan, Karachuk, Suweidiyah, Jebisseh, and Olayan) all near the Syria-Turkey-Iran triangle. All but the Jebisseh oilfield produced low-gravity (21° to 25° API), high-sulfur (4.5% to 9.5%) crude. Jebisseh had an estimated reserve of 350 million barrels of 40.5 API low-sulfur crude. Syria's total oil reserves were estimated at 1.6 billion barrels.

Oil production in Syria was controlled by the State-owned Syrian Petroleum Co., under the direction of the General Establishment for Geology and Mineral Resources. Government policy allowed cooperation with foreign firms, and several companies were awarded production-sharing agreements from 1977 to 1979. The Government retained a minimum share of 51% in all ventures. Of the 15 oil-producing rigs in Syria, 12 were State-owned, and one each was owned by Pecten Syria Co., the Syrian American Oil Co. (SAMOCO), and Rompetrol of Romania. Pecten operated a 21,800-square-kilometer production sharing concession north of Palmyra, which it acquired in early 1978. SAMOCO acquired a 15,750-square-kilometer concession, also on a production-sharing basis, in the Dair-al-Zur area in 1977, and had since spudded only one well. Rompetrol also operated a concession in northeast Syria, but no details were available on drilling operations. Challenger Desert Oil Co. of Panama (Chadoil) finalized a production-sharing arrangement in 1978, for a 17,000-square-kilometer concession south of Palmyra. Chadoil was to spend 4 years and not less than \$3.5 million on exploration. Should a commercial discovery be made, the output split, after cost recovery, was to be 75%/25% in Syria's favor. Marathon Oil Co. of the United States also signed a production-sharing agreement in March 1979 for a 15,000-square-kilometer concession 200 kilometers northeast of Damascus, but the agreement had yet to be ratified by the Syrian Government.

Syria continued its oil exploration efforts, in search of additional reserves. The Government commissioned its first national seismologic team in 1978 to study several areas in the northeast region. Digital Resources Inc. (United States) was awarded a \$1.5 million contract for a seismic data processing system.

The Homs refinery operated at 94% of its 38-million-barrel-per-year capacity during 1979. This was a substantial increase over the 72% utilization factor in 1978. Late in 1978, the Supreme Planning Council approved an allocation of \$76 million for modernization and expansion of the refinery. In December 1979, a new 120,000-ton-per-year asphalt plant was added. The plant, built by Technoexport of Czechoslovakia, which had constructed most of the units of the refinery, raised the plants output of asphalt to 250,000 tons per year. Bids were also invited for the planned construction of a 450,000-ton-per-year naphtha hydrotreater, a 370,000-ton-per-year kerosine and gas-oil unit, and a 380,000-ton-per-year premium gasoline unit.

Syria's second refinery, located in Banias, was inaugurated in August 1979. It was designed to process a blend of either 80% Iraqi-20% Syrian crude, or 50% Iraqi-50% Syrian crude. The refinery was constructed by Industrialexport of Romania. When the plant goes onstream in 1980, Syria's refinery capacity will exceed its crude oil output.

In 1979, the INOC pipeline from Iraq to Banias was reopened. The settlement with Iraq was to make available 37 million barrels per year of Iraqi crude to Syria at posted Persian Gulf prices. The agreement was to provide $120 million in revenues and import savings for Syria on an annual basis. The Homs refinery was to continue using Saudi Arabian crude for feedstock, while the new refinery at Banias was to use Iraqi crude from the pipeline.

Syria also planned to make full use of its gas resources. The Syrian Oil Ministry was considering commissioning a detailed study of the country's gas reserves. A $60 million contract was awarded to the French firm, Entrepose, to construct a gas-gathering and liquefaction plant. The contract also provided for the installation of a 60-kilometer pipeline network, construction of dehydration, desulfurization, gas-oil separation units, and a plant for the manufacture of industrial solvents and condensates. The plant, to be located in northeast Syria, was to process 58,000 tons per year of LPG by 1982. Syria's total gas reserves, both associated and nonassociated were estimated at 130 billion cubic meters.

Syria's phosphate industry registered a significant upturn in production in 1978-79, in response to improved prices. Production had fallen back to 425,000 tons in 1977, the lowest level in 5 years, but rose 40% in 1978 and another 25% in 1979. Exports in 1978 amounted to 895,000 tons, a 29% increase over 1977, and 1979 exports were estimated at nearly 1.2 million tons. Phosphate exports earned Syria over $23 million annually, with over 50% of production going to Romania, 20% to North Korea, 10% to Lebanon, and 7% to both The People's Republic of China and Bulgaria.

Phosphate production was concentrated in three areas, all located at Palmyra in central Syria. Al-Tadmuria, Mukaman Al Shargiya, and Mukaman Khunayfis had a combined production capacity of 1.2 million tons per year. These mines were under the direction of the General Co. for Phosphates and Mines (GECOPHAM), and were opened with financial and technical assistance from Poland, Romania, and Bulgaria. Crude mined phosphate from these areas had an average P_2O_5 content of 26% and was generally high in chlorine. Syria's total phosphate reserves were estimated at 600 million tons.

Phosphate mined in northeast Syria was trucked to the port of Tartous for export. The ports current handling capacity of 50,000 tons and loading capacity of 1,000 tons per hour was undergoing expansion in 1979 to bring storage capacity to 140,000 tons. Under the current 5-year plan, $38 million was to be spent to bring phosphate production to 3 million tons per year by 1981. Negotiations were underway with ENI (Italy) concerning a joint venture for exploration and development of new phosphate reserves. Hydrologic studies were also underway to determine the availability of water for use in new washing plants to improve recovery of phosphate rock. The washing facilities were ordered from Romania in 1979.

Syria's single fertilizer complex, at Homs, produced around 77,000 tons of nitrogenous fertilizer per year, well below its 110,000-ton-per-year capacity. Creusot-Loire (France) completed work on a 1,000-ton-per-day ammonia-urea complex at Homs, and was in the process of turning the plant over to the Syrians. Also near completion, in Homs, was a 450,000-ton-per-year triple superphosphate plant, scheduled to go onstream in late 1980. The plant was built by Industrialexport of Romania.

A railroad system to connect the mining district to the fertilizer complexes in Homs was under construction in 1979. Homs was already linked to the port of Tartous from which fertilizer production will be exported.

Iron and steel production in Syria remained fairly constant during 1978-79, averaging 100,000 tons per year. The General Co. of Iron and Steel Products operated three plants at its complex in Hama. A 110,000-ton-per-year cold rolling mill manufactured steel bars from billets imported from Italy, Bulgaria, and the U.S.S.R. A 20,000-ton-per-year merchant mill produced galvanized and ungalvanized pipe and a 120,000-ton-per-year sponge iron smelter produced billets from sponge and scrap iron. A feasibility study was being conducted by an Indian consulting company to evaluate the iron ore deposits in the Zabadani region, 50 kilometers west of Damascus near the Lebanese border. The reserves were estimated at 150 million tons of hematite with an iron oxide content of 27% to 30%. Iron ore deposits were also located north of Aleppo, but contained a high level of impurities, mainly silicon.

Cement production in Syria continued its gradual expansion, increasing an average of 15% per year, under the direction of the General Organization for Cement. The Chaba Cement Co. raised its production capacity to 1 million tons per year; it operated three plants near Aleppo at Sheikh Said, Muslimiyah, and Burg Islam. The Syrian Cement Co. operated a 460,000-ton-per-year plant at Hama, and a 110,000-ton-per-year plant at Homs. The National Co. for Cement operated a 280,000-ton-per-year plant at Dummar. Two new plants were scheduled to begin production in 1980; a 150,000-ton-per-year plant at Adra, and a 200,000-ton-per-year plant at Tartous.

In 1978, the general establishment for Geology and Mineral Resources contracted Industria Marmi e Graniti (Italy) to quarry marble at Damascus and Latakia. Marble production averaged 50,000 cubic meters both years and was used mainly for export. Quarrying of asphalt near Deir ez Zoor and Latakia began in 1976, and production increased dramatically in 1979. Syria has also mined salt since 1971, and nearly 120,000 tons were produced in 1979.

PEOPLE'S DEMOCRATIC REPUBLIC OF YEMEN

The mineral industry of the People's Democratic Republic of Yemen (PDRY) consisted of the refining of imported crude oil and the mining of salt. Refined petroleum products accounted for over 80% of total export value in 1978-79, estimated at $212 million[17] and $300 million, respectively. Other income was derived from the export of salt to African countries. PDRY's major imports were food ($225 million), cement and construction materials ($18 million), oil byproducts ($87 million), and industrial raw materials ($41 million). A combined low productivity in the industrial sector, and South Yemen's very limited natural resources contributed to a balance of trade deficit of over $200 million in 1979. The second 5-year plan (1979-83), which allocated 5% of total expenditure to petroleum and mineral exploration, was to be financed largely by foreign loans and grants. Financial commitments of $110 million from the U.S.S.R., $38 million from Bulgaria and Czechoslovakia, and $13 million from the Peoples Republic of China were received in 1978-79.

Port facilities at Aden, one of the worlds largest oil-bunkering ports prior to the closure of the Suez Canal in 1967, was being renovated and modernized through the assistance of a $14 million loan from the Arab Fund for Economic and Social Development (AFESD) and a supplementary loan from the International Bank for Reconstruction and Development (IBRD). Electric generating capacity, estimated at 100 megawatts, was to be doubled by the construction of two new powerstations in Aden and Mukalla, both to be financed by the U.S.S.R.

Within the Petroleum and Minerals Organization, the Geology and Mineral Exploration Department was responsible for the coordination and conduct of geologic and seismic surveys, and the Petroleum Exploration Department was responsible for all oil exploration activities. Under the second 5-year plan, the Government was to continue its investigation of potential iron and titanium resources in the Wadi Mikayris region, and copper occurrences in the Maahir-Ghabar area, 150 kilometers southwest of Mukalla.

The Petroleum and Minerals Board (PMB) opened five onshore areas to international bidding for petroleum exploration in 1979. The areas, all located in the north, were offered under production-sharing arrangements, with a minimum requirement that two wells be drilled within a 3 year period. In the event of a commercial discovery, the company was to recover their costs out of 40% of crude production. Sixty percent of the equity would go to PMB, for a further production split with the operator. Siebens Oil and Gas Ltd. (Canada) drilled and abandoned a wildcat in its 17,550-square-kilometer-concession on Socotra Island and offshore areas. Azienda Generale Italiani Petroli S.p.A. (AGIP) spudded a wildcat in its 10,000-square-kilometer offshore area near Sayut. In 1979, AGIP obtained a new 15,000-square-kilometer concession off the Mukalla coast. The Russian firm Technoexport also operated a 10,000-square-kilometer tract off the Thamud coast.

Late in 1979, the World Bank's International Development Association (IDA) approved a $9 million credit for a major petroleum exploration project. The project was to include a 15-month seismic survey over a large portion of the onshore area, as well as project management, technical assistance, data evaluation, and promotion of exploration areas to foreign oil companies. The survey was to be conducted by a team of expatriates, who were to assist in training a local Yemeni staff. PDRY contributed $1 million to the cost of the project, which was to be completed by 1982.

The petroleum refinery at Aden, owned by BP until nationalized in 1977, operated at less than 25% of its 160,000-barrel-per-day capacity for its fifth consecutive year. Production averaged 35,000 barrels per day in both 1978-79. The refinery imported crude oil from Kuwait, Qatar, and the United Arab Emirates. Saudi Arabia ceased exporting crude to PDRY in 1978 owing to political differences. The Government acquired ownership of all oil-bunkering facilities in Aden in 1978, under an agreement with BP. The Yemen National Petroleum Co. was created to assume responsibility for transporting, storing, marketing, and distributing petroleum products in the wake of BP's departure.

Salt production continued at a modest pace, averaging 75,000 tons per year in 1978-79. Salt was produced at the General Salt Organization's facilities at Khawr Maksoir northeast of Aden. The plant produced unrefined marine salt from the evaporation of seawater. Nearly 90% of production was exported to African countries.

YEMEN ARAB REPUBLIC

The mineral industry of the Yemen Arab Republic was of little significance to the country's economy. Mineral activity consisted of the mining of salt and gypsum, and the production of cement. Salt remained the only mineral export, with revenues of approximately $110,000[18] in 1978 and $280,000 in 1979. Exploration for petroleum resources and copper continued, but no production was registered for either commodity.

The Yemen Arab Republic's only significant export was manpower, with remittances from Yemenis working abroad, mostly in Saudi Arabia, amounting to $1.4 billion in both 1978 and 1979. Until 1977 or 1978, these remittances brought growing balance of payments surpluses and increasing foreign exchange reserves, despite a large balance of trade deficit, averaging $800 million for the 2 years. By 1979 the situation had changed. Remittances remained fairly constant, but because of a dormant industrial sector, the import bill began outpacing revenues, and the overall balance of payments surplus dropped from $340 million in 1978 to $160 million in 1979, and a deficit was expected for 1980.[19]

Under the 5-year plan (1976-80), Yemen's growth was continuous but uneven. GNP rose by 8% from 1978 to 1979, but 30% to 35% inflation remained a problem. Yemen's second 5-year plan was expected to concentrate on infrastructure development, expansion of the commercial-industrial sector, and increased agricultural output.

The Yemen Salt Mining Corp. continued its open pit mining of rock salt at Salif. Modernization of the mine and shiploading facilities in 1977 upgraded capacity from 100,000 tons per year to 1 million tons per year. The Salif deposit was located on the mainland side of the Kamaran passage which forms the sheltered deepwater harbor of Salif. The deposit was estimated at 250 million tons of rock salt with a 98.2% NaCl and 0.36% Ca content. The major stumbling block of the operation was no longer mining and loading, but marketing. During the 5-year modernization project, 1972-77, the company's major buyer, Japan, had found other sources of salt, and was unwilling to renew any contracts in 1978 or 1979. The company was forced to sell on the spot market and through short-term contracts. The United Nations stepped in to help in late 1977, and appointed Roskill Industrial Consultants (United Kingdom) to conduct a worldwide marketing survey for the Yemen Salt Mining Corp. North Korea and Bangladesh both agreed to import salt in 1978, and the industry was looking toward the opening of new chloralkali plants in the Middle East for an export market.

Gypsum was recovered in association with rock salt in Salif, and was sold to the

Government-run cement plant at Bajil. In 1978, the U.S.S.R. agreed to extend $38 million in credits to triple the plant's 100,000-ton-per-year capacity. In 1979, the Yemen Government awarded a $110 million contract to Ishikawajima-Harima Heavy Industries and Nissho-Iwai (Japan) for the construction of a 500,000-ton-per-year cement plant at Amran, northeast of Sana. The contract also covered installation of a powerplant and a workers' housing scheme. The project was scheduled for completion in 1982.

Oil exploration efforts continued in 1978-79, with Shell holding the only exploration rights in a 10,000-square-kilometer tract in the Tihama coastal plain. Shell drilled two test wells off the coast, and reported a noncommercial discovery of natural gas. Petro-Stock International of Texas was to begin exploration efforts in eastern Yemen late in 1979.

Efforts were also underway in 1979 to improve the supply and distribution of petroleum products. The Yemen Arab Republic imported all of its petroleum requirements, mainly from Kuwait and Saudi Arabia. Mobil Oil Corp. and the Yemen Oil and Minerals Corp. (YOMINCO) reached an agreement in mid-1979 for Mobil to construct and operate a plant producing lubricating and other oils. YOMINCO was also negotiating with Mobil for the construction of a pipeline for petroleum products to run from the port of Salif to Sana and the interior of the country.

Studies continued in the possibility of exploiting copper deposits near Taiz and Beida. Chemical analysis showed the Taiz deposit to be 15% to 19% Cu, with 2% Ni and 1.5% Co, but as of yearend 1979, there were no plans for production.

The Mineral Industry of Other Areas of South America

By Doris M. Hyde[1]

CONTENTS

ECUADOR

The petroleum sector continued to dominate Ecuador's economic activity in 1978, accounting for nearly 10% of the gross domestic product (GDP) and 42% of total export earnings. In 1978, a more flexible petroleum export price was adopted which permitted an expansion of foreign market opportunities. During 1979, Ecuador took advantage of disruptions in the world petroleum supply and renegotiated existing export contracts to accomodate the rapidly escalating world market price. Petroleum sales on the spot market were maximized, and prices reached unprecedented levels. By taking royalty payments in-kind, Ecuador increased its volume of petroleum available for term and spot sales. Although the volume remained about the same as in 1978, the total value of 1979 petroleum exports increased to about $920 million, reflecting a 76% increase over the $523 million received for 1978 crude oil exports.

Concerned about its steadily decreasing petroleum reserves (recently estimated at about 1.1 billion barrels), rapidly increasing and heavily subsidized domestic consumption, and the prospect of having to import substantial amounts of petroleum by 1983, Ecuador announced plans which it anticipates will double reserves within the next 5 years. The Government plans to spend $1 billion over the 5-year period. Plans include drilling 325 exploration and development wells and establishment of a secondary recovery program for the Sachs and Shushufindi fields. Some exploration wells are expected to reach a depth of 17,000 feet. It is thought that substantial reserves exist in the southeast Amazon region. Late in 1979, it was announced that some 10 million hectares will be available for exploration tenders—probably in blocks of about 200,000 hectares each—in the Amazon jungle of the Oriente and in the coastal and offshore regions. The Government planned to commission a private, independent analysis of Ecuador's petroleum reserves that would also include recommendations on efficient production levels.

Modifications to Ecuador's Hydrocarbon Law were made in 1978. These modifications allow the implementation of a new type of petroleum operations contract designed to attract foreign investors for exploratory activities. Under this type of contract, a foreign firm assumes exploratory risks in return for a share in any future production. If exploitable reserves are discovered, a percentage of oil production is assigned to the firm to repay all its costs, including amounts attributable to operations, transportation, and amortization, plus a fee to promote scientific and technological development in the energy field. The remainder of production is divided between the firm and CEPE according to the rate of return on investment agreed upon by the two entities. Discoveries of large volumes of reserves could yield returns on investment of up to 35% to foreign firms, while smaller discoveries would result in returns of at least 18%. Under the new contract arrangements, net profits would equal gross profits minus a percentage for labor profit sharing minus any taxes on the difference between gross profits and the profit-sharing percentage. Implementing regulations and a model contract are expected to be issued early in 1980.

Texaco, Inc. and Corporación Estatal Petrolera Ecuatoriana (CEPE) moved closer to forming a new company, Petroamazonas, intended to replace their present consortium. The new company was expected to become operational early in 1980.

In June 1978, City Ecuatoriana Production Co. (CEPCO), a subsidiary of the U.S. firm City Investing Co., and CEPE began transporting crude oil through the Trans-Andean pipeline from three fields in Oriente Province. Unable to reconcile differences with Northwest Pipeline Corp. for natural gas production from the Gulf of Guayaquil, the Government cancelled its contract with that company. Despite a controversy over economic feasibility, CEPE was expected to assume control of the Amistad gas field and proceed with contracting for construction of a petrochemical complex.

In April 1979, Gulf Oil Corp. received final payment for its assets sold to the Government in 1976; the total payment was $115.7 million. In December 1978, Gulf closed its 8,000-barrel-per-day refinery on the Santa Elena Peninsula. The refinery was reportedly sold and reopened that same month.

CEPE plans to increase Ecuador's total refining capacity to 185,000 barrels per day from the present level of 98,500 barrels per day. At a cost of about $200 million, plans are to increase capacity at the Esmeraldas refinery from the present level of 55,600 barrels per day to 130,600 barrels per day. Another $13 million investment is planned for a new 10,000-barrel-per-day facility to be built at the Sacha field in the eastern jungle.

Construction of the second stage of an offshore tanker terminal for exporting petroleum products from Esmeraldas was contracted in 1979. Plans are for this permanent facility to provide a two-berth sea-island terminal capable of servicing vessels up to 50,000 deadweight tons. A variety of products ranging from heavy fuel oil to liquid petroleum gas is expected to be loaded from the terminal.

Ecuador's nonfuel minerals industry remained of minor importance and no new mining operations were initiated during 1978 or 1979. Empresa Nacional Adaro of Spain has invested about $1.5 million over the past 2 years exploring for copper in a 36,000-square-kilometer area near Chaucha in the western mountains. The Ecuadorean atomic energy commission has been given the responsibility of exploring for and developing radioactive minerals. In 1978, it was reported that uranium deposits had been discovered in the eastern Andes.

In 1979, a geological survey sponsored by the United Nations Development Program reportedly found iron ore deposits in the province of El Oro, but the discovery awaits definitive geophysical and geochemical testing. In 1979, the local firm Cumbaratza contracted with the Government to explore for and develop copper, zinc, tin, nickel, gold, and silver deposits in the province of Zamora-Chinchipe. The company has planned an investment of $750 million.

Table 1.—Other Areas of South America : Production of mineral commodities

Area, commodity, and unit of measure	1976	1977	1978[p]	1979[e]
ECUADOR[1]				
Cadmium, mine output, metal content ---- kilograms	462	476	417	480
Cement, hydraulic ---- thousand metric tons	616	626	1,000	1,000
Clays: Kaolin ---- do.	1,138	1,427	1,185	1,000
Copper, mine output, metal content ---- metric tons	267	700	581	700
Gas, natural:				
Gross ---- million cubic feet	[r]11,949	12,290	12,429	12,600
Marketable ---- do.	3,713	1,490	[e]1,500	1,600
Gold, mine output, metal content ---- troy ounces	[r]11,014	7,649	3,213	3,500
Gypsum (for cement) ---- metric tons	43,762	43,762	45,359	45,000
Lead concentrates ---- do.	168	215	220	220
Natural gas liquids:				
Natural gasoline ---- thousand 42-gallon barrels	128	106	79	100
Liquefied petroleum gas ---- do.	39	36	721	800
Total ---- do.	[r]167	142	800	900
Petroleum:				
Crude ---- do.	[r]68,362	67,002	73,669	85,700
Refinery products:				
Gasoline ---- do.	6,079	6,144	7,293	8,500
Jet fuel ---- do.	467	537	985	1,000
Kerosine ---- do.	1,915	2,381	2,716	3,200
Distillate fuel oil ---- do.	2,886	3,234	4,518	5,500
Residual fuel oil ---- do.	3,776	6,602	13,018	15,000
Lubricants ---- do.	[r]167	194	234	300
Other:				
Liquefied petroleum gas ---- do.	40	192	200	200
Unspecified ---- do.	20	340	317	300
Refinery fuel and losses ---- do.	[r]145	721	1,016	1,000
Total ---- do.	[r]15,495	20,345	30,297	35,000
Silica ---- metric tons	NA	10,800	10,000	10,000
Silver, mine output, metal content ---- troy ounces	[r]47,382	57,223	64,000	70,000
Stone, sand and gravel:

Mineral tar and other coal-, petroleum-, or gas-derived crude chemicals	280	United States 218.

NA Not available.

FRENCH GUIANA

Except for minor amounts of domestically consumed sand and gravel and crushed stone, gold was the only mineral produced in French Guiana. A rapidly increasing world market price has kindled some interest in gold exploration and development, but the alluvial nature of the country's known deposits and their difficult access remain strong deterrents to large-scale development.

The offshore well drilled in 1978 by Esso Exploration Guyane, S.A.R.L., was abandoned at a depth of almost 13,000 feet after failing to encounter shows of oil or gas.

GUYANA

During 1978 and 1979, Guyana continued its attempts to stabilize a faltering economy. In both years the Government endeavored to follow guidelines set forth by the International Monetary Fund; however, declining bauxite and alumina shipments were among the factors that impeded economic stabilization efforts. In 1978, bauxite exports fell sharply, at first due to a slack market and later because of production problems. In 1979, labor strikes and slowdowns beset the bauxite industry, in addition to an apparent trend toward declining productivity. As a result, Guyana was not able to take full advantage of increased world demand and prices for bauxite.

The growth of the GDP, measured in real terms, was estimated to be zero in 1979, which was nonetheless up from the −6.2% and −1.0% growth estimated for 1977 and 1978, respectively. In 1978, Guyana succeeded in showing a positive balance of trade, but in 1979, soaring petroleum import costs and generally lower bauxite and agricultural exports contributed to a negative trade balance.

In February 1979, the Government announced a new Guyana Investment Code which reversed its policy of requiring government majority interest in joint ventures with foreign companies. The Government further announced its intentions to incorporate various existing and proposed investment incentive laws into one piece of legislation. The extent to which domestic and foreign investors would take advantage of the new investment code was uncertain, although some foreign companies entered into exploration agreements during 1979.

After 5 years of preparation, Guyana Mining Enterprise, Ltd. (GUYMINE), in mid-1979 officially opened the East Montgomery Mine. The mine represented the first expansion of Guyana's bauxite mining industry since 1971. Bauxite reserves at East Montgomery were estimated at 80 million tons with a mine life expectancy of 40 years. Initially, the mine is expected to provide about 12% of Guyana's calcined bauxite production, but this figure is expected to increase to 50% in 10 years. The new mine suffered a minor production setback when a landslide buried 80,000 tons of exposed ore shortly after opening. As with other bauxite mines in the Linden area, 200 to 250 feet of overburden must be removed, and mining activity is complicated as a result. In 1978, Guyana began operations at the Kaiakabra bauxite deposit, where proven ore reserves have been estimated at 500,000 tons of calcine grade bauxite.

Future assessments of total bauxite reserves may be substantially increased due to the inclusion of lateritic ore deposits occurring over 15,000 square miles of the Pakaraima Plateau in western Guyana. Reports on preliminary investigations have indicated the existence of billions of tons of ore that would require little—if any—overburden removal.

In 1978, it was reported that the U.S.S.R. would undertake a feasibility study for construction of a 600,000-ton-per-year alumina plant in Guyana. In 1979, Guyana's alumina capacity was about 300,000 tons per year.

A favorable feasibility study was completed in 1979 for the 750-megawatt Upper Mazaruni Hydroelectric Project, and Guyana has applied to the World Bank for financing. Companion to the hydroelectric project is the construction of a 150,000-ton-per-year aluminum smelter at a projected cost of $800 million. The search for a technological partner for the smelter to share construction costs was scheduled to begin in 1980, contingent upon financing of the hydroelectric scheme by the World Bank. The proposed smelter site on the Demerara River is only a few miles from an existing alumina plant and about 60 miles from the coast.

The Guyanese Government has urged gold miners to step up production in response to the dramatic surge in precious metal prices. In 1979 Guyana granted

nonexclusive uranium exploration rights to Compagnie Générale des Matiéres Nucléaires (Cogéma) of France and Grundstofftechnik GmbH of Essen, Federal Republic of Germany. In the late 1960's and early 1970's, results from aerial surveys for uranium were encouraging, but the areas involved difficult access and geological conditions, and no further exploration was undertaken.

In April 1979, Guyana granted a joint offshore exploration concession to Seagull International Exploration, Inc., of Houston, Tex., and Denison Mines, Ltd., of Toronto, Canada. The 4,000-square-mile concession is located about 20 miles offshore between the mouths of the Demerara and Berbice rivers. Deminex Oil Co. abandoned offshore exploration in 1976 after drilling two wells off the Essequibo coast. To retain the concession, Seagull-Denison must drill an exploratory well by the end of 1982. Part of the preparatory work planned by Seagull and Denison includes reevaluations of previous seismic and drilling efforts.

In October 1979, another petroleum exploration agreement was signed with a consortium of four Canadian companies: Home Oil and Gas Co.; Ranger Oil Ltd.; Voyager Petroleum Ltd.; and Norcen International, Ltd. Under the agreement, the Home Oil consortium will explore the Takutu Basin in the Rupununi District bordering Brazil. Drilling was projected to begin in 1981.

In November 1979, the U.S. firm Major Crude Oil Inc. signed a 5-year agreement with Guyana to explore for oil in a 9,830-square-kilometer triangular-shaped area extending from the mouth of the Courantyne River out to the continental shelf. Major's concession adjoins the concession granted to Seagull. Seismic study was scheduled to begin early in 1980. The company has agreed to invest $88 million and drill eight wells to a depth of at least 6,700 meters each.

PARAGUAY

The minerals industry of Paraguay continued to be limited to the production of nonmetallic industrial minerals for domestic consumption. The construction industry maintained its high rate of expansion as a result of the Itaipú hydroelectric and infrastructural projects as well as increased residential and commercial building. The Itaipú project continued to benefit the economy as demands for goods and services brought in large amounts of foreign exchange. However, inflation has accompanied Paraguay's prosperity; the cost of living rose over 10% in 1978 and increased by an estimated 30% in 1979.

The controversy between Argentina and Paraguay over technical specifications for the Yacyretá hydroelectric project appeared to have reached a settlement in mid-1979 when an agreement between the two countries was amended to allow for less flooding of Paraguayan territory and compensation to Paraguay for flooded land. Financing for the project was delayed by the disagreement, and doubts were cast upon the possibility of Paraguay and Argentina reaching an agreement on the proposed Corpus dam, which must also include Brazil and compatibility with the Itaipú project.

The Government confirmed the existence of uranium deposits in eastern Paraguay, but no information was available regarding the extent, quality, or commercial viability of these deposits. Uranium exploration was begun in 1978 by Anschutz Corp. and the Korea Electric Corp. Also in 1978, the Taiwan Power Co. signed a 2-year uranium exploration contract with Paraguay.

The Government signed an agreement with the Brazilian companies Siderúrgica Coferraz, S.A., and Técnica Nacional de Engenharia (Tenenge) to construct Paraguay's first steel plant, at Villa Hayes on the Paraguay River, 20 kilometers north of Asunción. The operating company, Aceros de Paraguay (Acepar), is 60% state-owned, with Coferraz holding 39% interest and Tenenge holding 1% of the remaining interest. Estimated to cost $81 million, the steel mill is planned to have an initial annual capacity of 100,000 tons of nonflat rolled products. Plans are for raw material to be brought down the Paraná River from the Urucum mines near Corumbá, Brazil. The plant has been scheduled to come onstream in 1982.

In 1979, UNC Resources, Inc., signed a renewable 5-year minerals exploration contract with the Government to develop the mineral potential of western Paraguay. Work is expected to begin in early 1980. UNC's concession includes about 55 million acres in the Chaco area, but liquid and gaseous hydrocarbons are excluded from the agreement.

Texaco Paraguay, Inc., and Marathon Oil Co. completed a joint petroleum exploration program in the northern Chaco area after drilling three dry holes in 1978. In 1979, Francana Oil and Gas, Ltd., began a $3.2 million geophysical program on its 28,900-square-mile concession. Francana is 54.9% owned by Hudson Bay Mining & Smelting Co. In 1979, Pectin International, a subsidiary of Shell Oil Co., assumed the exploration rights held in eastern Paraguay by Trend Resources Ltd. Pectin has initiated an extensive seismic program that may lead to drilling by 1981.

Crude oil shortages and dramatic increases in the price of petroleum products spurred interest in developing alcohol as a substitute fuel. In 1979, construction was underway on two ethanol plants that are designed to use sugarcane as raw material. The plants are expected to come onstream in 1981. One of these plants, which is owned by the state, is expected to produce 120,000 liters (31,700 gallons) per day of ethanol when fully operational; the other, a privately owned plant, is expected to produce 90,000 liters (23,775 gallons) per day. Plans are for this alcohol to be used as a substitute for gasoline.

Fuel shortages and petroleum import costs in 1979 prompted the Government to increase the domestic price of petroleum derivatives by 60.7% and to enact fuel conservation measures. The Government also ended state-owned Refineria Paraguaya S.A.'s (REPSA) monopoly over the import and refining of crude oil. A new company, Carburantes del Paraguay, was formed by private interests and was reported to be negotiating for oil imports from Argentina and Brazil.

Table 6.—Paraguay: Imports of mineral commodities

(Metric tons unless otherwise specified)

Commodity[1]	1977	1978
METALS		
Aluminum metal, all forms	475	1,529
Copper metal, all forms	2	41
Iron and steel metal, all forms	29,292	25,844
Lead metal, all forms	16	24
Tin metal, all forms	8	8
NONMETALS		
Cement, portland	4,530	58,378
Salt	24,895	23,036
Other, crude	21,848	23,221
MINERAL FUELS AND RELATED MATERIALS		
Asphalt, natural	2,729	3,617
Petroleum:		
Crude thousand 42-gallon barrels	1,736	2,451
Refinery products:		
Gasoline do	172	244
Distillate fuel oil do	520	631
Residual fuel oil do	171	124
Lubricants do	47	49
Total do	910	1,048

[1]In addition to the commodities listed individually, Paraguay reported the importation of "precious stones and metals" totaling 1 ton in 1977 and 4 tons in 1978.

SURINAME

Suriname continued to rely heavily on imported goods and services and was consequently affected by world inflation. For 1978, Suriname's rate of inflation was officially set at 10%, but by mid-1979 the rate had climbed to about 15%.

The burden of sharply increased petroleum prices gave added impetus to interest in hydroelectric development. In 1979, Guyana and Suriname were considering a $1 billion joint hydroelectric project on the Corantijn River. Also, the Kabalebo hydroelectric scheme, considered essential to the development of western Suriname, neared the final phase of financial and environmental impact study. It was estimated that construction could start by the end of 1980.

Tax negotiations between the Government and the Suriname Aluminum Co. (SURALCO), wholly owned by the Aluminum Company of America, ended in August 1979 when a new 3-year bauxite levy agreement was signed. A similar agreement to lower the levy was expected to be concluded with Suriname N.V. Billiton Maatschappij, owned by Royal Dutch Shell. It was anticipated that the reduced levy rate would allow Suriname bauxite to become more competitive in the world market. SURALCO and Billiton account for 85% of Suriname's total exports, about 40% of the tax revenues, and approximately 30% of the GDP. Suriname now produces about 6% of total world bauxite output, but at one time produced 25%.

In July 1978, Suriname and Venezuela signed an agreement to cooperate in bauxite mining and processing technology. Also in July, representatives of several Japanese companies discussed the possibility of investing in the development of the bauxite deposits in western Suriname. A favorable pre-feasibility study by Billition International was completed and a comprehensive study partially funded by Dutch sources was expected to be initiated.

Both Uranerzbergbau GmbH, of the Federal Republic of Germany, and the French State-owned Cogéma were interested in uranium deposits in western Suriname. Gold exploration in the rivers of southern Suriname was begun in 1978 by the Paramaribo Mining Co. It was reported that the company would invest $16.9 million in the venture. No reports have been made available regarding discoveries. In 1979, the United Nations Development Program began discussions with the Government on the possibility of copper exploration in western Suriname. Prior investigation had revealed indications of deposits in the Bakhuys area.

The multinational consortium headed by Esso Petroleum Suriname N.V. abandoned its search for offshore petroleum in 1978. The Venezuelan company Petrolera Las Mercedes S.A. continued onshore geophysical work. In mid-1979, Gulf Oil Corp. held discussions regarding a drilling concession off the coast of the districts of Saramacca and Coronie.

Table 7.—Suriname: Exports of aluminum[1]

(Metric tons)

[3]No aviation gasoline was reported in the International Petroleum Annual 1976. Figures were taken from the official Surinam trade statistics.

URUGUAY

Uruguay's economic growth rate fell to a low of 2.3% during 1978, but in 1979 the GDP was estimated to have increased by 8%. The country's 45% rate of inflation in 1978 and the 1979 rate of 84% indicated the failure of Government-initiated anti-inflationary measures. Increased inflation was partially caused by a lifting of price controls on many basic items and increased petroleum prices, but was mainly attributed to the surge of Argentine tourists who indulged in large-scale spending. Uruguay's trade deficit was about $72 million for 1978, but in 1979 it was estimated to have increased to as much as $250 million. This increase was not entirely due to the increased costs of petroleum imports; it was also caused by the overall expansion of the economy and a tariff reduction program initiated in December 1978.

As 1979 became the year of the seller's market for petroleum, Uruguay found that its policy of operating independently in the petroleum market was disadvantageous. Without long-term contracts and with suppliers defaulting on short-term orders, Uruguay was forced to purchase oil on the escalating spot market. As a result, petroleum represented almost a third of the country's import spending in 1979. To avoid a repetition of 1979's petroleum squeeze, the Government opened an embassy in Saudi Arabia. One objective was to establish closer contact with producers, which could help eliminate the necessity for spot purchases. Fuel conservation measures were initiated to curb manufacturing demand, decrease public service consumption, and lower speed limits on highways.

The prospects of Uruguay having commercial quantities of crude oil dimmed in 1978 after the Administracíon Nacional de Combustibles, Alcohol y Portland (ANCAP) drilled two dry holes in the Santa Lucía River basin 50 kilometers north of Montevideo. In 1978, Argentina's Yacimientos Petroliferos Fiscales undertook an evaluation of the area's petroleum potential and their negative finding, plus ANCAP's two dry holes, led to Uruguay's decision to abandon the Santa Lucía River basin as a potential source of crude oil.

Chevron's decision to withdraw from its offshore drilling contract was made final in early 1978, and Uruguay ended 1979 with no active petroleum drilling underway. In 1979 ANCAP contracted with the Bureau d'Etudes Industrielles et de Cooperation de l'Institut Francais du Petroleo to study offshore petroleum possibilities in Block III, an area which abuts Brazil's territorial waters. Also in 1979, ANCAP contracted with Resources Engineering and Management International, Inc., for an overall evaluation of existing data on Uruguay's petroleum potential on the continental shelf.

The joint Uruguay-Argentina Salto Grande hydroelectric complex was inaugurated in mid-1979. Argentina financed 65% of the $1.5 billion cost and will receive, by agreement, 83.34% of the power generated during the first 15 years of operation. Plans are for Argentina's share to be gradually reduced until it reaches 50% in 1995. Full capacity is not expected to be reached until 1981. Under the joint agreement, Uruguay will not receive enough of Salto Grande's power during the first years of operation to solve its immediate shortage of electricity. Very low reservoir levels caused by a severe drought at one hydroelectric facility and a lengthy repair shutdown at a thermoelectric plant necessitated severe power curtailments to private citizens and caused some industrial disruption. The Palmer hydroelectric project was in the beginning stages of construction during 1979, with completion scheduled for 1982.

Feasibility studies continued throughout 1978 and 1979 for the development of iron ore deposits at Arroyo Valentines. In 1978, ore samples were shipped to Europe for assay, and the results were reported as technically favorable. Further studies were underway in 1979. In late 1979, prequalifying bids were accepted from companies interested in developing the deposits. In 1979, it was reported that the International Iron Co. Inc. will build a $30 million high-carbon ferromanganese plant at Nueva Palmira. It is planned that the plant, which is scheduled to become operational by 1981, will have two electric furnaces and an ultimate capacity of 80,000 tons per year of ferroalloys. Initial capacity is expected to be 40,000 tons per year.

In 1978, Uruguay declared that increased production and export of semiprecious stones were important to the national interest. As encouragement, the Government lifted all import taxes for 2 years on capital goods used by this underdeveloped industry. Amethyst and agate found in the Department of Artigas are the two stones exported.

In 1979, the Federal Institute for Geosciences and Natural resources, Bundesanstalt für Geowissenschaften und Rohstoffe of the Federal Republic of Germany, began investigations of nonmetallic mineral deposits in Uruguay. This work was scheduled to be completed in September of 1980.

The Mineral Industry of Other South Pacific Islands

By Charlie Wyche[1]

CONTENTS

FIJI

Principal mineral products in the Dominion of Fiji were gold, silver, pit and quarry construction materials, and cement. In the years 1978-79, the combined total value of these commodities accounted for some $15 million,[2] or 85% of the total mineral output. Production of cement, sand and gravel, and quarry products increased substantially, but gold and silver output from Fiji's only operating metal mine continued the downward trend of recent years.

Mineral exploration by several international mining companies as well as by local prospectors was being carried out over much of Fiji, and a number of interesting prospects were discovered. One of these, a medium-size porphyry-copper prospect in the Namosi area of Viti Levu, was at a mining feasibility study stage. At Mount Kasi on Vanua Levu, an extensive program of geological sampling and mapping was being conducted, and surface sampling and drilling was taking place at some base metal prospects in the south-central parts of Viti Levu. Also, high gold values in surface samples were reported at Vuda in western Viti Levu.

At yearend, 39 mineral prospecting licenses, covering 4,220 square kilometers, and 4 offshore petroleum prospecting licenses, covering 30,850 square kilometers, were in force. Total exploration expenditure by United States, Australian, United Kingdom, French, and the Federal Republic of Germany interests exceeded $8,000,000 for the 1978-79 period.

In late 1978, the Mineral Resources Department took delivery of a fully operational research vessel, the *RV Bulikula*. The ship was designed and built in Fiji and equipped with a satellite navigational system which would facilitate a variety of offshore mineral investigations.

Table 1.—Other South Pacific Islands: Production of mineral commodities

Area, commodity, and unit of measure	1976	1977	1978[p]	1979[e]

SOLOMON ISLANDS[2]				
Gold ... do	600	372	[e]400	400

[e]Estimate. [p]Preliminary. [r]Revised.
[1]Produced from an unreported amount of domestically quarried limestone.
[2]In addition to the commodities listed, crude construction materials (common clays, sand and gravel, and stone) are produced, but output is not reported quantitatively and available general information is inadequate to make reliable estimates of output levels.
[3]Data represent exports.
[4]Data series is revised to reflect total cobalt content of nickel ores mined and cobalt actually recovered from these ores and/or from intermediate metallurgical products derived from these ores. Data reported in previous editions of this chapter on cobalt contained in metallurgical products of nickel are misleading because this cobalt content was not recovered for use.
[5]Nickel-cobalt content of metallurgical plant products, plus nickel-cobalt in exported ores.
[6]Reported figure.
[7]Data represent Japanese imports.

COMMODITY REVIEW

Metals.—*Copper.*—Copper Resource Ltd. finalized a preliminary study on the economics of the Namosi deposit on Viti Levu. The investigation, which included diamond drilling, collection of baseline environmental data, and geological sampling, indicated an ore body of 450 million tons at 0.4%-0.5% copper. The investigation also indicated that the deposit was minable by open pit, with a waste-to-ore ratio of around 2:1. Copper Resource Ltd. (a subsidiary of Conzinc Riotinto of Australia Ltd.) replaced Amax Exploration (Australia) Inc. as project manager. Other partners in the consortium included Anglo Pacific (Namosi) Ltd., subsidiary of Australian Anglo American Ltd., and Preussag Fiji Ltd. of the West German Preussag Group.

Gold.—Emperor Gold Mining Co. Ltd., the wholly owned operating subsidiary of Emperor Mines Ltd., continued to mine sulpho-telluride gold ores at Vatukoula on the north coast of Viti Levu. During 1978-79, the company employed 690 men to mine and treat about 325,000 tons of ore for a recovery of some 53,000 troy ounces of gold and 21,000 troy ounces of silver. The lower mine production compared with previous years was mainly due to the company's decision to reduce the underground work force in an effort to cut operating losses.

Labor problems existed at Emperor Gold Mines the past several years, and the company was considering closing the mine owing to heavy financial losses. To keep the mine operating, the Government continued to grant financial assistance in the form of tax relief and interest-free loans. Although the gold price was increasing, losses were incurred because of the declining millhead grades. The company considered a cutoff grade of 0.33 troy ounce per ton would be necessary to maintain a viable operation.

Measured underground ore reserves on June 30, 1979, were 686,867 tons at a cutoff grade of 0.27 troy ounce per ton.

Pacific Energy and Minerals Co. of Golden, Colo., started prospecting for gold near the Vatukoula gold mine. The company, under the name of Aurelia Resources Ltd., applied for licenses to prospect for precious metals in the southeastern area of Viti Levu. In this area, Fiji Mineral Resources Department reported traces of gold.

Other foreign companies, including Consolidated Gold Fields of Australia (CGFA), also applied for gold prospecting licenses. CGFA expects to explore the islands of Kadavu and Ono, which are 80 kilometers from Suva where gold was reported.

The Anglo American Corp. group recently completed a year of drilling at the Mount Kasi gold mine site on Vanua Levu, the country's second largest island.

Nonmetals.—Emperor Gold Mines continued to produce burnt lime from its limestone quarry at Tau but did not report production. The number of sand and gravel licenses granted continued to increase, although new procedures providing for determination of compensation for damages to fishing grounds were in force.

Fiji Industries Ltd. dredged 86,717 tons of coral sand from Suva Harbor and 58,578 tons of common sand and gravel from the Rewa River and its tributaries in 1978.

The Government's Mineral Resources Division was evaluating a phosphate clay deposit on the island of Tuvutha and reported resources of 1.5 million tons containing 10% P_2O_5.

Mineral Fuels.—*Petroleum.*—Mapco Ltd. and Pacific Energy & Minerals Ltd. were recently granted a license by the Government to carry out extensive oil exploration in four areas known as Bligh Water, Yasawa, Lomaiviti, and Great Sea Reef. Another application was under consideration. Assessment of seismic and other available geological information was in progress, and further surveys were being carried out in preparation for major programs of offshore drilling.

Table 2.—Fiji: Exports and reexports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1975	1976

NAURU AND OCEAN ISLAND

The Republic of Nauru and Ocean Island (the latter a member of the Gilbert and Ellice Islands Colony) lie just south of the equator, halfway between Honolulu, Hawaii, and Melbourne, Australia. Responding to increased demand in Australia, phosphate rock production from these two islands (primarily Nauru), by Nauru Phosphate Corp., increased significantly over that of 1977.

Of the 4.9 million tons produced in 1978 and 1979, some 60% went to Australia, 30% to New Zealand, and the remaining 10% to Japan and South Korea. The price for Nauru's phosphate generally follow Florida price trends, with allowance for quality.

As a majority of the phosphate was mined from between limestone pinnacles using grab buckets, means were being investigated to recover the residual phosphate estimated to be 6% to 7% of the total.

Present reserves of phosphate rock in Nauru were estimated at 38 million tons.

NEW CALEDONIA

New Caledonia's mineral activity consisted of the mining and smelting of nickel to matte and ferronickel, byproduct cobalt matte from the nickel smelting operations, chromite, and pit and quarry construction materials. The lack of nickel demand throughout 1978 and most of 1979 had an adverse effect on the country's nickel industry. As a result, output by Société Métallurgique le Nickel (SLN), New Caledonia's only producer of nickel products, declined to its lowest level in 10 years. Nickel ore exports were also lower than in 1977.

Nickel ore was produced at four major locations, three (Thio, Kouaoua, and Poro) near the east coast and one (Népoui) near the west coast. Work to expand output at Népoui to 2 million tons of ore per year and at Kouaoua to 1.5 million tons per year was continuing. Combined production of nickel ore for 1978-79 was only 44% above that of 1977.

In 1978, the island's only smelter, the Doniambo facility at Neumea, was closed for 50 days following a strike. When operation was resumed in midyear, the smelter operated at less than 60% of rated capacity during the remainder of 1978. The idle capacity resulted in a sharp decline in production of nickel, nickel matte, and ferronickel. Output in 1979 showed a slight improvement but was substantially below that of 1977.

Exports in 1978 were valued as follows (in thousands): Ore, $31,723;[3] matte, $56,827; and ferronickel, $97,863. Exports in all categories showed improvement in 1979.

The cobalt content of the nickel ore mined in New Caledonia for 1978 and 1979 was estimated at about 1,500 tons. The cobalt content in either the total ore production or in the intermediate metallurgical products was recoverable as cobalt or cobalt chemicals. A significant part of the total remained in nickel products.

Amax Nickel Inc. and Bureau de Recherches Géologiques et Minières (BRGM), the French Government-controlled agency, signed a final agreement leading to a joint development of an integrated nickel project in the Tiebaghi, Poum, and Isle d'Art regions at the northern end of New Caledonia. The agreement covers feasibility and financing studies and ultimate mine and plant construction and operation. The cost of the project was estimated at $600 million. Reserves of 55 million dry tons of ore at 2.5% nickel in garnierite, including 10 million tons of 3% nickel, would be mined at a rate of 1 million tons per year. Amax was interested in shipping nickel matte from this smelter to its Port Nickel refinery in Louisiana.

Inco Ltd. of Canada, under agreement with the New Caledonian Government, was studying the possibility of development of lateritic nickel deposits in the southern part of the island. Inco would be required to take a French partner before the development stage.

Production of chromite ore in 1978, containing 39.5% Cr_2O_3, in the Tiebaghi region, increased 16%, compared with that of 1977. Chromite exports, principally to Japan, had a combined value of $222,000 during 1978 and 1979. Société de la Tiebaghi, subsidiary of Inco Ltd., continued a drilling program that began in 1977.

The BRGM studied chromite prospects in peridotitic rocks along the southern coast.

Energy requirements were considered a potential problem since New Caledonia had no domestic energy resources. Light fuels were imported from Singapore, fuel oil from Australia, and industrial fuel from Bahrain. The Plaine des Lacs region was considered to have hydroelectric development potential. SLN used 85% of the industrial electricity in its mining and smelting operations.

NEW HEBRIDES

Production of manganese concentrate, the New Hebrides' only significant mineral product, ceased in November 1978. The only mine, located at Forari, 55 kilometers northwest of Port Vita on Vate (Efaté) Island, was operated by Le Manganese de Vate (LMV) and owned by Southland Mining Ltd. of Australia (87.5%) and public shareholders (12.5%). The decline in world steel production in 1977, which continued throughout 1978, resulted in low demand for the manganese. The mine is expected to reopen at some future date, although only some 120,000 tons of commercially minable reserves remain in the Forari mine. Japan purchased the total manganese output in 1978, which dropped 13% compared with that of 1977. The company had 100 employees, largely native New Hebrideans, and shipped a 40%-42% manganese concentrate of metallurgical grade. The market value was $35 per ton for 40% manganese product.

Although manganese concentrate was the only mineral produced for export in 1978, various mineral deposits were being exploited and others were the subject of investigation during 1978 and 1979. Samples of pozzolan, a consolidated volcanic ash, on Efaté and other islands, were being evaluated in Australia and Fiji for use in cement. Sand, limestone, coral reef, and gravel were used in road building, house construction, the building of airfields and other public works. Other resources included zinc, limestone, and copper on Santo Island, sulfur on Vanua Lava, and beach sand deposits containing magnetite, ilmenite, and other ore mineral on Pentecôte Island. None of these commodities was expected to be mined in the foreseeable future.

PAPUA NEW GUINEA

Papua New Guinea's (PNG) principal mineral products were copper, gold, and silver. Except for a relatively small output of gold in the Bulolo-Wau area, these commodities were produced by Bougainville Copper Ltd.'s mine at Panguna on North Solomon Island (Bougainville). They contributed significantly to Government revenues and the gross domestic product (GDP), estimated at $1,700 million[4] in 1978. Values of 1978 output were as follows: Copper, $184 million; gold, $134 million; and silver, $8 million. Total production value of $326 million was nearly 19% of the GDP. The only other minerals produced were small quantities of limestone and sand for local use. Despite the mineral industry's importance financially, it employed only about 7,200 people out of a total work force of over 350,000.

In 1979, the Government enacted legislation relating to the exploitation of mineral resources, including petroleum. Development of mining and petroleum projects were considered to be of the highest priority, and the basic principles of the legislation adopted were as follows:

Mineral resources belong to the people of Papua New Guinea and the Government, and the people must receive a fair price in return for extraction of the minerals.

Foreign enterprises exploiting Papua New Guinea's mineral resources deserve a reasonable return on their investment, but extraordinary gains above a reasonable return on investment will go in large part to the Government.

The Government has the right to regulate extractive enterprises so as to maximize the benefits to the local community while minimizing the potentially harmful social and economic costs.

A number of probable porphyry copper prospects were under investigation in 1978 and 1979. Some of these copper deposits contained potentially byproduct gold, silver, and/or molybdenum. Exploration was also underway for chromite, nickel, and hydrocarbon products.

COMMODITY REVIEW

Metals.—*Chromite.*—Nord Resources Corporation has found chromite mineralization in several areas of Papua New Guinea and was planning further detailed studies. The find was on parts of a 246-square-kilometer concession in the Ramu River area, close to the deepwater port of Madang. Amax Exploration Australia Inc., a subsidiary of Amax Inc., was evaluating chromite and other minerals in beach sands along the Morobe coast, between Salamaua and Salua. Preliminary estimates indicated reserves of 200 million tons of mineralized sands containing 1.5% chromium.

Copper.—Bougainville Copper Pty. Ltd.'s (BCL) copper mine at Panguna remained the only significant mining operation in Papua New Guinea. While the 1978 output of copper, gold, and silver was significantly above that of 1977, output in 1979 declined to the 1977 level. This resulted from a decline in both tonnage and grade of ore milled. Total ore milled dropped some 2 million tons in 1979 (36.17 million tons), compared with 1978 (38.12 million tons). Copper content declined from 0.60% in 1978 to 0.55% in 1979; gold, from 0.026 troy ounce per ton to 0.024 troy ounce per ton; and silver, from 0.058 troy ounce per ton to 0.054 troy ounce per ton. This trend could continue as mining operations extend into the lower grade sections of the ore body. At yearend 1979, ore reserves at Panguna were placed at 720 million tons at an average grade of 0.44% copper and 0.49 gram per ton gold.

In 1978, sales totaled 193,050 tons of copper, and 730,624 troy ounces of silver. Concentrates were shipped under long-term contracts to Japan, the Federal Republic of Germany, and Spain.

A major factor that contributed to the increased output in 1978 was the completion of a program that added 43 large-capacity dump trucks to the company's inventory. In the concentrator, production was raised by the addition of another ball mill, together with a program to increase the operating speed on all ball mills. The mill throughput was increased by about 3% without and falloff in grinding performance.

Bougainville Copper Ltd. signed a 3-year contract in March, to sell copper to Mainland China. The company will supply about 30,000 tons of copper concentrates to China each year, worth a total of some $45 million. The price was related to the London Metal Exchange copper price.

The feasibility study of the OK Tedi porphyry copper deposit in Papua New Guinea was continued. The study was being carried out by a consortium under the leadership of Broken Hill Pty. (BHP), which began to work at OK Tedi in 1976. The consortium consisted of Dampier Mining Co. Ltd., a subsidiary of BHP Co. (30%);

Mount Fubilan Development Co. Pty. Ltd., a subsidiary of Amoco Minerals Ltd. (30%); Kupferexploration GmbH, a West German group, (20%); and PNG Government (20%). Situated in the Star Mountains near the West Irian border, the deposit has ore reserves estimated at 300 million tons. Ore grade averaged 0.85% copper, and 55 grams per ton gold, with some molybdenum. Under the agreement with Papua New Guinea, the consortium presented the feasibility study to the Government on May 31, 1979. It was widely believed that the report would recommend that the project be developed, possibly by working the gold-rich part of the ore body first. In February 1979, a hydrographic, geophysical, geological investigation of the Fly River was conducted to assess the feasibility of transporting copper concentrates from OK Tedi via barge from Kiunga on the Fly River to an as-yet-to-be-selected deepwater port on the Gulf of Papua.

Other exploration was continuing on the Frieda River porphyry ore body estimated to contain 500 million tons averaging 0.5% copper. Although a major ore body was located in the Western Sepik Province, the development could be hampered by its low grade. The leases were held by MIM Holdings Ltd., and work carried out by Japanese interests earned them a 40% share in the holdings.

On Manus Island, 360 kilometers north of the PNG mainland in the Admirality Group, joint venture exploration by Exoil NL and Transoil NL indicated 160 million tons of ore at 0.32% copper, associated with gold, silver, and molybdenum, in ore of several known prospects. Some factors acting in favor of the Manus prospect were the limited infrastructural development required and relatively good accessibility compared with the mainland deposits.

Gold and Silver.—With rapidly rising prices, gold continued to be an important byproduct of BCL's Panguna copper mine. The combined gold sales totaled some 1.4 million troy ounces during 1978 and 1979. Byproduct silver recovery was also increased.

Output by New Guinea Goldfields Ltd., operated at Wau, where ore averaged 0.08 ounce per ton, remained relatively small. Placer Ltd. was continuing exploration work on a gold prospect at Porgera in Ega Province. Metallurgical work was being carried out by Consolidated Gold Fields Australia Ltd., which has an option to take up a substantial interest if data look promising.

Mineral Fuels.—*Petroleum.*—Petroleum prospecting continued, but no significant discoveries were reported. In August 1978, the Papua New Guinea Government signed petroleum prospecting concession agreements with Gulf Oil Corp., Australasian Oil Ltd., and BP Petroleum Development Australia Pty. Ltd. The concession areas involve two permits (Nos. 76 and 77). Permit 76 covered 7,300 square kilometers in the Western Province, and 77 covered 13,400 square kilometers in the Western and Southern Highlands Provinces. The cost of the exploration program over a 3-year period was estimated at $7 million. In another development, Esso Papua New Guinea Inc. announced it had spudded the Goari No. 1 well on the Paibuna River, 415 kilometers northwest of Port Moresby. Planned depth is 11,500 feet, and it is estimated that the well would take 55 days to complete.

According to legislation recently passed, the PNG Government would receive 60% to 80% of any future revenues from oil or gas production. Also, the Government would receive a 1.25% royalty based on wellhead values, a petroleum income tax of 50% of taxable income, a profits tax after an agreed rate of return is achieved, and a Government equity up to 22.5% with payment from the Government's share of production.

SOLOMON ISLANDS

Solomon Islands (formerly British Solomon Islands) became an independent nation on July 7, 1978. Inasmuch as the Solomons had been self-governing since 1976, independence did not bring major changes in the minerals industry, which was quite small. The only production in 1978 and 1979 was small quantities of alluvial gold and silver, valued at an estimated \$200,000.[5] In addition, marine shells have been harvested for lime, but production was not reported.

The Government was actively seeking investment as a major force in the country's natural resource development. A bauxite mine and smelter project on Rennell and Vaghena Islands have been surveyed but temporarily shelved due to low world bauxite prices. Conzinc Riotino Australia Ltd. (CRA), in partnership with Mitsui Mining and Smelting Co. Ltd. and the Solomon Islands Government, withdrew from the project, and Mitsui decided to defer further work because of the lack of market for aluminum. The project was to produce 1.5 million tons of bauxite and 600,000 tons of alumina per year from reserves estimated at 60 million tons of 45%-50% Al_2O_3.

The Solomon Islands Government announced in September 1979 that the natural resources of the country, including its offshore areas, would be explored and evaluated as quickly as possible. The Government was particularly interested in receiving proposals for hydrocarbons both onshore and offshore. A Petroleum Act that would establish the framework to enable orderly prospecting and development to be carried out by commercial companies was at an advance stage of preparation. Within the terms of the act, detailed agreements between individual companies and the Solomon Islands Government concerning work programs, expenditure levels, the extent and nature of Government participation were considered.

TONGA ISLANDS

Webb Tonga, subsidiary of Webb Resources of Colorado, an independent U.S. oil company, drilled three onshore holes on Tongatapu, the island center of the Kingdom of Tonga. All three Webb holes were dry, and the company never found the submerged reef it was looking for. The Tonga Government and Webb Resources were conducting negotiations for Webb to drill two offshore wells in 2 to 3 years.
